Researcher: Any polynomial function of third degree increases, decreases, and ...? [...] Always?

Diogo: Yes.

The concept image developed by Diogo, related with third degree polynomial functions, does not include monotone functions. This may be explained taking into account that cubic functions which students explored in the classroom involved, almost exclusively, functions with three zeros, with the exception of one example that the teacher showed which had a double zero. In any case, the covered functions always involved change in variation.

The transition from the representation displayed on the GC screen to its register on paper was done differently by the two students (fig. 1). Helena only considered the points of intersection with the x -axis, and drew the graphical representation as "viewed" on screen, without considering any scale. Diogo, on the other hand, tried to consider a scale, although not properly. In addition, he considered the intersections with the x -axis, and determined the points corresponding to the relative extremes of the function.

Working Group 15

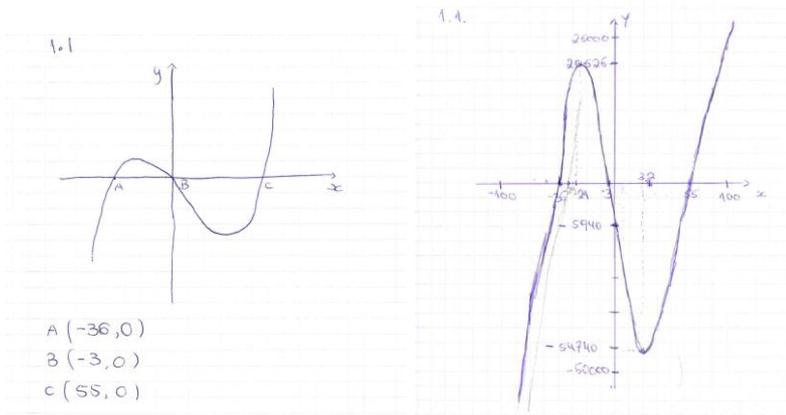

Figure 1: Graphic representations made by Helena (left) and Diogo (right).

For determining the zeros and, in the case of Diogo, also the relative maximum and minimum, they used the *Calc* menu of the GC. Students showed no difficulties, suggesting that the utilization schemes have been developed.

For the second question, both students correctly interpreted the influence of parameter k in the graph of the function p . It is clear that both students have already established the operational invariants, allowing us to infer that they used the following theorem-in-action: *The graph of function p undergoes a vertical translation associated with the vector* , as shown, for example, by this extract of the interview with Helena:

Helena: So, I have to find a value for k (pause). [...] So that the graph goes up or down (pause), and has only one zero.

Researcher: Hum. And why did you say go up or down?

Helena: Because it is ..., it is the influence of k .

However, she did not seem to have consolidated this knowledge. In fact, in an attempt to understand the influence of the independent term in the graph of the function p , when viewing the graphical representation of a new function which is the sum of p with 5940, Helena said that part of the graph went up and another part went down. This shows her difficulty in interpreting what she visualized on the CG display:

Helena: Here went up (pointing to left side) and here went down (pointing to the right).

Researcher: Do you think it went down, in some part?

Helena: (Observes the screen) No, it went up. (Goes to the function editor) This ...

To confirm the type of displacement suffered by the graphical representation, Helena returned again to the GC, taking advantage of the possibility of observing one graphical representation followed by the other: "No, it goes up. It goes up". Even so she showed some difficulties: firstly, to understand that it would be necessary to

Working Group 15

make the graphical representation of p go up (or down) in order that the minimum (or maximum) of the function stood above (below) of the x -axis, and, secondly, in taking advantage of the potential of the GC to determine a possible value for k :

Helena: So, to have only one zero, going up, haa, this part will have to touch at the x -axis (points with her pen at the relative minimum and shift it up to the x -axis).

Researcher: To touch ...?

Helena: At the x -axis. (Pause) Yes!

Researcher: If this part touches at the x -axis, will it have just one zero?

Helena: Yes. And going down, haa, it has to be this part (points to the relative maximum and makes a gesture down to the x -axis), touching the x -axis.

Researcher: Hum, so? (Long pause) How are you going to do this?

Helena: Well, I don't know! (Long pause).

During the interview, Helena finally understood that it was necessary to shift up the graphical representation of the function p , in order that the minimum remains above the x -axis, however, she was not able to find a more effective strategy than to assign values to k and observe the effects on graphical representation. Here she failed in constructing an efficient instrument that would allow her to answer the question immediately. Diogo, by contrast, was able to use an effective instrument, by linking together the graphical representation of p , the theorem-in-action and the concept of maximum and minimum of a function. For that purpose, he just looked at the graphical representation that he outlined in the previous question. He responds with confidence, not confirming the answer with the use of the calculator.

Diogo: It must goes up, haa, the function, the graph of the function. And the only way I see for having only one zero, is to shift up the graph, so that the point less 54740 [the minimum of the function p] stands above the x -axis. [...] Then, the value has to be at least ..., haaa, 55000! (Pause) Because if it goes up 55000, there will be only one point that [...] intersects the x -axis.

Researcher: There will be only one point of intersection with the x -axis? Why?

Diogo: Because, I shifted the graph up, and only this one stood here (pointing to the left side), that goes down, and which continues.

Similarly, he obtained the value less 22000 as another possible value for k (with opposite sign to the first). The exploration, done in the classroom, about this transformation of functions, allowed students to establish the operational invariants that have been implemented in this question.

The last question was the one that raised more difficulties for both students. Diogo began by trying to interpret the meaning of $p(x+7)$:

Working Group 15

Diogo: So, first I'll determine p of x plus seven, making a function equivalent [to write an equivalent expression] to, to become clearer. I'll replace p of x here; I will add seven in this equation (points at the expression of p).

Researcher: Are you going to add seven to the p of x ?

Diogo: To p of x . [...] Seven, no! I can't add seven. [...]

Researcher: Why is that?

Diogo: Because this is influencing the x and not the y .

Although Diogo initially misinterpreted the meaning of $p(x+7)$, immediately restates his interpretation as he understands that this transformation corresponds to a horizontal displacement. Even so, he chose the displacement in the opposite direction:

Diogo: I have to move, but (pause), it is in the axis of the ... (pause, make a gesture with his hand), of x . (Pause). The function, which I drew here (points at the calculator display), has to move together, seven "places", to the left.

Researcher: Has to move seven units to the left? [...] Why to the left?

Diogo: Because, it is plus, and as we know that (Pause) No, it should be minus! Okay, I don't know. [...] I am thinking how could it be (looks at the statement). I am reconsidering ..., actually is to the right. [...] Because any value of x plus seven (pause), goes to the right (laughs).

His first answer was correct, however, when questioned, he revealed the fragility of that knowledge, which suggests that the theorem-in-action had been memorized, and when challenged, it was eventually replaced by another one that is false. The GC could have been an important tool for deciding the direction of displacement, however, in this situation, he was unable to take advantage of the GC. Despite having decided the direction of the displacement, he tried to write an expression for that factor, however, he fails in developing the cube properly:

Diogo: x raised to three plus 21, because is x cubed, so, I have to repeat three times seven, that is 21! We add three times seven to the three x here.

Researcher: We add three times seven? (Pause) To the three x ?

Diogo: Because, usually, if there was only one x , we add seven units, but as there are three, so we have to add 21. (Pause) (Laughs) It is wrong, ok! (Pause) So, but I ... (he picks up the calculator).

His initial goal was to solve the inequality graphically and to do so, he needed to edit the function in the GC but, during the interview, he changed his strategy and decided to do a table of signs. Even then, he maintained the idea that he had to find an analytic expression for the factor $p(x+7)$ to edit in the GC. Despite the fact that he had started to draw what he considers to be the graphical representation of $p(x+7)$,

Working Group 15

which gives all the necessary information to fill the table of signs, he still tried to write an expression to obtain, with the GC, the information that he assumed:

Diogo: [...] (Makes a sketch of the graphical representation) I don't even need to draw, I already know the zeros, and they will be ..., minus 29, [...], four, and the other, 62. Now ... (very long pause). [...] Now I am going to put this in a polynomial. [...] I am writing an expression, with these zeros.

Researcher: Yes. And why do you need that expression? What for?

Diogo: To the table of signs. (Pause) To edit it back in the calculator, so that I can see the resultant graph, calculate the zeros, and make a table of signs.

The intention to write an expression to introduce on the calculator superimposes all his thoughts, leading him to a trajectory that makes no sense.

Helena also chose to solve the inequality using a table of signs, however failed to interpret the meaning of $p(x+7)$:

Helena: Hum, I do not understand what that p is doing there.

Researcher: What is that p ? (Long pause) OK, if p was not there, how would you do it?

Helena: If p was not there (pause). [...] I would just have to multiply this (points at x plus seven) by this (points at the other factor).

Researcher: Hum. Ok, so how would you do it?

Helena: (Long pause) [...] Maybe I would make a table of signs.

Researcher: Hum, hum. (Pause) Ok but, there is a p in there. [...] Ok, how do we read it? (Long pause) And if we had, instead, p of x ?

Helena: (Pause) Oh! So, it is this (p of x) plus seven, and multiplied by this one (points at the other factor).

The fact that the parentheses include the expression $x+7$ does not seem to bother her since she immediately decides to add seven to the algebraic expression of p . Then she uses the GC to determine the zeros and the sign of the two factors, but loses some time in finding an appropriate view window to determine the zeros.

CONCLUSIONS AND IMPLICATIONS

The two students are beginning to have an object-oriented view of function, which seems obvious when, for example, they refer to the effects that the transformation $p(x)+k$ has on the graph of the function p , showing that they can think about the concept as a whole. The exploration they made in the classroom of this kind of transformation on quadratic and module functions, using the GC, seems fundamental in the establishment of operational invariants that emerged in Question 2. Diogo, unlike Helena, was able to establish connections between the effects on the graph of the function p and various notions associated with the function concept, such as, relative extremes and zeros. Helena considered only zeros as relevant points, and did

not feel the need to determine the relative extremes of the function, which could have been useful for her to solve Question 2.

In the case of the transformation $p(x+h)$ it is clear that Helena has not developed the operational invariants. In fact, initially, she failed to assign meaning to the symbolic notation $p(x+7)$, and only connected it to the function p after the researcher's suggestion. After that, she addressed the issue without going into any kind of cognitive conflict, and integrated the GC correctly in her activity, i.e., she got all of the necessary information to complete the table of signs. Diogo was able to grasp the transformation produced on function p , however, he seems to have memorized the respective theorem-in-action, getting into cognitive conflict when questioned about it. Although he has understood that the analytical expression of the new function could be obtained by replacing x by $x+7$, algebraic difficulties did not allow him to obtain the simplified expression. He also failed in using his GC effectively, losing himself in a sort of vicious cycle that could have been avoided if he had been aware that it is not necessary to introduce a simplified expression in the function editor or if he knew that it is possible to edit an implicit function, although this hypothesis has not ever been discussed in the classroom.

The students' difficulties associated with the transformation $p(x+h)$ compared to $p(x)+k$ suggest that the approach developed in the classroom did not contribute to the development of operational invariants. Apart from the overall approach, made possible by the use of the GC, it might have been useful to do an exploration which focused more on the local behavior of functions, using numerical representation, so that students would be able to understand the translation direction. The transformations in analytical expression and in editing in the GC could have been simultaneously clarified through that approach. As Sfard (1991) stresses: "the terms "operational" and "structural" refer to inseparable, though dramatically different, facets of the same thing" (p. 9), and although the GC, through the graphical functionality, encourages a structural approach, it is important that, at least at the beginning, students also get the opportunity to work in a more operational way, relating the numerical representation with other representations of functions. The difficulties associated with the horizontal translation have been documented in other studies (e.g., Zazkis, Liljedahl, & Gadowsky, 2003). The GC could be used, in this topic, exploring the possibility of combining multiple representations of functions.

Concerning this particular task, the instruments developed from the GC by Helena are supported by its immediate power for visualization, while the instruments developed by Diogo are essentially supported by the establishment of connections with his mathematical knowledge, although, as noted before, not always successfully. The construction of instruments to perform a mathematical task depends on several interconnected factors, among which we highlight the utilization schemes socially developed in the classroom, the level of students' instrumentalization and instrumentation and their mathematical knowledge.

A SURVEY OF TECHNOLOGY USE: THE RISE OF INTERACTIVE WHITEBOARDS AND THE MYMATHS WEBSITE

Nicola Bretscher

King's College London

This study reports the results of a pilot survey of UK mathematics teachers' technology use (n = 89) in secondary schools. Previous surveys are confused by a lack of differentiation between hardware and software use. This survey aims to provide insight into the types of software teachers choose to use in conjunction with particular types of hardware. Teachers were asked about their access to hardware and software; their perception of the impact of hardware on students' learning; the frequency of their use of ICT resources and the factors affecting their use of ICT.

Keywords: technology, teachers, interactive whiteboards

INTRODUCTION

The survey reported in this paper aims to explore the types of software teachers choose to use with different types of hardware and the frequency of their use. The survey was conducted as a pilot study to test the feasibility of a large-scale survey of UK mathematics teachers' technology use and to inform the future collection of qualitative data to contextualise and validate survey findings. The large-scale survey will form part of a wider study into how Information and Communication Technologies (ICT) are used in mathematics teaching and how teachers' perspectives and practices have changed as a result of the introduction of the UK National Curriculum 2007.

Governments around the world have made huge investments in ICT for education (Selwyn, 2000). Despite these investments, the TIMSS 2007 study (Mullis et al, 2008) reports that using computers for any activity as often as in half the mathematics lessons was rare, even in countries with relatively high availability. In the UK, Ofsted (2008) report that opportunities for pupils to use ICT to solve or explore mathematical problems had markedly decreased over the previous seven years of unprecedented investment in technological infrastructure. The gap between investment in ICT and the reality of its use in classrooms seems clear. Investigating the choices teachers make about the technology they use in their classrooms is important in order to understand the apparent failure of ICT to make an impression on school mathematics.

TEACHERS' CHOICES: HARDWARE AND SOFTWARE

The type of hardware and its deployment appears to be an important factor in structuring teachers' choices about technology use in their classroom practice (Ruthven, 2007). In particular, the hardware available affects the types of classroom organisation possible and the nature of pupil interactions with any software used in

conjunction with the hardware. It seems reasonable then that the available hardware might also affect teachers' choice of software and how they choose to integrate the use of such software into their classroom practice.

Currently, little is known about what types of software teachers choose to use with particular types of hardware. In terms of hardware, the UK represents a special case since it became the first school-level market to invest heavily in interactive whiteboards (IWBs) (Moss *et al.*, 2007). However, large-scale surveys of technology use within the UK have tended not to report in detail on technology use within subject areas, such as mathematics, nor to differentiate sufficiently between hardware and software use. Thus whilst such surveys provide a broad picture of technology use, they have not provided much insight into the nature of the specific uses by teachers in general or by mathematics teachers in particular. For example, the annual Becta schools survey *Harnessing Technology* reports that 53% of mathematics teachers use subject-specific software in half or more lessons (Kitchen *et al.*, 2007). However, no further detail is given on what types of subject-specific software are used, nor an indication of the hardware involved. Surveys focusing on mathematics teachers' use of technology, such as the survey conducted by Hyde (2004), give a more detailed picture of the types of software used by mathematics teachers; however, this picture is again confused by the lack of differentiation between hardware and software use. Building on such surveys, this study aims to provide insight into the types of software teachers choose to use in conjunction with particular types of hardware. Further, this study aims to investigate the practices of ordinary teachers in ordinary classrooms, continuing the line of research suggested in Bretscher (2009).

THE SURVEY

The questionnaire design was informed by previous surveys of mathematics teachers' use of ICT, primarily Hyde's (2004) survey of mathematics teachers in Southampton and Forgasz's (2002) survey of mathematics teachers in Victoria, Australia. The questionnaire used both closed and open-ended response formats and contained sections on (a) *About you* - personal details; (b) *ICT in your school* - access to hardware/software and integration of ICT within the department; (c) *ICT use in your own mathematics teaching* - perceived impact and frequency of use of hardware and software; and (d) *Your beliefs about teaching and learning mathematics with ICT* - factors influencing the use of ICT. In line with the aims of this survey and in contrast to Hyde's (2004), teachers were asked separately how often they used software in a whole-class context (e.g. with an IWB or data projector) and how often they gave students direct access to the software (e.g. in a computer suite or with laptops). The list of software was derived from Hyde's list with the notable inclusion of the MyMaths.co.uk website since this site was known anecdotally to be widely used in UK schools. The *MyMaths* website is a subscription site offering teachers pre-planned lessons, on-line homework and many other

Working Group 15

resources. The lessons and homework are linked to an “Assessment Management system”, allowing teachers to track individual students’ progress.

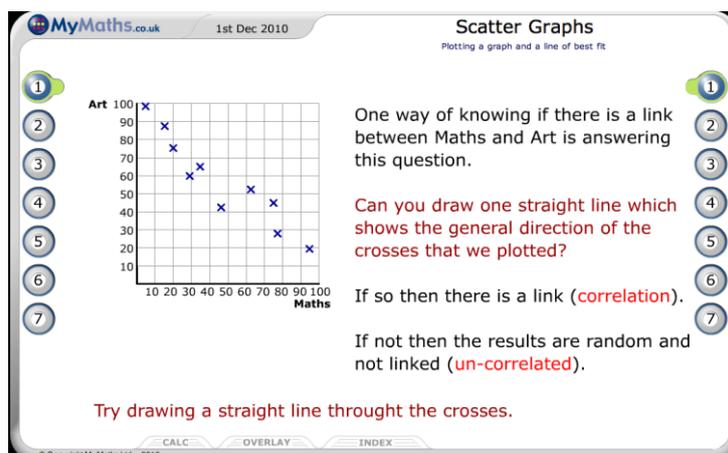

Figure 1. Screen snapshot of a *MyMaths* sample lesson on scatter graphs.

Ten questionnaires were sent to 27 schools working in partnership with King’s College London to offer initial teacher education in secondary mathematics, with 18 schools agreeing to participate in the survey. A total of 89 completed questionnaires were returned, an average of five per school: the lowest number returned by a school was 2 and the highest 9. Since the survey was a pilot study, it was not necessary to select a representative sample of schools. Nevertheless, the participating schools cover a range of characteristics including a wide range of attainment in national tests; some have speciality status and some do not; some are single sex and some are selective. The participating teachers (37 F; 50 M; 2 unspecified) had an average age of 37 years and an average length of service of 10 years. The low percentage of women (42%) is surprising since women tend to outnumber men in teaching. In common with Forgasz’ (2002) findings, no obvious differences in ICT use between the genders was found. The majority of respondents (41) described their main responsibility as classroom teacher. The sample also included 10 heads of department, 9 deputy heads of department and 13 Key Stage coordinators. Comparing themselves to their colleagues, 37.1% of teachers thought they used ICT much more or more frequently; only 11.2% thought they use ICT less or much less frequently. This might suggest that the respondents are relatively well-disposed towards ICT or that they wish to be seen as frequent users of ICT.

Data that could be analysed statistically were entered into PASW Statistics 18.0. This package was used to generate descriptive statistics (i.e. frequency distributions and means). Open-ended responses were analysed manually. In tables 1-3 in the results section below, the findings of this survey are compared with Hyde’s to give a sense of changes in ICT use over time. Hyde sent one questionnaire to each of the 38 schools working with the University of Southampton to deliver initial teacher education (33 returns). Her results give an overview of departmental ICT use whereas this survey reports individual teacher’s responses, thus comparisons should

be treated with some caution. Data was unavailable from Hyde's survey for comparison in tables 4 and 5.

RESULTS

Access to hardware and software

Only two schools did not have any IWBs in the mathematics department but each teacher in these schools had access to a data projector. Thus every teacher participating in the survey had access to either an IWB or a data projector. The apparent decline in access to data projectors from Hyde's (2004) survey is likely to be due to the rapid expansion of IWBs over the same period (see Table 1). Only 66% of teachers reported having access to a computer suite shared with other departments. This seems surprisingly low, especially when compared with the coverage of IWBs. In fact, in every school at least one teacher claimed to have access to a shared computer suite. The lack of consistency between teachers in the same school suggest that while some teachers are responding on the basis of the existence of hardware, others are responding according to their perception of availability of the hardware for use. Difficulties in booking computer rooms mean that, although shared computer suites exist, their availability is often severely restricted. The quote below is representative of many teachers' comments on hardware access and neatly summarises the contrast in accessibility between IWBs and computer rooms.

“Computer room access very limited due to lack of resource in school (and monopoly on it by ICT dept lessons). IWBs readily available in all maths teaching rooms.”

Access to hardware	Bretscher	Hyde
IWB	81	64
Data projector	63	76
Computer suite (shared)	66	-
Computer suite (maths only)	16	-
Laptops	26	-
Graphic calculators	26	94

Table 1: Access to hardware, $n = 89$. Hyde's (2004) figures are shown for comparison. All figures are given in percentages.

None of the teachers from schools with a computer suite dedicated to the mathematics department complained about lack of access to hardware. Although this seems a successful solution to the problem of computer room access, a mathematics only computer suite is still a rare resource (16% have access). Due to their portability, a class set of laptops might be seen as an alternative solution to the access problem. However, access to laptops is also fairly rare (26%) and comments by teachers suggest they may bring additional technical difficulties:

Working Group 15

“The laptops are of poor quality and not enough for 1 between 2 if you have a full class: there are 14.”

The collapse in access to graphic calculators since Hyde’s (2004) survey is impressive – this may be the result of their exclusion from A-level module examinations, whereas previously their use had been encouraged. Again there is a lack of consistency over access to graphic calculators between teachers in the same school. In thirteen of the schools at least one teacher said they had access to graphic calculators. The following comment suggests that the low reported access to graphic calculators may reflect a lack of awareness of their existence, rather than difficulties in booking the resource as in the case of computer rooms:

“We do have a department set of graphic calculators (ie. not explicitly for my classes) but they are rarely (if ever!) used.”

Access to software was not generally seen as a problem: access to generic software such as word processing and presentational software is almost universal (around 90%) and graphical software (81%) also appears to be readily available. Geometry software appears to have declined slightly (-13%) since Hyde’s survey, although the majority of teachers (60%) say they have access. Logo has suffered a sharp decline (-49%). In Hyde’s survey, 100% of teachers said websites were used in their school, however no further detail was given. The results from this survey suggest that access to the *MyMaths* website (91%) has risen to near ubiquity - it is possibly the dominant resource designed for mathematics teaching in the UK. It is unlikely that any textbook has such a wide coverage of schools, for example. Some teachers did complain about restrictions on downloading software, such as *GeoGebra*, and access to some websites being unnecessarily blocked. Although software was available, teachers expressed uncertainty over whether it had been installed on all computers, thereby adding complexity to conducting lessons in a computer suite.

“Some ICT suites do not have all the mathematical software which can mean plans and resources need to be adapted. Must check prior to booking.”

For many teachers, the software was readily accessible however they lacked training in its use.

“Access not a problem – time to train and develop is a problem. Desperately needs a directory/classification system.”

The time taken to develop and prepare lessons was seen as a considerable hurdle initially; however, once surmounted, teachers found that the resources could be re-used, thus reducing planning time eventually.

“Time required to prepare using ICT is a bar to entry however a number of resources I have spent time developing can then be reused very efficiently in other contexts.”

Working Group 15

Access to software	Bretscher	Hyde
Spreadsheet (eg Microsoft Excel)	92	97
MyMaths.co.uk	91	-
Word processor (eg Microsoft Word)	90	79
PowerPoint	90	79
Email	82	-
Graphing software (eg Omnigraph, Autograph)	81	73
CD-ROMs	67	85
Other websites	67	-
Geometry software (eg Cabri, Geometer's Sketchpad)	60	73
Database (eg Microsoft Access)	37	-
Logo	24	73
SMILE mathematics	17	-

Table 2: Access to software $n = 89$. Hyde's (2004) figures are shown for comparison. All figures are given in percentages.

Software access may present a new issue to consider when applying for a teaching position in the UK. On moving to a new school, one teacher found that his pre-planned lessons had been rendered useless since the IWB software he had used previously was not available. His time investment in planning these lessons had therefore been lost.

“Tech support have not installed Smart Notebook on the maths dept computers, and I have a lot of Smart Notebook files that I made at my previous school that I can't use now.”

Perceptions of the impact of ICT on learning

Teachers were asked whether they agreed with the statement ‘ICT resources can help students to understand mathematics’. In response, 97.8% agreed or strongly agreed with the statement. Teachers were also asked to rate hardware on the impact it has on student learning, using the scale in Hyde's survey from 1 (very little) to 4 (substantial). The results shown in Table 3 suggest that teachers' perception of the impact of ICT on learning varies considerably depending on the hardware being used. IWBs had the highest mean impact score (3.21), followed by data projectors (2.84). These items also came top in Hyde's survey although IWBs scored lower (2.95) and data projectors slightly higher (3.04). The reversal in score is likely to be due to the increased availability of IWBs, since they were a relatively new phenomenon in 2004 and comparatively few schools were equipped with them. Graphic calculators suffered a decline in score of 0.33. Perhaps of most interest is

Working Group 15

that a shared computer suite had the lowest impact score (2.34). A dedicated mathematics computer suite scored more highly (2.57), probably in part due to the greater ease in accessing the hardware. However the low impact score of computer rooms is also reflected in some teachers' negative comments about giving students direct access to the hardware:

“ICT maths lessons always seem tedious as the students' development is less than in normal lessons. But with *MyMaths*, as a revision/recap lesson, there are benefits now.”

“ICT is generally extremely inefficient.”

Not all teachers felt this way, some were more positive although many cited difficulties such as those detailed in the quote below:

“In our school it is not possible to find a venue where there is one computer per child. Therefore this is a very strong de-motivating factor when planning such lessons as I know the group-work element adds a layer of complexity. If it were guaranteed pair-work I might be more motivated but, for example, I recently tried a lesson like this and ended up with 10 computers between 31 students (the IT suite was supposed to have 16 computers!).”

Undoubtedly problems of access reduce the perceived impact of computer rooms, however the results from this survey suggest that teachers remain sceptical of the educational value of giving students direct access to ICT resources.

Impact	Bretscher	Hyde
IWB, $n = 78$	3.21	2.95
Data Projector, $n = 74$	2.84	3.04
Computer suite shared, $n = 73$	2.34	-
Computer suite maths, $n = 51$	2.57	-
Laptops, $n = 57$	2.40	-
Graphic calculators, $n = 59$	2.46	2.79

Table 3. Mean impact scores for hardware based on a scale where 1 (very little), 2 (some), 3 (significant) and 4 (substantial).

Frequency of hardware and software use

The majority of teachers use IWBs and data projectors in most lessons. The ready availability of IWBs and data projectors in normal classrooms makes it unsurprising that they are the most frequently used hardware. It is also likely that their high frequency of use contributes to the high impact scores noted in the previous section. Computer rooms shared with other departments have a much lower frequency of use, with 58% of teachers using them once a term or less and only 17% of teachers using them every week or more. As with IWBs, the frequency of use reflects both the accessibility and impact score of shared computer rooms. Computer suites dedicated

to the mathematics department appear to have much higher frequency of use than shared computer rooms, with 42% of teachers using them every week or more. This is likely to be the case (despite only $n = 14$) since not only is access easier than with a shared computer room, classes are often purposefully timetabled into mathematics only computer rooms to ensure the use of a relatively rare resource.

Frequency of hardware use	Never	Specific topics	Once a term	Once a month	Every week	Most lessons
IWB, $n = 70$	3	1	1	1	10	83
Data Projector, $n = 55$	7	0	4	0	24	65
Computer suite shared, $n = 55$	9	20	29	25	15	2
Computer suite maths, $n = 14$	0	21	7	29	36	7
Laptops, $n = 23$	26	13	13	9	39	0
Graphic calculators, $n = 22$	27	41	18	0	5	9

Table 4. Frequency of hardware use, with the modal frequency for each item highlighted in bold. All figures are in percentages.

The number of teachers with access to laptops and graphic calculators is quite low ($n = 23$ and $n = 22$ respectively) so it is difficult to draw any firm conclusions from the figures presented in Table 4. However it is worth noting that despite graphic calculators having a higher impact score than either laptops or shared computer rooms, they appear to have the lowest frequency of use with 68% using them for specific topics only or not at all.

Table 5 compares the mean frequency of software use in lessons with an IWB or data projector to lessons where students are given direct access to the software, i.e. those that take place in a computer room or with laptops. A score of above 2 indicates the software is used more than once a term. Email, databases, SMILE and Logo scored very low in both contexts so no satisfactory comparison can be made for these software packages. PowerPoint was the most frequently used piece of software (3.21) in conjunction with an IWB, closely followed by *MyMaths* (3.01). ‘Other websites’ and graphing software also scored above 2 for frequency of use with an IWB.

The frequency of use in lessons where students were given direct access to the software was low in comparison to lessons with an IWB: only *MyMaths* had a frequency score above 2. This is unsurprising given the frequency of hardware use in mathematics lessons reported above: computer rooms are used much less frequently than IWBs. However the decrease in use is not uniform across all types of software. In lessons where there is direct student access, most software packages have a frequency score between 0.9 and 1.1 lower than in lessons with an IWB. *MyMaths* had the smallest drop in frequency use between contexts (-0.5) and geometry software fell by 0.74. The frequency score of PowerPoint dropped the most (-2.51).

Working Group 15

Since the main purpose of PowerPoint is for presentation, it appears well suited to teacher exposition in lessons with an IWB but not so relevant in lessons where students have direct access to the software.

Frequency of software use	IWB/Data projector	Direct student access
PowerPoint	3.21	0.70
MyMaths.co.uk	3.01	2.51
Other websites	2.83	1.82
Graphing software (eg Omnigraph, Autograph)	2.01	1.09
Spreadsheet (eg Microsoft Excel)	1.91	0.97
CD-ROMs	1.84	0.74
Word processor (eg Microsoft Word)	1.76	0.84
Geometry software (eg Cabri, Geometer's Sketchpad)	1.44	0.70
Email	0.97	0.45
Database (eg Microsoft Access)	0.90	0.44
SMILE mathematics	0.54	0.37
Logo	0.22	0.25

Table 5. Mean score for frequency of software use with an IWB or data projector compared to use in a computer room where students have direct access to the software. Based on a scale where 0 (never) to 5 (most lessons), $n = 89$.

Thus not only are computer rooms and laptops used less frequently than IWBs: teachers appear to use a smaller range of software in lessons where students are given direct access to the software. *MyMaths* appears to dominate in both contexts, with the exception of PowerPoint being used more frequently with IWBs.

CONCLUSIONS

IWBs are the most accessible hardware and teachers rate them highest for impact on students' learning. Arguably, the introduction of IWBs has coincided with, if not encouraged, the apparent rise of *MyMaths* to near ubiquity in UK classrooms. Whilst positive about ICT resources in general, some teachers appear sceptical about the benefits of giving students direct access to software. Shared computer rooms scored lowest for impact and are used infrequently and although computer rooms dedicated to the mathematics department improve matters, they are still a rare resource. When students are given direct access to ICT, *MyMaths* is the most frequently used resource. The reasons for *MyMaths* apparent dominance requires further research. Research suggests that the use of IWBs coupled with PowerPoint and pre-prepared lessons of the sort available from the MyMaths website can lead to a reduction in the

quality of classroom interactions (Zevernbergen & Lerman, 2008). The Second Information Technology in Education Survey concluded that, given the right conditions, ICT might contribute as a lever for change (Law, 2009). Although the findings presented in this paper should be treated with some caution, they suggest that, in the UK, the conditions may be right for ICT to act as a lever for change in a direction that should be of some concern to both researchers and policymakers.

GRAPHIC CALCULATOR USE IN PRIMARY SCHOOLS: AN EXAMPLE OF AN INSTRUMENTAL APPROACH

Per Storfossen

Hedmark University College, Norway

This paper presents an empirically based case study design within a sociocultural theoretical framework. The research aimed to describe the implementation of a graphic calculator in a fifth grade primary school class when four students are engaged in mathematical activities performing tasks and challenges given by the researcher. The students' activities associated with the process of appropriation of a technological artifact played a prominent role in the data analysis. The distinction between artifact and instrument through the instrumental approach is in focus. Of special interest is the concept of protocol related to (the size of) the graphic calculator screen display associated with the types of tasks and challenges the students were given.

Keywords: graphic calculator, protocol, instrument genesis

INTRODUCTION

The study of the type of use and implementation of an advanced graphic calculator in a fifth grade primary school class was the focus of research described herein. Specifically, the responses of four students to mathematical tasks and challenges given by researcher are documented. The researchers' intervention was limited to the introduction of the graphic calculator in class, where a task portfolio adapted for handheld calculator was designed in collaboration with the teacher. The choice of research strategy can be described as a case study design (see the next section). Data were collected in video-taped interviews with students undertaken by the researcher. The study is presented in a sociocultural theoretical framework. The artifact properties, such as the size of the screen were variables considered in this study. The instrument-mediated activity approach was in focus.

Our research question is the following: In what ways the graphic calculator is incorporated, integrated and appropriated in the student's activities in the process of solving mathematical tasks and challenges?

A CASE STUDY ON TWO LEVELS

The framework of the study design applied to the research strategy and concerned the conduct of social research with the selection of methodological approaches to the gathering of empirical data (Bryman, 2008). The choice of research strategy in this study can be described as a case study design on two levels. On the first level, there were 23 students in a fifth grade primary school. The first level formed a backdrop for the next level, the selection of four students. There were two boys and two girls placed into two small groups one of each gender. The choice of the two boys and two

girls was partly based on pre-tests, achievement tests from a pilot study involving a representative sample of the class, but also on the students' motivation as two groups of friends wished to participate in this study that lasted over two years. We meant that the latter was a good argument for the participants not losing interest during the period of data collection. The second level of the case study consisted of the two respective groups, and was a continuation and an elaboration of the study where the entire class constituted the background. In this project, each student had two handheld calculators at their disposal. The four-function pocket calculator with one-line display which the students have been using for about three years and then there was the sophisticated icon-driven graphic calculator Casio fx9750G PLUS introduced by the researcher including a 21-character x 8-line display. The former calculator has a solar panel as an energy source, and the latter is powered by battery. The data collected and analyzed in this research study was from video-taped interviews when each of the four students were working individually, and when they were collaborating in small groups engaged in mathematical activities, challenges and tasks provided by the researcher. The mediated artifacts, among them calculators, were available and were included in their mathematical activities.

THEORETICAL FRAMEWORKS

A sociocultural approach

The Vygotsky-inspired sociocultural tradition constituted the theoretical framework of this study. The research question drew the attention to the analysis of students in a technical environment addressing the way mathematical activity was supported by material artifacts like computers, calculators, slide rules or abacus. The term artifact refers to an abstract (linguistic) or a material object. An artifact comprises objects, things or products made or modified by human beings specified for a certain purpose in reference to a historical and cultural setting (Säljö, 2006). The aim of utilizing an artifact is to sustain human activity in order to perform various types of tasks. From a sociocultural perspective, the artifact calculator is regarded as an external cognitive aid to mental processes. According to (Wertsch, 1998), we should focus on the process of turning an artifact into a useful mediated tool, the process of appropriation. In a sociocultural theoretical framework, the study has a two-sided perspective on focus. On the one hand, the focus is on individuals organized in pairs to exchange experiences and learn from each other both by applying the graphic calculators (tools) and doing mathematics. On the other hand, there are aspects concerning the individual process of appropriation of the artifact graphic calculator to become a mediated tool for the competent user. In the literature both the terms artifact and tool are used. In accordance with (Trouche, 2004, p. 282),

"when speaking of a tool before considering its users and its uses, I will speak of an artifact".

The terms artifact and tool in this study are viewed inseparable and are understood as ‘two sides of the same coin’. When the calculator is taking part in students’ mathematical activities, the calculator becomes a tool for the user. Artifacts are mediation means or cultural tools, devices that convey, shape, and transform physical processes with the purpose of mastering mental processes (Vygotsky, 1978). In a sociocultural perspective, the term mediation presupposes or requires the use of mediation means, and it is the human beings’ utilization of cultural tools that makes mediation possible. It is through or via mediation means the human agent interacts with the outside world, and the tools exert their impact when an agent uses them. Mediation refers to human interaction with one other in symbiosis with external tools as mediators (Daniels, 2001). “Mediation through artifacts applies equally to object and people” (Cole, 1996, p. 118), and artifacts “have been modified by human beings as a means of regulating their interactions with the world and others” (Cole, 1999, p. 90). According to Cole, mediation through artifacts refers to people acting with mediating artifacts which are emerging from historical and cultural settings. Throughout history human functions and competencies have been accumulated and transferred into external aids named artifacts. The mediated artifact graphic calculator was, in this study prominent, present and situated.

The unit of analysis

From the research perspective it is explicitly important to communicate the unit of analysis of the study. Data collection and data analysis are intertwined in social science research. It is therefore crucial for the researcher to be aware of this relationship and sort out the ‘what’ and ‘whom’ that is being studied (Lee & Fielding, 2004). According to (Wertsch, Rio, & Alvarez, 1995, p. 56),

“The goal of sociocultural research is to understand the relationship between human mental functioning, on the one side, and the cultural, historical, and institutional setting.”

The authors refer to a relationship between a sociocultural situation and mental processes, and

“it is essential for the research to formulate its position vis-à-vis the individual-society antinomy in some way” (ibid., p. 59).

Mental functioning and the sociocultural setting are understood as aspects of dialectically interacting moments, and the human action is the connection and is considered as the unit of analysis. (Vygotsky, 1978, 1986) focused on thinking, speech, i.e. mediated action, while (Bakhtin, 1986) maintained focus on utterances as a form of action. (Wertsch *et al.*, 1995) highlighted the research of human actions as a “dynamic human actions existing in real spatiotemporal and social context” (p. 62). Wertsch (1998) proposed mental functioning and sociocultural setting to be understood as dialectically interacting moments, aspects of a unit of analysis. In sociocultural research, the human actions serve as the cornerstone to be described and interpreted. The kinds of actions that concerned Vygotsky have been termed

“mediated actions” as the unit of analysis (Wertsch *et al.*, 1995). To provide an adequate foundation for an account of the action carried out, neither the mediation means nor the individual operates in isolation. The individual is not acting alone as an agent of actions. An agent refers to who is carrying out the actions, e.g. who is speaking. An appropriate description may be characterized by agents of actions like “individual-operating-with-mediation-means” as the unit of analysis, a framework grounded on actions. Mediated action can be transformed by mediation means like the case with the introduction of an advanced calculator. However, it is not so say that the mediation means, in a way, acts alone. The individual using mediated means has to change or adapt as well in response to new techniques and skills. In this study the research question draws the attention on an analysis of students in a technically supported environment, working in small groups engaged in mathematic activities, with natural verbal communication in the interaction. According to theorists like Vygotsky and Wertsch, the unit of analysis in this study can be modified and transformed to individuals-appropriate-technological-artifacts-in-cultural-practice.

The instrumental genesis approach

In this study, the sociocultural perspective was the theoretical framework. Mediated activity, transformed to individuals-appropriate-technological-artifacts-in-cultural-practice constitutes the unit of analysis. (Vérillion & Rabardel, 1995) and (Rabardel, 2002) drew on Wertsch’s key construct of mediated activity (Wertsch, 1998). The process of appropriation of an artifact to become an instrument, a tool for the competent user is further elaborated by (Trouche, 2004). The instrumental approach with the human/computer interaction and human use of tools constitutes two main processes of instrumented mediated activity. The process directed from the artifact towards the human agent is named instrumentation. The tools convey, shape and transform the human agency and the subject adapts to constraints and affordances the tool possesses. The other process, instrumentalization, is directed from the human agent towards the artifact (graphic calculator) which includes stages such as familiarization with the instrument, mastering the instrument and adoption of the instrument to one’s own personal specific needs. In this study the graphic calculator in becoming an instrument for the student, individual and collective activities have drawn on the instrumental genesis approach influenced by Rabardel (2002).

Protocols of actions

Dörfler in his work (2000) emphasized reflection and attention on actions. His constructed protocol of action consisted of records of actions, which can contain manipulations and interactions with objects-like models. Oral expressions and all kinds of counting activities are examples of protocol of actions.

“I use the term protocol to designate the related cognitive process of focusing attention on those stages, phases, results, and products of one’s action and constructions, and of describing and notating them by some means”. (ibid., p.111)

Working Group 15

The protocol of action (its schematic carrier) will include a kind of notation-suitable system that will make it possible for the individual or agent to reconstruct his or her activities for which it is a protocol. The protocol, the record of action, makes possible replication and reconstruction of the essential phases, stages of the actions, and transforming the result into a suitable notation system. A counting system is an example of notation system, like the decimal system. For example, a student has counted up the number of pens lying on a table; there are 38 pens, which are grouped into 3 groups of 10 pens and 8 individual pens. Another example of a protocol is given by a transformation; the rotation of a point in a plane is uniquely determined by an origin, the coordinates of a point and an angle. Records of physical objects or figures rotated using coordinates of the vertices is further a carrier (protocol of action) to abstract mathematical rotations. When an agent has developed a *specific protocol*, like the protocol for rotation of a point in a plane, the agent is able to replicate and reconstruct the mathematical actions from the record of actions which constitute the protocol. The specific protocol for an agent constitutes a characteristic, a quality the agent possesses. On the other hand, and on another level, Dörfler's *concept of protocol* of is a theoretical construct and is an analytic tool for the researcher to describe and to study an agent's performance in carrying out the mathematical activities like rotation of a point in a plane.

THE TASK PORTFOLIO

A task portfolio was designed in collaboration with the teacher of the class. The portfolio was adapted from the textbook and the curriculum for the 10-year compulsory mathematics education. An objective in designing the portfolio was to make the tasks concrete and in a context familiar to the students. The tasks were based on their everyday life experience, with the intention of students conceiving the tasks as realistic and a part of their daily life. A type of task in the portfolio was named exploration tasks (exploratory work) organized by mathematical topic. One of these topics was linear two-variable Diophantine equation that takes the form $ax + by = c$, $(a,b)=1$. The parameters a , b and c are integers, where a and b are relatively prime numbers. Two examples of this type of equation with which the four students were challenged are outlined as follows:

Task 1) A train is 78 meters long. There are two kinds of train carriages, carriages of length 7 meters and carriages of length 11 meters. How many carriages of 7 meters and how many carriages of 11 meters will give the length of 78 meters?

Task 2) An ice cream costs 3 euros and a hot dog costs 5 euros. How many ice creams and how many hot dogs can you purchase when you have 70 euros at your disposal?

The students were unfamiliar with a general solution for this type of equation. A method to find all the solutions for this kind of problems required theoretical knowledge and insight in mathematics at a level they did not have, but could later learn in an advanced course in mathematics. However, videotaped interviews show

that some students were able to find one or more solutions of this type of equation on their own, when they utilized the graphic calculator as an external cognitive aid to sustain mental arithmetic operations (See the example with the game 'Dart' below).

CALCULATOR DISPLAY AS A PROTOCOL

When a student is typing in numbers, signs or characters into the calculator, the results of these actions will appear on the screen display. The latter is a record of the actions performed by the student, a mathematical text or a syntax consisting of keystrokes. However, the calculator can interact with the student by giving a spontaneous response in the form of an answer to arithmetic operations or eventually give a syntax error (convention error) message to incorrect typing. The screen is displaying a semi-permanent record of actions. An interesting aspect associated with the type of use of the calculator is when the calculator is displaying more than one line of arithmetic operations with its corresponding answers. The protocol constitutes the activities the students were doing, signs and symbols they typed in the calculator. The calculator displays a mathematical text, a notation system which gives meaning through conventions. They may be read off the display as a semi-permanent inscription. Through the example of a transcript from a video clip excerpted below, we will give an account on how the screen display of a graphic calculator, for a student, become a protocol to develop strategies to find solution(s) to a mathematical task or challenge (see in particular the line 106 below). Here, the concept of protocol is functioning as an analytical tool for the instrumental approach when the focus is on part of the artifact, namely the size of the screen display and the activities that constitute the process of instrumental genesis.

The following excerpt is a transcript of a video clip of an interview of the two students Kate and Signe. The video clip is part of a comprehensive video material.

- 101 Interviewer: Can you say something about what you appreciate when using the graphic calculator?
- 102 Kate: It is pretty nice actually. It has a large screen and you can have several calculations simultaneously.
- 103 Interviewer: You said that with the graphic calculator, the screen made it possible to display several calculations simultaneously. But, is this possible with the one-line calculator?
- 104 Kate: No, you can only have one calculation at a time
- 105 Interviewer: What does it mean for you that it can display several calculations at a time?
- 106 Kate: It means a lot! Because, if you are going to figure out and calculate something important, you need to make miscellaneous calculations...and to move forward and get closer and closer. And then it is important to see the calculations that have been done before, so you don't need to calculate them once more
- 107 Interviewer: How about the one-line calculator?

Working Group 15

108 Kate: With the one-line calculator, you can only come with... have one calculation at a time. And then it is hard to know...

Later on in the interview the researcher asked the students about the type of task they preferred when using the graphic calculator.

190 Researcher: What type of task might suit this calculator?

191 Kate: Maybe the one with hot dogs and ice cream

192 Signe: Maybe the one with trains...

In the lines 190-192, the students referred to, and considered two prototypical situations of the ‘class of situations’ and tasks contained in the portfolio, two examples of linear two-variable Diophantine equations (see task 1 and task 2 outlined above). The students associated the type of calculator according to the type of task, and they preferred the multi-line display calculator rather than the calculator with one-line display with the Diophantine equation challenges. However, when the students were challenged with simple tasks such as calculating 38×17 which required only one arithmetic operation (calculation) at a time, or when there was no need for investigation, they prefer the simpler calculator. This may be the reason why Kate, in the line 108, says: “with the one-line calculator, you can only have one calculation at a time”. She is aware that the one-line display will be definitely sufficient when working with simple tasks or when there is no need to develop a strategy to solve an arithmetic problem. Otherwise, when handling complex tasks like the Diophantine equation problems (task 1 and 2), she will choose the calculator with the multi-line display. This process, instrumental genesis, of awareness of the type of task that can or cannot be solved with a particular type of calculator is a process of an artifact becoming part of an instrument in the hands of a student.

Develop a strategy by use of a protocol

$310 \div 7$	44.28571429
$119 + 77$	
$196 + 70$	196
$4 \times 11 + 266$	266

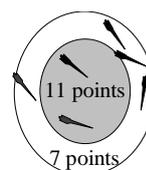

Figure 1: Display as a protocol for Signe

Figure 2: Game ‘Dart’

One of the tasks in the portfolio concerned the game ‘Dart’ (see fig. 1 and fig. 2). A hit with an arrow within the inner circle gives 11 points, while a hit with an arrow within the outer circle gives 7 points. The task was: How many arrows of 7 points and how many arrows of 11 points will give a total of 310 points? This is another example of a Diophantine equation. The description and analyses of the screen display above are based on the same interview with the other student Signe. The screen display shows part of Signe’s solution strategy which addresses how she managed to solve the problem using the calculator. Signe came up with one of the four solutions, here the solution $38 \times 7 + 4 \times 11 = 310$ or $\{38, 4\}$. The screen functioned as a protocol for her. Signe divided 310 by 7 to investigate the number of

Working Group 15

7-arrows there would be. The result of the previous calculations $119 (17 \times 7)$ she added to 77, yielding 196. The number 119 was previously calculated and is from a previous screen display. She then added 70 and calculated 266 (38×7) points. Finally, she went back to the first line in the display. Typed 44 (4×11) and added 266. The calculator gave her the answer 310. The calculator functioned as an external support for her mental arithmetic.

The result of Signe's activities consisting of keystrokes entering numbers, arithmetical operations, signs or other characters into the calculator and displayed on the screen are examples of an inscription. The semiotic display on the calculator screen is regarded as an inscription composed of a mathematical notation system. A student using the calculator dynamically and interactively is able to construct a system out of screen display lines showing arithmetic calculations within a single arithmetic problem, applying to the screen display a protocol of actions (Dörfler, 2000). A calculator screen displaying one or more lines of an arithmetic calculation is not a protocol for each and everyone. It depends on the person's internal processes, on how an individual reasons something out and the cognitive processes. For example, a student who performs isolated single calculations does not necessarily use the calculator screen as a protocol. Others may focus on the entire process to which they relate by using the calculator. For them it is not just a simple calculation they are dealing with, but they focus on the entire process of calculations when utilizing a calculator. Students who are working with the aim of developing a solution process without "going blind," may have found an overall strategy. It is therefore important to achieve a good interplay between the internal cognitive processes and the external artifacts. By having access to a larger screen with the ability to display multiple-lines of arithmetic calculations and corresponding answers simultaneously, Signe could read off the display, control and compare the results of several mathematical expressions she has typed in, keystroke by keystroke. A larger screen and use of protocol makes it possible for her to jump forwards or backwards between the calculations. For each calculation, Signe gets a quick response and she can immediately check the results. She can also return to the previous calculations and then continue where she was. In this way the mathematical process continues in a search for solution(s). As Kate describes in text line 106, and as Signe demonstrated in the game 'Dart', mathematical activities using the artifact can be described as an interactive process like the text in web pages on the internet. Searching in such text or amongst lines of arithmetic calculations is not a linear process because the student can move one or more steps backwards or forwards from where she was in the mathematical text. The availability of a larger screen display, listing up to 8 lines, opens up new opportunities because the user gets an overview of more information at once compared with one-line calculators. The graphic calculator gives her an advantage; the size of the screen display allows her to see several lines of arithmetic operations and opens up for articulation, reasoning and problem solving processes. "So you don't need to do the calculations once more" as she expressed in

the line 106. The interpretation is that the part of the artifact, the screen display can take part in her mathematical activities via the lenses of the protocol. In the 'Dart' example, the screen is a protocol for Signe and made it possible for her to reconstruct and replicate the arithmetic calculations on the screen display. The calculator becomes an external cognitive aid for the competent user to find solution(s) to a mathematical problem. The dynamic and creative aspects by utilizing the screen display in this manner can be described as instrument-mediated, appropriating the artifact as an instrument, turning the artifact into an instrument in the hands of a student. The interpretation is that the screen display has become a protocol for Signe. The concrete protocol is a property, a stage in a development in and is a quality she possesses. The protocol says something about how Signe relates to the part of the calculator that is the screen display, and how she is able to utilize the constraints and affordances, the potential of the screen. The concept of protocol is an analytical tool for the researcher to describe and to study how far the student has come in the process of instrumental genesis by studying their 'protocol scheme' through the student's use of the screen according to type of task.

CONCLUSION

The development of mathematics has always been dependent on the material and symbolic tools available for mathematical calculations (Artigue, 2002). A sociocultural tradition can shed light on how students can master and appropriate the graphic calculator in their mathematical activity and to make the artifact an instrument for the competent user. This is an individual process. The graphic calculator can be effective in helping students sustain their mathematical activities in the process of instrumental genesis. The process of instrumental genesis is suitable to analyze the processes of appropriation, the transformation of an artifact to become an instrument in the hands of a student. This study illustrates the influence the type of tasks and challenges given by researcher can have on student's instrument-mediated activity. The concept of protocol is used as an analytical tool to study student appropriation of the part of the artifact calculator, the screen display. The construct of protocol can thus give substance to instrument genesis by studying the constraints and affordances, through the student's use of the artifact screen display. There is a further need for empirical resources to develop theories that elucidate complex human-machine relationships and to better understand how they may function in different educational settings.

AN ONLINE GAME AS A LEARNING ENVIRONMENT FOR EARLY ALGEBRAIC PROBLEM SOLVING BY UPPER PRIMARY SCHOOL STUDENTS

Angeliki Kolovou, Marja van den Heuvel-Panhuizen

Freudenthal Institute for Science and Mathematics Education, Utrecht University, the Netherlands

The paper reports on a study of students working with an online archery game. We invited 318 students from grades 4, 5 and 6 to use the game at home to solve a series of contextual problems addressing covarying quantities. In particular, the study investigated how the students utilized the computer environment and the strategies they applied. The analysis revealed that the online working was positively related to success in a written posttest on early algebra problems. The learning environment stimulated the application of various strategies and the exploration of relations and structure.

Keywords: Early algebra, online game, problem solving strategies

INTRODUCTION

In primary school mathematics the focus is mainly on developing numeracy and calculation skills. However, several researchers (Goldenberg, Shteingold, & Feurzeig 2003; Harel, 2008) have pointed out that mathematics also involves ways of thinking or mathematical habits of mind, including seeking and exploring patterns, making conjectures and performing experiments, and applying heuristics to solve nonstandard problems. These ways of thinking should also be a vital part of mathematical instruction at primary school level. Along these lines, primary school students can be engaged in algebraic activities that provide them with the opportunity to practice both basic and more sophisticated thinking skills such as generalization (Kaput, Carraher, & Blanton, 2007). The integration of algebra in the primary grades is essential for adding coherence, depth, and power to school mathematics and can prepare students for the learning of algebra in the later grades (Kaput, 2007).

However, the inclusion of algebra in primary school does not imply adding traditional algebra to the primary school curriculum; rather, it means providing entry points for algebra through treating existing topics in a deeper and more connected way (Kaput *et al.*, 2007). For example, patterning activities can help students move towards understanding functional relations (NCTM, 2000). Rich problem contexts can play an indispensable role herein, as experience and reasoning in particular situations may support students in generating abstract knowledge (Carraher & Schliemann, 2007).

Although tables (Schliemann, Carraher, & Brizuela, 2001) and function machines (Warren, Cooper, & Lamb, 2006) have been employed for studying functional relations at primary school level, new technologies might bring further improvements herein. Computers can perform calculations and diminish the routine workload so that

students can focus more on exploring relationships. Furthermore, computer tools can surpass the constraints of paper-and-pencil methods by providing dynamically linked notations and instant feedback (Roschelle, Pea, Hoadley, Gordin, & Means, 2000).

In this study we offered primary school students an online environment including a dynamic game with which they could solve problems with covarying values (which we call early algebra problems). In particular, we sought to answer the research questions:

How do fourth to sixth graders utilize an interactive online environment including a dynamic game to solve early algebra problems?

Is students' working in this environment related to their performance in a written test on early algebra problem solving?

THEORETICAL UNDERPINNINGS

Algebra in primary school

Kieran (2004) argued that algebraic thinking in primary school entails mathematical activities such as problem solving, generalizing, analyzing relationships, and studying change; these are general activities for which algebra is used as a tool, but which are not exclusive to algebra. Van Amerom (2003) argued that students can acquire algebraic concepts before studying formal algebra through solving nonstandard problems. Their informal approaches can be seen as ways in which they try to deal with algebraic situations without having to rely on formal algebra (Johanning, 2004).

Variation theory

According to variation theory, for learning to occur, the learner should be able to experience and discern critical aspects of variation in the phenomenon under study (Runesson, 2006) and become simultaneously aware of the possible values that these aspects can take (Marton & Tsui, 2004). Although experiencing patterns of variation is significant for learning mathematics in general, it might be especially relevant to the teaching and learning of algebra, since the ability to generalize from particular instances implies that one can distinguish between what varies and what remains invariant. Variation theory can be used for designing learning situations by creating patterns of variation and invariance in relation to critical aspects of that learning (Runesson, 2006). According to Watson and Mason (2006), in comparison to unstructured sets of tasks, tasks that display constrained variation are likely to result in progress.

The role of computers in the teaching and learning of mathematics

Technology influences not only how mathematics is taught and learned but also what is taught and when it is taught; technological tools afford access to powerful visual models and enable the quick and accurate execution of routine procedures, which allows more time for conceptualizing and modelling (NCTM, 2000). Particularly, in simulations students are engaged in active exploration and discovery learning (Lou, Abrami, & d'Apollonia, 2001) and they are challenged to formulate strategies to deal with complex mathematical systems (Crown, 2003). Dynamic computer

environments offering animation-based feedback (Nathan, 1998) might be especially suitable for comprehending how quantities relate to each other, thus supporting algebra problem solving. Likewise, the use of spreadsheets can assist students in understanding the concept of variable as a varying quantity and in generalizing problem situations (Lannin, 2005). However, more research into the use of technology in the early grades is needed (Kilpatrick, Swafford, & Findell, 2001).

SET UP OF THE STUDY

Procedure

A pretest-posttest experiment was set up to investigate the influence of a computer-based intervention, including an online game, on students' early algebra performance. For working in the online environment each student received a login account and eight problems split in three sets. The students were requested to solve the problems in the online environment at home and write down their answers on a worksheet. This online activity was not compulsory. The students had approximately a week at their disposal to work on each set of problems. At the end of the week the students presented their answers in short follow-up discussions in class. The purpose of these discussions was not to teach students how to solve the problems, but to provide them with feedback on their answers and sustain their participation. Before and after the intervention a written test on algebraic problem solving was administered at school.

Participants

In total 318 students from grade 4, 5 and 6 from five schools in a major Dutch city were invited to participate in the study. These schools are situated in five city districts that cover a wide socio-economic range of student population.

Pretest and posttest on algebraic problem solving

The written test on algebraic problem solving that served as pretest and posttest included seven contextual problems, such as the following:

Quiz: In a quiz you get 2 points for each correct answer. If a question is not answered or the answer is wrong, 1 point is subtracted from your score. The quiz contains 10 questions.

Tina received 8 points in total. How many questions did Tina answer correctly?

The problems of our study can be solved by a formal algebraic approach that is setting up and solving a system of two linear equations with two unknowns, or by an arithmetic method in which students have to reason informally about the relationships between the quantities. Since formal algebra is introduced in the Netherlands in the first year of the secondary school, we expected that the primary school students in our study had only arithmetic approaches at their disposal.

The online environment

The environment developed to offer students experience in dealing with interrelated variables includes a dynamic game called *Hit the target* [1] (see Figure 1a/b), which

Working Group 15

is a simulation of an archery game. In this game the students can set the shooting mode (user or computer shooting) and the game rule mode (user or computer defined). The features of the game are dynamically linked. In the course of the game the values on the scoreboard update rapidly to provide information about the total score. In this way, students may become aware of the fact that the arrows, the score, and the game rule are related to each other so that a modification in the value of one of these variables has a direct effect on the other variables. Moreover, the game offers instant visual feedback by displaying the consequences of students' actions.

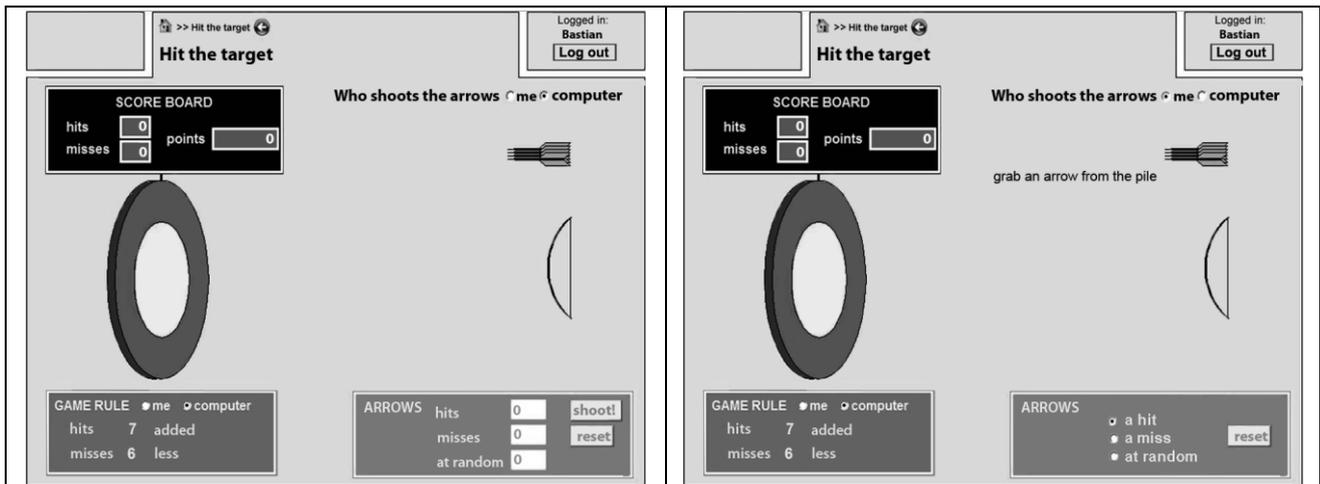

Figure 1a: Screen view of game in the computer shooting-mode **Figure 1b: Screen view of game in the user shooting-mode**

The problems that the students had to solve in this environment varied from finding the number of hits and the number of misses that produce a particular score, to generating a general solution by systematizing all possible answers. In general, two types of problems were included: problems that can be translated into a linear equation with two unknowns and problems that can be translated into a system of two linear equations with two unknowns. This series of problems aimed to support students in detecting patterns and generalizing, and confront them with situations in which multiple conditions should be taken into account simultaneously. Variation in the numbers among the problems was intended to help students grasp the invariant structure of a problem, despite the fact that the particular numbers can vary. Furthermore, the variables that were allowed to vary and the variables that were kept invariant differed between the problems. A selection of the problems is the following:

Problem 3: What is the game rule to get 15 points in total with 15 hits and 15 misses? Are there other game rules to get 15 hits, 15 misses, and 15 points?

Problem 4: What is the game rule to get 16 points in total with 16 hits and 16 misses? Are there other game rules to get 16 hits, 16 misses, and 16 points?

Problem 5: What is the game rule to get 100 points in total with 100 hits and 100 misses? Are there other game rules to get 100 hits, 100 misses, and 100 points? Can you explain your answer?

Working Group 15

Problem 8: For every hit you gain 2 points and for every miss 1 point is taken away from your score. You have 10 arrows in total. How many hits and misses do you have to shoot to get 5 points in total? Are there any other solutions possible?

The online environment offered students the opportunity to solve these problems by testing their ideas and receiving instant feedback. Moreover, the students' online activity was captured by special software, the so-called *Digital Mathematics Environment (DME)* [2]. The log data used in this study consisted of a list of the actions carried out by the students in the online environment classified into events (i.e., shooting actions) and sessions (i.e., series of events that students perform each time they are logged in) (Figure 3). A coding scheme for analyzing students' log files was developed in several rounds. Its final version consisted of 12 strategies. The interrater reliability was determined by calculating Cohen's kappa, which was considered to be sufficient (.84).

RESULTS

In total, 253 students logged in at least once. The frequencies of the logged-in students from grades 4, 5, and 6 were 74%, 88%, and 78% respectively. The students who did not log in had the same pretest performance as the students who logged in ($t(309) = -1.72, p > .05$). Table 1 gives an overview of the means and standard deviations of the pre and posttest performance, the login time, the number of events, the number of focused events (i.e., events related to answering the online problems), the percentage of focused events (ratio focused events to total events) and the number of problems students worked on per grade.

	Grade 4 (N=75)		Grade 5 (N=73)		Grade 6 (N=84)	
	M	SD	M	SD	M	SD
Pretest (proportion correct answers)	.06	.14	.23	.26	.38	.30
Posttest (proportion correct answers)	.11	.20	.30	.33	.48	.36
Login time (minutes)	35.70	41.63	25.75	18.69	32.22	54.46
N of events	17.04	14.77	17.81	13.34	13.34	9.90
N of focused events	5.68	7.61	9.60	8.15	7.48	8.07
% of focused events	26.7	26.9	50.6	31.1	46.2	33.7
N of worked problems	3.10	3.82	4.92	3.71	4.46	3.91

Table 1: Pre and posttest performance and characteristics of students' online working

The gain score calculated by the difference of the score in the items in the post and pretest was significant across all grades with moderate effect sizes (grade 4: $t(74) = 2.46, p < .05, d = .16$, grade 5: $t(72) = 2.93, p < .01, d = .24$, grade 6: $t(83) = 5.19, p < .001, d = .43$). The standard deviations show considerable variation in the way students utilized

the online environment. The fifth graders exhibited the highest number of events, focused events and worked problems and the highest percentage of focused events.

The partial correlations (Table 2) between the characteristics of the online working and the posttest performance controlling for the pretest performance reveal significant relationships between the posttest performance and the percentage of focused events and the number of worked problems for the students of grade 4 and 6.

	Posttest		
	Grade 4	Grade 5	Grade 6
Login time (minutes)	-.03	.03	-.03
N of events	.03	.07	.03
N of focused events	.17	.06	.07
% of focused events	.30**	.11	.21*
N of worked problems	.36**	.16	.22*

** $p < .01$, * $p < .05$ (one-tailed)

Table 2: Partial correlations between students' online working and posttest performance

Students applied various strategies to solve the problems (Figure 2). The mostly used strategy was trial-and-error (TE) (49%–64% of the students). Systematic trials (Sys) were, however, performed by only a few students. A high percentage of students (43%–58%) applied the Extreme strategy, which is a way of reducing the complexity of a problem by putting one variable to zero so that another variable in the linear relationship gets the maximum possible value.

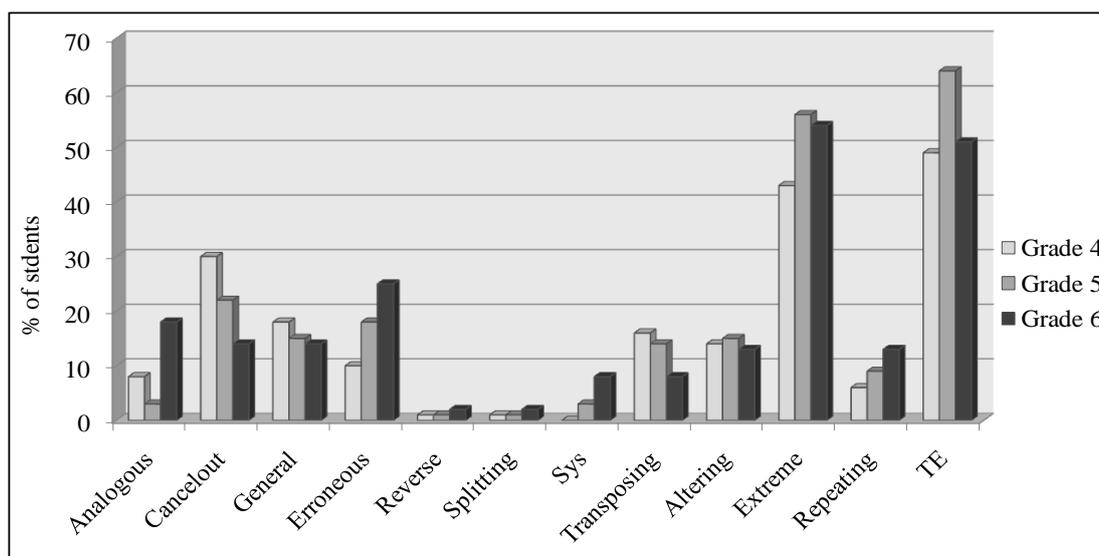

Figure 2: Relative frequencies of strategy use in grades 4, 5, and 6.

The Analogous strategy (e.g., in *Problem 5*: shooting 10 hits and 10 misses), the Splitting strategy (e.g., in *Problem 5*: first shooting 100 hits and 0 misses, then 0 hits

and 100 misses, and adding the partial scores to calculate the total score) and the Transposing strategy (i.e., the values of the arrows and the values of the game rule are exchanged) were less frequently applied. These strategies were particularly evoked when students tried to solve Problem 5. Since the maximum number of arrows to be shot at once in the game is restricted to 150, the students cannot shoot 100 hits and 100 misses at once, but should come up with other approaches to solve this problem.

Strategies like Altering (adapting part of the problem information), Extreme, Repeating (replicating a correct solution), and trial-and-error imply a focus on providing the (correct) answer. In contrast, the use of more sophisticated strategies is an indication that students explored relations and structure. Such strategies are Analogous, Cancelout (i.e., the total of hit-points cancels out the total of miss-points), General (looking for a general rule), Erroneous (i.e., applying an erroneously derived rule to produce additional solutions to a problem), Reverse (i.e., reversing a rule to produce additional solutions), Splitting, systematic trials, and Transposing.

Moreover, we could identify three levels of online working: free playing, (just) looking for answers, and exploring relations and structure. Level 1 includes the students who put little or no effort in answering the given problems, in particular, the students who performed less than three focused events or tried to answer less than three problems. Level 2 includes the students who mainly (just) tried to answer the problems. These students exhibited an activity which was equal to or beyond the threshold of minimum effort, but their main concern was to provide correct solutions as indicated by the use of less sophisticated strategies. Level 3 includes the students who also exceeded that minimum amount of effort and used sophisticated strategies, which indicates that the students explored relations and structure.

	Grade 4	Grade 5	Grade 6	Total
Free playing (Level 1)	60.8	29.5	39.6	43.1
(Just) looking for answers (Level 2)	12.7	41.0	28.1	27.3
Exploring relations and structure (Level 3)	26.6	29.5	32.3	29.6

Table 3: Percentages of students who applied a particular level of online working per grade

The percentage of students who performed free playing was the highest in grade 4, while the majority of the students in grade 5 were categorized at the level of just looking for answers. In grade 6 free playing was again the most prevailing activity. Nevertheless, the percentage of students who explored relations and structure increased slightly from grade 4 to grades 5 and 6.

Figure 3 shows the log file of a sixth-grade student's problem solving process that eventually led to the discovery of the general rule. In *Problem 3* the student found one solution by trial-and-error. In *Problem 4* she came to a general rule (i.e., the points per hit and the points per miss should add up to 1), which she also applied in *Problem 5*.

DISCUSSION

This study looked at how an online learning environment with a game and a series of problems can contribute to students' ability to solve problems with interrelated values. The analysis revealed that the ability to solve the problems increased over the grades with the highest gain in the grade 6. Despite the short duration of the intervention, the online working was positively related with success in the posttest for grades 4 and 6. Furthermore, the environment brought about various types of strategies. The dynamic character of the game offered students the opportunity to apply sophisticated strategies to explore relations and structure. In addition, the problems sequence turned out to be important as well. The log files revealed that by working on the series of problems, the students could experience how the values covariate, which prompted the discovery of the general relation between the values.

However, some limitations should be kept in mind. To begin with, our conclusions are based on the log files of the students' online activity, which might not entirely capture their cognitive processes such as the mental calculations. Nevertheless, the

collected data provided a step-by-step account of students' interaction with the computer environment. Furthermore, because the changes in the levels of online working across the grades followed an irregular pattern, the question is raised whether the students who participated in the study are typical. Due to cluster sampling, there is a higher probability of getting a non-representative sample.

Moreover, we could not control whether the students worked on the online problems on their own or with the help of a peer or family member. However, because the activity was voluntary and low-stakes, it is likely that the students did not feel the need for assistance. In addition, the diversity in the students' engagement in the online activity is an indication that the students worked on their own; had parents been involved, it would have been more likely for the students to try to solve all the presented problems.

However, in general, our results suggest that algebraic reasoning in the primary grades could be stimulated through computer environments. Furthermore, home computing may create an effective learning environment supporting and extending school learning. Yet further investigations are needed, in particular to examine the influence of the game when introduced as a compulsory activity in the classroom.

NOTES

1. The game 'Hit the target' is developed by the first author and programmed by our colleague Huub Nilwik.
2. The Digital Mathematics Environment (DME) is developed by our colleague Peter Boon.

FRAMING A PROBLEM SOLVING APPROACH BASED ON THE USE OF COMPUTATIONAL TOOLS TO DEVELOP MATHEMATICAL THINKING

Manuel Santos-Trigo
Cinvestav. Mexico

Matías Camacho-Machín
University of La Laguna. Spain

We outline problem-solving episodes dealing with mathematical tasks in which the use of the tools becomes relevant. The episodes involve the use of an inquiring process to approach problem statements or comprehend mathematical concepts. Questioning becomes a form or way of making sense of situations and of representing them in terms of using the tools' affordances. The episodes characterize a framework that teachers can use to structure and reflect on ways to use computational tools to foster their students' development of mathematical thinking.

INTRODUCTION

It is widely recognized that the use of computational technology could offer students and teachers various ways to represent and explore mathematical problems or concepts. There is also evidence that different tools might offer learners different opportunities to think of problems in order to represent, explore, and solve them. Recently, different research programs have analyzed and documented the role played by the use of diverse digital tools in the students' development of mathematical knowledge (Hoyles & Lagrange, 2010). For example, the use of dynamic software offers advantages to construct models of situations or problems in which the model components can be displaced within the representation to identify and explore mathematical relations, while the use of calculators offers advantages to represent and deal with problems algebraically. In general, research results indicate that it is important for teachers to incorporate in their teaching scenarios a systematic use of several computational tools to help students develop mathematical comprehension and problem solving proficiency. To this end, several recent curriculum proposals recommend that students use computational tools in their learning activities.

What type of tools should students use and how should they use them to enhance their problem solving approaches? What types of tasks should students work and discuss in order to transform technological artefacts into effective problem solving tools? What types of mathematical reasoning do students develop as a result of using a particular tool in problem solving activities? The discussion of these and similar questions is relevant to orient or guide teachers during the design and implementation of activities and tasks fostering the use of computational tools. The aim of this article is to identify dimensions and processes that characterize students' problem solving approaches fostering the use of several computational tools. In this context, we identify and discuss common math features that distinguish students' use of computational tools to solve problems. In order to do this, we focus mainly on problems where students use the tools to construct a dynamic model of the problems.

The model is then used as a departure point to look for mathematical relationships that become important to solve and extend the problem. It is important to investigate the extent to which the use of particular tools helps students develop knowledge and ways of thinking that are consistent with mathematical practice. In particular, we argue that teachers need to reflect on key issues and concepts concerning the process involved in using the tools in their problem solving approaches.

ON THE STUDENTS' PROCESS OF APPROPRIATION OF THE TOOLS

How should teachers decide what computational tools to use in their practices? What type of tasks and instructional strategies should they consider to use the tools in problem solving approaches? And what types of reasoning do students construct as a result of using certain tools in their learning experiences? Kaput (1992) stated that “[m]ajor limitations of computer use in the coming decades are likely to be less a result of technological limitations than a result of limited human imagination and the constraints of old habits and social structures” (p. 515). Nowadays, after almost two decades since Kaput’s statement, the math education community faces a challenge not only to clearly incorporate a systematic use of computational tools in curriculum proposals, but also to characterize learning scenarios in which students can efficiently use tools to learn and develop math knowledge. In other words, the use of the tools requires not only the transformation of classroom settings, but also the validation of emerging explorations including visual, empirical and formal reasoning. It is also important to recognize that the tool itself does not provide the media or ways needed for students to efficiently use it in problem solving activities; it involves an appropriation process in which the students transform an artefact into an instrument. This appropriation depends on cognitive schemata that students develop while using the tool to represent and explore the problem. Trouche (2004) stated that “an instrument can be considered an extension of the body, a functional organ made up of an artifact component (an artifact, or the part of an artifact mobilized in the activity) and a psychological component” (p. 285). The artefact characteristics (ergonomics and constraints) and the schemata developed by the students during the activities are important for them to transform the artefact into a problem-solving instrument. In this respect, Trouche (2004) related the students’ psychological component to the construction of a scheme with three functions: “a *pragmatic* function (it allows the agent to do something), a *heuristic* function (it allows the agent to anticipate and plan actions), and an *epistemic* function (it allows the agent to understand what he is doing)” (p. 286). Indeed, these three functions become essential to construct dynamic models of problems. The use of dynamic software plays an important role in constructing models of situations and tasks where the movement of particular elements can be examined and explained in terms of math relationships (Santos-Trigo, 2008). Models might involve configurations made of simple math objects (points, segments, lines, triangles, squares etc.) in which some elements of the models can be moved within the configuration in order to identify

and explore math relationships. These relationships and conjectures become a source that engages students in math inquiry and reflection. As a consequence, the process of model construction and exploration also incorporates a variety of ways to represent, formulate, and examine math relationships. For instance, with the use of the tool, the situations or problems are now analyzed in terms of the facilities and affordances offered by the tool such as dragging particular components, finding loci of points or lines, quantifying certain relations, using a Cartesian system to model the problem algebraically (Santos-Trigo, 2008). Indeed, the use of the dynamic software seems to offer problem solvers the opportunity to explore diverse routes to develop or reconstruct and examine basic mathematical results. In particular, the visual approach becomes relevant to identify mathematical relationships that later can be analyzed in terms of numerical and graphical approaches (Santos-Trigo, 2010).

BACKGROUND AND GENERAL CONTEXT

This study is part of an ongoing project whose general goal is to foster service and pre-service high school teacher use of computational technology as part of their regular practices. These teachers participate in regular problem solving sessions where they have the opportunity to use diverse computational tools to work on math tasks. The tasks include dealing with situations where the participants construct dynamic models or geometric configurations (formed by simple objects such as segments, points, lines, circles, etc.) that lead them to identify math relationships by moving elements within the model (Santos-Trigo & Espinosa-Pérez, 2010). In this type of task, there is no initial well-defined problem statement, and the problem solver formulates and pursues questions as a result of observing the behaviour of the involved objects. Other types of tasks include those that appear in regular textbooks, where the idea is to use tools to represent, explore and look for different ways to approach the tasks.

In this paper, we discuss math thinking features we have identified during the implementation of problem solving approaches in teaching scenarios where teachers systematically use diverse computational tools. Our synthesis is based on discussing with teachers and colleagues problem solving behaviour that our research group initially identified as being consistent while the project participants used the tools. This involves a retrospective account of what we observed in problem solving sessions that promoted the use of technology. Thus, by observing and analyzing teachers' and students' use of the tools in problem solving activities, we aim to identify common math behaviour that characterizes their approaches to the tasks (Santos-Trigo & Camacho-Machín, 2009). Our method of inquiry relies on observing teacher's behaviour when using computational tools in problem solving sessions. Thus, in order to introduce and discuss elements of the framework, we chose a task to illustrate different approaches to think of the task in terms of using a dynamic geometry software (DGS). The task is representative of a series of problems in which students deal with phenomena that involve parameter variations to determine

minimum or maximum values of a certain parameter (area, perimeter, length, etc). The task discussion leads us to identify components of a framework that teachers can use to structure and guide their students' use of several tools in problem solving approaches (Schoenfeld, 2010). The framework is presented in terms of episodes that extend the phases used by Polya (1945) to explain problem solving behaviour.

A PROBLEM-SOLVING FRAMEWORK TO DEAL WITH PHENOMENA OF VARIATION

An example is used to illustrate elements of a framework to organize and guide students' use of computational tools to represent and explore the area variation of an inscribed parallelogram. Another example of a task analysed in terms of the framework appear in the appendix. In particular, we distinguish episodes that show the relevance that it has for students to comprehend and think of the problem statement in terms of math resources. This initial comprehension of the task becomes crucial to construct a dynamic representation of the problem that can help them visualize parameter behaviour. The NCTM (2009) identifies both sense making and reasoning as crucial processes that students need to develop in their problem solving approaches. The exploration of dynamic models of the task provides useful information for students to think of the problem in terms of analytical and geometric knowledge and to reflect on the concepts and processes that appear throughout all the episodes.

The task: In a given triangle ABC , inscribe a parallelogram by selecting a point P on one of the sides of the given triangle. Then from point P draw a parallel line to one of the sides of the triangle. This line intersects one side of the given triangle at point Q . From Q draw a parallel line to side AB of the triangle. This line intersects side AC at R . Draw the parallelogram $PQRA$ (Figure 1). What happens to the area of the inscribed parallelogram $APQR$ when point P is moved along side AB ? Is there a position for point P where the area of $APQR$ reaches a maximum value? (Justify).

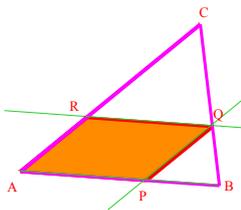

Figure 1: Drawing a parallelogram inscribed in a given triangle

Comprehension Episode. Polya (1945) identifies the process of understanding the statement of a problem as a crucial step for thinking of possible ways of solving it. Understanding means being able to make sense of the given information, identify relevant concepts, and think of possible representations to explore the problem mathematically. If students are to comprehend and make sense of the problem, they need to problematize the problem statement. They need to think of the problem in terms of questions to be explored and discussed with other students and the teacher. For example, in this problem, the comprehension stage involves discussing questions

such as: What does it mean for any given triangle? What information does one need to draw any triangle? Are there different ways to inscribe a parallelogram into a given triangle? For example, in Figure 1, one can draw from P a parallel line to CB (instead of AC) and this line intersects side AC and from that point of intersection, one can draw a parallel line to AB that intersects BC, thus, the two intersection points and point P and B form an inscribed parallelogram, the problem solver can ask: how is the former parallelogram related to the one that appears in Figure 1? Do they have the same area? How can I recognize that for different positions of point P the area of the parallelogram changes? This problem comprehension phase is important not only to think of the task in terms of using the software commands, but also to identify and later examine possible variations of the task.

A Problem Exploration Episode. The comprehension phase provides useful information to identify ways of representing and exploring the problem. The use of a DGS, becomes a powerful means to represent and construct a dynamic model of the problem. To begin with, students can draw a triangle by selecting three non-collinear points. Thus, they can discuss the conditions needed to draw a triangle. In addition, the use of DGS allows them to move any vertex to generate a family of triangles. In this case, they can select a point P on side AB to draw the corresponding parallel lines to inscribe the parallelogram. With the help of the software it is possible to calculate the area of the parallelogram and observe area value changes when point P is moved along side AB. Thus, it makes sense to ask whether there is a position of P in which the area of the inscribed parallelogram reaches either its maximum or minimum values. By setting a Cartesian system with the software, it is possible to construct a function that associates the length of segment AP with the area value of the corresponding parallelogram. Figure 2 shows the graphical representation of that function. That is, the domain of the function is the set of values that represents the lengths of AP when point P is moved along side AB. The range of that function is the corresponding area values of the parallelogram associated with the length AP. With the software, this graphical representation can be obtained by asking for the locus of point S (the coordinates of point S are length of AP and area of APQR) when point P moves along the segment. Here, it is important to observe that the graphical representation can be obtained without explicitly defining the algebraic model of the area change of the parallelogram.

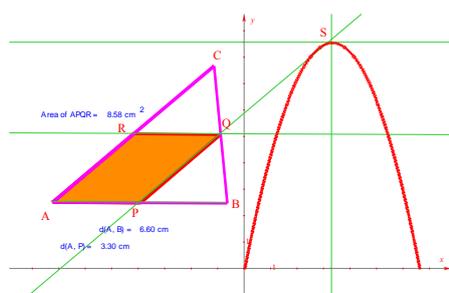

Figure 2: Representation and visual exploration of the problem

This graphical approach to solve the problem provides an empirical solution since it is visually and numerically possible to observe that in the given triangle the maximum area of the inscribed parallelogram is obtained when P is situated at 2.30 cm from point A. Here the area of the parallelogram is 8.56 cm^2 . Indeed, a conjecture emerges based on this information: *When P is the midpoint of segment AB, then the corresponding inscribed parallelogram will reach the maximum area value.*

The Searching for Multiple Approaches Episode. We argue that for students to develop a conceptual understanding of mathematical ideas and problem solving proficiency (Kilpatrick, Swafford, & Findell, 2001), they need to think of different ways to solve a problem or examine a mathematical concept. To develop this understanding, students should have the opportunity of using different concepts and resources to represent, explore and solve problems. In this context, the visual and empirical approach used previously to explore the problem provides the basis to introduce other approaches. For example, in the next two approaches the goal is to construct an algebraic model to represent the variation phenomenon. The first one relies on introducing the Cartesian system to represent and operate the main objects associated with the problem, while the second approach is based on the use of geometric properties (similar triangles) to represent relationships among objects. Thus, these two ways of thinking about the problem represent an opportunity for the problem solver to reflect on strengths and limitations associated with the use of different concepts and resources to solve the task.

1. Analytical approach. In this approach, the students' initial goal is to represent and examine the problem in terms of algebraic means. The use of the Cartesian system becomes important to represent the objects algebraically. The use of the software also directly provides the equations associated with the lines that are needed to determine the expression of the parallelogram area. The problem can be thought of in general terms as is shown below.

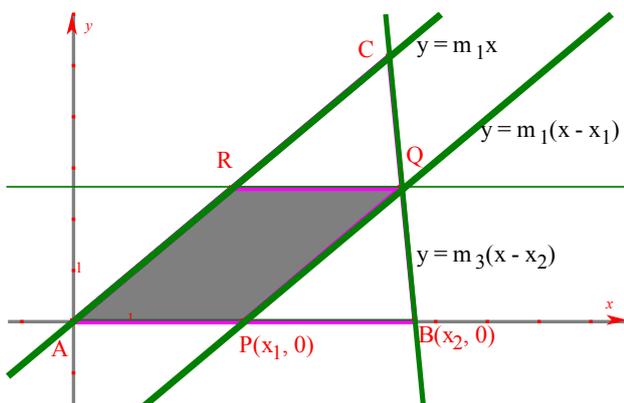

Figure 3: Using a Cartesian system to construct an algebraic model of the problem

Without losing any generality, we can always situate the Cartesian System in such a way that one side of the given triangle can be on the x-axis and the other side on line $y = m_1x$ (Figure 4). Point P will be located on side AB and its coordinates will be $P(x_1, 0)$. Point $B(x_2, 0)$ is vertex B of the given triangle (Figure 3). Based on this

information, the equation of line that goes through P and Q is $y = m_1(x - x_2)$ and the equation of line BC is $y = m_3(x - x_2)$. Solving the system of equations leads to $x = \frac{m_1x_1 - m_3x_2}{m_1 - m_3}$, then, substituting this value in $y = m_1(x - x_1)$ we obtain the y-

coordinate of point Q, That is, $y = \frac{m_1m_3(x_1 - x_2)}{m_1 - m_3}$ (this value corresponds to the height

of parallelogram APQR). Then, the function area will be $A(x_1) = \frac{m_1m_3(x_1^2 - x_2x_1)}{m_1 - m_3}$

(quadratic function whose roots are 0 and x_2). This function also has a maximum value if and only if $\frac{m_1m_3}{m_1 - m_3} < 0$. We are assuming that $m_1 > 0$. The assumption on the

triangle location guarantees that m_3 and $m_1 - m_3$ have opposite signs. Using a symmetric argument, $A(x_1)$ reaches its maximum at the midpoint of the interval

$[0, x_2]$, that is, at $x_1 = \frac{x_2}{2}$. To determine the maximum value of this expression by

using calculus concepts, we have that: $A'(x_1) = \frac{m_1m_3(2x_1 - x_2)}{m_1 - m_3}$, now, the critical

points are obtained when $A'(x_1) = 0$, $x_1 = \frac{x_2}{2}$ which is the solution of the equation,

then the function $A(x_1)$ will reach its maximum value at $x_1 = \frac{x_2}{2}$

($A''(x_1) = \frac{m_1m_3}{m_1 - m_3} < 0$). Thus, this result supports the conjecture formulated previously in

the graphical approach.

2. A Geometric approach. The focus here is to use geometric properties embedded in the problem representation to construct an algebraic model of the problem.

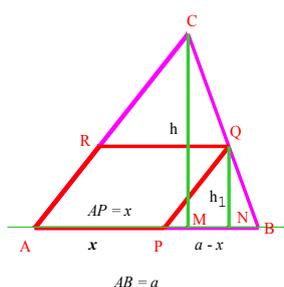

Figure 4: Relying on geometric properties to construct an algebraic model

For example, in Figure 4, it can be seen that triangle ΔABC is similar to triangle ΔPBQ , this is because angle PQB is congruent to angle ACB (they are corresponding angles) and angle ABC is the same as angle PBQ . Therefore, we have

it that $\frac{PB}{AB} = \frac{QN}{CM}$, that is, if $\overline{AP} = x$ and $\overline{AB} = a$, then $\frac{a-x}{a} = \frac{h_1}{h}$. Based on the former

relationship, $h_1 = \frac{h(a-x)}{a}$, area of APQR can then be expressed as $A = xh_1$, this latter

expression can be written as $A(x) = xh - \frac{hx^2}{a}$. This expression represents a parabola.

$A'(x) = h - \frac{2hx}{a}$, now if $A' = h - \frac{2hx}{a} = 0$, then $x = a/2$. Now, we observe that $A'' < 0$ for any point on the domain defined for $A(x)$, therefore, there is a local maximum for that function.

An Integration Episode. It is important and convenient to reflect on the process involved in the distinct phases that characterize an approach to solving mathematical problems that fosters the use of computational technology. Initially, the comprehension of the problem statements or concepts involves the use of an inquiring approach to make sense of relevant information embedded in those concepts or statements. This enquiry process provides the basis to relate the use of the tools with ways of dynamically representing the problem or situation. Thus, a dynamic model becomes a source by which the behaviour of parameters is explored visually and numerically, as a result of displacing certain elements within the problem representation. In particular, it might be possible to construct a functional relationship between a variable, for example the variation of the side AP of the parallelogram and its corresponding area.

An interesting feature of this functional approach is that the model can be represented geometrically without having expressed it algebraically. The graphical representation of the task provides an opportunity for the problem solver to understand and discuss the domain of the function and the behaviour of the parameters from a visual approach. For example, by moving point P along side AB, one can observe that there will be two different positions for point P in which the corresponding areas of the inscribed parallelogram will be the same except when the point is located at the midpoint of the side AB. Graphically, this means that a parallel line to the x-axis will cut the graph in two points except when the line passes across the maximum point. At that point, the value of the slope of the tangent line to the curve will be zero (Figure 5). In addition, it is noted that for any triangle with side AB and P situated on AB, then the maximum area for the inscribed parallelogram will be reached when point P is the midpoint of side AB. In general, the visual and numerical approaches to the problem become important to generate a series of conjectures or relationships that needs to be supported by formal arguments.

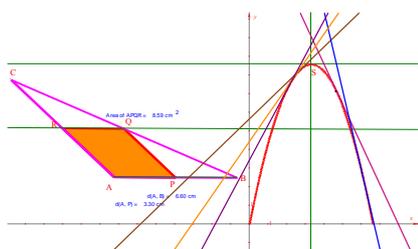

Figure 5: Examining properties of the area variation graphically.

Thus, the idea at this stage is to look for different arguments to formally support not only the visual solution to the problem, but also to justify the conjectures or

relationships that emerged during both the visual and numerical approaches. It is clear that even when the goal here is to represent the parallelogram area symbolically, the ways used to construct the model rely on using different concepts and resources. As a result, the problem solver has the opportunity to relate contents that are often present in different subjects studied separately. In this case, both the analytic and geometric approaches converge in the search for the algebraic model. The algebraic model represents the general case and it can be “validated” by considering the information of the triangle used to generate the visual model. In addition, it can be used to explore some of the relationships that were detected during the visual approach.

In conclusion, the systematic use of computational tools in problem solving approaches led us to identify a pragmatic framework to structure and guide learning activities in such a way that can help students develop mathematical thinking. A distinguishing feature of this framework is that constructing a dynamic model of the problems provides interesting ways to deal with the problem from visual and empirical approaches. Later, analytical and formal methods are used to support conjectures and particular cases that appear in those initial approaches. Thus, the use of computational tools provides a basis not only to introduce and relate empirical and formal approaches, but also to use powerful heuristic tools such as dragging objects and finding loci of particular objects within the dynamic problem representation. Prospective and practicing teachers can use the framework to focus their attention on the activities involved in each episode. In particular, they need to conceive of a task or problem as an opportunity for their students to represent, explore and examine the task from diverse perspectives in order to formulate conjectures and to look for ways to support them.

APPENDIX: Another example of tasks used in the project.

Three students got together to prepare their calculus final exam. After much hard work, when they were feeling hungry, they ordered a pizza and decided to divide it into three equal parts by making two vertical cuts (Figure 6). The pizza they ordered had a 40 cm radius. Where should they make the pizza-cuts so that each student gets the same amount of pizza? (Santos-Trigo & Camacho-Machín, 2009)

ANALYSING TEACHERS' CLASSROOM PRACTICE WHEN NEW TECHNOLOGIES ARE IN USE

Mary Genevieve Billington

University of Agder

This paper presents an analysis of teachers' practice in classrooms where new technologies are in use. An example of an analysis of data collected in mathematics classroom lessons in an upper secondary school is given. The analysis revealed how teachers structured the lessons and how the different tools were employed to achieve didactical and mathematical goals. The research contributed to research within the project "Teaching Better Mathematics" at the University of Agder.

Keywords: classroom, analysis technique, didactic process

INTRODUCTION

Newer technologies are increasingly used in schools. In Norway these technologies are termed "digital tools" and their use is now compulsory in all subjects and at all levels of schooling. It is argued therefore that it is important to learn more about how teachers integrate these tools into their classroom practice.

The classrooms studied were advanced mathematics classrooms in the second year of upper secondary school. In 2002 the school visited had initiated an internal ICT project. All students in advanced mathematics classes were issued with a laptop PC and classrooms were equipped with a screen and a projector. By the spring term of 2007 when the observations took place the classrooms had evolved to paperless classrooms; paper textbooks and notebooks were no longer in use. In the Norwegian context such classrooms were special but the project school was a normal school in that it operated in accordance with all formal regulations and guidelines. Practices described in this paper had evolved in a normal school environment with inherent functioning forces and tensions, not influenced by any external developmental project in mathematics education. I claim that this was an opportunity to observe and learn about ordinary teachers integrating new technology into their practice from the teachers' perspective. Monaghan (2004) and others have seen a need for such research. This feature of the data is seen to be especially interesting given the generally limited success in the integration of digital tools into mathematics classrooms (Lagrange, Artigue, Laborde, & Trouche, 2001).

This paper addresses the following research question: "How do teachers structure mathematics lessons where newer technologies are in use and which technologies and tools are employed to achieve which didactical and mathematical goals". An analysis technique was developed to analyse the classroom data. A detailed description of the technique is given before proceeding to the results of the analyses.

THEORETICAL FRAMEWORK

In the main study, the Instrumental Approach in Didactics provides the theoretical perspective. This approach combines elements from the Anthropological Theory of Didactic in mathematics education (Chevallard, 2005) and the Instrumental Approach from the field of cognitive ergonomics (Verillon & Rabardel, 1995). The approach is a middle range theory, domain specific to studying the use of newer technologies in mathematics education. Three main notions from the approach served to structure the analysis; *praxeology* and *didactic process* and *instrumental genesis*. In this brief paper *praxeology* and *didactic process* are discussed in depth.

A *praxeology* is defined as the basic unit of human activity. This therefore includes mathematical activity and didactical activity. A praxeology is constituted of two inseparable parts, the praxis part and the logos part and each of these parts consists of two components (Chevallard, 2007, p. 133). The praxis block is formed by types of problems/tasks and by the techniques used to solve these tasks. The knowledge block, the so called discursive environment (logos) is structured in two levels: the technology (the discourse about the techniques used) and the theory that constitutes a deeper level of justification of practice (Barbé, Bosch, Espinoza, & Gascón, 2005, pp. 235-238). In studying teacher action in the classroom I use the term didactical praxeology to refer to teacher activity directed towards promoting the students mathematical activity.

The term *didactic process* is used to refer to the process directed towards the setting up of the mathematical praxeologies for the students. The process is claimed to be made up of six moments; the moment of first encounter, the moment of exploration, the technological theoretical moment, the technical moment, the institutionalisation moment and the evaluation moment (Barbé *et al.*, 2005, p. 239). The analysis attempts to identify these moments in the classroom activity.

Two other notions used to structure the data analysis are *didactical configuration* and *didactical exploitation mode* (Drijvers, Doorman, Boon, van Gisbergen & Reed, 2009; Trouche, 2004, 2005). Drijvers *et al.* (2009) define these terms in the following way:

A didactical configuration is an arrangement of artefacts in the environment, or, in other words, a configuration of the teaching setting and the artefacts involved in it. These artefacts can be technological tools, but the tasks students work on are important artefacts as well. Task design is seen as part of setting up a didactical configuration.

An exploitation mode of a didactical configuration is the way the teacher decides to exploit it for the benefit of his didactical intentions. This includes decisions on the way a task is introduced and worked, on the possible roles of the artefacts to be played, and on the schemes and techniques to be developed and established by the students (*ibid.*, p. 2).

METHODOLOGY

Data collection

Data was collected over a two week period, alternating between two parallel classes. Two researchers were present at each observation allowing for one researcher to video-record the lesson and the other to take comprehensive field notes.

The Analysis Technique

The complexity of analysing classroom activity has been widely recognised (Abboud-Blanchard, 2008; Barbé *et al.*, 2005; Monaghan, 2004; Robert & Rogalski, 2005). In line with Robert and Rogalski (2005) my analysis focuses on teacher action rather than modelling the global system in the classroom.

The analysis technique involves four elements; organisation of space and time; the mathematical content; didactic episodes; and instances of instrumented activity. These elements are explained here.

1. *Organisation of space and time.* In this part of the analysis a detailed description of the physical environment and how this is organised is given. In addition, an overview of the time disposition in the lesson sequences is presented in table form.

2. *The mathematical activity.* In this part of the analysis the mathematical content of the lesson sequence is described by firstly presenting the relevant goals in the official syllabus and secondly identifying the four elements of the mathematical praxeologies; the tasks, techniques, discourse and theory. The mathematical problem and the techniques suggested by the teacher to solve the problem are identified and discussed. The main notions, concepts and mathematical notation employed in the lesson are presented. (Barbé *et al.*, 2005, pp. 236-238)

3. *Detailed analysis of didactic episodes with focus on tool use.* In reviewing the data material it was noted that each lesson sequence was clearly divided into time periods signalled by the teacher comments, such as: “ But now we are going to do something fun and this is something you have not done before” (My translation)

I decided to use these teacher made divisions in the analysis. I therefore define a *didactic episode* as a part of the lesson where the class engages in one primary activity as signalled by the teacher. For example: the first didactic episode in a lesson maybe an episode with recap of theory from the previous lesson; the second, correction of homework; the third, introducing new theory and so on. For each lesson sequence observed in the reported study a table, as shown below, was completed.

Episode Time min.	Teacher's goal – Moment of didactic process	Mathematical organisation	Didactical configuration		Didactical exploitation mode	
			Work mode	Tools used by teacher	Tool use - Didactical goal	Tool use - Mathematical goal

Table 1: Didactic episodes

The *episodes* are numbered and the time used on each episode is given. The *teacher's goal* is the goal perceived by the observer to be the goal of the episode, for example; a recap of theory. This goal is interpreted in relation to the moments of the didactic process. In the third column the parts of the *mathematical praxeology* presented in the didactic episode are identified as: task, technique, discourse, theory. Under the heading *Didactical configuration*, two sub-headings are included: *Working mode* and *Tools in use*. Working mode describes how and when the teacher devolves the mathematical task to the students. Four physical/material tool sets were observed to be in use by the teacher: the blackboard, a digital textbook, PC+ program Derive, body gestures. Each of these was used in conjunction with the voice and assumingly schemas (cognitive apparatus). The column *Didactical exploitation mode* has two sub-headings: *Tool use - didactical goal* and *Tool use- mathematical goal* included to describe how the teacher exploits the tools and with which didactical and mathematical intentions. The tools were sometimes used together. Instances when the teacher appeared to favour one tool over another or moved between the available didactical tools are identified. This practice of moving between tools within a didactic episode is termed weaving (Billington, 2009).

4. Analysis of instrumented activity in relation to mathematical tasks

In this part of the analysis focus is on instances of instrumented activity in the lesson sequences (Guin & Trouche, 1999, p. 201; Verillon & Rabardel, 1995). In each lesson sequence a few exemplary episodes are chosen for presentation and the manner in which the teacher uses the digital tools to solve the didactical task and the associated mathematical task/s is described. The instrumented technique/s used or advocated is/are identified and discussed.

APPLICATION OF ANALYSIS TECHNIQUE

This section contains an illustration of the application of the analysis technique. This is done by presenting **two** elements of a particular lesson sequence with Teacher1: organisation of space and time and didactic episodes.

Illustration starts

Organisation of space and time

A large blackboard covered almost the entire front wall of the classroom. A screen was positioned on the right hand side in front of the blackboard covering part of the blackboard. A laser pointer was available. The teacher's portable PC was placed on the large raised desk directly in front of the blackboard and screen. Students had only their portable PC on the desk and perhaps a backpack on the floor. The class came quickly to order. Students were not observed to use pencil and paper. A picture of the classroom and a diagram of the student seating arrangement are shown here.

Working Group 15

Figure 1: Picture of classroom

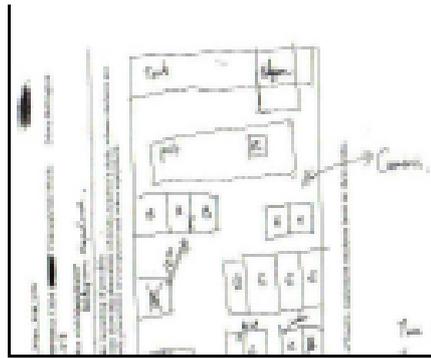

Figure 2: Student seating

Time disposition was analysed as Table 2. In the fourth column the activity is interpreted in terms of the didactic process (Barbé *et al.*, 2005).

Time (m.)	Time %	Activity	Moment of didactic process
14	18	Recap of theory and homework	Institutionalisation moment
14	18	Introducing new task	Moment of first encounter + exploratory moment
11	14	Students draw graph (Derive)	Technical moment
6	8	Trying example together	Technological-theoretical+technical moment
34	43	Students work with problems: teacher goes around	Institutionalisation moment
Tot. 79			

Table 2: Time/activity analysis

Didactic episodes

A table showing the analysis into didactic episodes was completed. A section of the table is given in appendix 1. The completed table showed that there were fourteen shifts in activity ranging from one to seventeen minutes in the duration of the lesson sequence. The lesson sequence could be divided into three main parts. In the first part: introduction with homework correction and recap of previous work (episodes 1-4: 15 min.) the digital textbook was the main or preferred tool used by the teacher. These episodes are interpreted as representing the institutionalisation moment of the mathematical organisation from the previous lesson. In part two, the new mathematical problem and the new techniques to solve the problem (episodes 5-9: 26 min.) were introduced using both the program Derive and the blackboard. The phenomenon of weaving was observed in episode 9. Episode 5 of 5 minutes duration encapsulated both the moment of first encounter and the exploratory moment. The technical-theoretical moment and the technical moment were contained in episodes 6 to 9. In final part of the lesson sequence, students worked individually or in small groups with the teacher assisting individual students in applying the new techniques

(episodes 10-14: 29 min.). These episodes are interpreted as the institutionalisation moment of the didactic process.

In seven of the fourteen episodes the teacher used the digital textbook. It was used as a pre-written blackboard to display the formal mathematical theory and completed and uncompleted exercises. The data indicates that the tool occupies a strategic place in the classroom praxeologies of this teacher. The digital textbook provided support with exercises and formal presentation of the mathematical theory.

The work mode descriptions indicate that the teacher clearly steered the lesson, presenting and explaining the mathematical concepts, tasks and techniques carefully without posing many questions to students. Questions posed required short answers. Student work was not displayed to the whole class. Students engaged actively in the discussion when the mathematical problem was posed in contextual terms. The mathematical tasks were only devolved to the students in the final part of the lesson which involved working on problems.

Conclusion of illustration

DISCUSSION OF RESULTS

All observed lesson sequences were analysed in the manner as described above and then compared. In this section I will discuss some of the results of the full analysis with respect to the research question presented earlier: “How do teachers structure mathematics lessons where newer technologies are in use and which technologies and tools are employed to achieve which didactical and mathematical goals”. The full analysis revealed that the teachers had actively taken in use the new technologies and had developed similar patterns of practice and usage in the classroom.

The physical environment and time allocation

The physical classrooms in use were traditional in design except for the rather haphazard installation of a projector, a screen and a large number of electrical contact points. Individual teachers may not have much say in such issues but the seating arrangement could be altered easily by the teacher. The seating allocation observed and described above lends itself to an expository mode of teaching as all desks were directed towards the teacher. The arrangement also made discussion between students difficult. The screen was visible to all students and this allowed the teachers to demonstrate techniques instrumented on the PC. This was observed constantly. It was also possible for students to present their work to the rest of the class by coming forward connecting their PC to the screen. This was not observed.

A comparison of the time allocation tables revealed an apparent lesson script of: teacher review; teacher leads to formula/technique; practice. This script is documented in research as a standard lesson script (Jacobs & Morita, 2002). The introduction of the new technologies had seemingly not altered the traditional lesson script. The further division of the lessons into didactic episodes showed that there

were a large number of teacher initiated shifts, varying from eight to fourteen shifts, in activity in the observed lessons. The effect of so many changes in activity on student learning may warrant further investigation. Further analysis is also required to ascertain if these shifts were caused or stimulated by the availability of the digital tools.

The didactic process

The moments of the didactic process were identified within each didactic episode. The analysis revealed that generally only a few minutes in each lesson sequence were given to the *moment of first encounter*, that is introducing the mathematical tasks and that the blackboard was the preferred tool when introducing the mathematical problem. In some of the documented lessons the students indicated that they did not really understand the problem with such comments as: “What is it actually that we calculate, because I don’t understand?”

The *exploratory moment* was allocated more time but the teacher always led the explorations with demonstrations. These demonstrations were enriched by the facility of the digital tools to reify the mathematical objects and relations. The technological-theoretical moment, that is the moment where the techniques are justified in reference to theory, tended to merge with the technical moment where techniques are practiced. These two moments together were given the largest time allocation in the public part of the lesson sequences. All techniques were instrumented through the digital tools. The largest relative percentage of time in lessons was given to the students solving exercises. Both *the institutionalisation moment* and the *evaluation moments* were realised through short public summaries by the teachers and through the longer periods of students working alone or individually on exercises. The analysis showed that teachers favoured an expository teaching mode; giving explanations, demonstrating, with elicitation of answers from students followed by students working alone.

Teacher tool use

The blackboard appeared to be the preferred tool when the teachers presented the mathematical task, gave an overview, illustrated notation; presented and/or discussed contextual examples and gave responses to spontaneous questions. A subjective observation was that the teachers were livelier when using the blackboard: moving around, using arm movements, tracing over important features of a curve with the chalk and so on. In contrast to its use in classrooms without PC and screen, the blackboard was used in a rough way for sketching out problems and solutions. The blackboard seemed to acquire the status of conceptual sketch pad.

The formal mathematical knowledge; both theory and the argumentation in worked exercises was presented pre-prepared through the digital textbook. This practice required extensive planning and preparation. The students thus did observe the teacher mathematician actually conducting, carrying through a mathematical

argumentation. The teachers clearly appreciated the word processing facilities offered by the digital tools as expressed in the following quotation.

Teacher1: Now everyone has the possibility to work down, now it is the mathematical, it is the logic that causes a stop; it is not all the writing that causes problems. (My translation from SM_070212)

The CAS program was employed in exploring the properties of mathematical objects in the exploratory moment and to demonstrate and justify techniques to solve the mathematical problems in the technological-theoretical and technical moments. Teachers planned for the technological-theoretical moment with the production and preparation of the interactive illustrations and demonstrations. All problems were solved with techniques instrumented through the CAS program although some of these techniques represented simulations of paper and pencil techniques.

A phenomenon, which I term *weaving*, was often observed whereby the teacher moved between the available tools of the blackboard and the digital toolkit when holding public discourse.

CONCLUSIONS AND FURTHER RESEARCH

It could appear that the new technology was used to strengthen rather than alter existing practice as has been found in other research (Cuban, Kirkpatrick, & Peck, 2001). The lesson observations were discussed with teachers informally and in a more formal meeting and these discussions provided insight into the logoi behind some of seemingly unchanged practices.

Regarding the analysis technique, one strength of the technique, as I see it, is that it divides the lessons according to the teacher determined shifts in activity. The imposition of the theoretical notions on the data may perhaps restrict the interpretation. I would like to further develop and adapt the analysis technique to analyse lessons other than mathematics lessons with a goal to identify commonalities and differences in practice.

IMPLEMENTATION OF A MULTI-TOUCH ENVIRONMENT SUPPORTING FINGER SYMBOL SETS

Silke Ladel, Ulrich Kortenkamp

CERMAT, University of Education Karlsruhe, Germany

Basic concepts of numbers and operations are fundamental for mathematical learning. Suitable materials for developing such basic concepts are hands and fingers. Among other things, this is because of their natural structure of 5 and 10. To support the development of concepts and the process of internalization a linking between different forms of representations by the computer can be helpful. To benefit of both, the advantages of the hands and fingers and the automatically linking, we suggest using multi-touch technology, i.e. computer input devices that are able to recognize several touch gestures at the same time. Here, children can present numbers with their fingers that produce virtual objects. These objects can be automatically linked with the symbolic form of representation.

Keywords: number concepts, finger symbol sets, multi-touch, early math, Cinderella

THE ORDINAL AND CARDINAL CONCEPT OF NUMBERS AND OPERATIONS

“How many things are there?” – For parents as well as for mathematicians, this is a common question to pose, if a child already has knowledge about numbers. For the child, this question is almost always the initiation to start counting verbally by saying the number words in a row (Fuson, 1988). The fundamental principles needed for answering the question are a) the one-one principle that relates every single object to exactly one numeral (Gelman & Gallistel, 1978), b) the stable-order principle prescribing the correct order of numbers (Fig. 1, left), and c) the last-word rule that assigns the last said numeral not to the last counted object, but to the quantity as a whole (Fig. 1, right).

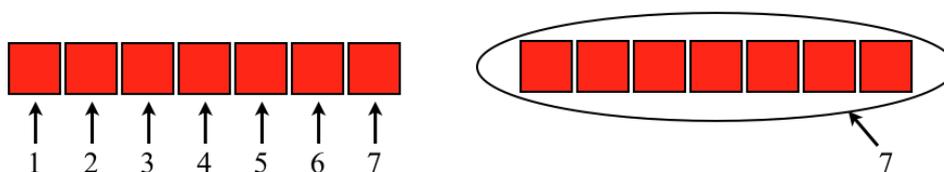

Figure 1: Ordinal (left) and cardinal (right) concept of numbers

Here, the change from the ordinal concept of numbers, where the numeral is part of the numeral row, to the cardinal concept of numbers, where the numeral identifies a quantity, is necessary. It is not necessary to count a quantity in order to know it, that is, the ordinal concept is not a necessity for the cardinal concept. Resnick, Bill, Lesgold and Leer (1991) distinguish the development of mathematical knowledge by two components that are developed independently: *protoquantitative schemata* and the *mental number line*. To build up a well-developed concept of numbers, these two

threads of development have to be linked. For many children this is a critical problem (Fuson, 1992, p. 63).

Children who do not have a proper linking between the two concepts can misinterpret addition and subtraction as a demand to count forwards or backwards. As long as the children calculate with numbers smaller than 20 they can apply this strategy successfully. But, for instance, when they want to add 55 to 27 and begin to count „28, 29, 30, 31...“, there is no chance to come easily and quickly to the correct result.

„The protoquantitative part-whole schema is the foundation for later understanding of binary addition and subtraction and for several fundamental mathematical principles, such as the commutativity and associativity of addition and the complementarity of addition and subtraction. It also provides the framework for a concept of additive composition of number that underlies the place value system.“ (Resnick *et al.*, 1991, p. 32).

For example when you want to add 6 and 8 with the use of the part-whole schema you can split and add in lots of ways (e.g. Fig. 2).

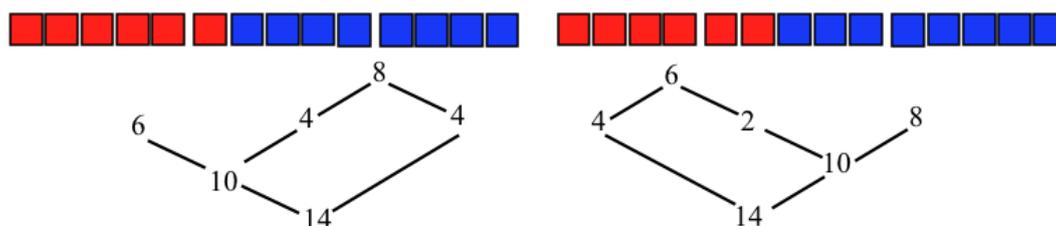

Figure 2: Different ways to add with the part-whole schema

FINGER SYMBOL SETS

Calculating with fingers has a very bad reputation in mathematics lessons, as it is usually seen as an indicator for counting. Most children do as they have learned from young days on and count objects by „Counting-Word Tagging to Number“ (Brissiaud, 1992). According to the ordinal concept of numbers each finger is related to exactly one numeral. To illustrate this we ask what happens if the sixth finger is buckled? The „name“ of the last finger, that indicated the quantity, was „10“ before, but now the finger has to be renamed into „9“ (Fig. 3).

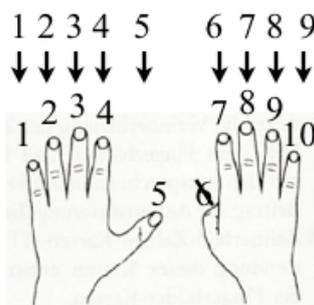

Figure 3: Order-irrelevance principle

Working Group 15

The child has to know that it is irrelevant which fingers it uses to present a quantity. To present „3“, the thumb, the index finger and the middle finger can be used as well as the little finger, the middle finger and the thumb, or any other combination of three fingers. As we point out below, the cognitive process behind this fact can be experienced and thus supported by the use of multi-touch technology.

Amongst others, the advantages of fingers and hands are their permanent availability and their natural structure in 10 fingers per child with 5 fingers per hand. The 10 fingers qualify the hands to work out questions about the decimal number system, e.g. „How many children do we need to see 30 fingers all at once?“ The „power of five“ (Krauthausen, 1995) is due to the ability to instantaneously recognize quantities (subitizing) up to 4. Applying this to the hands, the shown quantity of the fingers of one hand can be conceived simultaneously and hence the fingers of both hands can be conceived quasi-simultaneously. Furthermore, one hand gets a special status because children tend to present numbers greater than five sequentially (Brissiaud, 1992, p. 61). For example, to present „7“, they tend to use one full hand and then add two fingers of the other hand. In this way the decomposition of the numbers from 1 to 10 with the power of five can be worked out. But not only these, also all other decompositions are possible (Fig. 4) and can be conceived quasi-simultaneously.

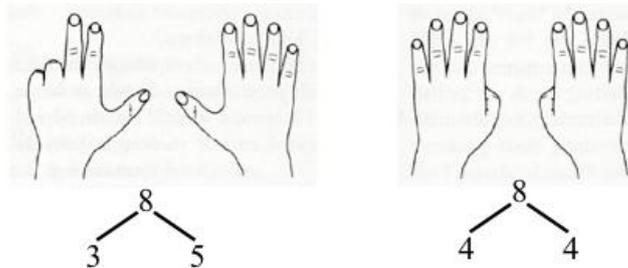

Figure 4: Decomposition of numbers with finger symbol sets

If the fingers are used like this, in sense of the part-whole schema, they are a qualified working material for a well-developed concept of numbers and operations (Steinweg, 2009). Brissiaud (1992, p. 56) coined the notion „From Finger Symbol Sets to Number“:

„Certain children who were not exposed early to the use of finger symbol sets may become counters, whereas children who were encouraged to use finger symbol sets may preferentially choose finger strategies“.

If children have a part-whole schema of numbers the transition to addition and subtraction is easy. It is just another way of nonverbal symbolic representation of the fact that „two parts make a whole“.

Further strategies like variation in the opposite or in the same direction can than be worked out easily: If one finger is buckled, than another finger must be stretched to keep the same quantity. To get the difference of two quantities, e.g. of 9 and 7, you can vary the numbers in the same direction. For example, a whole hand can be

omitted, which corresponds to subtracting five from each quantity. It is evident that the difference of 9 and 7 is the same as the difference between 4 and 2. Based on such strategies the decadic analogy can be build up.

It is important to pay attention to the fact that the children stretch their fingers *simultaneously* to represent quantities with them. If they show them one-by-one the positive effects of these strategies are lost and the children will still use counting for addition and subtraction.

This introduction can only serve as a small insight into the possible representations of numbers and operations by hands and fingers and their usage in early arithmetic. It is the process of internalization that is of essential importance: How can the children benefit from the mathematical content of these representations and actions and use them in their mental processes?

THE PROCESS OF INTERNALIZATION SUPPORTED BY THE USE OF MULTI-TOUCH-TECHNOLOGY

The process of early mathematical learning follows four stages, independent of the arithmetical subject (Aebli, 1987, Grissemann & Weber, 2000). Coming from concrete manipulations with different objects (stage 1), the children have to abstract these manipulations and operations to pictorial representations (stage 2). Subsequently they pass over to symbols (stage 3) with the aim to automate their actions (stage 4). For us, stage 2 is of special importance, because there the process of internalization takes place. The child has to comprehend the manipulation of concrete objects as a representation of a quantitative structure and it has to capture the structure and the relations of the concrete manipulation in an intellectual activity (Gerster & Schultz, 2004, p. 47). Lorenz calls this process „focus of attention“. To facilitate this process of focus and abstraction and to develop it, a dialog is essential (Lorenz, 1997, p.93):

„In talking about the working material and the relations between numbers and operations that it represents, the concepts in development of the learner are going to be clarified by verbalisation.“

In this sense, Aebli (1987) suggests that the children should review their concrete manipulations and make forecasts about further actions. Doing this, they comment their own manipulations by iconic illustrations till they are able to reproduce the structures and relations of the manipulations in conceptions. To support this process Aebli (1987, p. 238) established the following rule:

„Every new, more symbolic representation of the operation must be linked as closely as possible with the precedent one.“

The enactive form of representation with finger symbol sets should be related to the nonverbal symbolical form of representation (MER [1]) (Ainsworth, 1995; Mayer, 2005). But as studies show some of the children even don't link the different forms

of representations when they are designed in form of MERs (Clements, 2002). For them, an automatic linking designed with the computer (MELRs [2]) can help them to experience the relations (Thompson, 1992; Clements, 2002; Ladel, 2009). This experience should be as natural and direct as possible. In this article we suggest to use multi-touch technology for this experience, where the children can manipulate with their hands and fingers and an automatic linking with all other forms of representation can take place. In the remainder of this article we assume the availability of a multi-touch-enabled table. Such a table consists of a display surface connected to a computer and some tracking hardware that can recognize several touches on the display simultaneously and report them to the computer software. Similar technology with a different form factor is available in desktop monitors, tablet computers and devices like the Apple iPad, or mobile phones. With the availability of hardware as already imagined by Kay (1972) we now have to answer the question of the educational implications more than ever.

The basic underlying idea for all the activities sketched only briefly in the following is that the computer can track the children's actions on the table and give nonverbal symbolic representations of either the current situation or the action that lead to it in form of a written protocol.

In a first scenario, the children represent numbers with their hands and fingers as described before. This enactive form of representation shall produce an iconic one on the display. The computer creates quadratic pads on the surface of the multi-touch table. Through the contact of the fingers with the multi-touch interface there is not only a link between the enactive form of representation with other forms of representation but also between the tactile and the visual sense. While representing numbers enactively and thus iconically, there is an automatic link to a nonverbal symbolic form of representation. This representation can be imagined like a paper tape or sales slip and serves as a kind of protocol for the manipulations the children do. Such a protocol can support the focus of attention and the numerical aspects of a task (Dörfler, 1986).

In this activity it is possible for children to experience that it is of no particular importance which fingers they use to present quantities. At a table, it is also possible that the children work in teams: Two children can "share the work" to present two fingers if each touches the table with one finger. While this sounds funny for the number two, it is of great importance for partitions of larger numbers. Two partners can try to find all ways to partition numbers up to 20 into two numbers up to 10.

Working in teams or groups the children are also able to present numbers greater than 10, emphasizing the social aspects of learning. Because the protocol immediately reflects the actions of the children their focus of attention is on the mathematical content of their actions automatically, guiding them to abstraction.

It is also possible to support the four basic arithmetic operations and their basic concepts in such an environment. Regarding addition, students can develop the basic concept of a union by manipulating the virtual objects (pads) and arrange them close to each other. For example, if the child merges a group of 3 pads and a group of 5 pads the protocol will show the symbolic representation of this action as „ $3 + 5 = 8$ “. Here the focus of attention lies on the fact that this action constitutes a basic concept of addition, together with its nonverbal symbolic form of representation. In multi-touch technology there is also the possibility to draw a circle around some pads with the effect that these pads are bundled (a so-called lasso-gesture). This again is a manipulation based on the basic concept of union. Another task in the realm of addition and subtraction may be that 3 pads are shown and the child should create so many pads that in the end there are 7 ($3 + _ = 7$).

The basic concept of balance can be represented as well. Children can create quantities, remove from them, manipulate them with their fingers, and see the consequences of the manipulation at the same time in the nonverbal symbolic protocol. Likewise it is possible to give instructions in the nonverbal symbolic form and to see the output in the iconic forms with the pads.

It is rather easy to imagine that addition and subtraction can be done in such an environment, and we have shown some ways how the action or the state can be linked to a nonverbal symbolic representation. For multiplication and division it is advisable to take advantage of the time as another dimension. The temporal-successive idea of multiplication that can be traced back to a repeated addition is mapped to a repeated touch action of the same quantity of fingers several times. The protocol may then show, for four touches with five fingers, „ $5 + 5 + 5 + 5 = 20$ “ as well as „ $4 \cdot 5 = 20$ “. Thus the children can see that there are different ways to protocol their manipulation. If several children are working together they can take advantage of the spatial-simultaneous idea of multiplication, creating the same quantity by several children at the same time. For division, one example activity would be to move pads and build piles of the same amount to divide a given number of pads.

TECHNOLOGICAL IMPLEMENTATION

In order to implement prototypical environments and for recording experimental data of children's interaction with a multi-touch-enabled screen we used the interactive geometry software (IGS) Cinderella (Richter-Gebert & Kortenkamp, 2006), which acts as a standard tool for rapid prototyping of learning environments. The customization of the learning environments is done via the integrated scripting language CindyScript (Richter-Gebert & Kortenkamp, 2010). CindyScript is a functional programming language that was designed to match standard mathematical expressions as closely as possible, while still providing all the structural elements of imperative programming.

As CindyScript can be triggered by user actions (like pressing the mouse or a key, moving the mouse, or starting a simulation) it is possible to change the standard behaviour of an IGS into the required interaction for an experiment.

A striking example for such a change in user interface behaviour is the method of adding points in the DOPPELMOPPEL learning environment (Ladel & Kortenkamp, 2009). Here, instead of having a dedicated mode to create points, points can be created in drag mode by pulling them from a never-ending stock onto a virtual table, and they can be deleted by just moving them off the table. For finger symbol sets we adapt this technique: Pads can be created without referring to a stock pile, but just by placing fingers in an area next to the table. This allows for multiple pads to be created simultaneously, as is necessary for quasi-simultaneous representations of numbers.

This modeless operation of the learning environment (see Raskin (2000) for a discussion of modal operations in software) is necessary for any multi-touch environment: As one of the goals is the collaboration of several children, and the actions of the children cannot be differentiated, i.e., the computer cannot know which child is associated to which touch event, any mode would have to globally valid for all children at the same time. Switching to another mode (for example, switching between dragging pads and creating pads) would have to be announced and negotiated. Such negotiation would introduce too many obstacles in the user interaction and counters the collaborative advantages of multi-touch.

The latest version of Cinderella offers multi-touch support by adding the TUIO protocol for input events (Kortenkamp & Dohrmann, 2009). Currently, this support is restricted to allowing several elements to be dragged at the same time. Other modes, like the add-point mode or the add-line mode, are not multi-touch enabled. For the modeless operation, as pointed out above, we are using a helpful extension of the scripting facilities of Cinderella: Touch events (finger detected, finger moved, finger released) are translated into mouse events (mouse down, mouse move, mouse up). Using CindyScript, custom actions can be added to these touch events as it is possible with mouse events.

It is not straightforward to adapt a scripted interface to the fact that several press-drag-release sequences can happen simultaneously. It is customary to program user interfaces under the assumption that mouse events are exclusively delivered in the prescribed order of press, drag (possibly repeated), and release. This is relevant for example if a program assumes a “currently moved element”, like a currently moving point in an IGS. Designing software without that general assumption is much more difficult as it involves keeping track of all the current objects and states and their association to the touching fingers. CindyScript facilitates this design process by offering *touch-local variables*: Declaring a variable to be touch-local using the `mtlocal()`-function assures the availability of a different instance of that variable for each press-drag-release sequence of a finger. This is very similar to the concept

of switching contexts in recursive programs.

As an example, consider a program that will record the current mouse position in the mouse down event and then connect that position with the current mouse position in the drag event. A simple CindyScript implementation would be to place `start=mouse().xy;` in the mouse down event and `draw(start,mouse().xy);` in the drag event. Without declaring the `start` variable touch-local this would fail with multi-touch events, with the declaration `mtlocal(start);` it will work flawlessly with any number of simultaneous touches by recording the start position of each finger separately.

The exchange of global information (like the number of total touches) is easily possible by *not* declaring variables touch-local. Placing the commands `count=count+1;` and `count=count-1;` into the mouse down resp. mouse up events will keep track of the current number of fingers touching the surface.

We found the prototyping facilities of CindyScript with the touch extension to be very appropriate for our needs. The final behaviour of the learning environment is not yet determined and should be easily adaptable to empirical findings during the process of interface design. Also, any professional software programming services would need a full specification and, besides being too expensive in this early research stage, could not reflect the didactic considerations as described above.

FORECAST

We are currently working on implementing the above scenarios using a multi-touch table built at CERMAT. A first study that examines the critical point in translating numbers and operations from and in different forms of representation has taken place in October 2010. At the same time we conducted a pre-study about the way children touch with their fingers and present quantities on a table. The data analysis is in progress.

Finally, we aim to answer the research question about the impact of the availability of such multi-touch learning environments regarding the diagnosis and the support of acquiring basic concepts of numbers and operations.

RESEARCHING TECHNOLOGICAL, PEDAGOGICAL AND MATHEMATICAL UNDERGRADUATE PRIMARY TEACHERS' KNOWLEDGE (TPACK)

Spyros Doukakis, Maria Chionidou-Moskofoglou, Dimitrios Zibidis

University of the Aegean, Rhodes, Greece

Twenty-five final-year undergraduate primary education students, who were attending a six month course on mathematics education, participated in a research project during the 2009 spring semester. The course, based on the Technological, Pedagogical and Content Knowledge framework and design experiment procedure, was organised so as to incorporate educational software and educational mathematical scenarios in teaching approaches created by undergraduate students. This article presents the course design, the research procedure and some research results concerning the integration of educational software and mathematical scenario in students' teaching approaches.

Keywords: Mathematics, TPACK, Undergraduate Primary Education students

INTRODUCTION

Over the past few decades, one of the most important issues related to educational change and educational innovation is the integration of Information and Communication Technologies (ICT) (Hoyles, Noss, & Kent, 2004). ICT constitute an essential tool for teachers, since it can be used as: a) an educational method to support student learning; b) as a personal tool to prepare material for his/her lessons, to manage a variety of projects electronically and to search for information; c) as a tool to collaborate with other teachers or colleagues (Da Ponte, Oliveira, & Varandas, 2002). The 2003 reformed Greek National Curriculum in Mathematics has been implemented in the nine-year compulsory education since 2006, as 'Cross Curricular/Thematic Framework (CCTF)'. One of its general principles is "to prepare pupils to explore new information and communication technologies (ICT)" (Official Government Gazette, 2003, p.1). The Pedagogical Institute (Ministry of Education) has developed a compulsory national mathematics textbook for each school year, which is accompanied by national educational software. This is the case for all teaching subjects in the nine-year compulsory education. Despite significant political will and spending by governments on technical equipment and teacher training, ICT integration in schools is often low (Jimoyiannis & Komis, 2007).

Therefore, from a constructivist viewpoint (von Glasersfeld, 1995; Cobb, Stephan, McClain, & Gravemeijer, 2001), integration of educational software into undergraduate students' teaching practice is a crucial factor for teachers' future 'establishment' and improvement in classroom practices. During the 2008-2009 spring semester, a six-month course on primary maths teaching during practicum (school attachment) was organised by the researchers with the aim of integrating ICT

and especially-designed mathematical scenarios (Kynigos, 2006) in students' teaching approaches.

LITERATURE REVIEW

Cobb *et al.* (2001) explain - according to a constructivism theory - how learners make sense of their environments and experiences to create their own knowledge, while Schoenfeld (1998) argues that whenever the student is actively involved in an activity then s/he is more likely to learn its content. However, this process requires teachers to pose meaningful and worthwhile tasks to facilitate students' learning. Nowadays, research in educational technology suggests the need for Technological Pedagogical Content Knowledge (TPCK or TPACK) so as to incorporate technology in pedagogy (Mishra & Koehler, 2006; Angeli & Valanides, 2009). TPACK is based on Shulman's (1986) idea of 'pedagogical content knowledge', which is related with the Knowledge Quarter (Rowland, Turner, Thwaites, & Huckstep, 2009). This interconnectedness among content, pedagogy and technology has important effects on learning as well as on professional development.

Mishra and Koehler (2006, p. 1020) suggest that

“...a curricular system that would honour the complex, multi-dimensional relationships by treating all three components in an epistemologically and conceptually integrated manner”

and they propose an approach which is called 'learning technology by design'.

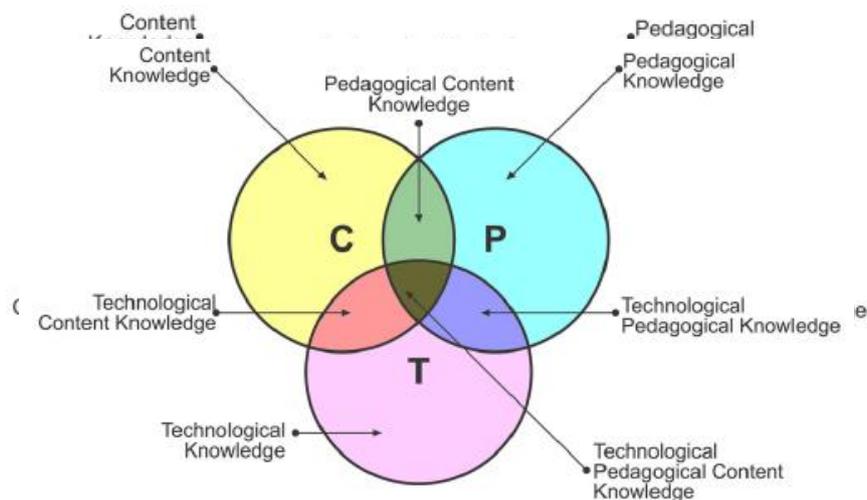

Figure 1: Diagram representing the overlapping components of technological pedagogical content knowledge (Source: Mishra & Koehler, 2006, p. 1025)

They propose a model suggesting three unitary components of knowledge (content, pedagogy and technology), three dyadic components of knowledge (pedagogical content, technological content, technological pedagogical) and one overarching triad of knowledge (technological pedagogical content). Therefore, Pedagogical Content

Knowledge (PCK) is the knowledge of pedagogy that is applicable to the teaching of a specific content (Mathematics). Technological Content Knowledge (TCK) is the understanding of how technology and content both aid and limit each other. Technological Pedagogical Knowledge (TPK) is the understanding of how teaching and learning changes when particular technologies are used. The authors have represented TPACK through the use of a Venn diagram (Fig. 1), where the individual circles represent the knowledge components of content (C), pedagogy (P), and technology (T) and the overlapping area of all three circles represents TPACK.

During the last two decades many research projects have made significant contributions to the teaching and learning mathematics. For example, researchers claim that when students are working with ICT, they are more able to focus on patterns, connections between multiple representations etc. (Laborde, 2002), but the integration of ICT progresses slowly in everyday school practices (Artigue, 1998; Laborde, 2002). In Greece, where technological tools are used, they are often used by teachers in whole class teaching rather than by the students themselves (Jimoyiannis & Komis, 2007).

Concerning TPACK in mathematics classrooms, research projects have already been done, exploring a) teachers' development model on TPACK (Niess, 2005), b) pre-service teachers' TPACK development (Cavin, 2007) and c) the use of TPACK to teach probability topics and data analysis (Lee & Hollebrands, 2008).

RESEARCH METHODS

In order to explore the development of TPACK, we have employed design experiments which constitute an effective methodology for studying teacher development in the setting of an education university department (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). The researchers have taken a triangulation multiple-method approach (qualitative and quantitative) to ensure greater validity and reliability.

The participants were 25 final-year undergraduate primary teachers (16 females and 9 males) in the Department of Primary Education at the University of the Aegean, who were attending the compulsory course 'Teaching Mathematics - Practicum Phase' during the 2008-2009 spring semester. The first two authors used to have a three-hour meeting with the participants in mathematics lab, twice a week. The lab held twelve PCs, with Windows XP, MS Office 2003, internet access, mathematical software (Educational Software of Pedagogical Institute for Mathematics (ESPIM), Geometer's Sketchpad) and presentation tools. The need for a technologically elaborate working environment that would encourage students to use technology led the research team to use many technological tools (the author's website, the course's electronic mail, Moodle as the course and learning management system, a forum, a blog and mobile SMS).

The research work was developed into five stages:

Working Group 15

1. During the first stage and before the beginning of the first lesson, quantitative data regarding undergraduate primary teachers a) background (studies etc.); b) individual learning style according to index of learning styles instrument (Felder & Silverman, 1988); c) attitudes towards ICT, based on Greek computer attitudes scale (GCAS) (Roussos, 2007); d) self-efficacy in ICT according to Greek computer self-efficacy scale (GCSES) (Kassotaki & Roussos, 2006); e) attitudes towards ES - for this purpose, we have designed an educational software attitudes scale (ESAS) based on Roussos' GCAS; f) self-efficacy in mathematics according to the content principles of the CCTF were gathered (GMSES). The same data were gathered from the participants at two more instances (after three months and at the end of the semester), in order to measure possible quantitative differences.

2. Cobb *et al.* (2003) experiment design procedure constituted the second stage. In particular: a) The participants were given a suitable student's worksheet and they worked on geometry tasks about square, rectangle, polygons, cube and parallelepiped (area, perimeter, volume, edge etc). b) After or before their paper and pencil work, they tried to work the same tasks by using the national ESPIM. Each lesson consisted in the teaching of those strategies that incorporate the usage of ICT, so as to involve undergraduate primary teachers in the investigation of geometrical shapes and forms. Teaching was limited to the investigation of geometry problems so that when the teachers come up with their own teaching scenarios (Kynigos, 2006) they will be able to use suitable technological tools that are both efficient and investigatory. The microworlds used were: geo-board, 3D solid manipulation (solid-board), calculator and table tracking from the ESPIM. c) In each lesson, researchers used technological tools while the teachers participated as students taking a lesson in class. d) At the end of each lesson, the teachers were asked to fill out an electronic feedback form, contributing thus further to a discussion of the three-hour lesson that had just finished. The form focused on the development of TPACK in mathematics, with questions on technological tools, teaching strategies and benefits gained from the lesson. This procedure was repeated eight times during the spring semester 2008/2009. For example, one of the worksheets proposed the following task to the students:

“An a-edge cube is transformed to another one with n-times the edge. What happens with the volume of the new cube?”

While the students worked on this worksheet it turned out that some of them had misunderstood the concept of the volume, so according to Cobb *et al.* (2003) procedure, an alternative design worksheet was given to the students to work on it and overcome this misunderstanding. A circled procedure like the latter one was followed by the researchers when it emerged from students needs.

3. The teachers had to write a first assignment that consisted in the search for all geometry problems, activities and exercises involving geometrical shapes and solids in the national math textbooks for the grades 5 and 6, as well as the grades 7, 8 and

Working Group 15

9. They also had to work on two activities, two exercises and two problems of their choice (from the above units) using ESPIM. Furthermore, they were asked to create a lesson plan spontaneously for teaching the "area of a parallelogram" chapter or "the volume of a parallelepiped" for grade 6 mathematics.

4. The teachers had to be taught the notion of the 'educational scenario (ES)' so they were asked to participate and act as students in an educational scenario created by the research group for the purposes of the lesson. The title of the scenario was 'Creating Mobile Phone Networks' and it constituted a holistic picture of a learning environment, without limitations but with the ability to focus on those aspects that the educator judged to be of importance (Kynigos, 2006). Then the teachers were asked to create their own ES, to be used with the chapter of the lesson plan they had already created. Therefore, with the theoretical and practical knowledge and the experience gained, the teachers produced their own ES over the following two weeks. Each ES was presented to their peers, who acted as students of a class. The latter provided feedback and assessed the ES on an especially designed form by the researchers. After that, the teacher, creator of the ES, having taken his/her peers' comments into consideration, returned two weeks later and presented his/her improved ES version. Security and originality were safeguarded as all ESs had been posted before the beginning of the presentations. ES presentations were audio recorded on a digital camera so they could be further analysed. Finally, the teachers were self-assessed and gave feedback on their own ES. In their fourth assignment (assessment) students had to create an ES to be used with the chapter of the lesson plan they had already created for grade 8 students.

5. During the above process, semi-structured interviews were conducted very frequently. The initial students' interview took place after the submission of the first assignment and the final interview was conducted after the completion of the second presentation of the ES. The purpose of these interviews was twofold; on the one hand, to investigate procedures followed by the teachers during the writing up of their first assignment and their ES, their perceptions of TPACK in math and the reasons for their inclusion or non-inclusion of ICT in the lesson plan. On the other hand, the purpose of the interview was to determine whether or not this constructivist design experiment procedure was personally suitable for them. Interviews were recorded for further analysis.

6. During the last meeting, the teachers were asked to anonymously complete a questionnaire regarding their satisfaction with the course. Twenty-four completed questionnaires were returned out of the twenty-five that were handed out.

7. Finally, we evaluated the teachers in "paper and pencil" and ESPIM work.

During the next school year (2009-2010), 11 out of 25 participants were hired as primary education teachers. Having completed their first year of teaching, we asked

them to fill out an online questionnaire to investigate if and how they integrate ESPIM and ES in their teaching.

In the next section, the results from a) the analysis of quantitative data on students' computer attitudes, self-efficacy in ICT, attitudes toward educational software, and self-efficacy in math, and b) the analysis of quantitative data on course satisfaction of participants will be presented.

SOME RESEARCH FINDINGS

In order to analyse the quantitative data gathered about course satisfaction of participants we applied a set of powerful ordinal regression methods. The most important results focus on the determination of the course weak and strong points, according to the MUSA methodology (Grigoroudis, & Siskos, 2002). The teachers' global satisfaction with the course was characterized as extremely high. The mean satisfaction value, as measured by the method, reached 98%, while it is of great importance to note that all comments were positive. The teachers also appeared satisfied in the partial (per criterion) satisfaction survey (Table 1), where negative comments were sparse.

Criteria	Satisfaction
Educational Program	90.02
Professor	97.10
PhD Researcher	92.05
Mathematics Lab	97.00
Educational Material	97.09

Table 1: Satisfaction per criterion

The research results from the study of the teachers': a) attitudes towards ICT (GCAS), b) self-efficacy towards ICT (GCSES), and c) self-efficacy towards mathematics (MSES) are the following:

a) The 30 items of GCAS (Roussos, 2007) were summed to provide a total score (from 30 to 150) representing the participants' overall attitude toward computers. Descriptive statistics of the first and last GCAS scores are reported in Table 2. The results show an improvement of teachers' attitudes toward ICT, which was not statistically significant [$F(1.4, 32.28)=2.28, p=.13$].

b) The GCSES (Kassotaki & Roussos, 2006) scores represent the participants' self-efficacy toward ICT (scores ranged from 29 to 145). The results (Table 2) again a statistically non-significant improvement [$F(1.57, 36.26)=1.43, p=.25$].

c) Finally, in order to explore the teachers' self-efficacy toward math (GMSES), we used the 7 content principles of the CCTF (problem solving, numbers and operations, measurement and geometry, gathering and processing data, statistics, ratios and

proportions and equations). The GMSES provided a total score representing the participants' self-efficacy toward math (scores ranged from 7 to 35). The results (Table 2) show that the teachers' self-efficacy towards math improved significantly during the semester [$F(1.58, 36.44)=3.98, p=.036$]. Post hoc comparisons using t-tests with Bonferroni correction demonstrated a statistically significant difference between the first and the second measurement stages ($p=.021$).

GCAS	Measurement Stages	Mean	SD	N
	1	103,08	20,61	24
	3	109,25	18,60	24
GCSSES		Mean	SD	N
	1	109,17	24,12	24
	3	113,46	20,74	24
GMSES		Mean	SD	N
	1	22,58	5,70	24
	3	24,21	5,32	24

Table 2: Means and standard deviations of the four scales for the two measurement stages (beginning and end of semester)

DISCUSSION AND CONCLUSIONS

Regarding to our final-year undergraduate primary education students' attitudes and self-efficacy towards ICT, it seems that the participants had already acquired the necessary knowledge of ICT usage before entering university or during their university studies and they were comfortable with its use, as the GCAS and GCSSES means from the research were consistent with Roussos (2007) and Kassotaki & Roussos (2006) research findings. Additionally, these findings were consistent with the Bahr, Shaha, Farnsworth, Lewis, and Benson (2004) results, who reported that pre-service teachers had positive attitudes towards technology and technology integration. Moreover, it seems that the participants of the present study had already reached high level knowledge of technology (TK). These findings are also consistent with the Wentworth, Earle, and Connell (2004) results. The positive attitudes towards ICT and ES had a positive impact on the university faculty who organise educational technology courses (Jimoyiannis & Komis, 2007). Moreover, it seems that the course experiment design and the involvement of undergraduate primary teachers with educational software for math improved their self-efficacy towards math. Also, undergraduate primary teachers improved their mathematical content knowledge. It seems, therefore, that the teachers' attitudes and self-efficacy constitute a force that needs strengthening if ICT is to be incorporated into their teaching practices.

Working Group 15

The extremely high results on students' satisfaction lead us to posing of new research questions. The high satisfaction level might be attributed to: a) The small number of undergraduate primary teachers-participants (Krentler & Grudnitski, 2004); b) The support the teachers received during the entire course via blog, forum, website and e-mail services. It is worth mentioning that the professor and the PhD researcher gave responses at the latest within the next day to the 400 e-mails received during the course. Furthermore, the forum received 140 messages (not counting those sent by the professor and the PhD researcher); c) The everyday communication between the teachers and two individuals (the professor and the PhD researcher); d) The possibility of 'self-defensiveness' on the part of the participants might have resulted in inaccurate responses since this was their first time to participate in a satisfaction research study.

It is our belief, therefore, that undergraduate primary teachers' satisfaction in a learning environment that combines teaching in the university classroom and support via an appropriate learning environment plays a crucial role in the sustenance of programmes that incorporate ICT in teaching and learning. Additionally, the correlation between satisfaction and undergraduate primary teachers' characteristics (learning style, attitude towards ICT and self-efficacy in the use of ICT) constitutes a crucial parameter in the improvement of the education provided. On the other hand, teachers' characteristics, their method of making undergraduate primary teacher contact and their teaching style seem to affect the teachers' satisfaction. The above mentioned findings reveal that each new educational establishment needs to adopt an evaluation programme for its provided services, in order to obtain, amongst others, the necessary data on undergraduate primary teachers' satisfaction about the course services (Elliott & Shin, 2002) so that a circled process will take place for the new course improvement.

In addition, it seemed that the crucial factors for the integration of educational software and scenarios into the teaching of mathematics are the students' positive attitudes towards ICT and educational software and the self-efficacy in technological tools and math. Further analysis of qualitative data (interviews, narrative observations and essays) concerning these quantitative research findings and also the students' scenarios structures, is currently under way so that these triangulation research methods will deeper our understanding of primary teacher training on Technological, Pedagogical and Content Knowledge in Mathematics education.

THE CO-CONSTRUCTION OF A MATHEMATICAL AND A DIDACTICAL INSTRUMENT

Mariam Haspekian

Laboratoire Didactique André Revuz, Paris, France

Spreadsheet is not given as didactical tool to serve mathematics education. It may progressively become such an instrument along a professional genesis of use on teachers' side. Using both the notions of distance and double genesis, the case study described in this paper illustrates the beginning of such a genesis and the complexity that comes along with it.

Keywords: ICT, instrumentation, double (professional / personal) genesis, instrumental distance.

INTRODUCTION AND DATA PRESENTATION

For several years now, research communities have paid an increasing attention to technology use in math education (see Drijvers *et al.*, 2010 for a historical overview). Theoretical frames as the instrumental approach (Artigue, 2002; Guin, Ruthven & Trouche 2004) have been developed around the concept of *instrumental genesis* focusing on ICT impact on pupils' work. This paper moves from this focus towards the impact of technology on *teachers'* practices. It focuses on the case of the spreadsheet which is not given as a didactical professional tool but that may progressively become such a didactical instrument through a professional genesis on teachers' side. In order to study these geneses, I introduced two theoretical constructs within the frame of Instrumental Approach. The paper illustrates a case study on how these two concepts are useful in analyzing the teacher's geneses with the spreadsheet and in describing the complexity of these geneses. The data on which we are illustrating the concepts are based on observations (on two consecutive years) of an experienced teacher, named Dan in the following, integrating spreadsheet for the first time in her classroom. The observation of Dan's spreadsheet integration shows some evolutions from a year to the next.

Few words about Dan

Dan is an ordinary teacher, having more than 10 years of experience, also involved in teacher training and having integrated dynamic geometry software, but spreadsheet is a new tool for her. During the first year, Dan was motivated by her participation in a research project focusing on spreadsheet use for *algebra* learning (Haspekian, 2005a). At the end of the research, an interview collected her thoughts and feelings about this experience. The following year, she used the spreadsheet by her own choice, without any research protocol. On that occasion, we recorded her first spreadsheet session and the following session in a paper-pencil environment. Some phenomena during this observation and the way Dan evolved in her practice with

spreadsheet as a didactical tool provide interesting data. Let us first present the evolutions at stake and then describe the theoretical frames to analyse these data.

Dan, year 2, or “the second trial of using spreadsheet in mathematics lessons”

During the second year, Dan introduced spreadsheet not with algebra but with statistics (headcounts, frequencies and cumulative frequencies after having seen these notions in paper-pencil). In this context, some of the observed elements are surprising: the lesson, showing very little statistics, is mostly centred on the tool use and functionalities, and reveals unexpected mathematics (notions of variable, formula, distinction between “numeric/algebraic” function...). The latter reflect the influence of the year 1 experience, centred on algebra, but this does not explain completely the evolution year 2 (variations and regularities) summarized in Table 1:

Use of spreadsheet	Year 1	Year 2
VARIATIONS		
Class level	7 th Grade (12 year old)	8 th Grade (13 year old)
Old/new content	New	Old
Mathematical Domain	Algebra	Statistics
Spreadsheet location	Limited to computer lab	Computer lab +ordinary classroom
Synthesis	No	Yes
Interactions Teacher-Students	Mostly individual	Individual and collective
Use of the video and collective presentation	Piloted by teacher, limited role	Teacher and student. Important role
Students Configuration	Work by pairs	Work by pairs + collective work: one student at the board
REGULARITES		
Maths objectives, teacher aims	Algebra	
Additional material	Worksheet for pupils and pre-organised spreadsheet file	
Institutionalisation	In an ulterior lesson, in ordinary classroom	

Table 1: Comparison Year 1- Year 2

How can we explain these observations, the variations and the emerging regularities?

THEORETICAL FRAMES TO UNDERSTAND THE OBSERVATIONS

To understand teacher’s practices, the “didactic and ergonomic approach” developed by Robert and Rogalski (2002) describes teacher’s activity through 5 components: personal, mediative and cognitive dimensions, as well as institutional and social constraints. The *cognitive* and *mediative* components relate to the choices made by the teacher in the spatial, temporal and mathematical organisation of the lessons. For Robert and Rogalski (2002) teachers are not totally free in these choices; they are more or less constrained by *personal*, *institutional* and *social* dimensions: the personal component relates to the teacher as a singular subject, with his own history, practices, vision of mathematics learning. The institutional and social dimensions relate to curricula, lessons duration, school social habits, math teachers habits etc.

This first frame is used at a global level. In the case of ICT practices, instrumental aspects seem to interfere with each of these components. This leads to the use of the instrumental approach in order to analyse at a more local level some of the phenomena observed during the year 2.

What are Dan's evolutions through these 5 components?

Table 1 shows an evolution of the mediative and cognitive components (math domain chosen, way of introducing spreadsheet, class level, etc.). This indicates (and it is confirmed by the phenomena observed during the lesson) that Dan's personal component evolved too. How can we explain this evolution? Our analyses lead us to consider two main results: first, a phenomenon of *double instrumental genesis* takes place in the evolution of Dan's personal component, and second, all changes operated by Dan in her mediative and cognitive choices go towards a *reduction of the instrumental distance*. Let us precise more these theoretical issues.

The idea of *distance* has been introduced (Haspekian, 2005a) to take into account, beyond the "computer transposition" (Balacheff, 1994), the set of changes (cultural, epistemological, institutional) introduced by the use of a specific tool in math "praxis". For a given tool, a too big distance to the "current school habits" is a constraint on its integration (Haspekian, 2005b). On the other hand, didactical potentialities of technology rely on the distance it introduces as regards to paper-pencil (providing new representations, new problems...). In (Haspekian, 2005a) we have brought out 4 types of elements that can generate some distance. Some are directly linked to the *computer transposition*, as the representations and the associated symbolism. They can also be of an *institutional nature* [1], *didactical nature* (vocabulary, field of problems they allow to solve...), or *epistemological one* (what gives the tool an epistemological legitimacy). This is linked to teacher's personal component (her representations of math, of math teaching, of the role this tool plays in the development of math).

Then, the way teachers orchestrate and support pupils' instrumental geneses evolves year after year. Considering spreadsheet as an instrument for the teacher, allowing her to achieve some teaching goals, we consider a process of instrumental genesis *on teacher's side*. The same artefact, the spreadsheet, becomes an instrument for pupils' mathematical activity and an (other) instrument for teacher's didactical activity.

In Dan's case, this process is even more complicated since it is split in two. There is a *double instrumental genesis* because Dan is not developing one but two instruments from the artefact spreadsheet. The personal instrumental genesis leads to the construction and appropriation of a tool into an instrument for math work, which differs from the *professional instrumental genesis* that leads to the construction and the appropriation of the previous instrument into a didactical instrument for math teaching. The didactical functionalities of this tool are not pre-defined, the teacher must develop and integrate them in her usual teaching practices and habits. My

hypothesis is that these two processes are not independent for Dan as they happened simultaneously in her case. Neither are they independent of pupils' geneses as we will see. Let us first describe more precisely the *professional genesis*:

Applying the instrumental approach to the spreadsheet seen as a *teaching* instrument that the teacher builds along a professional genesis, we can bring out two processes:

- An instrumentalization process: the tool is instrumentalized by the teacher in order to serve her didactic objectives. It is distorted from its initial functions and its didactical potentialities are progressively created (or “discovered” and appropriated in the case of an educational tool);
- An instrumentation process: a teacher will have to incorporate in her teaching schemes that were relatively stable some new ones integrating the tool use. She will progressively specify spreadsheet use to a particular class of situations (as “take advantage of spreadsheet for algebra learning”) and organise her activity in a way that will become progressively invariant for this class of situation (the Dan's case already shows some regularities from year 1 to year 2).

Dan builds up *schemes of instrumented action* [2] aiming at using spreadsheet to teach algebraic concepts (e.g., variables, formulae through the use of the copy, or by taking benefits of the numerical feedback to infer the equivalence of two formulae). This brings into play some usage schemes concerning material aspects, as the tool integration in a larger set of instruments (with the video projector), the organisation of the lessons, that are schemes that will undertake the modes of exploitation and the orchestrations, for instance, using a video projector at the beginning of the session for collective explanations, making pupils communicate and work by pairs, giving a sheet of instructions and a pre-built computer file to gain time, but also regularly “clicking on cell to check whether the pupils have edited a formula or numerical operation, or even directly the numerical result...).

I said this professional genesis was not independent of Dan's personal genesis, but interfered one on the other [3]. I also said that the professional genesis is made more complex by the fact that Dan wants her pupils to manipulate spreadsheet too (one could imagine a spreadsheet usage only under the teacher's control) and learn math through this activity. Thus pupils' instrumental geneses are part of the teacher's instrumental genesis. Here again, the two phenomena are imbricate and interfering. Some of our teacher's activity observations during the year 2 result from these interferences. We will show an example in the next section.

TEACHER'S DOUBLE GENESIS INTERFERING WITH PUPILS' INSTRUMENTAL GENESES

As we mentioned, Dan has inscribed the introduction of spreadsheet in her class within the domain of statistics. Fig.1 is an excerpt of a pupil's exercise that shows the corresponding spreadsheet file with the pre-edited formula built by Dan:

Working Group 15

Step 2 : usage of formulae et the «handle of recopy».

distance (km)	0<d ≤5	5<d ≤10	10<d ≤15	15<d ≤20	total
headcounts	16	14	12	8	50
frequencies (%)	32				100

- 1) a) What is the total number of items? _____
 Where is this number located? What is the formula to calculate it? _____
 b) If one changes the headcounts for $0 < d \leq 5$, does the frequency change?

	A	B	C	D	E	F
1						
2						
3	Etape 2 :	calcul de fréquences				
4						
5	distance (km)	0<d ≤5	5<d ≤10	10<d ≤15	15<d ≤20	total
6	effectif	16	14	12	8	=SOMME(B6:E6)
7	fréquence (%)	=B6/\$F\$6*100				100

Figure 1: Dan's final version of formulae

It is interesting to notice that this file has been modified three times by Dan. In its first version, the formula calculating the frequency (in B7) was: **=B6*100/50**. This formula, if copied along line 7, calculates the correct frequencies for the corresponding data of line 6. But it is not adequate regarding the question b) [4].

The day before the lesson, Dan realised the mistake and changed the formula into: **=B6/F6*100**. She confided she did not feel yet totally comfortable with spreadsheets. If her own instrumental genesis with spreadsheet as a mathematical instrument probably plays a role here, we also see that the key point of the problem comes from the spreadsheet as a *didactic-oriented* instrument. From the spreadsheet as a “calculus-oriented instrument” point of view, the formula was adequate. It is the didactical aim (showing the mathematical dependency between the number and the frequency) that leads Dan to ask the question b), which turns the formula wrong. Dan did not realise this when she built first her formula. At that moment, the personal instrument stands at the front of the scene, and covers up the professional instrument and its didactical aims (the question b).

Interference between the personal and the professional instrument can be seen again in the continuation of the story. The new formula, “**=B6/F6*100**”, is now adequate for question b, but it is **still not convenient** if we consider the next question (Fig. 2) for inverted reasons! Dan wants pupils to copy the formula in order to fill line 7 and meet this functionality and the automatic incrementation of cell references (B6 becomes B7...). This time, this is part of her goals for students' instrumental geneses.

- 3) Complete the table using the formula in B7:
 Recopy the formula on the right. (see instructions below for the “cell recopy”).
 What is the formula contained in C7? D7? E7?

Figure 2: The continuation of the task

Working Group 15

But the formula above, if copied on line 7, does not fit anymore, as the cell referring to the total, F6, will be changed into F7, F8... along the copy. A solution to this problem is to fix the cell F6 in the recopy by using the "\$" functionality. But Dan did not want this functionality to appear in the first spreadsheet session. It was over the level of instrumentation she wanted for her pupils at this moment. When she built her new formula for question b, the \$ was not in her mind and she did not put it, forgetting that it will create false results at question 3. The day before the session, after discussing over a phone call she realised the mistake and integrated finally the \$ in a last-minute decision!

This time the formula was wrong regarding an instrumental goal: the \$ symbol was over Dan's instrumental objectives and she did not keep it in mind. It is neither easy nor trivial to bend to all the constraints, all the more that she had already changed her very first version of formula for a mathematical aim, now she had to change it again for an instrumental aim... This time, it is the professional-oriented instrument that overrode on the personal one, by taking into account pupils' geneses and the level of instrumentation that she wanted them to reach.

These successive formulae somehow disrupted the session: Dan put the \$ sign in the formula and wanted to avoid speaking about it with pupils, but it has been of course highlighted during the session! Facing pupils' questions, she was compelled to explain but she just said that it is not important to write it in paper-pencil environment. Then, when a pupil came to the board to write the spreadsheet formula, he forgot the \$, the "division by zero Error" appeared after copy and Dan said "*now you happy?*" but did not explain the message nor the division by zero![5].

Interpretation: the complex and "split in two" geneses on teacher's side

This example shows how the double genesis on the teacher's side may interfere with pupils' geneses: spreadsheet constraints interact with the teacher's goal and didactical expectations (she wanted to introduce only a basic level of spreadsheet functionalities). She has not yet turned her personal instrument into a math teaching one. This process is made more complex by the different geneses at stake. As we saw in the example, it is constrained by:

- The mathematical learning the teacher aims at (statistics and algebra),
- Pupils' instrumentation, that is how to make them work math through spreadsheet (as the mathematical headcount-frequency dependence through the change of the frequency cell after changing the value of the headcount cell),
- Pupils' instrumentalization, that is which functionalities are aimed at, which schemes of use do we want them to build - here: relative references and automated incrementation of cell references with the copy, but not yet the absolute references, the \$ sign and its different behaviour in the copy.

Managing all these constraints at once is not easy: spreadsheet is not given as a

didactical instrument, the case of Dan shows that such an instrument is only progressively built along a complex professional-oriented genesis.

Understand the global coherence in the evolution of the teacher's practices

As a synthesis, we can say that institutional and social components, together with Dan's own reflection on her practices, lead her to evolve in her conception of the spreadsheet use. Here are the observed evolutions:

1. **Higher level of class** : she uses spreadsheet with 8th graders instead of 7th graders
2. **Lower quantity of « new » concepts**: avoid mixing the introduction of the spreadsheet with the introduction of new math notions
3. **Domain change**: introduce the tool with statistics which seemed to Dan more appropriate than algebra
4. **Contents shifted towards the instrument but conditioned by the level of instrumentation fixed by Dan** (she did not want to stress the \$)
5. **Deeper articulation between social and individual schemes**, the importance of the articulation in instrumental geneses has been mentioned by Trouche (2005). In the interview, Dan says she did not organise moments of mutualisation enough and she explicitly wished to take care of this point the 2nd year.

Observing deeper these evolutions, they all appear to converge in the direction of *reducing* the instrumental distance. The next section develops this point.

REDUCTION OF THE INSTRUMENTAL DISTANCE ALONG TEACHER'S PROFESSIONAL GENESIS

At different levels, Dan's modifications year 2 tend to decrease a too big instrumental distance of the spreadsheet.

1. Changing the class level: Higher level of class

This modification comes with the change of the domain (point 3): in French curricula, spreadsheet is explicitly mentioned with statistics for 8th Grade pupils. In the 7th Grade curriculum, spreadsheet appears in a more general and vague way. It requires from teachers a deeper work and thought to define its potentialities for learning math notions, these latter appear more distant from spreadsheet math than in the 8th Grade, where spreadsheet appears clearly in relation with precise notions of the curriculum. Thus, choosing this level allows Dan to reduce the distance and match more easily with the official prescriptions. Besides, year 1, Dan found pupils' instrumentalisation not easy in 7th Grade (difficulty to use the "recopy", select a single cell, edit a formula). Older pupils seem to be more skilful and problems linked to instrumentalisation should be less interfering with the math work. With 7 graders, manipulations of the tool seemed more difficult and the tool appeared less transparent.

2. The “old/new” game in the mathematical and in the instrumental contents

Year 1, Dan introduced a new instrument when she introduced new math contents (algebraic notions). The ratio old/new is different in year 2 and also goes in a direction of reducing the distance by reducing the part of “new”: all the math notions at stake in the spreadsheet session (headcounts, frequency, cumulative frequency) had already been seen previously in paper-pencil. This work (new environment with “already-seen” concepts) will then serve Dan as a basis to work later algebraic notions (new concepts in an “already-seen” instrument).

3. Domain changing

The math domain chosen by Dan in year 2 also reduces the distance as regards to algebra, for at least three reasons. The domain of statistics is usually seen to be more in conformity with the representations of a spreadsheet work than algebra. Furthermore institutional pressure is less important in statistics than algebra, a more classical and traditional domain strongly linked to paper-pencil math. On the contrary, statistics are nowadays seen as more fitted to technologies. At last, in the spreadsheet language, one can find more common terms with statistics whereas the distance to the traditional algebraic vocabulary is important (Haspekian, 2005b).

4. A deeper care to instrumental aspects

Distinguish the instrumental genesis on pupils’ side and the dual genesis on teacher’s side allowed us to understand better the teacher’s activity and the phenomenon observed during the session. Dan’s didactical instrument is improving along the experiences and the examples above (click on the cell to see if pupils edited a formula, use the recopy, introduce the relative references but not the absolute ones, not to introduce the logical functions...) show that spreadsheet sessions require careful consideration of all these instrumental aspects. But this is not evident and the first section illustrates difficulties and interferences between these three geneses. Dan’s evolution shows a deeper care of the instrumental aspects with the pre-determination of a level of instrumentation for pupils, well defined, not too high and not too far from usual (not using the \$, not introducing the “IF” function etc.).

5. Moments of mutualisation and articulation with paper-pencil mathematics

Dan introduced year 2 some moments of mutualisation in spreadsheet sessions. In the interview, she affirmed her will to increase the similarity with the traditional sessions. She said having the feeling that it is necessary to multiply the links with the paper-pencil math (e.g., she started the sequence by a paper-pencil session, then worked the same notions in a spreadsheet session, then she came back on the work done with spreadsheet in a paper-pencil session, etc.). All these actions contribute to reduce the distance with paper-pencil, to mix these two environments in a greater proximity. This is a key point to integrate spreadsheet: in (Haspekian, 2005a), teachers who used to integrate spreadsheet had these characteristics. It is thus

interesting to notice that Dan's professional genesis follows the same line. The "old/new" game mentioned above is another characteristic found in expert practices.

CONCLUSION AND PERSPECTIVES

Many reports deplore the poor integration of ICT in math teaching and researchers stress a phenomenon of "disappointment" after an enthusiastic period where pioneers claimed ICT benefits to learn math. One of the reasons is the "teacher barrier" (see Ruthven, 2007 or Balanskat, Blamire & Kefala 2006) and particularly the importance of teachers' practices, which is seen as a key issue in ICT integration. This is why it seems crucial to progress in understanding of practices and instrumental geneses. In this understanding, the previous study appears to shed light on two elements.

The notion of distance to the referential environment plays a role in technological integration. As we saw, it explains some of Dan's evolutions in terms of a *reduction* of the distance (either by making this distance more explicit or by multiplying moments that alternate work in the two environments enriching both of them). This constitutes a significant creative task for teachers as the tool is not given with any didactical functionalities, it requires a professional instrumental genesis on teacher's side different from the personal genesis and also different from that on pupils' side.

Thus the dual genesis on teachers' side is another interesting element to consider in order to study both local phenomena that can be observed in a session, and the more global evolution of practices, year after year. Dan's emerging practice with the tool is understood better in this frame of double geneses.

Several questions remain, as delimiting more precisely different criteria that create some distance. To understand practices, it is also necessary to determine which elements may counterbalance the distance and play in favor of the tool integration (such as institutional injunctions, or tool epistemic value, didactical design...). We also have to characterise better geneses on teacher's side compared to pupils' one.

NOTES

1. Beyond the computer transposition that modifies math objects, the modification, from an institutional point of view, concerns the whole ecology of these objects (tasks, techniques, theories). The idea of "distance" reflects the gap between praxeologies associated to two different environments (paper-pencil being a peculiar environment of the math work).
2. Rabardel (2002) distinguishes two types of schemes: *usage schemes* (related to the *material* dimension of the tool) and the *schemes of instrumented action* (related to the global achievement of the task, with goals and intentions).
3. It may not be the case for all teachers: unlike Dan's case, the first instrument can already be constituted in a more advanced way, long before trying to make it a didactical instrument. .
4. The formula refers to the value 50 for the total. If one changes the value of any headcount, then the total will change and the formula becomes wrong.
5. Increment of references after copying make the formula refer to empty cells, by default, empty cell are treated in formulas as if they contain the value 0, this is an option that can be changed.

WORKING WITH TEACHERS: COLLABORATION IN A COMMUNITY AROUND INNOVATIVE SOFTWARE

Jean-Baptiste Lagrange

IUFM, University of Reims, France and LDAR, University Paris-Diderot

This paper is based on an experience of a small scale community around Casyopée, innovative software produced in the ReMath project. A first assumption was that dissemination of research outcomes is possible through the development of communities involving researchers and teachers. Another assumption was that all teachers are not to be considered at the same level. “First-adopters” are teachers that chose to be associated with the project development from the beginning. “Mid-adopters” are teachers that can be interested by using innovative software in the classroom, but will choose to do it only when it brings a real added value. All other teachers potentially users of Casyopée make a third layer. This paper is a first step in the study of communication and collaboration in a “multi-layer” community.

Keywords: teachers, innovative software, collaboration, community, dissemination

INTRODUCTION

Relatively to the integration of digital environments in mathematics teaching and learning, the gap between researchers' expectations and the reality of classroom uses is often stressed. In my view, this gap is not merely quantitative. In a country like the United Kingdom, where uses by teachers are quantitatively high, researchers have concerns relatively to the quality of uses: Miller and Glover (to appear) regret that

“many teachers make progress using the presentational capability of interactive whiteboards but that failure to use associated digital technologies and to make a significant pedagogic change will (...) lead to wasted opportunities”.

Among the opportunities wasted, I count the difficult dissemination among teachers of innovative software designed by research. Soon after the computer appeared and was regarded as useful in the classroom, researchers in mathematics education thought than designing digital learning environments was part of their work, considering that design principles and decisions are of didactic nature and have a deep effect on classroom use of technology. This ‘tool design’ dimension was important in the European project ReMath (IST4-26751). The development of six ‘Dynamic Digital Artefacts’ (DDAs) that is to say innovative software for mathematics teaching and learning, was central in this project. Bridging the gap with classroom and teachers was also an objective of the project, that was aimed (1) through the elaboration of an integrated theoretical framework that should help to communicate between researchers and also between researchers and teachers (2) the elaboration of scenarios of use of the DDAs with a special version for teachers written after experimenting in the reality of actual classrooms (3) the publication of all this material on a communication platform.

While these outcomes of Remath are significant, it would have been very naïve to consider that, by them, they allow teachers to appropriate DDAs and associated educational strategies. A more reasonable assumption is that this appropriation is possible through the development of communities involving researchers and teachers. The aim of this paper is then to discuss an experience of development of a small scale community around one of the ReMath DDAs: Casyopée. The creation of communities of teachers working to produce varied resources associated to the use of technology has been studied by authors like Guin & Trouche (2008). On the one hand, the problematics of the work presented in this paper is convergent with these studies, in the sense that the goal is also to develop the use of a given technology by way of collective work of teachers. On the other hand, the issue here is dissemination of research production and the real question is then the process of collaboration between actors in different positions towards research, rather than the internal functioning of a teacher community. In this process, the outcomes of Remath could act as “boundary objects”, a notion introduced by Fuglestad, Healy, Kynigos and Monaghan (2009) to make sense of the collaboration between researchers and teachers in the integration of technology.

CASYOPÉE: EPISTEMOLOGICAL CHOICES AND CONSTRAINTS

Casyopée has been developed for ten years in a project involving researchers from the Didirem team and teachers after they experimented with ‘standard’ Computer Algebra Systems (CAS) (Lagrange, 2010). The aim was to take up the challenge of teaching about functions at upper secondary level. The team was concerned that while technology is able to offer multi-representational and symbolic manipulative capabilities very effective for solving problems and learning about functions, no tool really adapted presently exists for students’ use. CAS are designed for more advanced users. Dynamic Geometry (DG) offers means for constructing operational figures and exploring co-variations and dependencies in these figures, but exploration is limited to numerical values. Students are neither encouraged nor helped to use algebraic notation and to work on algebraic models. The focus of ReMath was upon computer representations of mathematical objects. Thus it was an opportunity to extend Casyopée representational capabilities, in order to consider functions as models of non-algebraic dependencies. The choice has been to consider 2D geometry and magnitudes as a field of experience. The result is that Casyopée has now two main windows. In the symbolic window the fundamental objects are functions, defined by their expressions and domain of definition. Other objects are parameters and values of the variable. Casyopée allows students to work with the usual operations on functions like: algebraic manipulations; analytic calculations; graphical representations; support for proof... A new window offers usual DG capabilities and also distinctive features: geometrical objects can depend on algebraic objects and it is possible to export geometrical dependencies into the symbolic window in order to build algebraic models.

On the one hand, these epistemological choices are consistent with the notion of function as considered at secondary level and thus they should facilitate Casyopée integration. On the other hand these choices introduce non trivial constraints and differences with software tools generally proposed for classroom use at this level. First, offering symbolic calculation has been decided in order to help students to identify the different stages in a solution of a problem; this decision also implies that Casyopée relies on computer algebra algorithms which are not always deterministic: for instance, it happens that two expressions are mathematically equivalent but also that none of the algorithms implemented in the computer algebra kernel can recognize the equivalence. More generally, Elbaz-Vincent (2005) points out the “decidability limitation” inherent to computer algebra, and concludes that an ‘intelligent usage’ of CAS in mathematical courses is not obvious. Second, DG in Casyopée is designed to help students in modelling algebraically geometrical dependencies. This implies to carefully distinguish between “variable objects” involved in the dependency and “generic objects” that have to be handled as parameters of the problem. For instance in the following problem: *ABC a triangle, [CH] an altitude of this triangle, find a rectangle MNPQ with M on [HA], N on [AB], P on [BC], Q on [HC] and with the maximum area*, in DG environments, numerical exploration of the dependency between point *M* and the area of the rectangle is possible with *A*, *B* and *C* defined as free points. With Casyopée, this exploration is possible, but, to model the dependency as an algebraic function of one variable, which is Casyopée’s potential, the area has to depend univocally of one point. Then, in situations proposed by the Casyopée team, a “generic object” (here the triangle) is defined by way of parameters and a “variable object” (here the rectangle) is defined by way of a free point.

COMMUNITIES AROUND CASYOPÉE; GOAL AND HYPOTHESES

Before and during the ReMath project, Casyopée was mainly a research tool. During ReMath, Casyopée like the other DDAs has nevertheless been a ‘boundary object’ for small communities especially through the methodology of cross-experimentation: Casyopée has been “cross experimented” by an Italian team and our French team (Maracci, Cazes, Vandebrouck, & Mariotti 2009). Only by the end of the project, the development of a “real world” community around Casyopée could be considered. It was based on the assumption developed in the introduction that researchers have to consider the dissemination of their production as a research work in itself. The issue of collaboration also raised in the introduction implied that all teachers are not to be considered at the same level in this process of collaboration. Teachers that have been associated with the project development can be considered as “first-adopters”, or “experts”. I consider also “mid-adopters”, that is to say teachers that can be interested by using innovative software in the classroom, but will choose to do it only when they will be convinced that it brings a real added value to their teaching strategies. All other teachers potentially users of Casyopée (that is to say, every

mathematics teacher at upper secondary level) would make a third layer. The idea was then to use classroom scenarios as means for communicating between layers: the elaboration and experimentation of scenarios by mid-adopters would be first a way of collaborating between experts and mid-adopters: mid-adopters would propose uses corresponding to their needs and ask the experts for their advice and support. The scenarios would be built in order to be proposed to all teachers and thus designed as a way to communicate between the second and third layer. The goal of the research was then to investigate what particular approaches those “mid adopters” take when working at these interfaces with the first and the third layer. A first hypothesis was that, like in the collaboration between the French and Italian team, the design of scenarios with the help of experts would help the understanding of Casyopée’s potential and constraints. The second hypothesis was that like in the case of Italian teachers, the mid adopters would adapt the use of the software to their needs and sensibility. I expected that these teachers would be primarily interested in easy-to-achieve and close-to-curriculum applications of Casyopée, and sensible to problems and constraints related with the time required by implementing technologies in their classes, with curriculum requirements, with training needs, etc. Thus their production would provide useful material for an easy integration by teachers in the third layer.

METHODOLOGY

Expert teachers: the first-adopters or “experts” were two teachers that had been involved in the cyclical process of specifying functionalities for Casyopée, contributing to the software development, and experimenting with their classes. Crucial steps in the project were undertaken as a consequence of dissatisfactions they expressed after classroom experimentations. The decision to develop a software environment around a symbolic kernel for classroom use of symbolic computation derived from the difficulty they felt when using standard CAS. The decision to append a DG window was taken after a long term experiment of Casyopée in their tenth grade classes. Modelling geometrical dependencies was a central problem in the series of lessons on which the experiment was based. Students had to explore a dependency between magnitudes using a DG package. Then the modelling process implied to choose a variable and calculate an algebraic formula representing the dependency before students could study algebraically this dependency with Casyopée. Because of the lack of links between the DG package and Casyopée, this crucial step had to be done in paper pencil. It was quite difficult for students and it had to be managed with a too strong mediation of the teacher.

Mid adopters: in the same region of Brittany where the experts teach, a group of six teachers had been constituted in the IREM (Institute for Research in Mathematics Teaching) to experiment the use of the Interactive White Board (IWB). During two years they used software packages (DG and CAS) on the IWB and they were keen to enter a new project. For me they were good candidates to be “mid adopters”: they

were convinced that technology can support mathematical teaching and learning, they were relatively experienced in the classroom use of technology but were not involved in Casyopée history. I refer to these teachers as “group members”.

The third layer: the region of Brittany was developing its professional platform for teachers, students and families. The group could use this platform for its internal communication, but also for communicating with all mathematics teachers in the Brittany region. It was judged better to address a specific group of teachers via their professional platform rather than to disseminate through an open website. The third layer was then mathematics teachers at upper secondary level in the Brittany region, a group of around 500 teachers.

Data: the group met 12 times along two years in 3 hour sessions gathering researchers, the two experts and the six group members. Six experimentations of scenarios were done in common, one group member offering his class and the rest of the group acting as observers. Communication between the sessions was done via the professional digital platform using a virtual group feature. The data consists in the video recording of the sessions and experimentations, the messages and files exchanged on the platform and the scenarios proposed and experimented by the group as published on the professional digital platform.

PRELIMINARY FINDINGS

The data exploitation is still in progress. In this paper I report on features that I found relevant or surprising in the meetings and in the productions relatively to the above hypothesis and illustrate by outlining the evolution of two group members, Chris and Rose. The next step in the research will be the systematic exploitation of the data in order to strengthen the findings. The main features in the first year were:

1. The group members engaged in scenario design slower than expected. The reason is that it took time for them to understand the potential of Casyopée. An expectation was that modelling geometrical dependencies for optimisation problems would be an attractive perspective and that they would work from situations they experimented before using standard dynamic geometry software, adapting these situations to take advantage of Casyopées’ symbolic features. Actually, the teachers were keen to exploit Casyopée’s potential to go beyond numerical exploration, but they could not achieve this goal. For instance, in the second meeting Rose protested that she could not implement Casyopée for an optimisation problem she used to propose her students (figure 1). She considered two free points in the plane A and B and a free point M on the segment $[AB]$. The exploration was done numerically like in other DG systems. After that, Rose wanted to take advantage of Casyopée for exporting the dependency into the algebraic window in order to solve the problem algebraically. She chose AM as the independent variable and the calculation $:\frac{AP^2+MQ^2}{2}$ as dependent variable. But Casyopée replied that the calculation depended of more than

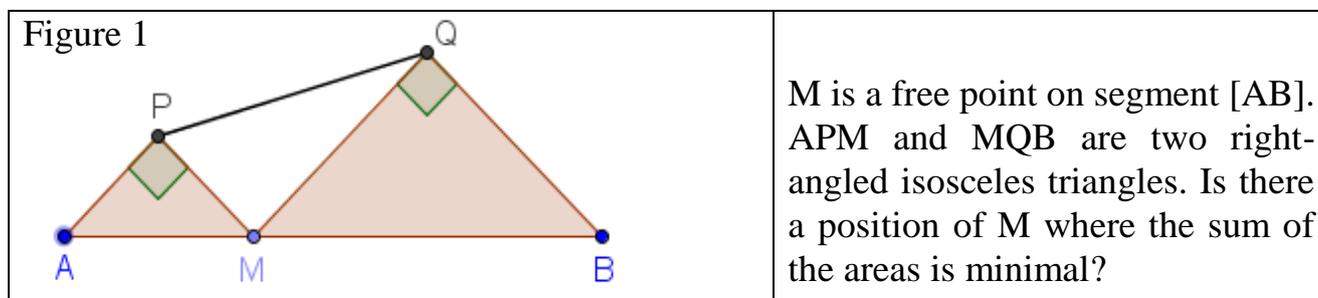

a free point and the exportation was unsuccessful. Rose expected a function like $x \rightarrow \frac{x^2}{4} + \frac{(AB-x)^2}{4}$ but in Casyopée, functions cannot depend on geometrical objects.

The approach is to define the two points A and B as coordinated points, possibly depending on a parameter representing the distance AB . For instance A might be at the origin and B might be $(0; a)$. With these settings, Casyopée exports the dependency as $x \rightarrow \frac{x^2}{4} + \frac{(a-x)^2}{4}$. In contrast to Rose, the expert teachers understood the constraint of a distinction between “variable objects” involved in a dependency and “generic objects” and conceived adapted scenarios.

2. Group members also thought that a symbolic system like Casyopée would be particularly useful for problems with complicated algebraic calculations. That is why they proposed scenarios with situations resulting in very complex expressions that the symbolic kernel and other modules of Casyopée had difficulties to handle. It took time for these teachers to realise how the limitations of the symbolic kernel stressed above influence Casyopée’s operation. For instance in the third meeting, Chris expressed her concern that, for two functions with equivalent expressions, Casyopée was not directly able to recognize their equality, and that only one of the symbolic calculations provided by Casyopée returned zero for the difference. This is different of expert teachers, who saw the potential of Casyopée in the security and easiness that symbolic calculation provides in ‘ordinary’ calculation.

3. Many scenarios proposed by the group members in the first meetings could not be directly implemented because of limitations of Casyopée. Some of these limitations were inherent to fundamental epistemological choices like those raised above, and some other to the current state of the software. Casyopée is an evolving project and although many efforts had been devoted to software development in ReMath, it could not be considered as an achieved stable environment. This character had not been an obstacle when working with expert teachers who understood well the difference between fundamental choices and minor defects and adapted the scenarios accordingly. Also expert teachers were used to ask for corrections of minor defects before using in the classroom. In contrast, the group members claimed that they could not update the software in the school computer rooms under short notice. The experts tried to propose alternative feasible scenarios and procedures for updating without success. A consequence is that a good part of the discussions in the meetings was devoted to the software itself. These discussions and the pressure that group members put through the scenarios they wanted to implement implied more work on the software than expected. A part of this work was devoted to adapt Casyopée for the intended scenarios and was achieved during the year. Roughly, the scenarios developed and experimented in the first year were of two types: (a) scenarios at tenth grade about linear functions and product of these, taking advantage of the symbolic window only, and of specific features like the display of a table with signs of

functions, in close connection with rules and ways of proving that the teachers want students to discover and remember (b) scenarios at twelve grade involving advanced functions (logarithms) and curves of these. In these scenarios, the teachers seek to take advantage of representing and symbolic computing facilities of Casyopée. Considering curves as geometrical objects and treating symbolically its elements was seen as an attractive capability.

These scenarios are more sophisticated than what was expected. Note also that during the first year, in spite of the expectations, there was no outside communication towards the third layer of teachers. The group members were reluctant to publish material not really achieved. They insisted on publishing reports on successful sessions with a deep didactical analysis, rather than “raw scenarios”.

In the second year a significant part of the meetings was again devoted to comments and discussion by group members about the software in parallel with the preparation and exploitation of classroom experiments. After adaptation by the designers, the features in development were tested in the experts’ classes, group members feeling they could not deal with provisional versions. Like in the first year, more efforts than expected had to be devoted to software development. After the experimentation of scenarios these efforts could be directed towards curricular conformity and students’ understanding of commands as well as towards the general ergonomics. The appropriation of Casyopée by the group members progressed notably especially with regard to the relationship between the algebraic and the geometric windows. This appropriation was done through the preparation and experimentation of scenarios but also seems inseparable from the discussion on the software itself. Why is it designed like that? Could other options be decided? In the discussion, reference was often made to other CAS or DG.

The communication through the professional platform was organised around eight mathematical themes. Two of these themes are related to the experiments in the first year, two derive from the scenario experimented in ReMath, one was imagined by the experts and myself as a way to introduce 10th grade students to modelling. It was consistent with an evolution of the curriculum at this grade, but considered too difficult to handle by group members. Three others illustrate an evolution of the group members and two will be detailed in the next section. Communication itself was done through eight high quality “mini web sites” [1]. Group members insisted on publishing detailed scenarios with precise objectives and account of the

advantages brought by Casyopée. The group members' concern for a strong didactical added value clearly appears in these productions. It implied deep reflection after the experiments and could be achieved only by the end of the year.

TWO EXAMPLES

Optimizing pipes (11th grade, non scientific students)

This problem was originally proposed for 12th grade, non scientific students. The context is drain pipes on a rectangular wall, and the optimal point is the Torricelli point in an isosceles triangle. As said above, Chris, the teacher who initiated this theme and experimented the associated scenario expressed often her concern for “how Casyopée does symbolic computation”. Her work in the mini site, as well as her declarations in the meetings, helps to understand that this concern was linked with her ambition to offer non scientific students realistic optimisation problems and her view that Casyopée should be used to scaffold these students' weakness in algebraic computation. In 12th grade, studying the Torricelli point generally involves a variable angle. But this has not been implemented in Casyopée and 11th grade non scientific students do not know about oriented angles and trigonometry. Chris realised that on the one hand, Casyopée allows an easy modelling using a variable length with two possible choices, an interesting feature for her students. The resulting algebraic forms can be handled by Casyopée, especially Casyopée calculates different expressions of the derivatives, a task that these students could not tackle alone. On the other hand, she was worried that Casyopée could not calculate the zero of the derivatives because it is the difference of two square roots. Then she adapted her scenario in order that the students realize that the equality of two square roots implies the equality of the expressions and then a polynomial equation that Casyopée could solve. This work on modelling and on symbolic expressions is very unusual in non scientific classes because these students are generally scared of algebra. Through this experience Chris realized the actual potential of symbolic computation in Casyopée: it does not everything by miracle, but it can help when one understands its limits and considers relevant “techniques of uses” (Lagrange, 2000).

Towards the quadrature of the parabola (12th grade)

Rose saw the potential of Casyopée for “advanced topics”. Her previous experience was using separately DG to make students express conjectures and CAS to help for an algebraic proof. Considering geometric properties of curves was for her an appealing field for using Casyopée because it involves geometry *and* calculus. She chose a task based on a result by Archimedes: the area enclosed by a parabola and a cord AB is $\frac{4}{3}$ times the area the triangle ABC , C being the point where the tangent is parallel to the cord. She considered the exploration of the figure and the discovery of the linear relationship between the two areas as very important and then she complained that Casyopée did not offer the means for exploration that she was used to. She met also the same issue as in the problem of figure 1 a year before: the figure

depends on the two points A and B that she wanted to define as two free points on the parabola, but, as explained above, a function cannot be exported from a calculation depending on two free points! The experts and I explained that the two points could be defined as coordinated points depending on parameters, but Rose wanted that students explore by way of free points and not parameters. We also suggested a simpler definition for C , because the calculations were heavy with the definition above. There was a long discussion and finally Rose accepted the suggestion. She maintained a free point for B and chose to define A as a fixed point. With these changes, the scenario was feasible.

This is how Rose describes the use of Casyopée in the mini site. *“The steps of the proof derive from those highlighted by the exploration. Throughout the exploration, students have to identify these steps and propose calculations. To achieve the algebraic proof they have to establish different expressions. The software provides several aids: it exports geometric calculations into formulas for the areas. The student can either prove them or admit them temporarily and continue, it helps for different forms of expressions (development, factoring) or controls the expressions obtained by the student.”* This helps to understand Rose’s position towards Casyopée. She really wanted to take advantage of aids provided by the software for proving, but she also wished that students base their proof on a thoughtful exploration and she found hard to implement this exploration with Casyopée. While the experts and I tended to consider that adapting to Casyopée constraints could be done without much loss, Rose saw this as a dilemma. Many changes in the recent development of Casyopée result from discussions we had on this point.

CONCLUSION

This experience of a small scale community around Casyopée was surprising by many aspects. It was expected that the collaboration would be around scenarios as it was the case in the ReMath Franco-Italian experiment, rather than on the software itself. Actually, the “mid adopters” had to reflect deeply on their expectations with regard to the software and often to reconsider what they saw as Casyopée potential. As stressed above, it implied also reconsideration for the experts and I, and more work on the software than expected. Kynigos (2007) conceptualised the work between researchers and teachers on software, using the term of “half baked” microworld. Casyopée was not conceived as a “half baked” microworld, but certainly one has to think of innovative software as a never finished product, evolving through communities. The communication with the third layer consisted in the publication of the mini-web sites. It seems that “mid adopters” privilege a communication with their colleagues based on high didactical quality production. This is also different of what was expected. As said in the introduction, I am interested in the gap between expectations and the reality of classroom use of technology. I have the feeling that this experience can help to identify reasons for this gap, because it shows what obstacles “mid-adopters” positively oriented towards innovative software can meet.

Working Group 15

More work has to be done in order to capture its specificity. At a practical level, the exploitation of the data has to be completed and at the theoretical level an “activity theory” framework has to be built in order to conceptualize a “multi-layer” community around innovative software.

EXTENDING THE TECHNOLOGY ACCEPTANCE MODEL TO ASSESS SECONDARY SCHOOL TEACHERS' INTENTION TO USE CABRI IN GEOMETRY TEACHING

Marios Pittalis & Constantinos Christou

University of Cyprus

The purpose of this study was to modify and extend Technology Acceptance Model to assess secondary school teachers' intention to use Cabri in geometry teaching. We developed a measurement-structural model and enriched TAM by integrating in the model a new significant parameter, "perceived pedagogical-learning fit", which refers to evaluating the pedagogical-learning appropriateness of teaching geometry with Cabri based on a cognitive-learning model. One hundred and five pre and in-service secondary school mathematics teachers answered a questionnaire that was developed based on related research studies. The results of the study proved that perceived pedagogical-learning fit and attitude towards the use of Cabri are key determinants of teachers' behavioural intention to use Cabri in geometry teaching.

Keywords: technology acceptance model, Cabri, task technology fit, teachers' view

INTRODUCTION

The technology acceptance model (TAM) is well known and widely accepted in the study of specific behaviours to understand how users' beliefs and attitudes affect their technology usage behaviour (Teo, Lee, Chai & Wong, 2009; Venkatesh & Davis, 2000). TAM has been used widely in different domains and cultures to test models in technology acceptance (Dishaw & String, 1999; Lee, Yoon & Lee, 2009) and has received extensive empirical support. TAM applications are mostly related in the outcome chain on intention to use or actual use by taking into consideration as fundamental determinants of user acceptance the variables perceived usefulness and perceived ease of use (Davis, 1989). Having in mind the business and commercial origins of TAM, not surprisingly, it has had limited applications in education. Recent research studies of TAM in education have explored students' or teachers' acceptance towards new technologies such as online learning, and technology in education (Lee, Yoon, & Lee, 2009; Stols, 2007).

Dishaw and Strong (1999) support that a weakness of TAM is its lack of task focus and extended the model to integrate task-technology fit (TTF), which refers to matching the capabilities of the technology to the demands of the task. In the present study, we integrate TAM and TTF theoretical considerations to extend and propose a structural and measurement technology acceptance model that assesses the intention of pre and in-service secondary school teachers to use Cabri, a dynamic geometry software, in geometry teaching. To evaluate the intention of use of Cabri based on a theoretical geometry learning model, we modified TAM by adding in the model

teachers' perceived learning fit of Cabri on a task-technology fit theoretical assumption.

THEORETICAL CONSIDERATIONS

Technology Acceptance Model

TAM is based on the Theory of Reasoned Action (Ajzen & Fishbein, 1980) and explains how users' beliefs and attitudes affect their intention to use a specific technological device. TAM explains the interactions among attitudes, beliefs and intention to use technology. The two belief variables refer to perceived usefulness and perceived ease of use (Teo *et al.*, 2009). Perceived usefulness refers to the subjective belief that the use of the new technology will improve job performance and productivity. Perceived ease of use refers to the subjective belief that the use of the new technology does not demand considerable time and effort. Recent studies have shown that the above variables affect users' intention to use and their attitude towards technology use (Cheung & Huang, 2002; Raaij & Schepers, 2008). Attitude has been doubtfully hypothesized to influence the behavioural intention to use the technology and was therefore not considered in later assessments (Venkatesh & Davis, 2000).

Although TAM'S perceived usefulness concept implicitly includes task, the model has been criticized for the lack of task focus and its application revealed mixed results in information technology evaluations (Dishaw & Strong, 1999). In contrast to TAM, the theoretical foundation of the task-technology fit model (TTF) lies in the assumption that technology will be used if, and only if, the functions available to the user fit the activities and needs of the user. Thus, TTF explicitly includes task characteristics and tests for direct effects of task and technology characteristics on utilisation.

Mathematics Teachers' views about using DGS

Dynamic geometry software (DGS) has been considered as an effective tool in the teaching and learning of geometry and proved to have the potential to regenerate geometry in schools (Hollebrands, Laborde, & Straesser, 2008). DGS have become beneficial tools in geometry teaching, because they support students' visualization of the features of geometric shapes and facilitate the interaction of geometrical objects. However, research studies have shown that DGS classroom use has remained limited (Ofsted, 2004). Researchers noted that a significant parameter of the problem is the absence of teachers' contribution (Lagrange, 2008). Jones (2002) asserted that, in the DGS field, there is a need for research on teachers' input and impact. Therefore, the success of a DGS geometry teaching program depends on the extent to which educational decision makers take into consideration teachers' needs and beliefs and educational objectives. Thus, the development of an appropriate DGS teaching program is a complicated task and requires a multidisciplinary approach. Teachers'

evaluation of the DGS and their beliefs and attitude towards the DGS should be a fundamental pillar of the initiative.

Cabri is one of the dominant software in the domain of dynamic geometry for dynamically creating, exploring, elaborating, analysing and synthesizing geometrical concepts (Laborde, 2001; Laborde & Laborde, 2008). It could facilitate the process of discovering geometrical concepts by first visualizing, analyzing and then making conjectures. Several research studies have shown that geometry teaching and learning in Cabri could promote and enhance students' visualization, reasoning and construction processes (Olivero, & Robutti, 2007).

Despite the potential of Cabri as a tool to enhance students' geometric thinking and improve their geometry performance, its value will not be realized if teachers do not accept it as an effective learning tool. TAM has been utilized and extended for research purposes in education to assess pre or in service teachers' acceptance of other information technology innovations, such as e-learning (Lee *et al.*, 2009) and virtual-learning (Raaij & Schepers, 2008). Results showed that perceived usefulness and perceived ease of use proved to be critical parameters of the acceptance and usage of the innovation as an effective and efficient learning technology.

THE PRESENT STUDY

There is a research need to establish an empirical link between TAM and specific mathematics geometry software. Thus, the main purpose of the study is to extend TAM and propose a structural and measurement technology acceptance model that could be used to evaluate the intention of teachers to use Cabri in geometry teaching. The present study adds to the research literature on TAM and DGS in a number of ways. First, it integrates TAM and TTF theoretical considerations by proposing a model that evaluates the task-technology fit of Cabri based on teachers' perceived pedagogical-learning fit of the software. By the term "perceived pedagogical-learning fit" we refer to teachers' perception about the quality of teaching and learning of geometry with Cabri and whether the specific software could meet the learning needs of students in geometry. To do so, the study proposes a model that evaluates Cabri's perceived pedagogical-learning fit based on Duval's cognitive geometry reasoning model (Duval, 1998). Second, the study may provide a worthwhile starting point in mathematics educational technology field in developing appropriate evaluation models that could be used to evaluate the pedagogical value of DGS.

Aims of the study and the proposed model

The purpose of the present study is to propose a model that extends TAM to assess teachers' intention to use Cabri in geometry teaching based on teachers' perceived pedagogical fit of the software. Specifically, the aims of the study were to (a) to validate the measurement model that describes teachers' perceived pedagogical fit of

Cabri based on Duval's geometry reasoning model and (b) to extend and modify TAM so it could potentially be used to assess, on a task-technology fit basis, the intention to use Cabri by integrating in the model, as a task-technology fit parameter, the effect of teachers' perceived pedagogical fit.

In this paper, as it is highlighted in Figure 1, we hypothesized that an additional parameter, "perceived pedagogical-learning fit", influences teachers' intention to use Cabri in geometry teaching. Specifically, based on the literature we assumed that a theoretical construct "perceived pedagogical-learning fit" describes teachers' perceived pedagogical and learning appropriateness of geometry teaching with Cabri to develop students' visualisation, reasoning and construction processes. Based on Duval's model (1998), geometrical reasoning involves three kinds of cognitive processes which fulfil specific cognitive processes; (a) visualization processes that refer to the visual representation of a geometrical concept, (b) construction processes that can be developed in Cabri by appropriate tools and (c) reasoning processes that are necessary for the extension of knowledge, for explanation and proof. Thus, the latent construct "perceived pedagogical-learning fit" consists of three first-order latent factors that refer to teachers' perceived visualization, construction and reasoning processes fit of teaching with Cabri. In addition, based on TAM theory (Dishaw & Strong, 1999), we hypothesized that teachers' intention to use Cabri in geometry teaching is influenced by teachers' (a) perceived usefulness of Cabri and (b) their attitude towards the use of Cabri. Perceived usefulness was also hypothesized to be influenced by perceived ease of use and attitude towards the use of Cabri was assumed to be predicted by the factors perceived ease of use and perceived usefulness.

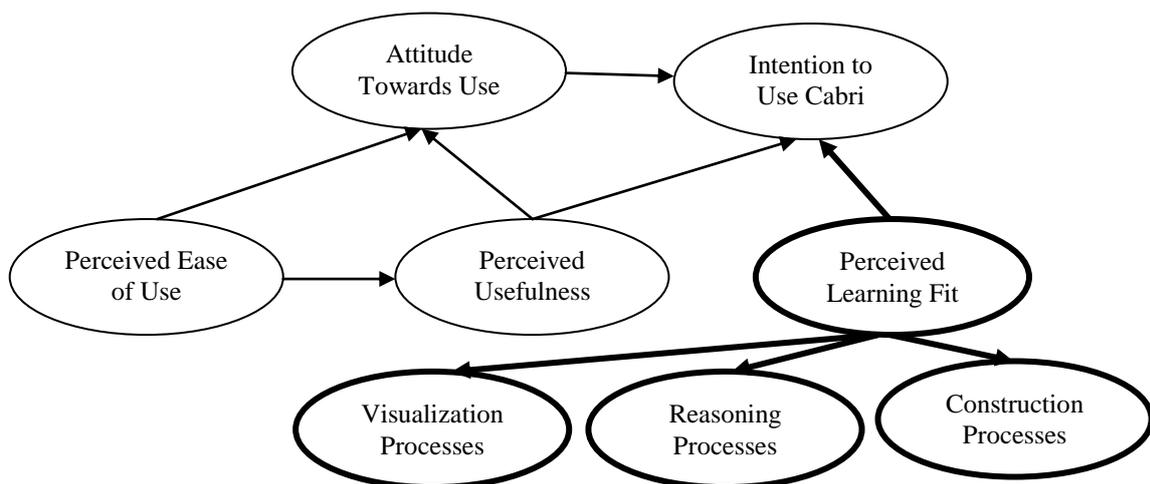

Figure 1: The hypothesized model

Subjects

The sample of this study consisted of 105 pre and in-service secondary school mathematics teachers; 45 pre-service and 60 in-service teachers. Forty two teachers were males and 63 females. All the subjects attended a compulsory 9-hours module regarding Cabri and its pedagogical applications during their teacher training program in the University of Cyprus during spring 2010. The questionnaire was administered after the completion of the Cabri module. None of the subjects had previous experience with Cabri.

Instrument construction

A questionnaire instrument was developed for this study. TAM scale items were adopted from previous studies (Dishaw & Strong, 1999; Lee *et al.*, 2009; Teo *et al.*, 2009) and were modified to meet the needs of the present study. Our research TAM model consists of 12 items (see Table 1) that measured “perceived ease of use” (3 items), “perceived usefulness” (3 items), “attitude towards use of Cabri” (3 items) and “use intention” (3 items). In addition, based on the existing literature on geometry reasoning discussed in the previous sections, we developed 10 items that measured teachers’ perceived pedagogical-learning fit. For example (see Table 2), the item “Teaching geometry with Cabri helps in visualizing geometrical concepts” was used to measure “visualization processes” fit, the item “Cabri’s measurement and dragging tools help students making generalisations” was used to examine the “reasoning processes” fit and the item “Cabri’s tools make easy the construction of complex geometrical constructions, such as locus” was developed to examine the “construction processes” fit. We developed multi-item Likert scales which have been widely used in the questionnaire-based perception studies, using the seven-point Likert scale, with 7 being “Totally Agree” and 1 being “Totally Disagree”.

Factor	Items
Perceived usefulness	Q1. Using Cabri in geometry teaching will enable me to accomplish my tasks more quickly.
	Q2. Using Cabri in geometry teaching will enable me to enhance my effectiveness in teaching.
	Q3. Using Cabri in geometry teaching will enable me to increase my productivity in teaching.
Perceived ease of use	Q4. My interaction with Cabri tools will be clear and understandable.
	Q5. I will find the Cabri tools to be flexible to interact with.
	Q6. I will find the Cabri tools easy to use.
Attitude towards	Q7. I think it would be very good to use Cabri in geometry teaching rather than traditional methods.

Use	Q8. In my opinion it would be very desirable to use Cabri in geometry teaching rather than traditional methods. Q9. Teaching geometry with Cabri makes the lesson more interesting.
Use intention	Q10. I will use Cabri in geometry teaching rather than traditional methods of teaching geometry. Q11. My intention is to use Cabri in geometry teaching rather than traditional teaching methods. Q12. In geometry teaching, I would rather use Cabri than traditional methods.

Table 1: TAM items

Data Analysis

The goal of the analysis was to estimate the relative strength of the proposed models. Because we proposed a theoretically driven model about the components of “perceived pedagogical-learning fit”, our first interest was in the assessment of fit of the hypothesized a priori measurement model to the data. Then, we examined the validity of the hypothesized structural model. One of the most widely used structural equation modelling computer programs, MPLUS, was used to test for model fitting (Muthen & Muthen, 2007) and three fit indices were computed: The chi-square to its degrees of freedom ratio (χ^2/df), the comparative fit index (CFI), and the root mean-square error of approximation (RMSEA). The observed values for χ^2/df should be less than 2, the values for CFI should be higher than .9, and the RMSEA values should be lower than .08 to support model fit (Marcoulides & Schumacker, 1996).

Factor	Items
Visualization processes	Q13. Teaching geometry with Cabri helps in visualizing geometrical concepts. Q14. Cabri facilitates the dynamic visualization and understanding of geometric theorems. Q15. Cabri’s functions (i.e. dragging) help students to “see” the properties and characteristics of geometric shapes. Q16. Cabri offers dynamic images that promote dynamic visualisation of geometrical concepts.
Reasoning processes	Q17. Teaching geometry with Cabri helps in developing students’ reasoning and conjecturing thinking. Q18. Manipulating shapes in Cabri contributes in understanding geometric shapes’ relations. Q19. Cabri’s measurement and dragging tools help students making generalisations.
Construction processes	Q20. Cabri’s tools make possible the construction of geometric shapes based on their properties.

Q21. Cabri's tools make easy the construction of complex geometrical constructions, such as locus.

Q22. Constructing geometric shapes in Cabri is not a mechanical process, but it develops students' construction abilities.

Table 2: Perceived Pedagogical-Learning Fit items

RESULTS

In this section, we refer to the results of the analysis, establishing the validity of the latent factors and the viability of the structure of the hypothesized latent factors. In this study, we posited an a-priori measurement model and tested the ability of a solution based on this structure to fit the data and then conducted a structural analysis to examine the relation between the factors of the modified TAM.

To examine the first aim of the study, we conducted a confirmatory factor analysis (CFA) to validate a measurement which should have been able to model teachers' perceived pedagogical-learning fit of Cabri. The descriptive-fit measures indicated support for the hypothesized measurement model ($CFI=.94$, $\chi^2/df=1.32$, $p>0.05$, $RMSEA=.06$). The parameter estimates were reasonable in that all factor loadings were statistically significant and most of them were rather large. The analysis showed that each of the 10 perceived learning fit items employed in the present study loaded adequately only on one of the three geometry processes fit factors, giving support to the assumption that the three first-order factors could represent three distinct dimensions of teachers' perceived learning fit. Moreover, the factor loadings of the first-order factors (visualization, reasoning, and construction processes learning fit) that corresponded to teachers' perceived pedagogical-learning fit were extremely high (.90, .99 and .99 respectively), claiming that a general type of belief that refers to teachers' perceived pedagogical-learning fit could explain very accurately teachers' variances in evaluating Cabri.

To examine the second aim of the study, we tested the validity of the hypothesized structural model, which claimed that the intention to use Cabri is influenced by the factors "perceived usefulness", "attitude towards use of Cabri" and "perceived learning fit". The descriptive-fit measures did not support the hypothesized structural model ($CFI=.86$, $\chi^2/df=1.56$, $p<0.05$, $RMSEA=.09$). Thus, we examined the validity of alternative structural models to trace the relations between the factors of the model. Figure 2 presents the modified model that best fitted the empirical data ($CFI=.92$, $\chi^2/df=1.34$, $p<0.05$, $RMSEA=.07$). As it is highlighted in Figure 2, the results of the study revealed that the factor "perceived pedagogical-learning fit" is a strong predictive factor of teachers' intention to use Cabri ($r=.69$, $z=4.02$, $p<0.05$). In addition, teachers' perceived pedagogical-learning fit predicts (a) teachers' attitude towards the use of Cabri ($r=.66$, $z=3.44$, $p<0.05$), (b) teachers' perceived ease of use ($r=.56$, $z=3.09$, $p<0.05$) and (c) teachers' perceived usefulness ($r=.96$, $z=4.02$,

$p < 0.05$). It could be concluded that teachers' perceived usefulness is strongly affected by their perceived pedagogical-learning fit. The structure of the modified model showed that attitude towards the use of Cabri is also predicted by teachers' perceived ease of use ($r = .47$, $z = 3.71$, $p < 0.05$) and attitude towards the use affects directly teachers' intention to use Cabri ($r = .36$, $z = 1.97$, $p < 0.05$). Further, the solution of the modified model did not validate the direct effect of the factor "perceived usefulness" on other variables. On the contrary, it was deduced that teachers' perceived usefulness does not influence neither their attitude towards the use of Cabri, nor their intention to use it.

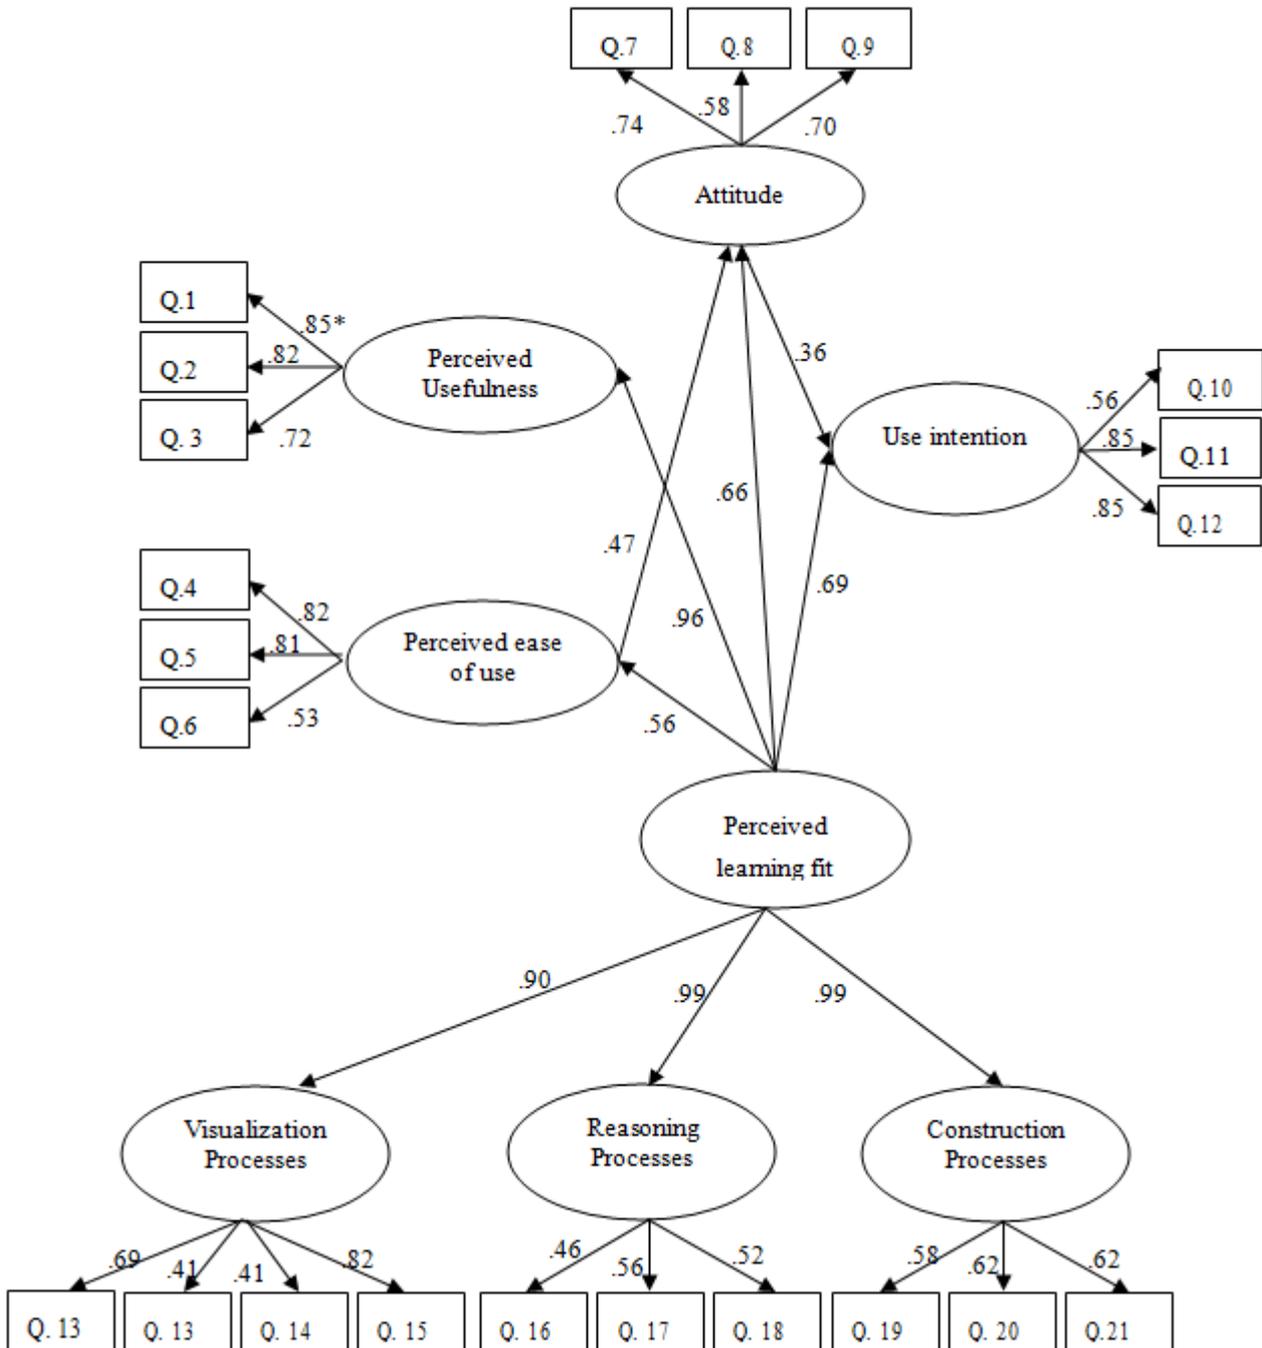

Figure 2: Modified Technology Acceptance Model

DISCUSSION

This study attempts to modify and extend TAM by integrating in the model a new significant parameter, “perceived pedagogical-learning fit”, which refers to assessing the pedagogical-learning appropriateness of teaching geometry with Cabri based on a cognitive-learning model. In examining the relations among the constructs in the modified TAM, this study found that perceived pedagogical-learning fit and attitude towards the use of Cabri were key determinants of teachers’ behavioural intention to use Cabri in geometry teaching. Attitude towards the software proved also to be significant predictor in other research studies that examined users’ intention to use computers in education (Teo *et al.*, 2009; Venkatech, Morris, Davis & Davis, 2003).

It is important to note that adopting non-educational derived behavioural intention models to assess teachers’ intention to use software in teaching might give misleading information. Our results yielded that an important parameter that should be examined is teachers’ perceived evaluation of the pedagogical learning fit of the software. The results of this study suggest that teachers’ perceived ease of use, their attitude towards the use and especially their perceived usefulness are significantly influenced by their pedagogical-learning evaluation of the software. For teachers what matters to use the software is the additive, learning value of the software. Thus, although for the past two decades, numerous studies using the TAM as a research framework have been conducted, there is a need for future research in mathematics education domain that modifies TAM according to the learning needs that the innovative technology should meet, based on well established learning and cognitive models.

CHALLENGES TEACHERS FACE WITH INTEGRATING ICT WITH AN INQUIRY APPROACH IN MATHEMATICS

Anne Berit Fuglestad

University of Agder

During more than two decades Norwegian educational authorities have promoted the use of computers, calculators, and more recently, digital tools in teaching in general in various school subjects. This paper reviews efforts to use digital tools in teachers' and pupils' work and problem solving in mathematics within the frame of two research and development projects in six lower secondary schools in Norway. The analysis sets out to characterise and contribute to a deeper understanding of the challenges teachers face with inquiry approach to mathematics.

Keywords: digital tools, TPACK, teachers' role, teachers' competence, development

BACKGROUND AND RESEARCH QUESTION

A brief history of ICT in Norwegian schools

Since 1984 educational authorities in Norway have promoted the use of Information and Communication Technology (ICT) such as computers and calculators in schools. Some teachers and schools introduced computers on a trial basis in the 70's, but the major effort from educational authorities came with the Stortingsmelding 39, 1983-84 (KUF, 1984) which included a four-year plan of action to implement computer technology in some selected trial schools, starting in 1984. The aim of introducing computers was to learn about computer technology in society and to use computers as a teaching aid, particular attention was directed to vocational education and pupils with special needs. A goal was to avoid introduction of new reasons to create differences between pupils. Emphasis was placed on introducing computers with software that represent new opportunities to support learning which other material or teaching aids cannot provide. A number of schools became experiment schools and were provided with equipment. Furthermore an office for coordinating and leading the effort was established on national basis. This happened at a time (1984) when micro computers were fairly new and with limited graphics, memory and processing capacity. To educate teachers for use of ICT a course of 40 hours was offered and half year courses (30 ECTS) were developed for teacher education. The content was dominated by programming, use of databases, and limited education about teaching with ICT. The implementation of ICT as a teaching aid was not clear and purposeful. "Let a thousand flowers bloom..." and find out what works seemed to be the idea.

The first plan of action was later followed by new strategic plans for ICT in schools, and computer technology was built into national curriculum guidelines (UFD, 2004; Krumsvik, 2007). Despite the official policy and initiatives the introduction of ICT in education has been slow in particular related to specific subjects (ITU, 2009).

In the most recent curriculum guidelines, the “Knowledge promotion” from 2006, facility with digital tools [1] was made compulsory as one of five basic competencies and to be utilised in all school subjects. Furthermore, it is implied that use of digital tools will be accessible in examinations with the requirement that some test items have to be solved with computers.

Access to and use of digital tools

Recent surveys show that computers are now widely accessible in Norwegian schools and many pupils have their own portable computer, either private or provided by the local school authorities. On average there are 4.7 pupils per computer in primary and lower secondary schools, and 1.8 pupils per computer upper secondary schools. Internet is accessible from 90% and 98% of the computers respectively. Until recently use of digital tools, except calculators, has been limited in school subjects, and notably less in mathematics than in Norwegian, English and Social studies. This is documented in biannual reviews of technology use in schools (ITU, 2010; Arnseth, Hatlevik, Kløvstad, Kristiansen & Ottestad, 2007). Furthermore, teachers seem to be happy with learning digital competence through trying out themselves and getting guidance from colleagues.

In mathematics a spreadsheet like Excel is the most commonly used software. Dynamic geometry like Cabri, and more recently Geogebra has become popular. Internet is used like in several subjects to search for information and numerical data, e.g from Statistics Norway, (<http://www.ssb.no>). Drill and practice software is used to develop skills with numbers, perhaps most common with younger children. Recently computers have been introduced in the final examinations in mathematics in lower secondary schools, so far this is mainly the use of spreadsheets, and this raises the demands to use digital tools in teaching.

So, the problems related to lack of equipment are mainly solved in Norwegian schools, and suitable software is available. The limited use of digital tools for mathematics teaching and learning indicates there is a challenge related to understanding and appropriate use of digital tools for teaching and learning mathematics. Related to this some questions arise: What is the role of ICT in learning mathematics? What is the nature of digital tools and how can they be utilised? This leads to the following research question related to teaching mathematics:

Research question

What challenges do teachers meet in teaching mathematics supported by digital tools and to provide learning experiences with an inquiry approach for their pupils to develop mathematical understanding and skills? Digital tools here are computers with open software.

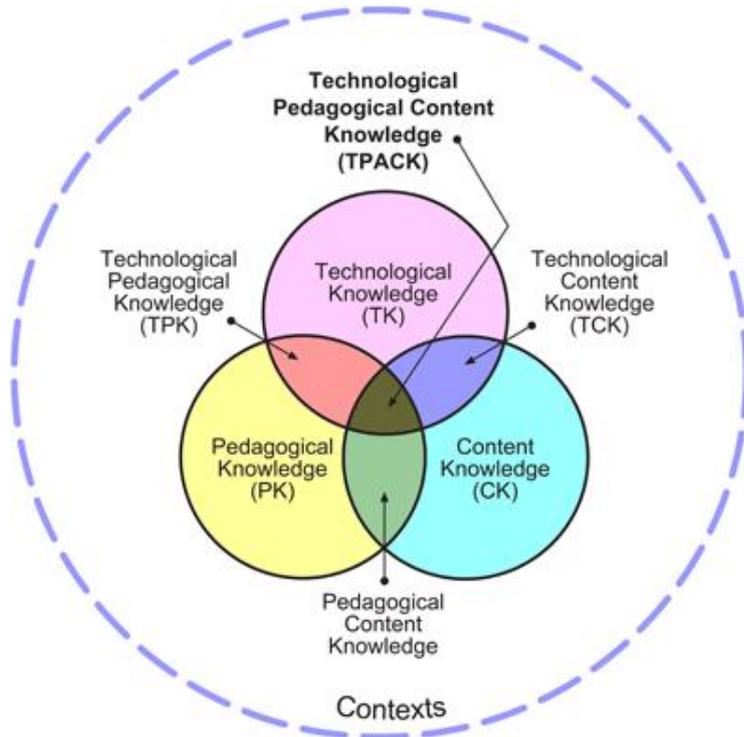

The question can be divided into several sub questions related to understanding of the role of digital tools in work and learning of mathematics, challenges related to the digital tools per se or related to organising computer use integrated in the mathematics classroom. In the following I will focus on the subject oriented use of computers with an inquiry approach to mathematics. The research question will be investigated by reanalysing/ review cases from two projects on ICT in mathematics with regard to teachers' understanding of technology, mathematical representations and teaching approach.

THEORETICAL BACKGROUND

Teaching in general and with digital tools particularly is a complex activity for the teachers; it involves deep insight in the subject, knowledge of the digital tools, and understanding of pupils' thinking. Furthermore, it involves pedagogical approaches and relating these to the curriculum plans and policy involved and so on, all in a dynamic changing environment. Shulman (1986) introduced the term *pedagogical content knowledge*, PCK, to denote the intersection of pedagogical and content knowledge in order to consider the complex interaction between pedagogy and subject content. The mathematical content and pedagogy, including the teaching approach or considerations related to teaching a specific content or subject, cannot and should not be separated. For mathematics it involves for example how to approach particular mathematical ideas and processes and make the subject accessible for pupils, to understand common errors and various ways pupils think about the subject. Ball, Thames & Phelps (2008) study teaching practice to understand what they call *mathematical knowledge for teaching* and found this knowledge is highly specialised for mathematics. The teacher needs to know more than to find a solution; they need to know various approaches and to be able to follow up pupils thinking. Mishra and Koehler (2006) extended Shulmans' model for teacher knowledge to include technology and introduced the term *technology pedagogical content knowledge*, TPCK, later recast as TPACK (Koehler & Mishra, 2009). Figure 1 (from <http://tpack.org/>) indicates several areas of knowledge. In particular there is a need to understand and develop the knowledge related to technology and content TCK, technology and pedagogy TPK – or how technology affords new approaches to teaching. In the centre is the integration and dynamic interplay of content, i.e. mathematics, with technology and pedagogy (Niess, Ronau, Shafer, Driskell, Harper, Johnston, Browning, Özgun-Koca, & Kersaint, 2009).

Introduction of technology or more specific, digital technology, in teaching implies not just learning to handle the computers with software and other digital tools, but relating the technology to the other knowledge areas, pedagogy and mathematical content knowledge. General knowledge of computer software, i.e, TK, like handling menus and keyboard commands, handling file system and even perform operations specific to the software is not sufficient. In order to develop TCK for mathematics it is necessary to understand how mathematical concepts and relations are, or can be

represented within the software. Furthermore, insight is needed to realise how the software bring in new affordances and constraints related to investigation and solving mathematical problems. An example is spreadsheets where it is possible dynamically to manipulate and experiment with a whole table generated by formulae, and illustrate the distribution of values with a diagram based on the table.

Spreadsheets have common mathematical and statistical functions built in and provide search and sorting facilities. However, as pointed at by Dettori, Garuti, Lemut & Netchitailova (1995), spreadsheets have limitations with lack of symbolic manipulation and are numerical, not algebraic in nature in spite of the use of

Figure 1: TPACK - Technological Pedagogical Content Knowledge

formulae for calculations. Another example of mathematical software is dynamic geometry like Cabri, Geogebra and others. After constructing a figure using built in features in dynamic geometry, part of the figure can be dragged to test if the construction is robust, i.e. not falling apart when dragging one part of the figure. A constructed figure in Cabri is not the same as a drawing which can be represented with various constructed figures in Cabri with different properties (Laborde, 1995). The order of the single constructions for composing a figure make the figure specific and different from the same shape constructed in another way.

The development of deep knowledge TCK can be expressed with terms from the instrumental approach as turning the artefact into an instrument for the user (Trouche, 2005). For a specific artefact this implies to develop utilisation schemes, knowledge on the level of simple usage schemes and more elaborated instrumented

action schemes. Without going in detail I find the terms helpful to indicate the depth and complexity of knowledge involved.

Mishra and Koehler (2006) point to how the TPACK framework can be used both as an analytic tool and as a tool for designing curriculum development. In particular they point to learning by the design based on principles of learning by doing and with less emphasis on overt lecturing and traditional teaching.

RESEARCH AND DEVELOPMENT WITH ICT IN MATHEMATICS

During the last decade ICT in mathematics has been studied in several developmental research projects at the University of Agder (UiA) with close collaboration between teachers and didacticians. During the years 2001 - 2004 the *ICT competence project in mathematics in lower secondary schools* [2] was set out develop pupils' competence with ICT tools so they could judge and choose for themselves which tools to use for a mathematical task, just pencil and paper or computer. Software in use was a spreadsheet, dynamic geometry and a graph plotter, intending to stimulate an investigative approach to teaching and learning.

ICT and mathematics learning (ICTML)[3] ran through 2004 – 2007 in parallel with the project *Learning Communities in mathematics (LCM)*, both with emphasis on developing a learning community with teachers and didacticians, with inquiry into mathematics and mathematics teaching as fundamental basis for the projects (Jaworski, Fuglestad, Bjuland, Breiteig, Goodchild & Grevholm, 2007). The projects employed a socio cultural view of learning. The pedagogical (or didactical) content of the projects emphasised pupils and teachers inquiry, to wonder and ask questions, investigate and explore and develop an inquiry attitude to teaching and learning.

ICT has also been an interest in the most recent project, *Teaching Better Mathematics (TBM)* (2007-2010) which build on the same fundamental principles and extend the work on ICT to upper secondary school. The projects have been concerned with how ICT can provide learning experiences for pupils through an inquiry approach to teaching and learning. Work with teachers in workshops and school team meetings to stimulate the development have been central for the development and research carried out on all areas of the work. The research methodology was developmental research (Gravemeijer, 1994) with strong interaction and integration of development and research. In all the projects mentioned a qualitative research approach was employed utilising field notes, pupils' computer files, video and audio recording of meetings, workshops and interviews. All kinds of events were recorded and additional information in e-mails and pupils work on paper or computer files were collected

SMALL CASES FROM PROJECTS

In this paragraph I will not provide the full background of the projects, but will present some episodes that can illuminate challenges teachers face as they use digital

tools in their classrooms. The teachers all had some background with ICT, mainly on spreadsheets, but had hardly any experience from using ICT for mathematics teaching (Teaching here includes providing learning experiences for pupils).

Case 1: The teacher solved the task

In a working period over a couple of weeks to summarise and evaluate the effects of the ICT competence project, the pupils were given a booklet of 10 tasks from which they could choose which tasks to work on, and whether they would like to use just pencil and paper or computers. Most pupils worked in pairs or small groups.

Some pupils in one class worked on the stamps task: to combine some stamps of two kinds worth 2.50 NOK [4] and 1.80 NOK to get the value 20.40 NOK for sending a small parcel (Fuglestad, 2007). Several pupils worked on simple tables in a spreadsheet to combine some of each kind of stamps adding up to 20.40 NOK. They experimented with swapping the values and how many stamps they needed. However, I observed one group of three pupils preparing a large table in Excel to make all possible combinations of number of stamps, to be sure to get all the different solutions. When I asked them to tell about their work, the pupils described their table and how they could find all the solutions. Then they commented they really did not understand, but when they asked for help the teacher, Ivar, instructed them how to make this table. Later I learned from Ivar that he made this table for himself the evening before as a preparation, and he interpreted the task to find all possible, not just one solution. The task invites to trial and error more than setting up an algorithm, and asks only for a combination of stamps, not all possible. In fact there is just one solution, but several with slight misreading of the numbers given, and so the teacher moved on to find a more general solution. Ivar seemed to think, he had to be able to present a complete solution, and when pupils asked he showed his solution.

Through his thorough preparation the teacher tells that he feels responsible to have a solution ready. When the pupils asked perhaps he too quickly provided a solution, and did not urge the pupils to investigate with sufficient time for their own solution. There is also the pressure from pupils to give help, and difficulty to know how to help except give a solution. The situation indicates the teacher put a lot of effort to solve the task, but perhaps used less time thinking of how to tackle the pedagogical task.

Case 2: Exploring Snow man in Cabri

Trude, a teacher at Fjellet School taking part in ICTML, decided to implement Cabri with her class of grade 8 pupils over some weeks (Fuglestad,

- 1) Snow man with a stick, hanging together
- 2) Make a figure by reflection
 - a) Reflection in a line
 - b) Reflection on a point
- 3) $\triangle ABC$ $AB = 5$ cm
 $BC = 4.5$ cm
 $AC = 2.5$ cm
- 4) Make the circumscribed circle

Figure 2: Task on flipover

2010). She did not use any prewritten material but wrote the task on a flip-chart (translated in Figure 2), planned for pupils inquiry into Cabri. She gave only a short introduction to the tasks and encouraged the pupils to investigate and find out how to solve it. The pupils were asked to experiment and find out about facilities in Cabri, including meaning and effect of some menu items and in this way build usage schemes, the simple one step operations. The pupils worked together in small groups or alone, and had opportunity to discuss their solutions with peers or the teacher. Trude wandered around and supported the pupils with questions or hints and in this way supported their further development of Cabri as an instrument, developing their instrumented actions schemes by combining several operations. In particular she emphasised the feature of dragging objects to test if the figure “hangs” together, in particular relevant for the Snow-man task.

Trude later presented her work in a workshop in the ICTML-project. She did not know Cabri before but was first introduced to it through the project, and worked a lot on her own to prepare before using Cabri with her pupils. She emphasised the need to learn Cabri before she “dared to use Cabri in the class”. Trude became stressed by preparing for the Cabri sessions, but also expressed great enjoyment arising from her work on Cabri with her pupils. Also on other occasions she talked about excitement over how pupils’ became engaged with investigations. Trude’s own development during the work seems related both to the technology and the pedagogy component of TPACK. The technological mathematical knowledge or more precisely TCK is also affected in this as it is necessary to know the way mathematical relations are represented in Cabri.

Case 3: Cabri and classical constructions

At another ICTML school, Austpark, the teacher team talked about introducing Cabri, but had experienced problems to get started due to several practical obstacles. Two factors seemed to encourage their decision to implement Cabri in their classes. A course day for preparation was provided from the ICTML-project at their school and a new teacher, Jacob, started working at the school. Jacob had experience with ICT and dynamic geometry. All teachers at grade eight and two on grade nine started to use Cabri. The teachers choose to use some worksheets that were introduced by Jacob and they regarded this material to be suitable as they found it covers a substantial part of the syllabus and it was close to their own way of working (Erfjord, 2008). The material consisted of seven two-page worksheets and was structured with explanations and step by step instructions of how to carry out constructions in Cabri. The approach characterised as direct instruction with supportive comments was also observed in the teaching of classes at Austpark (Erfjord, 2008). The teachers implemented constructions using Cabri in parallel with use of compass and ruler which is the traditional way in plane geometry in schools. In addition to this convenient approach, they also argued that they expected the classical constructions to be necessary for the coming final examination for pupils. They seem not to

consider other more investigative material that had been presented in a workshop in the project.

In conversations with a didactician the teachers claimed they found it difficult to be more innovative and make their own tasks. It seems difficult to both change style of teaching into an inquiry approach and introduce digital tools at the same time. Erfjord (2008) characterised this as a *double innovation* embedded in the project goal of ICTML. The teachers developed their competence with Cabri for mathematics, the TCK, but preferred to develop their TPK close to their tradition. The reasons are understandable and reflect the pressure for curriculum, coming examination and time constraints, but also their reluctance to engage deeply to change teaching style.

Case 4: Develop material for investigation using Excel

Three teachers at Dalen school set their goal for their participation in the ICTML-project to develop their own library of Excel-tasks to complement the textbook they used (Fuglestad, 2010). The tasks would support pupils to investigate mathematical connections and properties of percentages, fractions and decimal fractions, area and volume of specific object and the like. The Excel-tasks were to support pupil' inquiry and experiments, and follow on with support for pupils own work to prepare new spreadsheets for other tasks. During the work, tasks were tried out in the class with one or two didacticians observing together with colleagues, and later follow up with discussing experiences and further or new development in the school team which met regularly every second week. Development of the tasks challenged the teachers both on technology and on pedagogical approaches. For example with a task to investigate equal-valued fractions and display several of the same value, it was necessary to develop complicated formulae with nested if-sentences. This was solved by discussing ideas and consulting another colleague who had long experience with Excel. Pedagogical challenges like judging how complicated a comparison would look for pupils, came up after observations in discussions. The interaction between didacticians and teachers was seen useful for both parts in the collaboration and also for stimulating the further development.

Several spreadsheet tasks were made in a similar way, with setting up an environment for the pupils to explore, to insert numbers and observe the results, discuss and experiment to find relations. The tasks may seem fairly directive, setting limits for investigations, directed to certain relations planned for inquiry in a limited knowledge area. However, there were also more open tasks, and tasks to develop their own set up or models on a spreadsheet after using the pre-made tasks for investigations.

DISCUSSION AND CONCLUSION

Although the cases presented are all different they show some similarities. Some key words are: preparation, confidence and control. Furthermore: limitations in understanding of the TPCK as integrated knowledge.

The teachers feel the responsibility to have solutions to the tasks they present for the class. Both Trude and Ivar put a lot of work into their preparation, solved the tasks for themselves and worked on learning the software. This is probably reflecting their wish to feel confident and in control over what will happen or feeling the responsibility for having a solution at the end of the lesson. Trude expressed this as she needed to learn Cabri for herself to dare to use it in class. The pedagogical/didactical challenges related to implementing an inquiry approach with use of ICT seemed to put extra pressure on the need to prepare to feel confident.

Some teachers were reluctant to change teaching approach and therefore tried to implement ICT alongside traditional methods, to avoid large changes. Even if the teachers want to use digital tools with the resulting changes, there seems to be some deep seated traditions and external pressure that make changes difficult. At Austpart this was expressed and commented on when they choose the teaching material that was close to their tradition, and wanted to be sure pupils also could handle ruler and compass for construction.

Also the teachers at Dalen invested a lot of time and effort to learn to use the tool, Excel, and to develop their own teaching material on file, prepare the lessons and discuss experiences and development. Reflecting on issues of control and inquiry, they seemed to find a way between the two sides, and planned for inquiry into a limited mathematical topic. On the other hand, the teachers seemed open and confident to use an inquiry approach in their classes.

As noted in the introduction of this article the process of implementing ICT tools in mathematics teaching has been slow and is still limited. Experiences in general, and from the projects point to hindrances and resistances experienced even when teachers wish to use ICT tools. Perhaps this is due to lack of understanding of what is involved in developing the technological pedagogical content knowledge, the TPCK for mathematics. Affordances and constraints are related to the various areas of knowledge as shown in Figure 1, in particular how mathematics is represented, how the pedagogy if inquiry approach can be implemented with ICT and so on. I think a study of the various knowledge areas and combination of partly and full integration of mathematical content, inquiry approach, affordances and constraints of relevant technology would prove useful to guide further developmental research in the area.

NOTES

¹. ICT and digital tools will be used interchangeably

Working Group 15

².The ICT competence project was supported by a grant from the Department of Education to stimulate ICT in schools

³. LCM and ICTML were supported by The Research Council of Norway (RCN), TBM was supported by RCN and The Competence Development Fund of Southern Norway.

TECHNOLOGIES AND TOOLS IN TEACHING MATHEMATICS TO VISUALLY IMPAIRED STUDENTS

Iveta Kohanová

Faculty of Mathematics, Physics and Informatics, Comenius University

Bratislava, Slovakia

In this paper we describe the effort of the Support Centre for Visually Impaired Students in Bratislava to design an effective and helpful digital tool for learning and teaching mathematics to visually impaired students. In the first phase of our research methodology, which follows the design-based approach, we focus on mapping of the actual situation of teaching math to those students at each level of education in Slovakia. The emphasis is placed on tools and technologies these students use, as well as on problems that occur when using these tools. Later on we focus on LAMBDA editor, which seems appropriate for learning and teaching math to those students. Its adaptation to local conditions, which consisted of several iterative cycles of analysis, development, evaluation and revision, is reported in the second part of the paper.

Keywords: visually impaired students, digital tools for teaching mathematics, LAMBDA editor

INTRODUCTION

The changes in society, brought up by an inflow of liberty and humanism, have led to the integration of handicapped people in Slovakia in 1993, and it has become an actual problem. Besides new social relations and situations it was also important to pay more attention to collective education of sighted and non-sighted students, which is particularly difficult when teaching mathematics. It is obvious that reading and writing standard text is completely different than reading and writing mathematics. One can consider mathematics even as a language on its own relying on different types of representations. This raises a question: how can we teach math to a student who is visually impaired? Practice shows that it requires using various tools that can give to the visually impaired students new view on mathematical objects, in order to support their imagination and simplify their manipulations with these objects. General approaches to the teaching math to visually impaired students in the world use tactile representations, audio aids, tonal representations, haptic devices and integrated approaches. The study of the actual Slovak situation, reported in the next section, points out the most serious problem, which is the absence of a uniform linearized notation. We thus focus on looking for a digital tool that could enable visually impaired students to write mathematical texts and perform calculations.

Overview of the actual situation

Primary school

Most of the Slovak visually impaired children (blind and partially sighted) attend special primary schools (in Slovakia, primary school lasts 9 years). During mathematics lessons, students use Braille books with tactile pictures, electronic notebooks to take notes and mechanical typewriters for calculations. The disadvantage of a typewriter is, first, that the way to get a result of a calculation takes too long, the pupils thus try to calculate in their minds and, second, the notation of the calculations is too verbiage, so after a while the pupil is lost. Teaching mathematics at the primary level means first of all helping children to use and organize their experiences, which they gain from actions and interactions with the world around them. Some authors claim that the main goal of mathematics education is to develop an awareness of numbers and coping with different relations and dimensions (Csocsan, Klingenberg, Koskinen and Sjostadt, 2002). The most frequent difficulties blind pupils encounter in mathematics are the following:

- generalizing – finding similarities in different activities in everyday life,
- translating activities and actions into a mathematical language,
- lacking flexibility in problem solving and in calculations,
- translating and transferring three-dimensional objects into two-dimensional iconic forms.

Secondary school

There are special secondary schools for visually impaired students in Slovakia, which are mostly oriented on music or some handicrafts (they usually last 3-4 years). If a student wants to come into contact with mathematics then s/he needs to attend a "normal" secondary school, which usually lasts 4-5 years. As we know, mathematics is a subject which is important for studying not only natural sciences such as physics, chemistry, computer science or biology, but it also begins to be popular in human sciences such as psychology, philology, sociology, etc. The direct consequence of this mathematical requirement almost everywhere is that also more and more visually impaired students today start their education in mainstream schools, which is the place where they can study math. Since the teachers in these schools are not specially educated in this field, they often have to use a "trial and error" method to find out the best way of teaching their blind students who are integrated among sighted students. Visually impaired students also face a lack of textbooks and study material, as well as a limited Braille math notation. On the other hand, most of visually impaired students at this level of education do not have difficulties to work with laptops with integrated screen reader and in this way to perform calculations; they already know all basic mathematical operations. However, the complexity of mathematical knowledge increases here very quickly in all fields: algebra, analysis, and geometry.

Hence, the students will have to overcome a lot of other new challenges, especially with the Braille notation of all new symbols. After having studied systems of Braille notation (Kohanová, 2003) in several European countries, we can state that more or less each of the mentioned norms suffers from a lack of rules for the notation of mathematical text. Therefore, the major part of visually impaired students creates their own particular mathematical language that is adapted to their conditions and requirements and the notation of these languages has a linearized form. But this raises new difficulties, because these “languages” are not necessarily comprehensible for people who the visually impaired students communicate with.

Communication with visually impaired students

The integration of visually impaired students among sighted ones in the common schools creates new relations in the classroom. One has to distinguish three types of communication within these special conditions: communication between teacher and sighted students, communication between teacher and non-sighted students, and communication between non-sighted and sighted students. The first case is dominant and it can have various forms. Oral communication is essential in education; however, this fact is not valid in mathematics. In addition, mathematics requires exactness, definiteness, totality and comprehensibility of presentation. Teaching and learning mathematics is very arduous only by oral communication (e.g., when modifying expressions or making geometric constructions) and it is therefore supported by a graphical way - text or picture. It is very common that some students rather prefer notation or picture to talking/argumentation; in the case of visually impaired students it is practically essential. If we talk about graphical communication in the frame of communication between teacher and non-sighted students, we mean communication supported by typhlographic pictures and planes [1] or space models (construction kit, cubes, skewers, paper). Another form is communication supported by laptop; a non-sighted student takes notes or performs computations in the electronic form, mainly linearized. Data from interviews with visually impaired students and their teachers show that it happens quite often that two visually impaired students, who are in the same classroom, use different notations when working with mathematical text (Kohanová, 2003). This phenomenon complicates markedly the communication not only between the student and the teacher, but also between students. Another issue is the question of educational goals. Since in Slovakia there are no standards for teaching mathematics to integrated visually impaired students at the secondary level, the teacher thus has to determine requirements for these students on her/his own, on her/his subjective opinion.

University level

Comparing to the secondary education, there is quite a different situation for blind students at the university in math. The students are supposed to have skills necessary for studying - take notes during lectures, read scientific texts, perform complex calculations, communicate with teachers and other students in written form, etc.

Much more autonomous work is required. If the student graduated at a special school/class and used only the Braille notation and spoken language for the before mentioned purposes, s/he will have to overcome a lot of new challenges. There are very limited sources of scientific literature accessible to a blind student. Therefore s/he should be able to read different mathematical notations. Another way of delivering mathematical expressions in an accessible written form is the electronic text document on a personal/portable computer or a special note taker for the blind users. This sort of document usually contains a linear mathematical notation with expressions built up of ASCII characters. A blind student can access this type of notation in two ways. S/he can either use the refreshable Braille display and read line by line the corresponding Braille cells (groups of 6 or 8 raised dots) by touch, or s/he can listen to a synthetic voice, which reads each written ASCII symbol for him/her. The second method is more difficult for reading complex mathematical expressions, however it could be quicker for longer text with simple mathematical expressions. The ideal is a combination of both methods, when student can choose the appropriate method depending on the current situation (what s/he is reading, writing or calculating). Some solutions, originally dedicated to electronic publishing of scientific text documents (TeX, LaTeX, AmSTeX, HrTeX, MathML), could be read and written by a blind student.

Computer Algebra Systems (CAS), such as Derive, MuPAD, MAPLE, MathCad or Mathematica, are dedicated at the first place to algebraic calculations, e.g., differentiation, integration or solving equations. They are also able to perform numerical calculations and to visualize graphs of functions, curves and 3-dimensional objects. They contain as well a lot of functionalities for analysis, linear algebra, statistics, numerical analysis, number theory, etc. These systems are also useful for visually impaired students, especially the calculation functionalities. It makes no sense to urge visually impaired students to perform calculations that are often just very tedious and mechanical. That is why CAS are helpful. If the commands entered into the command-line are linear, it means that they are fully textual and therefore suitable for visually impaired students. Another advantage of CAS is that the screen-reader does not have any problem to read linear text on the screen; it is thus accessible to the student. Therefore, blind students in Computer Science use CAS for example for calculations during Algebra seminars. It is a useful tool for calculations with matrices, which are time consuming and quite complicated. If they understand the principle, such a tool can save time and a lot of manual work.

ITERATIVE DEVELOPMENT OF LAMBDA SYSTEM

As we mentioned above, the information and communication technologies (ICT) might be very helpful for visually impaired students studying mathematics, since they have largely improved educational opportunities. ICT have begun to be a very important part of the material milieu of didactic situations. The most important requirement for secondary school students is to handle mathematical expressions as

quickly and efficiently as their sighted classmates. Teachers who do not have any knowledge of Braille (usually those in integrated schools) ask for most suitable tools to facilitate the communication with visually impaired students. Later on, at the university, it is important to have a mathematical writing system that is powerful, flexible, and compatible with most common format standards, to enable independent scientific and mathematical work to be distributed digitally. The fact that has to be considered is accessibility. Recently, LAMBDA - Linear Access to Mathematics for Braille Device and Audio-synthesis appeared to supply all needed requirements. The LAMBDA project makes the provision for an integrated system based on a linear code and a software management system (the editor). The editor allows writing and manipulating of mathematical expressions in a linear way. A few facts about Lambda (according to Fogarolo, 2006):

- LAMBDA is intended to be used mostly by young people who learn mathematics, especially visually impaired students.
- LAMBDA is above all, even if not only, a didactical tool. It is the functional component which implements strategies devised in order to make text and mathematical expressions easy to read, write and manipulate by means of vocal output and Braille display, in an educational setting.
- It is important to define didactical requirements needed for a software writing system compared with Braille traditional ones. The change towards mechanic writing systems (such as typewriter and PC) requires skills relative to the management of textual documents using PC. If they are missing, traditional tools are preferable and the passage to new technologies has probably to be put off.

Methodology – Setting of the research

We have first got in contact with LAMBDA system in December 2005 at the international conference in Rome: „*I don't see the problem: new prospects to access Mathematics and Scientific studies for Blind students*“, where the software was presented by its authors and by Italian visually impaired pupils who used and tested it. Later on, on the initiative of the Support Centre for Visually Impaired Students, Comenius University in Bratislava, we decided to investigate whether the LAMBDA system could be used as an educational tool to teach mathematics to visually impaired pupils in Slovakia. In the case that LAMBDA would prove to be a significant tool, the Support Centre planned to find ways of its practical application in Slovak schools. The methodology adopted in this research follows the design-based research approach. According to Plomp (2010), this methodology might be realized in a number of the following phases: preliminary research, prototyping phase and assessment phase. Our preliminary research consisted in mapping the actual situation in Slovakia with focus on tools and technologies used in math education of visually impaired students (see above). The prototyping phase is composed of four iterative

cycles of analysis, development, evaluation and revision of LAMBDA system used in Slovakia. All four iterations had a form of a course for visually impaired students or teachers, who were observed and interviewed in order to get feedback on the actual LAMBDA prototype. The assessment phase should give us an answer on the above-mentioned research question concerning LAMBDA as an educational tool.

Process of iterations

The first iteration of the prototyping phase was conducted in spring 2006 in one of the two schools for visually impaired pupils in Slovakia. We organized together 5 lessons where the LAMBDA system (English version) was introduced. The study group was formed of 5 pupils of 9th grade (4 boys and 1 girl). The pupils were chosen by using a purposeful sampling method (interest in studying mathematics at upper secondary school; basic English and basic computer skills were required). Two of the pupils were short sighted, two virtually non-sighted and one non-sighted. The data for the next iteration were collected from observations during the lessons and from a semi-structured interview after the course.

During the course the participants became familiar with the working environment and the following important and useful features of the software (as advised in Bernareggi, 2006):

- Various possibilities to input characters and mathematical symbols.
- In many situations, it is important to perceive global information, related to the structure or the relation, to define every single time the most suitable paths and methods to face different issues. For example, given the following expression:

Its linear representation $\frac{x^2 - 4}{x^2 + 4x + 4} + \frac{4}{x + 2}$ in LAMBDA is:

`//x^2-4/x^2+4x+4//+//4/x+2//`

It is evident that in reading the linear representation it is more difficult to find specific parts and to quickly understand the relations among the structures making the expression, which is an immediate operation for sighted people who use global and bidimensional exploration. Therefore, we presented effective exploration strategies to the students. LAMBDA offers exploration through movement operations, in the sense that one can move to the next numerator, denominator or corresponding separator or tag. The second possibility is a tag structure of an expression that enables to understand the overall structure of the expression and to find its specific parts. The most compressed structure of the above-mentioned expression is:

`//+//`

Another

depth level looks as follows:

$$\frac{x^2 - 16}{x^2 + (-8x) + 16} + \frac{x - 12}{x - 4} =$$

This visualization modality that hides the content of the block by maintaining blank spaces is useful as well to get some information about the size of the hidden blocks.

- Even the linear notation in LAMBDA is more or less intuitive; the graphical visualization (Fig. 1) might be helpful for the teachers, parents or sighted schoolmates in order to be able to help the visually impaired student or correct his/her productions by doing calculations.

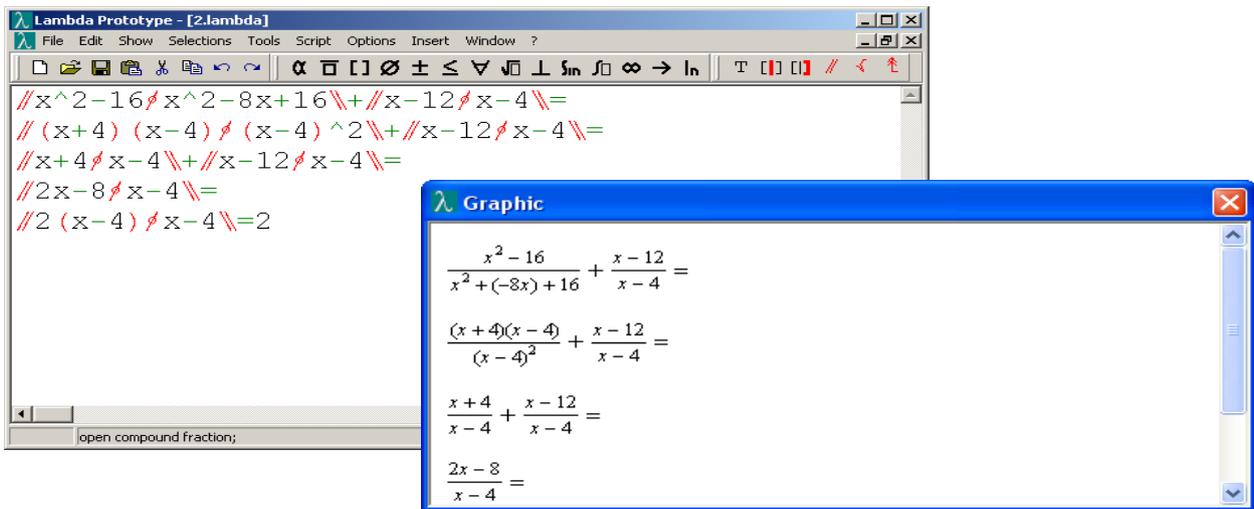

Figure 1: Graphical visualization of the calculation

- Another beneficial tool that was introduced is a scientific calculator that is able to calculate numerical expressions and paste the result.
- LAMBDA enables automatic double copy of a selected row, we thus get “checking” and “working” lines. Here we have the possibility of checking the steps against a previous, unchanged “checking” line.

Two open-ended and two closed-ended questions were asked to the pupils during the interview after the course:

“Tell me about your experiences with LAMBDA during the lessons.”

“In your opinion, what advantages and what disadvantages LAMBDA has?”

“Do you think you have learnt how to work with LAMBDA?”

“Can you imagine working with LAMBDA when studying mathematics at school or at home?”

The data obtained from observations and interviews confirmed that all 5 pupils had learnt how to work with LAMBDA. Pupils considered LAMBDA as user friendly, more effective and also as a useful tool to do mathematics in comparison with the mechanical typewriter they used before the course. They appreciated the LAMBDA feature of “working” and “checking” lines, as well as the possibility to see what

Working Group 15

structure they are working with. As expected, all pupils considered the English language as the biggest disadvantage; they would prefer to work with Slovak version.

The second iteration focused on the translation of the LAMBDA menu into Slovak (September 2006 – August 2007). During the academic year 2007/2008, we continued with courses, whose primary aim was to test the prototype of LAMBDA in the Slovak language and the secondary aim was to get another feedback from pupils on LAMBDA as a tool for studying mathematics. In September 2007, we realized a one-day intensive course for three students who were integrated in a “normal” classroom of an upper secondary school (at that time). All three of them participated in the previous course. This course helped us to discover several errors (terminological and semantic) and imperfections, their corrections were afterwards implemented into LAMBDA system.

The third iteration was realized in December 2007, when 7 students coming from primary or secondary schools in Slovakia attended the third course. This course focused on a revised Slovak version of the software and on the appropriation of some new functionalities of LAMBDA added by the authors. Four participants already knew LAMBDA from the previous courses (2 of them worked with the English version, 2 with the Slovak version) and for the others LAMBDA was new. The latter were observed during the course and asked the same questions as in the first research phase. The data obtained from these interviews showed again that pupils are able to learn how to work with LAMBDA, perform various mathematical calculations and they consider it as an effective tool for doing mathematics. Students who already worked with LAMBDA were interviewed once again. We were interested in what problems and complications they encountered when learning mathematics with LAMBDA at school or at home, that means, in situations when they had to communicate with their sighted schoolmates, teachers or parents, who are not used to a linearized form of mathematical calculations. This was our input data for a forthcoming seminar on how to use LAMBDA organized for mathematics teachers of visually impaired students. After the course, all students were asked to write us feedback on LAMBDA (regarding understanding, complexity, heavy operations, etc.) on the basis of their experiences during the summer term 2008. All highlighted defects were again corrected in the new version of the Slovak editor.

As it was already mentioned, the next iteration focused on teachers at primary and secondary schools who teach mathematics to visually impaired students, because they are also important in the process of studying mathematics. In February 2008, the Support Centre prepared a course for teachers in order to introduce them to LAMBDA as the educational tool. 23 teachers from various parts of Slovakia attended it. They got familiarized with principles of text linearization, LAMBDA basic functionalities, they learnt how to work with it and what are its advantages in comparison with other systems. They could observe one non-sighted student working

with LAMBDA, who demonstrated how quickly and effectively he is able to write dictated mathematical text and, later on, to edit (calculate) it. At the end of the seminar, the teachers expressed their willingness to use LAMBDA in their classrooms, when communicating with their visually impaired students.

In March 2008, we have created a web-forum for students and teachers who work with LAMBDA in order to help them with any problem that could arise. One of the outputs of the realized courses was also a methodical guide of using LAMBDA intended for teachers and parents of visually impaired students, which was distributed to them.

DISCUSSION AND CONCLUSION

In the last years, the solution of the problem of accessibility to mathematics visually impaired students face seems to have an electronic form, which was studied by several authors (Kobolková & Lecký, 2002; Miesenberger, Klaus and Zagler, 2002). There exist systems that are blind friendly so that visually impaired students can do (calculate, read, write) mathematics in the way that is also accessible for their sighted schoolmates and teachers. In Slovakia, we have started to use the LAMBDA system and adapt it to the local conditions in several steps/iterations in accordance with the design-based research methodology. Thus, during the years 2006-2008, we realized several courses for visually impaired students and their teachers in order to find out whether LAMBDA system could be used as an educational tool for visually impaired pupils studying mathematics in Slovakia. Data obtained from observations and interviews first showed the need of LAMBDA localization into the Slovak language. Later on, when LAMBDA was used in math education by a few students, other problems arose. We tried to solve those problems and implement their solutions into the subsequent versions of LAMBDA. Through active web-forum, we got, during the years 2008-2009, a request from students and teachers for further development of the software, which appeared as not usable and quite demanding, since meanwhile LAMBDA became a commercial tool. These facts make it impossible to use LAMBDA as a norm in Slovakia. That is why we decided to develop a new tool for visually impaired users for working with mathematics in the electronic form. It should comply with the following features:

- open-source application, platform independent and providing support for free screen readers;
- usage of standardized formats (XML) to store the results;
- easy language localization and easy extension of new symbols and functionalities;
- standard graphical visualization of the notation for sighted users;
- easy program control not only for visually impaired users, but also for sighted users.

Working Group 15

These features should reduce almost all problems that caused the impossibility to adapt LAMBDA software to Slovak conditions. Further research will show whether the new developed tool will prove as effective and helpful tool for learning and teaching mathematics at Slovak primary and secondary schools and universities. In addition, further research should also study teacher's instrumental orchestration (Trouche, 2004) in such specific conditions, where visually impaired students are integrated into a common classroom with sighted students.

NOTES

1. Typhlographic pictures and planes enable visually impaired people to explore things that are usually not accessible to them. They can touch objects that are distant (sun, moon, clouds), too big (castle, train) or too small (butterfly, ladybird) and they can thus feel their shapes, develop imagination or orient themselves in space.

A STUDY ON MATHEMATICS TEACHERS' USE OF TEXTBOOKS IN INSTRUCTIONAL PROCESS

Meriç Özgeldi¹, Erdinç Çakıroğlu²

¹Mersin University, ²Middle East Technical University

This paper provides an analysis of mathematics teachers' use of curriculum materials. 13 elementary mathematics teachers participated in the interviews for how they used the curriculum materials, specifically textbooks. The purpose of this study is to examine what mathematics teachers do with curriculum materials and how they use them for mathematics. The results of the interviews indicated that mathematics teachers used different textbooks to make instructional decisions, and they mostly adapted problems and examples in a constructive way.

Keywords: mathematics teachers' use of curriculum materials, mathematics textbooks, and teachers' instructional decisions

INTRODUCTION

One crucial role teachers play in the school context is to transform and implement curricular ideas in classrooms. In their implementation processes, they often benefit from different types of curriculum materials, including textbook and other written resources. Curriculum material is an integral part of teachers' daily work and offer ongoing support for pedagogy and subject matter content throughout an entire school year (Collopy, 2003). They provide ideas and practices which frame classroom activity via text and diagrammatic representations and help teachers in achieving goals that they presumably could not or would not accomplish on their own (Brown, 2009). Certainly, written curriculum materials such as the textbook, worksheet, and teachers' guide are mostly used curriculum materials in the school context. Particularly, textbooks are among the most widely used and trusted curriculum materials that are directly related to teacher's teaching and student's learning (Beaton, Mullis, Martin, Gonzalez, Kelly, & Smith, 1996). Although the term 'curriculum materials' has a general meaning involving a variety of resources, the current study focuses on mathematics textbooks and accompanying student workbooks, teacher guidebooks, and other written resources that are available to teachers.

In general, mathematics curriculum materials such as textbooks, texts, computer software, and geoboards are integrated into mathematical and instructional intentions and possibilities for school mathematics (Adler, 2000). Mathematics curriculum materials have been viewed as critical resources for students' learning of mathematical content and teachers' mathematical instructional decisions; and teachers are accustomed to using them to guide instruction (Stein & Kim, 2009). In this sense, mathematics textbooks are used "as source[s] of problem and exercises, as reference book, and as a teacher in themselves" (Howson, 1995, p.25) because

teachers often rely heavily on textbooks for many decisions such as what to teach, how to teach it, what kinds of tasks and exercises to assign to their students (Robitaille & Travers, 1992). Therefore, it is reasonable to argue that the mathematics textbook is an important part of mathematics learning and teaching context in which students and teachers work.

Studies covering period of 25 years on characterizing and studying how the curriculum is actualized in schools addressed teachers' interactions with curriculum materials and the role of the curriculum materials implementation. The critical point for understanding the curriculum use depends on the process of understanding what teachers do with mathematics curriculum materials and why as well as how their choices influence classroom environment (Remillard, 2009). Their value is likely to depend on the ways they are used (Cohen, Raudenbush, & Ball, 2003). In this sense, understanding the use of textbooks and other relevant written resources by teachers plays an important role in exploring the pedagogical approaches used in the classroom.

Research has shown that when teachers interact with curriculum materials, they do so in dynamic and constructive ways rather than a straightforward process (Brown, 2002; Davis & Krajcik, 2005; Remillard, 2005). Teachers frequently make changes in the curriculum intentions and modify them according to the structure and the purpose of lessons. In doing so, the availability, quality, and flexibility of the curriculum materials play a critical role in teachers' decisions. In general, teachers transform the curriculum ideas, lesson plans, and mathematical tasks into real classroom activities (Remillard, 2005). Therefore, understanding the teachers' interactions with curriculum materials requires an integrated analysis of their uses in the classroom teaching and learning context. For example, Brown (2009) has revealed a kind of interaction between teacher and curriculum materials which involves multiple steps. According to this interaction, teachers first *select* materials; however, the options offered to the teachers are often restricted by higher organs in the educational hierarchy. Second, they *interpret* these materials in planning and during instruction with regard to their perception of materials. Third, they *reconcile* their perceptions of the intended plan with their own goals and with the limitations of the setting. Fourth, they *accommodate* the students' interests, experiences, and limitations. Finally, they *modify* the setting according to their own decisions and to their students' capacities. In fact, these steps proposed by Brown partly reflect the dynamic and constructive relationship between teachers and textbooks.

In sum, understanding teachers' use of textbooks and other relevant curriculum materials provides insight into the contribution of such materials to classroom learning. In this context, the purpose of this study is to reveal what curriculum materials-specifically the textbooks- are crucial to mathematics teachers, and how they utilize them for mathematics. The specific research problems addressed in this study are the following:

- What are the uses of written curriculum materials (mathematics textbooks and accompanying student workbooks, teacher guidebooks, and other written resources) in classroom mathematics for the middle grades mathematics teachers?
- For what reasons and purposes do mathematics teachers select and utilize the written curriculum materials?

METHOD

TEXTBOOKS IN TURKISH SCHOOLS

Any textbook to be used in Turkish elementary schools needs to be officially approved by the Turkish Ministry of Education. The state publishes textbooks for each subject matter included in the curriculum. In addition, private publishers may also publish textbooks for schools. Among the approved textbooks, the ministry of education decides which textbook can be used by which schools, and distributes them free of charge to students and teachers. Typically, a set of mathematics textbooks includes a student course book and student workbook, as well as a teacher guidebook.

PARTICIPANTS

In this study, the data were collected through interviews. For the interviews, all middle grades mathematics teachers working in 11 different schools selected from a district of the western Turkish town İzmir were invited to participate in this study. Among them, 4 male and 9 female mathematics teachers were invited to participate in the study. A purposeful sampling method was used to ensure that a variety of teachers with different teaching experience were questioned. The interview participants had a minimum of 5 years of experience in mathematics teaching. In particular, 7 teachers had taught for over 10 years, and 2 teachers had taught for 25 years or more at the elementary school level. At the time of the data collection, the teachers were working at sixth through eighth grade levels. Furthermore, they were using the same mathematics textbooks.

DATA COLLECTION

During the fall semester of 2009, 13 mathematics teachers were interviewed about how they used mathematics textbooks, and what other resources they used to plan and implement the mathematics lessons. The interviews were conducted for the purpose of obtaining data about how teachers used mathematics textbooks for planning, implementing, evaluating the lesson in the context of the Turkish school culture, as well as their perceptions of the textbook. Interviews were conducted in teachers' schools and took about 40 to 60 minutes with each teacher. Teachers were asked semi-structured questions, and the interviews were tape recorded and transcribed verbatim for the data analysis.

DATA ANALYSIS

The researchers drew on the interview data to identify the use of textbooks by mathematics teachers. In analyzing the interviews, teachers' utilization of student course book, student workbook, teacher guidebook, and other resource books were analyzed in light of the research questions. Particularly, the researchers analyzed their use in the process of planning, preparing, enactment, and assessment of mathematics instruction.

RESULTS AND DISCUSSION

Results of the analysis indicated that mathematics teachers were using student course book (CB), workbook (WB), teacher's guidebook (TG), and other resource books (OB). The reports of teachers showed that teachers generally utilized the TG and CB in preparing the mathematics lesson. Moreover, they looked at the TG to make possible a connection between the curriculum intentions and classroom activities. They stated that their first resources for making decisions which topics to teach and how to present them were the TG and CB. As Ms. Aksu stated:

I use the guidebook very frequently because I think that the guidebook gives useful information. For example, it provides information about how I can teach the lesson.

In this case Ms. Aksu uses the teachers' guidebook to make decisions about how to teach the topic. Similarly, Mr. Çelik stated that he uses the TG to determine content boundary in his classes. He stated:

I look at how the subject is covered [*in the textbook*], how it is explained, what the levels of the examples are, what kind exercises there are? [*I use the course book*] to get an idea about where the unit starts and ends, I mean, in order to determine a framework [*for the class*].

Mr. Çelik's use of the TG was limited to determine the level and depth of the topic to be taught. Other participants also made use of the TG or CB in order to review the lesson objectives. Mr. Salih, on the other hand, focused more on the CB. He stated that he usually searches for engaging and sense-making activities from the CB.

I try to start my instruction with activities and real life connections as this makes it easier to reach my students. I use the textbook for trying to reach ideas for this.

Similar to Mr. Salih, other participants preferred to situate the problems in a real-life context from the CB. Particularly, one of the most important uses of the TG and CB were about the selection of in-class questions and exercises to be studied. For instance, Mr. Emre stated:

We first solve the examples, questions in the course book together with students, and then after teaching the topic, I definitely make my students solve the "your turn" part in the book. For the higher-level students, I solve problems from the test books after covering the rules from the course book.

Working Group 15

In this case, Mr. Emre used the CB as the main source for examples and problems and looked at the OB to find different and upper level problems. Mr. Hüseyin also mentioned that the teaching experience he had was very crucial in adapting the problems and examples for the level of students in his classroom. He stated that:

The level of the students is important for sure. I select more advanced books if the level is high, and easier books if the level is low... I arrange it by myself, actually based on my experiences. For example, sometimes I change a question while I am writing it. I change the questions considering the level (of the students) because I feel, I can see where a student can get it and where s/he cannot.

In this case, Mr. Hüseyin, who had nearly 25 years of experience in mathematics teaching, expressed that he makes use of his teaching experience in selecting the problems and modifying the setting according to his own decisions and students' capacities. Similarly, the other participants reported that they created problems and questions using those textbooks, and adapted to problems and questions in the CB, WB, and OB. As Mr. Sinan expressed, he focuses more on the WB and creates his own problems by the help of questions in the textbook. He stated:

I change the form of the questions in the course book, or I write sub-questions for the questions in the book and pose them to students.

Moreover, the participants expressed strong messages about the importance of addressing students' needs for preparing high stake national exams-namely SBS in Turkey. They adapted and supplemented the questions in the course book to be in line with the national examinations in order to help students achieve better test scores. As Ms. Mine stated:

I always make my students solve the problems at the end of each unit in the course book. I make use of the book, because it is based on the curriculum and because I do not want my students miss any questions in SBS

In addition, Ms. Tülin stated:

In my classroom exams I ask similar questions to the national test.

Similar to those cases, the participants aimed not only the preparation for high stake tests, but also for in-class examinations. Generally, the participants utilized the CB, WB, and OB to select problems and applications for in-class assessment. They generally used these materials to give homework and prepare the exam questions. As Mrs. Akif stated:

I generally use the workbook to assign homework. Most of the questions (in the workbook) are not like the traditional ones such as 'what is x?', but there are figures and tables in them. The questions in the course book and the student workbook are similar, so I assign the workbook to the students.

Similar to Mrs. Akif, the other participants used the WB in their classrooms to ask similar problems in the CB and they gave the problems in the WB as homework.

CONCLUSIONS

According to Remillard (1999), when teachers read the textbook, they attend to some parts of text and dismiss others. They bring their interpretation to what they read. This is because reading text involves “a series of tacit decisions about what to attend to and how to interpret it” (Remillard, 1999, p. 324). In this current study, the mathematics teachers focused on the mathematics textbooks and accompanying student workbooks, teacher guidebooks, and other written resources in order to make particular decisions about the instruction. For example, they selected the real-life examples from student course book and decided on the problems from student workbook or other source book. Therefore, the use of textbooks by mathematics teachers was based on their interpretations of textbooks in this study.

The results of the study indicate that teachers mostly relied on the official course books and accompanying teacher guidebooks for planning and preparing mathematics instruction. They were generally helpful for teachers about what topics to teach and how to make connections with real life and the other lessons. During the instruction, the teachers preferred to use again the course books for more process oriented activities such explaining topics, focusing on concepts, and assigning projects. For evaluating mathematics instruction, teachers preferred to utilize the course books, workbooks, and the other resource books in order to evaluate students and give homework. The data indicate that the most of the teachers stated that they followed the mathematical content and sequence presented in the CB by a little change. The teachers reported that they adapted the tasks from the CB and OB to give examples, exercises, and problems. For example, according to teachers, they felt that they had to review problems and examples in all resources because the classroom settings (e.g. the level of the students or time) always restricted the teachers. Most of the teachers also stated that they looked at the OB considering that they could not find challenging problems in the CB. Therefore, they stated that they used the OB when they preferred to solve different kinds of problems. Particularly, the teachers mostly adapted problems and examples when they were enacting in classroom and evaluating students. This would eventually indicate that teachers interacted with textbooks in a constructive way rather than a straightforward process.

Furthermore, the teachers used the CB, WB, and OB to select problems and applications for assessment and evaluation. For instance, they stated that they generally utilized them to give homework and prepare the exam questions. Most of the teachers reported that they created problems and questions using those textbooks, and others made few or no adaptations to problems and questions in the textbooks.

A general conclusion in this study is that the teachers mostly rely on the course book and the other resource books for selecting problems to work in class or use in examinations. These resources are mostly the self-study books that aim to prepare students to high stake exams. The scope of such books is usually focused on the preparation for the tests and the problems are usually in multiple choice format.

COLLECTIVE DESIGN OF AN ONLINE MATH TEXTBOOK: WHEN INDIVIDUAL AND COLLECTIVE DOCUMENTATION WORKS MEET

Hussein Sabra, Luc Trouche

INRP & LIRDHIST (Université Lyon 1, France)

This paper focuses on the documentation work in the mathematics teaching. We show up the individual and collective components of this documentation. We present a new theoretical framework, the documentational approach, which seems adapted for studying this issue. We applied it on a particular project of the French teachers association Sésamath: the collective design of an online mathematics textbook. We present a methodology for observing both this collective project and the case of Anaïs, a teacher involved in this project. We study her professional interest in Sésamath, her didactical interactions with the other project members, and their effects on her professional knowledge.

Keywords: documentation work, professional knowledge, resources, community of practice.

INTRODUCTION

Digitalization deeply changes conditions of thinking and sharing knowledge at each level of the society (Pédauque, 2006). Its visible manifestations, in mathematics teaching (Hoyles & Lagrange, 2010), are both the *profusion* of resources available via Internet and the *diversification* of technologies that could be used by teachers (USB keys, interactive whiteboard, calculators, software). These evolutions dramatically modify the conditions of professional practice (for *preparing* as well as for *doing* the teaching). They prompt new collective forms of teachers work: on the one hand, digitalization makes *potentially* easier sharing and exchange of resources between teachers, on the other hand, its complexity (dispersion of resources, rapid technological evolutions) makes *necessary* for teachers to help each other. These new forms of collective work among mathematics teachers change the conditions for their professional growth: *teams, networks and communities* appear as new opportunities for teachers to learn (Krainer & Woods, 2008).

The most significant phenomenon of this trend, in France, is, for us, the appearing of Sésamath [1], a French online association of mathematics teachers, aiming to provide mathematics teachers with free online resources. For achieving this goal, Sésamath develops collaborative work of teachers, around common projects (Sabra, 2009). We address, in this article, two questions: why do teachers engage in Sésamath? How do they articulate their work on resources for individual purpose and for Sésamath purpose?

We first introduce a new theoretical approach, which seems necessary for addressing these issues. Then, we present our experimental field, specify our questions and set out our methodology. Finally, we display some preliminary results and propose some new questions that this research raises.

THEORETICAL FRAMEWORK

Our research relies on a new approach to teachers' work with *resources* and professional development, already presented in CERME 6 (Gueudet & Trouche, 2009) and developed further (Gueudet, Pepin & Trouche, to appear): *the documentational approach of didactics*.

It is built on a distinction between *resources* and *documents*, extending the one introduced by the *instrumental approach* (Rabardel, 1995) between *artefact* and *instrument*. The choice of the word "resource", instead of artefact, aims at catching a great variety of things intervening in teachers' work: textbook, piece of software, student's worksheet, Internet resource, discussion with a colleague, etc. We call *documentation work* what a teacher needs to do for designing her teaching: looking for resources, integrating them in her personal *resource system*, implementing it in practice, sharing it with colleagues, renewing it taking into account various feedback, etc.

A teacher draws on resource sets for her documentation work. A process of genesis (Fig. 1) takes place, producing a *document* [2], made of resources and a scheme (i.e., an invariant organization of the activity to perform a type of task - here a task of preparing and performing a given teaching). Each scheme encapsulates professional knowledge, both shaping teacher's activity and permanently reshaped by this activity. Shulman (1986) proposed a categorization of teacher's professional knowledge. We are particularly interested in Pedagogical Content Knowledge (PCK) that a teacher develops to help her students in their learning (Grossman, 1990).

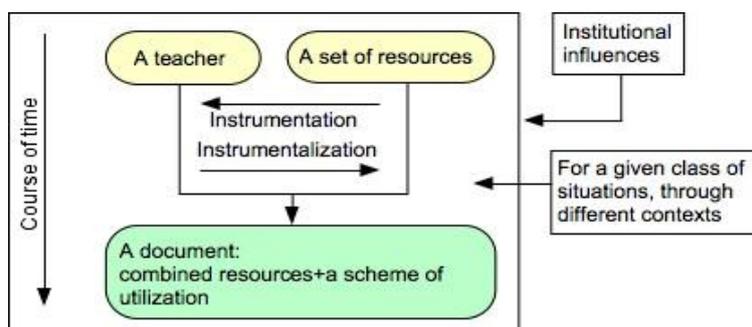

Figure 1. Schematic representation of a documentational genesis

The documentational genesis combines two interrelated processes: the instrumentalization (the teacher acting on resources), and the instrumentation process (resources supporting teacher's activity).

Considering teachers' collective work leads us to articulate the documentational approach to the frame of *communities of practice* (Wenger, 1998). A community of

practice (CoP) is a human group presenting three main features: *mutual engagement* of its members, active *participation* to a joint enterprise, and *reification* of elements of practice (i.e., production of things, results of the common practice, and recognized as a common wealth). This frame appears relevant for studying interplay between a group of teachers and sets of resources they are working on/with. Instead of reification (referring to congealed entities), we coin the expression *community documental genesis* to describe the process of gathering, creating and sharing resources to achieve the community teaching goals. The result of this process, the *community documentation*, is composed of the shared resource repertoire and shared associated knowledge (learnt from conceiving, implementing, discussing resources).

OUR EXPERIMENTAL FIELD

Sésamath is a math teachers association founded in 2001. Its kernel is constituted of about 100 subscribers (math teachers), sharing a set of principles inscribed in a charter [3]: common philosophy of public service, “math for everybody”... Elected by this kernel, the Sésamath board regularly launches new project groups for designing resources on a given theme corresponding to teachers’ special needs and interests (new curriculum subject, new textbook... Fig. 3). These groups gather about 5000 teachers (a number of teachers belonging to several groups at the same time), working mainly at distance, via a platform and mailing lists. The group members can benefit from the assistance of employees and computer developers hired by the association (Fig. 3). All these groups present the CoP features, at different levels of development: the project groups appear, at the beginning, as *potential* CoP (Wenger *et al.*, 2002), while Sésamath kernel appears as a *maturing* one (*ibid.*). Sésamath, beyond its regular members, thus constitutes a *constellation of CoP* (*ibid.*), each of them sharing a same commitment for the association principles. A questionnaire (Sabra, 2009), proposed in 2008 to 36 members of the Sésamath kernel [4], gave some answers to our first question: why do teachers engage in Sésamath?

What are, for your teaching, your sources of documentation?	Online resources (33/36); Resources that you have developed in previous years (35/36)
What are your professional reasons for engaging in Sésamath?	Training (16/36); Exchange of experience (23/36); Exchange of resources (13/36).

Table 1. Questionnaire to Sésamath, two questions (among 39) and their answers

The first item (Table 1) confirms the Sésamath members’ interest for online resources and evidences the place, for them, of resources *reuse* (revealing the importance, for Sésamath work, of exchanging, combining, modifying his/her own existing resources). The question item reveals that the main motivation, for joining Sésamath, is the *exchange of experience*, which evidences Sésamath role for its members’ professional development.

Going further in our research required to monitor the documentation work of one Sésamath project group on the field. We have chosen the group (named DT10), created in 2009, aiming to design a digital textbook for the beginning of the French high school (grade 10). This choice was motivated by two reasons: 1) after having designed textbooks for the French college (grades 7 to 9), Sésamath thus addresses, for the first time, the more complex, grade 10 math; 2) after having designed “classical” textbooks (pdf, OpenOffice files teachers can download and modify) with complements (spreadsheets and interactive applications), Sésamath aimed to create a new type of *digital* textbook, that a teacher can appropriate and adapt to her own needs. We hypothesised that these new challenges (mathematical and technical) could enrich the documentation work of this group, and thus make it more interesting for our research.

Answering our initial questions needed also monitoring the complete documentation work (both for Sésamath and for their own classes) of some DT10 members. For this article, we have chosen to present Anaïs’ case. Anaïs is particularly engaged in DT10. She is 57 years old. After 15 years of various occupations (including a few years as a member of a commune in the countryside), she came back to the university, achieved her math studies and got a position as a math teacher. She has now 18 years of teaching experience (15 years for grade 10). Why does Anaïs engage in the DT10 project? How does her professional knowledge interact with individual and community documentation?

METHODOLOGY

Observing the individual and collective documentation is a complex task. It requires taking into account several conditions: long time observing to highlight regularities; individual and collective observing; observing *in* and *out* of classroom; following both teachers’ activities and resources. In some methodology of CoP observation, the researcher is engaged in practices (Jaworski, 2009). In our case, we have just observed the practice as an outsider.

The reflexive investigation for observing individual documentation

To observe Anaïs’ documentation, we adopted a methodology designed by Gueudet & Trouche (2010): *reflexive investigation* considering the teacher as an essential actor in data gathering. Among its methodological tools: interview at home, ‘guided tour’ (the teacher being the guide) and schematic representation of her *resource system* (SRRS); questionnaire about her vision of math and of math teaching; follow-up during several weeks including a logbook fulfilled by the teacher, collection of the resources, classroom observations. Anaïs became sick at the beginning of the follow-up, thus a direct classroom observation was impossible. We have adapted the methodology, by observing (and videotaping) Irvin, Anaïs’ substitute in class, who actually used Anaïs’ resources, and discussing afterwards with Anaïs on Irvin uses of her resources. In this paper, we only exploit data from the Anaïs’ interview at home,

from her comments on Irvin's video, from her SRRS and from a set of resources she designed for the teaching of functions (according to the discussion in DT10).

Designing a methodology for observing community documentation

Extending this methodology relying on *individual* reflexive investigation, new methodological tools have been designed for fostering teachers' reflection on their *collective* practice. Among them, an *agenda*, fulfilled by some members of the CoP, chosen for the role that they had in the project (e.g., Adam was selected for its role identified in the mailing list as an effective coordinator of DT10). These agenda aim to identify and analyze, from different points of view of different actors, the effects of the *incidents* (something unexpected needing to reformulate the common goal or to reorganize the community documentation) occurring throughout the common project. We have also asked DT10 members a *schematic representation of collective interactions* (SRCI) in the case of Sésamath, and collect the mathematical resources that they designed.

The methodology takes also advantage of *natural data* which offers the experimental field. We thus exploit the Anaïs' online notebook, the DT10 mailing list offering discussions about project organisation, as well about mathematical, didactical and epistemological aspect of the community documentation work. During our follow-up period (11 months), 627 messages have been exchanged via the mailing list, involving 27 members (including Adam, Anaïs, John, Ben, Pierre and Henry). Anaïs has authored 111 messages out of the 627. We particularly exploit the DT10 *thread of discussions* concerning the "math functions" linked to an incident: a curriculum change occurring in the midst of DT10 work and provoking a more intensive discussion.

DATA ANALYSIS AND DISCUSSION

We first analyze Sésamath and Anaïs' documentation, and then present the didactical interactions between Anaïs and DT10.

Documentation work: DT10 and Anaïs

Most of Anaïs' resources (courses, exercises, homework) are digital, stored in an external hard disc. This digital form facilitates the sharing with other teachers via USB key or Internet. The Anaïs' resource system is strongly articulated with Sésamath resources (see Anaïs SRRS, Fig. 2): emails, students' sheets and other resources exchanged with Sésamath seem to have a major role in her documentation. This *osmosis* between Anaïs and Sésamath resources facilitates Anaïs' participation in DT10 work.

Anaïs's documentation is conditioned by three factors: "curriculum changing, institutional recommendations and classroom general level" (Anaïs' interview). For example, her teaching of "function" is strongly related to curriculum change. She said that she lived "*two different spirits*" of teaching functions: "it was, before, more

Working Group 15

guided and now the curriculum recommends open questions... so that students have more initiative” (Anaïs' interview). She seems very sensitive to the students' level: this year, I had a low level class. I will modify [the documents of the previous year] by adapting them to the level of my class. But maybe, the next year I will have good students; I will reuse the document in the present form” (Anaïs' interview).

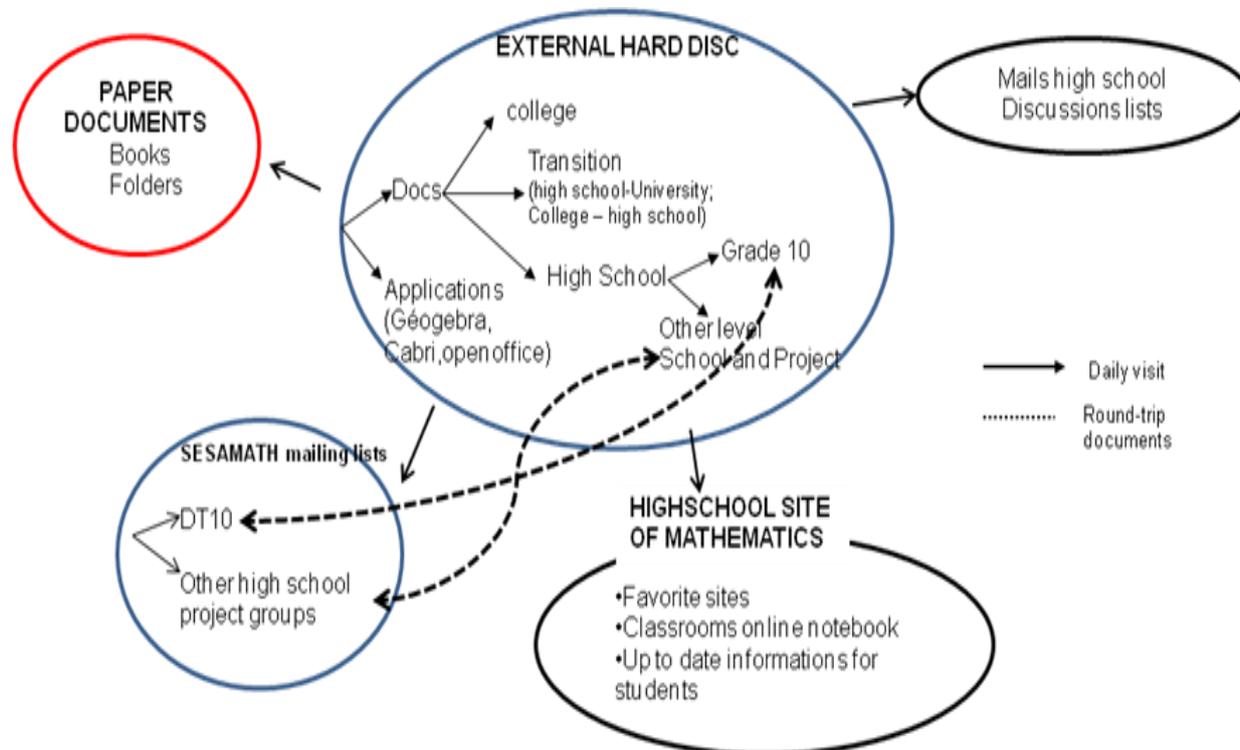

Figure 2. Anaïs' SRRS, our translation and schema as close as possible of the original

DT10 documentation is also sensitive to curriculum changes and keeps Sésamath resources as a general background support (particularly when an incident occurs), as it appears in the following excerpt of the DT10 mailing list:

John: The curriculum has profoundly changed and we must rebuild the chaptering. This chaptering is very important because it is common to several Sésamath projects that involve the grade 10. Thus, I propose to do a general RESET.

Henry: We will create a general mailing list for all Sésamath projects linked to the secondary level as there issues intersect. We will thus share resources and general links that might be useful to all.

John: This list must first allow everyone to have a clear idea of what is done in different projects.

DT10 and Anaïs' documentation do not answer to the same constraints: DT10 has to move forward systematically with other high school projects, while Anaïs is attracted by her pupils' level, particularly in the new curriculum spirit. But both documentations are conditioned by the institutional recommendations, which constitute the joint constraint for designing the resources.

Anaïs' interactions with DT10 are linked to her general interest for collective matters, and particularly in this project. Anaïs underlines, in her SRCI for Sésamath (Fig. 3), that each project is constituted by teachers who are interested the project topic. More precisely, her participation resulted from a professional interest: participating in DT10, constitutes, for her, an occasion for searching ideas for her own classroom course. She confirms this idea in the interview, illustrating the productive aspects of instrumentalisation process: “for example, for the chapter “Variations and Extrema of functions” [named 2N2], I don't have constructed the lesson yet. In fact, I will transform it [the lesson designed in DT10] and I will reuse it for my classroom. I will adapt it for my classroom”.

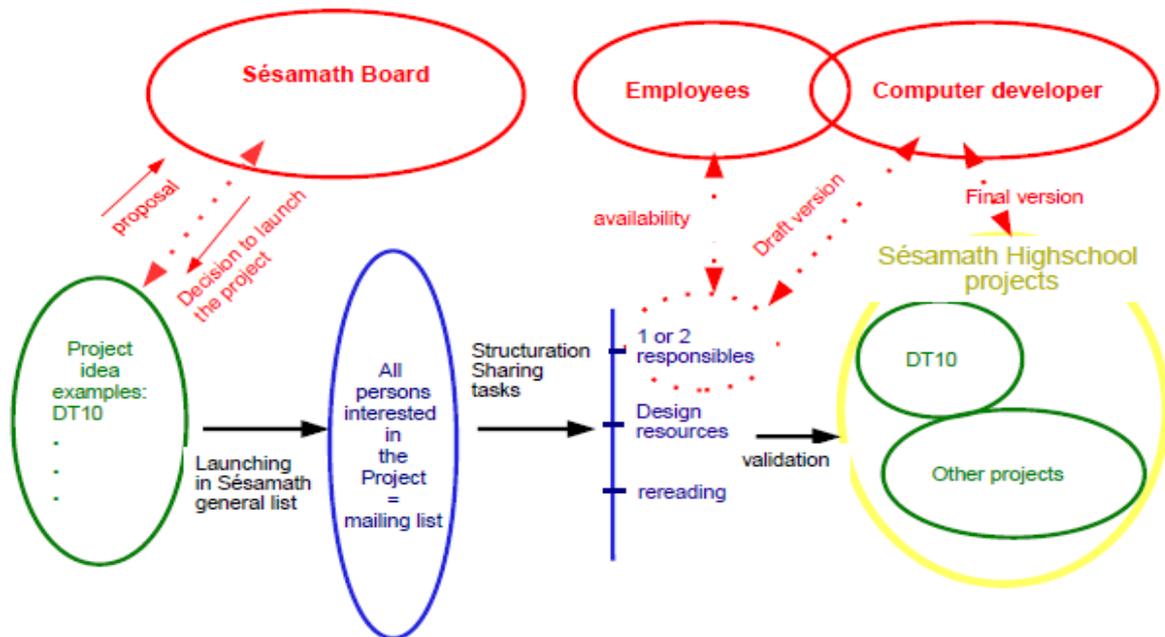

Figure 3. Anaïs's SRCI, our translation (see comments on project groups §3)

We analyze in the following section the didactical aspects of the interactions between Anaïs and DT10 members.

The didactical interaction between Anaïs and DT10 members

The didactical interactions between Anaïs and other DT10 members take place mainly through the project mailing list. Most of the didactical discussion, in the thread “Create textbook chapters”, concerns the theme “mathematics functions”. This discussion came under the PCK category “instructional strategies for teaching the functions”, as it appears in the following extract of DT10 mailing list about the 2N2 chapter (evidencing Adam's role as coordinator):

Ben: We need to cut up 2N2 chapter. What are your proposals?

Pierre: ... How far will we go with the concept of variations? My proposal: 1) the notion of functions variation (from a curve); 2) Maximum and minimum of a function, 3) graph and table of variation; 4) comparison of numbers.

Working Group 15

Anaïs: My proposals: 1) functions variations and graphical reading... 2) variations and calculations: square function ...inverse and linear functions, 3) Maximum and minimum of a function, 4) table of variation.

Adam: I have a slight preference for Pierre’s proposal ... because I think that the table of variation is simpler to understand than computations for comparing numbers ... I think that slowly increasing the difficulty is a good strategy.

Anaïs’s chapter happens following another structure. She first introduces the concept from what she calls a “start-up activity”, with the aim of presenting the semantic values of the “mathematics functions” terminology; then, “the course” where she presents the main definitions (and related examples); at the end, the “series of exercises”, and “homework and assessment”. This structure appears in her online notebook (table 2).

Monday 21/09/2009	Constructing, from a sheet of paper, a box whose volume is the biggest one
Friday 25/09/2009	Definitions: set of a function definition, variable, image, and antecedent. Table of values and graph using a calculator.
Monday 28/09/2009	Area of a rectangle with a given perimeter. Table of values and graph of <i>reference</i> functions (that are inverse function, square function, square root function...)
Thursday 1/10/2009	Different ways of saying that $f(a) = b$
Friday 2/10/2009	Exercises on image of an interval; first assessment.

Table 2. An extract of the Anaïs’ online notebook

In the thread of discussion “Extremum 2N2”, that concerns designing an exercise for 2N2, Anaïs initiates didactical discussions about the terminology:

Anaïs: $f(x)$ is smaller than (or the image $f(x)$ is smaller than?). It seems...

John: For M being a maximum, it must be both an upper bound and an image by f . That is to say, for all x belonging to a given interval I , $f(x) \leq 4.5$, then 4.5 is an upper bound. And it is a maximum if it is also an image of some x belonging to I .

Adam: I propose this formulation: for every real x belonging to I , $f(x)$ is smaller than, or equal to, $f(3)$, which equals 4.5.

Anaïs: Either like this: for every x in the interval I , $f(x) \leq 4.5$ with $4.5=f(3)$.

Also, when she discovered Irvin’s video, she has particularly commented the language used by the teacher:

Anaïs: the expressions ... he says “the straight line $3x + 1$ ”, or the straight line Y . What does that mean? He should say the line whose equation is $y = 3x + 1$.

Me: why does it bother you? How this is a problem?

Working Group 15

Anaïs: I think we should be highly accurate, even when we talk. Being vague or loosely makes fuzzy pupils' mind, especially when introducing new concepts...

We remark a difference between DT10 (more precisely DT10 members taking in charge this question) and Anaïs in the instructional strategies for teaching function. DT10 constructs a “function” concept from very simple tools (reading of curves and table of values), then it moves to more complex tools like calculation and articulation between different types of representation (algebraic, graphical). Anaïs takes care, in her documentation, of the terminology of mathematical concept and its use. This *gap* is an opportunity for Anaïs to discuss her view with other DT10 members.

On another subject, the design of a problem-situation reveals a *convergence* between Anaïs' and other DT10 members' documentation: Anaïs fosters the place of conjecture and experimentation. She presents thus a resource (interview):

Anaïs: I like to ask them first to experiment with a calculator... try first with the calculator, guess the number of solutions ... for example $f(x) = 0$ they speculate with the calculator and ... Once they guess, after they do the proof by calculation. **But I think it is important to first think about from free explorations.**

The thread of discussion “test_2N2” reveals, within DT10, a shared point of view on problem-situation. The problems designed consist in modelling geometrical situations with a function, graphing this function with a calculator and elaborating conjectures before computing and searching for evidence.

CONCLUSION

We have presented in this paper a theoretical approach and a methodology aiming to analyze the didactical interactions at stake within a *community documentation work*. We have carried out this approach and this methodology in the case of a documentation project, DT10, of an online teachers association, focusing on Anaïs, a member of this association.

Anaïs and DT10 have a common interest in collaborating for designing resources and collectively facing *incidents* (like changes in the curriculum). Anaïs has also an individual interest linked to her documentation needs: discussing the mathematics terminology and language, and its values in the documentation work. When Anaïs perceives that didactical discussions are part of her interest, she participates strongly in the community documentation.

Three factors seem to stimulate the active participation of a teacher in the community documentation: osmosis between her resource system and the CoP resources; a gap between the teacher and the CoP in the strategies for teaching a subject; a shared interest in the subject of discussion that is the origin of gap. Following an episode of Anaïs's active participation in the community documentation, we identified an aspect of her professional knowledge: the introduction of a concept has to be based on a precise introduction of terminology and language associated, and its uses.

Working Group 15

This study revealed a question that deserves more deepening: how identifying the effects of the community documentation on the teacher professional knowledge in the case of convergence between the individual and community documentation?

NOTES

1. <http://www.Sesamath.net/>
2. The choice of vocabulary intended to match the terminology of document management research. According to Pédaque (2006), “A document is not anything, but anything can become a document, as soon as it supplies information, evidence, in short, as soon as it is authoritative.” (p. 12, our translation).

DEVELOPING A COMPETENCE MODEL FOR WORKING WITH SYMBOLIC CALCULATORS

Hans-Georg Weigand

University of Wuerzburg (Germany)

There is a worldwide claim that the actual use of Information and Communication Technology (ICT) is only partially integrated into mathematics learning and teaching. Reasons concerning this issue are fairly diverse. One argument might be the complexity of the integration process in the actual teaching. In the M³-project (Model-project with new Media in Mathematics lessons) in Germany, students' knowledge and abilities are evaluated in the frame of a "competence model" while working with a Symbolic Calculator (SC) within the context of the concept of functions. This article demonstrates the way of constructing the (theoretical) competence model while working on different levels of SC-use and while working on different levels of the understanding of functions. It also discusses the results of a first experimental evaluation of this model.

Keywords: Competence model, functions, symbolic calculator, experimental evaluation

There are many suggestions, lesson plans and empirical investigations concerning the use of ICT in mathematical learning and teaching. But despite of the positive results of many of these empirical investigations "the actual use of ICT in real school environments is still having a limited impact" (Bottino & Cerulli, p. 1). This is also noticed quite often in the actual ICMI study 17 (Hoyles & Lagrange, 2010), e. g. "technology still plays a marginal role in mathematics classrooms" (p. 312) or "the impact of this technology (CAS) on most curricula is weak today" (p. 426) and especially in the closing address Michèle Artigue, the president of the ICMI, points out:

"The situation is not so brilliant and no one would claim that the expectations expressed at the time of the first study have been fulfilled" (p. 464).

The complex area of integrating new technology into common school lessons has been underestimated by teachers and researchers (Trouche, 2005).

"Increased technological power, nevertheless, generally goes along with increased complexity and distance from usual teaching and learning environments" (Artigue & Bardini, 2010, p. 1).

We know, especially from the results of the theory of instrumentation and instrumental genesis (Guin *et al.*, 2005), that only local strategies for learning and teaching, for example in the frame of lesson units, will not give successful results. It is necessary to have a global view of the entire learning and teaching process, which includes the teacher, the learner, the content and the learning environment.

In the following, we develop a *competence model*, which shows on the one hand goals of teaching with ICT in the frame of a special content – we have chosen the function concept as one of the most important concepts in the mathematics curriculum. On the other hand, it allows the evaluation, classification or categorization of students' competencies in the use of the digital tool.

FOUNDATIONS OF A COMPETENCE MODEL

The concepts of *competence* and *competence (level) models* have aroused interest in mathematics education in the past years. Starting with the NCTM Standards (1989) and especially the PISA studies, *competence* and *competencies* are expressions, often used in the context of standards, goals envisaged, knowledge and abilities in mathematics education (OECD, 1999; Niss, 2004).

Concerning our competence model, we decided to concentrate on the concept of functions, as it is a central concept in mathematics and in mathematics education. Moreover, it plays a crucial role in our M³-project. These *content competencies* become apparent in understanding functions (UF) and in relation to *tool competencies* (TC) while using the SC.

DEVELOPMENT OF THE COMPETENCE MODEL

Understanding of functions (UF)

Concerning the *understanding of functions*, we use a four level model developed by Vollrath (1993), as these levels are already expressed in special competencies (knowledge, abilities) which students are expected to have at each level:

Level 1: *Intuitive Understanding*

Level 2: *Conceptual Understanding*

Level 3: *Relational Understanding*

Level 4: *Structural Understanding*

The model includes the dual nature of mathematical concepts: processes and objects (Sfard, 1991) and the instrumental and relational understanding of Skemp (1976) [1]. Compared to the models of Sfard and Skemp, it explicitly describes the competencies a learner should have related to the understanding of functions. For detailed information concerning this model see Weigand & Bichler (2010).

Tool competencies (TC)

The ability or the competencies *to use SCs* adequately requires technical knowledge about the handling of SCs. Moreover, it requires the knowledge of when to use which features and for which problems it might be helpful. In the following, *the use of SC* is classified concerning the way representations are used. We distinguish three levels, which might also be categorized by using SCs as a (simple) function plotter, as a tool for creating dynamic animations and as a multi-representational tool:

Level 1: Using the SC as a tool, which produces static representations. We speak of a *Static Mode* (StaticMode).

Level 2: Creating dynamic representations. We speak of a *Dynamic Mode* (DynaMode).

Level 3: Using the SC as a multiple representational tool. We speak of a *Multiple Mode* (MultiMode).

The UF-TC relationship

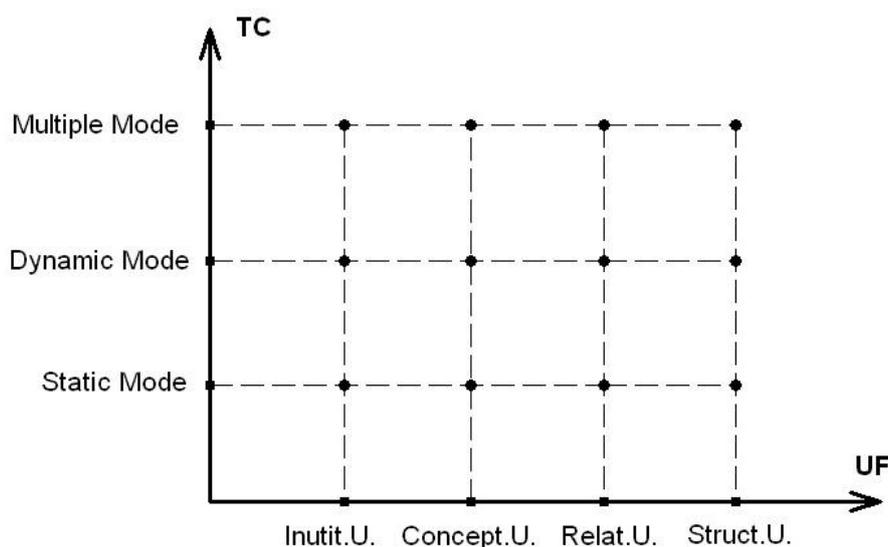

Figure 1: UF-TC-relationship

The relationship UF-TC is established by special problems or tasks, showing on the one hand the level of understanding and on the other hand the way a student uses the symbolic calculator. In Weigand & Bichler (2010), an example for every single cell of the matrix is given.

THE EMPIRICAL EVALUATION OF THE COMPETENCE MODEL

Concerning the empirical justification of the theoretical model and including the aim of constructing an *empirical* competence model, some questions are to be answered.

- *The validity of the model:* Do the solutions of the problems constructed for each cell of the UF-TC matrix require the competencies the cell stands for? To answer this question, problems dealing with the competencies of each cell will be developed.
- *From a qualitative to a quantitative model:* The PISA studies use a model which is based on the relative frequency with which students are able to solve a problem. The problem that has been solved successfully is taken as a measure of the difficulty of the exercise. The scale is standardized on a mean value 500 with a

standard deviation of 100 (OECD, 1999; 2003). This might also be an aim in the context of this competence model.

PILOT INVESTIGATION - TEST QUESTIONS

In a first step, we considered the two-dimensional matrix UF-TC (Fig. 1) and created problems concerning the cells of the matrix. The second step – which is still in progress – will be the development of problems on different levels of “cognitive activation” for each cell of the UF-TC-matrix. In July 2010, nearly 700 students of grade 10 had to solve the following problems. We classified these problems concerning the UF-TC-relationship. This relationship is not unique and depends on the solution strategy of the student. We also classified the problems concerning the representations which might be used – in our opinion – in the problem solving process: numerical (N), graphical (G), and symbolic (S) representations.

Problem A1. Solve the equation $\frac{1}{3}x^3 - 3x - 5 = 0$. Give the solution up to two post decimal positions. Explain!

Intuit.U	Concept.U	Relat.U.	Struc.U		Static M.			Dynamic M.			Multiple M.		
					N	G	S	N	G	S	N	G	S
Functional Understanding					Tool Competencies								

Problem A2. Solve the equation $-\frac{1}{2}x^2 + x - 1 = 0$ graphically! Give the solution up to two post decimal positions. Explain!

Intuit.U	Concept.U	Relat.U.	Struc.U		Static M.			Dynamic M.			Multiple M.		
					N	G	S	N	G	S	N	G	S
Functional Understanding					Tool Competencies								

Problem A3. Draw some graphs of the family of functions f_a with $f_a(x) = a \cdot x^2 - 4 \cdot a + 1$, $a \in \mathbb{R}$. Are there any points which are common to all graphs? What are the coordinates of these points? Give reasons!

Intuit.U	Concept.U	Relat.U.	Struc.U		Static M.			Dynamic M.			Multiple M.		
					N	G	S	N	G	S	N	G	S
Functional Understanding					Tool Competencies								

Problem A4. Given is the function f_c with $f_c(x) = \frac{1}{2}x^2 - 6x + c$, $c \in \mathbb{R}$. For which values of c does f_c have exactly one zero? Give reasons!

Intuit.U	Concept.U	Relat.U.	Struc.U		Static M.			Dynamic M.			Multiple M.		
					N	G	S	N	G	S	N	G	S
Functional Understanding					Tool Competencies								

Working Group 15

Problem A5. Are there any x -values, which fulfill the equation $\sin^2(x) + \sin(x) = 3$, $x \in \mathbb{R}$? Give reasons!

Intuit.U	Concept.U	Relat.U.	Struc.U		Static M.			Dynamic M.			Multiple M.		
					N	G	S	N	G	S	N	G	S
Functional Understanding					Tool Competencies								

The participants of this test used the symbolic calculator for one year in the classroom, for their homework and also in tests and examinations. Polynomial and trigonometric functions are regular content in class 10 in German high schools (Gymnasium).

THE STUDENTS' QUESTIONNAIRE

In order to establish how the calculators were used, we applied a new investigation method: the students completed a questionnaire on the SC-use immediately *after the test*, giving details of whether and how they used the calculator. This test was intended to answer the following questions:

- How do students use the calculator?
- In which phases of a problem-solving process do the students use the calculator?
- Which functionalities (symbolical, graphical or numerical) do the students use?

This research method gives insight into the working style of all students participating in the test. Evidently, it only reproduces the subjective descriptions given by the students. A comparison of the answers of the students and the test results show large conformity and lead us to the conviction that students answered quite seriously. We posed the following general questions:

- a) Did you find the symbolic calculator was helpful when completing the tasks?
- b) Did you experience any difficulties when recording the use of the symbolic calculator in your solution in written form?
- c) Did you have any difficulties operating the symbolic calculator?
- d) Would you agree with the statement that the symbolic calculator gave you a feeling of security when completing the tasks?
- e) If you reflect your so far experienced lessons with the symbolic calculator, did you find them interesting?

THE TEACHERS' QUESTIONNAIRE

Before each test was carried out, the teachers provided an estimation of the extent to which students would solve the problems and how they would answer the general questions a) – e) (see above).

RESULTS

Fig. 2 shows the percentage of students' correct answers to the problems A1–A5 (y-axis: 1 \cong 100 %). The decreasing percentage of correct answers from problem A1 to A4 confirms our assumption – and so the constructed competence model – concerning the increasing difficulty from static over dynamic to multiple tool competencies. Problem A5 plays a special role (it was labeled as an “additional problem” in the test).

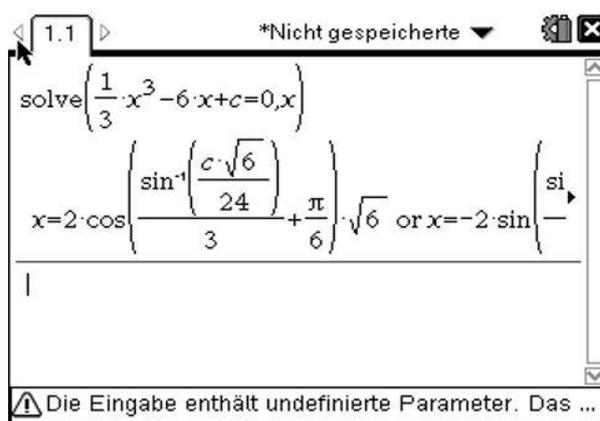

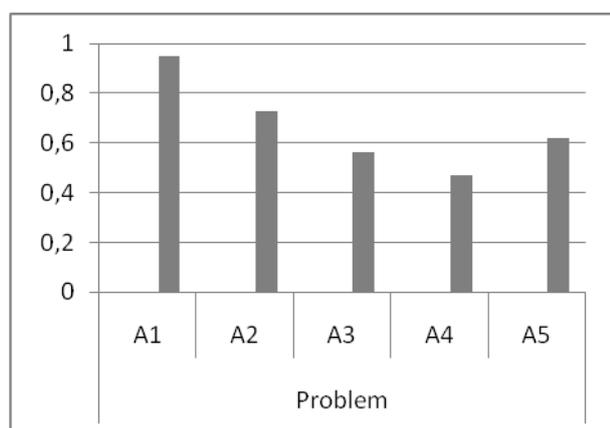

Figure 2: Percentage of students' correct answers

Figure 3: The symbolic SC-solution of $f_c(x) = 0$ (problem A4)

Problem A4 reveals some problems while working with the SC. To find the value for c ($f_c(x) = \frac{1}{2}x^3 - 6x + c$) for which f_c does have exactly one zero, you can try to find a symbolic solution with the SC (Fig. 3). But this solution cannot be interpreted by the students yet and means nothing to them.

Another possibility in order to get the solution is the dynamic representation, where students change c with a slider. Fig. 4 shows the graphs of f_c for $c = 8$ and $c = 8.1$. (For $c < -8$ and $c > 8$ f_c does have only one zero.)

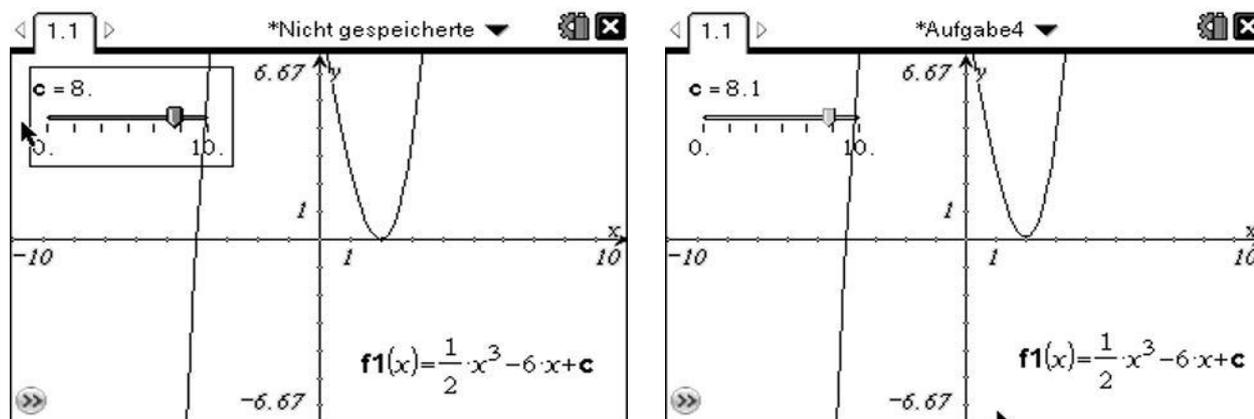

Figure 4: The graphs of f_c for $c = 8$ and $c = 8.1$

Working Group 15

We have got the following incorrect students' answers:

- “For all values from 8 the function has one zero.”
- “Slider $c = 8,1$. From $c = 8,1$ (and more) the function $f_c(x)$ has only one zero.”
- “ $c > 8,1$ the function has one zero.”
- “ $c \geq 8,1$ ”

This shows students' missing ability to think in continuous intervals.

Moreover, is it quite difficult – the students did not know calculus – to *give reasons* for the correct answers. You have to know that for $c = -8$ the graph has $(-2; 0)$ as a maximum and for $c = 8$ it has $(2; 0)$ as a minimum. This gives you the basis for the argumentation.

Fig. 5 shows the percentage of students' answers and the teachers' prediction to the general questions of the questionnaire. It shows especially that the teachers' predictions correlate with the students' answers. This means that the teachers know students' abilities and difficulties quite well. They also notice that solutions and concepts are required to overcome students' obstacles.

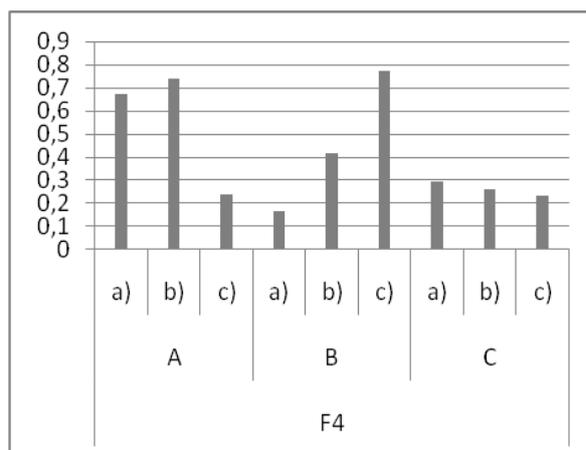

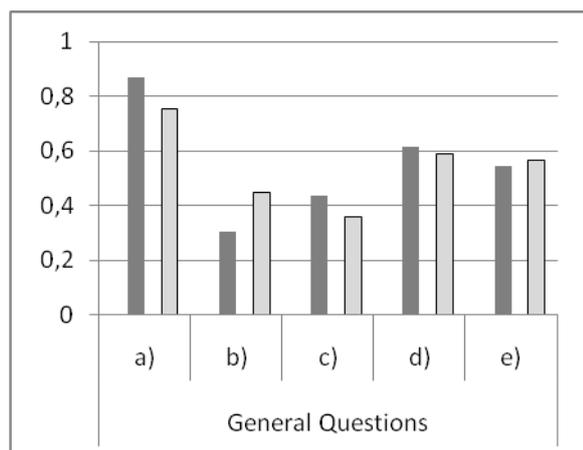

Figure 5: Percentage of students' answers (dark bars) and teachers' prediction (light bars)

Figure 6: Students' answers to the questions how they worked during the problem solving process

Moreover, for each problem, the students had to answer the following multiple-choice questions:

A: When did you use the SC during the problem solving process?

- a) At the beginning b) During the process c) At the end

B: If you used the SC. What have you done with it?

- a) I calculated numerically b) I solved equations c) I drew graphs

C: Which difficulties did you have with the use of the SC?

- a) I have had no idea how to use it

Working Group 15

b) I have had problems with the numerical commands

c) I didn't know how to draw the family of graphs

Fig. 6 shows the percentage of students marking the according answer. The percentage of students who still have had problems with the use of the symbolic calculator after one year of practice is surprisingly high.

FUTURE DEVELOPMENTS

As a diagnostic goal, the competence model has the description of the anticipated aim in the context of the project, but also the detection of the abilities missing whilst students are working with symbolic calculators. But the evaluation or the diagnosis is only the very first step. The second step is to think about consequences based on the evaluation. How can the student be supported to progress to higher levels of understanding and higher competence levels while working with the symbolic calculator?

NOTES

1. Skemp uses the expression “instrumental” in the sense of “rules without reasons” and in a different sense than it is used e. g. in the theory of instrumentation while working with new technologies. He also uses the expression “relational” in a quite open meaning (“Pupils knowing both what to do and why”), whereas in our model it is limited to relations between objects like functions or relations between properties of functions.

INTRODUCTION TO THE PAPERS OF WG 16: DIFFERENT THEORETICAL PERSPECTIVES AND APPROACHES IN RESEARCH IN MATHEMATICS EDUCATION

Introduction to the Papers of Working group 16

Ivy Kidron^a, Angelika Bikner-Ahsbabs^b, John Monaghan^c, Luis Radford^d, Gérard Sensevy^e

^aJerusalem College of Technology (Israel), ^b Universität Bremen (Germany), ^cUniversity of Leeds, (United Kingdom), ^dUniversité Laurentienne, (Canada), ^e INRP Rennes (France)

The diversity of different theoretical perspectives in mathematics education research can be seen as a problem or as a benefit to the advancement of the field. This Working Group, which was established at CERME 4 (2005), seeks to: explore ways of handling the diversity of theories in order to better grasp the complexity of learning and teaching processes; and understand how theories can be connected or not in a manner that respects their underlying assumptions. The central term that emerged from the CERME 4 working group was *networking*. In order to promote the networking of theories it was suggested: to make explicit the level at which a theory operates; to increase our awareness of the underlying assumptions of each theory. Both of these aspects were revisited in CERME 7 where the question of underlying assumptions also concerned questioning *the nature of mathematical objects*.

After a two stage peer review process, 15 papers were accepted for discussion in the Working Group. We revisit the 15 papers to raise themes that emerged from the conference discussion. The first is strategies for networking which includes the dialectical development/transformation of theory(s) and theorist(s) (see Monaghan, 2011) and the semiosphere (see Radford, 2008). We then discuss the 15 papers with respect to the spectrum of networking strategies developed by Prediger, Bikner-Ahsbabs & Arzarello (2008) represented by the diagram below. Then we devote a subsection on the nature of mathematical objects as discussed in the working group.

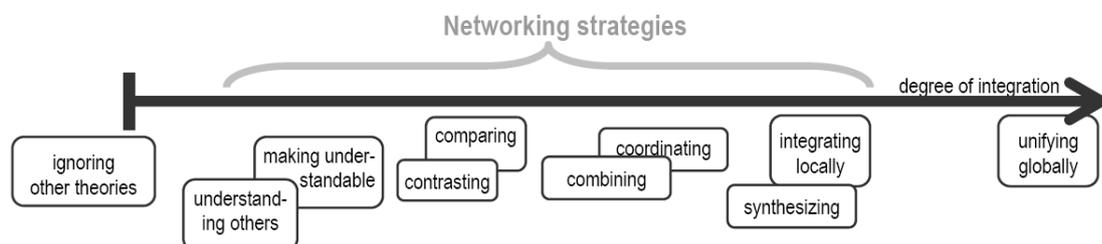

Figure 1: Networking strategies

STRATEGIES FOR NETWORKING

Towards a “theory of networking theories”

A central term that emerged from the working group was *transformation*: after networking researchers are often transformed and are able to see things which they could not see before; negotiating meanings as a sub-issue here concerns the conditions which permit fruitful dialogue; and methods for networking theories can be intentional or implicit. Papers considered under this theme are those of: Artigue, Bosch & Gascón; Mason; Monaghan; and Radford (2008). Although the latter is not a CERME paper, it was repeatedly raised in relation to its idea of *semiosphere*, i.e., a multi-cultural space of meaning-making processes and understandings generated by theories as they come to know and interact with each other. In the *semiosphere*, a theory is considered as a dynamic interrelated triplet (P, M, Q) formed of theoretical principles (P), methodologies (M), and research questions (Q). Strategies for networking depend to an important extent on how “close” or “far” the networked theories are located in the *semiosphere*. Mason’s paper is couched in his discourse of ‘shifts of attention’ (Mason, 2003). He suggests that “theories in mathematics education consist of collections of frame(work)s, which themselves consist of labels for distinctions ... [with] assumptions and values which, when combined with the distinctions, suggest actions that might be taken”. A theory allows one to discern detail through making distinctions. He is critical of the *semiosphere* as a means to compare theories without attending to “the intentions or uses of those theories and to reach mutual clarification of the worlds of experience they occasion, including the phenomena they recognise and at what grain size, and the sorts of conclusions, explanations etc. they afford.” It was argued, however, that the intentional aspect of a theory is already captured in its research question component, Q; in a similar manner, the assumptions and values are embedded in the theoretical principles, P.

Artigue, Bosch & Gascón consider the potential offered by the Anthropological Theory Didactics (ATD) for addressing issues of networking between theories, which they term ‘research praxeologies’. Although ATD developed as a theory within mathematics education, it is sufficiently general to be applied to other spheres of human activity. Praxeologies consist of two blocks each with two elements: (i) practice of research (*types of problems* and *techniques* used in these problems); (ii) the *technological-theoretical* discourse used to describe, justify and interpret both the research practice and the results obtained. An important adjunct is the construct of ‘didactic phenomena’. Some phenomena “enrich the initial theoretical framework to produce new interpretations and techniques or research methodologies, while others remain at the level of ‘results obtained’ and are reinvested to formulate new problems or to propose new diagnostic and practice-development tools”.

Monaghan explores the ‘theoretical genesis’ of an informal meta-theory presented in Ruthven, Laborde, Leach, & Tiberghien (2009), a construct coined in analogy with ‘instrumental genesis’. The analogy has some cogency, both concern an agent

appropriating an artefact for a purpose over time and a dialectic between agent and artefact/theory exists, but Monaghan also explores the limits of the analogy. Factors involved in the theoretical genesis include writing, learning, engagement with research and other voices; making one's theoretical stance explicit to intended journal article readers from a different research culture appeared particularly important. It was recognised, during the working group discussion, that much in Monaghan's paper could be rewritten in terms of research praxeologies.

Some efforts were made to find links between these four approaches to researcher networking; an effort of networking "approaches for networking theories". Initial considerations focused on the possible use of these four approaches in the concrete examples of networking in the papers in the working group, but at this point in time we are not in a position to present an overall schema for how they interrelate (or not) nor to matters which they, collectively, do not address.

DISCUSSION OF THE PAPERS WITH RESPECT TO THE SPECTRUM OF NETWORKING STRATEGIES

Understanding/making understandable

Craig offers a way of exploring patterns of research collaboration within the mathematics education research field. Kaenders, Kvasz & Weiss-Pidstrygach present categories of mathematical awareness (an analytical tool) connected to activity theory.

Comparing/contrasting

LaCroix compares two activity theoretical perspectives with resemblance in their sources: Cultural Historical Activity Theory –Engeström's interpretation and Radford's theory of knowledge objectification. It is argued that the unit of analysis in 3rd generation activity theory is too big to understand micro-genetic development.

Sollervall deals with semiotic representations to negotiate disciplinary and individual perspectives on the notion of meaning in mathematics. He uses Peirce's semiotic triangle and Duval's theory of registers. Peirce's theory is used to develop a unified model of theoretical constructs to account for the role of external representations as mediators of individual meanings in mathematics classrooms.

Combining/coordinating

Douek coordinates socio-cultural theories to answer the question of how to deal with the learning difficulties of poor learners. Goodchild coordinates two socio-cultural perspectives with fundamental differences: the theoretical basis of the Communities of Practice approach is distinct from that of Cultural Historical Activity Theory. The aim is to develop a community of inquiry. Both are (separately) useful for research taking into account two kinds of development: extrapolation and expansion.

Ligozat, Wickman & Hamza and Tabach & Nachliel use networking theories to analyze mathematical classroom discourses. Ligozat et al. look at classroom activities from

different perspectives: the institutional and the participant and combine two theories with focus on social aspects. Tabach&Nachlieli offer an example of networking two theories with focus on socio-cultural and linguistic approaches.

In Santi's paper two semiotic approaches are coordinated which provide (rather like Goodchild's) complementary views of Duval's and Radford's theories which can only be linked in a diachronic way due to strong differences in theoretical principles.

Integrating/synthesizing

Jay's paper deals with difficulties of networking the cognitivist and socio-culturalist perspectives. The reconciliation of perspectives is permitted by a semiotic approach which appears to offer a neutral arena for negotiation of definitions of crucial terms like concept, understanding, learning.

The paper by Kidron, Bikner-Ahsbahs & Dreyfus deals with a second iteration of networking between two theoretical frames. Their first iteration networking focused on two theoretical concepts: the need for a new construct, and interest. A benefit of this previous networking was the insight that besides interest and the need for a new construct, a more general epistemic need (GEN) can drive students' progress in learning processes according to the challenge they meet within a situation. The second iteration concerns the different roles of the GEN from each perspective.

Font, Malaspina, Giménez&Wilhelmi ask "What is the nature of the mathematical objects?" They explore this question by the use of a synthesis between the onto-semiotic approach (OSA), APOS theory and the cognitive science of mathematics (CSM) as regards their use of the concept 'mathematical object'. APOS theory and CSM highlight partial aspects of the complex process through which, according to OSA, mathematical objects emerge. OSA extends APOS theory by addressing the role of semiotic representations; it improves the genetic decomposition by incorporating ideas of semiotic complexity, networks of semiotic functions and semiotic conflicts; it offers a refined analysis due to the way in which it considers the nature of such objects and their emergence out of mathematical practices.

THEMES FOR FURTHER CONSIDERATION

Further to issues already raised we find, in comparing examples of specific networking strategies, that approaches can be very different concerning the function of empirical content. LaCroix is concerned with the phenomena of learning whereas Sollervall seeks to develop a tool for the analysis of empirical phenomena. A similar situation holds with regard to Jay's and Kidron et al.'s papers. Although both papers aim to connect individual and social learning, Jay aims to offer an integrated tool to analyse empirical phenomena whereas Kidron et al. start with the empirical situation building up to a point of integration. At CERME6, a distinction between top-down networking, bottom-up networking and a kind of mix between both was discussed. Our knowledge is still at a level of craft knowledge, but we have experienced

progress in that examples show the potential of networking for improving the quality of research practices gaining linked results. We hope this work towards a *theory of networking theoretical approaches* helps the community develop in the direction of scientifically based multi-theoretical empirical research.

RESEARCH PRAXEOLOGIES AND NETWORKING THEORIES

M. Artigue,^I M. Bosch,^{II} & J. Gascón^{III}

^IUniversité Paris 7 (France), ^{II}Universitat Ramon Llull (Spain),

^{III}Universitat Autònoma de Barcelona (Spain)

Abstract: In this contribution, we consider the potential offered by the anthropological theory of the didactic (ATD) for addressing the issue of networking between theories through the extension of the notion of praxeology, which is at the core of ATD to research praxeologies. After introducing such an extension, we discuss its implications in terms of networking, giving a crucial role to the notion of didactic phenomena. We then use this language for reflecting on two networking experiences in which we have been involved.

INTRODUCTION

In accordance with the work done by the ‘theories group’ in the last two CERMEs, this contribution joins the efforts made to support a productive cooperation in European mathematics education research, in order to overcome the framework compartmentalization that could hinder the capitalisation of knowledge and its practical exploitation. These efforts have shown that the interaction between researchers working with different approaches has to go further than the ‘communication paradigm’ that dominates exchange activities in most international conferences. It needs real ‘teaching and learning’ activities to explain what one does and to understand what the others do. Experiences in ‘networking theories’, carried out in this sense⁸⁰, have shown that their productive development also requires the consideration of a shared epistemological model, that is, a common way of thinking and talking about what scientific work is and how it evolves. In fact any research activity supposes a particular implicit way of interpreting the nature of problems that are approached, the empirical field to consider, the kind of methodologies that can be used and, more generally, what research is and what it is for. When the exchange between researchers attains the level of the theoretical bases – as is the case in the ‘networking theories’ activities –, then it becomes necessary to question the implicit epistemological model of each approach, looking for a common language to express and discuss the respective epistemologies. In this sense, the Anthropological Theory of the Didactic (ATD) that we use in our research and, more concretely, its central notion of ‘praxeology’ has progressively appeared to us as a useful tool to develop such a common ‘language’ or epistemological model. Here we present the recent work we have undertaken in this direction.

⁸⁰ We refer more especially to the so-called ‘Networking group’ led by Angelika Bikner-Ahsbabs that emerged from CERME4 and to the work carried out by the first author in European projects like TELMA and ReMath.

‘THEORIES’ OR RESEARCH PRAXEOLOGIES?

If, according to ATD, we assume the general anthropological postulate that all human activities can be described in terms of ‘praxeologies’ (Chevallard, 1999, 2006), this must be also the case for research activities. Any kind of research, including ‘networking’ projects, should thus be subsumed under the notion of *research praxeologies*. In this perspective, talking about ‘theories’ (as in the expression of ‘networking theories’) is the result of a metonymy used to point to the whole – *research praxeologies* – by only indicating one part, the theoretical block of praxeologies. As any other praxeology, research praxeologies are indeed composed of an amalgam of pieces that can be described by a set of four elements [T/τ/θ/Θ]. The pair [T/τ] corresponds to the ‘practice’ (or know-how) of research, with the *types of problems* *T* that are approached and the *techniques* *τ* used to approach the problems. The block [θ/Θ] forms the *technological-theoretical* discourse used to describe, justify and interpret both the research practice and the results obtained. This theoretical block corresponds to research ‘knowledge’ and is often considered as the representative of the whole praxeology, with the limitations and biases that this reduction can generate in the approach to and treatment of ‘networking’ issues.

We postulate that the notion of praxeology can help overcome these limitations and that it can also be useful to retrospectively reflect on networking efforts. We also find it important to stress that research praxeologies, as any other praxeological form, are ‘alive’ entities that evolve and change, which affects at the same time their four components [T/τ/θ/Θ] and the interaction of these. The evolution of the practical block [T/τ] produces new theoretical needs that make the theoretical block [θ/Θ] progress and, reciprocally, the evolution of concepts, interpretations or ways of thinking and the emergence of new results lead to the construction of new techniques and the formulation of new problems. Research praxeologies can appear as different kinds of amalgams, more or less organised depending on the maturity of the field. It is the historical development of the field that helps structure these praxeological amalgams, making them more coherent and easier to disseminate according to different didactic and institutional transposition processes. Beyond the static description of research praxeologies in terms of their practical and theoretical blocks, processes piloting their dynamics are still to be analysed in depth. Our contribution consists in considering the notion of ‘phenomenon’ and relating it with the ‘technological’ element of praxeologies, which will highlight its crucial role in the dynamics of praxeologies.

‘PHENOMENA’ AND THE DYNAMICS OF RESEARCH PRAXEOLOGIES

The notion of ‘didactic phenomenon’. Today the notion of ‘phenomenon’ does not happen to have a central function in many didactic approaches. It did however play a crucial role in the emergence of the theory of didactic situations (TDS) and its vision of didactics as a scientific discipline. In the first developments of TDS in the 1980s,

and through several different formulations, Guy Brousseau (1997) defined didactics of mathematics as the science the essential aim of which is the knowledge of *didactic phenomena*, that is, phenomena appearing in the teaching, learning or, more generally, diffusing of mathematical knowledge in social institutions (including school ones). Hence, didactic phenomena have to be considered both as a construction and as an object of study of didactics, in the same way that physics studies the specific construction ‘physical phenomena’, or sociology studies and also defines social phenomena, etc. –including all the historical controversies about phenomena delimitation in nature and social sciences.

What is the role played by *phenomena* in relation to *research praxeologies* and their evolution? In a first approach, we can characterise didactic phenomena as empirical facts, regularities that arise through the study of research problems. Some of these phenomena enrich the initial theoretical framework to produce new interpretations and techniques or research methodologies, while others remain at the level of ‘results obtained’ and are reinvested to formulate new problems or to propose new diagnostic and practice-development tools. In order to clarify the relation between the notion of phenomenon and the four components of a praxeology, let us start from a very simple example of mathematical praxeology. Let us consider Pythagoras’ theorem or, to be more precise, the phenomenon underlying this theorem, that is, a certain regularity between the measures of the sides of right triangles. At the beginning we can consider a *type of mathematical problem* that could be formulated as the problem of the characterisation of a right triangle or the graphical representation of a right angle. The answer to this problem appears as a *technological element* (the description of a property of a given set of figures) within the mathematical praxeology that emerges around this type of problems. This technological element is not only the description of a regular fact: it also produces new *mathematical techniques*, helps formulate *new problems* and discover new regularities, thus producing more *technological results*. In the long run, if the initial regularity appears to be strong enough, then it comes to integrate the *theory* of the praxeology as a basic principle of certain kind of geometries (those with a Euclidian metric).

It is thus an entire mathematical praxeology, with its types of problems, its techniques and its technological-theoretical discourses that the expression ‘Pythagoras theorem’ refers metonymically to. Behind a technological ingredient such as a theorem – or any other description of a regular fact or *phenomenon* – we can find a whole set of praxeological ingredients (problems, techniques, etc.), which this technological ingredient contributes to structure. Taking all necessary precautions, we will briefly establish a parallelism between this example and research praxeologies in didactics. We will use a concrete example, the phenomenon

of didactic transposition, to illustrate our proposal⁸¹ which is to see the role played by phenomena in the ‘structuring’ of praxeologies, that is to say in their *dynamics*.

Phenomena and type of problems. As any scientific discipline, didactics of mathematics aims at identifying and studying a specific kind of phenomena (didactic ones) in order to attain a greater capacity of action and comprehension. Any research question or problem thus has to be related – even if this relation is mostly done a posteriori – to the highlighting of a phenomenon, its delimitation, the conditions needed for its existence and evolution, etc. Even if research takes as a starting point a problem emerging from a very concrete teaching or learning practice (as it often does), an effort is always made to formulate the problem in a more general way, implicitly considering it as a specimen of a given ‘type of problem’. This is a first step in the work that follows: looking for regularities related to the practical issue approached, trying to characterise them and, to some extent, ‘understand’ or ‘act upon’ them. Let us consider, for instance, the phenomenon of didactic transposition as it was characterised by Yves Chevallard (1985). Several new problems have been raised and studied that could not even have been formulated before the identification of the phenomenon (see Bosch & Gascon, 2006 for a recent review).

Phenomena and technological components In research processes, the results obtained as an answer to the raised problems generally contribute to enrich the initial research technology by integrating new characteristics of the studied phenomena or even new derived phenomena. There always exists a double-direction effect between the results obtained and the evolution of the technology of research praxeologies, which can be considered at the core of progress of scientific research.⁸² For instance, the study of transpositive processes in different mathematical domains has highlighted various phenomena that, in turn, have been used as a starting point to formulate new problems and draw attention to new regularities. A good example is the phenomenon of the ‘algebraisation’ of Calculus at upper secondary school level (Artigue, 1995), a result that has then been used to analyse the teaching of limits of functions (Barbé et al., 2005). Other examples coming from the didactic transposition processes are the derived phenomenon of the ‘stoppage’ of didactic transposition (Assude, 1993) or of ‘detransposition’ (Antibi & Brousseau, 2000).

Phenomena and technical components The study of phenomena not only generates the description of regularities, restrictions or ‘paradoxes’ (like those of the ‘didactic

⁸¹ We are perfectly conscious of the distance between mathematics and didactics as fields of research. However, commonalities can be established and can be productive in both senses: sometimes the maturity of mathematics hides some evolution phenomena that are more visible in the recent and less developed dynamics of didactics.

⁸² This is less true when the theoretical block of the research praxeology comes from a different discipline. We then obtain a single-direction effect which ‘breaks down’ the dynamics of scientific research: for instance, when a given notion of cognitive psychology is used to analyse some facts related to the learning of mathematics, because the ‘external’ character of the results obtained, they will have no effect on the development of the initial psychology notional frame.

contract', for example). It also leads to new ways of doing research, that is, new techniques and new methodologies. In the case of transpositive phenomena, the highlighting of relations and differences, both chronological and diachronic, between the 'scholarly knowledge', the 'knowledge to be taught' and the '(actually) taught knowledge' has now become a technique of didactic analysis by itself. Almost any problem studied within the ATD or the TDS includes, to some extent, a questioning about which is the knowledge at stake, where does it come from, what 'scholarly knowledge' legitimises its teaching, what changes have been operated on it, what 'noospherian' discourses support or hinder its teaching, etc. The notion of didactic transposition has represented an important enlargement of the field of study of didactics because it has pointed out the need to also consider the mathematical activities that exists outside the school (Bosch and Gascón, 2006).

Phenomena and theoretical components. In a praxeology, the 'theory' component includes the set of notions and relations that are used to apprehend phenomena (describe them, formulate questions about them, etc.), to develop them and to identify new regularities. The 'theory' appears as the second level of validation of the activity, as an explanation and justification of the 'technology'. It contains the assumptions taken, that is, the technological elements that come up being taken for granted because of their solidity and persistence. At this level we find questions such as: What phenomena are studied? What is a problem in didactics? Why can this or that result be assumed as such? The empirical enlargements mentioned before are also integrated at this level as far as they become basic and implicit assumptions. At the same time, the unit of analysis that is assumed determines the kind of phenomena that can be considered and the kind of data that are being collected to bring evidence to the study. For instance, the existence of transpositive processes between institutions is a theoretical assumption that is not questioned, nor questionable, in ATD. The 'kind' of transpositive processes that are taking place, their main characteristics and the conditions and restrictions they create on teaching institutions are, on the contrary, some of the main problems considered by this approach.

The praxeological dynamics we just described may help understand the processes through which the studied phenomena produce new technological results that partially become new theoretical tools and produce in turn new research techniques allowing the identification or construction of new phenomena. It is this praxeological dynamics that we propose to consider here in order to analyse – and guide – two networking experiences between European research teams.

THE EXPERIENCE OF THE GROUP « NETWORKING THEORIES IN MATHEMATICS EDUCATION »

The working group on 'networking theories' was created in 2005. It includes 12 researchers from six different countries and its work aims at the exchange, comparison, and connection between theoretical frameworks. Results obtained have

Working Group 16

been presented in previous CERMEs and more recently in a research forum at the last PME conference (Bikner-Ahsbals et al., 2010). In this section, we analyse an episode of its work, already evoked at CERME6 (Artigue, Bosch, Gascon & Lenfant, 2010), with the aim of showing how research questions and theoretical components of praxeologies influence research methodologies (technical components), the units of analysis considered pertinent, and the didactic phenomena identified.

The initial work of the group was based on a video realized in a grade 10 Italian classroom and additional material considered necessary for its analysis by our Italian colleagues. Each team was asked to analyze the video from its own theoretical perspective but the data provided was judged insufficient by each except the Italian team. The video showed two students working in a pair, with little intervention of the teacher. Additional information provided on the session itself and its context was quite limited, making an analysis supported by TDS very hypothetical and an analysis supported by ATD nearly impossible. A questionnaire was then addressed to the teacher in charge of the classroom, asking for additional information to allow the different teams to complement the partial analyses already carried out. In the teacher's answers, the attention of several members of the group was especially attracted by the following excerpt:

I try to work in a zone of proximal development. The analysis of video and the attention we paid to gestures bring me to become aware of the so called 'semiotic game' that consists in using the same gestures of students but accompanying them with a more specific and precise language in a relation to the language used by students. Semiotic game, if it is used with awareness, may be a very good tool to introduce students to institutional knowledge.

This convergence of interests led the group to develop a new strategy for progressing in the collaborative work undertaken: The TDS team should associate a question articulated in the TDS framework to this excerpt, and then each of the other teams should rephrase this question according to its own perspective. We reproduce below the text introducing the TDS question, which in fact also uses some ATD constructs.

The connection between the mathematics produced by students in what we would label, using the TDS frame, an adidactic situation through interaction with the adidactic milieu of this situation on the one hand, and the institutional knowledge aimed at on the other hand, generally requires at least changes in the ways the mathematics at stake is expressed in order to progressively tune these it conventional forms of expression. The teacher considers that he has a specific mediating role to play for making this connection possible and uses semiotic games as a tool for that. In other terms, semiotic games can be considered as components of the praxeology (or more certainly one of the praxeologies) that he has developed in order to solve this didactic task.

The expression "semiotic game" thus denotes what can be seen as a technique, a component of a teaching praxeology, resulting from the identification of some particular phenomena of semiotic mediation. Interpreted that way, it shows how a theoretical focus (in this case a semiotic focus) can lead to the identification of

specific phenomena, and from that to theoretical constructs or to didactic techniques, considered as tools for improving the efficiency of learning and teaching processes. A TDS perspective leads to question the efficiency of such a didactic praxeology for two reasons at least. The first one is that very often interactions with the adidactic « milieu » do not guarantee the possibility of establishing a direct connection with the institutional knowledge aimed at. These limitations are the source of different didactic phenomena identified as paradoxes of the didactic contract: Topaze effect, Jourdain effect, meta-cognitive slide. The second reason is that the adidactic situations most often observed in classrooms are situations of action, not situations of formulation. In such situations, some linguistic activity generally takes place but it is not taken in charge in the piloting of the situation through didactic variables.

From this perspective, the video analysis leads to the postulate that, in this particular context, the distance between what the students have autonomously produced and the forms of knowledge aimed at by the teacher, as expressed in his answers to the questionnaire, makes problematic the productive character of such a *semiotic game*. Thus the question proposed to the group:

Do the episodes at our disposal allow us to identify characteristics of the semiotic game technique that would help us to understand their potential for compensating the possible limits of the interaction with the adidactic milieu for achieving the expected mathematical goals, and linguistic evolution linked to the needs of institutionalization processes?

In the networking group, each team has rephrased this question from its specific theoretical perspective. This episode shows how the consideration of a new theoretical framework, here TSD, can lead to question a didactic praxeology, legitimately considered as a research result in another didactic culture. For addressing this question, a new research praxeology has been developed, a research praxeology which had no reason to emerge in either of these didactic cultures and only exists because a specific networking activity has been undertaken. In the limited space of this contribution, we cannot present the results produced by this research praxeology, nor their elaboration into didactic phenomena. We nevertheless hope to have shown up to what point the relationships existing between the different components of research praxeologies and the didactic praxeologies emerging from research results, deserve our attention. We also hope to have shown that an approach in terms of praxeologies can be helpful for addressing networking issues.

THE EXPERIENCE OF THE EUROPEAN PROJECT REMATH

The experience of the European project ReMath (<http://remath.cti.gr>) offers complementary insights for putting to the test an approach of networking theories in terms of research praxeologies. An essential goal of this project was to support the capitalization of research on digital technologies in mathematics education, through the development of an integrated theoretical framework, with a focus on the affordances of digital technologies for mathematics learning in terms of

representations, and more globally of semiotic activities. Six European teams worked on this project during four years, relying on the previous experience of the European research team TELMA (Artigue, 2009). A sophisticated methodology was developed for this project. It relied on a meta-language created in TELMA and a system of cross-experiments using the same digital technology in different didactical cultures, whose negotiation, implementation and analysis was taken itself as an object of research. This project also allowed the researchers involved to insert the networking activity into a permanent dialogue between the design of digital artefacts and the design of scenarios for their educational use in different educational contexts.

Looking back at this project through the lens of research praxeologies, it looks clear that the methodology used allowed the ReMath teams to organize their work around the collective study of their respective research praxeologies. These research praxeologies were made explicit enough in their different components for ensuring the productivity of comparative analyses, and particularly that of the cross-case studies of the different experimentations carried out with the same digital artefact. The articulation of common research questions to be addressed by the different cross-experiments and then the addition by each team of questions reflecting its specific concerns, the strict organization of interactions between teams all along the process, from the design of artefacts to the a posteriori analysis of cross-experimentations, the meta-language of concerns, played an essential role. The design of artefacts and the cross-experimentations contributed ipso facto to two different types of research praxeologies: on the one hand, praxeologies inserted in the didactic culture proper to each team and, on the other hand, a “networking praxeology” still in development. The problem addressed by the first ones was the identification of the learning affordances of the systems of representations of mathematical objects implemented in the six digital artefacts, and of the conditions for a possible ecology of these in realistic contexts. The problem addressed by the second one was networking between theories. It situated at a meta-level with respect to the first ones, and the results it produced have a different nature. Some are methodological and a priori regard more the practical block of this networking praxeology, for instance those concerning the technique of cross-experimentation, an essential ingredient of the networking praxis progressively refined. Some are more likely to contribute to its theoretical block. This is the case for the boundary objects identified for facilitating the communication between the theoretical frameworks at stake and for the STF (Shared Theoretical Frame). Some results show the possibility of connections and even offer partial integration of theoretical frameworks while some others identify limits to such ambitions, but it is worth noticing that, at this stage, none of these results has been given a clear status of phenomenon. Due to these characteristics, there is no doubt for us that a systematic a posteriori analysis of the ReMath project using the notion of research praxeology should be helpful

CONCLUDING REMARKS

The retrospective analysis of the two research projects outlined above seems to confirm our initial postulate that networking between theoretical frameworks must be situated in a wider perspective than that consisting of the search for connections between the objects and relationships structuring these. From this point of view, our approach is fully coherent with that developed by Radford (2008) who, defining a theory as a triplet made of a system of principles, a methodology and a template of research questions, insists on the necessity of considering these three components in networking activity. Space limits do not allow us to enter into a comparison of our approach with that presented by Radford conceiving a network of theories as a semiosphere, but we hope that the discussions in the CERME Working Group will contribute to clarify similarities and differences. In our approach for instance, the notion of phenomenon appears as a crucial notion for understanding the dynamics of research praxeologies and the evolutionary links between their different components, while the word phenomenon is absent from Radford's text. This is an intriguing difference which certainly needs to be collectively analysed and discussed.

Our reflection tends to show that an approach in terms of research praxeologies can be productive for networking between theories, especially because it helps address the essential issue of the functionality of theoretical frameworks, by inserting these in systems of practices. Networking between theoretical frameworks, if considered as a task to be solved, requires nevertheless the development of specific praxeological elements that cannot be separated from research praxeologies. The European projects evoked above attest the existence of such elements, with emerging techniques and embryonic technologies made of classifications, structured landscapes, meta-languages. The model of praxeologies could thus help us compare the different existing efforts of networking and develop more productive ones. This is nevertheless only a hypothesis which has not yet been seriously worked out. Finally, we would like to stress that when adopting such a perspective, one must remain sensitive to the fact that this approach, as any other one, can also introduce some limitations. Considering them is indeed part of the epistemological vigilance required in any research process.

EXPLORING FRAGMENTATION IN MATHEMATICS EDUCATION RESEARCH

Ayshea Craig

Institute of Education, University of London

This paper reports on a study which uses techniques from social network analysis to explore patterns of research collaboration within the mathematics education research field, focusing on English language publications. The results suggest that the perceived theoretical or methodological fragmentation in mathematics education does not translate in a straightforward way into a fragmentation between researchers. This result is used to argue for a method for connecting research practices complementary to some of those discussed in previous papers in the CERME working group. Namely, that existing collaborations could be used to promote increased theoretical or methodological coherence across the research field when combined with the strategies already developed by the group.

INTRODUCTION

One of the reasons often given for addressing the multiplicity of theoretical perspectives and approaches in mathematics education and for attempting to connect them has been to reduce the perceived fragmentation and diversity in the field (Prediger, Bikner-Ahsbals, & Arzarello, 2008; Prediger, Bosch, Kidron, Monaghan, & Sensevy, 2009). The field has been criticised (from within and without) for lack of coherence, for failing to build on previous results and for susceptibility to fashion and cyclically reinventing old ideas (see for example references in English, 2002; Maasz & Schloeglmann, 2008; Sierpinska, 2003). The fragmentation and diversity is not just a result of lack of agreement about the theoretical framework we should work in, or even about whether we should work in one, or what role it ought to play. It can also be understood as a result of the social organisation of research and the conditions under which it is carried out, in particular, its openness as a field to political and other external influences, the different national contexts (intellectual, social, political) in which it is carried out, and the diverse educational and training backgrounds of those carrying out research.

Any programme for managing the fragmentation and diversity of the field needs to draw on an understanding of the state of the field and the mechanisms which have led to and perpetuate the current fragmented state. Based on such an exploration we can recognise and develop possible mechanisms for change and ask questions about the social conditions necessary for change. Additionally, the social conditions of research place constraints on the goals which are possible in addressing the theoretical and methodological diversity of maths education research. An awareness of this adds an important dimension to discussions of what mathematics education research as a field should aim to be, or how it ought to develop.

Working Group 16

Discussions in the papers of the CERME working group on theoretical diversity in the European mathematics education research community and ZDM special issue 40(2) have made a move from the abstract discussion of principles etc. to more concrete attempts to connect theories and this move has been accompanied by questioning of the different ways in which theory can be defined, and (to a lesser degree) the nature of theory and theory/practice relationships. In particular, the idea of theory has been developed and expanded by a number of authors beyond assumptions, principles and concepts, to include methodologies, research questions and even 'ways of seeing'. This is a change of focus from theories themselves to theories-in-use in research and through that to research practice more generally (see, for example, the final remarks in Prediger et al., 2009), where this practice can be seen as a theoretically guided activity. This move from connecting theories to connecting research, or research practices, or even to connecting researchers and the accompanying changing goals, suggests that there may be some value in revisiting the initial assumptions about the theoretical fragmentation and diversity of approaches in mathematics education and to ask what these mean in terms of research practices and researchers. Although we can sketch an a priori argument for the possible value of revisiting these assumptions, and that of exploration of the social conditions of research in mathematics education more generally, any particular implications, for understanding and managing diversity, must be demonstrated empirically.

In the study reported here I use techniques from social network analysis in order to examine evidence of fragmentation or diversity through existing collaborative research links between mathematics education researchers. We might expect that the theoretical and methodological divides would be seen in patterns of collaboration, since we would expect individuals using the same theories or working within the same perspectives to be more likely to collaborate with one another than with those working with different theories. This would then be evident in collaboration patterns with more densely connected groups loosely connected to other groups.

In looking at collaborations using social network analysis we create only one of many possible views of relations in mathematics education research, but an important one. Collaboration which results in a research publication implies a strong connection and investment of time. We might assume that even outside of the connecting theories endeavour, research collaborations are places where ideas meet, are elaborated and negotiated, both in the research process and in order to create a joint production which all parties are happy to put their name to. As such, evidence of connectedness across the field at the level of research collaborations would raise questions about assumptions of fragmentation of theoretical frameworks and research approaches, leading us to question the nature of this fragmentation.

This research is part of a larger project looking at the mathematics education research community in England and so focuses on collaborative links both within the

group of researchers based in England and between these researchers and the broader mathematics education community. My analysis suggests that these mathematics education *researchers* as a group are less fragmented in terms of their research collaborations than perceptions of theoretical and methodological fragmentation in the field, and in particular of mathematics research in England, might suggest.

METHODOLOGY

The study reported here using techniques from social network analysis to explore patterns of collaboration within the mathematics education research community using data collected from a large number of co-authored research papers.

The data used consisted of all research papers published in nine, largely English-language, international mathematics education journals between 2000 and 2009. Short editorials, book reviews, and announcements were excluded. Five journals were more general: *For the Learning of Mathematics*, *Educational Studies in Mathematics*, *Research in Mathematics Education*, the *Journal for Research in Mathematics Education* and *ZDM-International Journal on Mathematics Education*, along with four more specialised journals: The *International Journal for Technology in Mathematics Education*, the *International Journal of Computers for Mathematical Learning*, *Teaching Mathematics and its Applications* and the *Journal of Mathematics Teacher Education*. Journals in which English authors more commonly publish were preferentially selected, as the broader study, of which the reported research is a part, focuses on England. The final data set included 2264 papers in total, of which 1098 had more than one author.

In social network analysis (Hanneman & Riddle, 2005; Scott, 2000) individuals and the relations between them are modelled as the nodes and edges of graphs or networks. Tools from graph theory, along with some developed for use in the social sciences, are then employed to analyse and visualise these networks in order to explore or answer particular questions about their structure. In this study, researchers were represented by nodes and two researchers were linked by an edge if they had co-authored at least one paper in the data-set. Exploratory analysis of the resulting network focused on the number and sizes of connected sub-graphs (or components), how centralised the network was, whether there were relatively isolated sections, and how dense the connections were. Some of these measures are based on the distances between nodes within connected components of the network: the *degree of separation* of a node is its average distance from all other (connected) nodes and the *average degree of separation* for the component is calculated by taking the average of this value across all the nodes in the component. This type of measure can be used to make comparisons with other networks. *Cut-points* are nodes or edges which would disconnect sections of the network if they were removed. These can be used to explore how robust the features of the structure are, and as a measure of 'connectedness' by asking how hard it is to disconnect groups of nodes.

RESULTS & DISCUSSION

The list of 2264 research papers was used to generate a list of authors publishing in the journals and to identify who they had written papers with. Overall 2199 unique authors were identified, 1737 of whom had written a multiple authored paper in at least one of these journals within the ten year period specified. A further 462 authors only produced individually authored papers, i.e. they had not collaborated on any papers in the dataset. Most of the authors (66%) published only one paper within these nine journals, with 17% publishing two papers, 12% between three and five papers and only 3% of the authors publishing more than five.

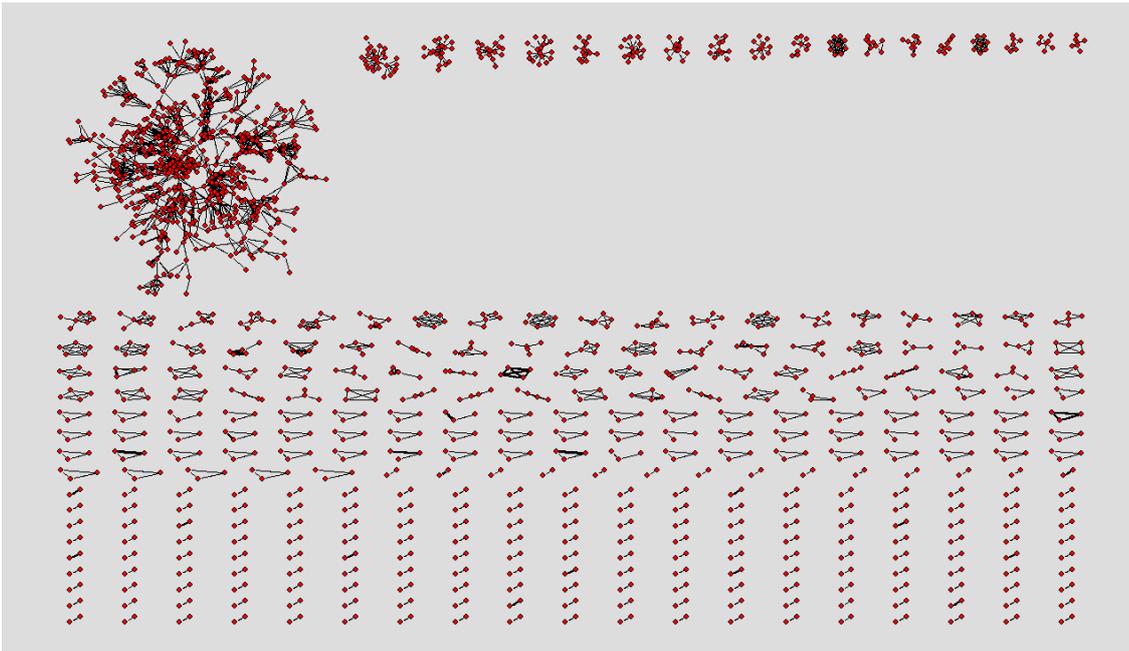

Figure 1: Visualisation of the collaboration network of links between authors, generated using the freeware package Pajek (<http://pajek.imfm.si/doku.php>)

Figure 1 shows the visualised network of collaborations produced from this data. In the figure, researchers are represented by nodes and two researchers are joined by an edge if they have published a joint paper (authors who did not collaborate at all are excluded to save space but could be represented as 462 additional isolated points). The most striking feature of the network is that it has a single ‘giant’ connected component, seen here at the top left, containing 28% (or 612) of the authors. The remaining authors are all connected through collaboration to smaller groups of at most 27 authors. This pattern of one giant component and a number of much smaller connected components is characteristic of scientific collaboration networks (Newman, 2001, 2003) and is a pattern which proved to be robust to the addition and removal of particular journals (although the percentage coverage of the giant component varies).

I will use two particular results from my early descriptive analysis to address the question of the fragmentation of the field at the level of researchers. The first result

is that theoretical divides or other fragmenting factors discussed in the literature aren't seen at the level of patterns of collaboration. Of course within small research groups this is the case, with many joint papers turning into a dense cluster in the network. However, looking for larger groups we see little evidence of clustering.

Analysis of the structure of the giant component to identify subgroups of more densely connected researchers reveals a 'small worlds' structure (Newman, 2001). This is as expected; small world structures arise naturally in many diverse systems. The average degree of separation of two nodes within the giant component is 7.6 i.e. researchers are connected to one another by on average a chain of only six or seven intermediate collaborators, with a maximum distance of 18. Overall the giant component is characterised by small distances between researchers and few (significant) cut points meaning that the structure is quite robust to the removal of ties or individuals.

This can be contrasted with patterns of collaboration in the hard sciences which are traditionally considered to be much less fragmented and more theoretically and methodologically coherent than mathematics education research. The measures of distance within the giant component are comparable (although his study used a much larger data set) with measures from Mark Newman's study of collaboration patterns in the hard sciences (Newman, 2001). In fact, Newman's study showed average distances of between 4 and 7 in six databases drawing on different areas of research and of 9.7 in a computer science database. In other words, there is a subset of mathematics education researchers with mutual patterns of collaboration which are not obviously more dispersed than those found among scientists in the hard sciences, particularly when compared to the sciences with lower average numbers of authors per paper. Unfortunately there are few similar studies of other social sciences with which to compare.

The second result from the network analysis relates to the proportion of the authors found within the giant component, in other words the proportion of authors connected to a significant number of other mathematics education researchers by collaborative links. Only 28% of all the authors publishing in the nine journals over the ten year period were connected in this way (or 35% of those who had published collaboratively). This is a low proportion compared with that found in studies of the hard sciences, which was over 50% in all subject areas examined and closer to 80 or 90% in many (Newman, 2001). The low proportion in the data is relatively robust to the removal, interchange or addition of journals (any 8 of the 9 producing a giant component covering 20-30% of the authors). This suggests that the low proportion is not just an artefact of the particular publications selected, nor a result of the relatively small number of publications being considered. Of the 1587 authors outside the giant component it is useful to separate them into two groups: around 70% of these have collaborated, but their collaboration still leaves them relatively isolated. Most are connected through collaboration (meaning that we consider their

collaborators and their collaborators' collaborators and so on until there are no more connections to exploit) to only a small number of other researchers (on average to 4.4 others outside the giant component). The other 30% of authors outside the giant component have not collaborated on any papers within the data set. This significant proportion of *authors* who have not collaborated in the data set (21% of the total authors), along with the large number of *papers* in the original data with only one author (52%), is another point where the results differ sharply from patterns of collaboration familiar from the sciences. Even within subjects like mathematics, where working alone has traditionally been seen as the norm, there has been a trend of increased collaboration (Burton 1999 cited in Burton & Morgan, 2000). It would make an interesting further study to look at whether trends in mathematics education tend towards more or less collaborative research.

Interpreting this result requires more information and further research. We might ask what it means in practice to be inside or outside of the giant component in this maths education collaboration network. A researcher may tend to work alone but be actively involved with the community in other ways, or they may work alone as a result of geographic or institutional isolation; they may largely collaborate outside mathematics education, straddling several fields, or they may have published only one or two papers as part of a doctorate before leaving academia; they may publish occasionally but see the bulk of their work as lying outside research, in teaching, policy-making or administration for example. Clearly there are many different research profiles compatible with a position in the relatively unconnected sections of the network diagram, and so any single account will fail to capture this diversity of experience. Within the UK, education academics work in widely differing institutional contexts, with different patterns of research funding and different balances between their research and teaching functions (Lawn & Furlong, 2007; Oancea, 2005); additionally the career backgrounds of academics differ with many second-career researchers with varied experiences of research training (Mills et al., 2006). It may be that the giant component can be interpreted as representing a core of research-focused academics who focus on mathematics education and that the fragmentation of mathematics education can be partly understood through the relatively small size of this core with respect to the overall number of people publishing in the area.

FOCUS ON COLLABORATION IN CONNECTING THEORIES RESEARCH

Debate about the strengths and weaknesses and mutual compatibility of particular theories has a long history (Bikner-Ahsbals & Prediger, 2006; Cobb, 2007; Sierpiska & Kilpatrick, 1998; Sriraman & English, 2005) and more recently this tradition of abstract discussion has been joined by moves (within the working group on theory at CERME 4, 5 and 6 and associated special issues of ZDM) to take a more practical approach to the problem by exploring strategies to connect theories in the context of empirical research.

One consequence of the move from debate about theories to practical strategies to connect theories is that it seems to have necessitated a different sort of engagement with the idea of theory. Discussions of the different ways in which theory can be defined for the purposes of connecting theories (Bikner-Ahsbabs & Prediger, 2006; Radford, 2008) or thought about in relation to empirical research (Cerulli, Trgalova, Maracci, Psycharis, & Georget, 2008; Prediger, 2008) can be seen as grappling with the difficulty in separating theory from theory-in-use. The use of ‘static’ definitions of theory has been challenged, introducing the idea that theories are tied up in the work of those who use and write about them and hence that a more fluid or ‘dynamic’ idea of theory is needed for a discussion of connecting theories through research (Prediger et al., 2008). In particular a possible change of emphasis has been suggested from networking theories to ‘the *networking of research practices*’ (Prediger et al., 2009, p. 1534, emphasis in original).

These changes of focus have brought with them the need to reconsider what might be the possible aims or goals for explorations of diversity and attempts to connect theories (ReMath first deliverable quoted in Artigue et al., 2009; Prediger et al., 2009). Across the papers of the CERME working group and the ReMath project there are discussions of important outcomes in terms of the ways researchers see their own work differently as a result of working with others who use different theoretical ideas (e.g. Trgalova, 2008). These experiences are described as a valuable part of the work by many, yet it seems clear from the discussion that it is an individually experienced result of the actual process of engaging with others in theory-focused research collaboration, rather than an insight which can be shared in a straightforward way with others or which might be seen as a tangible result of the research. Given the experiences reported, a valuable additional way of looking at the research of the CERME working group on theoretical and methodological diversity, and of thinking about the ways in which it could contribute to reducing the fragmentation of the field, might be to think of it as an exploration of the potential of collaboration, where that collaboration focuses on connecting theories and approaches to research, to act as a mechanism for change in dealing with fragmentation in mathematics education research. This move is consistent with the change of focus from connecting theories to connecting research practices.

CONCLUSION

I argue that the significance for mathematics education of the relative ‘closeness’ of researchers working with very different approaches and from different theoretical perspectives within the field of English-language publications is in the potential it suggests for using these collaborations to develop a greater sense of coherence in the field. Strategies developed from the connecting theories literature could play a role in developing the potential of existing collaborations. To explore this potential further suggests the need for work on the nature of existing collaborations and the extent to which researchers bring different theoretical perspectives into focus and debate when

Working Group 16

collaborating, and whether this process could come to be seen as part of what is worth reporting about the research process. In doing this it would be important to recognise different ways of collaborating and working. The pattern of working illustrated in the data here suggests that in order to use collaboration as a mechanism to increase the coherence of mathematics education what may be needed is not necessarily more collaborations between researchers working within different theoretical traditions or with different approaches, but the exploitation of existing collaboration and the creation of new collaborative links to researchers without existing links.

The exploration of collaboration patterns in mathematics education research reported above raises some interesting questions about the assumption of fragmentation in the field based on theoretical or methodological divisions. Much fragmentation undoubtedly exists at the level of researchers collaborating, with high proportions of papers single-authored and a large proportion of the researchers publishing in mathematics education relatively isolated within the field in terms of collaborations. However there exists a smaller core of researchers who, despite differences of approach and theoretical perspective, remain quite closely connected through a relatively robust network of collaborative links.

The original study reported here was not designed to explore collaborative research connection across the whole mathematics education research community but instead to explore those of researchers working in England, and consequently it focused on research published in English. The result is that while we can draw conclusions about patterns of collaboration within the English-language literature, researchers who do not publish exclusively in English are systematically excluded or misrepresented, and so we need to take care in drawing conclusions about the whole field of mathematics education research. We might ask what degree of clustering a broader dataset would reveal, in particular around language groups. Education research generally differs from the sciences studied by Newman, in that English is not the only international publishing language although it remains dominant. Despite this limitation I would argue that the lack of evidence of strong disconnection among researchers' collaborations warrants further exploration.

An issue in using network analysis and visualisations of collaborations in this research has been the ease with which one can move between the language of network analysis and the use of overlapping language employed generally within mathematics education research to discuss the state of the field in terms of methodological and theoretical diversity, and more specifically to the language of connecting theories and practices used by some in the CERME working group. The ideas of *fragmentation* and of *connections* or *connectivity* are particularly problematic here and care must be taken to trace differences of meaning between these terms as they are used in different contexts. Also the application of these terms in turn to theory, research, research practices, approaches and researchers can

unintentionally blur arguments and ideas which are specific to one into the others. A question raised here is what it might mean, and whether it is reasonable, to talk about the community of researchers in mathematics education as fragmented, and how this fragmentation might relate to theoretical or methodological fragmentation.

I see the use of network analysis techniques to explore collaboration patterns as just one of many possibilities for exploring the social context of research with a view to inform discussions about possibilities for reducing the fragmentation evident in mathematics education research. This could be an important complement to concrete attempts to connect theories and more abstract debates about the role of theory in research, the range of theories and the different approaches to research found in maths education and their implications for the knowledge production of the field. The social as well as epistemological, ontological or conceptual causes of theoretical fragmentation mean that even if we were to satisfy ourselves about the connectivity or otherwise of theories in mathematics education research, we would still find that fragmentation and diversity remained. The exploration of theories as theories (on an abstract level and through concrete attempts to connect theories and research), and the exploration of theoretical diversity as it has arisen from the social conditions of research, are both necessary in order to address the broader fragmentation of the field.

COMPLEMENTING AND INTEGRATING THEORETICAL TOOLS: A CASE STUDY CONCERNING POOR LEARNERS

Nadia Douek

IUFM C. Freinet Université de Nice, UMR ADEF Université de Provence

This paper contributes to the debate about comparing and using different theoretical constructs in Mathematics Education through a case study concerning two poor learners. Complementing and integrating theoretical constructs of different sources resulted in an operational tool to benefit from the resource of a specialised teacher and allow poor learners' to be productive participants to whole class activity.

Key words: theoretical tools; poor learners; problem solving; mathematical concepts

INTRODUCTION

In the last two decades of the 20th century the discussion about the nature of Mathematics Education as a scientific domain and its relationships with other disciplines (psychology, epistemology, sociology of education, etc.) developed together with an increase of knowledge and theories in the field. Different positions emerged. According to H. G. Steiner (Steiner, 1985) and others in more recent years (Arzarello & Carolina Bussi, 1998), the development of the field requires theoretical constructs borrowed from different disciplines; and its autonomy as a field of research consists in the appropriate choice and adaptation of those constructs and in the construction of new theoretical tools needed to deal with specific teaching and learning problems. Without denying the importance of borrowed tools, researchers like G. Brousseau and Y. Chevallard engaged in constructing autonomous, specific theories for Mathematics Education. The volume “Mathematics Education as a Research Domain: A Search for Identity” edited by J. Kilpatrick and A. Sierpiska and published in 1998 by Kluwer represents the debate at that moment. Recently, interest shifted towards how to exploit and deal with the numerous theories and tools elaborated within mathematics education or adapted from other disciplines. L. Radford's (2008) construct of semiosphere frames theory connections at the levels of their system of principles, their methodologies and their template of research questions.

I will use the semiosphere framing to underline the connections between theoretical constructs that I used to design specific tools to analyse the learning difficulties of “poor learners” and to organise the teaching sequences in order to help them contributing to the whole class activity, thanks to the mediation of a specialised teacher. So, this paper aims at contributing to the present debate by providing an example (the object of our case study) in which theoretical constructs are adapted and implemented by *complementing* each other or by *integrating* them according to specific needs, and by discussing the level of their connections. By “complementing” we mean using different constructs to deal with different aspects

of a given problem, by “integrating” we mean grafting elements of a construct on another, to elaborate a more powerful and comprehensive analytical tool to deal with a problem.

POOR LEARNERS: A CHALLENGE FOR MATHEMATICS EDUCATION

Following literature, poor learners (Shuell, 1983) are those with no neurological or physical impairment, but considered as having difficulties with learning. They often have difficulties in being inserted in the class community, suffer from unfavourable environmental or family conditions and represent a heavy load for the class teacher. In France poor learners of a classroom are supported by an auxiliary “specialised teacher”, who usually tries to achieve learning goals through small group extra-class work concerning easy fundamental notions and techniques of the curriculum, but seldom allowing students' to productively participate in ordinary classroom work. The result is often an exclusion both from practice of high-level mental processes (like arguing, or producing, contrasting and validating hypotheses), and from culture in a long-term perspective (especially when family cannot provide general enculturation). Also, social insertion in the classroom community may be problematic.

In spite of different orientations (see Dunn, 2004; Perrin-Glorian, 1993), current literature on poor learners in mathematics agrees on some means favouring progress in learning mathematics and inclusion like : engaging them in small group activities supported by the teacher and concerning ordinary classroom tasks; teaching mathematics in context; and promoting awareness of the ways of solving problems. Further work is needed concerning planning, monitoring and adjusting mathematics teaching to their needs when a specialised teacher works with them.

The case study presented in this paper explores the potential of complementing and integrating different theoretical tools, chosen as appropriate to deal with the problem of teaching and learning mathematics to poor learners in primary school. They were used to plan, manage and analyse a sequence of activities performed by a specialised teacher and aimed at developing students' mathematical knowledge and favouring their productive participation in classroom activities.

CHOICE AND ADAPTATION OF THEORETICAL TOOLS

Socio-cultural theories offer suitable general perspectives to tackle the problem of mathematical enculturation of poor learners: in particular, the Vygotskian elaboration about teachers' mediation in student's zone of proximal development (ZPD) engages identifying and exploiting their learning potential. The Vygotskian elaboration about “scientific concepts” (SC) and “everyday concepts” (EDC) dialectic offers a *complementary* tool to model the enculturation problem of a subject as a long term development within tensions between different socio-cultural webs he/she is inserted in. This model favours exploiting what poor learners (like all

students) bring to the classroom from their everyday experience as a resource to be developed in a dialectic relationship with the culture brought (and mediated) by the teacher. Vygotsky's description of SC offers useful criteria to describe some requirements typical for school culture (development of systemic links, conscious and voluntary use, etc...)

These contributions of Vygotsky have been *integrated* by the Genoa research team according to specific mathematics education needs (for all students in general and poor learners in particular) by developing two original interrelated constructs: “experience field” (Boero, 1989; Dapuzo & Parenti, 1999; Douek, 2003) and “experience fields didactics” (Boero & Douek, 2008). “Experience field” construct frames the identification of human culture areas, rich in opportunities for developing mathematical knowledge and skills (like money use in first grades), immediately or potentially accessible to all students. An *experience field* consists of three components (teacher's internal context, student's internal context and the external context - signs, objects, physical or social constraints) mobilised and evolving during classroom activities led by the teacher. Experience fields didactics consists in the long term organisation of teacher's activity exploiting resources of a given experience field to engage in a dialectic relationship between SC and students' EDC. A crucial element is the sequencing of cycles: given a problem contextualised in the experience field, students produce (individually, and/or with teacher's help) written solutions; a few solutions selected by the teacher are discussed under his/her guide and mediation; then a written synthesis is produced (individually and/or with teacher's help). Writing and discussing are also framed in a Vygotskian perspective: see Boero, Douek & Ferrari (2008); Bartolini Bussi (1996) and Boero & Douek (2008).

In the experience field didactics, Vygotsky's EDC-SC dialectics offers a cultural model for conceptualising and guiding the elaboration of the teacher's mediation within the student's ZPD. Further *specific* epistemological and cognitive analytical tools for the process of *mathematical* conceptualisation are provided by *integrating* Vergnaud's construct of concept (Vergnaud, 1990) within Vygotsky's SC-EDC dialectics (see Douek, 2003). Vergnaud defines a concept through its three components: its reference situations; its operational invariants (theorems and concepts in action); and its semiotic representations.

Our integration allows a finer analysis of these components: we consider that they reflect and depend on the subject's activity as inserted in a socio-cultural web and we can point to their possible different cultural roots. We study concepts from a plural point of view and follow the subjects' school activity as in tension within different socio-cultural webs. The resulting analysis tool allows identifying elements of conceptualisation in what students already know and are able to do, and in what the teacher brings through interaction. In more detail, it allows to analyse the evolution of: systemic links between reference situations and semiotic representations of a

concept or of different ones; operational invariants and schemes relying on them; conscious and voluntary mastery of concepts. Such analysis is applied to student's production (verbal or more general activity) and used to organise teaching sequences and particularly teacher/ students interaction.

THE ANALYSIS TOOL AT WORK: KEN AND MELVIN'S CASES

Ken and Melvin were two “poor learners” in a third grade class of 22 students of a school in a “priority education zone” of France (a zone with social problems). Both the classroom teacher and the specialised teacher had taken part in an in-service teacher education activity; they volunteered to adopt the experience field didactics methods and connect the specialised teacher's action to the whole class activity, so that Ken and Melvin may take part in the class activity of solving the (relatively) difficult problems posed to the whole class, as protagonists, overcoming their usual marginal position. Adjustments of the planned teaching were made according to the analysis of students' behaviours, using our tool resulting from integration.

In the reported initial activity (a third of the whole activities planned with the teachers) the mathematical problem was contextualised in gardening. The class regularly practiced it, we can consider it a meaningful experience field. Students had some knowledge about it and about related practical problems, and the two boys were well concerned with it. They were offered interaction with the specialised teacher for a longer period of time than was offered to the whole class. Then they participated in the subsequent collective activities. For all the students, working pace was much slower than usual; contextualised complex problem solving was new, and so was the equilibrium between oral and written verbal activities (they were not accustomed to write down in words their problem solving reasoning).

The class teacher, though interested in the proposed activities, in this phase missed several crucial indications proper to the experience fields didactics. He preferred a traditional exposure of the problem with its stereotyped linguistic form and all the necessary data (whereas we wished that the problem was posed in a familiar way and that students gather data from their everyday practice within the familiar context). He chose light interactions with students. He felt uneasy with ZPD-related practices and feared excessive influence on student's activity. On the contrary the proposition was close enough to the specialised teacher practices and she easily adapted her methods. However the classroom teacher adopted the proposed methodology in a more and more coherent way during the subsequent activities (not reported in this paper).

The teaching experiment

During the first session the problem was presented to the whole class. Then the specialised teacher took Melvin and Ken to another room to solve it, while the rest of the students worked individually in the main classroom. Two additional sessions with the specialised teacher allowed Melvin and Ken to conclude their work. Then a

Working Group 16

second whole class session was dedicated to discuss the solutions and a third to individual synthesis (the boys were attended by the specialised teacher in the main classroom), according to the cyclic structure of the experience fields didactics.

The collected data were: all the students' individual productions; the specialised teacher field notes about her interactions with the students (including utterances, gestures) and remarks about their behaviour (like impatience, enthusiasm, difficulties of expression), and elements of on the spot interpretation that helped us to build the consecutive sessions; videotapes of the collective debates. The methodology used to analyse data and the evolution of students' skills is the interpretation of their oral and written productions and gestures through the cognitive and epistemological components of our integrated theoretical framework concerning conceptualisation: the evolution of Vergnaud's concept components according to a SC-EDC dialectic.

First whole class problem solving session

The problem was presented to the whole class through the following text:

We need to know the dimensions of the parcels of the garden in which we will be planting flowers. We have a 2m60 by 2m80 rectangular parcel in which we want to delimitate 4 identical parcels with two paths crossing between them.

He presented a rectangular schema with the four parcels, and specified that the paths had to be 40 cm wide. He encouraged interactions and noted on the blackboard:

Ingi: $130+130=260$. We make the middle to trace the pathway, 130 and 130 to have identical parcels

Antoine: there are two pathways to trace

Emir: yes 130 and 130 and the pathway ?

Victor: $130+130+40=300$ impossible... we have 260

The problem's difficulty was implicitly visible by the students' remarks in the discussion: the pathways width must be considered in the calculations. After the discussion, the classroom teacher asks the students to solve the problem individually, and to write explanations and justifications. Explanation and justification tasks are essential in experience field didactics and are generally supported by the teacher's mediation, but they are unusual in this class' didactical contract. Insufficient mediation made the task difficult. Meanwhile, Melvin and Ken followed the specialised teacher into another classroom.

First interaction session with Ken and Melvin:

The specialised teacher encouraged the students to recall the task and the data and to try to find a way to solve the problem. She used the schema, accompanied her verbal interaction with gesture and tried to stimulate the students' ideas and verbal expressions. At the beginning they just repeated the statement of the task.

Working Group 16

Interactions revealed important aspects of the students' conceptualisation, and allowed the teacher to adapt her activity to their ZPD. For instance:

Teacher: the pathway must be right in the middle of the parcel. What to do to place it at the right place? (gestures close to the schema)

M: we could try to find where is the middle of this side (showing the longer side)

Teacher: what to do to find the middle?

K: we measure with the ruler

The boys searched middle points by trials, Ken measured to verify and got upset: lengths are not equal. The teacher noticed that they don't use numerical data to find the length of half a side. So, she suggested a numerical procedure reciprocal to their's, based on their gestures and verification efforts.

Analysis: Ken related “middle” and “measurement with a ruler”. The students' systemic links between the concepts of “middle” and of “measure”, with procedures were weak and not used intentionally with a precise goal. A theorem in action (Vergnaud, 1990) seems to guide Ken's action of placing middles and verifying them by measuring. This theorem could be expressed as: *the measures of the segments at each side of the mid-point must be equal*. Ken also used semiotic representations of the middle of a segment. Links between spatial midpoint and numerical half were missing.

Using our integrated analysis tool, we estimated Ken's conceptualisation related to this situation (with these theorem in action and semiotic representation) as his EDC concerning middle point, half and measure and we conceived their potential development in relation to the teacher's references and goals. This guided the design of the next sessions according to the aim that students develop a more scientific conceptualisation: Stabilise semiotic representations (geometric representation, gesture, verbal expression, numerical symbols and schematisation) concerning length, measure, middle, half (they will need them to act upon this situation); direct students to relate explicitly and functionally geometric middle point with measure and numerical half, to favour systemic links typical for a “scientific” conceptualisation of these notions and to approach a numerical procedure; make Ken's theorem in action explicit, linked with useful semiotic representations and with the procedures to be built, and using it for verification; engage in the EDC/SC dialectics. We also had to help students expressing the purposes of the activity, in order to maintain control on meaning. The teacher's explicit use of elements reflecting student's actual conceptualisation engaged them in the activity and reassured them. They could see their activity as constructive and acknowledged.

Second interaction session with Ken and Melvin

A third student, Grace, joined the group. The boys explained their work.

Working Group 16

K: ... to find the middle of 280

Teacher: what does it mean the middle of 280?

M: for example, we draw a line of 30 and the half is 15 because 15 and 15 makes 30.

Analysis of evolution towards SC: Melvin became able to explain a numerical calculation to find the middle point of a segment. His explanation had a character of *generality*. The link between measuring procedure and numerical calculation was interiorised and the student could call it up *intentionally* for a purpose that was clear to him (generality and intentional mobilisation belong to the scientific level of conceptualisation). And a spatial reference situation for calculation became available.

Third interaction session with Ken and Melvin

Using the schema and strips of paper representing the pathways, the students concluded the problem solving through interaction, and dictated a synthesis:

Melvin proposed to find the middle of 280 to put the pathway right in the middle. We prepared a strip of paper.

It was difficult, so he proposed to split 28 into halves. Together with Ken he found that it was 14, because $14+14$ makes 28.

Ken said we must add the 0 of 280. So we also added 0 to 14 and the half of 280 is 140, because 140 and 140 makes 280.

Grace showed on the backboard that the pathway had to be moved apart 20 and 20 because it makes 40.

Analysis of evolution: This text reveals important progress in understanding the problem, the relation between half and mid-point, the problem solving steps, the calculation and the final purpose. The students' improved mastering semiotic tools that helped them dealing with the situation. Using the word "écarter" (move apart) they imagined how to pose the pathway on the ground (the French expression is not appropriate, but is meaningful: it was related to the gesture of joined hands put in the middle and parted to form the pathway).

The problem solving context allowed the students to preserve the goal and a coherent relation between the different working stages. Text production reinforced this. Note that these students had tremendous difficulties to mobilise their mathematical knowledge and often lost the goal of their activity. Written text production has a crucial role in experience field didactics: it dialectically favours and requires reasoning to be organised (see Vygotsky, 1985, Ch. VI), thus scientifically conceptualised. The students were not able to produce the written text on their own, but they had to take the responsibility of producing the text orally and organising it.

Second whole class session: mathematical discussion

The students who stayed in class worked individually in a rather autonomous way. Our analysis of their production revealed that: The majority did not appropriate the schema drawn on the blackboard. Their expression was reduced to calculations; most students who elaborated a correct problem solving procedure were those who offered ideas during the preliminary discussion. Martine is the only student who produced a text explaining a procedure. It was poorly structured, short with a correct schema. Most written productions show limited evolution of ideas when compared with the blackboard's ones. Middle level students did not grasp the problem nor did they engage in the resolution. On the contrary, Melvin and Ken's ideas evolved greatly. We distributed an excerpt of Martine's text and one of the boys:

Martine: I make $280 : 2 = 140$ to find the middle and I looked for half of the pathway. Half of 30 and $30=20$ $140-20 = 120$

Melvin and Ken: Melvin proposed to look for the middle of 280 to put the pathway right in the middle. We prepared two strips of paper. Grace showed on the backboard that the pathway had to be moved apart 20 and 20 because it makes 40

We asked the students to compare their own ideas with this document, to compare the two texts, then to interpret Martine's calculation. Her mistake favoured interpretation efforts and allowed to identify the role of the data; it also favoured personal positioning. Melvin and Ken's word "move apart" helped interpreting her text and the reason why 20 was a half. Afterwards we asked Melvin and Ken to explain their text in order to involve them (they did it with some difficulties), then we asked Martine. The aim was to stabilise the boys' expression and understanding, and asserting their role in the collective construction.

Analysis: Discussing procedures and reconstituting reasoning relying on collective interpretations of the texts favoured the enrichment of reference situations and schemes for middle level students concerning parting procedures, and allowed conscious mobilisation of systemic links. Students were encouraged to refer to a well known reality. Acknowledgement of the two texts' contributions and debate were essential ingredients to realise the Vygotskian EDC-SC dialectics and, on the other side, the productive participation of Melvin and Ken.

Collective resolution ended with the first pathway situated and drawn on the schema.

Third whole class session: individual production of synthesis

We asked the students to solve again the problem, individually, drawing the schema on a squared paper and giving explanations. Most students (13) solved the problem and drew the schema correctly. The boys worked individually like their classmates, they drew the pathways and solved the problem only for the first pathway (like it was done collectively). Producing explanations was difficult for all.

DISCUSSION

Complementing and integrating suitable theoretical tools borrowed from other disciplines (Vygotsky's elaboration about ZPD and SC-EDC dialectics, Vergnaud's definition of concept) together with mathematics education tools (experience field and experience field didactics constructs) resulted in a toolkit that enabled us to plan, manage and analyse activities aimed at developing the two poor learners' mathematical competencies in relation to a complex third grade problem situation and to allow them to take part as protagonists in the subsequent discussion.

Our integrated theoretical tool allowed to frame the specialised teacher practice, and probably to improve her decision making in relation to the students' activity. She was already well aware of the importance of combining different semiotic means, and of referring to student's surrounding reality. She was able to calm their anxiety about failure; the familiar context of gardening experience field was a favourable condition for that. She offered verbal expressions to meet students' utterances and gestures, and legitimate them. Their legitimacy depends on our capacity for analysis: we "saw" in these concept components signs of an EDC related to the aimed conceptualisation. The teacher arranged them and inserted them into a more scientific discourse; she recycled the students' explanations into more complete ones, favouring systemic links between the SC in construction and their own conceptualisation. Local syntheses insisting on semiotic means helped stabilising the new developments on different levels, and keeping control on activity. The specialised teacher engaged in activities and decision making coherent with the theoretical perspective proposed by the researcher; while the classroom teacher only accepted the idea of working on a common task with her. This particular situation allowed comparing the development of problem solving and related conceptualisation processes in different educational settings, showing the potential of intentional, coherent mediation of conceptual elements and levels in students' ZPD on the basis of our theoretical frame of conceptualisation. Getting back to Radford's semiosphere: Experience fields didactics is based on Vygotskian principles; Vergnaud's definition is integrated into the SC/EDC dialectics on the method level, it does not contradict the Vygotskian principles. The question (including poor learners to class complex problem solving) emanates from the observation of a "phenomenon" (see Artigues & Bosch, 2011) through the lenses of experience fields didactics: ordinary class mathematical situations seldom rely on culturally meaningful context. In such cases poor learners are forbidden to do collective meaning making: minimal common meaning due to common cultural background is not available. Whereas experience fields perspective is to engage students in mathematical activity within a culturally meaningful context, and to insure a collectively shared sensitivity to the context and constructive activity. This phenomenon and this question modified the integrated theoretical frame of conceptualisation: it favoured the interpretation and instrumentalisation of the EDC/SC dialectics as a tension between socio-cultural webs of knowledge (see

Douek, 2011) that Vergnaud's component allowed to capture at various levels of evolution.

MATHEMATICAL OBJECTS THROUGH THE LENS OF THREE DIFFERENT THEORETICAL PERSPECTIVES

Vicenç Font*, Uldarico Malaspina **, Joaquin Giménez* and Miguel R. Wilhelmi***

*Universitat de Barcelona, ** Pontificia Universidad Católica del Perú,
***Universidad Pública de Navarra

In this paper we establish a link between the onto-semiotic approach (OSA) to mathematics cognition and instruction, APOS theory and the cognitive science of mathematics (CSM) as regards their use of the concept 'mathematical object'. It is argued that the notion of object used in the OSA does not contradict that employed by APOS theory or the CSM, since what the latter two theories do is highlight partial aspects of the complex process through which, according to the OSA, mathematical objects emerge out from mathematical practices.

INTRODUCTION

One characteristic of the research community in mathematics education is its diversity of different theoretical perspectives, and hence there is a need for strategies that connect theories. Each theoretical perspective tends to privilege certain dimensions of reality over others. Thus, it is not always easy to identify links between research questions, descriptions, methodologies and conclusions that are elaborated within different paradigms. In this paper we establish a link between the OSA, APOS theory and the CSM as regards their use of the concept 'mathematical object'.

We begin by arguing that the notion of 'object' used in APOS theory is the result of a cognitive process referred to as 'encapsulation', which, in our opinion, is no different from the process of reification. Hence, this is a cognitive view of mathematical objects. We then argue that in the CSM the notion of object emerges through the metaphorical projection of a series of image schemas, and especially that it is the result of the object metaphor. Finally, it is argued that the notion of object in the OSA is broader than that used by the other two theories, although it does not contradict them. This is because what both APOS theory and the CSM do is highlight partial aspects of the complex process through which, according to the OSA, mathematical objects emerge out of mathematical practices.

THREE DIFFERENT THEORETICAL PERSPECTIVES

The OSA

Figure 1 (Font, & Contreras, 2008, p. 35) shows some of the theoretical notions contained in the onto-semiotic approach to mathematics cognition and instruction (Godino, Batanero, & Font, 2007). Here mathematical activity plays a central role and is modeled in terms of systems of operative and discursive practices. From these

Working Group 16

practices the different types of related primary objects (language, arguments, concepts, propositions, procedures and problems) emerge, building epistemic or cognitive (depending on whether the adopted point of view is institutional or personal) configurations among one another (see hexagon in Figure 1).

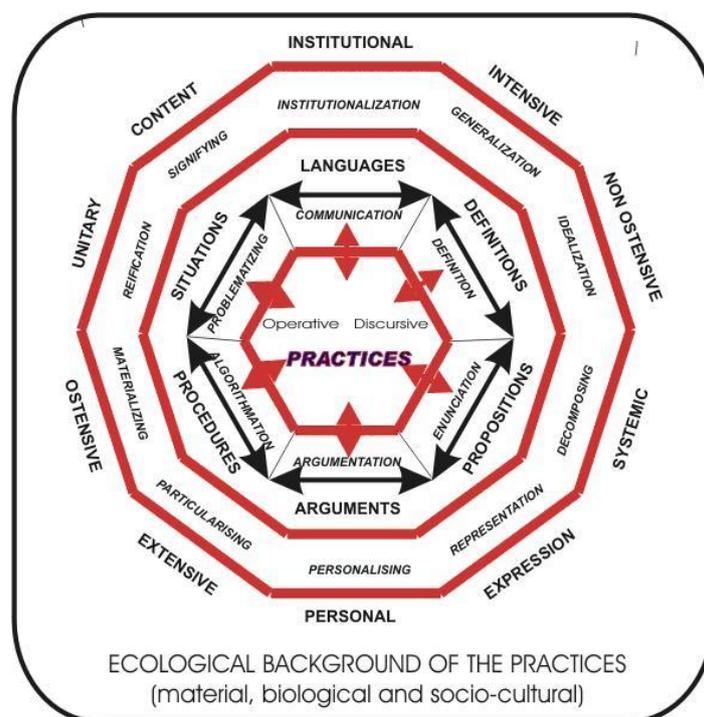

Figure 1: An onto-semiotic representation of mathematical knowledge

Problem-situations promote and contextualize the activity, languages (symbols, notations, graphs) represent the other entities and serve as tools for action, and arguments justify the procedures and propositions that relate the concepts. Lastly, the mathematical objects that emerge from the mathematical practices depend on the “language game”(Wittgenstein, 1953) in which they participate, and might be considered from the five facets of dual dimensions (decagon in Figure 1): personal/institutional, unitary/systemic, expression/content, ostensive/non-ostensive and extensive/intensive. Both the dualities and objects can be analyzed from a process-product perspective, a kind of analysis that leads us to the processes shown in Figure 1. Instead of giving a general definition of process the OSA opts to select a list of processes that are considered important in mathematical activity (those of Figure 1), without claiming that this list includes all the processes implicit in mathematical activity; this is because, among other reasons, some of the most important of them (for example, the solving of problems or modeling) are more than just processes and should be considered as hyper- or mega-processes.

The APOS theory

APOS (Asiala et al., 1996; Dubinsky, & McDonald, 2001) is an acronym that stands for the types of mental structures (Action, Process, Object, and Schema) which students build in their attempts to understand mathematical concepts. A learner, to

whom we usually refer as a student, uses certain mental mechanisms called interiorization, coordination, and encapsulation to construct these structures. According to APOS theory, the formation of a mathematical concept involves applying a transformation to existing objects to obtain new objects. An action is any transformation of objects according to an explicit algorithm in order to obtain other objects, and is seen as being at least somewhat externally driven.

As an action is repeated and the individual reflects upon it, it may be interiorized into a mental process. An important characteristic of a process is that the individual is able to describe, or reflect upon, the steps of the transformation wholly in her/his mind without actually performing those steps. Additionally, once a mental process exists, it is possible for an individual to think of it in reverse and possibly construct a new process (a reversal of the original process).

When an individual becomes aware of the process as a totality and is able to transform it by some action, it is said that the process has been encapsulated as an object. When necessary, an individual may de-encapsulate an object back to its underlying process. In other situations, the individual may think of the transformation in terms of actions.

A schema for a certain mathematical concept is an individual's collection of actions, processes, objects and other schemas linked consciously or unconsciously in a coherent framework in the individual's mind.

The research method or investigative approach of this framework consists of three-step cycles. The first step is a theoretical analysis of the actions, processes, objects, and schemas that a learner may construct in order to learn a given/specific mathematical concept. The resulting description is called a genetic decomposition of the concept. This is used to design and implement the second step, the instructional treatment. The third step is the collection and analysis of both quantitative and qualitative data.

Cognitive Science of Mathematics

In this paper we are interested particularly in Lakoff and Nunez's account. This is a very particular and, may be, controversial interpretation of "cognitive science of mathematics". Lakoff and Núñez (2000) state that the mathematical structures people build have to be looked for in daily cognitive processes, such as image schemas and metaphorical thinking. These processes allow us to explain how the construction of mathematical objects is supported by the way in which our body interacts with the objects of everyday life. To achieve abstract thinking we need to use basic schemas derived from the immediate experience of our bodies. We use these basic schemas, called image schemas, to make sense of our experiences in abstract domains through metaphorical mappings. Lakoff and Núñez (2000) claim that metaphors create a conceptual relationship between the source domain and the target domain. They distinguish between two types of conceptual metaphors in relation to mathematics: a)

grounding metaphors that relate a source domain outside of mathematics with a target domain inside mathematics; and b) linking metaphors that have their source and target domains within mathematics.

THE LINK BETWEEN THESE FRAMEWORKS

The emergence of objects in the OSA

The OSA considers that the process through which mathematical objects emerge out from mathematical practices is a complex one and that at least two levels need to be distinguished. The first level corresponds to the emergence of representations, definitions, propositions, procedures, problems and arguments (primary objects). As regards the nature of these objects, the OSA, in line with the philosophy of Wittgenstein, considers that the type of existence which can be ascribed to the concepts/definitions, the propositions and the procedures is that of conventional rules. From this point of view, mathematical statements are rules (of a grammatical kind) for using certain types of signs, because in fact they are used as rules. They do not describe properties of mathematical objects that exist independently of the people who wish to know about them or of the language used to know them, even though it may appear that this is the case.

Although the OSA adopts a conventionalist point of view on the nature of mathematical objects, it is acknowledged that a descriptive/realist view of mathematics is implicitly suggested in teaching processes. In order to explain how this vision is generated it is necessary to consider a second level in the emergence of mathematical objects; an example might be the object ‘function’, which is considered as an object that is represented by different representations that may have several equivalent definitions, which have properties, etc.

In order to explain how primary objects emerge, the metaphor of ‘climbing stairs’ proves highly useful. When we climb stairs we have to stand on one foot as we move, but that foot then moves progressively to a higher stair. Mathematical practice can be considered as ‘climbing stairs’. The stair on which we stand in order to carry out the practice is an already-known configuration of primary objects, whereas the higher stair which we then reach, as a consequence of the practice carried out, is a new configuration of objects, one (or more) of which was previously unknown. The new primary objects appear as a result of this mathematical practice and become institutional primary objects due, among other processes considered in Figure 1 (including reification and idealization), to processes of institutionalization that form part of the teaching-learning process being studied.

The second level of emergence is the result of several factors, the main ones being as follows: 1) mathematical discourse, explicitly or otherwise, gives students the message that mathematics is a ‘certain’, ‘true’ or ‘objective’ science; 2) the predictive success of the sciences that make use of mathematics is used, explicitly or

otherwise, to argue in favor of the existence of mathematical objects; 3) the simplicity that derives from postulating the existence of mathematical objects. Their postulation is justified on the basis of the practical benefits, especially as regards simplifying the mathematical theory which is being studied. Indeed, it is highly convenient to consider that there exists a mathematical object that is represented by different representations, which can be defined by various equivalent definitions, or which has properties, etc. 4) The object metaphor is always present in teachers' discourse because here the mathematical entities are presented as "objects with properties". It is common in mathematics discourse to use certain metaphorical expressions which suggest that mathematical objects are not constructed but, rather, are discovered as pre-existing objects; for example, words such as 'describe' or 'find', etc. 5). As discussed in Font, Godino, Planas and Acevedo (2010) it is possible in mathematics discourse (a) to talk about ostensive objects representing non-ostensive objects that do not exist (for example, we can say that $f'(a)$ does not exist because the graph of $f(x)$ has a pointed form in $x = a$), and (b) to differentiate the mathematical object from one of its representations. Both aspects lead students to interpret mathematical objects as being different from their ostensive representations.

These five factors generate, implicitly or explicitly, a descriptive/realist view of mathematics which considers (1) that mathematical propositions describe properties of mathematical objects, and (2) that these objects have a certain kind of existence that is independent of the people who encounter them and the language through which they are known. This view is hard to avoid since the reasons why it is adopted are always operating, albeit subtly. More than a consciously assumed philosophical position we are dealing here with an implicit way of understanding mathematical objects.

Objects in APOS theory

In APOS theory (Asiala et al., 1996) encapsulation and de-encapsulation play an important role. APOS theory begins with actions and moves through processes to objects. These are then integrated into schemas which can themselves become objects. The ideas arise from attempts to extend the work of Jean Piaget on reflective abstraction in children's learning to the level of collegiate mathematics.

In the paper titled "Reification as the Birth of Metaphor," Sfard (1994) reports on the interviews she conducted with three renowned mathematicians. In these interviews the three mathematicians talk about the mathematical concepts that they study as if they were concrete in some way. The term that Sfard uses for this cognitive phenomenon is reification, which is similar to Dubinsky's construct of encapsulation.

Reification is a term used in philosophy that means, etymologically, "to treat something like a thing." In the processes of mathematical reification, abstract notions are conceived like objects. To reify (or encapsulate) is to regard or treat an

abstraction as if it had a concrete or material existence. One example of reification is when we assume — or state linguistically — that there is an object with various properties or various representations.

The link between the OSA and APOS theory

In accordance with the onto-semiotic approach (see section 3.1) we consider that reification (encapsulation) is very important in terms of explaining the emergence of mathematical objects, but that it is insufficient to describe adequately this emergence and the nature of mathematical objects. Furthermore, we believe that APOS theory has a number of limitations, two of which we regard as especially important: 1) in APOS theory the construct ‘object’ is considered as the product of the encapsulation (reification) process. However, with this characterization, which basically comes from psychology, it is not clear how to address some issues related to mathematical objects, such as the nature of mathematical objects, their various types, the way in which they are formed and how they participate in mathematical activity.

In order to overcome this limitation it is helpful to consider the proposal of semiotic perspectives, especially the OSA, which regard mathematical objects as emerging out from mathematical practices. 2) The construct of ‘semiotic medium’ is not explicitly addressed by APOS theory, which does not specifically address the role of semiotic representations.

Recent research that has extended APOS theory through the incorporation of semiotic perspectives turns either to Duval’s theory of semiotic registers (Trigueros, & Martínez-Planell, 2010) or to the OSA (Badillo, Azcárate, & Font, 2010; Font, Montiel, Wilhelmi, & Vidakovic, 2010). In line with Badillo, Azcárate and Font (2010), we consider that the OSA complements APOS theory as follows: 1) it extends APOS theory by specifically addressing the role of semiotic representations; 2) it improves the genetic decomposition by incorporating the ideas of semiotic complexity, network of semiotic functions, and semiotic conflicts; and 3) it offers a more detailed notion of mathematical objects due to the way in which it considers the nature of such objects and their emergence out of mathematical practices.

Objects in the CSM

The group of grounding metaphors includes the ontological type, where we find the object metaphor. The object metaphor is a conceptual metaphor that has its origins in our experiences with physical objects and enables the interpretation of events, activities, emotions and ideas, etc. as if they were real entities with properties. This type of metaphor is combined with other ontological, classical metaphors such as that of the “container” and that of the “part-whole”. The combination of these types leads to the interpretation of ideas and concepts, etc., as entities that are part of other entities and which are constituted by them.

Ontological metaphors are considered as a group of metaphors that result from the projection of image schemas (container, whole-part, object, etc.) which, in our view, share a ‘common territory’; therefore, there may be a certain hierarchy among them. One question that remains open (Santibáñez, 2000) concerns the relationship between these image schemas. For example, one could consider that the object image schema is the fundamental schema and that the others are derived from it, or alternatively, that there is some other schema from which all (or some) of those mentioned are derived, for instance, the entity schema (Quinn, 1991) or the notion of thing (Langacker, 1998).

The link between the OSA and the CSM

In line with the onto-semiotic approach we consider that the process through which mathematical objects emerge from mathematical practices is highly complex (see section 3.1). Therefore, we believe that Lakoff and Núñez’s methodology of “mathematical idea analysis” is very important in terms of explaining the emergence of mathematical objects, but that it is insufficient to describe adequately this emergence and the nature of mathematical objects. This limitation was pointed out by various authors in the discussions that followed the publication of Lakoff and Núñez’s book (e.g. Sinclair, & Schiralli, 2003).

The way in which the OSA explains the emergence of mathematical objects not only extends and improves upon the explanation offered by the CSM, but also provides clarification of one of the central processes considered by the latter, namely metaphorical processes (Acevedo, 2008; Malaspina & Font, 2010; Font, Montiel, Wilhelmi, & Vidakovic, 2010). The reasons for this are set out below.

Here we are interested in observing metaphorical processes from the ‘unitary/systemic’ duality proposed in the OSA, since the reification/decomposing processes in the OSA are associated with this unitary/systemic facet or dimension. When a mathematical abstraction is treated as an object, this is equivalent to adopting a unitary point of view on this object. On the other hand, the mathematical object can be treated from a systemic viewpoint, considering the actions that a subject can make on it and on the other objects, parts or processes that compose it. In the work of Lakoff and Núñez (2000), the unitary/systemic duality has a central role. On the one hand, the metaphor is elementary (A is B). However, the metaphor allows us to generate a new system of practices (systemic perspective) as a result of our understanding of the target domain in terms of the source domain. The CSM develops the elementary/systemic duality for different metaphors, a good example of which is the object metaphor (Font, Bolite, & Acevedo, 2010, p. 139): Unitary: “Mathematical objects are physical objects.” Systemic: “Table 1. Metaphor projection.” In fact, most research on metaphors has been mainly targeted at studying such a duality. In other words, given a metaphor, the source and target domains are decomposed to determine what concepts, properties, relationships, etc. from the source domain are transferred to the target domain. The systemic vision of a

metaphor leads us to understand it as a generator of new practices. The OSA considers that in order to carry out a mathematical practice the agent must have the basic knowledge required to do so. If we consider the components of the knowledge that the agent must have in order to develop and evaluate the practice that enables a problem to be solved (e.g., propose and solve a system of two equations with two unknowns), we can see that certain verbal (e.g., solution) and symbolic (e.g., x) language must be used.

Source domain: Object image schema	Target domain: Mathematics
Physical object	Mathematical object
Physical objects are manipulated, found, discovered, etc.	Mathematical objects are manipulated, found, discovered, etc.
Physical objects are different from their material representations (i.e., a clock is different from the drawing of a clock)	Mathematical representations are different from the mathematical objects they represent
Properties of the physical object	Properties of the mathematical object
Physical objects exist	Mathematical objects exist

Table 1: “Mathematical objects are physical objects”

This language is the ostensive part of a series of concepts (e.g., equation), propositions (e.g., if the same term is added to the two sides of an equation, an equivalent equation is obtained) and procedures (e.g., solution by substitution) that will be used in making arguments so as to decide if the simple actions that make up the practice (where this is understood to be a compound action) are satisfactory. Hence when an agent carries out and evaluates a mathematical practice, it is necessary that it activates some (or all) of the elements mentioned above: situation-problems, language, concepts, propositions, procedures and arguments. By articulating these types of objects we obtain the configuration (hexagon in Figure 1). If, in addition to the “structure”, it is necessary to analyze the genesis and functioning of the mathematical activity, other tools are necessary, especially some of the processes shown in Figure 1, as well as the metacognitive processes. The epistemic configuration tool allows us to see the structure of those objects that make mathematical practice possible and which regulate it within a specific institutional framework. Because the OSA considers that, among other aspects, an epistemic/cognitive configuration (depending on whether the adopted point of view is institutional or personal) has to be activated in order to perform mathematical practices, and that the systemic vision of the metaphor leads us to understand it as a generator of new practices, it is natural to ask ourselves the following question: How is the metaphor related to the building components of epistemic/cognitive configurations? The conclusion drawn by Acevedo (2008) on linking metaphors, after he had studied in detail the linking metaphor used by Descartes when solving the problem of Pappus within the framework of analytic geometry, is that a linking metaphor projects an epistemic/cognitive configuration onto another one.

The epistemic/cognitive configuration construct allows us to explain and make precise the structure that is projected onto the linking metaphors. There is a source domain that has the structure of an epistemic/cognitive configuration (whether the adopted point of view is institutional or personal) and which projects itself onto a target domain that also has the structure of an epistemic/cognitive configuration. This way of understanding the preservation of the metaphoric projection improves upon the explanation of such a preservation given by Lakoff and Núñez (2000), who simply give a two-column table in which properties and concepts are mixed. The reader can intuit that the properties are projected onto properties and the concepts onto concepts. The question which remains to be resolved is: what structure is projected in the case of a grounding metaphor? We believe that unlike in the case of linking metaphors, only some parts of the epistemic/cognitive configuration are projected. The specific study of each grounding metaphor will allow the identification of these parts.

FINAL CONSIDERATIONS

A sound theoretical understanding of mathematical objects must be a key part of any research on mathematics learning. The way in which the OSA understands the emergence of mathematical objects enables us to explain: (1) how primary mathematical objects emerge from mathematical practices and they construct among one another cognitive or epistemic configurations; and (2) why a descriptive/realist view of mathematics is usually presented in mathematics classrooms. This account goes beyond the explanations offered by APOS theory and the CSM regarding the emergence of mathematical objects, and shows that what the latter two approaches do is highlight partial aspects of the complex process through which such objects emerge out of mathematical practices.

USING DIFFERENT SOCIOCULTURAL PERSPECTIVES IN MATHEMATICS TEACHING DEVELOPMENTAL RESEARCH

Simon Goodchild

University of Agder, Norway

Communities of practice theory and cultural historical activity theory are considered alongside each other and argued to be incompatible on the grounds of their treatment of human agency. It is then demonstrated that it is of value to use both perspectives in the context of mathematics teaching developmental research. The introduction of inquiry into community of practice theory, it is asserted, creates a different type of community, a community of inquiry, and from this perspective developmental research is argued to be consistent with the critical research paradigm. The combination of theories is shown to be useful as theoretically heuristic, and each has a value as teaching is studied at different stages in the developmental process.

INTRODUCTION

At CERME5 in 2007 Barbara Jaworski and I presented papers within the “theories” group. In these we discussed theoretical issues relating to a mathematics teaching development project in which we were both engaged. Barbara’s paper (Jaworski, 2007) took a social practice perspective, taking Community of Practice Theory (CPT) as a starting point. My paper (Goodchild, 2007) was from the perspective of Cultural Historical Activity Theory (CHAT). It was our deliberate decision that we should adopt different perspectives in our papers. However, in our collaboration we share both perspectives, and Barbara, at that time and subsequently, has published from both. Barbara concluded her CERME5 paper with the following observation:

We recognize also that employing a multiplicity of theoretical perspectives begs some overall theoretical rationalization – not a unification, but a clarity on how the theoretical perspectives we are using are juxtaposed and what issues of commensurability arise from juxtapositioning. Space here has limited further discussion of such issues. (Jaworski 2007, p. 1696).

The purpose of this present paper is to take up this discussion and consider some of the issues that arise when using these two theories alongside each other.

I use the rather unusual approach here and refer to Barbara Jaworski’s contribution reported in her CERME5 paper (Jaworski, 2007), using her first name only. My purpose is to reflect the fact that within the projects we are close colleagues, developing ideas (with others in our research group) in critical collaboration. However, it should be recognised that Barbara is the principal architect of the ideas she expresses. I will revert to the more conventional form of citation when I refer to her other published work. Barbara has read a draft version of this paper and is largely in agreement with the content but we have not had the opportunity to discuss details.

At the time Barbara and I presented the papers at CERME5 we were coming to the close of the project Learning Communities in Mathematics (LCM, 2004-2007), and it was on this project that our reports were based. Concurrent with LCM ran another mathematics teaching developmental research project ICT and Mathematics Learning (ICTML). Subsequent to LCM and ICTML a follow-on binary project Teaching Better Mathematics / Learning Better Mathematics (TBM/LBM, 2007-2010) continued with a majority of the schools and teachers participating throughout both project periods. LCM, ICTML and TBM were supported by the Research Council of Norway. Further support for TBM and support for LBM came from the Competence Development Fund of Southern Norway. All projects were based on the principle of developing communities of inquiry (CoI) comprising teams of teachers in schools and a team of about 10 didacticians at the university. There were eight schools participating in LCM, four of these also in ICTML; nine schools and four kindergartens, and the leaders of three school authorities participated in LBM/TBM. Details about the methodology and implementation of the projects will emerge in the discussion that follows. This paper draws on experience from all the aforementioned.

The paper continues with a brief outline of CPT and CHAT, and goes on to expose fundamental differences between them. The second (smaller) part of the paper sets out some of the ways the projects are better served by taking more than one perspective; this is illuminated using an illustration from the projects.

A VERY BRIEF INTRODUCTION TO CPT AND CHAT

To fulfil the purpose of this paper it is necessary to provide a brief introduction to the two theoretical perspectives and draw attention to their fundamental differences. This is problematic for several reasons. First the theories are complex and some of their key ideas are subtle and need to be interpreted with care. Moreover, key words are used with different meanings or nuances, for example words such as *practice*, *community*, *activity* and *action*; a word ascribed a special meaning in one theory may be used in an everyday sense in the other, and as Radford observes (in Bikner-Ahsbals et al., 2010) “the semantic value of a theoretical term ... in a theory results from its position in the main web of dynamic interconnections that characterize the theory as a whole” (p. 169). Second, much has been published on both theories; brief summaries will inevitably be incomplete and therefore liable to mislead. Third, there are differences and developments within the theories themselves. For example, Kaner and Lerman (2008) expose differences within CPT, in particular, between Wenger’s (1998) ‘Communities of Practice’ and Lave and Wenger’s (1991) ‘Situated Learning’. I believe Lave’s (1988) ‘Cognition in Practice’ introduces a third variety or nuance within CPT. Similarly CHAT is traced through three ‘generations’ of development through the works of (amongst many others) Vygotsky, Leont’ev, and Engeström whose names I use here as representatives of successive generations. In the following I combine sources to articulate one version of CPT, and one version of CHAT. This may be unsatisfactory in regards to exploring the theories themselves but I believe there is sufficient internal consistency to enable a discussion of

differences between CPT and CHAT.

First, one must consider whether there is any a priori basis to suppose that there are fundamental differences between CPT and CHAT; they are both considered to be within the family of sociocultural theories, and exponents of both refer to Vygotsky's contribution. I begin, therefore, by attending to what key protagonists of each have to say. In a substantial review of CHAT, Roth and Lee (2007) explicitly exclude works from a CPT perspective because despite 'strong family resemblances' they claim CHAT and CPT to be 'distinct'. Roth and Lee do not, however, go into detail about the distinguishing features. Wenger (1998) claims there are ontological differences between CPT and CHAT. However, in my opinion, his argument is based on an interpretation of 'mediated action' that is not consistent with CHAT, as developed, for example, by Wertsch (1994). Nardi (1996) compares and contrasts CPT (situated action), CHAT, and distributed cognition perspectives, and finds differences between them. Nardi points to the treatment of goals as a distinguishing feature: "Attention to the shaping force of goals in activity theory ... contrasts with the contingent, responsive, improvisatory emphasis of situated action" (p. 79). I argue below that this, in the context of mathematics teaching developmental research, is the kernel of an essential incompatibility between the theories. Further, Kaner and Lerman (2008), in their discussion of differences within CPT note their opinion that both articulations of CPT lack a theory of mediation. This lacking feature emerges in our theorising of the projects as Barbara explains in her CERME5 paper (Jaworski, 2007) as she extends CPT using principles of mediation based on CHAT.

In CHAT, *activity*, Leont'ev (1979) asserts, is "the nonadditive, molar unit of life ... a system with its own structure, its own internal transformations, and its own development" (p. 46), and later he asserts, "there can be no activity without a motive" (p. 59). Activity is thus the unit of analysis. I will illuminate Leont'ev's definition by developing an illustration used by Vygotsky (1986). If the object of study is water, the unit of analysis must be water – one could have more or less water, but it is nonadditive in the sense that more does not make it more waterish. Water is a compound comprising elements of hydrogen and oxygen, but if the object of study is water, little from the perspective of (classical) chemistry or physics will be learned by studying the elements, water is the 'molar unit'. Activity, Leont'ev (1979) explains is comprised of (conscious) goal directed actions, and actions are comprised of (sub-conscious) operations within constraints or conditions. Actions are conscious and mostly observable (maybe mental actions are not observable but then their effect may be), but an action needs to be analysed in the context of the activity-motive in which it arises. Water also has properties (density, transparency, etc.) that distinguish it from other liquids; similarly, one might describe as properties of activity that distinguish one activity system from another, these are: the person or group, and the object of their activity, cultural artefacts or tools that mediate actions, community, and the rules and division of labour within the community. Engeström (1993) refers to these as 'components' or 'elements', which relate dialectically to each other within an 'activity system', and he draws attention to the historical nature

of activity by observing “An activity system ... is composed of a multitude of often disparate elements ... This multiplicity can be understood in terms of historical modes, as well as buds or shoots of its possible future” (1993, p. 68). Thus, whereas actions occur *in time*, activity endures (and changes or develops) *over time*.

In CPT, Wenger (1998) argues that “community of practice constitutes *a level of analysis*” (p. 122, my emphasis). Lave (1988) however, identifies three levels of analysis – “semiotic systems *with* their structural entailments, ... relations among person-acting, setting and activity, ... (and) dialectical relations between an experienced world and its constitutive order” (p. 179). A ‘community of practice’ might also be explained as a characteristically distinct compound of elements, Wenger (1998) describes three ‘dimensions of practice’ which he explains are ‘the property of a community’ these are ‘joint enterprise’, ‘mutual engagement’ and ‘shared repertoire’ (p. 73). *Practice*, Wenger (1998) explains “is doing in a historical and social context that gives structure and meaning to what we do” (p. 47). At this point one might be tempted to question whether there is any substantive difference between *practice* in CPT and *activity* in CHAT. A definition of practice offered by Scribner and Cole (1981) provides a clue to what might fundamentally distinguish the theories. They explain, practice is “a recurrent, goal-directed sequence of activities ... (it) consists of three components: technology, knowledge and skills ... Practice always refers to socially developed patterned ways of using technology and knowledge to accomplish tasks” (p. 236). The point that I draw attention to in Scribner and Cole’s definition is that it is ‘practice’ that is goal directed, rather than the participating person. This is emphasised by Lave (1988) “motivation is neither merely internal to the person nor to be found exclusively in the environment ... goals ... are not *prefabricated* by the person-acting or some other goal-giver as a *precondition* for action” (p. 184, emphasis added). As Nardi (1996) observes, in explaining the entailments of CPT based on Lave (1988), in CPT “goals are our musings out loud about why we did something *after* we have done it” (p.79).

In CHAT actions are goal directed, whereas in CPT actions emerge dialectically between the person and the environment, this is a difference that reveals CPT and CHAT to be incompatible – in other words, they cannot co-exist peacefully. The impossibility of peaceful co-existence is evident in Engeström’s observation “Activity theory contends that ... a notion of context beyond our influence is a fiction, a fetish ... human agency is necessarily realized in the form of (goal directed) actions” (1993, p. 66). I inserted ‘goal directed’ in the above quotation to act as a reminder and emphasise that in CHAT actions are ‘goal directed’. As Roth observes, “Fundamental to CHAT is the human ability to act or agency” (2006, “Power to act, agency” Para. 1). Wenger (1998) is clear that his work does not focus on agency; thus giving the impression that the concept is not so important in his articulation of CPT. I assert that the introduction of ‘inquiry’ to CPT entails a shift into the critical paradigm; because it is in the critical paradigm that the goal is to empower actors to exert their agency and transform their practice. Thus, I conclude that CPT and CHAT are incommensurable. Moreover, CHAT offers a model, in the form of expansive

learning that fits the critical paradigm. The adoption of different theoretical perspectives has been discussed by, for example, Cobb (2007) who proposes that different perspectives can be “sources of ideas that we can appropriate and modify for our purposes as mathematics educators” (p. 29). From outside mathematics education Guba and Lincoln (2005) defend “borrowing” from different theoretical perspectives where it “seems useful, richness enhancing, or theoretically heuristic” (p. 197). In the next section I demonstrate how reference to both CPT and CHAT is useful in the theoretically heuristic sense within our mathematics teaching developmental research.

DIFFERENT PERSPECTIVES ARE “THEORETICALLY HEURISTIC”

A model of development is explicitly articulated within CHAT by Engeström (1987, 2001), and, I believe, a theory of development is implicit in Wenger’s (1998) articulation of CPT. In CHAT, Engeström (2001) explains development in terms of expansive cycles through which activity systems pass as groups (of participants) address the tensions and contradictions (double binds) of their activity system. Double binds might be thought of as ‘lose-lose’ situations, such as faced by teachers with a demanding curriculum and high-stakes examination AND pressure from their professional subject milieu to teach for ‘understanding’. Attending to the demand of one side appears to threaten losing out on the other. Briefly, expansive cycles take the form of successive phases of internalisation and externalisation. First persons engage in activity and appropriate (internalise) the routines and practices of the activity. As they continue in the activity they become increasingly aware of the double binds and embark on a search for solutions to resolve the tensions and contradictions. Initially solutions are found in the form of creative innovations external to the activity system (externalisation), and the activity system then ‘expands’ to accommodate the innovations. Within the projects, inquiry, operationalised as an inquiry cycle, is argued to be a purposeful realisation of expansion. Within CHAT, inquiry can be conceptualised as both action, and a tool mediating action.

To build a theory of development from Wenger’s (1998) CPT, I start with the ‘modes of belonging’ that Wenger describes in the context of an individual’s identity. Identity occupies an important position in CPT because, as Wenger explains, the discussion of identity “narrows the focus onto the person ... from a social perspective” (1998, p. 145). Wenger argues further: “To make sense of ... processes of identity formation and learning, it is useful to consider three distinct modes of belonging: ... engagement ... imagination ... alignment” (pp. 173-174). Imagination enables a person to extrapolate from his/her own experience, or that shared by others to expand oneself and ‘transcend engagement’ (p. 177).

It is through imagination that we see our own practices as continuing histories that reach far into the past, and it is through imagination that we conceive of new developments, explore alternatives, and envision possible futures. ... By taking us into the past and carrying us into the future, it can recast the present and show it as holding unsuspected

possibilities. (Wenger, 1998, p. 178)

However, Wenger also draws attention to possible “trade-offs of imagination” in particular of the “risk of losing touch with the sense of social efficacy by which our experience of the world can be interpreted as competence” (1998, p. 178). This resonates strongly with our observations in the projects when experienced teachers have been encouraged to try out some innovation (which inevitably entails risk because it is a departure from the known) and the outcome has disturbed the teacher’s experience of competence (Jaworski, Goodchild, Daland, & Eriksen, in press).

I find it difficult to perceive of the extrapolation of practice, and possible trade-offs, in the absence of an individual’s intentionality and agency. If it were possible to leave out the issue of agency a synthesis of ‘extrapolation’ and ‘expansion’ might be possible. And such synthesis provides a useful tool for analysing development.

CPT does not explicitly include a consideration of inquiry, thus one is challenged to explore how a theory of inquiry can be integrated with CPT, or indeed how a community of inquiry (CoI) can be expressed in terms of CPT. Here the notion of alignment is valuable in terms of being ‘theoretically heuristic’ as Barbara demonstrated in her CERME paper. Barbara starts from Wenger’s explanation: alignment is about participation and engagement and doing “what it takes to play our part” (1998, p. 179) in the practice. It can be noted that here again, Wenger identifies ‘trade-offs’ in particular that alignment ‘can ... be blind and disempowering’. Barbara continues by explaining how the introduction of inquiry transforms ‘alignment’ into ‘critical alignment’, “inquiry brings with it a critically questioning attitude towards practice and knowledge in practice that allows critical reflection on the practice of teaching and hence can lead to development of teaching” (Jaworski, 2007, p. 1693). The introduction creates a ‘community of inquiry’ which Barbara describes as “extending Wenger’s exposition of community of practice” (p. 1693).

I believe that the combination of inquiry and communities of practice is not just an extension of CPT but that it constitutes a paradigm shift. In Goodchild (2008) I attempt to produce a mapping between critical alignment and Freire’s (1972) articulation of ‘conscientization’. The point is that critical alignment enables teachers and didacticians to become aware of the oppressive force of the double binds that constrain mathematics teaching practice and development, and inquiry is a means of liberation. Furthermore, the inquiry cycle, plan-act-observe-reflect-feedback (Jaworski, 2007, p. 1694) is closely related to the action research cycle, thus I see CoI as a developmental methodology within a critical research paradigm. It was Barbara’s articulation of CPT, inquiry and critical alignment that resonated with Freire’s work.

THE VALUE OF USING DIFFERENT THEORETICAL PERSPECTIVES

The projects in which Barbara and I have collaborated have been built on theoretical constructs of CPT, inquiry and community; it is on the latter of these that I now

focus. It has been a condition of joining in the projects that there are at least three participating teachers in each school and that the project has the support of the school principal. The school 'project' community is important as a source of mutual support and encouragement, ideas and critically reflective thinking, opportunities for joint activity, observation, and joint reflection. The school community is also intended to provide a critical mass that will facilitate teaching development beyond the life of the projects. A wider project community is envisioned comprising all participating teachers together with the team of didacticians at the university. The project community comes together for workshops three times each semester. Workshop activity comprises presentations by didacticians and participating teachers, and group discussion activities that focus on mathematical problems and approaches to teaching mathematics. As Barbara illustrates (Jaworski, 2007), a mathematical problem is introduced in a workshop plenary session, and then worked on in small groups. When the teachers return to their school they (as a school team) prepare the mathematical problem to present as a class task, the task is implemented with subsequent reflection in the school team and the cycle returns to the point where teachers report their experience in a subsequent workshop, and possibly initiate a further cycle.

There is a further methodological concept that is central in the implementation of the projects: the relationship between teachers and didacticians is based on a 'co-learning agreement' (Wagner, 1997). This emerges from ethical and practical principles; it respects teachers' expertise in their practice and casts the research enterprise as something in which all contribute and from which all can learn in relation to their own interests and concerns. Further, it recognises that substantive changes in teaching will only be achieved *by teachers in their own classes*. In effect it means that didacticians do not presume to *tell* about or demonstrate better methods of teaching. The intention is to stimulate discussion and inquiry about mathematics and teaching mathematics, mediated by tasks that are designed to stimulate mathematical inquiry, and critical reflection on teaching mathematics. Thus, the projects are not based on notions of novice and master/expert in the sense that Lave and Wenger (1991) use in their description of learning in practice as 'legitimate peripheral participation'. With this in mind I return to the notion of development as 'extrapolation'.

It is possible that development is restricted to a modest 'tinkering' with practice rather than fundamental changes; this could happen if no-one comes with experience of teaching practice that transcends what 'normally' occurs. This can be illustrated by a case study within the projects that focused on teaching developments in three project schools, specifically with reference to ICT use, and the introduction of dynamic geometry software (DGS) (Erfjord, 2009). A little over a year after the projects began there appeared to be only limited signs of development at one of the schools, which prompted the project directors to visit the school to see if further support were necessary, and 'encourage' project related activity. One outcome was an arrangement in which an experienced teacher and specialist in using digital

technology with his classes in another project school was asked to lead some school based workshops. In this, one might see an ‘outsider’ providing additional experience from which the teachers could develop their imagination and extrapolate practice. However, it was the appointment of a novice teacher some months later that was decisive. He introduced some teaching resources for using DGS. These resources were closely aligned to the teachers’ existing practice and led the introduction of DGS at the school. The point is, there need to be opportunities to extend participants’ experience in practice. Perhaps a fundamentalist attitude to the co-learning agreement in the context of CPT could hinder this if the principle of ‘co-learning’ were to prevent the purposeful introduction of ‘outsiders’ to offer support and new ideas. However, the project ideal was co-learning within a community of inquiry. Erfjord’s case study of the school, in which the teachers remained aligned to their regular practice, might be interpreted as providing evidence that a CoI had not yet been established. In this instance, CPT provides the analytic categories to make sense of the observations: the development is characteristic of extrapolation.

DISCUSSION

Evidence from some of the case studies in the projects, such as discussed above, combined with other discussions of teaching development (e.g. Cuban, 2001) suggests that teachers will adapt a new technology (such as ICT, or ‘inquiry tasks’) to their existing practice before they see new technology as an opportunity for creative development within their practice. This supports a conception of development as extrapolation and possibly reveals the strength of alignment to existing practice. In this regard CPT can be seen as providing a useful model, and explanatory tools for the stable situations in which incremental development is observed, as in the example provided. This is consistent with teachers incorporating research into their practice which Jaworski (1998) describes as ‘evolutionary’. However, the goal is to create a CoI and thereby the development of practice that is better characterised as expansion.

‘Inquiry’ transforms alignment into critical alignment. The intention is that inquiry will heighten awareness of the apparent constraints that limit teaching and learning, *and* provide the means of addressing those constraints. One teacher, for example, after six years of participating in the projects claimed that ‘inquiry’ based teaching and learning offers an approach to practice in mixed attainment classes (grouping students by attainment is illegal in Norway). Inquiry empowers, it also destabilises practice by bringing constraints into view, and provides a means to achieve new forms of stability through creative innovation. CPT provided a model for initiating the projects in which inquiry was seen as an important element of practice, CHAT was introduced later as an analytical tool. The combination of CPT and inquiry to theorise the envisioned communities of inquiry is ‘theoretically heuristic’. Consideration of ‘alignment’ from CPT and ‘critical alignment’ developed from the theorisation process resulted in the realisation that the transformation from CPT to CoI is more than a development of CPT, it constitutes a paradigm shift. CPT, and

CoI analysed within CHAT, provide alternative lenses that can explain different forms of development. Thus, the combination of CPT and CHAT, argued here to be both incompatible and incommensurable, is theoretically heuristic because they draw attention to qualitatively different forms of development of teaching practice. CHAT also offers a tool for conceptualising and analysing development, as expansive cycles, which follow creative innovation in response to constraints and tensions experienced in activity.

THE POSSIBILITY OF APERSPECTIVAL RESEARCH ON MATHEMATICS LEARNING

Tim Jay

Graduate School of Education, University of Bristol

The difficulty in reconciling the differing commitments – ontological, epistemological and methodological – of the various perspectives on research on mathematics learning is well established. As an example of this difficulty, there will be some discussion of cognitivist (e.g. Anderson, Reder & Simon, 1996, 1997) versus socioculturalist (e.g. Greeno, 1997) perspectives on mathematics learning. The claim will be made that problems of language, pace Wittgenstein (1953) and Derrida (1997), are at the heart of the apparent irreconcilability of these two and other perspectives, and that this apparent irreconcilability can be at least partly remedied through a post-structuralist, semiotic, approach. Some practical examples of the problem and some advantages of this approach are described and discussed.

PERSPECTIVES AND METAPHORS

My introduction, as many others', to some of the knotty theoretical problems faced by mathematics learning researchers, was through the papers of Anderson, Reder and Simon (1996, 1997) and Greeno (1997). Anderson et al. (1996) sets out a set of 4 purported claims of situated learning researchers; that "action is grounded in the concrete situation in which it occurs" (p.6), that "knowledge does not transfer between tasks" (p.6), that training by abstraction is of little use (p.8) and that instruction needs to be done in complex social environments (p.9). Each of these claims is dismissed in turn, the authors referring principally to cognitive psychology literature in their critique. The point of view expressed by Anderson et al. is that learning is fundamentally an individual process. They claim that whilst they unreservedly recognise the "profoundly social nature of the human species" (p.20), this social nature is best researched by analysing the "complex social situation into relations among a number of individuals and study the mind of each individual and how it contributes to the interaction" (p.21).

The response from Greeno (1997) consists in an attack, not on the evidence for the critique, but on the status of the four claims themselves. Greeno argues that the four claims set out by Anderson et al. demonstrate a misunderstanding of "the important differences between cognitive and situative perspectives" (p.5), and constitute something of a straw man for the cognitivists to attack. The substance of Greeno's response is that cognitivist and situative researchers differ primarily in terms of their 'primary focus of analysis'. The primary focus of analysis for the cognitivist is the set of processes and structures that exist within the individual mind, whilst the primary focus of analysis for the situativist is "at the level of interactive systems that

include individuals as participants, interacting with each other and with material and representational systems” (p.7).

Recently, two books have been published, Anderson (2007) and Sfard (2007), that set out updated theoretical frameworks from the two perspectives. There is still a very clear division between the two. Anderson (2007) involves the development of the ACT-R (Adaptive Control of Thought - Rational) architecture for creating models of human thinking, using data from human participants solving problems together with fMRI scans of brain activity in order to provide evidence for the validity of those models. The models created in ACT-R are capable of learning from instruction, but not spontaneous learning, or learning from peers. So whilst Anderson’s perspective has expanded in order to incorporate some neuroscientific thought and method, there has been no incursion into sociocultural thought. Sfard (2007) develops a theoretical framework centred on ‘commognition’, emphasising the fact that cognition is communication. However, the model is firmly sociocultural, and Sfard is explicit about the fact that she is concerned with thought that is exclusively human; that involves language. This approach precludes the researcher from incorporating aspects of cognitivist method into the study of learning.

THE LANGUAGE PROBLEM

This paper focuses on language in the reconciliation of perspectives. In fact, rather than treating this exercise as a reconciliation this paper, as is suggested in the title, takes the position that a more fruitful approach may be to abandon perspectives in favour of an aperspectival approach; binding the researcher to as few ontological and epistemological commitments as possible. This paper has already highlighted language as a key factor maintaining the dichotomy of perspectives. Researchers on both sides claim that their point of view has been misunderstood or misinterpreted by the other side. The problem to solve is that of dealing with a dichotomy that is obstructive and misleading. The solution we want to achieve is a theoretical framework that allows us to talk about individual cognition and learning, about sociocultural objects and processes and learning, and about interactions between these. Two approaches suggest themselves. The first is Derrida's (1997) deconstruction. Deconstruction feeds on dichotomy, subsuming the two sides of a dichotomy within a more comprehensive account. The second is Wittgenstein’s (1953) philosophy of language. Wittgenstein's later period involved a rejection of philosophical problems, and a claim that what appeared to be philosophical problems were in fact linguistic puzzles.

These two approaches, the deconstruction of the cognitivist/socioculturalist dichotomy, and the reconstitution of problems of ontology as problems of language, appear entirely compatible. In fact, it seems that to apply one approach is to apply the other. A demonstration that what appears to be a dichotomy is in fact an incompatibility of two language games appears to be an instantiation of

deconstruction. A deconstruction of a dichotomy appears to be equivalent to the founding of a language game in which that dichotomy dissolves. So we aim to solve the problem of this obstructive dichotomy then, by applying an analysis informed by Derrida and Wittgenstein. The primary resources for the framework are the constitution of the research process as a set of language games and the use of a semiotic account in order to construct the framework. Some previous literature has considered a possible role for this form of analysis in mathematics learning research, although the focus has generally been on the use of post-structuralist, semiotic analysis as a means of describing classroom activity (e.g. Brown, 1997; Evans & Tsatsaroni, 1996); and as such these have taken a sociocultural perspective on mathematics learning. In this paper, we are working at a different level, addressing questions of mathematics learning more generally.

THE PROBLEM: A RESEARCH EXAMPLE

This section presents an example of research in mathematics learning, addresses the issue of what exactly is the problem with the existing dichotomy of perspectives, and introduces questions that are difficult to engage with within this dichotomy.

Jay (2009) makes use of priming protocols, employed within experimental method, to demonstrate a relationship between number knowledge and strategy use in young children. The study focused on children's use of the 'tie' strategy, for solving near-double single-digit addition problems with solutions greater than 10. For example, the problem '7+8' could be solved by solving '7+7+1', making use of the 'doubling fact' '7+7=14'. In this study, children between 7 and 9 years of age took part in two activities; a) solving a set of single-digit problems with solutions greater than 10, reporting the strategy used following each problem (children had a free choice regarding strategy), and b) completing a set of priming trials designed to test for the automaticity of activation of doubles in response to single-digit stimuli (testing whether '7' activates '14', for example). The priming trials were based on previous research demonstrating automatic processing of numerals and relations amongst numerical information by, for example, Garcia-Orza, Damas-Lopez, Matas and Rodriguez (2009) and Reynvoet and Brysbaert (2004). The sample of children was divided into two groups, one group consisting of all of the children who used the tie strategy at least once whilst working through the set of addition problems, and a second group consisting of all those who did not. The two groups were then compared with reference to data from the priming trials. This analysis showed that only the children using the tie strategy showed evidence of automatic activation of doubles. This in turn suggests that automatic activation of doubles is a key resource in children's development of the tie strategy.

Up to this point in the description, Jay (2009) will appear to be situated firmly within the cognitivist perspective, utilising experimental psychology methods. However, this study is best seen as situated within the primary school classrooms in which the

research took place. Conversations with the children forming the sample for the study (5 classes in 2 schools took part), and with their teachers and the mathematics coordinators for the schools, made clear a number of points with a bearing on the interpretation of the findings. Firstly, all of the children involved in the study knew about doubles, and were able to give the double of a single-digit number with only a short delay. Secondly, classroom mathematics instruction had involved making children aware of the variety of strategies for solving simple addition problems, and encouraging children to make use of these strategies in order to increase the efficiency of children's problem solving, since at least Year 1 (the children in the study were in Years 3-5). Mathematics lessons took place for one hour every day for all children in both schools.

Within the wider context of the classes and the schools in which the children's mathematics education is taking place, the results of Jay (2009) raise some interesting questions. Firstly, why do some children have automatic activation while others do not? A second question is; what can we do in order to help children develop and use the tie strategy and other efficient strategies for solving arithmetic problems? This is not just a developmental issue; some children in each year group from year 3 to 5 (age 7-9) did not automatically activate doubles in response to single-digit stimuli. It is not just a matter of having had experience of doubling; all children could calculate a double without difficulty and all had significant experience of having been taught about doubles and their relevance for calculation in the classroom. Now, the question I would like to pose next is: within which perspective ought we to proceed? The problem faced at this point is that neither the cognitivist nor the socioculturalist perspective offers an appropriate language for asking the kinds of questions we are going to want to ask. This research situation is a clear example of one in which we will need to ask not about individual thought and learning processes, not about social or group cognition, and not about broader sociocultural process, at least not in isolation from one another. What is needed in order to really address the problem are questions that focus on the *interactions* between these processes. As long as the cognitivist and socioculturalist perspectives are considered separate and mutually exclusive, it is very difficult to ask question that address interactions between biology, cognition, classroom interactions and wider sociocultural objects and processes.

A POST-STRUCTURALIST ANALYSIS

The purpose of this treatment is to reject the dichotomy between accounts of the individual and accounts of the group. This leads us towards a distributed, situated account of thought and learning. It also leads us to deconstruction. A first principle of this approach is to say that all we can talk about are signifiers and relationships amongst signifiers. All thought consists of signifiers and relationships amongst signifiers. This is very much related to Derrida's suggestion that there is 'nothing outside the text' (e.g. Derrida, 1997) – there is nothing we can say about thought that

is outside what we can say about signifiers. If we want to talk about learning, then we consider all aspects of learning part of the one single-order text, whether biological, cognitive, sociocultural or otherwise.

So, what do we have to do in order to demonstrate that a semiotic account functions as a framework for theoretical discussion of learning? What affordances must such a framework have? I want to claim that there are just two criteria for a theoretical framework to meet; we want to be able to demonstrate the fact that we can ask the questions that we want to ask about learning and we want to be able to demonstrate the fact that those questions are answerable. Of course, we will have to be able to say what is meant by conventional uses of terms such as 'knowledge', 'concepts', 'learning', 'mind', or at least construct meaningful and useful definitions of these terms within the framework, but that is just one example of a criterion that is necessary for the two principle criteria to be met.

The purpose for rejecting the dichotomy between individual and social accounts of learning is that it is becoming increasingly clear that any genuine, meaningful, account of learning is going to depend on being able to describe the interplay between individual and social factors. So, the kinds of questions that we want our theoretical framework to help us ask and answer include all those asked by cognitivists (lots of 'what' questions), all those asked by socioculturalists (lots of 'why' questions) and those addressing the interaction between the two.

APPLICATION TO EARLY NUMBER

How is the semiotic framework going to work? What is it going to look like? This section presents an example involving a child's developing understanding of number, taking the number 4 as an example. A child, during the course of their first few years of life, will come to recognise and use several signifiers related to the number 4. Some examples: the Arabic digit '4'; the written English word 'four'; the spoken English word 'four'; the four fingers (without the thumb) of one hand; and the arrangement of 4 dots on one side of a 6-sided die. There are likely to be many other signifiers directly related to the number 4. For example, my son, at the time of writing is three years old. He identifies very strongly with the number 3. If he sees the digit '3', he will often say something like, "I'm that number". I imagine he will continue to say something like that when he is four years old, although I expect it will be interesting to observe how this kind of statement will develop as he comes to adjust his differentiation of his use of number-signifiers for their various purposes.

Now, we have said above that these are examples of signifiers related to the number 4. We might want to ask, what then is the signified? Is it '4'? This is a very important step in the development of our account. We cannot talk about a signified, only about other signifiers and relationships amongst signifiers. If we can't talk about signifieds then how do we deal with questions of meaning? We might normally want to talk about the meaning of a particular signifier associated with a signified. It might still

be useful to think in this way, but we also need to remember that we have no way, within the language system available to us, to talk about signifieds. So we try to describe signifieds – by instantiating new signifiers and new relationships amongst signifiers, in an attempt to, little by little, close the gap between signifier and signified. The gap can never be completely closed, because we are using a language system to describe and define something outside of that language system. In Lacan's (e.g. 2001) framework, we are trying to bridge the gap between the Symbolic order and the order of the Real, the unbridgeable gap referred to as the 'lack'.

So what is the meaning of the Arabic symbol '4'? Its meaning consists in the relationships that it has with other signifiers. '4' has a relationship with the other signifiers given in the list above. It has a relationship with the signifier for 'a sense of four-ness'. It has relationships with signifiers of '3' and '5', because we are habituated to seeing and thinking about '4' in its place in the sequence of natural numbers, or integers. An important point must be made here regarding this account of meaning. The statements above could be read in a relatively simplistic way, if one assumed that relations amongst signifiers are constrained by the bounds of an individual brain or mind. However, once we reject this boundary it is clear that the simplistic reading needs further development. Here again there is correspondence with Wittgenstein's (1953) account of language. 'Meaning is use' and the Private Language argument tell us that no analysis of meaning can take place entirely within the bounds of an individual brain/mind. Meaning of language (consisting of signifiers) consists in the role that language (that set of signifiers) plays in acts of communication amongst brains and minds. So, the analysis of the meaning of '4' can be developed as follows: The meaning of the signifier '4' consists in the role that '4' plays in acts of communication both intra- and inter-personally. This is close to the position taken by Sfard (2008), although Sfard appears to take a position restricting analysis of cognition to exclusively human modes of thought. It is clear from the cognition literature that the deliberative portion of human thought is largely dependent on automatic, uncontrolled processes (see for example, reviews of the Stroop effect [MacLeod, 1991] and of priming studies [e.g. Kinoshita & Lupker, 2003]). Our response to the signifier '4' is largely involuntary, at least in the first few milliseconds after perceiving it. However, involuntary or not, there is no reason for doubting that the meaning of a signifier consists in its role in an act of communication – after all, involuntary responses to a signifier are not limited to intra-personal communication. Involuntary responses are also clearly apparent in inter-personal communication (see again priming studies). This is not to say that these data regarding automatic responses contradict Sfard's theory, but rather to say that Sfard's theory does not *encompass* these aspects of what we know to be a fundamental aspect of thinking and learning.

Defining key terms

We are in a position now where we need to define some key terms. If we want to be able to talk individual and social learning, subsuming cognitivist and socioculturalist perspectives, then we are going to need to know what we want to mean by terms such as 'concept', 'knowledge', 'learning', 'understanding', 'mind', and so on. These terms themselves have potential to act as barriers to interdisciplinarity, due to substantial differences in their definition and interpretation by researchers operating from different perspectives. Each term is a reification, brought into being by the researcher/observer. A 'concept' is nothing but an observer's definition. So the substantially different definitions of 'concept' by, for example, cognitivist and socioculturalist researchers, constitute a significant barrier to communication. It is important that such terms ('concept', 'knowledge', 'understanding' and so on) are recognised as reifications, in order to provide a means and an arena for the negotiation of their meaning. Some initial sketches of meaning might be as follows:

Signifier: A signifier is a unit of meaning. It might be a word, symbol, image or object. It might have a physical instantiation (ink on paper, physical object, photograph, audible sound and so on). The meaning of a signifier consists in its relation to other signifiers.

Concept: The network of signifiers and relationships among them, that relate to a given signifier. So the concept 'addition' consists in the set of signifiers that relate to the signifier 'addition', plus the relationships amongst them. Such related signifiers might include words like 'sum', 'add', 'plus', the symbol '+' and addition facts such as '2+2=4'. Also strategies or algorithms for solving particular addition problems (we might, as researchers/observers, refer to these as 'count-on', 'min' and so on – others will not use these names, however the algorithm itself constitutes a signifier). It is clear that any concept is a dynamic entity. Concepts change as the focal signifier is associated with new signifiers, or relationships amongst a set of signifiers alter.

Mind: The set of signifiers, and relationships amongst those signifiers, for some definable set of individuals. We can talk about the mind of an individual – that is the set of signifiers for that individual (the external physical objects that have meaning for that individual, plus the neurologically instantiated signifiers for that individual, plus the relationships amongst these signifiers).

Understanding: This seems to be a term that refers to the intersubjective aspects of 'concept'. One might be said to have understood a concept when one has developed a signification network that is sufficiently similar to that of a community with which one wants to engage with reference to that concept.

Two important points should be made apparent at this time. One is that it is clearly possible to define these and other terms within the proposed semiotic framework. That is to say that the framework appears sufficient for the discussions that we want to have about learning. The second point is that the framework makes clear the fact

that each term is a reification that, if it is to be used in any meaningful way, must be defined within a shared framework. The proposed semiotic framework appears to offer a sufficiently neutral arena for negotiation of such definitions amongst researchers from traditionally disparate or dichotomous perspectives.

RETURN TO THE RESEARCH PROBLEM

As a conclusion to this paper, we return to the discussion above regarding Jay (2009). What can be done to address the research problem; why do some children not automatically activate doubles, and what can be done to help them? What kind of research questions arise from the kind of analysis described above? At the heart of the proposed framework is an imperative to focus on the interactions amongst cognitive and sociocultural objects and processes. To address these interactions, we describe the situation in terms of signifiers and relationships amongst signifiers. Let us begin with a description of the research situation within the individual child. Firstly, we are interested in why it is that some children automatically activate doubles in response to single-digit numbers. This is to say that we are interested in why some children exhibit a very strong connection between the signifier '6' and the signifier '12', between '7' and '14' and so on. We are also interested in the role that this set of activations plays in the use of the tie strategy.

On the sociocultural side we are again interested in how number signifiers and relationships amongst them are used, but this time we are interested at the level of interaction amongst actors in the classroom. Stahl's (2005) 'group cognition' might be a useful way to think about some of the processes that might be involved in this activity, as long as we remember that within social processes we are dealing with exactly the same kinds of signifiers and relationships amongst signifiers that we deal with within the individual.

The first thing to realise is that this approach allows now to hold some apparently contradictory things to be true. So within any given individual in the classroom, the meaning of '7' consists in the relationships that '7' has to other signifiers. So one particular child might relate '7' to 'seven', 'holding up 7 fingers', 'my age', '6' and '8' (due to proximity on the number line). Other children might relate it to 'prime', some others to '14' (double 7). So, from the cognitivist perspective, we talk about *an* individual child that doesn't exist; we talk about a generalised, average, child. In fact, just looking at the meaning of '7', it is likely that, firstly, different children will relate different signifiers to '7', and secondly, the strengths of these relationships will be different. So '7' has a different (even if only subtly) meaning for each person in a classroom. Aside from all of the individually constituted meanings, there is also a socially negotiated meaning of '7' for the *classroom*. This is formed through interactions amongst members of the group. The negotiation of meaning of signifiers in the classroom is dynamic; there will be a constant dynamic interaction between socially constituted meaning of signifiers and meanings of those same signifiers held

by individuals. In turn, meaning for the classroom, is tempered by, and interacts with, meanings of wider and external communities and groups. So, for example, each child brings with them aspects of meaning from their own families. In the context of the research situation, this opens us up to dealing with some new questions, focusing on interactions between meanings constituted by individuals, and meanings constituted, or negotiated, by the group. In general, we can ask questions about how children's knowledge, accessible to cognitive and neuroscientific methods, interacts with (influences and is influenced by) classroom activity. Specifically with regard to Jay (2009), it would be informative to ask what differences there are in terms of engagement in classroom interaction between those children who exhibit a priming effect for doubles and those who do not. It might also be possible to investigate how knowledge such as this spreads through a classroom, through group interaction.

CONCLUSION

This paper has argued for a post-structural, semiotic, treatment of research on mathematics learning in order to reconcile traditional perspectives and allow the possibility of asking questions about interactions between individual/cognitive and group/sociocultural, aspects of learning. These kinds of questions offer an opportunity to engage with research on learning with greater depth than is possible with more restrictive, traditional, perspectives on mathematics learning research. There is much more to do in the development of this approach. Existing research conducted from multiple perspectives can be interpreted within this framework in order to understand points of conflict and potential interactions more clearly. It will be important to thoroughly test the claim made here that this framework offers the potential to fairly represent existing perspectives on mathematics learning.

The poststructuralist approach provides a means of being explicit about what aspects of what questions of learning we are interested in, without excluding other aspects from the arena. We can be free to talk about what meanings are common amongst a particular population of children in a particular domain of mathematics, including trajectories of individual development, relationships between knowledge and understanding, knowing-that and knowing-how, as well as talking about individual differences within that population. We can also talk about classroom activity and the development of socially negotiated meaning through classroom interaction. As a result of using the same language, of signifiers and relations amongst signifiers, in discussions of individual and social thought and learning, some barriers to discussions of interactions between individual and social are removed.

RECOVERING MATHEMATICAL AWARENESS BY LINGUISTIC ANALYSIS OF VARIABLE SUBSTITUTION

Kaenders^a, R.H., Kvasz^b, L., Weiss-Pidstrygach^c, Y.

University of Cologne^a, Charles University in Prague^b, University of Mainz^c

How are we to understand and distinguish qualities of mathematical acquirement? The authors show with help of a school relevant example how mathematical awareness can be classified. The classification uses linguistic methods to identify factors important for conceptual understanding of mathematics. The analysis relates historical to activity theoretical aspects.

INTRODUCTION

Usually mathematical awareness of a student puts itself into effect in his approach to problems, a mathematical topic, in the way the student conceptualizes a mathematical object and uses it as tool. We use this aspect of student's cognition in order to relate two models describing the quality of mathematical acquirement from different perspectives both by linguistic means.

The first model takes an activity-theory approach (Weiss-Pidstrygach, 2011). Symbols, definitions, formulas, skills and approaches are linked to object-oriented activities, externalisation and internalisation. The second model uses different qualities of *mathematical awareness* (Kaenders & Kvasz, 2011, 2010) to describe mathematical aptitude. The classification is given by the three dimensions (content, skill and thinking activity) and by the quality these dimensions are linked together. The classification by different qualities of awareness is based on historical considerations and patterns of change in the development of mathematical language (Kvasz, 2008).

This approach is based on three basic convictions:

- Mathematical awareness is a *holistic* concept that unites such qualities like number sense in arithmetic, symbol sense in algebra and geometrical awareness in geometry.
- It is *topically neutral*, i.e. awareness acquired in one area can be transferred to another.
- It has different degrees that are closely related to *different degrees of rigor*.

In order to motivate a discussion about possible combining frames of these two models, their further differentiation, their relevance for mathematics education we explain our approaches with the help of an example from the school curriculum.

VARIABLE SUBSTITUTION AT SCHOOL

How do we have to modify the graph of f in order to find the graph of the function g which is given by $g(x) = f(x+3)$?

The problem is standard and appears first for a quadratic function f in Grade 8 and in the above general phrasing in the context of modeling and preparation of the “small chain rule” in Grade 10. (German curriculum)

Understanding of the mathematical question takes for granted some experience with the mathematical objects involved in the formulation of the problem as well as their relations and role in a wider context. Examples of prerequisite mathematical objects in the German curriculum are coordinate system, units, correspondence, linear functions, different representations of functional dependencies with and without calculator (value table, graph, term, text), standard functions, such as rational, trigonometric, exponential functions. The understanding and handling of these objects by students depends a lot on the attitude of the teacher and ranges from recalling definitions or knowing the calculator commands up to their conceptual use as a tool.

In the last decade, the theoretical approach to functional dependencies in textbooks became extremely pictorial, bounded to CAS supported graphs and concrete functions. On the other hand, later on, in the context of modeling, maximum and minimum value problems and integration problems are often formulated in algebraic notations (e.g. $f(x) = \sin(ax+b)$).

The existing teaching and textbook culture defines a certain linguistic frame for the determination of the graph in question.

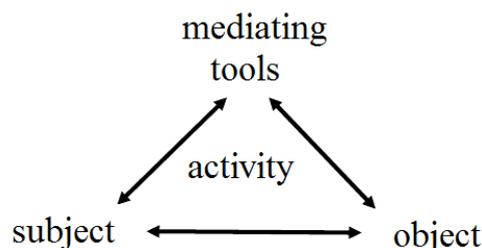

The Graph of $g(x) = f(x+3)$ can be found by various thinking activities, using various skills, solving problems formulated in various contexts and answering differently interpreted questions, following instructions or working in a group, trying to solve a problem or to teach the rules to somebody else...

The solution itself tells little about the mathematical acquaintance of the student, it could e.g. be an imitation learned by rote. His mathematical awareness manifests itself in the way the student talks about his solution, his first intuition, the appearance and development of his assumptions, doubts he has, thought experiments he went through. Thereby his possibilities to couch generalizations, analogies, counter examples etc. will depend on the language of the mathematical concepts of which the objects involved make a part.

In different concepts the denotation given to the objects can coincide: the (pointwise defined) *polynomial function* is also the *polynomial function* defined by its coefficients and is also the *polynomial function* as an element of the set of all continuous functions.

The meaning of the mathematical object as a concept itself is constituted by different contexts the object can be embedded into (part of existing mathematical theories), as well as by the problems which can be solved by using it as a tool. The tool-object-duality was explicitly introduced by R. Douady and used in the context of didactical engineering for concept development (e.g. Douady, 1997). We interpret this principle in an activity frame in order to change the constructivist perspective by a social-historical one.

Speaking in the terminology of activity theory: the mathematical concept “substitution of variables” can in the model of an action appear in two positions: as an object and as a mediating tool. The general model used in activity theory can be represented by the diagram on the right.

This general scheme can be applied to a concrete mathematical problem in two different ways (see fig. 1).

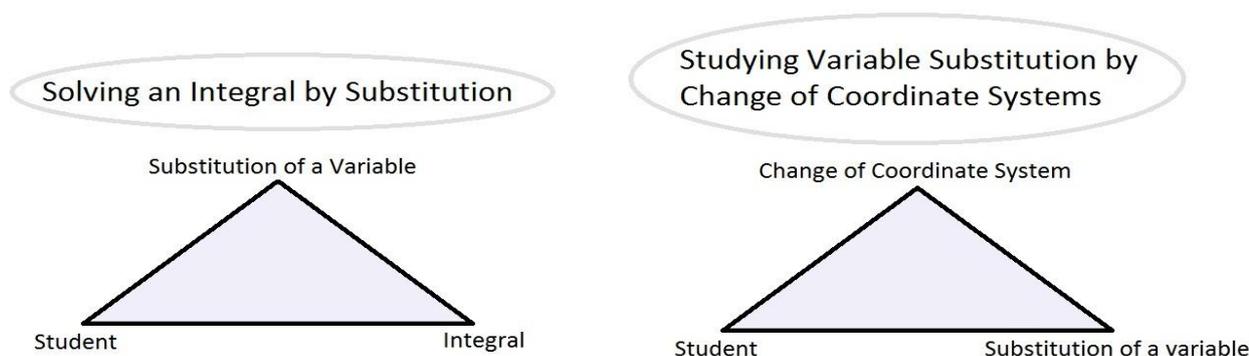

Figure 1: Substitution of variables as an object and as a mediating tool.

We can for instance consider variable substitution as a special case of a considerable more general method (concept): structure preserving transformations. Typical problems, which are solved by using structure preserving transformations are: finding a representative with the same structure but easier to handle (e.g. nicer coordinates) or transforming a given object in order to get a whole class with the same properties (possible solutions of an equation). We can also look at variable substitution as special case of the method of introducing coordinates, i.e. coordinatization. Typical problems handled by this method are finding explicit solutions in local coordinates (Taylor expansions, equations on manifolds...)

In other words the given mathematical object can be conceptualized in different ways, creating different methods for problem solving. Also the mathematical object on its own can be defined in different ways using different mathematical languages – and therefore predetermining different conceptual developments.

In the following we sketch different approaches to find the graph of $g(x) = f(x+3)$ and indicate the concept it belongs to. To this end we represent the respective correspondence given by value table, graph or term. The students are used to situations in arithmetic where '+3' indicates '3 to the right' or '3 upwards'. For the graph of $g(x) = f(x)+3$ this rule of thumb seems to be consistent. Finding the graph of $g(x) = f(x+3)$ therefore causes for many students an intuitive conflict.

POSSIBLE APPROACHES TO FINDING THE GRAPH OF $f(x+3)$

The problem of finding the graph of $g(x) = f(x+3)$ has a rich mathematical and didactic structure. There are many different approaches which the teacher can adopt. We would like to mention ten *examples*:

- 54 Given a function f by $x \mapsto f(x)$, take the definition of g and evaluate for any x the function f at $x+3$. Draw the graph of g from the table of values.
- 55 Insert the term of a special function f in a graphical calculator, compute and plot the associated value table of the function $g(x) = f(x+3)$.
- 56 We can use path-time diagrams as a metaphor for a general function. For instance think of two motorcyclists driving exactly the same way. The path-time diagram of one of them is given by the graph of f i.e. at time x she is at distance $f(x)$. Her colleague however has started already 3 minutes earlier and has at time x already reached $f(x+3)$. Of course, the path-time diagram of the early rider has to be drawn three units to the left from the one who departs on time.
- 57 We can also interpret the formula $g(x) = f(x+3)$ as recipe for *picking up values* of g (see Fig. 2). If we want to determine the height of the graph of g at the value x we go 3 units to the right and pick up the value of f . When we proceed like this several times it becomes apparent that the graph of f will be shifted 3 units to the left.
- 58 Another way to look at this particular shift to the left is to use nomograms for the composition with the linear function $x+3$ and to combine it with the graph of f (see Fig.2).

Substitution of the variable using the set-theoretic definition of the graph: We can consider the graph of a function h as consisting of points with coordinates of the form $(x, h(x))$. When we move the points $(x, f(x))$ of the graph of f with 3 units to the left, then a point $(x, f(x))$ is moved to $(x-3, f(x))$. Now we look for a function g such that $(x-3, f(x))$ is a point $(x', g(x'))$ on the graph of g . Hence $x' = x-3$ and $g(x') = f(x'+3)$.

These approaches consider the graph of a function as a pointwise defined object.

We can also let f be the graph of a function, perceived as a curve, drawn or plotted in a coordinate system, representing a function as an entire object.

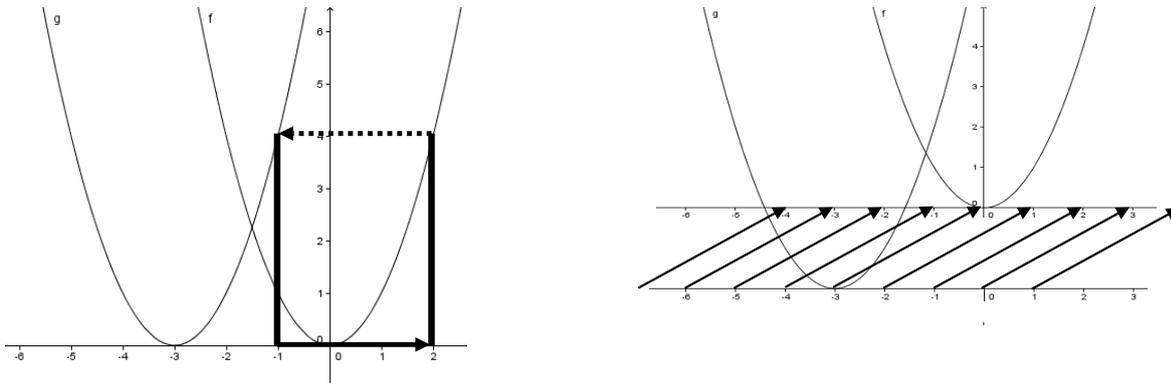

Figure 2: ‘Picking up’ values of g and combination of g with a nomogram.

In this situation, examples to find the graph of $g(x) = f(x+3)$ are the following.

- 59 Using a DGS device for shifting the curve around (e.g. GeoGebra or appropriate applets). Insert the term of a special function f and plot the corresponding graph. Shifting the graph changes the term and vice versa. It turns out that a movement to the left corresponds to adding a positive constant to the argument x of the function f .
- 60 By variation of the graph by e.g. dynamical geometry, using a parameter a one can see how the graph of a function $g(x) = f(x+a)$ behaves. This general observation can be confined to $a = 3$.
- 61 The shift $x \mapsto x+3$ can be seen as a shift of the coordinate system where the origin is moved 3 units to the right. The graph of the function f remains unchanged in the plane and hence moves – seen from the coordinate system – to the left.
- 62 Any function depending on a variable x can be *developed around* $x_0 = -3$. That is to find a function $g(x')$ with $g(x') = f(x'+x_0)$. The approved way to do this is to substitute x by $x'+x_0$ or to write $f(x) = f((x-x_0)+x_0)$.

The described interrelation between definition, embedding, conceptualization and operationalization of mathematical structures shows that parts of the zone of proximal development for a mathematical activity are defined and can be understood in linguistic terms. The language in which the relevant mathematical objects are named and presented provides a presetting for the local scaffolding, in particular the language for diagnostics of the zone of actual development and variations of the task. The compatibility and transferability as a tool for problem solving depends on the grammar of the concept (relations, hierarchy, dependencies between objects inside the local theory) and possible changes of perspective for the speaker (existence of a

paradigm). It seems to us that these linguistic data structure the zone of proximal development in the way in which speech and motivation are interacting with thinking.

LINGUISTIC ANALYSIS OF THE EXAMPLE $f(x+3)$

For the conceptual framework of *mathematical awareness* we distinguish three aspects *contents*, *thinking* and *skills* as three main dimensions in which mathematical aptitude can be positioned. The basic idea is: the quality of the respective mathematical awareness is not an additional dimension in this diagram but it qualifies the way in which the contents, skills, and thinking are connected, thus it qualifies *the way in which* for example someone *argues* in *arithmetic* by *visualizing* or someone *proves* in *calculus* by *algebraizing*.

On the level of contents we distinguish arithmetic, synthetic geometry, algebra, analytic geometry, calculus, logic, set theory, probability.

Introduction of other subjects would be possible. The ordering of the topics follows roughly the order of historical development of mathematics, and also the growing complexity of the mathematical language (cf. Kvasz, 2008).

The dimension of skills is separated from the dimension of the thinking activities. We address the following skills: to count, to calculate, to draw, to construct, to symbolize, to algorithmize, to visualize, to recognize patterns, to establish dependencies, to use limit transitions and to employ language. Particular skills are best acquired in corresponding contents, as for instance counting in arithmetic, drawing in synthetic geometry, etc. Nevertheless, one of the reasons for separating skills from contents is to emphasize the possibility (and actually the necessity) of transference of skills from one content to another. Thus we usually apply addition to numbers, but we can add intervals, polynomials, vectors, functions, etc. So mathematical awareness is the awareness of the transferability of skills from one content to another. It is precisely the failure of many forms of mathematical instruction that particular skills are strictly tight to their corresponding content. Competence models, on the other hand, are tight to certain practical requests. Their solution requires different skills but remains on a certain level of thinking. In our model the relations between contents, skills and thinking allow a great variety of combinations.

We distinguish the following possibly not exhaustive list of thinking activities: to observe, to formulate, to argue, to explain, to verbalize, to classify, to define, to prove, to confine, to generalize, to vary, to concretize, to analogize, to structure. As in the previous case, also in the case of thinking, the role of an independent dimension emphasizes the manifold relations of thinking activities with the various topics and with the different skills. The student needs to master sufficiently a particular skill in order to be able to explain, define, or generalize a mathematical

phenomenon. One of the important aspects of the mathematical awareness is the awareness of the adequate degree of rigor and justification that is sufficient for a particular calculation or construction.

Mathematical awareness then is a quality, how our knowledge of some mathematics contents, skills and thinking are linked together. It is not an extensive notion but describes intensity of the amalgam, which links these three aspects with each other. It is rather a color or a taste than a position of some mathematical ability. The list of the different qualities is possibly not exhaustive:

- social awareness
- imitative awareness
- manipulative awareness
- instrumental awareness
- diagrammatic awareness
- intuitive awareness
- experimental awareness
- strategic awareness
- contextual awareness
- argumentative awareness
- logical awareness
- theoretical awareness

Here we want to discuss the possible different linguistic indications to varying qualities of mathematical awareness that we can think of when we consider the different ways to find the graph of $g(x) = f(x+3)$.

i. Social awareness

This is the first possible level of awareness and it might be that many people stay on that level all their life. A solution to the above problem is that ‘+3’ in $f(x+3)$ has to be interpreted as ‘3 units to the left’ since the teacher did so in class. Moreover, also the fellow students do it that way.

- **Imitative awareness**

The above insight can also be explained by the teacher step for step. It is possible to reproduce each step of the argumentation without understanding its complete strand. And, look, it works. Also this very classical type of awareness is of great importance for the understanding of mathematics. To any student this approach gives a possibility to betake oneself in the middle of the subject guided by the authority of the teacher.

- **Manipulative awareness**

If we look at the substitution of the variable using the set-theoretic definition of the graph in *example 6* and the development of the function around $x_0 = -3$ in approach i), then we see that still an insight in the manipulations with variables is necessary. The procedure can be understood just from the manipulations with $x = x' + x_0$ and $f(x) = f((x - x_0) + x_0)$. In particular with polynomials we can use long division. The

solution is obtained by applying these two mechanical rules in the algebraic expressions.

- **Instrumental awareness**

Plotting of a value table or using a DGS device for shifting the curve around yields instrumental awareness. It is true, that the students know the result only thanks to the use of the instrument, but the teacher would compromise his credibility if he would insist that they don't know the solution yet. Of most things in life we neither have a better knowledge nor a higher form of awareness. The instrumental awareness is what the CAS-system or likewise a graphical device tells us: the result is correct – it came out from the computer and I do not know how – not more but also not less.

- **Diagrammatic awareness**

Using $g(x) = f(x+3)$ as recipe for *picking up values* in *example d)* or the interpretation by a nomogram in *example e)* as well as the shift $x \mapsto x+3$ of the coordinate system in *example i)* are ways to come to a diagrammatic awareness. In any branch of mathematics pictures, graphs and diagrams play a central role. We can represent for example, arithmetic relations by dot pictures, functions by graphs or nomograms, polynomials by Newton diagrams. It is possible to argue, to define and to perform most thinking activities in a diagrammatic way. Diagrammatic awareness is indispensable for understanding mathematics, although there is always a risk by stopping at the level of diagrammatic awareness to prevent further growth to logical and theoretical awareness.

- **Intuitive awareness**

The expectation, based on experiences in arithmetic, that '+3' indicates '3 to the right' or '3 upwards' is an example of a wrong intuitive awareness. The shift of the coordinate system to the right in *example i)* or the adoption of a nomogram in *example e)* on the other hand are able to foster a better intuitive awareness. In some cases there exists a feeling, which leads to a hypothesis. That is different from experimental awareness since there we only find an assertion to be true in the case of some cases.

- **Experimental awareness**

The calculating and plotting of a value table in *example a)* and *b)* and the shifting of the graph in a DGS device in *example g)* founds an experimental awareness. It is nothing but: I tried it, and it worked out this way. Mathematicians know also the converse experience: Even if one has proven something in a general setting, a concrete calculation with the predicted result is not necessarily superfluous and can very well be an enhancement of one's awareness. More generally, experimental awareness can be the study of particular cases for a more general situation without worrying about the legitimacy of the particular steps supplemented by heuristic arguments.

- **Strategic awareness**

Also to find the graph of the function $g(x) = f(x+3)$ needs an appropriate strategy depending on the context. In trigonometry other ways seem appropriate than by the idea of moving the coordinate system. Especially for problem solving, at least since Poincaré, Hadamard, Polya and Schoenfeld, mathematicians are conscious of the fact that one needs more than just factual knowledge and skills. What is needed is the knowledge and the experience of steps one can take even if one does not finally know how to proceed successfully. Polya introduced for this the term *heuristics*. On the highest level, also building of a theory requires strategic knowledge: which facts will be put into axioms and which can better be proved. We see that strategic awareness goes beyond problem solving in the narrow sense.

- **Contextual awareness**

The metaphor of the two motorcyclists in *example 3* provides us with a context that allows getting insight into the relation between the two graphs. However, not every graph of a function may be interpreted as path-time diagram of a motorcycle. In general we can speak of contextual awareness when we attribute semantics to a mathematical topic. As well for mathematics teaching as also for professional mathematicians this type of awareness is of crucial importance. Contextual awareness constitutes *mental objects* (Freudenthal, 1991, p.19). In order to build such mental objects Freudenthal formulated the principle of *rich contexts* (p. 73).

- **Argumentative awareness**

Before proving an assertion within a theory we can argue independently of the particular theoretical framework that it must hold. For instance when we argue that it is the coordinate system that is shifted instead of the graph or when we speak of picking up the values of f , we give an argument which is not a logical one. However it serves for our argumentation. We argue by means of actions, heuristics, algorithms, and estimations etc. that help us to trust our result. We can also argue by thought experiments and or by applying metaphorical arguments.

- **Logical awareness**

Logical awareness is the awareness that ensures us of mathematical proofs and arguments. It enables us to check proofs and to distinguish heuristic arguments from logically necessary ones. But without all the other types of awareness we can hardly think logically. For example the substitution of the variable using the set-theoretic definition of the graph is a logical argument within a theoretical framework.

- **Theoretical awareness**

By theoretical awareness we understand the ability to see mathematical propositions as relative to particular theoretical frameworks, the ability to relate proposition to different frameworks and to relate frameworks to each other. Although theoretical

awareness may in some sense be considered as the highest form of mathematical awareness, it becomes a kind of fata morgana without grounding on other types of mathematical awareness. In our example one could realize that the set-theoretical construction of graph is a very general construction which is used in topology or algebraic geometry to equip the graph of a function with topological or algebraic structure.

DISCUSSION

The work in our group was most inspiring. Discussions and demonstrations of various ways to link and join theories (cherry picking, organized networking, applied networking theories...) encouraged us to more problem and attention oriented developments of our approach. We are grateful for directing our attention to Regine Douady's model and realizations of the tool-object-duality and to John Mason's complex and multi-purpose work on the development and education of awareness. The latter helped us in particular to place our approach and to structure what is to be done next.

HOW A GENERAL EPISTEMIC NEED LEADS TO A NEED FOR A NEW CONSTRUCT

A CASE OF NETWORKING TWO THEORETICAL APPROACHES

Ivy Kidron^a, Angelika Bikner-Ahsbahs^b, Tommy Dreyfus^c

^aJerusalem College of Technology (Israel), ^bUniversität Bremen (Germany),

^cTel Aviv University (Israel)

Abstract: Two students were asked to carry out an activity about continued fractions in the presence of an interviewer. We present two separate analyses of a central episode from two theoretical perspectives focussing on what drives the students' progress of coming to know. Making intensive use of the notion of general epistemic need, we show how such needs arise and are expressed, and how they lead to the need for a specific new construct. The paper concludes with reflections on the networking process, highlighting conditions that have supported the process and hence emergence of a more integrated view of the episode.

INTRODUCTION

Networking of theories has recently become an important endeavour of mathematics education (Bikner-Ahsbahs et al., 2010). We present a facet of an ongoing research project that investigates effective knowledge construction in interest-dense situations¹. We found it useful to proceed by networking two theoretical approaches, the perspective of abstraction in context (AiC) and that of interest-dense situations (IDS) with particular focus on two theoretical concepts: the need for a new construct, and interest. In both perspectives epistemic processes play a central role.

AiC focuses on the construction of knowledge by individuals or small groups, using a model based on three epistemic actions: *recognizing* constructs known from previous activity, *building-with* these recognized constructs, for example to solve a problem, and *constructing* new knowledge while building-with recognized previous constructs. While the model serves to analyse the central stage of the emergence of a new (to the learners) construct, the researchers postulated that a necessary condition for such emergence is that the learners experience a need for the new construct (see Schwarz, Dreyfus, & Hershkowitz, 2009, for a detailed description of AiC).

Interest-dense situations (IDS) focus on the epistemic processes within social interactions. These are situations that are constituted by students who are collectively *deeply involved* in a mathematical problem, *constructing mathematical knowledge* in a deep way and *highly valuing* the mathematics they consider. This approach uses an epistemic actions model that comprises three collective epistemic actions: *gathering* and *connecting* mathematical meanings and *seeing* mathematical structures. Any IDS lead to structure seeing, and students who are engaged in an IDS show situational

interest. Situational interest holds when an individual experiences involvement and meaningfulness of a topic (see Bikner-Ahsbahs, 2005, for a detailed description).

In a previous paper (Kidron, Bikner-Ahsbahs, Cramer, Dreyfus, & Gilboa, 2010), we exhibited the methodology of networking the two approaches on the basis of common analyses of interview protocols from both perspectives. One benefits of networking was the insight that besides interest (IDS) and the need for a new construct (AiC), a more general epistemic need (GEN) can be the driving force that makes students to progress in learning processes according to the challenge they meet within a situation, individually and socially. The GEN is the need to develop an initially vague idea further, leading to a more definite one, in accord with Davydov's (1972/1990) view of abstraction. The GEN is experienced according to the demands of the situation and hence becomes specific, for example as a need to be more precise that is shown by student actions and can be observed.

In the present paper, we continue the previous research using a different set of data. We carried out a networked analysis of an epistemic situation from the two perspectives concerning the roles of the GEN for constructing knowledge. The general result of the analysis is a holistic view of the learning process integrating both perspectives. An important specific result is that the GEN develops, at least in this case, into a need for a specific new construct as postulated by AiC.

SETTING AND TASK

Two grade 10 students work on a task about the continued fraction $1 + \frac{2}{1 + \frac{2}{1 + \frac{2}{1 + \dots}}}$ in

an interview situation. The main role of the interviewer is to support these students with hints (beginning with very weak hints) when they fail to progress. The students were asked to calculate the first seven fractions, expressing them as simple fractions; it was suggested to denote the x^{th} fraction by $f(x)$, beginning with $f(0)=1$. The students were then asked to represent the first 20 fractions as decimal numbers, to look for patterns, make conjectures, and explain why these conjectures are true.

The students discovered that the decimal numbers in even places (x even) begin with a 1, the decimal point being followed by a number of nines, and the ones in odd places begin with a 2, the decimal point being followed by a number of zeros. They also noticed that the number of nines, respectively zeros grows as more fractions are computed.

The students later observed the following rule: when the x -value passes a perfect square, the numbers of nines (zeros) increases by 1 and becomes equal to the root of that perfect square. When formulating this rule, they were talking in terms of a "space of places" (places referring to decimal places). They also noticed that this rule was valid only approximately. The rule may appear as an expression of a polynomial

growth law to the expert, but at least at this stage, the students considered it only locally, for fixed x .

THE ROLE OF THE GEN FOR ABSTRACTION IN CONTEXT

The GEN and the seeds for a constructing action

In the transcript (available from the researchers) we observe some phenomenological identification of patterns (in utterances 719-1353), which we may consider as *seeds for constructing actions* that take place later. By *phenomenological*, we refer to the fact that the elements of the sequence are considered as strings of digits rather than as numbers. The expression “space of places” (which we will abbreviate henceforth as SP) appears in 818 and there is some indication for an epistemic need in the efforts of the students to clarify this notion and to assign it a name. We submit that when somebody expresses the same phenomenon in different ways in an attempt to associate meaning with it, we have an indication for a GEN. This was the case in relation to the expression “space of places”. In addition to the different ways the students expressed the SP, we also discern a double interpretation of the SP: (i) SP as an interval on the x -axis, which numbers the elements, specifically the interval in which the number of nines/zeros remains the same; and (ii) SP as a part of the decimal expansion of $f(x)$, specifically the part containing the nines (or zeros). This double interpretation reinforces our interpretation of the SP as a seed for later constructing, as something that is not precise and needs to be elaborated.

The Role of the GEN in constructing actions

We first relate to one specific aspect of the GEN, namely the need to understand the present situation in terms of the previous knowledge or previous experience, to engage with the challenges offered by the task. Then, we note how this need and the limitations of the previous knowledge [specifically that the previous knowledge was adequate to empirical computations while the strings of digits were explicitly written and observed] lead to other specific aspects of the GEN, namely the need to be more general and the need to clarify. Finally, we will observe how these specific aspects of the GEN lead to the emergence of the need for a new construct as postulated by AiC.

After the phase described above as phenomenological, we observe a striking change in the students’ attitude and way of thinking: They start giving reasons rather than only phenomenological descriptions. We interpret this as a consequence of the interviewer’s initiative to ask questions concerning the SP for $f(1'000)$ (in 1354) and for $f(1'000'000)$ (in 1397). The students express their need to understand the new situation in terms of their previous empirical experience, and express their thinking that they need to do all 1000 computations by recursion (in 1359-1362). The limitation that results (“we cannot do all the 1000 computations”) leads to the *need to be more general* and to apply their “theory” that the length of the SP approximately equals the square root of x more generally (1382).

The next initiative of the interviewer, the question “How would it work then?” (in 1424) - again causes the students to experience a limitation of their previous experience and it leads them to the need to think in a more general way. This need directed the students towards the beginning of a constructing phase in which infinity plays a role. We note the important role of the interviewer but at the same time also the fact that the notion of infinity was expressed on the students’ initiative. The students express a need to understand the meaning of “infinite[ly many] zeros” (in 1429), and ”infinite[ly many] nines” (in 1431) as well as the meaning of a sequence approaching a number: “it keeps on leaning closer to zero-, closer to two, both numbers” (1427). Hence, we observe constructing actions that relate to convergence and accompany the students’ extension of the growth pattern of the SP from the initial 20 elements to 1’000, 1’000’000 and beyond, to what the students call infinity.

A first constructing action that we denote C_0 , *Convergence as coming very close to ...*, appears in 1418 and more clearly in 1427. Then, we observe C_1 , *the Potential Infinite* process view in 1427 (see above) but also, for example, “If one looks at it precisely, it never reaches two, even if there are infinite nines, after it there always comes seven three two whatever, can be anything the following numbers, we have not even looked at them yet, could be that they have a pattern too, but I don’t, personally I don’t see anything there (M laughs)” (in 1473). C_1 is accompanied by C_2 , *Infinite as a façon de parler: very, very large but finite*, as well as C_3 , *the strange infinite object is legitimate only in the mathematical world*, for example in 1356:

1354. T: Because one, one nine ninth is namely one point nine nine nine nine nine nine nine nine, a-and two, because one plus nine ninth is definitely two but nine, one ninth, is zero point one one one one one

1355. M: Yes but then, if you want to make nine ninth, then it would be two

1356. T: Theoretically (M laughs)

C_3 is similarly expressed in “If, if you insert infinity it theoretically equals two” (in 1437), which somewhat later leads them to write “ $f(\infty)=2$ ” on their worksheet. Another aspect of C_3 is the transition from infinite as a façon de parler to infinite as a legitimate object in the mathematical world.

C_1 , C_2 , and C_3 develop in parallel: At the same time that the potential infinite process view is developed, the students also begin manipulating the infinite as a legitimate mathematical object as they have done previously for large but finite numbers. The occurrence of so different (and somewhat contradictory) constructing actions in parallel places heavy demands on the students. This leads to a feeling of unease, of confusion, which is expressed in 1473 (cited above) and causes the expression of a need for a new construct in 1478: “The best would be of course if we had a functional equation right? Thus if one could say exactly, f of x equals (...)”. We can see this need as a consequence of the limitations of the students’ previous experience: In the present situation, they are not able any more to use what they

know from the finite case. Therefore, a need for a new view is expressed. This need leads to the construction C_4 , *transition from a numerical way of thinking (with empirical results calculated by the students) to a more general way of thinking (which does not depend on specific cases)*. A new construct is needed to permit this transition. The need for this new construct is explicitly expressed in 1478. During this search, the students continue giving reasons rather than only describing phenomena. This new approach in which the students explain their way of thinking provides evidence for the passage from the seeds of constructing to the beginning of the constructing process. The seeds of constructing also influenced later constructions. This appears, for example, when the students express the distance of $f(x)$ from 2 by means of their idea of SP (in 1534) and point out that the SP is the base 10 logarithm of the distance.

THE ROLE OF GEN IN INTEREST-DENSE SITUATIONS

The social interactions in IDSs can be regarded from a mathematical point of view as a flow of mathematical ideas that produces mathematical knowledge in an effective way by the epistemic actions of *gathering*, and *connecting mathematical meanings*, which lead to *structure seeing*. Figure 1 shows pictograms of the six phases of the analyzed episode. All are initiated by the interviewer (see the arrows). Phase I mainly consists of gathering, in phases II, III and VI gathering and connecting are merged. In phases IV and V, the students reach structure seeing including validating structures.

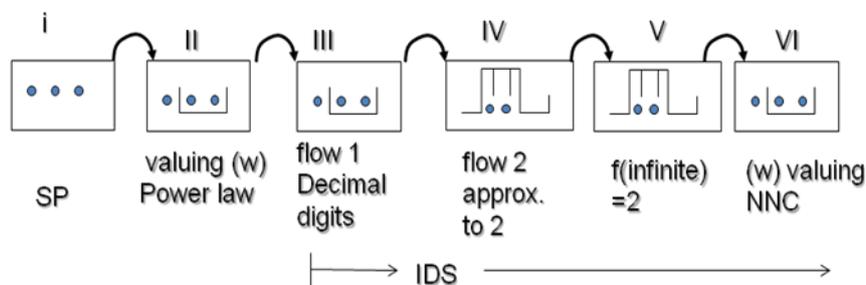

Figure 1: Phase diagram of the analyzed episode (1333-1512), phase I: 1333-1353, II: 1354-1401, III: 1402-1423, IV: 1424-1454, V: 1455-1466, VI: 1468-1512

Epistemic actions serve to describe the flow of ideas and to investigate what drives the epistemic process in the flow and where it leads. A *flow of ideas* is a horizontal scanning of the mathematical aspects of a problem expressed in the utterances towards oneself and the other in order to describe, concretize, understand, progress, ..., but also to inform the other, to take up her idea and develop it further, negotiate, explain, ... It is an evolution of ideas associated with a given mathematical problem, building on previous experiences. Within a constructing process driven by a GEN the flow of ideas may lead to: *recognizing* an idea as fruitful, which may lead to further developing it; *connecting* the aspects together, which may lead to *building-with* a

Working Group 16

comprehensive view; *seeing* a *structure* or *constructing* something new; checking, understanding, making concrete and justifying the structure or the construct.

For example in phase III (1397-1423), the flow of ideas refers to how the digits of $f(x)$ for $x=1'000'000$ may look like. The status of the power law for the length of SP had been made clear before as a conjecture that leads to estimations about it. The focus now is on how the decimal numbers look as compared to 2. $f(1'000'000)$ cannot be computed explicitly. Therefore, the question how $f(x)$ looks for $x=1'000'000$, turns the argumentation into a hypothetical direction, connecting it to the SP and to how the sequence might go on:

1413. /M: But what we do know in any case is that eeh there is a one before the decimal point, well not for one thousand and one, for thou- for one-

1414. /T: No, for one thousand and one there is a one in front of the decimal point, well no wait yes a two

1415. /M: That's an odd number, yes

1416. T: Two point zero zero zero zero zero

1417. /M: Yes because its an odd eeh place

1418. T: Yes, so its very close to two already

1419. M: Yes

1420. T: Those are then about a hundred zero or so (laughs), and then comes some different number

In the end the last idea is confirmed (1422, 1423). This flow of ideas describes horizontally how the decimal number $f(1'000'000)$ might look without going a step further. However, this horizontal scanning process implicitly produces the aspect of approximation to 2 that is *recognized* as fruitful for answering the interviewer's question "and how would it work then?" (1424). It is further developed in the next flow of ideas as a process leading to *structure seeing*: "it keeps on going" (1425) (seed for infinite as a process), "an infinite number" (1426) (length of the decimal number), "leaning closer to zero, closer to two, both numbers" (1427), (structure seeing because of the leaning-key-idea of approximation, grasping the convergence to 2, and referring to both numbers, meaning converging from both sides), "but no never becomes 2" (sequential process of potential infinity), "there are always infinite zeros" (1429) (here the value of the digits connected to the process directs the view to the actual infinite), "it's infinite that's just it" (1430) (the length of the decimal number), "at the end there are infinite zeros or infinite nines, and there is something" (1432) (the image of the infinite length is rooted in the experience of the finite).

Here again an aspect is further developed that has been prepared by enlarging the size of x -values from 1'000 to 1'000'000. Before, the flow of ideas was concerned with the infinite length of the decimal numbers, whereas now the students take infinite as an actual value of x , which they consider substituting in a functional term:

actual infinity is reached (1434), structure seeing took place. This kind of substitution changes the view from function values to the variable x . Based on that, the students several times use an if-then consideration and a flow of ideas about the conclusion arises: if "we insert infinity" (1435), "will always be the same" (1436), "if you insert infinity, it theoretically equals two" (1437), "then it would be two" (1438). "One point nine period" (1440), "equals two then" (1442), "equals about two" (1443), "equals two" (1444), "so close, ah ok" (1445).

The students agree about the if-then-argumentation and the data but not about the conclusion. Here we have a flow of ideas leading to dispersing views. T is bound to the view of potential infinity (1437, 1443, 1445) whereas M reaches actual infinity ("we can insert infinity" 1434, see also 1442, 1444). The difference between these views is not overcome because of their incompatibility. This is an experience of limitation and brings about a need for certitude referring to and repeating what the teacher has said. M recognizes an argument of their teacher as fruitful and together they reconstruct it: manipulations leading to $1.9999\dots = 2$ as learnt in school.

In addition, the flow of ideas can lead to the experience of limitations such as not being able to continue solving the problem. This can happen when the students do not have access to tools that would help them progress, but it can also happen when they have a different understanding of an aspect that cannot be overcome in this moment. However, limitations do not necessarily have to lead students to give up; they can be overcome in different directions. They may lead to changing the conditions, going back to a clearer situation, taking a more general view; they may also lead to the *need for a new construct (NNC)*. We now discuss some of these possibilities.

1. Giving up

In this case the students are not driven by a GEN nor do they find an adequate expression of it (no GEN); for example in phase I they are ready to give up since the flow of ideas dries out because they have experienced that the power law is not always valid: "we could probably work on this all day long" (1340) and "yes but I think it's enough" (1341).

2. Changing the conditions

Changing the conditions with a potential for progress involves a mixture of a need for clarification and a need to progress: The demand to use the function value of 1000 that seems too big to compute, and the attempt to use the power law that cannot be applied directly, make them change the conditions. Instead of 1000 they take 100 first and then 1024, since these are numbers with well known square roots (1370).

3. Going back to a clear situation

This reaction is concerned with a need for certitude: the demand to look at 1'000'000 makes them change the conditions first and then a need for *certitude* leads them to

say what “but what we do know in any case is that eeh there is a one before the decimal point, well not for one thousand and one, for thou- for one-“ (1413), which is confirmed by T in 1414, and again in 1477.

4. Taking a more general view

This may be connected to a need to be more general: the demand of the interviewer to look at 1000 or 1001 led to a limitation “one can’t say anything else” (in 1359). This caused a need for being more general “wait, we have our theory” (1360) that they applied afterwards.

5. Expressing the need for a new construct

This need arises when the students describe what they would need in order to continue and why they do not have it yet: In 1473, T experiences a deep personal limitation, “personally, I don’t see anything there” (see above for the full citation) although there is a specific epistemic need to be general. T tries to transfer his images of finite numbers to the infinite ones but this is not observable. Therefore he experiences a lack of tools to continue and that confuses him. The GEN is expressed by a need for a new construct in 1478 (see citation above).

Situational interest empowers the students to act epistemically

In 1467, the students turn to the task of justifying their conjecture, which makes them laugh. As before, the students do not take the demand to justify seriously. However, they value this task now as being more difficult. In 1469, the interviewer acknowledges “I find your last aspect just now most interesting”. This changes the situation completely. M confirms: “Yes that’s really is interesting how“ (1470), without laughing. T describes what is really interesting: “yes, so theoretically it keeps on leaning closer to two” (1471). Both students take the aspect of approximation as what is most interesting. The number 2 is understood as the leaning point including the experience they have made (1471): theoretically, by hypothetical thinking, approximation to 2 is understood *as leaning to 2* (from potential infinity in the direction of actual infinity). The term *leaning (anlehnen)* is non-conventional in this context also in German, the language of the students. Explaining why causes confusion, a deep personal limitation. The interviewer’s repeated demand to explain why, makes M express the GEN as the need for certitude “let’s look at the beginning again here” (1477) while T expresses a need for a new construct “it would be best if we had a function equation...” (1478), valuing highly the construct he looks for, compared with the less valuable representation they have “we only have a functional equation just dependent on the variable before” (1480). Directly after that, the students refer to the need for a new construct expressing their willingness: ”right, shall we try to discover something like that ‘cause that would be” (1485), “on that depends on x right?“ (1486), “Yes, so f of“ (1487).

The above shows the students' deep involvement accompanied by meaningfulness, ending up with valuing highly what they do not yet have, expressing a *need for a new construct (NNC)* by situational interest. This scene also shows how the students' interest is caught: The interviewer values aspects as being most interesting. This empowers the students to act: they immediately deepen their involvement, express their personal experience of limitation, which caused their need for a new construct, which in turn empowered their willingness to construct it. Thus, interest is held, since the NNC and situational interest are mutually reinforcing the students' progress.

REFLECTING ON THE NETWORKING PROCESS

AiC postulates that without a need for a new construct (Hershkowitz, Schwarz, & Dreyfus, 2001) the process of constructing such a new construct will not be initiated. When trying to identify such a need for a new construct in data sets, we discovered that it was not always clearly identifiable. However, IDS showed that the learning process was driven in such cases by far more general epistemic needs such as described in this paper as GEN. The previous research also showed that the GEN was closely linked to seeds for later constructing actions. The main contribution of the present paper is to show that a GEN cannot only drive the epistemic process but may lead to a need for a specific new construct.

Another important result is an integrated view of how the individual and social construction of knowledge promote and call for each other. The flow of ideas as a social flow describes the process as an evolution of ideas in the community. This can happen by gathering and connecting pieces of knowledge that may bring to the fore an aspect that can be recognized as fruitful to be further developed, driven by a GEN or even a specific need for a new construct. This may lead to limitations that again may reinforce the expression of a GEN meeting the situational challenge. Hence, GEN and experiencing limitation fruitfully interact.

We conclude this paper with a reflection on the networking process and on conditions that influenced it positively and negatively. The networking process concerned the different roles of the GEN as seen from each perspective. For AiC, the role of the GEN is its relationship to the seeds of constructing and to the emergence of the need for a specific new construct that marks the beginning of the construction process. In IDS, on the other hand, the role of the GEN is related to situational interest, empowering the students to progress in the construction of knowledge. The GEN is transformed into actions progressing within the flow of mathematical ideas.

The networking process was basically enabled by the following features, in which there was a synergy between the two research teams, already at the outset:

- a. The research questions asked by the two teams are rather closely related and refer to how knowledge is constructed by means of epistemic processes and what factors influence processes of constructing knowledge.

Working Group 16

- b. The theoretical frameworks used by the both teams are based on epistemic actions; while these are not identical, they are complementary.
- c. The methodologies used by both teams include fine-grained microanalyses of interview protocols. This afforded us the opportunity to consider a single data set at a similar level of depth from different points of view: We used a three stage cross-analysis methodology that helped overcome some of the difficulties listed below: (i) separate analyses by each team; (ii) re-analysis by each team, in view of the other team's analysis; (iii) common analysis by both teams in meeting.
- d. The notion of GEN that emerged from a first stage of networking (the previous study) has become an integral part of both perspectives and hence a catalyst for further stages of networking (the current study). Hence, the role of the GEN has turned from that of a research result into that of a base for further research using both theoretical frameworks in unison.

On the other hand, some differences between the approaches of the two teams caused difficulties that turned out to be fruitful for challenging our cross-analyses:

- a. The AiC approach puts the cognitive aspects in the centre, considering social aspects as important but secondary, whereas the IDS approach considers the social aspects to be of primary importance in constructing knowledge.
- b. Therefore, there are differences between the natures of the sets of epistemic actions, which turned out to provide complementary insights.
- c. The two approaches espouse somewhat different views of what constitutes construction of knowledge, in particular what kinds of knowledge can be the object of a constructing process and how it could be fostered.

Since the two research teams have already been working together for more than two years, we have reached a state of profound mutual understanding. Hence, each perspective contributes to deepen the insight of the other one into the development of the students' process of constructing knowledge.

MATHEMATICS LEARNING THROUGH THE LENSES OF CULTURAL HISTORICAL ACTIVITY THEORY AND THE THEORY OF KNOWLEDGE OBJECTIFICATION [1]

Lionel N. LaCroix

Brock University, Canada

This paper draws upon analysis of an adult student as he learns to read fractions-of-an-inch on a measuring tape with the researcher as tutor. This provides a basis for comparing two activity-theoretical perspectives: cultural historical activity theory as developed by YrjöEngeström and his collaborators and Luis Radford's recent elaboration of activity theory, the theory of knowledge objectification. The former perspective provides a general framework for analyzing activity as a whole, whereas the later draws attention to particular genetic aspects of the mathematics learning and thinking of individuals. Insights gleaned through the use of each theory in analysis of this activity are summarized in-turn and contrasted for the purpose of showing the utility of each approach for the analysis of mathematics learning.

INTRODUCTION AND THEORETICAL FRAMEWORKS

Activity theory is a cross-disciplinary framework for examining how humans purposefully transform natural and social reality, including themselves, as a culturally and historically situated, materially and socially mediated process. Originating in the dialectical socio-cultural psychology of Vygotsky, this work was subsequently developed into a theory of activity by his student and colleague, A. N. Leont'ev (cf., 1978) and others. Today in the west this perspective is often associated with the work of Engeström and his collaborators and is referred to as cultural historical activity theory or the acronym CHAT, emphasizing the essential situated nature of activity. It continues to develop in different ways, highlighting both its complexity and the fact that CHAT remains, in many ways, a work in progress.

The impromptu tutoring session involving a pre-apprentice in the pipe trades and the researcher that formed the basis of this analysis focused on learning to read fractions-of-an-inch to sixteenths-of-an-inch; an essential skill in this training program and the workplace. The present paper uses an analysis of this workplace training course as a whole as well as an in-depth analysis of the targeted tutoring session using two complementary perspectives, Engeström's interpretation of CHAT and Radford's theory of knowledge objectification (TO). This, in turn, provides a basis for comparing and contrasting these two perspectives. This analysis is part of a larger study of mathematics learning within apprenticeship training conducted in a number of pre-apprenticeship and apprenticeship training programs in the construction trades.

A brief overview of Engeström's interpretation of activity theory

Engeström's work develops the implications of Leont'ev's ideas and systematizes them in the form of an activity system. (Because of space restrictions, a figure showing Engeström's well known triangular activity system model will be provided only in the results section.) Included as the co-mediating elements within an activity system are the subject, community, tools (including signs and artifacts), rules or norms, and division of labour; all oriented towards the object and outcome of the activity (cf., Engeström, 1987, 1993, 2001). And, for any activity system, it is the meeting of a human need that motivates the activity.

Engeström also articulates a number of key principles of activity. The following of these are most pertinent to the present assessment of this perspective for the analysis of mathematics learning:

- that a collective, artifact-mediated and object-oriented activity system, seen in its network of relations to other activity systems, is taken as the prime unit of analysis...;
- [that] an activity system is always a community of multiple points of views, ... and interests....;
- [that] activity systems take shape and get transformed over lengthy periods of time. Their problems and potentials can only be understood against their own history...; [and]
- [that] contradictions [play a central role] as sources of change and development [of an activity], ...; (Engeström, 2001, pp. 136-137).

The large scale view of activity taken by this perspective considers learning in terms of fundamental qualitative changes in an activity system as a whole, a process that Engeström calls expansive learning. This occurs as a result of deliberate efforts by participants over time to resolve conflicts and contractions that are an inherent part of any activity system. Engeström's theorization provides little, if any, explicit direction for understanding the place of mathematics within activity nor provides details relating to the learning processes of individuals within activity systems. He does, however, acknowledge the need for context-specific concepts and methods to be created and employed when applying CHAT to particular empirical cases (Engeström, 1999, 2008).

A brief overview of Radford's theory of knowledge objectification

Based on his reading of Vygotsky's semiotics, Leont'ev's activity theory, and the more recent work of Felix Mikhailov and Evald Ilyenkov, Radford has developed the TO specifically for unpacking nuances and processes of the mathematics activity and learning of individuals from a cultural-semiotic activity perspective (cf., Radford, 2006, 2007, 2008b). In contrast to Engeström, Radford's work focuses on specific aspects of the consciousness, learning, and being of individuals as well as the

semiotic and social dimensions of mathematics activity from an activity perspective. Foremost in Radford's theorization are emphases on:

- 1) the intimate and dialectical relationship between human thinking—including mathematical thinking—and the material and cultural world,
- 2) the central role of semiotic resources used within culturally and historically situated practices and social interaction in mathematical activity and learning, and
- 3) the twin dialectical processes of *subjectification*—the process of becoming, and *objectification*—the process of making sense of and becoming critically conversant with the cultural-historical logic with which systems of thought, such as mathematics, have been endowed (see also Radford, 2008a, 2009);

In the TO, learning is conceptualized as an interactive and creative acquisition of historically constituted forms of thinking. Such an acquisition is thematized as a process of *objectification*; that is, as a process of making sense of and becoming critically conversant with the cultural-historical logic with which systems of thought, such as mathematics, have been endowed (see also Radford, 2008a, 2009). Radford's concept of objectification is a refinement of Vygotsky's notion of internalization in that it emphasizes the dialectical relationship between the subject and the cultural object being attended to. *Semiotic means of objectification* (SMO) is the empirical reflection of this process. This refers to the use of semiotic means to draw and sustain the attention of others and one's own attention to particular aspects of mathematical objects in an effort to achieve stable forms of awareness, to make apparent one's intentions, and/or to carry out actions to attain the goal of one's activity. Radford identifies the following three processes as forms of SMO from his empirical research of collaborative mathematical problem solving and learning:

- 1) *Iconicity*—the process of noticing and re-enacting or re-voicing significant parts of previous semiotic activity for the purpose of orienting one's actions and deepening one's own objectification (Radford, personal communication, September 29, 2008),
- 2) *Semiotic nodes*—places in mathematical activity where multiple semiotic resources are used together and in a coordinated manner to achieve knowledge objectification. "Since knowledge objectification is a process of becoming aware of certain conceptual states of affairs, [changes in] semiotic nodes are associated with the progressive course of becoming conscious of something. They are associated with layers of objectification" (Radford, 2005), and
- 3) *Semiotic contraction*—the process of coming to recognize and attend to the essential elements within an evolving mathematical experience; and making one's semiotic actions compact, simplified, and routine as a result of this acquaintance with conceptual traits of the objects under objectification and their stabilization in consciousness (Radford, 2008a).

It should be noted that the process of mathematics learning or objectification can be accounted for readily within the theory of knowledge objectification through analysis of social interactions and the use of semiotic means of objectification within mathematics learning activity (Radford, 2008b).

METHOD

Data collection

The empirical data that provides the basis for the present analysis was collected in a pre-apprenticeship training class for the pipe-trades conducted at trade union run school in British Columbia, Canada. This program involved classroom work as well as practical work in the shop. The course content was selected to give the pre-apprentices a head start with important skills that would be addressed subsequently in the early years of their formal apprenticeship training in a number of different pipe-trades.

The researcher visited the class extensively over its eight-week duration and served as a math tutor for any pre-apprentices who asked for his help. The researcher also observed pre-apprentices and engaged them in discussion about their mathematics related coursework as they were working on it. The mathematics related activity of individual and groups of pre-apprentices, working either on their own or with the researcher, was documented using a video camera and field notes, and copies of the course print materials and the pre-apprentices' written work were retained for analysis. The researcher also conducted ongoing formal and inform discussions with the course instructor and administrator of the program, as well as many students and kept field notes of these encounters. The data used in the present analysis was drawn from this collection of data. This particular 33-minute tutoring session was selected for fine-grained analysis from the approximately 35 hours of video data from this pre-apprenticeship class on the basis that it was, by far, the longest episode of a student focused on a particular mathematical object (here the pattern of binary fractions-of-an-inch used in linear measure) that was central to this vocational training. This, in turn, provided a unique opportunity to examine ways in which a pre-apprentice's thinking developed in relation to this mathematical object and was reflected both in his actions and in his interactions with the researcher-as-tutor.

Prior to the data analysis (as part of the larger research study involving multiple workplace training sites) the researcher made extensive visits to an earlier session of this same pre-apprenticeship course as well as a fourth-year plumbing apprenticeship program at a local technical college. Extensive visits were also made to all three levels of an iron-working apprenticeship program also at the local technical college and short visits spanning one to a few days were made to a variety of other apprenticeship programs for a variety of construction trades. In all cases the focus was on observing and documenting the mathematics related parts of these programs.

This experience served to inform the researcher's analysis of the activity within the target pre-apprenticeship program.

Data analysis

The multi-semiotic analysis of this activity takes place on two levels, reflecting the breadth of foci of the two theoretical perspectives used. The various elements of the activity system of the pipe-trade training program, for example, were discerned from the entire corpus of related data identified above. At another level the multi-semiotic analysis of the pre-apprentice's and the researcher-as-tutor's joint activity during the tutoring session began with the construction of a verbatim transcript of the entire tutoring session from the video recording. This included the construction of a detailed account of significant actions including the use of various semiotic resources, gestures, body position, and artifacts. Episodes in the data were then coded, first to identify the various aspects of reading the fraction-of-an-inch pattern being attended to, and then to identify actions related to both the pre-apprentice (who will henceforth be referred to as "C") and the researcher-as-tutor's (who will henceforth be referred to as L) objectification of the pattern of fractions of an inch on the measuring tape and subjectification as participants within this activity. At times this process required slow motion and frame-by-frame analysis of videotape to assess the role and co-ordination of spoken language with the use of artifacts and gestures.

RESULTS AND DISCUSSION [2]

A summary analysis using Engeström's interpretation of activity theory

A detailed analysis of the elements of the tutoring session activity system is provided using a triangular activity system model in Figure 1. The lines between the nodes or elements of the activity are intended to draw attention to the mediating relationships amongst them—an essential feature of such a system. While it is not possible to determine the precise mediating roles of each of these elements throughout the activity, there is evidence of each playing a dynamic role in shaping the course of events. The various semiotic resources employed in the discourse, for example, serve to draw C's attention to particular aspects of the object of the activity and to deepen his understanding. The design of the particular measuring tape used (marked in thirty-seconds-of-an-inch up to twelve inches and in sixteenths thereafter) necessitated that this difference be attended to explicitly and negotiated during the activity. And, the conventional design of the measuring tape with the endpoints of subintervals of the inch indicated by a system of signs necessitated that C attend to the intervals between these divisions rather than the division markings themselves in the process of learning to measure.

A number of contradictions in the form of breakdowns, misunderstandings, and complications exist on different levels within this activity. These levels include complications within individual elements of the activity such as the object of the

activity itself—the system of multiple binary fractions-of-an-inch represented by a single inscription pattern on the measuring tape—and with L given his dual roles as tutor and researcher. Between different elements of the activity there are a number of other misunderstandings and breakdowns.

Tools (artifacts and signs): a pencil, a pen, paper, and L's set of rulers on transparencies

Semiotic resources used include:

- spoken and written language including mathematics vocabulary
- written mathematics notation
- the pattern of fraction divisions on the measuring tape and the set of rulers on transparency
- gestures, e.g., pointing, sweeping, and chopping gestures
- a line drawn to represent $5/8$ "
- indexical inscriptions e.g., circling or underlining existing inscriptions
- counting
- rhythm when speaking and/or in gesturing
- physical position, orientation, and alignment of physical objects

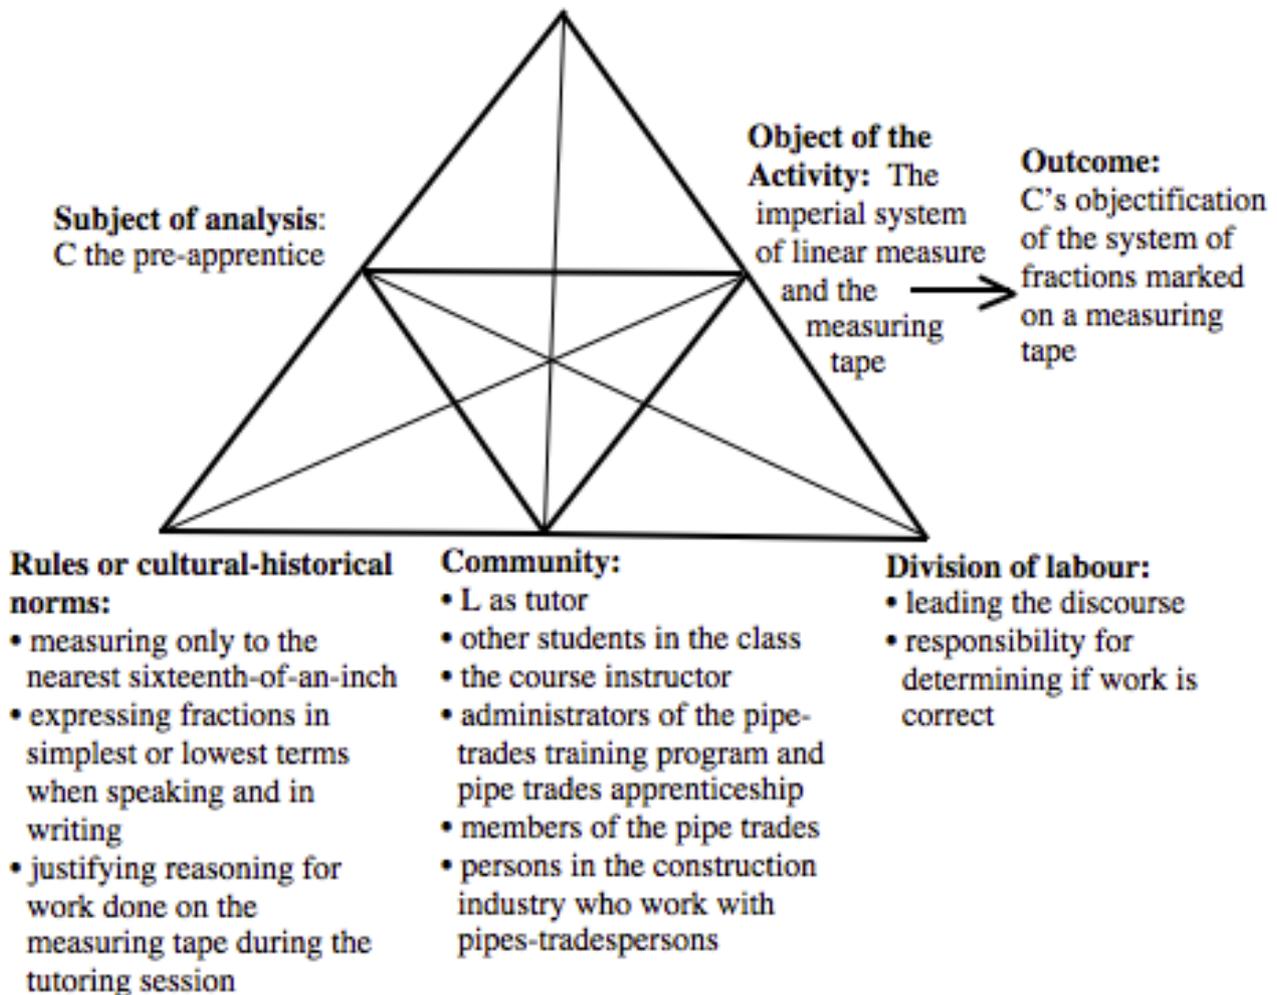

Figure 1. Activity system of the pre-apprentice learning to read the measuring tape

These include C's unfamiliarity with the imperial system of linear measure that he is required to use in his practical work, his limited understanding of the meaning of the denominator of a fraction represented in digit form at the start of the session, communication difficulties between C and L, and L's initial approach to identifying various fraction-of-an-inch intervals on the measuring tape with C. Considerable effort is made by both participants throughout the tutoring session to attend to and resolve these contradictions as they arise within the activity.

A summary analysis using the theory of knowledge objectification

A number of processes that are parts of the mathematics learning process identified by the TO figure prominently within C and L's discourse. For example, C repeats what L says or re-enacts his actions relating to the task at hand on 60 separate occasions during the 33 minute tutoring session. These actions reflect an effort to deepen his sense of—literally, to deepen his sensory experience of—these statements or actions using the same means of semiotic expression used by L or other semiotic means. On one occasion C re-enacts a unique form of interval gesture that he had just used himself and on another occasion L creates a zone of proximal development for C to help bring coherence to his understanding of the division pattern on the measuring tape by inviting C to explain what he (L) had said earlier while providing him with verbal prompts to help him along. And, this is not a one-sided affair. On a few occasions L also re-enacts or repeats what C had done or said earlier. These examples of repeating or re-enacting what another has said correspond to the process of iconicity, identified by Radford as a significant part of the process of attaining a cultural logic of thinking or knowledge objectification. [3]

The ways that L and C use multiple semiotic resources together (semiotic nodes) throughout the tutoring session and, in C's case, the further enactment of semiotic contractions, reflect their understandings of the object of the activity. L's frequent use of various combinations of words, pointing and sweeping gestures, fractions written using digits and words, the fractions-of-an-inch division pattern on the measuring tape and transparency rulers, along with other semiotic resources in a coordinated manner draws and maintains C's attention to/on various aspects of the system of binary fractions-of-an-inch on the measuring tape. And, given L's extensive experience working with the system of binary fractions-of-an-inch extending back to his own elementary school days, it is not surprising that his use of various semiotic resources remains relatively consistent during his explanations to C throughout the tutoring session, reflecting little or no change in his understanding in the process.

In contrast, there is a marked shift over the 33 minutes of the tutoring session in the way that C expresses his understanding using various combinations of semiotic resources as he communicates with L and works to bring clarity to his own thinking. Early on, when C responds to L's request for him to explain what difference he notices in the patterns of divisions below and above twelve inches on the measuring

tape, C's response is predominantly gestural, accompanied by only a single sentence and two sentence fragments. As the tutoring session progresses, C's means of expressing himself shifts completely, at times, to the clear and succinct use of words alone—an ultimate form of semiotic contraction.

The last process from the TO to be summarized here is that of C and L's subjectification. C becomes more active in the way in which he participates in the activity over the duration of the tutoring session. This is evidenced by the collective changes in the patterns of his gaze and attentiveness, his role in the dialogue, his affective responses, and his own expressions of agency and self-reliance regarding his use of the measuring tape. C also nods his head or says "okay" or "yeah" on numerous occasions throughout the session acknowledging to L that he is following what he is saying. This also reflects part of C's process of subjectivity within the activity. L changes during the tutoring session as well, but in a less obvious way. Specifically, L changes in his approach to teaching C how to read the measuring tape from a more general approach (intended for use with a measuring tape or ruler marked to any one of a number of subdivisions of the inch, e.g. sixteenths, thirty-seconds, or sixty-fourths) that is typical of school mathematics teaching, to a much more practical one tailored specifically to workplace demands within the pipe trades where lengths are taken only to the nearest sixteenth-of-an-inch.

Comparing these two activity-theoretical perspectives

Engeström's activity-theoretical perspective focuses on activity systems as a whole, including relationships and contradictions at various levels of activity and the ongoing transformation of activity over long periods of time. His more recent work (e.g. Engeström, 2008) continues at the activity system level focus by addressing interactions between multiple activity systems. These dynamics of activity, while useful for research in many contexts, do not address in a direct way mathematics educators' practical interests in teaching and learning activity, that is, individual students' mathematical enculturation on a day-to-day, if not minute-to-minute basis. Furthermore, Engeström's work does not make clear a means to talk about, nor situate mathematics within activity.

Radford's theory of knowledge objectification, in comparison, focuses on the microgenesis of the mathematics thinking and learning of individuals. It provides a way of defining and positioning mathematics as a cultural practice within particular forms of activity, articulates a clear view of mathematics learning and thinking, and unpacks the dialectical relationship between the subject of activity and the object of activity through the theorization of objectification and subjectification thus revealing an important but often tacit dimension of mathematics learning. (For a detailed discussion refer to Radford, 2008b.) In stark contrast to Engeström who theorizes learning within activity theory as change in an activity itself, Radford focuses on the learning of individuals as they become participants within existing historical-cultural activity.

CONCLUDING REMARKS

The analysis of a one-on-one tutoring session with a pre-apprentice learning to read a measuring tape summarized here using both Engeström's perspective on CHAT and Radford's theory of knowledge objectification illustrates differences between these two approaches for the analysis of mathematics learning. Clearly both of these complementary activity-theoretical perspectives have contributed and will continue to contribute to mathematics educators' understanding of mathematics activity and learning. But given the objects for which each was developed, on the one hand Engeström's theorization for activity in general and, on the other, Radford's theorization for mathematics learning activities in particular, it should come as no surprise that Radford's theory of knowledge objectification provides a more powerful and directly applicable tool for investigating and understanding mathematics learning at the level of the individual. In pragmatic terms, before embarking on any activity-theoretical analysis in mathematics education, it is advisable for researchers to consider and draw from a range of activity-theoretical perspectives given that this field is evolving in a variety of different ways.

NOTES

1. This paper is the result of a research program funded by The Social Sciences and Humanities Research Council of Canada / Le Conseil de recherches en sciences humaines du Canada (SSHRC/CRCH).
2. Given the focus of this paper on comparing different activity-theoretical perspectives and space limitations, only a summary can be provided of the analysis done using each perspective.
3. A detailed analysis of the different forms of iconicity evident within a single 21 second clip from this tutoring session was the focus of a paper presented at CERME-6 (see LaCroix, 2010).

USING PRACTICAL EPISTEMOLOGY ANALYSIS TO STUDY THE TEACHER'S AND STUDENTS' JOINT ACTION IN THE MATHEMATICS CLASSROOM

Florence Ligozat¹, Per-Olof Wickman² & Karim Hamza²

¹University of Geneva; ²Stockholm University

This paper aims at characterizing the teaching actions that are used in a primary school mathematics lesson, and their consequences for the learning progression. To proceed, we explore the analytical outcomes of combining two analytical frameworks, namely the Practical Epistemology Analysis of classroom discourse (Wickman & Östman, 2002; Wickman, 2004; 2006) and the triple [Meso; Topo; Chrono]-Geneses featuring didactical transactions in the Theory of Joint Action in Didactics (Sensevy, Mercier, Schubauer-Leoni, Ligozat & Perrot 2005; Ligozat & Schubauer-Leoni, 2010; Sensevy 2010). The analytic approach is exhibited through an empirical sample of a mathematical lesson about the learning of surface area with 4th grade students. Analyses are guided by two questions: 1) testing the PEA for identifying the content learnt in transactions in the case of mathematics; 2) examining how PEA may augment the MTC-Geneses description to characterize the learning progression over time within the teacher's and students' joint actions. This later question is crucial to understand the generalization of the students' experience against the teaching process unfolded by the teacher.

THEORETICAL BACKGROUND

Practical Epistemology Analysis (PEA)

In the Swedish pragmatist approach to science learning, the PEA framework was developed as an analytical tool for characterizing the meaning-making process in science-classroom discourse. This approach features learning as the unfolding of purposeful action and change of habits for coping with reality (Rorty 1991). Cultural practices entail epistemologies, as implicit rules for acting adequately in social groups. In designing and carrying out classroom work, the teacher makes explicit and implicit decisions about the situations that the students will experience. Wickman (2004) suggests that as the curriculum unfolds in the teacher's and the students' actions and discourse, a *practical epistemology* is shaped. Hence, from the student point of view, learning content is dependent on the epistemologies developed in the classroom, as a set of epistemic and social norms that guide the selection of relevant actions to achieve a purpose. Of course, such norms are tied to the socio-historical traditions embedded in curricula. We do not aim at describing such rules and power relations *per se* but we seek for the connection between how classroom participants produce meaning and what meaning is produced in a specific practice.

The model of Practical Epistemology Analysis developed by P.-O. Wickman and collaborators relies upon L. Wittgenstein's notion of *language-game* (Wittgenstein

1967) and J. Dewey's theory of *continuity in experience* transformation (Dewey 1938/1997). For the former, meaning is a given in the socially shared rules supported by a language proper to a context. Learning is then mastering a language-game, i.e. the grammar of actions featuring a practice. For the latter, experience is continually transformed by the transactions taking place between an individual and his environment. Subjects build continuity between past and present experiences so that experience earned in a given situation becomes an instrument for understanding and dealing with the situations which follow (Dewey 1938/1997, p44). PEA is grounded on *four categories* for analyzing discourse as a transformation of experience within a language game (Wickman & Östman 2002; Wickman 2004; Wickman 2006).

(i) *Encounter*: an encounter delineates a specific situation in terms of what can be seen to meet or interact in actions and discourse. This involves human beings as the participants of the situation and the "things" that become part of the experience in this situation. These may include physical objects, signs, words, utterances, phenomena like natural facts and events as well as recalled experiences.

(ii) *Stand fast*: in an encounter, certain objects are manipulated without any questions arising about their use. Such objects and words stand fast in the encounter. What stand fast in one situation may later be questioned in another situation. Neither does stand fast necessarily imply a correct use from the observer's perspective. It simply implies that the meaning of certain words in discourse is self-evident for the participants with respect to this specific situation.

(iii) *Gaps and relations*: in an encounter participants notice gaps. They then establish difference and similarity relations to what stand fast. If participants succeed in filling a gap with relations they build continuity between past and present experience. If they fail, the gap lingers and the course of action may change direction toward another purpose.

It is important to notice that the four concepts of PEA enable a first analysis of meaning-making from the interlocutors' perspective. From the observer's perspective (the researcher in this paper), "something" is learnt when the activity moves on, that is when there is evidence that the participants can proceed towards a purpose. Learning proceeds when people notice gaps and fill them with relations to what stand fast in encounters. This inclusive account of learning focuses on what works in the situation in order to overcome it and not solely what is right or wrong with respect to conceptual knowledge. Questioning truth is central in scientific reasoning but it is only one of several ways to proceed in everyday life practices (Habermas, 1984/1990). PEA accounts for the meanings being construed in action without prioritizing what is true / not true and what should be said or done in order to acquire the expected knowledge. This may also be understood as a methodological caution aiming at minimizing the risk of overlooking certain forms of learning just because they were not included in the definition from the outset.

The triple [Meso; Topo; &Chrono]-Geneses

The Joint Action Theory in Didactics (JATD) envisions the teaching and learning practices as a *didactical game* in which the teacher achieves his/her goal - making the students learn knowledge content- only if the students get involved and act in *a certain way* (Sensevy, 2010). The expected way of acting defines the rules of the learning progression. For the student to learn, the teacher has to design *a set of conditions* made of material and symbolic objects bound to a question, task or inquiry to be attended and featuring the students' ends in view. This set of conditions is viewed as the "primitive" milieu (or a teaching design) from which certain meanings are construed in action. The teacher and the student(s) cannot achieve their respective purposes without paying attention to the action of the other and moreover to the object of the other's action. An "object" is anything that can be the target of attention of an individual and that can be designated by him. The meaning of an object is given to an individual by the way in which the others are prepared to act toward it (Mead 1934/1992). The teacher's action and the student's action are *joint actions* in which each participant adjusts his action to the other's line of action (Blumer 2004). In the framework of the JATD the triple [Meso; Topo; Chrono]-Geneses models the construction of a *common ground* of meanings in the joint actions that are performed by the teacher and the student(s).

(i) *Mesogenesis* - The fitting of lines of actions of the teachers and the students (or within a student group) to achieve their respective purposes generates new meanings through the relations that participants establish to the objects of their environment. In adopting this point of view, the milieu in which actions unfold, is not just the set of conditions defined in the teaching design, regulated by the teacher over time, and against which the student would play a game (i.e. the milieu in TSDM; Brousseau 1997, p55-58). It is *a constant build up of relationships* to objects in discourse and actions, i.e. a mesogenesis in Chevallard's words (1992). Mesogenesis takes up both the students' elaboration of meanings and the teacher's elaboration of meanings on the basis of what the students produce.

(ii) *Topogenesis* – Each category of participants (teacher versus student) lives in distinctive epistemological positions within the classroom collective. They do not share the same perspective on the task at the same time. These positions are movable but they never merge. The moves in the epistemological positions (either towards a reduction of the gap or towards its deepening) feature the topogenesis. Topogenetic moves result from *the division of the activity* between the teacher and the students, but also among students themselves according to their potentialities in a specific situation.

(iii) *Chronogenesis* - The teacher knows the overall direction that learning should take on the knowledge timeline. The learning content expected by the teacher in the first place corresponds to an institutional purpose in terms of contents and values to be conveyed to the students. Such a purpose is described as pieces of knowledge to

be learnt, attitudes to be adopted, competencies to develop...etc. in curriculum texts that reconfigure outer-school socio-cultural knowledge historically construed in the human activities. The overall direction that the learning progression takes in the classroom is described by the chronogenesis. Chronogenetic moves result from the legitimating process of certain meanings made by the students in the collective and /or the introduction of new relations directly made by the teacher.

The primitive milieu designed by the teacher is continuously augmented over time by the meanings arising in the participants' fitting lines of action. Meanings are epistemologically distributed across the classroom collective between the students' position(s) and the teacher's position. Certain meanings construed at a time in the mesogenesis may be judged relevant or not by the participants with respect to 1) their potential to support the ends-in-view structured by the task (epistemic relevance); 2) the expected learning content that is the overarching goal of the teacher (didactical relevance). The outcome of the collective analysis of situated actions is the departure point for the participants to further their activities. We contend that the meanings built in the mesogenesis undergo a selective process to become part of a "supposed-to-be-shared" common ground in the classroom collective (Ligozat & Leutenegger 2008). The ongoing construction of this reference is an institutionalizing process of meanings construed in the situated actions towards a *collective objectivation of knowledge* in discourse.

EMPIRICAL FINDINGS

In the following, we attempt to use PEA for describing meanings made in the contingencies of mathematical activities with primary school students. In particular, we try the analytical categories of the PEA approach (encounter, stand fast, gaps and relations) for describing the dynamics of purposes in the joint action and the content of the mesogenesis. The chronogenetic and topogenetic moves feature how the teacher directs the students' attention towards certain relevant objects and correlations in the setting in order to achieve a mathematical task. We merely use a short excerpt of classroom discourse to highlight the analytical potentialities of combining both PEA and MTC-Geneses frameworks. The students are working in small groups, with a set of 13 geometrical shapes and with a worksheet bearing the instructions i) "rank the shapes from the smallest to the largest according to their area"; ii) "justify your ranking"). They first make conjectures about the use of the objects provided [Gap 1: what should we do?]. When the teacher comes nearby, the students call upon her for helping. The teacher tells the students to read the instruction and asks them about the meaning of the word "area". A new gap is noticed [Gap 2: what is area?]. The students suggest that "it is the shapes", i.e. a word that stand fast to them in this situation. From the teacher's perspective, the students do not manage to construe any relevant relations to the word "area" (something like "it is the surface of the shapes" or "the space lying inside the borders

Working Group 16

of the shape" may be expected). At min 3:29, the teacher goes back to the instruction in the following way:

43. TEACHER : [...] it is written / rank from the smallest to the largest
/// actually from the largest to the smallest-

44. KAM : well / first we know that this one is the smallest (*takes triangle H out of the set*)

45. TEACHER : how do you know that it is the smallest / how can you prove that it is the smallest+

46. MAR : (*puts square C close to triangle H [PICT2]*) because this one is smaller

PICT 2

47. DIA : it is half of it-

48. MAR : (*murmuring*) but we can't prove it-

49. TEACHER : (*looking at Mark*) OK but... / this is your feelings OK+ / but how can you prove it+ // because here (*points at the corner of triangle H – PICT 3*) / one may say / it sticks out a little bit- / so how can you prove that it is really the smallest+

PICT 3

50. DIA : (*getting excited*) I know I know+

51. MAR : oh like this / according to their area / we've got to set in line (*sets the base of triangle H on the same line as square C [PICT4]*)

PICT 4

52. DIA : no look + / I disagree / this is smaller because this (*picks up triangle H*) is half of the square (*puts H onto C [PICT5]*)

PICT 5

53. TEACHER : ah+ / do you think this could be a proof+

54. [silence 5 sec]

55. KAM : this / that's two / mmh / the whole square that's twice this one (*points at H*)

56. TEACHER : how did Dina do to prove you this+

57. KAM : she puts it over (*points at H again*)

58. TEACHER : yeah / she puts it over the square / she superimposed the shapes // now / you have some transparent paper / some square grid paper // and by using Dina's technique / you've got to find some tricks / that to prove that / a shape is larger or smaller than another one

Our 1st analytic focus looks at encounters, stand fast words and gaps to describe the dynamical structure of the joint action. The encounters delineate the relationships developed on a small portion of time by the participants with respect to certain objects (words, things, signs) that become parts of their environment. A new encounter opens up when we identify some changes in the participants' purposes during the course of action.

Working Group 16

- Encounter 1 (line 43-45) → Mark, Dina, Kamer and Teacher take into account shape H and shape C (among all the set), smallest (a word from the instruction sentence)
- Encounter 2 (line 46 – 57) → Mark, Dina, Kamer and Teacher take into account shape H and shape C (among all the set), know, prove, proof, stick out, set in line, half, twice, put over.
- Encounter 3 (line 58) → Mark, Dina, Kamer and Teacher take into account shape H and C (among all the set), put over, superimpose, transparent paper, square grid paper, Dina's technique, tricks, prove, larger, smaller.

In this case, changes in purposes and so the openings of new encounters are prompted on the basis of *gaps indicated by the teacher*. As such, they coincide with some chronogenetical moves (CM) and topogenetical moves (TM). Encounter 2 corresponds to an *expansion of teaching time* to attend the need to "prove" (CM); the teacher adopts a feigned "low" position supposed to give some responsibilities to the students in finding "proof" arguments (this TM analysis will be nuanced in our 2nd focus of analysis). Encounter 3 corresponds to a *contraction of the teaching time* with the acknowledgement of the superposition technique as a to-be-shared reference (CM); the teacher uses her institutional power to prompt a new purpose in the joint action (TM). Through the dynamics of encounters 1, 2 and 3, we get an insight of the nature of the expectations upon the student's actions: i) sum up what is known from the reading of the instruction, ii) how we get to know it, and iii) extend the use of the "put over" technique. Changes in purposes may also originate in the students' course of action when a gap cannot be filled. For instance, at the very beginning of the group work session, when the students cut off the shapes from the cardboard, one of them tried isolating the smallest shape, another tried to order the shapes according to their alphabetical letters, then they tried ordering 4 shapes on a same line. At some point, the students stopped manipulating the shapes because they could not find a way to determine what to do, or more exactly, what they are expected to do in this situation. Gap 1 [what should we do?] lingers, resulting in a change of purpose from trying to do something with the shapes to getting an explication from the teacher. Hence, encounters, stand fast words and gaps reflect the evolution of the reciprocal expectations in the teacher and students' joint action.

Our 2nd analytic focus is put on gaps and relations to describe the epistemic content built up in the mesogenesis. In bold characters, are the teacher participations; in italic characters are the students' participations.

Table 2: Gaps and epistemic relations developing in the mesogenesis

line	GAPS	RELATIONS
infra	G1: <i>what should we do?</i> => linger	
infra	G2: What is area? => linger	
44		Rel-a : <i>know- smallest- (triangle H)</i>
45-49	G3 : How do we know/prove [Rel-a]? => filled by Mark and Dina	Rel b : knowing –need to prove => implicit Rel-c : <i>(triangle H) – half – (square C)</i> Rel-d : <i>[Rel-a] – can't prove</i>
49-52	G4 : Could C be the smallest? => filled by Dina	Rel-e : (triangle H) – sticks out – (square C) – (parallel bases) Rel-f : <i>area – (aligned bases)</i> Rel-g : <i>[Rel-a] –because- [Rel-c] – (triangle H over square C)</i>
53-56	G5 : is [Rel-g] a proof? => filled by Teacher	Rel-h : <i>whole square – twice (triangle H)</i> Rel-i : [Rel-g] – a proof
56-58	G6 : how did Dina proved [Rel-f]? => filled by Kamer	Rel-j : <i>prove- put over</i> Rel-k : prove – superimpose the shapes => implicit
58	G7 (\rightarrow Gap1) : what should we do? => (implicit); partially filled by Teacher	Rel-l : transparent paper – square grid paper- Dina's technique – tricks – prove – smaller /larger shapes

(i) Gap 4 is a challenge to Mark's belief that we can't prove that H is smaller than C (line 48; Rel-d). Mark attempts to fill Gap 4 in establishing some conditions for triangle H to be smaller than C (line 48, Rel-f). He tries an inferential relation between the word "area" for the first time at this point and "set in line". The inference is: if the criteria "according to area" (that does not stand fast) was to mean "set in line" (that stand fast in actions), then the conditions for H to be smaller than C would be warranted. Unfortunately for Mark, this inference cannot be sustained in the common ground of meanings privileged by the teacher because this is not compliant with the mathematical culture. The teacher opposes Mark's relation with another relation (line 46; Rel-e) stemming from a change in the relative positions of the two shapes. The consequence is that in this position, triangle H may not be smaller than square C. Indeed, the order relation between H and C depends on the geometrical objects considered: side length of square C is smaller than base length of triangle H but side length of square C longer than the height of triangle H. These order relations on length are more or less salient depending on the relative position of the shapes in space (parallel bases VS aligned bases of the shape). The teacher uses spatial contingency to increase uncertainty and make the students noticing Gap 4 [Could C be the smallest?]. We have an example of a topogenetical move toward more responsibilities to the students in assessing a relation being made with respect

to the geometrical relationships among the shapes in the primitive milieu managed by the teacher (moving the shapes).

(ii) To fill Gap 4, Dina brings in a new relation that aggregates previous ones into a causal pattern (line 52; Rel-g). This relation ties in discourse the order relation [H is smaller than C] and a new pattern of the relative positions of shapes H and C in space [H over C]. From the researcher's perspective, the statement [H is half of C] is a quantification of the magnitude of the surface area of triangle H with respect to square C as a standard unit. It is an argument to prove that the surface area of H is smaller than the surface area of C. But what is the significance of Rel-g for the students? The mere thing we can do is to track any correlated relations unfolding in the participants' action and check whether these relations stand fast in furthering the activity. In eliciting Gap 5 [is Dina's utterance a proof?], the teacher tries to empower the group with the task to assess Dina's relation with respect to Gap 3 and gap 4. But the word "proof" does not stand fast to the students and Gap 5 cannot be filled by the students themselves. In noticing Gap 6, the teacher introduces a relation (Rel- i; line 56) that implicitly fills Gap 5. The responsibility given to the students is too high about a task (identifying a proof) that is out of reach of the students. The teacher subtly moves back toward high position, to manage the answers and reduce uncertainty. In this topogenetical move, the focus on "what" is proved is drifted towards "how" it is proved.

The mesogenesis is a *series of ephemeral and situated encounters* which are co-elaborated by the participants. Certain words and actions stand fast in these encounters. We contend that the student's experience in which epistemic relations is made is an *individuated* experience stemming from a collective experience made of joint actions and shared meanings. "Smallest", "largest", "set on a line" are recognized with respect to the collective experience shared in the group about ranking objects activities like sticks, blocks, etc. What stand fast describes the reference from the participants perspective. But what stand fast *hic et nunc* in an encounter may also remain contingent for the students. Indeed, observing the students' action in the subsequent encounters of this lesson show that the students go on with making superimpositions of shapes but they hardly draw conclusions from them, in terms of larger/smaller shapes. From this, we understand that "Dina's technique" does not make sense in the collective experience as a generalized content (or knowledge) which in turn, could be a resource for each student in further activity. Furthermore, since the word "area" was not related to this rule, the concept of surface area does not earn significance in action. From the succession of gaps highlighted by the teacher and featuring a fine-grained chronogenesis, we understand that the knowledge of the mathematical concepts (what is surface area?) and practices (knowing in mathematics is proof-based) is prioritized over the relations *effectively made* by the students in the encounter (ordering the shapes by sight estimation, comparing side lengths, finding a numerical ratio between the shapes). Of course, the

teacher takes up these relations (cf- Gap 6), but these relations construed in situated action remain contingent from the student's perspective. Each time that a gap is filled, it is replaced by a new one prompted by the teacher without enabling the students to proceed with the new relations made.

CONCLUDING REMARKS

We now discuss the implications of our analysis for the (re)conceptualization of PEA tools in the JATD. PEA empowered us with high resolution tools to analyse the content being learnt in classroom joint action from the participants' perspective. From this analysis it can be seen that the basic concepts of the lesson (proof and area) do not make sense to the students as part of the purpose of ordering according to size, without being reformulated as different kinds of doings (putting side by side, superimpose). This demonstrates that the teacher, in joint action with the students, would need to construe relations between those terms which the students are supposed to learn (proof, area) and those that stand fast (putting side by side, superimpose). Here there is no evidence of this in action, and so there is no evidence to the teacher that students have learnt what proof and area means in terms of habitual ways of talking and acting mathematics. [MTC]-geneses augment the analysis in directing analysis on the overall joint action about how the relations sum up (mesogenesis), the role of the student vis-à-vis the teacher (topogenesis), and how the learning progresses over time (chronogenesis). The MTC-analysis offers a means to analyse the social control on the meanings to be learnt from an institutional perspective. Thus, the power of this combined analysis lies in its ability to elucidate the meaning-making process from the participants' perspective (PEA-analysis), and combine this with an analysis of the consequences of the teacher managing the learning progression in certain, specified ways (MTC-genesis analysis). If teaching is organizing "signs" (words, symbols, constellation of artefacts) to make someone learn a content, learning involves making sense of such signs and forms in order to act adequately with respect to the sign-maker/organizer's purposes. But learning cannot be unilaterally controlled by the organization of signs in a teaching design, however genuine it may be. Learning is contingent on the experience of the learner and on the haphazard sequence of events developing in the joint action of the classroom (Hamza, 2010). Meanings arising in encounters are not "controlled" at their source (in the mind of the students) by the teacher but they are shaped in discourse according to a collective process of selection, aggregation and social validation and so needs close empirical examination.

DISCERNING IN AND BETWEEN THEORIES IN MATHEMATICS EDUCATION

John Mason

University of Oxford & Open University

Abstract: the conjecture is put forward that the most important feature of theories in mathematics education are the frame(work)s, which consist of labels for distinctions. These determine what can be attended to, and what therefore is not attended to. These distinctions incorporate assumptions and values which together suggest actions that might be taken. The discourse of 'shifts of attention' is used to structure an analysis of what theories might and might not be able to contribute to the improvement of teaching and learning, drawing on a background theory called 'Systematics'. My conclusion is that to compare or conjoin theories requires a generally accepted way of agreeing meaning of technical terms so that misunderstanding and mis-appreciation of distinctions is minimised.

INTRODUCTION: THEORIZING AS A WHOLE

The plethora of research papers in mathematics education, and the considerable degree of overlap between issues and phenomena studied, using a wide range of theoretical constructs, distinctions and methods is fostering concern about how theories might be integrated, compared and conjoined (Sriraman & English 2010, PME34 research forum, CERME Working Group 2008).

At ICME-2 in Exeter, René Thom put forward a typically Continental position, that "In fact, whether one wishes it or not, all mathematical pedagogy, even if scarcely coherent, rests on a philosophy of mathematics". In other words, 'every pedagogical choice rests on a theory about effective teaching and learning', just as 'every research choice depends on a theory about enquiry'. An implied concomitant sentiment is that until the theory is articulated, action ought to be delayed. The action is two-way however, for although theories are how we make sense of experience, experience is possible only through actions involving theory.

Having been bothered for some time by the demands of journal editors to situate studies within acknowledged and named theories, it seems appropriate as a contribution to this working group to reflect on the nature of theories in mathematics education so as to clarify my own actions and choices. While well aware that there have been several similar discussions based on other approaches using semiotics (Radford 2008), and collections of essays (Sriraman *et al. op. cit.*), I choose a structural approach, using constructs elaborated by Bennett (1993) under the heading of *Systematics*, which has its roots in ancient psychology in drawing on qualities of numbers and which focuses on details overlooked in other expositions.

The overall structure of this paper self-referentially follows the discourse of the structure of attention (Mason 1996), since theories direct attention, and the direction, focus and nature of attention can be said to constitute one's theory. Useful distinctions within the discourse surrounding shifts of attention are the states of *holding wholes* (gazing), *discerning details*, *recognizing relationships* amongst what is discerned in the specific situation, *perceiving properties* as instantiated in the particular, and *reasoning on the basis of agreed properties*. Although closely aligned with generalized van Hiele levels (van Hiele 1986), the major difference is that rather than defining 'levels', shifts are likely to take place moment by moment, back and forth in no particular order. The alert reader will discern that 'holding wholes' was the orientation and role of this introduction.

THEORISING THEORIES

What do theories consist of, what are they useful for, and at the core, what really is a theory? Following the structure of attention, and having considered briefly the whole, I consider distinctions, relationships, properties, and potentialities in turn.

Theory as Discerning Details through Making Distinctions

To discern detail is to distinguish some 'thing' from 'something else'. The root meaning of 'theory' lies in the Greek *theorein* meaning 'to see' and hence, through extension, 'to perceive'. Thus at its core a theory enables the discerning of detail, and it does this through providing labels for distinctions considered worthwhile, and embedding these in a larger discourse. For example Bruner (1966) distinguished three modes or worlds of experience, *enactive*, *iconic* and *symbolic* which provide distinctions between how thoughts or awarenesses are (re)presented, while *scaffolding* (Bruner 1966) and *scaffolding & fading*, (Brown, Collins & Duguid 1989) label ways of choosing between teacher actions in relation to learners.

That "observation is theory laden" (Hanson 1958) has been noted many times. Indeed Goodman (1978) suggested that "we want our theories to be as fact laden as our facts are theory laden". In other words, the theoretical constructs proposed need to be observable and present in relevant situations to the same extent that the distinctions made arise from and are based in an articulation of the theoretical stance.

There are severe ontological consequences of the hyparchic act of labelling a distinction. Labelling a situation or action tends to reinforce its existence. For example, distinctions between conceptual and procedural, or between instrumental and relational understanding begin by being helpful, but then mislead people into talking, and then acting, as if the distinctions were natural, rather than regions in a continuum arising from people stressing some features and downplaying others.

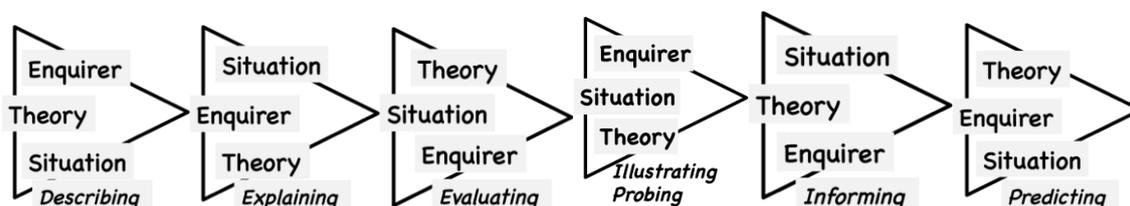

Theory as Recognising Relationships and Undertaking Actions

Developing vocabulary is only part of the sense-making process that drives theorizing. Once discerned, details can be related to each other. A discourse

develops, incorporating (literally) the labels. Collections of related distinctions form *frames* or *frameworks* through which or by means of which one makes sense of and perceives phenomena. But sense-making must involve more than the use of technical terms and metaphors in order to qualify as sense-making. There must be some consequences beyond mere description.

Theories contribute relationships to recognise between discerned elements, including related and relevant actions which may be informed by or be justified by use of the discourse. The more elaborate the discourse, the stronger the impulse to perceive through that discourse. Labels can be used superficially to avoid thinking, to bypass insight, and to masquerade as wisdom, at least as easily as they can support and promote insight.

Theories have been classified by a variety of adjectives, including descriptive, illustrative, explanatory, informative, predictive and evaluative, but these functions are more usefully seen as modes of interaction between an *enquirer* (researcher or teacher) a classroom or pedagogic *situation* and a *theory*. Bennett's Systematics suggests that actions require three impulses (initiator, respondent and mediator), and so can take place in any of six modes derived from the six permutations of the three impulses. Each mode is depicted below as a triangle, with the initiator shown at the top, the respondent at the bottom, and the mediator in the middle. The mediator binds the other two together so that an action can actually take place. The result of the action is an actualisation or amplification of the mediating term. These actions can be read from the following diagrams, though there is not space here to elaborate.

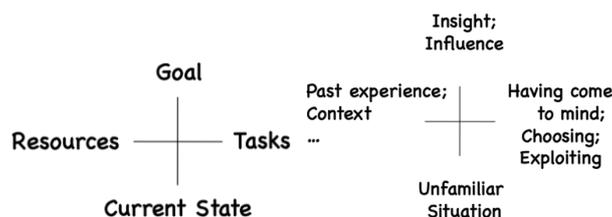

This sixfold structure can be used whenever something is perceived as mediating.

Theory as Instantiating Perceived Properties in Activity

Activity is recognisable through discerning details and recognising relationships as they emerge dynamically, but not in isolation. There is always a history, both personal and socio-cultural which influences the activity. In Systematics, activity is seen as involving four terms based on two axes: one based on resources and tasks and the other on the motivational gap between present-state (as perceived) and goal-state (as desired). If space permitted, it would be possible to look at the researcher's activity in relation to the teacher's or learners' activity.

Working Group 16

For example, Gibson's affordances, constraints and attunements (Greeno 1994) relates what is available, what is (necessarily) constrained or excluded, and what is needed in order to make use of the affordances and the constraints.

Sustaining and promoting effective enquiry depends on perceiving properties of methodologically, epistemologically and philosophically well-founded activity as capable of being instantiated in the specific activity. As one use of this way of perceiving activity, the resources a researcher has to call upon include their past experience, their awarenesses, the situation as experienced and interpreted, the mathematical and research processes in which they have engaged, their socio-cultural-historical appreciation of the context and of pedagogic strategies and didactic tactics, and so on. But these have to come to mind, and that happens through metaphoric resonance and metonymic triggering, filtered through a value system. What comes to mind (phrased and framed in the discourse of the theory) informs and dictates what is possible: what specific acts will be instituted, what tasks will be undertaken and so on. Tasks need to be in balance with available resources (too rich or too impoverished a resource base makes choice difficult or limited), and to be appropriate to the desired movement in the motivational axis. Similarly the current and goal states need to be in relation, neither too far apart (too great a challenge) nor too close together (too trivial to be worth bothering about).

Each of the triples in the tetrad can be analysed as an action with its six modes, but there is no room for elaboration here. Theory can be read into a situation by observing the teacher's actions, and by seeking both prospective articulation of choices and retrospective justification of actions.

Theory as Providing Potential through Reasoning on the Basis of Agreed Properties

Theorizing is fed by enquiry, by the wish to 'make sense', by desire to repeat and improve actions or interactions in some situations and not to repeat others, by desire to develop over time, in short by questioning. At the very least, a theory provides distinctions to discern. According to associated epistemic and ontic commitment, a theory articulates what sorts of questions can be asked, what sorts of things are deemed to be data (what details to discern), what form of analysis might be undertaken (what features to attend to), what kinds of narratives are woven around that analysis, and what products (findings, insights, potential actions etc.) might emerge. Concomitantly, theory provides a discourse through which to validate those products. What theories contribute to is a sense of meaning, significance, insight and

Working Group 16

a format for communicating findings, as well as prospectively informing actions or retrospectively justifying.

At their best, theories provide a complete *weltanschauung*, a way of being as an enquirer, whether teacher, researcher, educator or learner, and they make it possible to communicate effectively both with oneself and with others through negotiated ways of working together so that insight and creativity inform future actions.

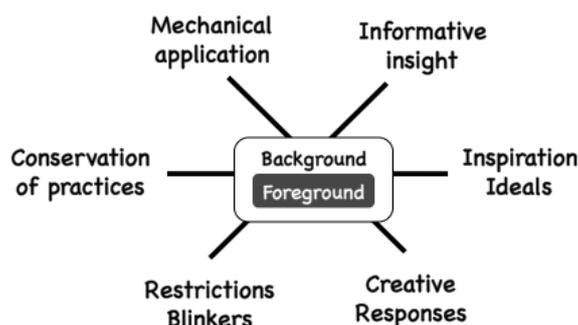

All this amounts to theories as, at their most comprehensive, incorporating (again, literally) worlds of experience. These worlds encompass epistemic and ontic-hyparchic commitment; they generate both a system of values which justify the kinds of products that merge, and the forms of validation that make sense within that world; they entail a view of the psychological and sociological influences and how the environment in its broadest terms influences the actors in the enterprise of mathematics education. For example (Mason 2002),

A world of external facts entails and requires repeatable experiments, as in the natural sciences;	A world of opinion and belief entails and requires surveys, questionnaires, interviews, as in sociology;
A world of others' experience entails and requires participant observation and ethnographic and anthropological approaches;	A world of involvement in action entails and requires change, prediction and evaluation, as in action research;
A world of personal experience entails and requires sensitising oneself to notice what was previously not noticed, as in phenomenological & phenomenographic approaches;	

These 'worlds' encompass assumptions, some of which are implicit while others may be explicit, and values concerning various aspects including what is data, what is done with data and what actions are promoted or critiqued.

STRENGTHS AND LIMITATIONS

Theories foreground some aspects and so necessarily background others. "To express is to over stress" (Mason 1987), which is a necessary but ultimately limiting feature of human sense-making. All sense made is partial. At any moment attention may be dominated by one or more of the aspects displayed below.

Conservationists of particular theories need to guard against inappropriate expansion, restriction or reinterpretation of distinctions, while eclectic gathering of useful distinctions, actions and relationships into explanatory narratives can all too readily become superficial. Focussing exclusively on the left-hand three 'directions' in the diagram can be stultifying or simply jargon-ridden; focus exclusively on the right-hand three can lead to unsubstantiated claims and the preference for values over facts.

Problematic Aspects of Theories in Mathematics Education

I have already raised the issue of the ontic consequences of hyparchic acts of distinction making and labelling. Two further issues of particular concern are the lack of any generally agreed approach to agree on the meaning and use of technical terms within the mathematics education community, and the paucity of conclusions drawn from theories: can description be a sufficient end in itself?

How is the use of technical terms agreed?

Developing a discourse is one thing, but getting agreement as to the meaningful use of that discourse is quite another. To 'use a theory' is, at the most basic level, to make distinctions which others who use the same theory would also make. This is a matter of some significance, on a par with the notion of robustness of social-science research instruments. It deserves far more attention than it gets. What mathematics education as a domain of enquiry notably lacks is an explicit and generally accepted method for how meaning is to be agreed or enriched. Curiously, there seem to be widely shared practices involving pre- and in-service teachers working on tasks through which they are likely to gain direct experience of what is being discerned and labelled (Watson & Mason 2007).

A mathematical approach was adopted by the Open University in its many courses for teachers of mathematics over 30 years. We employed a parallel between the mathematical practice of offering examples and discussing explicitly in what way the example actually exemplified the construct, with constructs from mathematics education having origins in different disciplines (Mason & de Geest 2010).

Is theory being illustrated, tested, or used to some other end?

When data is collected, distinctions made, phenomena identified and labelled, there is a pressing question: are the technical terms from the theory being exemplified and illustrated, are they being validated in some way, are they simply being used as descriptors to classify observed actions, or is the theory being used to draw conclusions? Sometimes it is difficult to work out which if any of these are intended. This applies especially to papers introducing a new or refined distinction, or drawing attention to a previously overlooked relationship that might, if accepted and acknowledged, constitute a phenomenon, a property perceivable as being instantiated. Typically papers do this in the early stages of the growth of a complex

of distinctions, relationships and properties in an effort to persuade others that the theory is pertinent, plausible, or useful. Unfortunately once absorbed into a complex theory distinctions and relationships become less attractive. Can it ever be sufficient to claim simply that distinctions can be made? Does it confirm a theory if the distinctions it comprises are 'shown' to be discernible? In what way is a researcher's perspective transformed simply by using a richly technical language for describing observation?

One weakness of current theories in mathematics education is a lack of definite conclusions, as well as an incomplete set of necessary conditions. But what conclusions might be possible? A plausible conjecture is that there is an often unstated assumption or hypothesis when theories are called upon: if the conditions of the theoretical constructs are met (if the labels really do apply), then learning will take (or have taken) place. However, to make such a conclusion possible it would be necessary to articulate a large number of conditions concerning the psyche of the learner(s) and teacher, their current states, and the many forces acting upon the situation from institutional pressures of all kinds.

Variation theory (Marton 2006) provides a notable exception, because it attempts to articulate certain conditions that are necessary for something to be learned; if those conditions are absent, learning will be at best fragmented and partial.

COMING TO APPRECIATE A THEORY OR PARTIAL THEORY

In order to use and appreciate what a particular theory offers, it is necessary to locate what is discerned and discernible, what relationships are afforded or highlighted, what properties are consequences, and what grain size the theory addresses. This in turn requires perceiving theoretical properties or constructs as instantiated in the particular or specific situation.

Bricolage

If while reading a paper or attending a session a distinction offered that makes immediate sense of past experience or current enquiries, it may be adopted and adapted for use. This can be called *cherry-picking* (after the expression in English which summons up an image of picking the best fruit but leaving the rest of the tree and its life-cycle alone), but more positively, it contributes to *bricolage* (the use of found objects and available resources to create works of art or to make repairs). Reading around the distinction, finding examples of its use, perhaps becoming informed about its origins and where it arises in the overall thinking of the originator can be thought of as movement along a spectrum of involvement towards *immersion*.

Immersion

To immerse yourself in a theory is to engage with all of its constructs, and, strictly speaking, not to stray outside of those boundaries, at least until it is completely familiar. Acceptance is achieved when papers are published in journals refereed by other experts who are also immersed in the same theory.

Along a Spectrum

Complete immersion is relatively rare. Most researchers depend upon the elaborations of a few scholars who devote considerable time and attention to immersion. A common pattern is for an idea (a distinction, a construct) to be introduced into mathematics education (cherry-picking/bricolage) and when it is picked up and used by a few researchers, people begin to probe its origins, moving along a spectrum of increasing immersion in the setting and the background.

It seems that adopting a distinction is relatively easy to do, especially where it makes sense of past or current experience and where it informs future actions. However it is all too easy to misinterpret or mis-appreciate the core meaning and use of a distinction, and then to use it in ways unintended by the originators. The *ZPD* provides an excellent example: misunderstood through a single example, it became a metaphor for almost any teacher initiated action. Picking up a framework of distinctions is slightly more complex but can be assisted by relating the distinctions to personal experience (Mason 1999, Mason & deGeest 2010).

Absorbing a complex of frameworks and a theoretical perspective that generates or encompasses them is much more difficult, and much less congenial for people who want to get on and act in the world rather than becoming scholars of someone else's ways of thinking, expressing and acting.

DISCERNING BETWEEN THEORIES

In order to distinguish between theories it is necessary to appreciate both, and to work at agreeing the meanings of technical terms (distinctions) to see whether there is overlap or significant difference. What the theory foregrounds, and what therefore its backgrounds, are critical. To do this effectively requires a commonly accepted approach to agreeing meaning through usage.

When searching for a 'suitable theory' on which to base an enquiry, what is really being sought is resonance with underlying assumptions and approach, with distinctions being made as being pertinent to the enquiry and as being likely to be observable, and with the sorts of conclusions, explanations, valuations etc. likely to arise. Too often the search ends when something doable has been located.

CONDITIONS FOR CONJOINING THEORIES

Radford (2008) has coined the notion of a *semiosphere* as a semiotic domain in which different theories might be conjoined, amalgamated or at least compared and

contrasted, through considering the principles, methods and questions associated with them. I propose that in order to compare, conjoin or even confirm theories successfully it is necessary to be clear on the intentions or uses of those theories and to reach mutual clarification of the worlds of experience they occasion, including the phenomena they recognise and at what grain size, and the sorts of conclusions, explanations etc. they afford: in short, what they foreground as worthy of attention. More specifically, this means the details discerned, the relationships recognised, the properties perceived as instantiated, and any consequences.

For me the only underlying problem about conjoining theories (apart from intense investment in and identification with a particular discourse) arises from participants' relation to complexity (Davis, Summara & Simmt 2006). Consistency and compatibility can be valued, but so can contrast/contradiction in a multiplicity of perspectives corresponding to the perceived complexity of the domain. The former stresses orthodoxy, the latter is flexibility.

What blocks the comparison of theories is commitment to and investment in the exclusivity, the universality of different perspectives by different people. Underlying perspectives may differ, and there may be variation in what is considered worth attending to and for what purpose, but no theory can expect to be universal. The ancient teaching-story of the blind men and the elephant (Shah 1970 p119) comes to mind (an example of a situation resonating and-or triggering connections). Multiple theories applied to the same situation are likely to reach multiple conclusions, to characterise situations in different and even apparently incompatible ways.

The real difficulty in conjoining theories is in finding a language which accepts that the situation being analysed, like the elephant, is always greater and more complex than the sum of the component observations. One aim of Systematics is the eventual abandoning or fusing of insights gained through discerning various 'systems', in order to return to a richer in-dwelling of the complexity of the experience. Complexity theory (Davis *et al. op. cit.*) appears to attempt something similar. Whether other theories aspire to their own transcendence is not so clear.

One of the unfortunate features of theories is that the use of assertions such as '... is ...' implies exclusiveness. Thus 'mathematics is social' or 'mathematics is communication' can be taken to imply that other ways of perceiving are invalid, that mathematics is 'nothing but' social or communication. Replacing 'is' by 'can be seen as' is one way to gain flexibility, acknowledge complexity, enrich analysis and be open to insights from other perspectives. To express is, again, to over-stress.

CONCLUSION

My analysis of theories has used the first five terms of a structural approach based on qualities of numbers known as Systematics (Bennett 1993). My discourse is centred on the structure of attention, suggesting that each individual or group of researchers accumulates a collection of distinctions, relationships, properties, significances and

values, and a discourse of technical terms for these. These then form the discourse in which actions and activity are described, actions planned, observations and experience analysed, salient results reported, and claims validated. Most importantly, developing a common approach to agreeing meaning of technical terms takes place through discerning situations or incidents, recognising relationships, proposing these as instantiations of phenomena (perceived as having properties), and seeking agreement with colleagues about the relevance of the labelled distinctions, relationships and phenomena.

THEORETICAL GENESIS OF AN INFORMAL META-THEORY TO DEVELOP A WAY OF TALKING ABOUT MATHEMATICS AND SCIENCE EDUCATION AND TO CONNECT EUROPEAN AND NORTH AMERICAN LITERATURE

John Monaghan

School of Education, University of Leeds

This paper explores the development of ideas in a recent journal paper that connects theoretical approaches in mathematics and science education. It re-constructs the development of the ideas presented in the journal paper through data obtained from interviews with the authors. This paper considers writing, engagement with research and other voices when people connect theoretical approaches.

INTRODUCTION

At CERME 6 Michèle Artigue (verbally in the theoretical perspectives working group) and I (Monaghan, 2010) raised a possible analogy between ‘instrumental genesis’ (Guin & Trouche, 1999) and the development of researchers’ theoretical ideas; we referred to this as ‘theoretical genesis’. In this paper I explore the genesis of an informal meta-theory presented in Ruthven, Laborde, Leach, & Tiberghien) 2009). With regard to the CERME 7, Working Group 16 ‘call for papers’, the current paper touches upon issues in the 3rd, 4th, 5th and 8th bullet points – strategies, limits, conditions and outside (of mathematics education) influences in connecting theories.

This paper is structured as follows. The first two sections explore the construct ‘theoretical genesis’ and then outlines the Ruthven et al. (2009) paper. The next section outlines my methodology, and the coding, for exploring the theoretical genesis of these four researchers. I then present a ‘story’ of the development of ideas in the course of writing Ruthven et al. (2009). This is followed by a discussion of issues raised by the story. I end with issues for further consideration.

THEORETICAL GENESIS

As the term ‘theoretical genesis’ was coined by analogy to ‘instrumental genesis’ I begin with a summary of the latter term. The root word ‘instrument’ pays homage to Vérillon & Rabardel’s (1995) distinction between a tool, as a material object, and an instrument as a psychological construct – a tool is just an artefact until someone appropriates it and integrates it into activity. Tool and person are interrelated: the tool shapes the actions of the person, *instrumentation*; the person uses the tool in specific ways, *instrumentalisation*. The process of making a tool an instrument is called ‘instrumental genesis’. This basic account, constructed to analyse students, and later teachers, use of technological tools in mathematical activity, is, to me, important, suasive and open to analogies of taking theories as tools which are appropriated by researchers in mathematics education activity. Subsequent

development of instrumentation theory, in which the psychological component, gestures and instrumental genesis are explained by way of the Piagetian notion of a *scheme*, are, I believe, a little problematic in themselves (see Monaghan, 2007) and not particularly useful for the analogy considered in this paper.

Monaghan (2010) was a reaction to Bikner-Ahsbabs (2010) which addressed ‘networking theories’. An important part of this reaction was that theories cannot be separated from the people theorising. I stated that researchers come to theories with past experiences and ideas. They interact with theories in the light of these past experiences and ideas and, if the theory, or rather, a part of it, is convincing for the researcher, then the researcher develops and a variant theory, adapted to the past experiences, ideas and needs of the researcher, emerges. This is what I referred to as theoretical genesis. On reading Ruthven et al. (2009) the idea of interviewing these authors about their theoretical genesis arose.

Although the term ‘theoretical genesis’ is new, it relates to the history of ideas. In the history of mathematics Lakatos (1976) challenged then dominant ideas on the development of proofs and the importance of counterexamples. A forerunner in the sociology of scientific knowledge is Kuhn (1970) who characterised the history of science into periods of normal science punctuated by periods of radical reconceptualisation. Further developments, including actor network theory accounts of scientific advance, reconceptualised the nature and importance of agency in the development of ideas/knowledge (see Pickering, 1995). There is not space to do more than acknowledge this field here but I briefly return to this matter in closing.

RUTHVEN, LABORDE, LEACH, & TIBERGHYEN (2009)

Ruthven et al. (2009) is an important paper which advances the literature on connecting theories. I summarise it for the sake of completeness but this summary does not do justice to the rich details and arguments. I recommend the reader reads it.

The paper frames its focus in terms of recent interest in design research, e.g. Kelly (2003), and the contribution of European didactical research in the design of teaching sequences that pay high regard to content knowledge. The authors comment that didactical design may be informed by tacit professional knowledge and/or ‘grand theory’. They note a move to develop “specific frameworks, intermediary between grand theory and the process of design” (Ruthven et al., 2009, p.330) and attempt to “develop more overarching ideas about the relations between grand theories, intermediate frameworks, and design tools” (ibid.); in the words of one author, after the paper appeared, they developed “a kind of informal meta-theory of design tools, intermediate theories, grand theories”. Their first example concerns Brousseau’s Theory of Didactical Situations (TDS) as an approach to the design of teaching sequences in mathematics. Grand theories used come from Piaget and Bachelard; TDS is the intermediate theoretical framework; design tools are didactical situations and didactical variables. They then present and contrast two design approaches in science education in which design tools are informed by grand

theories and intermediate theoretical frameworks. Terms and theorists aside there are commonalities in these science education design research approaches though “different cultural emphases and values can act against synthesis of intermediate frameworks and promote a proliferation of design tools” (p.341). Intermediate frameworks and design tools are viewed as ‘instruments’ to guide theoretically informed decisions about the design of teaching sequences. TDS is sufficiently developed and recognised that reference to grand theories behind it are rare; “the final teaching process results from ... what is usually an iterative process of development” (p.332). The science education intermediate frameworks, like TDS, relate epistemology, learning and teaching. They mainly draw on grand theories about epistemology and learning rather than teaching; teaching activity is developed from professional knowledge. The paper notes: not all design tools are strongly theorised; it is important to raise awareness of design tools available; the importance of differences in the grain size of teaching sequences; the value of dialogue between different traditions of design research to develop a more comprehensive perspective.

METHODOLOGY

I approached the four authors (referred to as AT, CL, JL & KR) about interviewing them regarding their theoretical development in the course of writing this paper. Two group interviews were conducted by *skype*TM, the first with AT and CL, the second with AT, JL and KR. Both interviews lasted about 45 minutes. Each interview had three questions: how did this paper begin; what did you learn in the process; how does the paper advance knowledge. I viewed the first question as crucial as it related to theoretical genesis. In both interviews about 2/3 of the time was spent discussing the first question. The interviews were semi-structured in as much as I asked sub-questions to follow up themes the authors introduced. The authors spoke freely and most of the interview transcripts consisted of interviewee text.

The purpose of the interviews was to get an account of the development of ideas, a story of theoretical genesis; there is a sense in which research is story-telling which aspires to objectivity. The story, in my plan for the paper, would be the basis for my discussion of theoretical genesis. A problem (of sorts) was that the interviews provided two (interrelated) stories. I subjected the transcripts to open coding (à la Strauss and Corbin, 1998) but did not follow a grounded theory approach further than this as I had a theoretical framework, instrumentation theory. I marked extracts of transcribed text and gave them names (codes) which resulted in a lot of codes. I then merged codes where possible to produce a manageable number. An example of a merged code is ‘people’ and the following extracts were all ‘people’ codes: I asked several people to help me; AT had been working with several colleagues; JL contacted KR. There was no opportunity for a second person to code the transcripts, so my codes are open to criticism with regard to reliability. The codes were:

Communication, e.g. “to speak with the audience”

Communities of practice (CoP), e.g. “in the European academic community”

Working Group 16

Design, e.g. “thinking that would be the design of teaching”

Learn, “it helped me to see what a future agenda for work is”

Meet, e.g. “I popped in to see KR at Cambridge”

People, see above

Purpose, e.g. “trying to put together academic perspectives”

Subject (mathematics/physics), e.g. “I’m on the side of mathematics”

Theory, e.g. “we don’t have the same theoretical framework”

Write, e.g. “we would like to publish this work in English”

There was overlap between the codes, e.g.[our problem] “how to report about research done in very different theoretical frameworks” was coded ‘theory’ and ‘write’. The codes, however, were simply a means towards producing a story. After coding I produced a narrative from each interview, a summary using the interviewees’ own words, paraphrases and my codes. I then merged the two narratives to construct the ‘story’ presented in the next section.

A STORY

The following is based on the interviews and narratives. It uses the participants’ own words and my codes wherever possible.

AT, CL, JL & KR are senior academics and, as such, write and attend conferences (meet people). AT knows CL through French didactics CoPs, and knows JL through science education CoPs. CL knows KR through mathematics education CoPs. JL knows KR through British education CoPs. About six years ago AT was asked, by a research council, to write a review on naïve knowledge on the design of teaching sequences. She collaborated with others and decided the review should have four chapters. Towards this she worked with CL on one chapter and asked JL to give a keynote speech at a conference in Paris. JL’s work was also focused on the design of teaching sequences. AT and CL worked on their chapter for one year and wanted to write a paper in English. Simultaneous with this AT met JL at several European conferences and they also exchanged ideas via e-mail. Both AT and JL place considerable value on subject knowledge in teaching and learning and felt that they has important things to say on the design of teaching sequences that would advance research but a stumbling block was differences in theoretical perspectives, basically that Francophone researchers embraced theory in a way that Anglophone researchers, in general, did not; communicating nuances of French didactical theory in English was not going to be easy. They needed a person who could help them to disseminate their ideas and KR, as a bi-lingual British researcher with a good knowledge of French didactics, was approached. It was decided that rather than writing a book integrating big strands of the literature, the publication should ‘scale down’ to an aspect that was central to everyone’s interest, the design of teaching sequences.

Thus the group of four was formed: AT and JL as members whose past research formed the basis for an intended journal publication; KR and CL as members who

Working Group 16

would find a position from which to reflect on this research, and its theoretical bases, to facilitate effective dissemination across different academic CoPs and their practices in academic discourse, as well as bringing a mathematics education perspective to the intended publication. There were two meetings of this group of four with the single focus of writing a journal paper, one in 2006 and one in 2007, but there were also a number of sub-meetings of two members before, between and after these whole group meetings, as well as e-mail exchanges.

A key event in the 2006 meeting was collective reading of a special issue of *Educational Researcher*¹ on design experiments Cobb et al. (2003) in particular. The group worked intensively on those texts and AT/CL brought perspectives from Francophone didactics literature/theory. They attempted to locate perspectives against and alongside each other (rather than making links between theoretical perspectives) in order to make decisions about which aspects to address in their journal paper². At this time the construct ‘intermediate framework’ was not explicit; both science educators had, with colleagues, published papers on design tools and their relation to grand theories but without mentioning intermediate frameworks. It was on the second day of the 2006 group meeting that the construct ‘intermediate framework’ was formed because of a realisation that “we were mainly speaking about tools without really distinguishing them” (AT). JL likened intermediate frameworks to Cobb’s (2007) phrase “make the theory do the work”.

The writing of the original paper was shared out, by sections, between the four members. This was a learning experience for all in terms of learning about each others research, constructs and theoretical orientations and also in terms of learning more about familiar theories and the new theoretical development. CL’s work illustrates learning through writing. CL was assigned the section on TDS in the original paper. CL knew this theory well. It was not her intention to summarise the entire theory, only aspects relevant to the paper. CL became aware, through writing, that TDS was, in her words, an epistemological obstacle to her as, at the beginning of the collaboration “it was very clear that when we did a design we had to use this theory” but by the end of the collaboration, with the grand theory-theoretical framework-design tools development, “I could see the TDS within a range of different theories, I could structure more a range of theories through the tools we were proposing, through the intermediate theory, through the design tools” (CL). Further to this, the didactical situation tool of the Ruthven et al. (2009) paper was not present in the original draft of the paper (more on this below).

The paper was submitted in June 2008 and revised in December 2008. Writing the original submitted and the revised versions of the paper brought in two other groups of people the audience (*Educational Researcher* readers) and the reviewers.

... we needed to think about ... who is the audience for the work that we want to write, where are they coming from, what are their understanding, what are the ideas that they already know ... [and to show] the design research community that has its base in the US ... what the distinctive contribution might be of the European approaches to that North

Working Group 16

American audience, so I think a lot of writing ... [was to bridge ideas] between the European tradition, primarily a didactical tradition, and a North American learning sciences tradition.

The reviewers gave extensive and, to the authors, useful feedback which provided an occasion to develop the ideas further. Commenting on this feedback an author stated:

the notion of design tools was well developed in the science education [work] ... and [in] the version of the article that was originally submitted ... [this idea] was more tied to the science education work ... [in response to reviewer] comment on the fact that this just wasn't just developed in relation to Brousseau's TDS ... [in the process of rewriting] we talk about the a-didactical situation tool. The didactics variables tool was already there and was kind of recognised as a tool even if it hadn't directly been given that name but one of the main aspects of the rewriting was to formulate this notion of the a-didactical situation tool. As the article points out, this is not that way that Brousseau himself ... would talk about it ... so it's a good example of ... a process of writing for an audience and then getting feedback from reviewers, can ...[shift]... the model that you build in writing a paper so that it develops greater coherence and communicates more effectively.

The development of this 'grand theory-theoretical framework-design tools' meta-theory, then, can partially be ascribed to the need to communicate in writing for a specific journal and these other voices. Indeed, all of the authors repeatedly and positively mentioned personal development through the need to be explicit in the writing, as AT noted:

... in France we are very theoretically orientated and it is not easy to disseminate, to make clear our theoretical orientations ... [so collaboration] is very, very fruitful for us because it make explicit our own approach and it is a shared experience.

DISCUSSION

I raise four interrelated themes from the above story which I consider important to the development of theories before revisiting the construct 'theoretical genesis'. The four themes are writing, learning, engagement with research and other voices.

Writing is a recurring thread in the above story: the paper started when AT was asked to write a review; AT worked on a draft chapter with CL which they wanted to write in English; when the team of four was composed, they decided to write a journal paper and targeted a specific journal; decisions of what to include were partially determined by the constraints of writing journal length papers; the writing was shared out; the submitted paper was rewritten. Whilst this is hardly surprising, as writing is a part of the job of academics, writing as a goal of joint activity of researchers networking theories is not something which I am aware has been raised in the literature on networking mathematical education theories. Writing to these authors was theory directed action and the need to be explicit in their writing acts was a part of their theoretical development, as the AT quote above demonstrates.

The need to be explicit shows that researcher learning in networking and developing theory is linked to writing (for other academics). I am sure that this will resonate with the experiences of most readers as they recall times where they have spent hours trying to get the words in the paragraph they are writing to express the thoughts in their mind. It is evident in the story that each of these four researchers learnt about the research and theoretical constructs of the other three researchers but they also learnt about their own theoretical stances. Networking theories usually involves networking with people and communicating ones own understandings, and sometimes we realise aspects of our own understandings in communicating that were hitherto implicit and we develop theoretically in the communication process. This happened in the case of CL in the section of the story which refers to epistemological obstacles. Brousseau's (1997) writings have popularised this construct amongst mathematics educators but Brousseau adapted the construct from the French philosopher Bachelard who applied it more widely than to just mathematics. An epistemological obstacle is any piece of knowledge that is relevant to a particular stage of a person's knowledge development but becomes an obstacle for further knowledge development. In the act of writing CL realised "when we did a design we had to use this theory" but networking theories enabled her to not only view learning design anew but to see TDS as an epistemological obstacle for her.

Networking theories in mathematics education is a process and a moment in the trajectory of theory development which interrelates with at least two other trajectories, networking researchers' own research and the research of others. In this paragraph I dwell on the research of others but first note that the advancement of and the networking of AT and JL's own research was clearly a catalyst for Ruthven et al. (2009) and the development of the informal meta-theory. The collective reading of the special issue of *Educational Researcher* and the paper of Cobb et al. (2003) was clearly an important event: "this was a kind of source of inspiration for us", AT/CL interview; "one of the key events was actually when we started reading and taking seriously the articles in the special issue of *Educational Researcher*", AT/JL/KR interview. Whilst the special issue and the Cobb et al. paper were valued by the authors, they also felt that related design research had been going on in Europe for some time and that there were differences in what the research communities either side of the Atlantic did, in particular that European researchers, in general, take subject content (mathematics & science) more seriously than North American (NA) researchers. So an emergent issue, reactions to the special issue, was transformed into a goal of Ruthven et al. (2009): to communicate European design research to a NA audience, which leads to the next theme of this discussion, other voices.

In academic writing other voices (Wertsch, 1993) enter our writing: research collaborators, authors of research papers that have influenced us, the audience (for the journal we have selected) and, later, reviewers. These other voices were explicitly mentioned in the interviews, as interview extracts in the story above show. More controversially I hold that the audience and the reviewers' voices actually contributed to the networking and the theory development. *Educational Researcher*

is a respected NA-based journal. In order to communicate with its NA readers it was important, as an interview quote in the story makes clear, to mediate or bridge, i.e. to network, ideas from a European didactical approach and a NA learning sciences approach. In the case of the reviewers, they commented that the notion of design tools was not well developed in relation to Brousseau's TDS which led to the inclusion of the a-didactical situation tool in the revised paper.

I now consider the term 'theoretical genesis', its validity and whether it is appropriate to describe the four authors' development in the writing of Ruthven et al. (2009). I start by noting that the term is just two words and we can describe the process without the use of these two words. Nevertheless, constructs as terms, can be useful to encapsulate a set of ideas, though it is wise to avoid an unnecessarily large number of pseudo-scientific terms. Theoretical genesis, as noted above, was coined by analogy to the term 'instrumental genesis' and I look at it via the main features of instrumental genesis, which I consider to be: it concerns an agent (or agents together) appropriating an artefact for a purpose; it is a process over time (though the duration is not important); there is two way interaction (instrumentation and instrumentalisation) between agent(s) and artefact; the agent(s) recognise and utilise affordances and constraints of the artefact. These features, I argue, were present in the development of Ruthven et al. (2009). A theory is an artefact and just an artefact until a person appropriates it and integrates it into academic activity; the team of four appropriated various (bits of) theory for a purpose (writing the paper). Ruthven et al. (2009) was a process that went through several stages: AT's initial discussions and writing with CL and JL; the recruitment of a 'go between' (KR); meetings and sub-meetings to clarify ideas; reconceiving ideas; various writing and rewriting actions. There was a two way interaction between authors and the theories, the authors shaped (bits of) theory for their purposes and theory advanced their thinking of design issues. The authors learnt many things in the process and this included the affordances and constraints of theories with regard to their goal of understanding the role of theories in the design of teaching sequences, e.g. CL's epistemological obstacle regarding TDS. But there are limits to the analogy, at least with regard to Guin & Trouche's (1999) technological instrument focus, because a theory, unlike a calculator, does not require physical manipulation and personal agency is greater with a theory than with a calculator, i.e. I am free to regard Brousseau as a constructivist or whatever but I am not free to do something on a calculator that it is not wired or programmed to do what I want it to do. Further to this, but neutral with regard to the analogy, instrumentation and instrumentalisation appear more pronounced with a theory-person dyad than with a calculator-person dyad: a theory, even a misunderstood theory, will shape my data analysis and hence my interpretation of data and I will adjust, consciously or not, the theory to my perceived needs. The term 'theoretical genesis' does, to me, appear to be a valid term to apply to appropriation of theory in the course of writing Ruthven et al. (1990). This writing of this paper, however, generated a new theory (artefact), albeit an informal meta-theory, which is not something expected in instrumental genesis.

Regarding the development of the four authors in this theoretical genesis I turn to what they claimed to have learnt. AT, CL and JL learnt about the work (including the theoretical stance) of the others and about their own work, which may be taken as learning about positioning their own work in relation to the work of others (CL “I could see TDS within a range of different theories”). Theoretical genesis appears, for these researchers, to include making connections between theoretical stances. KR’s theoretical genesis also concerned such connections but as an ‘outsider’ “trying to find some position from which to reflect on these theories”. Further learning in this theoretical genesis included using the theory. AT learnt “how to manage, how to construct these intermediate theories”. CL learnt that “didactic variables could be used not only in mathematics”. JL learnt that “you can actually strip away the theory now and use them [design tools] as tools” [in the design of teaching sequences]. The use KR mentioned is encapsulated in the title, a way of talking about mathematics and science education and to connect bodies of literature.

ISSUES FOR FURTHER CONSIDERATION

Space is limited but I briefly raise issues for further consideration concerning this study, the sociology of scientific knowledge and research praxeologies.

The networking and generation of theories/theory explored in this paper is only one example of theoretical genesis and is, I suspect, quite an atypical example. As evidence for this consider Radford (2008), cited by many papers in the theoretical perspectives section of the CERME 6 proceedings. Radford states that “a theory can be seen as a way of producing understandings and ways of actions based on” (p.320) a system of basic principles, a methodology and a set of paradigmatic research questions. I think that this statement holds for much theory-informed empirical research but not for Ruthven et al. (2009) as it does not include a set of research questions. In this respect, then, it is atypical. It would be interesting to research theoretical genesis in research conforming to Radford’s statement but there would be considerable difficulties in conducting such research. More realistic research could monitor theoretical development/genesis in post graduate student research.

At the beginning of this paper I raised links between the focus of this paper and work in the sociology of scientific knowledge. It is interesting that there are few references in the mathematics education networking theories literature, including CERME proceedings, to this field of study. Study of generating and networking theories in mathematics education in the wider setting of the sociology of scientific knowledge would, undoubtedly, be useful. As a small step towards this CL’s epistemological obstacle, considered above, might be seen as a ‘local’ (21st C France) instance of Kuhn’s (1970) hold of ‘normal science’, and one researcher’s realisation of this

During CERME 7 WG 16 Artigue, Bosch and Gascón (this volume) was discussed and it was clear that much that I report on here could be recast in terms of research praxeologies but there is, unfortunately, no space left for me to do this.

NOTE

¹*Educational Researcher*, **32**(1), 2003.

²Not all aspects were included in Ruthven et al. (2009) due to length considerations and the refinement of ideas, e.g. in 2006 the paper had a semiotic dimension that was not in the final paper.

MEANING OF MATHEMATICAL OBJECTS: A COMPARISON BETWEEN SEMIOTIC PERSPECTIVES

Giorgio Santi

NRD, Department of Mathematics, University of Bologna, Italy

In this paper we present a networking of semiotic perspectives to frame the issue of meaning of mathematical objects. We will connect Duval's structural approach and Radford's cultural semiotic approach to analyse students' difficulties with the meaning of mathematical objects when exposed to semiotic transformations.

Keywords: semiotics, transformations, networking theories, objectification, meaning

INTRODUCTION

D'Amore (2006) shows that, at all school levels, students encounter difficulties in coping with the meaning of mathematical objects in relation to their semiotic representations. These results question Duval's claim that *conversion* (transformation that involves 2 semiotic systems) is the key cognitive function that guarantees a differentiation between mathematical objects and their representations, and that conversion is *the* cognitive threshold the student has to overcome in order to reach a correct conceptualization. Furthermore, Duval considers conversion the main source of difficulties when learning mathematics since it clashes with the cognitive paradox that leads to identify the mathematical object with its semiotic representation. D'Amore's results show that at all school levels students find severe difficulties *also* when they are exposed to *treatments* (transformation within the same semiotic system). We have singled out 2 episodes taken from primary school and university.

Primary school students working on probability recognise that $3/6$, $1/2$, $50/100$, 50% represent the probability of rolling an even number, when throwing a 6 face die, after performing both treatment and conversion transformations. But after a treatment transformation from $1/2$ to $4/8$ students and teacher don't recognise in $4/8$ the same probability. It is interesting that the teacher declares that « $4/8$ cannot represent that event because the die has 6 faces. Dice don't have only 6 faces, there are also dice with 8 faces; in that case yes, the fraction $4/8$ represents the probability of rolling an even number».

The research problem has been framed within Duval's structural and functional semiotic approach that considers meaning as a relation between the *signifier* and the *signified*, i.e. between the representation and the entity the representation refers to. Since a mathematical object has more semiotic representations there are more signifiers for the same signified, that are equisignificant. D'Amore termed the phenomenon we described above as a *change of meaning due to treatment transformations*, to express the idea that students break the equisignificant relation

that binds the different representations through the common mathematical object they denote.

The intrinsic inaccessibility of mathematical objects makes changes of meaning an expected phenomenon in conversion transformations since the passage from one representation to the other is not sustained by the direct reference to the common object nor by transformation rules that bind the two semiotic systems. It is an unexpected phenomenon in treatment transformations since the passage from one representation to the other is sustained by the specific transformation rules of the semiotic system involved.

This paper addresses the issue of changes of meaning by networking Duval's and Radford's semiotic approaches. Using suitable networking strategies, our aim is to provide a conceptual framework to scrutinize the issue of "changes of meaning". The networking process we propose leads to the broadening both of the notion of sign and the notion of meaning, by integrating different ontological and epistemological standpoints. In the next section we provide basic theoretical tools regarding the connection of theories in Mathematics Education. Then we construct a conceptual framework that we will use to analyse a protocol taken from an experimentation with primary school students. In the last section we propose some concluding remarks.

NETWORKING THEORIES

Connecting theories is important to reduce the inflation of theoretical perspectives thereby bestowing mathematics education a global coherence, theoretical and methodological unity, effective research design. It also enhances a spin off in education to improve teaching and learning. We introduce some basic conceptual tools that play an important role in the networking of theories.

Radford (2008a) develops his analysis of theories within a social-cultural space that he calls the *semiosphere*, a space that fosters interaction and dialogue between different cultural identities. In a networking perspective, the semiosphere blends two important plots, *integration* of its entities in view of a synthesizing objective and *differentiation* that fosters *identity* and self-knowledge.

In a networking perspective it is useful to give an effective characterization of theories in mathematics education. For our purposes we focus on Radford (2008a) who identifies a theory T in mathematics education as a triplet $T(P,M,Q)$, a dynamic structure consisting of a *system of principles*, a *methodology* and a *template of research questions*. The system of principles defines the nature of the theory. It is important to note, especially when connecting theories, that the principles of a theory are not a juxtaposition of claims but they belong to a structured system. We must take into account not only the principles themselves but also their *hierarchical* position in the system. One or more principles can be common to more than one theory but this doesn't imply that such theories are equivalent, if such principles have a different position and relationship in the hierarchy. The system of principles

is very effective to outline the boundaries (Radford, 2008a) of a theory. The *boundary* of a theory is a threshold that cannot be overcome without loss of identity. The boundary sets the limit of discourse of a theory, beyond such limit the theory contradicts its systems of principles.

Networking of theories in the meta-theoretical space of the semiosphere, requires to blend integration and identity/differentiation plots. There are two possible extreme behaviours. On the one hand, if we overweigh the plot of identity, the risk is to have a set of disarticulated theories that ignore themselves on the other hand if we overweigh the plot of integration we end up with “a theory of everything” that is unable to frame the complexity and variety of teaching-learning processes.

Prediger, Bikner-Ahsbals, & Arzarello (2008) propose a “landscape” of possible connecting strategies that, within the space of the semiosphere, balance identity and integration. The following schema taken from the aforementioned article shows the networking strategies ordered according to their degree of integration:

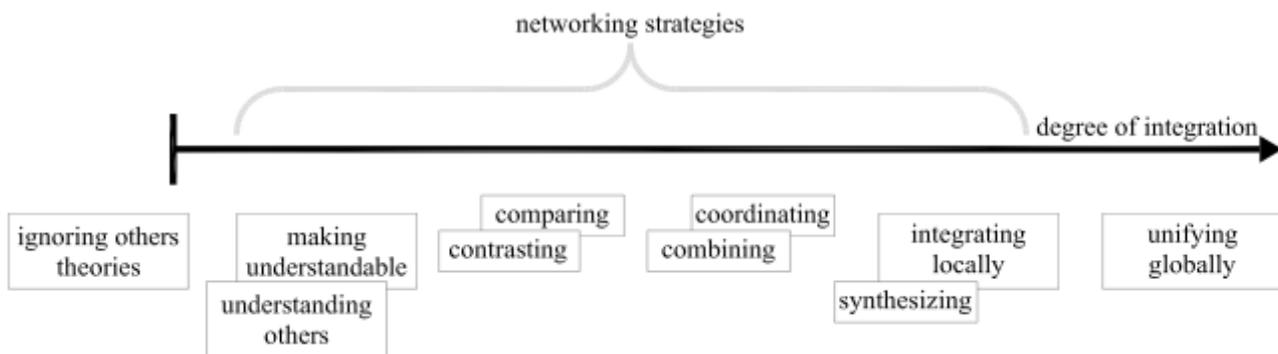

Fig. 1: Degrees of integration in networking strategies.

In this paper we will apply *coordinating* as networking strategy. Coordinating is a strategy that connects two or more theories in view of describing an empirical phenomenon or tackling a particular research issue. The outcome of this connecting strategy is not a coherent complete theory, but rather a conceptual framework that allows to coordinate different theoretical tools for the sake of a specific objective. Coordinating is a viable strategy when it connects theories that share a high level of *complementarity* and coherence.

A CONCEPTUAL FRAMEWORK FOR CHANGES OF MEANING

Before connecting the two semiotic perspectives we briefly recall Duval’s and Radford’s system of principles, focussing in particular on how the two perspectives frame the meaning of mathematical objects.

Duval’s Structural and Functional Approach

Duval’s (1995) approach stems from a realistic view point that considers mathematical objects *a priori inaccessible* ideal objects. Since mathematical objects are inaccessible entities, the theory pivots around the notion of *semiotic systems* and

the coordination of semiotic systems through *treatment and conversion* transformations. A semiotic system is characterized by a set of *elementary signs*, a set of *rules* for the *production* and the *transformation* of signs and an underlying *meaning structure* deriving from the relationship between the signs within the system.

Mathematical objects, that cannot be referred to directly, are recognised as invariant entities that bind different semiotic representations as treatment and conversion transformations are performed. Duval identifies the specific cognitive functioning to mathematics with the coordination of a variety of semiotic systems. Both the development of mathematics as a field of knowledge and its learning are accomplished through such specific cognitive functioning.

Duval develops Frege’s classical semiotic triangle (*sinn-bedeutung-zeichen*) and identifies meaning with the *couple (sign-object)*, i.e. a relationship between a sign and the object it represents. The sign becomes a rich structure that condenses both the semiotic representation (*zeichen*) and the way the semiotic expression offers the object in relation to the underlying meaning of the semiotic structure *sinn*. Meaning therefore has a twofold dimension: *sinn*, the way a semiotic representation offers the object; *bedeutung* the reference to the inaccessible mathematical object. Meaning making processes and learning require to handle different *sinn*s networked through semiotic transformations without losing the *bedeutung* to the invariant mathematical object.

The following schema represents the construction of meaning when several semiotic systems are coordinated to conceptualize a mathematical object.

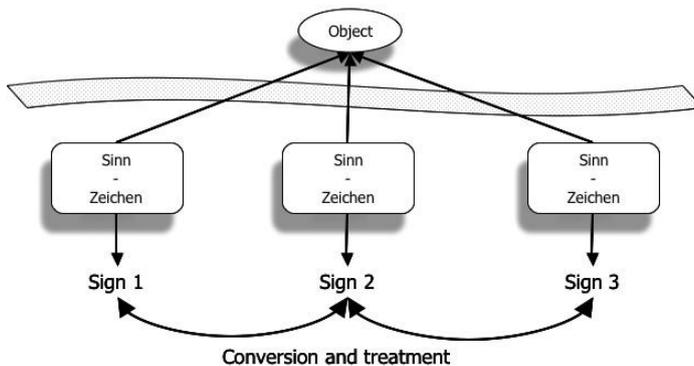

Fig. 2 Meaning and changes of meaning in Duval’s approach

In this framework, the research question is: how can students recognize the common *bedeutung* as the *sinn* changes through semiotic transformations? What we have above termed a “change of meaning”, is a change of *bedeutung* as the *sinn* changes.

Radford’s Cultural-semiotic approach.

Within a socio-cultural and phenomenological standpoint, Radford’s (2008) approach ascribes *reflexive mediated activity*, a central role both in cognition and in

the emergence of mathematical objects. The reflexive activity entangles mathematical objects, semiotic resources, individuals' consciousness and intentional acts, within social practice and a cultural and historical dimension.

Mathematical objects are *fixed patterns* that emerge from the reflexive mediated activity. Mathematical objects lose any ideal and a priori existence but they are ontologically intertwined with the mediated activity from which they emerge. Nevertheless, mathematical objects acquire a form of *ideality* and *existence* in the *culture* that encompasses the reflexive activity.

Learning is considered an *objectification* process accomplished through a reflexive activity, a *meaning* making process that allows to become aware of the mathematical object that exists in the culture, but the student doesn't recognize. The complexity of the objectification process requires to broaden the notion of sign and go beyond its representational role, since signs culturally mediate activity and direct the individual's intention towards the mathematical object. Signs are termed as *semiotic means of objectification* and they include, artefacts, gestures, language, rhythm. Semiotic means of objectification stratify the mathematical object into levels of generality according the reflexive activity they mediate.

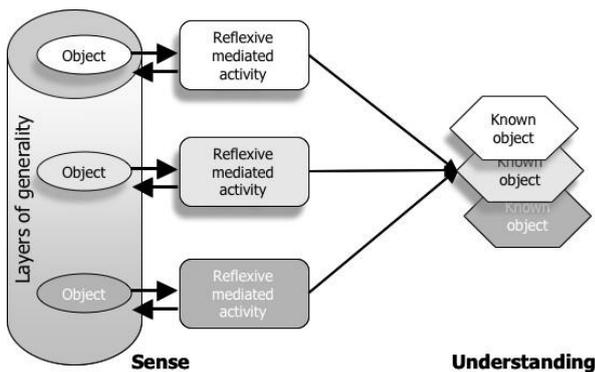

Fig. 3 Meaning and changes of meaning in Radford's perspectives

Meaning is no longer a mere relation sign-object, but is deeply interwoven with the reflexive activity, with intentional acts culturally mediated by semiotic means of objectification. Meaning is a double sided construct with a personal and a cultural dimension. The personal dimension refers to the individual's intentional acts directed towards a cultural unitary object. The cultural dimension refers to cultural and historical features that are condensed in the general and interpersonal mathematical object brought to the individual by teaching activities. The expected outcome of learning as an objectification process, is the alignment of the *personal meaning* with the *cultural meaning*.

Boundaries

Although both the theories we analysed are semiotic perspectives - if we look at the relationship with cognition - semiotics has a different hierarchical position in the respective system of principles. Therefore, the two theories have strong boundaries

that separate them. This brings along also differences regarding the nature of mathematical objects and processes. In Duval's approach semiotics plays a *representational* role and it is the very *substance of cognition* that is identified with the coordination of semiotic systems. In Radford's perspective cognition is considered a process of objectification in which *signs mediate* a reflexive activity. Furthermore, the way signs are used is very different. In Duval's perspective, semiotic representations are used *diachronically* through treatment and conversion transformations. Whereas in Radford's perspective, a wide range of semiotic means of objectification are used *synchronously* organized around a particular mediator that changes as the level of generality changes. The different hierarchical position of semiotics allows Radford to broaden the notion of sign to include gestures, artefacts, rhythm, kinaesthetic activity etc. that Duval would never consider semiotic.

The different hierarchical position of semiotics stems from the different ontologies behind the two theories. The structural and functional approach has a realistic view of mathematical objects that ascribes to semiotics a representational role and to meaning a relation sign-object. The theory of objectification has a pragmatic stand towards mathematical objects that ascribes to semiotics the role of mediating a reflexive activity, the "substance" of ontology, meaning and cognition. Mathematical process are also differently positioned in the system of principles. Duval identifies the mathematical activity with the transformation of signs, subsumed in the robust structure of the semiotic systems that accomplish discursive and meta-discursive functions. Radford considers activity a form of reflection that involves the individual as a whole – his consciousness, feelings, perception, sensorimotor activity etc-immersed in a system of cultural signification that orients his intentional acts.

Networking by "Coordinating" strategy

At a more profound level, any attempt to enlarge one of the theories subsuming elements of the other conflicts with its epistemological foundations. Nevertheless, the boundaries that separate the two theories do not imply an opposition between the two perspectives. Ullmann (1962) highlights two complementary features that characterise the development of mathematical objects: the *operational phase* and the *referential phase*. On the one hand mathematical objects and their meaning emerge from and are objectified by a reflexive activity, on the other hand it is necessary to linguistically refer to the entities that emerge from such practices. The dual nature of mathematical objects – as patterns of activity and as "existing" ideal entities in the culture – implies that also meaning and semiotics have a dual nature. In the connecting theories terminology, the strong differences result in a high level of *complementarity* that accounts for networking by *coordinating* the two perspectives, respecting their *identity*. Coordinating Duval's and Radford's theories allows to encompass the double-sided nature of objects, meaning and representations.

The emergence of a mathematical object and its objectification is described by the cultural semiotic perspective whereas the reference to the object is accounted for by

the structural and functional approach. Meaning as a sense making process of the individual and as the activity culturally condensed in the institutional object are described by Radford's approach; meaning as the interplay between *sinn* and an *bedeutung* is framed by Duval's approach. The coordination of the two theories is in turn achieved by the dual nature of semiotics. On the one hand signs mediate reflexive activity on the other hand they represent objects and broaden our cognitive possibilities through semiotic transformations. Our general conjecture is that a successful outcome of mathematical learning processes rests on the dual nature of semiotic resources, i.e. as semiotic registers and semiotic means of objectification; as a semiotic mean of objectification a sign *-synchronically* interwoven with a rich arsenal of mediators – supports the reflexive activity; a sign belonging to a semiotic system can be *diachronically* transformed into another to connote and denote mathematical objects. They are two complementary and interwoven aspects of the same phenomenon.

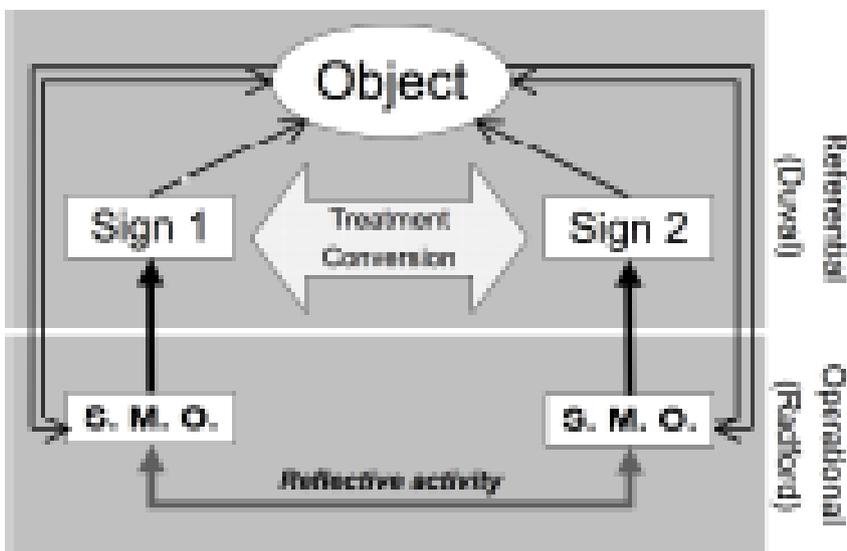

Fig. 4 The complementary roles of Duval's and Radford's approaches in framing the meaning of mathematical objects.

If we disregard signs as semiotic means of objectification, learning is an empty and meaningless manipulation of signs, if we disregard signs as belonging also to semiotic systems, mathematical objects wouldn't have developed into the form of rationality we know today and their conceptual acquisition would be impossible. The changes of meaning can be traced back to semiotic transformations that are not sustained by a mediated reflexive activity that guarantees the relation to the common cultural meaning of the mathematical object. The technology of the semiotic system allows the transformations of signs, but meaning in its cultural and personal sense evaporates, thereby losing also the correct interplay between *sinn* and *bedeutung*.

ANALYSIS OF A PROTOCOL

Methodology

The experimentation was carried out with grade 5 students (10 years old) of a primary school in Bologna. The class (20 students) worked according the following schema: presentation of the activity by the teacher and the researcher; students work in small groups with the help of the teacher; general discussion with the whole class. Students worked on sequences represented in a figural register; they were exposed to 3 figural representations of the same sequence. We will analyse the sequence $a_n = n^2 + 2n$ focussing only on two different figural representations that are reported below.

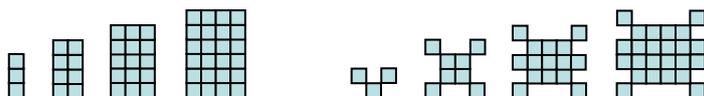

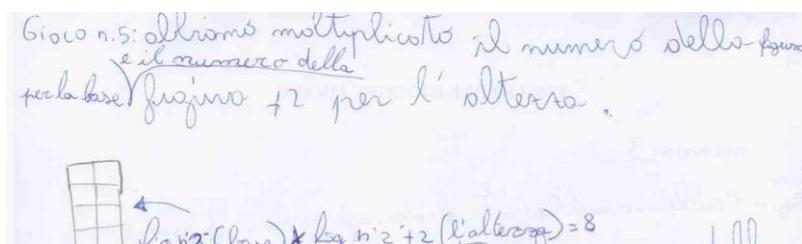

Fig.1 Fig. 2 Fig. 3 Fig. 4 Fig.1 Fig. 2 Fig. 3 Fig. 4

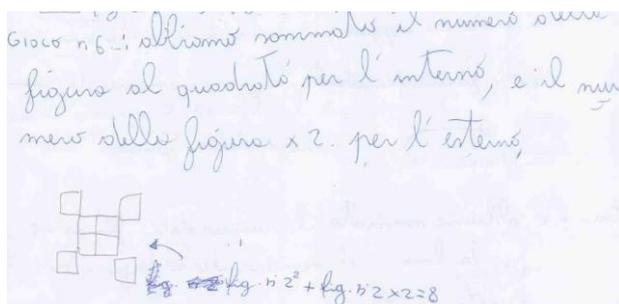

Students were asked to find the general schema to determine the number of elements for any number of the figure. Then they were asked if the different figural representations referred to the same sequence.

Results

Most of the groups that were able to determine the general schema, also recognized the same sequence as the figural representation changed. Without any explicit request, some students even attempted a first algebraic symbolism to express the general rule. Video tapes testify also students' rich sensory-motor activity, conveyed mainly by gestures, that I cannot relate here but it is clearly condensed in the explanation of the two schemas where the generality of the rule is expressed with spatial-geometrical properties as base, height, inside, outside. Below the protocol of group 5 with the general schema to determine the number of elements of any figure of the sequence.

We multiplied the number of the figure for the base and the number of the figure +2 as the height.

We added the square of the number of the figure for inside and the number of the figure x 2 for outside.

Interpretation

The pupils were successful in finding the schema for the general term of the sequence⁸³ and they didn't change meaning when exposed to treatment transformation in the figural register. To understand how students accomplish this result we have to use the conceptual framework we constructed above. Using semiotic resources both as semiotic means of objectification and semiotic registers, pupils grasp the dual nature of mathematical objects and their meaning.

Cultural-semiotic interpretation: Students objectify the mathematical sequence within the sociocultural space of the classroom. The use of semiotic means of objectification pivots around the figural representation that allows also the synchronic use of gestures and the sensorimotor activity. The activity was extremely meaningful to the students because it was intimately connected to their embodied experience. As the students are more and more involved in the reflexive activity there is an increasing agreement between the personal meaning and the cultural meaning of the mathematical object, thereby accessing higher levels of generality. This accounts for both the recognition of the same sequence, as the figural representation changes, and the spontaneous attempt to introduce a syncopated algebraic notation for the general term of the sequence.

Structural and functional interpretation: Students carry out a complicated network of semiotic transformations that involve both treatment and conversion. The task proposed to students, requires to connect three semiotic systems: the figural register, natural language and the arithmetical register. First of all, a very difficult conversion is necessary to construct the function that associates the number of elements in the figure to the number of the figure. Also to recognize the general schema of the sequence, students perform a conversion that involves the above registers; they first find the number of elements for a small number then they generalize the schema to a big number, thereby arriving to the general term of the sequence. The conversions are carried out passing the following order: figural register-arithmetical register (to calculate the number of elements in the figure)-natural language (to represent the general term). The outcome of the coordination of such semiotic systems is that students recognize the common reference (bedeutung) as the figural representations (sinn) changes.

Our contention is that students are able to handle meaning correctly at the referential level because the semiotic transformation is supported, at the operational level, by a

⁸³ Without an algebraic expression the sequence could not be univocally determined but the figural representation somehow fixes the general schema. Furthermore, the search for a general schema in this type of task is a social practice recognized by students, that allows to objectify the cultural object "numerical sequence" at a lower level of generality.

strong embodied reflexive activity that involves the students consciousness within a sociocultural space of signification.

CONCLUSIONS

This paper shows the effectiveness of *coordinating two complementary* semiotic perspectives to understand a specific didactical phenomenon. The analysis of the protocol shows that complementarity entails a *diachronic* use of the two perspectives. The systems of principles of the two perspectives fix and determine the phenomena we are looking at and the questions we are addressing. The cultural semiotic approach allows to investigate, from a sociocultural viewpoint, *objectification processes* whereas the structural approach, from a realistic standpoint, allows to analyse the *coordination of semiotic systems*. The boundaries between the systems of principles require a diachronic shift from one analysis to the other and we cannot merge the two theories into a synchronic analysis.

On the one hand networking at the level of coordination fosters the plot of identity without reaching a more encompassing new theory, rather a new conceptual framework. On the other hand the lower degree of integration allows to tackle a specific empirical phenomenon that allows a transformation both of our discipline and researchers. The plot of identity enhances a negotiation between theories and researchers in a process that Radford (2008a) calls *togethering*. Something I personally experienced in my doctoral research from which this paper stems.

MODELING EXTERNAL REPRESENTATIONS AS MEDIATORS OF MEANING IN THE MATHEMATICS CLASSROOM

Håkan Sollervall

Linnaeus University

As mental constructs, mathematical objects are of abstract nature and have no references in the physical world. The mathematical objects are experienced and processed through various external representations. We propose a structural model that accounts for external representations as mediators of meanings in the mathematics classroom. During construction of the model, we particularly pay attention to negotiating disciplinary and individual perspectives regarding structure and specific constructs, with the objective to support understanding of the role of external representations that are used and processed in the mathematics classroom.

INTRODUCTION

It may be argued that the development of cognitive capabilities is inseparable from the sociocultural practices that constitute the context of their development (Cobb, 2006). On the other hand, we may argue that some structural features of cognitive development are independent of context, for example connecting modes of interaction in the physical world with modes of thought that we acquire through processing of impressions and experiences from this interaction (Bruner, 1966).

The philosopher Charles Sanders Peirce proposed in the late 19th century a theory of signs that accounts for human understanding of impressions and experiences based on interpretation of physical entities (Houser & Kloesel, 1992). Peirce's theory of signs is structural and general in character, makes no paradigmatic assumptions about learning, and therefore appears to be consistent with any learning theory. There are several instances of important theoretical constructs in mathematics education that may be interpreted within Peirce's theory of signs, for example *procept* as the amalgam of process and concept (Tall et al., 2001) and *registers* of representations that allow mathematical processing (Duval, 2006). We will propose a unifying structural model, based on Peirce's theory, as a structural foundation for understanding the role of representations in the mathematics classroom.

We will consider mathematics classroom practice from a pragmatic viewpoint, as a practice within which mathematics teachers teach the subject and also teach to their students. The disciplinary learning objectives, as expressed in steering documents and interpreted by the teacher, relate to features of mathematics as a school subject and do not explicitly account for individual variation in knowledge between students. With regard to teaching mathematics, such a *disciplinary* perspective reasonably has to be combined with an *individual* perspective which considers each individual student as a learner in the classroom. The two perspectives relate to the dichotomy between mathematics as a body of knowledge and as a social domain of

enquiry (Ernest, 2004). In the current study, disciplinary and individual perspectives are readily combined as they are considered from a pragmatic viewpoint, simply as two perspectives that have to be accounted for and negotiated with respect to teaching and learning in the mathematics classroom.

RESEARCH OBJECTIVE

We aim to develop a unifying model of theoretical constructs and theories to account for the role of external representations as mediators of individual meanings in the mathematics classroom. The model will attempt to account for learning mathematics as a negotiation of individual and disciplinary meanings.

Although such a model puts focus on individual cognition, our ambition is to avoid making paradigmatic choices regarding learning theories, so that the model may be interpreted as a local but universal complement to understanding individual cognitive development in the context of mathematical classroom practice.

THE ESSENTIAL ROLE OF REPRESENTATIONS IN MATHEMATICS

From an epistemological perspective, mathematical objects have a very specific status compared with objects in many other domains of scientific knowledge as the mathematical objects are never accessible by perception or by instruments (Duval, 2006, p. 107). We gain access to the mathematical objects through their representations. For example, the number “five” cannot be experienced in the physical world, in contrast with the physical object “tree” which we can access directly through our senses. We can understand quite a lot about a tree through our senses and without representing it, for example by taking a picture of the tree, talking about the tree, or by recalling its name and associating the name to known facts about that particular kind of tree. The figures below, following Duval (2006, p. 114), summarize the differences between representations of mathematical and physical objects. In these figures, “content” should be understood as a mental construct or internal representation, while “representation” refers to the external representation which is accessible for inspection. Furthermore, “object” should in both cases be regarded as a mental construct, while the notion “physical object” refers to physical (external) instances of the object.

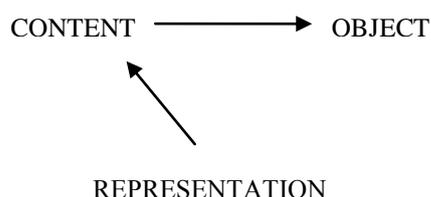

Figure 1: Mathematical (mental) objects

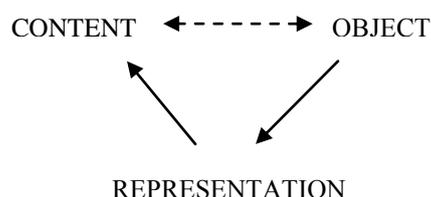

Figure 2: Physical objects

In Fig. 2, there is an obvious causality in that the physical object is a natural reference for the representation. The representation of a physical object may be regarded as a consequence of the object, while the representation of a mental object (Fig. 1) evokes a content which is required to experience the object. A mathematical object such as five cannot be experienced directly through our senses but must be understood in terms of its representations, neither of which should be confused with the mathematical object. To avoid the mistake of confusing the mathematical object with any of its representations, several representations of the same object should be experienced and contrasted by the learner. The mathematical object may be regarded as the invariant of the representations.

When the learner becomes acquainted with a mathematical object through its representations, it is reasonable to claim a direct connection also between object and representation. The two models above may then be merged into one model, where the objects are allowed to be either of mental or physical nature. This unifying model is often referred to as Ogden’s semiotic triangle, although there are several similar versions in the literature (Fig. 3, following Ogden & Richards, 1923, p. 11). The symbols stand in direct relation to thoughts (content) and only indirectly to things (objects) in that the symbols direct and organize thoughts, record and communicate thoughts (ibid, p. 9). With regard to mathematical objects, we find it more fruitful to draw on the model in Fig. 1 and the corresponding “mature” model in Fig. 4, which may involve not only one but several representations of the same object.

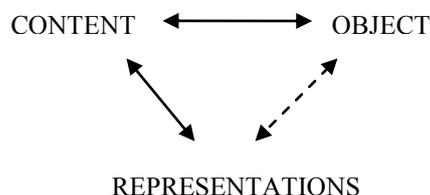

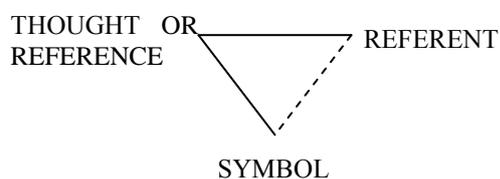

Figure 3: Ogden’s semiotic triangle

Figure 4: Physical or mental objects

Each representation enriches the content and may both strengthen and extend our understanding of the object, which in turn may influence new representations which add to the content in a cyclic process. Especially with regard to problem solving, it is important to note that a specific aspect of the content may not be supported by an arbitrary representation. For example, it is not possible to make sense of addition of positive whole numbers by representing them *as points* on a number line. However, addition may be understood on the number line if numbers are represented dynamically as repeated one-step jumps or by number arrows (vectors).

When the student processes a new representation, preliminary content and a preliminary object (Fig. 5) are attributed to the representation. The student may spontaneously construct thematized objects of thought (Piaget; in Tall, 1999) by making connections between preliminary objects (Fig. 6). The process of thematizing may for example be supported by baptizing objects (Sfard, 2000) or by supplying

concept definitions (Tall & Vinner, 1981). For example, baptizing five apples as “five” and baptizing further representations (such as five fingers, the symbol 5, five marks on a paper) using the same name, may support students’ associative processes towards perceiving “five” as a thematized object. Another approach to supporting association of representations would be to define the concept “five” as referring to a certain number of objects, for example “as many as the fingers on one hand”.

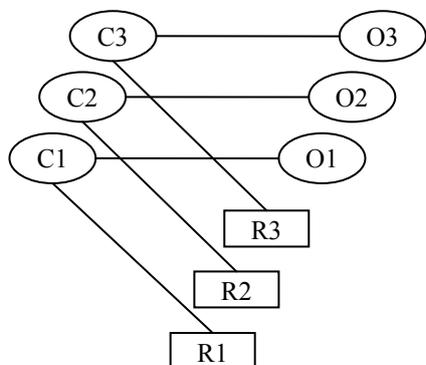

Figure 5: Preliminary objects

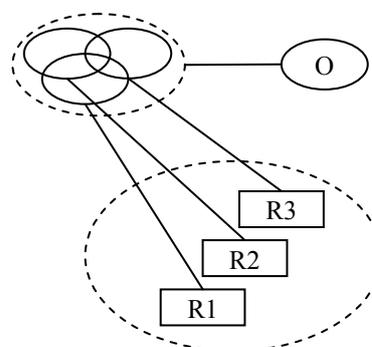

Figure 6: Thematized object

NEGOTIATING DISCIPLINARY AND INDIVIDUAL PERSPECTIVES

What is a mental object? According to the model in the previous section, the object emerges as a consequence of thinking about an external representation. Obviously, different individuals may think about the same representation in different ways. Nevertheless, the notion of object is often used from an objectivist perspective, where a pre-defined content is assigned to objects based on (some) disciplinary understanding of mathematics. Such a definition rules out the possibility of relating to students’ preliminary objects as individual mental constructs associated with one or several representations. With regard to our research objective of negotiating the notion of meaning in the mathematics classroom, it is necessary to acknowledge individual differences while still accounting for meanings that may be attributed to mathematics as a discipline. However, we find it neither necessary nor fruitful to define *one* notion of content and object. Rather, we will propose two separate definitions, one from an individual perspective and one from a disciplinary perspective. But first, we would like to discuss two examples which highlight the problems with a one-sided objectivist perspective on the notion of content and object.

Our first example is attributed to Husserl (quoted in Ogden & Richards, p. 271) who claims that equiangular triangles and equilateral triangles “name the same object”.

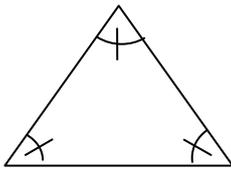

Figure 7: An equiangular triangle

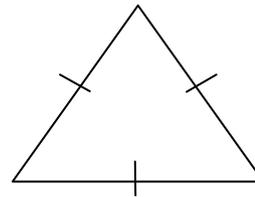

Figure 8: An equilateral triangle

Husserl acknowledges that the two entities have different ontological status in that he states that there are two distinct meanings related to each name. Nevertheless, the claim is that the two expressions *name the same object*. Certainly, it is well known within the discipline of mathematics that equiangular triangles and equilateral triangles name the same class of *mathematical* objects. As *mental* objects (of thought) we argue that the individual student may not conceive these as the same object, since that conclusion requires that the individual acknowledges the identification at a cognitive level. This identification may be considered a mathematical learning objective in itself, and will therefore be accounted for in the constructs that we propose in the current work.

We will elaborate briefly on how to model the process of identification in this case. Initially, the two classes `{Triangle | equiangular}` and `{Triangle | equilateral}` are defined in the mathematics classroom. The classes are defined according to different criteria and hence have different ontological status. So far we agree with Husserl. But we find it unreasonable to claim that the individual student, who has not yet connected the two classes in his or her mind, may consider these as the same object. However, when the student has made this connection, the (common) class may be interpreted as a thematized object `{Triangle | equiangular and equilateral}`, which inherits all established properties of the two previous classes. We consider this to be an important structural feature of mathematics teaching and learning that we would like to account for in our proposed model.

Our second example concerns a different domain of mathematics, namely fractions: “The symbols “ $2/3$ ” and “ $12/18$ ” mean the same because they refer to the same number” (Sfard, 2000, p. 37). As Sfard argues, an indirect procedure is required to prove the equivalence of the two expressions. From a disciplinary perspective, it is well known that the two symbols $2/3$ and $12/18$ represent the same number. But fractions are not only numbers. They may, for example, be thought of as ordered pairs of numbers. Proving equivalence of fractions rests upon defining an equivalence relation on the set of fractions. This equivalence relation *may* be defined in terms of comparing fractions *as* numbers, but the equivalence relation may also be defined algebraically based on interpreting the fraction as an ordered pair of numbers. We claim that both understanding the principles of identification (no matter how they are defined) and applying these principles to the specific fractions are learning objectives for each individual student. The two fractions $2/3$ and $12/18$ can not “mean the same” to the individual student until the student has noted that

they are (mathematically) equivalent. Furthermore, the example may be viewed as trouble-some not only from an individual but also from a disciplinary perspective, since the conclusion (that the two fractions “mean the same”) rests on the implicit assumption that the fraction as an object is determined based solely on its interpretation as a number. For comparison, Davis (2010) argues in a similar direction regarding justification of $3 \times (-4) = -12$, noting that the diversity of implicit assumptions is as important to attend to as the diversity of explicit representations of multiplication.

We note that justifications of $2/3 = 12/18$ and $3 \times (-4) = -12$ may rest on different assumptions in different classrooms. Therefore, it is not apparent how a disciplinary perspective on content and object should be defined.

TWO PERSPECTIVES ON REPRESENTATION – CONTENT – OBJECT

With regard to our research objectives, we would like to connect disciplinary and individual perspectives on representations, content, and object, in such a way that the reader (and the teacher) has freedom of interpretation to balance these perspectives according to her own preferences. Our strategy to achieve this connection is to relate to the semiotic triangle from both perspectives. The representation, as an external construct, is independent of the choice of perspective. On the other hand, the choice of perspective affects the interpretation of content and object as mental constructs. The individual content and object relate to constructs of the individual student, while the disciplinary content and object are not well-defined constructs (as noted in the previous section). As our ambition is to account for learning mathematics as a negotiation of individual and disciplinary meanings, we regard disciplinary content and object as *learning objectives*. As learning objectives, disciplinary content and object may still be defined in several different ways. We invite the reader to interpret learning objectives (for example) either from a student perspective, from a teacher perspective in terms of notions that the teacher aims at establishing with respect to the students, from a community perspective as a joint learning objective for teacher and students, or from an institutional perspective according to steering documents. Independent of choice of perspective, the disciplinary content and object are learning objectives that someone is pursuing, or would like to be pursued, in a general or specific mathematics classroom.

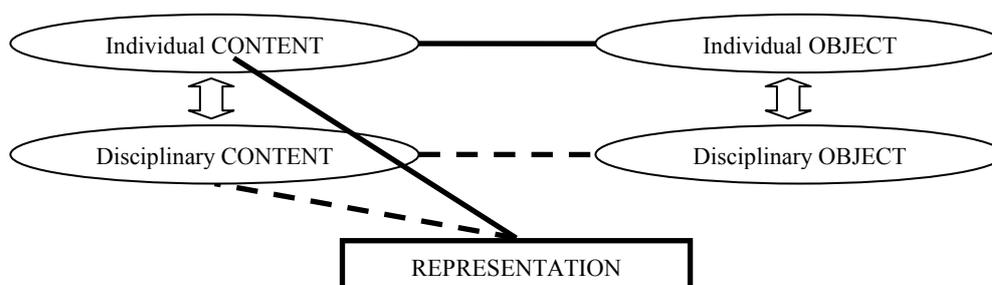

Figure 9: A model that connects disciplinary and individual perspectives

The arrows in Fig. 9 indicate a negotiation between individual and disciplinary learning objectives that we do not elaborate on in this short paper. An obvious shortcoming of this model is that it only describes a state and only implicitly implies what is expected to happen in the mathematics classroom. This leads us to consider *how* content and object may emerge in the classroom. While linguistic interpretations depend on the syntactical embedding of each word, mathematical interpretations depend essentially on processing of representations (Duval, 2006). Manipulation and processing of mathematical objects may be interpreted from either an external or internal (cognitive) perspective. The notion of representation is relevant to discuss from either perspective, and it is well known that there is a close correlation between external and internal representations (Baddeley, 2007). In this paper, we consider representations only as external constructs.

MATHEMATICAL PROCESSES

We will use theories of semiotics as a point of departure for modeling processing of representations. As a point of departure, we briefly relate to the works of the Swiss linguist Ferdinand de Saussure (1857-1913) who defines a *sign* in terms of two components, the signifier (*signifiant*, the form, pattern of the sign) and the signified (*signifié*, the content, thought of the sign). The sign itself is formed by the associative link between the signifier and the signified and gets its meaning in relation to or in contrast with other signs of the same nature (Engström, 2002). The American philosopher, logician, and mathematician Charles S. Peirce (1839-1914) defines the notion of sign in a way that explicitly accounts for relations with other signs, in a way that (not surprisingly) seems to fit mathematical structures particularly well. Our interpretation of Peirce, in comparison with Saussure, is that he includes two dimensions in the thought of the sign. He names these dimensions *object* and *interpretant*, where the latter “fulfils the office of an interpreter” (Houser & Kloesel, 1992, p. 5) and hence involves translation of the sign. The object relates to how the specific sign is understood, as a concept, while the interpretant concerns translations, applications and consequences of the sign, including processes. The dimension of the interpretant is particularly important in mathematics, as argued by Duval (2006, p. 106): “... the leading role of signs is not to stand for mathematical objects, but to provide the capacity of substituting some signs for others.” Peirce’s third notion *representamen* corresponds to Saussure’s signifier, that is, the pattern of the sign. The two models are summarized in the figures below (Engström, 2002).

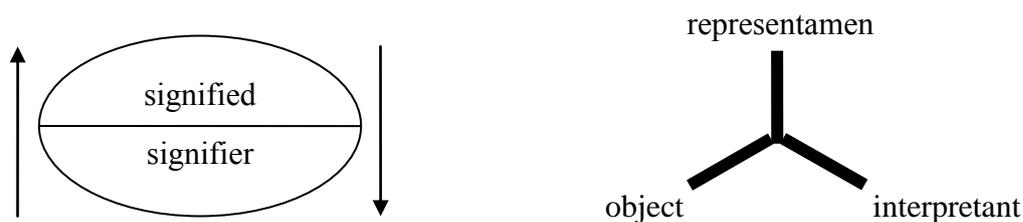

Figure 10: Saussure's model of the sign Figure 11: Peirce's model of the sign

Peirce introduces many other notions of seemingly abstract philosophical nature. One such notion is the distinction between *firstness*, *secondness*, and *thirdness*, which he refers to “as modes or tones of thought” (Houser & Kloesel, 1992, p. 247). Firstness concerns the representamen, which is always present. Secondness requires that the interpreter associates either object or interpretant with the representamen. Thirdness is the desired state of the sign and requires that both object and interpretant are associated with the representamen. Peirce discusses the notion of *degenerated secondness*, where either the object or the interpretant may be weak. An example of degenerated secondness is when a learner is able solve linear equations by following formal rules, but having a weak understanding of what an equation is. In this case, the learner can solve the equations by manipulating symbols but can not interpret the equations, which indicates a strong interpretant but a weak object. Another learner may be able to interpret an equation but not know how to solve it, thus having a weak interpretant but a strong object.

Raymond Duval (2006) highlights several characteristics regarding forms of representations that have important didactical implications. First, he provides a qualitative classification of semiotic representation systems in terms of *registers*, which by definition have (potential) thirdness. Second, he puts focus on two different types of transformations: *treatment* within a specific system (such as $34+25=50+9$) and *conversion* between different systems (for example, pictures to symbols) as two distinct types of processes that describe how learners engage in mathematical activities and specifically when solving mathematical problems. From a disciplinary objectivist perspective, Duval classifies registers according to their degree of pre-defined regulation of treatment. However, from an individual perspective any representation has potential thirdness depending on how an individual interprets and interacts with the representation. For our purposes, we choose to interpret Duval's notion of register as a relational rather than a pre-defined disciplinary construct.

CONNECTING PEIRCE, OGDEN & RICHARDS, AND DUVAL

There are no apparent inconsistencies between Peirce's sign (Fig. 11), the semiotic triangle (Fig. 1, Fig. 3), and Duval's theory of registers. This is not at all surprising, since the latter authors explicitly draw on Peircean semiotics but with focus on different relations, respectively representamen-object (Fig. 12) and representamen-interpretant (Fig. 13). Specifically, Duval (2006) puts focus on the processes of treatment and conversion which both refer to the interpretant dimension of Peirce.

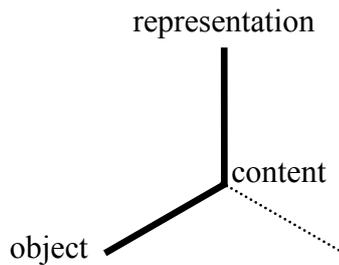

Figure 12: Fig. 1 in Peirce's sign

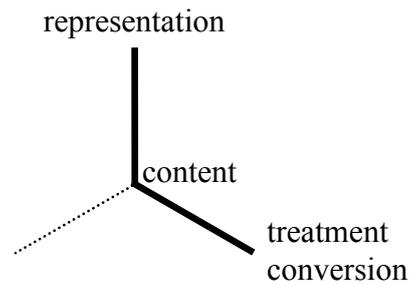

Figure 13: Processes in Peirce's sign

While Duval (2006) explicitly discusses the object dimension, he puts focus on the interpretant in terms of treatment and conversion. In Ogden & Richards' semiotic triangle (Fig. 3) we may interpret the referent as including both object and interpretant, but with a clear emphasis on the object dimension. As mathematicians, both Peirce and Duval recognize the importance of processing signs in order to create mathematical meaning, while authors such as Saussure, and Ogden and Richards, whose main interest is natural language, do not explicitly consider the notion of processing. However, the models of the latter authors do not exclude including an explicit dimension related to processing. To account for both a disciplinary and an individual perspective on content and object, we may readily connect the previous models, particularly those represented in Fig. 13, Fig. 11, and Fig. 9, keeping in mind that (the external) representation is common for the perspectives, as are (the resulting external representations of) conversion and treatment, while content and object (as mental constructs) depend on choice of perspective. Furthermore, we choose to highlight conversion and treatment as two separate processes by splitting the interpretant in two separate legs. The resulting model is shown in Fig. 14.

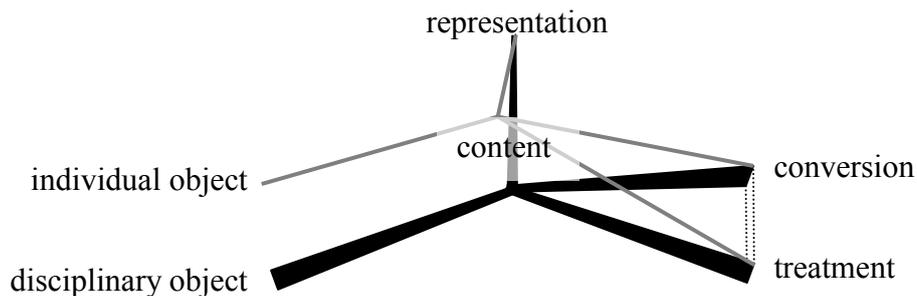

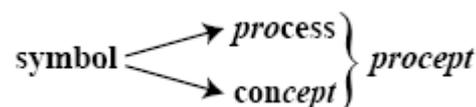

Figure 14: Integrated model coordinating disciplinary and individual perspectives

As noted earlier, the semiotic triangle (Fig. 1) with vertices representation – content – object, appears in two versions to the left in Fig. 14. For comparison, Saussure's model may also be interpreted in Fig. 14 with representation as the signifier and object together with treatment and conversion (as processes) as elements within the signified. While the semiotic triangle and Saussure's sign are redundant in Fig. 14, they provide support for our model as a globally unifying construct, in the sense of Prediger, Bikner-Ahsbabs & Arzarello (2008).

CONCLUDING REMARKS

The investigations that resulted in the current paper originated as a survey of research concerning semiotic representations, particularly stimulated by Duval's notions of registers, and the processes of treatment and conversion. As our work progressed, Peirce's theory of signs emerged as a unifying theory. The final model (Fig. 14) may be interpreted mainly as accounting for underlying theoretical structures rather than innovative networking of theories, in the sense of Prediger et al. (2008). Our contribution to the model is the refinement of the interpretant and coordination of individual and disciplinary perspectives. Peirce's theory of signs seems to have served as a natural foundation for research focusing on structural aspects of semiotic representations. Some authors, such as Ogden & Richards, explicitly refer to Peirce, while others, such as Tall et al., do not. We feel that interpreting specific theoretical constructs within the model provides a context that may guide interpretation of these constructs. For example, the reader may interpret the following visual model of Tall et al. (2001) with respect to Fig. 14 by visually rotating either model. While these visual models do not have any inherent meaning, they may still serve to guide a reader's understanding of underlying theoretical constructs.

COMBINING THEORIES TO ANALYZE CLASSROOM DISCOURSE: A METHOD TO STUDY LEARNING PROCESS

Michal Tabach

Talli Nachlieli

Tel Aviv University

Levinsky College of Education

This paper focuses on learning processes of prospective elementary school mathematics teachers who are studying a course on functions and graphs. Specifically, we address the questions – "What were the modifications in students' ways of mathematizing about functions?" and "How did the teacher's and students' actions enable and promote modifications in the students' ways of mathematizing?". For this purpose, we analyze the mathematics classroom discourse that developed in class by combining two theories – systemic functional linguistics and the commognitive framework. In this paper we present the method that we have developed and exemplify its use and advantages by analyzing an episode of a mathematics classroom. By doing so, we provide a lens to think about and capture complexities of instruction.

INTRODUCTION

It is widely accepted today to focus research on learning processes in classrooms, rather than just on the outcomes of learning. This raises substantial theoretical and methodological issues. In this paper we suggest a method for analyzing classroom discourse to learn about instructional processes, and specifically, to address questions such as *What were the modifications in students' ways of mathematizing¹ about functions? and How did the teacher's and students' actions enable and promote modifications in the students' ways of mathematizing?* Specifically, how did the teacher and students organize the mathematical discourse so that peripheral participants (Lave and Wenger, 1991) could become more active participants of the canonical mathematical discourse? For this purpose we draw on two theories that each seems to have the potential to address different, yet complimentary, aspects of those questions - Systemic Functional Linguistic, (SFL, Halliday, 1978; Halliday & Matthiessen, 2004) and the commognitive framework (Sfard, 2008). This combination enabled us to develop a new perspective with which to investigate classroom learning. The data used to exemplify the suggested tool is taken from a study² that aims at identifying instructional processes of prospective teachers, attending a functions and graphs course. In the following sections we outline the basic principles of SFL (Halliday, 1978), followed by basic tenets of commognitive framework (Sfard, 2008). Then we describe and exemplify how we use the suggested method.

THEORETICAL BACKGROUND

Systemic Functional Linguistics

According to SFL (Halliday, 1978; Halliday & Matthiessen, 2004), language is a resource for making meaning through choice. This approach is concerned with the analysis of how language is used to achieve certain discursive goals and the analysis of the choices that have been made in any instance of language use (O'Halloran, 2005:61). The sets of possible choices were clustered by Halliday in terms of the functions that they serve (and therefore are called metafunctions): (1) *the ideational* – the content function of language, what is talked about. This metafunction expresses those things in language such as the objects, actions, and relations, of the world and of our own consciousness; (2) *the interpersonal* – the participatory function of language, through which "*the speaker introduces himself into the context of situation, both expressing his own attitudes and judgments and seeking to influence the attitudes and behaviour of others.*" (Halliday, 1978:112); and (3) *the textual* – the organization of the text. This is the metafunction that "*makes language relevant. ... it expresses the relation of the language to its environment, including both the verbal environment – what has been said or written before – and the non verbal, situational environment.*" (Halliday, 1978:112-113).

That is, any language use, serves three functions simultaneously, constructing some aspect of experience, negotiating relationship and organizing the language in a way that it realizes a satisfactory message (Christie, 2002).

The commognitive approach to study learning

The commognitive framework (Sfard, 2007; 2008) is a socio-cultural approach. Within this framework *thinking* is defined as an individualization of interpersonal communication, although not necessarily verbal³. *Discourse* is considered a special type of communication, made distinct by its repertoire of admissible actions and the way these actions are paired with re-actions. To emphasize the unity of cognitive processes and communication, the word *commognition*, a combination of the two, is used to name the framework.

Mathematics, as any academic discipline, may be considered a form of discourse made distinct by four characteristics: words and their uses, visual mediators, routines and endorsed narratives, as detailed below.

Words and their uses. Any professional discourse has a unique vocabulary. Some of the words may be used in other discourses, either in the same way or according to a different definition. Words and their uses are central to a discourse as often they determine what one can say about the world. With regard to the area of functions and graphs, we find words such as slope and function with unique uses in the mathematical discourse.

Visual mediators. Those are the objects acted upon as a part of the communication. While colloquial discourse is mediated mainly by images of concrete objects that exist independently of the specific discourse, in mathematics, most symbols and other mediators were created mainly for the purpose of communication. Visual mediators of the mathematics discourse include algebraic symbols that mediate ideas such as written numbers and graphs, or other symbols like those that represent variables, coefficients and equality. The mediators used in the communication often influence what one can say about the idea discussed. To illustrate, while solving equations in algebra, students often participate in a different discourse if they use graphs as their visual mediators, or if they refer to the algebraic symbolic equation as their discursive objects.

Routines. A routine is a set of meta-rules defining a discursive pattern that is repeated in similar types of situations. Those rules are the observer's construct as they describe past actions that were noticed by the observer. Although they describe past actions, routines are helpful in learning a new discourse as our ability to act in new situations often depends on recalling one's or others' past experiences. An example for a routine often practiced in mathematics regards finding the slope of a given linear function. The specific mediator chosen for a function (e.g. graphs or algebraic symbols) often dictates the routine chosen for that purpose.

Endorsed narratives. Endorsed narratives are any text that can be accepted as true by the relevant community. Specifically, in mathematics, the endorsed narratives are those narratives that become "mathematical facts". Narratives such as axioms, definitions and theorems are all endorsed narratives, with each of them being derived differently.

Combining the theories

Our focus is on instructional processes – on the processes by which learning is enabled and enacted. For this we seek a theory that views language as a set of choices. Moreover, the unit of analysis relevant for our suggested studies is the discourse itself (or parts of it). These two requirements are met by both theories. In Gellert's (2009) words, the underlying principles of the two theories are 'near enough'. However, whereas SFL focuses on language, that is, on the verbal aspects of discourse, commognition holds a wider view and considers also non-verbal aspects of the discourse (e.g. routines and visual mediators.) In addition, while SFL explicitly distinguishes between the content function, the participatory function and the organization of the text, studies conducted under the commognitive framework focus on making explicit routines, endorsed narratives, words and visual mediators of the discourse. While commognition is a socio-cultural approach that aims at providing a lens to study learning processes, SFL is a linguistic approach may help researchers focus on specific choices of participants' language use that may be overlooked.

For our purposes, each theory has an added, complementary, value – we wish to distinguish between the three metafunctions, as is called for by SFL, and we wish to identify the various discourse characteristics, as is called for by commognition. We believe that this dual analysis would allow noticing aspects of classroom discourse that were not identified thus far.

THE METHOD

In the following sections we present the data to be analyzed, the unique method that we developed to analyze classroom discourse and an example of using this method to analyze classroom discourse. We begin by specifying our research questions in light of the theoretical frameworks that we adopt.

Research questions

What were the modifications in students' ways of mathematizing about functions? Specifically, what are the modifications and changes in students' use of words, visual mediators, routines, and endorsed narratives, while they participate in a mathematics discourse? The focus of attention here is Halliday's ideational metafunction. We broaden this metafunction to refer not only to what is being said, but also to the actions performed as a part of instruction (e.g. calculations in writing and drawing.)

How did the teacher's and students' actions enable and promote modifications in the students' ways of mathematizing? Specifically, what are the actions that the teacher and students perform to organize the mathematics discourse so that peripheral participants could become more active participants, with regard to the ways by which they use words, visual mediators, routines, and endorsed narratives? How do the teacher and students develop social relationships and how do the participants orient themselves to the learning of mathematics and to others? Here the focus is dual – first, the textual metafunction, that makes language relevant (Halliday, 1978: 112-113). We use this category to refer to what it is that one (usually the teacher) assumes others (usually the students) already know and what it is that is assumed new, and therefore – how the teacher organizes the discourse so that students, as novice participants, could participate. The second focus is the interpersonal metafunction, which regards the ways by which the teacher and her students develop social relationships and by which they orient themselves to each other and to the mathematics.

Data collection and documentation. The following transcript⁴ is an example of the type of data to be analyzed, and of our method of presenting transcriptions. It was taken during a whole class discussion in a 1st year course for prospective elementary school teachers in a college of education in Israel. All 14 lessons were video and audio taped and are used in a larger study that focuses on learning about functions. In the following task, the students were asked to compare the steepness of five segments (see Figure1). Noam suggested that AB was the steepest, and was asked to explain why:

Working Group 16

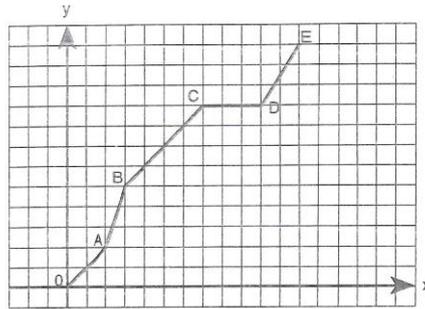

Figure1: The graph presented to the students

49. Noam I, like, used a silly method.
50. Teacher What method?
51. Noam I said that, like, in one x, like, the segment AB, then in one x it went up a lot.
52. Teacher Wait, wait, wait. I want you all to listen to Noam. Noam is trying to explain why, what was the segment that you said is steepest?
53. Noam AB
54. Teacher Come, show it on the graph. Come, come, come. Noam wants to explain something, and, a method she worked according to. Come, stand where I stand, and with the pen you can show here on the, ... you see, the segment AB is here... come, show them.
55. Noam [walks to the overhead. She points with her pen towards segment AB.]
56. Noam Segment AB went up by, like, only, eee... only in this x [moves her hand parallel to the x axis along one unit] it went up a lot [moves her hand parallel to the y axis along three units.] see Figure1
57. Teacher That means, what are you saying, that you moved from A, from point A towards the positive direction of the x axis in one unit [moves her hand parallel to the x axis along one unit].
58. Noam Yes
59. Teacher What did you see, that it went up by how much?
60. Noam Three y [the teacher moves her hand parallel to the y axis along three units.]
61. Teacher That is, y changed by three [the teacher moves her hand along segment AB]
62. Noam Yes
63. Teacher When x changed by one, y changed by three.
64. Teacher As opposed to the other segments... what is it?
65. Noam Let's say, in OA and in BC
66. Teacher OA, look, in OA, what happens in OA?
67. Noam It is equal because there is the same increment, two x, two x. Points at segments OA and BC]
68. Teacher That is, what is there in OA? When x went up by... when x increased by 1, by how much did y change?

Working Group 16

69. Student By one
70. Teacher Thank you.

Method of analysis and examples of findings. We use the lens of SFL in general, and specifically, that of the ideational, interpersonal and the textual metafunctions to differentiate between the three discourses that are a part of the mathematical classroom discourse – the mathematical⁵, the social and the organizational. For that purpose, we broaden each of the metafunctions to refer not only to what is being said, but also to the actions performed as a part of instruction (e.g. calculations in writing and drawing). Specifically, we use the textual meta-function to refer to what it is that one (usually the teacher) assumes others (usually the students) already know and what it is that is assumed new, and therefore – how the teacher organizes the discourse so that students, as novice participants, could participate.

For each metafunction, we refer to the words and visual mediators that participants use, the routines that could be identified and the narratives endorsed.

We summarize and exemplify our method in the table below, with regard to the given transcript. We realize that our sayings are limited due to the shortness of the analyzed excerpt.

Discourse characteristics Metafunction	Words and visual mediators	Routines⁶	Endorsed narratives⁷
The ideational	<p>The words and visual mediators used in class that relate to the mathematics.</p> <p>Examples: Student: "Three y" (60) Teacher: "That is, y changed by three" [the teacher moves her hand along segment AB] (61)</p> <p>Student: "in one x, it went up a lot." (51) Teacher: "when x changed by one, y changed by three" (63)</p>	<p>The routines observed in class that relate to the mathematics.</p> <p>Examples: The student refers to a routine by which she decides which segment is steepest. She calls it "a method" (49). She compares the graphs qualitatively (and not quantitatively.) (turns: 49, 51) The teacher compares the steepness of graphs by referring to their slopes (63).</p>	<p>The narratives that are discussed in this learning community that relate to the mathematics.</p> <p>Examples: at this time there is no evidence that the students and teacher endorse the same narrative. There is evidence regarding the narratives that some of them endorsed:</p> <p>Student: "in one x, it went up a lot." (51) Teacher: "when x changed by one, y changed by ..." (63)</p>
The inter-personal	<p>The words and visual mediators by which people orient to the mathematics, to themselves or to others, and by which they develop social relationships and a learning community.</p>	<p>Discursive routines that relate to the ways by which people orient to the mathematics, to themselves or to others, and by which they develop social relationships and a learning community.</p>	<p>Endorsed narratives that relate to the ways by which people orient to the mathematics, to themselves or to others, and by which they develop social relationships and a learning community.</p> <p>Examples: (our examples are from the rest of the lesson.) "This is great." (487)</p>

Working Group 16

	<p>Examples:</p> <ul style="list-style-type: none"> - The student evaluates a method that she chose to use to solve a problem: "I use a silly method" (49) - The teacher marks Noam's method as important for the entire class: "Wait, wait. I want you all to listen to Noam." (52) 	<p>Examples:</p> <p>The teacher empowers students by inviting them to stand in front of the class and tell their ideas in their own words. (e.g. 52, 54)</p>	<p>"You are doing a wonderful job"</p> <p>"Do you understand why?" the teacher's disposition towards learning and knowing: – to know includes explaining why. The students' answers repeatedly included explanations or saying of the type: "I know that this is so, I do not know why" even when were not asked to explain explicitly.</p> <p>Another disposition: "you should work in small groups"</p>
The textual	<p>The words and visual mediators that relate to the ways by which the participants organize the mathematics discourse so that peripheral participants could become more active participants.</p> <p>Examples:</p> <ul style="list-style-type: none"> - Choosing the task: comparing steepness of graphs, before actually talking about the slope of a graph. <p>"that means, what you are saying..." (57)</p>	<p>Discursive routines that relate to the ways by which the participants organize the mathematics discourse so that peripheral participants could become more active participants.</p> <p>Examples:</p> <ul style="list-style-type: none"> - Repeating her way of comparing steepness of graphs. - Revoicing. (e.g. "that means, what you are saying...", (57) - Realizing the need for a publicly seen mediator to communicate ideas (graphs on overhead.) 	<p>The narratives that are endorsed by this specific group that help organize and enable the communication between peripheral and expert participants.</p> <p>Examples:</p> <p>"you should work in small groups"</p> <p>"that means, what you are saying...", (57)</p>

Table2: A method to analyze classroom discourse

FINDINGS

Mathematics classroom discourse interweaves several discourses – the mathematical, social and pedagogical. We identify the mathematical discourse with the ideational metafunction⁸, the social with the interpersonal metafunction and the pedagogical⁹ with the textual. That is, for those discourses we focus on each of the table's rows separately. For each discourse, we consider each of its characteristics separately, by considering the table's columns.

The following findings are restricted to the given episode, and are therefore limited in their scope.

Working Group 16

Mathematical discourse. This focus exposes differences in the teacher's and students' ways of mathematizing – their use of words, visual mediators, routines and narratives. The student's word use is more colloquial ("it went up a lot") and the ideas expressed are imprecise. In the context of comparing slopes, while the teacher compares slopes by referring to it quantitatively, the students compare them visually.

Social Discourse. The teacher empowers students by allocating time and place for them to present their ideas to the other students and by evaluating their work. The teacher's disposition towards learning seems to be that small group discussions promote learning and that understanding why and being able to express that are crucial for learning.

Pedagogical Discourse. The teacher performs several actions to organize the mathematical discourse so that the students could become less peripheral participants. Those actions reveal her dispositions towards learning mathematics: e.g. using revoice as a pedagogical strategy; this way she shows respect her students' ideas, yet able to use them as a springboard to present mathematically accepted ways of doing and saying.

FINAL COMMENTS

In this paper we suggested combining two theories, SL and commognition, to learn about instructional processes. The suggested combined method is a practical and coherent way of analyzing classroom discourse to study about learning processes. Thus it provides a conceptual framework by which various aspects of classroom discourse could be observed, identified and thought of. In other words, the combined method helped us to "*direct researchers' attention to particular relationships in providing meaning for the phenomena being studied*" (Silver and Herbst, 2007: 373). As can be seen, it allows one to focus on each of three discourses that develop in class – the mathematical, the social and the pedagogical. Its importance lies at the underlying assumptions that to improve our understanding of mathematics learning and teaching, one should focus on processes rather than on end-results only, and on those processes that take place in classroom rather than in different "laboratory-like" settings.

NOTE

- ¹ Mathematize: participate in a mathematical discourse; "doing" mathematics (Sfard, 2008).
- ² This study is supported by the Israeli Science Foundation, no. 446/10.
- ³ This is coherent with Vygotsky's theory regarding the higher mental functions that appear first in the social plane and are only then individualized (Vygotsky, 1986).
- ⁴ The transcript was translated from Hebrew by the authors.

Working Group 16

⁵ The ideational metafunctions refers to what is talked about. For our purposes, we suggest narrowing the scope addressed by this metafunctions and relate only to the mathematical content discussed.

⁶ To identify a routine we would need longer stretches of text or declarations regarding how one often acts. As we only exemplify a short episode, the routines are generalized from analysis of a larger corpus of data.

⁷ While narratives may be presented in a single sentence, their endorsement by the class community may be identified only in longer episodes. Therefore, our examples are taken from a larger corpus of data.

⁸ We do not claim that the ideation metafunction includes only parts of the discourse that are about mathematics. For our purpose we choose only those parts.

⁹ In the literature, the pedagogical discourse is often used to consider what we refer to as "classroom discourse" (e.g. Christie, 2002). We use it to refer to teacher's choices regarding the organizations of the discourse so that students, as novice participants, could participate.

INTRODUCTION TO THE PAPERS OF WG 17: FROM A STUDY OF TEACHING PRACTICES TO ISSUES IN TEACHER EDUCATION⁸⁴

Leonor Santos (Portugal), Claire Berg (Norway), Laurinda Brown (UK),
Nicolina Malara (Italy), Despina Potari (Greece), Fay Turner (UK)

Overview: There was recognition of the value and complementarities of different approaches to the professional development of teachers. However, it was also recognised that there are constraints and affordances for different approaches, which vary between cultural contexts. Working across cultures on teacher development projects, which employ different strategies, was considered to be a useful way of moving forward our understanding of different approaches. There were some attempts to synergise different frameworks in research and development activities that were reported in the papers. However, there remains considerable work to be done in understanding how different frameworks relate to one another and in supporting researchers in selecting elements of different frameworks that will enable them to answer specific research questions.

Group 17 received 57 proposals (48 for papers and 9 for posters), which involved 129 authors from 28 nationalities. Each paper was reviewed by one of the group leaders and two authors. For most proposals we asked for some revisions. In the sessions of the working group during the conference, 37 papers and 8 posters were presented.

According to what had been proposed in CERME 6, the working group split into two subgroups (WG17 A and WG17 B). The group was all together for only the first part of session one and for the last session. All the papers were grouped into seven topics and distributed to the two subgroups. All the participants were informed in advance of the distribution of the papers in the two subgroups.

All participants of WG17 were expected to have read papers previously to the session in which they were presented. In each session, three or four authors sketched the key ideas of their report (5 minutes each). One of the group leaders or participants then gave a prepared reaction to the set of papers (10 minutes). In most cases, the reactor attempted to make links between the papers and suggested questions arising from the papers that might form the basis for discussion.

The organisation of the sessions was highly rated by the participants, as was the atmosphere. Nevertheless, at the final session, the group coordinator presented several possible scenarios to organize the working group for the future, given that

⁸⁴ Alena Hošpesová (Czech Republic) contributed as a group leaders, being in charge of part of the review process

participation remains high. Although no decision has been taken, a general opinion was voiced against the possibility of splitting this working group into two new ones.

Topics

We present the issues and ideas that emerged in reference to seven central topics.

Topic I: Mathematical content knowledge for teaching

The categorisation of knowledge needed for the teaching of mathematics and how such knowledge might be identified in the practice of, or when discussing teaching underpinned many of the papers discussed in WG 17A. Ball et al's 'egg' appeared to be generally accepted as a useful framework for categorising knowledge and Rowland et al's Knowledge Quartet was frequently used as a means for identifying the situations in which such knowledge was revealed in the practice of teaching. This common language and understanding of frameworks represented a clear progression from the discussion in CERME 6.

Topic II: Professional knowledge for teaching

The papers discussed referred to a number of different approaches to the development of mathematics teaching through both Initial Teacher Education (ITE) and Continuing Professional Development (CPD). Although supporting learning in knowledge about mathematics and mathematics pedagogy was seen as the foundation for developing mathematics teaching, it was recognised that it was developing the application of this knowledge in action (knowing how to) that should be our ultimate developmental and research concern. The balance between focusing on the development of knowledge about and the development of knowing how to was considered in relation to how this varies between ITE and CPD.

Topic III: Reflection in mathematics teachers' professional development

One approach that seemed to be effective was the use of theoretical concepts and frameworks by the teachers in discussing and analysing mathematics teaching. Although teachers' interpretations of these concepts and frameworks and the way they link them to teaching are often idiosyncratic, the studies indicate that this approach promotes critical reflection of teachers' beliefs, knowledge and practices. Another issue that emerged was that teachers' reflection on a number of mathematical, teaching and learning phenomena can improve both their mathematics and pedagogical content knowledge. Finally, mathematics educator's learning from teachers' reflection is also an important issue that needs further research attention.

Topic IV: Collaboration in mathematics teachers' professional development

Within teachers' professional development the modes of collaboration between the different actors are of crucial importance for achieving successful development. The three papers related to this topic present different models concerning the

collaboration between teachers and didacticians, teachers with colleagues, and teacher students and teacher educators. These studies share a willingness of considering teachers, colleagues, or teacher students as true partners in the process of change, and this seems to be one of the principles of professional development. However, issues related to sustainability of such collaborative models need to be critically addressed and carefully investigated in future.

Topic V: Professional development

A significant discussion in the working group concerned the long-term effectiveness of professional development programmes, in particular related to mathematics teacher education. It is necessary to understand, in a deep way, the characteristics of professional development for sustainable impact. Is it really possible to know what is the impact after some years? What does sustainability mean in a society where people change profession?

The working group also discussed whether there are different issues concerning pre-service and in-service teachers education programmes.

Topic VI: Conceptions and practices

The papers presented in this session concern mainly the study of particular aspects of teachers' practice, highlighting the relationships between teachers' beliefs, knowledge, didactical and methodological choices and students' learning.

Two studies are devoted to the analysis of teachers' work in their daily practice, with the aim of collecting data useful to find ways to improve teacher training and show the incidence of the teacher's beliefs in management of their class work. Another paper focused on collaborative curriculum management in the context of a school mathematics department focusing on sustainability of the culture. This contrasted with a study involving prospective teachers, evidencing trainees' difficulties in theoretical and methodological analysis, given their lack of teaching experiences and the short length of their course. The personal dimension seems to have a real influence, including negatively, documented by a study involving teachers who, convinced that metacognitive activities can be practised exclusively with more gifted students, were negatively influenced in their teaching by this belief.

Topic VII: Interaction in the classroom

The four papers were in the frame of teachers' educational projects centered on laboratories devoted to classroom practice either in pre-service or in service education. In general terms, these projects are aimed at developing the teachers' ability to enact generative teaching, to refine their communicative practices (posing questions, listening and answering) to control the cognitive implications of their behaviors and to assess the students' mathematical learning. Even if framed in different theoretical studies, all the research projects are realized over the long term (at least one year), through collaborative work between teachers and

mentors/researchers.

PRIMARY SCHOOL TEACHERS' PRACTICES USING A SAME MANUAL WRITTEN BY DIDACTICIAN

Sara Ardit

University of Paris VII Denis Diderot

Our thesis work reviews teachers' practices when using the same manual written by didacticians. The study aims to analyse variability in specific teachers' practices when they use different types of problems from the same manual written by didacticians and also to analyse several teachers' practices when they use the same problem written by didacticians. This paper reports the comparative analysis of ways teachers carry out a problem about fractions proposed in the manual Euromaths with children aged 9 or 10 years. This comparative analysis raises questions about the reproducibility of situations written by didacticians. This study could contribute to a characterisation of didacticians' intervention latitude. It could also contribute to find ways to improve teacher training.

Keywords : practices, conceptions, manual, transmission, reproducibility

INTRODUCTION, THEORITICAL FRAMEWORK AND METHODOLOGY

The question of how problems written by didacticians are transmitted is often raised by the didactician community. According to Artigue (Artigue, 1989) questions about transmissibility of such problems lead to questions about their reproducibility. Manuals are written by didacticians to transmit problems contingent on recent research results. But, the confines of a manual forces the author to transpose the problem and its analysis which may make the transmission more difficult. It is especially difficult for the "a priori" analysis to be entirely written in the teachers' book. My thesis work aimed to analyse the way in which problems and teaching sequences written by didacticians are transmitted to practitioners through teaching manuals. So, it reviews the practices of teachers using the same manual written by didacticians. The meaning of "practices" according to Robert & Rogalski (2002) is what the teacher does before, during and after class, encouraging the practices into the class.

In this paper the analysis of teachers' practices using a problem written by didacticians are focused on. The aim of this study is to determine, at least partially, the spectrum of ways teachers carry out the same problem written by didacticians. The spectrum extent will suggest how effectively the chosen problem has been transmitted and if it can be reproducible. A problem will be reproducible if it has the ability to create necessary conditions (expected by the didacticians who wrote it) for the students to learn. But, to talk about reproducibility doesn't really fit the situation of ordinary primary school teachers. So, in order to determine the spectrum we chose to study teachers' appropriations of a *Euromath's* problem. The term appropriation seems to better describe how teachers understand a problem written by didacticians

and how they make it their own (Bolon, 1996). To determine those appropriations, the distance between tasks proposed by the manual to the teachers and tasks proposed and carried out in the classroom has been examined.

I use the theoretical framework “double approche”, developed by Robert (Robert, 2001). It says that “teachers’ practices in class are the result of their work - though partly implicit - which has its own consistency and may not be reduced to a mere analysis of students’ potential learning”. The analysis only of what students learn is not enough to understand teachers’ practices. My teachers’ practices study will then include two points of view: the student’s learning for one part and the teachers’ work for another part. So I analyse expected scenario, mathematics’ tasks proposed to the students and teachers’ speech in order to have an access to students learning possibilities. Then, I adopt the second point of view about teachers’ work to understand teachers’ choices and their consistency. They develop some personal strategies according to goals and pressure of their work. Those depend on several factors such as their beliefs about mathematics, their beliefs about how to learn, their knowledge of the mathematics content of schools curriculum but also their experiences as a teacher or a student (Robert, 2004; Perrin-Glorian, 1995).

The research was carried out with five teachers in CM2 (children aged 9 or 10) or CM1/CM2 (children aged 8, 9 or 10) grades. All the teachers chose to use Euromaths in their class. They had different professional backgrounds, some of them had scientific or didactical background (3 of the 5 teachers). They were different ages, they were both male and female and they had been teaching for more or less time. In order to read the paper more easily, I call the teacher A, B, C, D and E according to the distance between the tasks they carry out and the manual tasks *a posteriori*. In the following table I present some of teachers’ personal data we used to understand the practices. According to Shulman (1986), mathematics knowledge, pedagogical mathematics knowledge and curricular knowledge are three points to look at to understand if a teacher may be able to teach in a certain way. That’s why I focus on the teachers’ scientific background, didactical background and teaching experience with or without *Euromaths*.

Teachers	Grade	Scientific background	Didactical background	Teaching years	Euromaths manual used years
A	CM1/CM2	Yes	Yes	3	2
B	CM2	No	Yes	10	2
C	CM2	Yes	No	10	1
D	CM2	No	No	25	3
E	CM2	No	No	30	1

Table 1: Teachers’ personal data

I went into each teacher’s class to observe and tape all the work on fractions (5 to 20 session per teacher). I interviewed the teachers before the beginning of this work and

after it ended. The lessons and interviews were transcribed. According to Robert (2004) even if teachers' espoused practice might indicate that their conceptions are close to the authors' conceptions, their actual practices may be really different. For this reason, in order to analyse teachers' practices (and conceptions) I used the lessons transcription rather than interviews. I cut the transcriptions into different episodes like "proposition of the task by the teacher", "students' research", "collective work" etc. and I analysed each episode.

To determine the spectrum of teachers practices when they use a problem from the manual, I identified for each teacher the distance between tasks proposed by the manual and tasks proposed and carried out in the classroom. The M-tasks I consider are the tasks written in the textbook but also the different ways they can be carried out according to the authors' conceptions. Both texts (the problem text in the textbook and the guideline in the teacher book) have been analysed to understand what could happen in the class. According to those analyses we determined the knowledge contained in the tasks, the possible ways to carry the tasks out and I defined the points on which we will especially focus.

The indicators we used to understand teachers' practices are the tasks proposed by the teacher to his student (T-tasks) and the tasks actually carried out in the classroom (Co-Task) which includes the way teachers share responsibilities with their students.

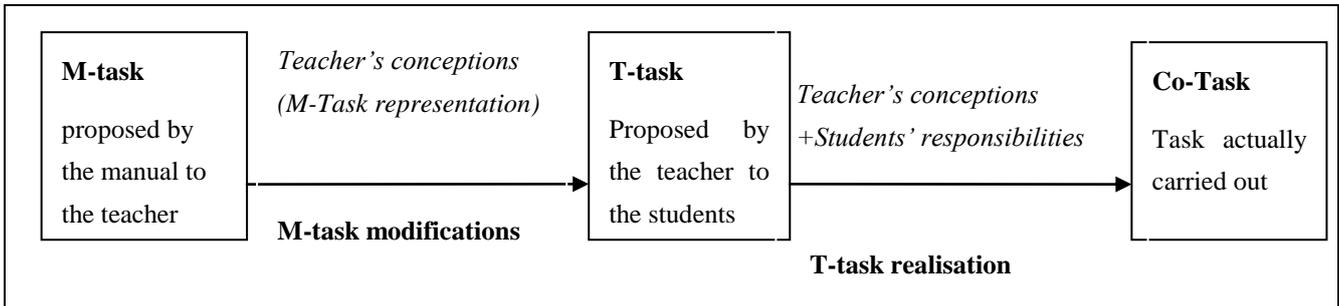

Table 2: Distance between M-task, T-task and Co-Task

The T-tasks are the tasks the teacher propose to his students for their individual or group work. To understand what those T-tasks were I analysed the teachers' work episodes happening before the students' work episode. I analysed how the teacher changes the problem text if he does, what kind of help he gave the children before their individual work, of what he reminds his students if he does remind something, etc. Then I did an "a priori" analysis of the T-tasks proposed to the students. Indeed, according to Leplat (Leplat, 1997) the Co-tasks actually carried out in the classroom have to be analysed according to the new tasks logic i.e. to the T-tasks logic. The "a priori" analysis of the T-tasks also allow us to measure the distance between the T-tasks and the M-tasks. The T-tasks proposed by the teacher to his students for their individual or group work may not match with the M-tasks. Those "new" tasks (T-tasks) will depend on the teachers' representation of the M-tasks which depends on their conceptions of mathematics, of teaching and of their students, etc. So, the

differences between the manual's tasks and the tasks proposed by the teacher to his students gave us some first elements to understand teachers' conceptions and the way they "read" the situation. By "reading" the situation I mean what the teachers think they have to do, what they think the students have to do and the knowledge they think is contained in the problem before carrying it out.

To measure the distance between Co-tasks and M-tasks I therefore analysed the realisation of the T-tasks according to the T-tasks logic but also to the M-tasks logic. To understand how the T-tasks were carried out I especially looked at the students responsibilities for the construction of knowledge. The responsibilities given to children were identified in relation to their individual or group work time, what they are asked for (about tasks they worked on, about questions they had to answer in collective work, about the way the teacher listened to what they say and adapt the work...) and the way they are asked (open or closed questions, often or not and which students are asked). I also looked at how the teacher helps the students and how he or she uses what they do or say.

THE PROBLEM

The *Euromaths*' problem I chose is about fractions in the measures framework. It is a transposition of a didactical engineering built by Perrin-Glorian and Douady (1986). This problem's transposition is the following.

To measure a segment length, Leïla used the u -segment as unit.

(The segment is drawn in a corner, just below a character who is often used in the manual says : To have $1/3$ of the unit, I bend in three like an accordion the unit strip.)

She transfers one time the unit u , then the half of u , and finally the third of u .

She wrote : $1 u + \frac{1}{2} u + \frac{1}{3} u$.

Question 1 : Reproduce the unit strip u . Using this strip find which segment Leïla has measured. (Five segments are drawn which measures are : $AB = 1 u + \frac{1}{2} u$; $CD = 1 u + \frac{2}{3} u$; $EF = 1 u + \frac{1}{2} u + \frac{1}{3} u$; $GH = 1 u + \frac{1}{2} u + \frac{1}{4} u$; $IJ = 2 u$.)

Question 2 : Find the measures of other segments' length, using the unit u .

Question 3 : Leïla says that the segment $[GH]$ measure $7/4$, is she right?

Table 1: Euromaths' tasks

The aim of first question is for the children to build a technique to measure segments. The way the question is asked might encourage them into the "complex writing" of measurements (a sum of an integer which here will be 1 and of one or several fractions which are less than one). The aim of second question is to practice this technique and to arrive at the complex writing measurement for the $[GH]$ segment. The real aim of the problem is in the third question. The children will have to point out that Leïla's segment measure matches to the measure they obtain in a complex

Working Group 17

writing form. They can check that the complex writing measure they obtain is equal to Leïla's measure, i.e. that $1 + \frac{1}{2} + \frac{1}{4} = \frac{7}{4}$ or $1 + \frac{3}{4} = \frac{7}{4}$. The aspects of knowledge contained in this problem are the meaning of a half, a third or a quarter according to the split of the unit but also the use of complex writing and the equality seen in the second and third questions (for example : $1 + \frac{1}{2} + \frac{1}{4} = \frac{7}{4}$).

The tasks of this problem are open. Students can find several techniques to answer the questions and can find several ways of writing the measures for the segments. The two first questions cannot be validated by the student themselves. The validation episode might be too complex if teachers don't want to give children the answer and if they want to keep the problem open for everyone. Concerning the last question it can be validated by the children themselves.

The different ways to carry out the two first questions depend especially on the way responsibility is shared for the individual work on the questions and on the collective summarizing work. The third question also depends on the sharing of responsibility but also on the framework used to answer the question. It can be the measure's framework, the numerical framework or both.

RESULTS

In order to understand the analyses results we present what are the T-tasks, Co-tasks, student's responsibilities, teachers' help and responsibilities in the following table.

Teachers	T-tasks	Student's responsibilities	Teachers' help	Teachers' responsibilities	Co-tasks
A	M-tasks (question 1, 2, 3)	All the students have responsibilities	Individual help Don't reduce the tasks	Tutor	M-tasks
B	M-tasks (question 1, 2, 3)	All the students have responsibilities	Individual help Don't reduce the tasks	Conductor	M-tasks
C	M-tasks (question 1, 2, 3)	Students with difficulties have responsibilities	Individual help Don't reduce the tasks	Tutor	Reduced M-tasks
D	Reduced M-tasks : 1. Find Leïla's segments already knowing the technique to measure 2. Measure others segments	None students has responsibilities	Collectives help Reduces the tasks	Knowledge's owner	T-task (question 1) M-tasks (question 2)
E	Radically different from the M-tasks : Measure all the segments	Very good students have responsibilities	Collectives help Reduces the tasks	Knowledge's owner	Reduced T-task

Table 4: Teachers' practices when using the Euromaths problem results

The first result according to the distance between the manual's tasks and the tasks carried out in the classroom is that teachers A, B and C share the author's conceptions. On the contrary, teachers D and E do not. They are the knowledge owners and the student's work in their classes seems to be reduced to reproductions of exercises the teacher showed at first. The second result is that the spectrum extent of ways teachers carry out the problem is very large. In each class the students work on different tasks and the knowledge pointed out by the teacher is also different.

Teachers proposing the manual's problem to their students

Three of the teachers (teachers A, B and C) propose tasks which match to the problem in the manual. It means that when they give time to the children to work, it is on the M-tasks. All the questions are proposed like they are written in the manual and the different tasks are not reduced. The meaning of reducing a task is to give students more elements to solve the tasks than are contained in the manual which will make the problem easier. Moreover, for those three teachers the knowledge they want to teach is the same as in the manual.

Teacher proposing a reduced problem to her students

One of the teachers (teacher D) reduced the problem according to the style of her practice. She gave children lots of elements which made the tasks easier, less problematic and no more related to the other tasks. She didn't radically change the problem but she changed the meaning of it. Children simply had to measure the segment and not to think about how to measure it. Moreover the teacher didn't propose the last question which is the real issue of this problem. The problem is reduced to an application exercise which the teacher has shown at first, i.e. measuring segments using a unit strip. Thus, the knowledge contained in the tasks proposed by the teacher is about knowing how to measure segments using a unit strip.

Teacher proposing a tasks radically different from the manual to her students

The last teacher (teacher E) radically changed the manual tasks. Firstly, like teacher D she reduced the problem giving the students the way to measure the segments. Secondly, teacher E changed the problem text. She didn't give students some of the information given in the manual (she didn't tell them to read the text and she didn't read it to them, and most of the students didn't think to read it). So, they missed Leïla's segment's measure and the way she measured it as well as the way to bend the unit in three equal parts. Then, the teacher changed the questions and asked the children to measure all the segments. This task is radically different from the manual's problem. Notably, children had to measure the segment [EF] (Leïla's segment which has not to be measure according to the manual but found in the complex writing form : $1 u + \frac{1}{2} u + \frac{1}{3} u$). It is a new didactical variable. They can find Leïla's measure or the measure $1 u + \frac{5}{6} u$. To validate the equality of these two measures might be difficult. Either students could check if the measure is right but

they will have to bend the strip in six parts which is quite difficult at their age, or they have to understand the equality $\frac{1}{2} + \frac{1}{3} = \frac{5}{6}$ in the numeric framework which may be more difficult. Moreover, the knowledge contained in the T-tasks according to the teacher is about a fraction more than one whose numerator is bigger than the denominator. This knowledge is quite different to the knowledge contained in the manual's tasks according to the "*a priori*" analysis.

First conclusion about the tasks proposed to the students in the different classes

The spectrum of tasks' proposed by the teachers to the students seems to be large. Three of the teachers propose the manual's tasks without changing it. They are the three teachers with scientific and/or mathematical background. The two other teachers who do not have this background propose a reduced or radically different problem. Their representations therefore seem to suggest conceptions different from the authors' conception.

Teacher carrying out the tasks they wanted to carry out

Teachers A and B, in different ways (being a tutor or a conductor) give students the responsibility for the knowledge construction. Children have a lot of time for individual or group work and they can validate their results themselves. The tasks carried out by the teachers A and B match to the problem they propose and to the authors' conception. On the contrary teacher D doesn't give any responsibility to her students. The task she proposed to the students is reduced. Children don't have much individual work time and don't speak a lot, contrary to students in teachers A and B's classes. Teacher D therefore controls the realisation in the classroom and carried out the tasks she proposed to the children (a reduction of the manual's tasks).

Teacher carrying out different tasks from what they propose at first

Teacher C gave responsibilities to children who have big difficulties. The rhythm in the class is then very slow and most of the children are bored and off-task. Because of this very slow rhythm, the teacher has to go very fast on important phases. Thus, this teacher who didn't change the manual tasks at first, reduces it when she carried it out because of the way she shares responsibilities with the students. Teacher E appeared to be trying to match with the authors' conceptions and gave responsibilities to students. However, she only gave responsibility to the very good students. The rhythm was then really fast and most of the children were lost. Moreover, according to what they do or say she changed her objectives and taught for example how to sum $\frac{1}{2} + \frac{1}{3}$ which does not need to be known by children aged 9 or 10 years.

First conclusion about the tasks carried out in the different classes

The responsibilities sharing is really different according to the teachers' practices. It has an influence on the tasks they carry out. The teachers who share the responsibilities with all the students carry out the tasks they have proposed, while the teachers who share the responsibilities with one only kind of students do not.

Moreover, when they try to fit with the author's conception (although their own conceptions are far from it) the teachers' practices might be problematic.

CONSEQUENCES OF TEACHERS PROBLEM'S APPROPRIATION

Teachers' A and B carried out the manual's tasks without any problem. But, it seems that teachers C, D and E didn't carry out these tasks which might be problematic for the student's potential learning. We will see that the association of their practices and of this problem can lose the students or even make the differences between good students and students who have difficulties larger. But, I will also see that the use of the problem can change their practices.

Practices and manual written by didacticians problematic association

Teacher C, because of the responsibilities she gives to students with very high difficulties, made the rhythm really slow and lost other students attention. That might be a problem for students' potential learning.

Teacher E proposed the students really different tasks from the manual's tasks which created difficulties, e.g. the question about $1u + \frac{5}{6}u$ and $1 + \frac{1}{2}u + \frac{1}{3}u$ equality. This question introduced a new variable and to answer it the teacher introduced knowledge which children aged 9 or 10 would not be expected to have. This is really problematic. Moreover, in this class the students were not all working on the same tasks as they were not working with the same responsibilities. Firstly, some students work on the manual's problem while the others work on the radically different teacher's problem. Unlike the other students, the good students had all the necessary conditions, like Leïla's segment measure, to solve the problem. Secondly, good students had enough time to answer the questions the teacher asked because they worked very quickly while other students didn't have time to think of it. So, good students participate and can debate about their results while the others are just listening. I have also to point out that it's according to their answers that the teacher changes her objectives losing the other students' attention. Thus, in this class, because of the teacher's practices when using this problem, the difference between the students levels increase which is really problematic.

Manual problems traces on teachers' practices

On the contrary, because of the responsibilities given to the children by the manual's tasks, which is not radically changed by the teacher, teacher D's practices seem to change. She gives more responsibilities to her students which might improve their potential learning. Thus, it seems that the manual can change the teachers' practices in the direction of the authors' conceptions. Indeed, we saw that for the teacher D, the knowledge contained in the problem was about measuring segments using fractions (she didn't propose the third question but only the first two which are about measuring segments). I also saw that she didn't share responsibilities with her students. But, when she proposes the second question, children proposed several results for each segment measure. Thus, the teacher has to give more responsibilities

to her students to explain their results and the knowledge about equality of a complex writing form and a factionary form was explored even though the teacher didn't think of it before. When she carried out the reduced tasks proposed to the students the teacher changed her practices and came back to the manual's tasks and to the knowledge contained in them. The problem seems to be constructed in a way which can change the way this teacher carried out the tasks and especially the way she shared responsibilities with students. This new responsibilities sharing may improve student's potential learning and because of the definition of practices which include the potential learning, I may say that the use of this problem might improve teachers' practices.

POSSIBLES TEACHERS' PRACTICES / MANUAL'S PROBLEM INCOMPATIBILITY FACTORS

Even if all the teachers say they share the author's conceptions (that's why they choose this manual). Teachers A, B and C are the only three who seem to really share their conceptions and teachers A and B are the only two who seem to manage carrying out the manual's problem. However, I saw that teacher D changed her practices according to the authors' conceptions. According to the practice's analyses, I point out several things which might be the reasons for an incompatibility of the teachers' practices and the manual tasks.

Firstly, the knowledge contained in the problem might not be understood by the teacher at first sight. Without an "*a priori*" analyses or without reading the teacher's book (most of the teacher don't read it), teachers might not "see" what knowledge is pointed out by the problem. Thus, I saw that two of the five teachers didn't point out this knowledge and made the students work on something else. Unlike the other three, these two teachers didn't have a scientific or didactical background. It could mean that these backgrounds are necessary to understand the problems' objectives.

Secondly, it seems to be necessary to share responsibilities with all the students in order to present the problem in the way intended by the manual. This kind of responsibilities sharing needs the teachers to really pay attention during the realisation of the manual tasks and needs them to be able to adapt themselves really quickly. Moreover, children cannot validate the results themselves for questions one and two. In order to leave the problem open, teachers have to find ways which are not obvious. It means another occasion when they have to really pay attention and to adapt themselves really quickly if they didn't think about it earlier.

The problem seems so to be difficult to carry out, needing teachers to have a mathematical or didactical background, a real attention and capacity to adapt themselves and needs them to give the students some responsibilities. Moreover, the ways teachers A and B carry out the manual's tasks (being a tutor or a conductor) according to the authors' conceptions are not economic which mean that they could be difficult to transpose to other teachers.

CONCLUSION AND PERSPECTIVES

The spectrum of teachers' practices using the same 'written by didacticians' problem seems to be large. Some of the teachers who share the authors' conceptions make good use of the problem. For such teachers, the manual may be helpful especially to gain time. I also saw that for teachers who didn't change the problem radically and who carried it out with their own conception even if they are far from the authors' conceptions, the use of the problem written by didacticians can improve their practices. It is a result which has to be developed analyzing more than one problem being carried out. But, the use of the manual can also be problematic if the teacher's conceptions are far from the author's conception and if the teacher tries anyway to carry the problem out according to the authors' conceptions without understanding them. Teachers' practices can then lose their consistency which is quite a problem. I therefore have to know if for such teachers the problematic use of the problem can be reduced and how this might be done.

The analysis of only one use of problem is not enough to understand teachers' practices. I will have to analyse several problems with different characteristics to understand what may make the use of the manual by some teachers problematic and what exactly may improve teachers' practices when using such manuals.

A STUDY OF A PROBLEM SOLVING ORIENTED LESSON STRUCTURE IN MATHEMATICS IN JAPAN

Yukiko Asami-Johansson

University of Gävle, Sweden

This paper presents and analyses “Mondaikaiketsu no jugyou” which translates to “the problem solving oriented – approach”. It is a set of didactic techniques with the aim of motivating the students’ positive attitude toward engaging in mathematical activities and fostering mathematical thinking. As an analytical tool, The Anthropological Theory of Didactics (ATD) will be applied.

Keywords: Problem solving, Japanese mathematics class, ATD.

INTRODUCTION

Teaching methods were developed differently in Japan compared to other industrialized countries. Hiebert, Stigler and Manaster (1999) argue that Japanese teachers emphasize mathematical thinking rather than mathematical skills. This goal is reached by having the students discuss with the teacher and peers on the settlement options of problems presented to the whole class. I will call this type of didactic techniques, where students work on whole-class problem solving, for *problem oriented lesson structure* (POLS).

A basic problem in mathematics education, and in the training of teachers, is to find ways to organise the classroom work so as to make the students active learners of mathematics, without losing the focus on the mathematical content. Japanese teaching methods, like the ones described, have attracted attention in Sweden lately (Dagens Nyheter, 2009), and it has been discussed as a possible model to develop in Swedish school system.

Kazuhiko Souma is one of the teacher educators/researchers who has proposed, introduced and elaborated on POLS. He calls his method “*The problem solving oriented*” approach (shortened to PSO; the author’s translation; “*Mondaikaiketsu no jugyou*”, in Japanese). Like POLS in general, it aims to enhance the students’ attitude towards engaging in mathematical activity in the classroom. In Japan, there is a tradition of publishing practical books for mathematics teachers as the target group. This literature aim to present ideas and concrete lesson plans, based on well-constructed mathematical problems, according to the proposed teaching methods (Souma, 1995; Kunimune & Koseki, 1999; Tsubota, 2007). Souma has written and edited a number of such books and his method is actively and widely used by teachers in service. It has received little attention from the academic community, perhaps because of its practical attribute and the lack of clear theoretical base. The lack of theoretical overhead is perhaps part of the appeal, but becomes a problem when one is to describe and assess such approaches.

I conjecture that PSO (and POLS in general) could make a beneficial contribution for pre-service teacher education due to its distinct didactical structure, but the lack of a theoretical base is a hinder. The aim of my paper is therefore to present and analyse PSO in relation to other Japanese POLS approaches. To illustrate, I will analyse an episode of a practical application of PSO in a Japanese classroom.

As an analytical tool, I will use the anthropological theory of didactics (ATD) developed by Y. Chevallard (2006), with the assumption that ATD has the right level of abstraction for the purposes of didactic planning. The focus of this paper is on how the proposed didactic techniques and lesson structure of PSO relates to the description in ATD of the didactic process. In a follow-up paper I intend to shift focus to the mathematical content and in particular to how Souma's ideas regarding the construction of problems can be analysed in ATD.

BACKGROUND TO The PSo APPROACH

The Anthropological Theory of Didactics

The anthropological theory of didactics (ATD) approaches learning and knowledge as institutional issues. Mathematics learning can be modelled as the construction, within a context of social institutions of interlinked *praxeologies* of mathematical activity, which we also refer to as mathematical organisations (MOs) (Chevallard, 1999 in Barbé, et al., 2005). A praxeology is described by its *tasks* and *techniques* (*praxis*), together with its *technology* and *theory* (*logos*). Technology constitutes the tools for discourse on and justification of the techniques and the theory provides further justification of the technology and connections to other MOs. The process, under which a mathematical praxeology is constructed within the educational institution, is called the *didactic process* (ibid.). Chevallard proposes to describe it as being organised in six “moments” that can be thought of as different modes of activity in the study of mathematics. The moments are: (FE) the moment of *first encounter* (or re-encounter) of tasks associated to the praxeology, (EX) the *exploratory* moment of finding and elaboration of techniques suitable to the tasks, (T) the *technical-work* moment of using and improving techniques, (TT) the *technological–theoretical* moment in which possible techniques are assessed and technological discourse is taking place, (I) the *institutionalisation* moment where one is trying to identify and discern the elaborated MO and (EV) the *evaluation* moment which aims to examine the value of the MO. The description of mathematical knowledge (the MO) and learning/teaching of this (the didactic process) is referred to as the *epistemological* component of ATD.

To organise the work of achieving an appropriate MO, the educator faces the task of designing and controlling the didactic process. To this end, one develops a didactical praxeology, or a *didactical organisation* (DO), consisting of didactic techniques together with a technology/theory to describe and justify those techniques.

I think it is fair to say that ATD carries both a *normative* and *descriptive* component. As an analytical framework, it holds that any didactic processes can be *described* as the construction, via the six moments, of a praxeology. Similarly, the didactic organisation can be described in terms of its praxis and logos block, independently of whether the studied DO's have ATD incorporated as an epistemological model of the learning object and the didactic process. But, when used as a design tool, ATD also carries some normative implications, so that the resulting MOs and DOs can be compared with respect to how suitable, structured, and useful (or *legitimate*) they are. A typical implication is that the local MOs should integrate with and reinforce larger superstructures in the form of global praxeologies and that all moments of the didactic process needs to be visited and such local objectives are compatible with the aims of Souma's writings. In this paper, I will attempt to use ATD to describe the DO proposed by Souma and also use the epistemological component of ATD to motivate some of Souma's didactic techniques. Thus, in a way, propose an *extension* of the DO proposed by Souma with a technological-theoretical block from ATD.

The PSO lesson template

PSO has the form of a proposed lesson structure and Souma states that it is instrumental that the PSO approach is applied with the same basic form regularly. The motivation is that familiarity with the situation makes the students feel secure in participating in the discourse and engaging in the didactic process.

Souma, like most Japanese writers of this genre, often gives general didactic advices: to be generous with positive feedback, taking care of shy students, etc., in order to handle the long-term didactic goals, such as “fostering the students to active learners of mathematics”. The explicit motivations are often taken from a technological-theoretical block, which could be referred to as Japanese “didactical/pedagogical common sense”, although, as stated below, Souma explicitly refers to the cognitive theories of Dewey and Polya as a motivation. The epistemological description is usually a concrete mathematical example and listing presupposed knowledge and goals for the lessons. This format is natural for this type of inspirational literature, but has its limitations when one wants to discuss the generalities. A central recurring term is that of “mathematical activity”, which measures the degree of interest, independence and motivation with which students are carrying out the mathematical work.

In order to make a fair description of Souma's approach, it does not seem reasonable to eliminate all such psychological aspects. Therefore, in this description below, I will make qualifications when talking about the didactic process: like the degree of *participation* in the didactic process and “*invigorate* the didactic process” to mean, “increasing the *mathematical activity*” of the didactic process.

According to Souma's example from his book (1995), a typical POLS lesson starts with a teacher giving a problem, for instance, “Show that the difference of the

squares of two integers that follow each other is equal to the sum of the two numbers ($5^2 - 4^2 = 9 = 5 + 4$, $24^2 - 23^2 = 24 + 23$ and so on).” The students try to solve the task and some students write their solutions on the blackboard and explain their solution orally. Souma wonders (pp. 103-104) if the students in this situation will feel a “necessity” to reflect upon the task. Furthermore, some students might not get any ideas on how to solve the problem and will therefore become alienated from the discourse. As an alternative, he proposes the following variation of the problem formulation: The teacher writes down expressions on the blackboard without any comments;

$$5^2 - 4^2 = 9, \quad 24^2 - 23^2 = 47, \quad (-9)^2 - (-10)^2 = -19$$

and asks the students what they can observe. All students are supposed to be able find such observations, perhaps working in groups. Students may answer, “It becomes odd numbers”, “The differences equal the sum of the integers”, “The differences equals the first integer times two minus one”, “The last integer times two plus one”. After the response of the students, the teacher then controls that all proposals are correct on the blackboard and says; “Now we try to prove each of the statements”. Ideally, the formulated problems have many possible roads to solutions: Several students may use the formula for expanding the square of a sum; and several others, using x to the first integer and y for the second integer, the rule of the conjugate.

Souma proposes to use a didactic technique, which I refer to as *guessing*. One should, regularly, let all students guess an answer or formulate hypotheses about the phenomena. It is implied that the “guess” is something that all students can participate in. In the example the students are not asked to simply guess an answer, but they are invited to, discover patterns by themselves, make hypotheses about the phenomena and by implication set their own tasks. By committing to make a guess or a hypothesis, especially in the social context of the class, the student will have a stronger motivation to study the task and follow it up.

We can find explicit theoretical motivation of the DO in Souma’s description (1997) where he declares that he is inspired by John Dewey’s theory of reflective thinking. Dewey (1933) presents five cognitive phases of problem solving. 1. Recognize the problem. 2. Define the problem. 3. Generate hypotheses about the phenomena. 4. Use reasoning if the hypotheses are viable to solve the problem. 5. Test the most credible hypotheses. Dewey’s theory has a general scope and is applicable to any problem context. It is also concerned with the cognitive dimensions, rather than the didactic process as such. Souma states that educators in mathematics may have a tendency to hurry up to address the later phase to “use reasoning”. In this way, the development of reflective thinking and motivation may be impeded. Souma thus feels that it is necessary to pay attention especially to the first three phases. He expresses that (1997), from Dewey’s theory, we may infer that it is important that we should “(a) have an aim for why we solve the task, (b) feel a necessity to solve the task and (c)

have made hypotheses before starting the reasoning process.” (p. 34) Souma also refers to Polya’s (1957) cognitive theories on problem solving and, in particular, Polya’s insistence on the importance of guessing. Polya states that our hypothesis may of course be wrong, but the process of examining the guess should lead to improved hypotheses and a deeper understanding.

The focus on motivation on the first encounter and the exploration, together with the insistence on a well defined and controlled mathematical content, is perhaps the point that, most distinctively, sets PSO apart from other proposed DO’s in the POLS tradition. Souma states that the teacher much take care to plan how the problem is presented and reflect on how students will to act. Souma names (1987) the type of tasks a teacher should aim at, as “*open-closed*” tasks that stimulate conjecture and application of guessing. In ATD terms one can say the task should be “closed” so as to give a *controlled* vector from the (FE), the moment of first encounter, to (EX) and (T), and also a (somewhat) predictable outcome during the following discourse, which usually would concern the establishing of the technological-theoretical environment (TT). The task should also be “open”, by giving the student a chance to make individual choices during the exploration (EX), and later give ample material for discussion, so as to invigorate the didactic process.

Souma means that, starting from standard tasks in the ordinary textbooks of mathematics, the teacher can modify parts of the tasks or change the way of stating them as in the example we saw. If the tasks presented during a sequence of lessons, are carefully constructed, it lead to conjectures, new problems and methods that, in ATD terms, productively connects the local MO’s covered with more global ones and inspire to technological and theoretical discourses on higher-level MOs. The insistence on open-endedness of the task is common with the “open approach method” (Nohda, 1991), which is another proposed variant of POLS. The open approach method is used and analysed by Japanese educators (Hino, 2007). Open-ended problems often take the form of formulating a mathematical model for some phenomenon that lead to multitude of problem formulations, techniques and solutions. The intent is to let students develop and express different approaches and let them reflect on their own ideas by seeking to grasp those of their peers (Miyakawa & Winsløw, 2009). Souma (Personal Communication, 2010) judges the open-approach method as something that cannot be used in everyday school mathematics. POLS lessons applying too ambitious open-ended problems might be isolated from ordinary lessons that, for instance, aim to train students’ basic mathematical skills, but Souma (1987) acknowledge this type of projects at the end of a course. Nohda also notifies that “We do the teaching with the open-approach once a month as a rule” (Nohda, 1991, p. 34). Bosch et al. (2007) have discussed the danger with open-ended activities, which are introduced at school without any connection to a specific content or discipline. They state that this type of didactic

technology suffers the risk of causing the construction of very punctual mathematical organisations, since this is what students are trained to study.

If we return to the lesson template and the example, the teacher should let students who have different types of solutions present their problem in class. The teacher then leads the class to discuss the reason behind each method and have all students determine which of the techniques they have used and why. This is the didactic technique of *whole class discussion* of solutions, which PSO has in common with POLS in general. The discussion of alternative solutions gives an opportunity to introduce, establish and reinforce technological and theoretical components of the MO studied, like in this case, the expansion of the square, the rule of the conjugate and the different use of variables. The primary motivation is to steer the didactic process into (TT), where new methods and techniques are approved. Solutions and motivations given by the students are sometimes unexpected and may make more sense for other students. The class discussion also serves the purpose of increasing the participation in the didactic process.

After this, Souma recommends that the students have an opportunity to reflect upon the mathematical theory. The teacher can point out what they have learned by having a student read out from the textbooks explanations of the theory relevant for the lessons. During this *theoretical reflection*, the teacher can steer the didactic process towards, say, (I) institutionalisation or (EV) evaluation. Souma states firmly (1997) that studies in mathematics should be organised and based on a well-written textbook that gives a clear explanation of the mathematical definitions and theories. The classroom discourse is only one form of the study process, the study of mathematics will always entail individual studies and individual problem solving inside and outside school. Moreover, the textbook allows the students to recognize and get familiar with the theory, which the textbooks usually explain in more full detail. In other words, the *textbook technology* is proposed, for the purpose of further covering of all six moments.

a mathematical problem oriented class in Japan

The following episode illustrates a mathematical problem oriented lesson where the teacher practices the PSO approach. This study take place during a lesson study in grade eight at a lower secondary school affiliated to the School of Education in Asahikawa, Japan, 2009. The teacher is a former Masters student of Souma. The number of students in this class is 40. The lesson is about how to solve a system of linear equations and is the third lesson on this topic. The students have already studied the addition method by solving linear equations obtained from word problems with an everyday life character. The lesson plan was written and distributed by the teacher to us observers beforehand. Posing the mathematical tasks and problems presented during the lesson is common with the POLS based lesson plans, but distinct to PSO is, that it is always written “students possible conjectures”

and “students possible solutions”, so that teachers always prepare different didactic responses depending on which act students take (Souma, personal communication, 2010).

In the guidebook of Japanese national curriculum standards “The curriculum guidelines” (2008) for mathematics for Japanese secondary school, a system of linear equations with two variables is described (p. 90) as follows: “Solving a linear equation with two unknowns is to make clear that this can be done by using a method that eliminates one of the two variables and then solve equations with one unknown, which is a method students already know”. Thus, the didactic transposition of the praxeology “System of linear equations” to the knowledge to be taught in class (Chevallard, 1985 in Bosch & Gascón, 2006), focuses here on the technique of elimination; reducing the pair of two variables equations to one equation with one unknown. Techniques and technological terms present are substitution, row operations, isolation, coefficients, variables, etc. which are collected from the theoretical base of “Elementary algebra”.

The lesson

As the first step, the teacher shows the problem by verbally reading out a system of linear equations; $\{7x + 3y = 30, x - 5y = 26\}$ and the students are asked to copy this in writing. He asks: “There are two boys, Taro and Jiro, who both solved this problem. Taro said, “I eliminate x ”. Jiro said, “I eliminate x as well”. Their answers were the same, but their methods of the solutions were different. Today’s task is to consider how they solved the problem differently”. The teacher does not show the techniques; the students must consider the possible techniques, which obviously is not only one.

The teacher gives them a few minutes (“individual thinking activity” –according to the lesson plan) and encourages them to find as many solutions as possible. He states in lesson plan that this is especially meant for the gifted students who find solutions quickly. The teacher picks up two students who have obtained different techniques and lets those two students write their solutions on the blackboard. The teacher asks the class how many of them used the technique one of the two students has used. The students raise the hands and it is 37 of them. The teacher asks what is the name of this technique and gets the answer “the addition method” which the class already learned at the previous lessons. The teacher asks the class how this technique works. A student answers “Change the coefficient to the same and erase one of the variable”. The student who has written the solution on the black board explain her reasoning how she has “changed the coefficient”. She says, “ x ’s coefficient must be changed, so I multiplied it by 7”. The teacher responds, –“OK, you multiplied by 7 and got the same coefficient for all the x :s”. He changes his voice tone a little and then asks “And then, (looks around the class) *what can you do with the x ?*” Several students respond, “We can *eliminate* the x ”.

They later discuss the other solution technique called the “substitution method”, He inquires again how many of the students came up with an example of that technique (17; –many of them used both methods), and asks for the name of the technique, and then lets the students explain how the technique works. (Some students might already have learned about the technique at “Juku” – a private school offering special classes held on weekends and after regular school hours.) The teacher later asks if there are any students who found variants of the addition method, with an intention to let the students be aware to variation of techniques of the addition method. One student presents his solution by multiplying with $-1/7$ to $7x + 3y = 30$, instead of multiplying by -7 to $x - 5y = 26$. This presentation awakes a big discussion in the class if it is not a bit too complicated. The teacher concludes the discussion by encouraging the student with: “But it worked? Didn’t it?”

After the class has had this look at the two different techniques, the teacher lets one student read out loud a passage from the chapter in the textbook, explaining the substitution method. The students work out three to five textbook problems using the substitution method from the book. Afterwards, the teacher asks the class “In which types of problem do you use the addition method and in which types do you use the substitution method?” He lets the students write down their reasoning. The students are then encouraged to *create* several examples of problems they think fit each technique and different proposals are then later discussed.

ATD analysis of the lesson

The purpose of this lesson is to introduce the substitution method and compare it with it to the addition method and to show that both methods reduce the system to the one-variable one-equation case. In his lesson plan, the teacher writes that “The aim of the task” is to “make the students *find out* that there is an another method than addition method through mentioning that two boys use different methods”. He asks how to reconstruct the solution of two boys, instead of asking them “Solve this system of linear equations using the substitution method”. This is an instance of the Souma’s guessing technique, since all students are assumed to be able to use the addition method and students are requested to make proposals rather than final answers. This is also an example of an “open–closed” task; with alternative solutions, but a limited number of possible outcomes. As intended, the task steer the didactic process from (FE) to (EX) and (TT), since it is about finding a new technique, where (TT) is mainly covered during the whole class discussion. The task will also entail (T), technical work, since the students should solve the system with the chosen method. The teacher stimulates *participation* by having all students report which method they have followed. In the discourse, the teacher takes care to make the students use the correct technological terms, like “addition method”, “substitution method”, and the use of “eliminate” rather than “erase”. Much of the same holds for the final task when they are asked to construct problems that are suitable for each method. As proposed by Souma, reflection on theory is carried out

when one student reads out loud from the textbook. This steers the didactic process to the moment of (I), so that the class now verifies what they have done during the lesson. More (T) is covered when the students work on problems in the textbook.

DISCUSSION AND CONCLUSION

One can summarise Souma's approach as one firmly grounded in the POLS tradition. PSO, in particular, focuses on how to start up the didactic process using the guessing technique by adding the elements of conjecture, construction and choice from the start, stimulate students' curiosity to tackle with the mathematical tasks. Souma argues for the didactic techniques of presenting problems followed by whole-class discussion, theoretical reflection and the use of textbooks. The main difference with POLS in general is *guessing* and that Souma stress the need for *open-closedness* when it comes to task construction. Souma holds that a DO based on open-ended activities needs to be established as a long-term *didactical contract* (Brousseau, 1998) and that it should be used as the regular lesson structure.

In this paper I *describe* PSO using the analytical framework of ATD and also use ATD motivate the didactical techniques: By using the *guessing* technique, the teacher allows *all* the students in the class to *participate*. *Open-closed* tasks, *textbook* and *theoretical reflection* are techniques with the dual purpose of both *invigorating* and *control* the didactic process. Some qualitative predicates, like "participation", "activity" and "invigorate", regarding the didactic process were introduced to cover the psychological/cognitive motivations, which are implicit and explicit in PSO. ATD is of course a theory with a wide scope and is also a "radical" theory that problematises the content of mathematical curricula, and, in this respect, Souma's insistence on following a textbook and the focus on closedness is perhaps a contradictory "conservative" trait. But, on the whole, I think that most normative implications of ATD are in line with PSO and with POLS in general. Fundamentally, by attacking problems and following up by whole-class discussion, one links praxis with logos.

LESSON STUDY AS A PROCESS FOR PROFESSIONAL DEVELOPMENT: WORKING WITH TEACHERS TO EFFECT SIGNIFICANT AND SUSTAINED CHANGES IN PRACTICE

Jenni Back and Marie Joubert

University of Plymouth and Bristol University

This paper draws on data from lesson study initiatives within the Researching Effective Continuing Professional Development (CPD) on Mathematics Education (RECME) (Joubert, Back, DeGeest, Hirst, & Sutherland, 2009) and subsequent work with lesson study groups through the Centre for Innovation in Mathematics Teaching at the University of Plymouth. We explore how teachers engage with the process of lesson study and to identify features of involvement which lead to significant changes in practice that may be sustained over the longer term.

Keywords: lesson study, continuing professional development, teacher change, knowledge for teaching

INTRODUCTION

This paper is concerned with a model of professional development known as ‘lesson study’. It draws on data from lesson study initiatives within the Researching Effective Continuing Professional Development (CPD) on Mathematics Education (RECME) and subsequent work with lesson study groups through the Centre for Innovation in Mathematics Teaching (CIMT) at the University of Plymouth.

Lesson study, as with other models of professional development, aims to develop teachers’ professional knowledge, and hence to improve (change) teachers’ classroom practice. Improved student learning is sometimes used as an indicator of improved classroom practice. The paper uses these indicators to explore the professional development of teachers involved in lesson study initiatives. The research questions considered are: What evidence is there of professional development of teachers of mathematics who engaged in lesson study? How do teachers engage with the process of lesson study? What features of this engagement may contribute to significant and sustainable changes in their professional knowledge as it is revealed in practice?

BACKGROUND

Professional development for teachers of mathematics typically aims to develop aspects of teachers’ mathematical knowledge for teaching, which is generally agreed to include: knowledge about mathematics, knowledge about ways of teaching mathematics and knowledge about the ways in which learners engage with and make sense of mathematics (Joubert & Sutherland, 2008).

Working Group 17

Lesson study, which pays attention to all these aspects of mathematical knowledge is a form of CPD based on Japanese models of professional development to a greater or lesser extent (Lewis, 1995) (Fernandez & Yoshida, 2004) (Burghes & Robinson, 2010), which particularly emphasises student learning. The process of lesson study involves a group of teachers in collaboratively planning a lesson called the ‘study lesson’ or ‘research lesson’ and one of the teachers teaches this lesson. It is videoed or observed by the whole team, with a particular emphasis on the student responses to the lesson, after which the group meet to discuss the video or observation. The lesson is then developed on the basis of the students’ responses to it and re-taught to a different group of students. This may then be repeated or a different lesson may be developed. Generally speaking, lesson study groups involve up to six teachers with a minimum of three, but this may vary considerably.

This constitutes the basic pattern of the approach but there are many variations on it both in Japan and in other contexts, which engage with the principles underpinning lesson study to a greater or lesser extent. Engaging with these principles is not straightforward or easy, and learning and change tends to be slow. As James Stigler says in his foreword to Fernandez and Yoshida’s book:

A superficial implementation of lesson study is not likely to have any positive impact on the learning of teachers and students and, given our impatient political climate, a lack of immediate results may result in lesson study being declared a failure before it is even understood in any deep sense.

METHODOLOGY AND METHODS

This study draws on our research into three lesson study initiatives from the RECME project (Joubert, et al., 2009) and two from CIMT. We were interested in the influence of the lesson study initiative on the teachers and their commitment to it. This suggested the need for rich and deep data, and hence a qualitative methodology using interviews and observations. In all five cases we observed CPD meetings and observed lessons taught by the teachers involved. We also interviewed some of the teachers involved. The data were collected in the form of field notes, video and audio recordings. To address the question of the influence of the lesson study initiative on the teachers, data was analysed within a framework of teacher learning in mathematical knowledge for teaching, changes in practice and improved student learning. For the question of teachers’ commitment to the ideas of lesson study, data have been analysed using an approach based on grounded theory (Sinclair & Coulthard, 1975). In many cases the data have been fed back to the participating teachers and their comments used to co-construct accounts of the professional development and its consequences for them professionally. Evidence for professional change is accepted as reported by the teachers involved although some triangulation was possible through observations of the study lessons and other lessons taught by the teachers involved.

FINDINGS

This section reports first on the influence of the lesson study initiative on teachers' professional development (learning, changes in practice and improved student learning). It goes on to report on teachers' commitment to the principles of lesson study.

Teacher learning

Knowledge of mathematics: In lesson study, focusing on the details of one lesson and the approach to teaching a specific topic tends to lead to the group addressing mathematical ideas in great detail. In fact the topic for the lesson is often chosen because it is problematic to teach or the teachers find it hard to teach. One example from our studies involved a group of primary school teachers. One of the teachers said:

T 1: I think also having the time to research particularly something in maths was good because time and time again I'm finding I need to ask whether my subject knowledge is really that hot on that area of maths. So having read all the research and bringing it all together you get that clearer vision, don't you?

She went on to say that being a participant in the lesson study group:

T 1: raises your awareness about the importance of mathematical subject knowledge and relevant terminology and how much you should be using and what you should be using and why – it means that instead of making some glib comment about something that you might think is mathematically correct you would take the time to make sure

The leader of this group expressed the view that the lesson study helped to develop a different approach to subject knowledge from that which he had held previously:

T 2: it's sort of your mentality and your attitude to subject knowledge. It's not that you need to fill your head with vast amounts of knowledge for every subject, it's that your attitude to it is slightly different, as you work with the children in it. It's thinking well maybe we need to look into that a bit more and not seeing it as a bank of stuff that you have to get into children's heads. I think that's a huge shift.

From these comments it seems that the development of teachers' subject knowledge occurs through the consideration of the mathematics that they intend to teach. We observed this group of teachers talking about their developing understanding of the concepts involved in fractions as well as the different processes which they hoped to tackle with their students. They talked about the distinction between continuous and discrete quantities and offered examples of their students' in a task involving finding fractions of quantities. It seems that this understanding was new to them and was gleaned from their reading of professional and research literature such as (Halletta, Nunes, & Bryant, 2010; Thompson, 2005; Williams & Shuard, 1970). The detailed attention paid to the learning opportunities to be offered to the students seemed to force these teachers to pay close attention to the ideas involved and we suggest that

this led to the development of their subject knowledge in a way that was strongly practical and related to their pedagogy.

Knowledge of ways of teaching mathematics: As teachers consider the topic of the lesson that is their focus, they consider different approaches to teaching the topic and resources that they might use to support their teaching. In one secondary school lesson study, previous approaches to teaching had been dominated by textbooks. For the study lesson they developed resources based on approaches they had discovered through researching their topic of factorising quadratic expressions. These approaches were based on principles of ‘active learning’ originating from a professional development course developed for college tutors (Swan, 2005) which is widely available to schools in England. The task that they chose to adapt for their lesson involved sorting and matching different quadratic expressions with their factors.

One primary school group focused on finding fractions of quantities and they intended to give the children different experiences of finding fractions of quantities that were both discrete and continuous. They had long discussions about how they should do this and were concerned that the tasks should be creative and realistic. They wanted to offer the children open learning settings and they discussed the nature of the learning opportunities involved in the study lesson in detail:

T 2: I think the issue of open versus closed is quite interesting as well because actually that was quite a closed activity. There was an outcome, they had to do the picnic. It was more or less set up for them. It was quite actually, quite closed. That issue of deciding you know how closed or open activities should be and deciding what kind of an activity it is because I think sometimes as teachers we think they should be exploring but if we are clear about what kind of activity it is then it shouldn't be a problem

Knowledge of ways in which students make sense of mathematics: The detailed focus on the specifics of the teaching of one topic tends to lead the teachers into a lot of research into the topic and associated misconceptions and problems with teaching it. In one primary group, the articles found by their leader were used by them to inform the decisions they made about the content of the lesson. This led them to focus on the need to make sure the vocabulary they and the children were using was correct:

T 3: I think what we were saying earlier about using maths vocabulary and making sure that children are at ease with that and they use it confidently. I think I would put more of an emphasis on that from having had been involved in this process I've seen how important that is.

Another teacher in the group was struck by the ways in which the lesson they developed was applied to a practical problem and made use of a range of different units of measure:

Working Group 17

T 1: For me making sure that we had a range of ... um, that we looked at grams, that we looked at millilitres and we looked at centimetres and so we were trying to draw lots of areas of maths together. ...

T 2: It sort of fits in with the research that showed that they need lots of different representations and practical experiences of concepts and the language has to come out of the experiences rather than just being told.

The focus on considering how students make sense of mathematics is captured in the following comment from one of the teachers:

T 2: There's a level when I'm reading about maths, there's a level at which I just don't understand it and there is a level where I think is it just me that I can't understand it because I should be able to understand it only I can't. Now children are getting to that level at almost a very basic level with even counting – they're the same level as me when I read a book that has complicated formulae umm so it's sort of empathising with anybody who doesn't know anything at whatever level – children are in the same position as us trying to teach fractions.

This shows the teacher making connections with his own understandings of mathematics and the things he struggles with and seeing how his feelings of being out of his depth might relate to those of the children he is teaching. This empathy and understanding illustrates how the lesson study process has deepened his understanding of how his students might make sense of mathematics.

A teacher from one secondary group found that the process of acting as the camera man and making the video of the study lesson enabled him to focus on the ways in which the students were making sense of the mathematics. He felt this was subtly different from other observations that he had done as the leader of the mathematics department in this school. We got a sense that he had an understanding of the potential of the students to engage in mathematical activity, as evidenced, for example, by the following comment:

T 4: I think what the lesson study work has made me realise is that it is quite deep and impacting on a very subtle basis. Obviously it is interesting filming a lesson that you know you can be taking. I think with the emphasis of the lesson study being on the girls and filming the girls - it felt very different from being the teacher going round

Changes in classroom practice

Many teachers claimed that their general practice has been transformed by their involvement in the practice of lesson study. As one of the primary teachers said of the impact of lesson study on her teaching:

T 3: I think it definitely makes you look at other aspects of maths not just fractions and it has made me think every time I've planned lessons since like 'how could I do this differently this time?' And I look into different ways of exploring a lesson that I've done before and again maybe looking in to research based on that concept.

Working Group 17

This teacher's comments indicate that she sees research related to teaching specific mathematics topics as a possible source of information about how she should approach teaching them. The group of primary school teachers to whom this teacher belongs spoke about all of the aspects of professional development that have been identified as important (Joubert, et al., 2009): knowledge of mathematics, knowledge of ways of teaching it and knowledge of the ways in which students make sense of mathematics but it was their students' learning to which they paid the most attention. For them it was this focus on the learning of their students that was the motivating factor as they continued their work in their group and constituted a change in their focus away from their teaching and onto the learning opportunities they offered their students. We would suggest that this constitutes a significant change in their approaches to their practice.

Similar evidence was found in the data gathered from one of the secondary groups. In talking about the impact of involvement in the lesson study process on his teaching more generally, one of the teachers commented:

T 4: I feel more confident in the sense, not of my knowledge base, but more confident in front of the class, putting across more excitement and enthusiasm... I think it has chivvied me even further along the road of getting the girls involved more, of taking a slightly more background role.

This also illustrates the focus of the lesson study on the learners and shows a teacher who is willing to pass over more control of the learning to his students.

Student learning

The observations of the study lesson by the whole group of teachers have the effect of focusing the observers' attention on the students' responses to the learning opportunities that the lesson offers. This is a development of the process of engaging with the ways the students make sense of the mathematics. The central thrust of a study lesson is often to make the students' learning visible to the teacher and observers and this is accomplished through choosing tasks that facilitate this and encourage students to express their mathematical ideas both orally and on paper. Once this has been planned the observations can focus on noting the students' learning. The teachers in the primary group were struck by how observing the learning in this way altered their perceptions of the lesson:

T 1: The thing with observing which is really helpful is that you kind of put yourself in the position of the child whereas when you're teaching – yes, you're thinking about their learning but you've also got to think about what you're doing and how you're sort of delivering it. With observing you listen to the teacher as if you were that child and so you really see how they are learning.

T 2: So it's enabled you to draw out what's happened that you might not have seen as a teacher. Knowing that children might be having really rich discussions even though you

Working Group 17

haven't heard them as a teacher is really useful to know. It gives you the confidence to think that you don't need to direct everything.

The second comment draws attention to the additional information that the team of observers were able to gather from watching the lesson: they had been able to comment on all the talk of all the different working groups within the class. This would not be possible with one teacher in the classroom and it had shown them that the mathematics in the talk of all the groups was sound and that the discussion was about the task.

These comments from the teachers were supported by observations of the study lessons that they developed as part of their work. In these lessons the students were actively engaged in solving mathematical problems related to the aims of the lesson and their conversations illustrated their thinking about the mathematics involved rather than echoing a procedure that their teachers had demonstrated. In this the study lessons did begin to make the learning of the students more visible.

Engaging with lesson study

We described above how lesson study is organised and emphasised that it is not always easy or straightforward. It involves a significant time commitment on the part of the teachers involved, which in turn implies that, without the support of their schools, they will not be able to engage fully with the process. Our sample includes three initiatives which demonstrate the difference this commitment seems to make.

In the first, the teachers came from three different secondary schools and their work was carried out in their own time after school. They had little support or recognition of their efforts from senior managers in any of their schools and it was difficult for them to arrange time within the school day to collaborate and teach together or observe each others' classes. They planned a lesson together, but then each taught a part of it and none of them was able to observe students' responses while a colleague taught. Although the teachers reported that the collaborative planning of the lesson had been of value, we suggest that their experience could have been more valuable if they had had the opportunity to observe the students more closely. The point is that they did not seem to understand that lesson study involves more than collaborative planning.

In a second example, a group of teachers working under the strong leadership of the head of the mathematics department has been engaged in the process of lesson study over a period of several academic years. The head of department was well informed about the Japanese lesson study model and he showed us a shelf of books about lesson study he referred to in discussions with us and the members of his department. He said that he encouraged the group to follow the model very closely and this was apparent in the Open House which the department put on showcasing two study lessons and their analysis for a large audience. Each member of the department is part of a lesson study group and the focus of the work for the whole department is

Working Group 17

linked with a theme that applies to all those involved. Senior management including the head teacher support the process of lesson study and the teachers are allowed time to engage with the process and to observe one of the study lessons. Our observation of one of their lesson study meetings suggests that the teachers are used to the idea of attending to all three aspects of mathematical knowledge for teaching and that they were fluent in talking about expected and actual student responses to the study lessons. It seems that the time these teachers put into the lesson study initiative, and the commitment they have to the ideas behind lesson study, have resulted in significant professional learning.

In terms of changes in classroom practice, it seems that there has been significant and sustained change amongst the majority of members of the department. The head of department reported that most teachers took a more 'open' approach in their teaching and encouraged their students to discuss their mathematical thinking more. One of the teachers told us that much about the way she teaches has been influenced by the lesson study. She said that she has learnt to let go of control and to let all the students have a voice.

T1: I now let the students come up to the board and make contributions. I am much more aware of what I do in the classroom.

She reported that she is also more of the possible approaches students might take, and she takes these into account when she is planning. Our observations of one of her lessons confirms that she encourages her students to discuss mathematical ideas and it seems that she provides an environment in which they feel able to put forward their ideas.

It is not surprising, given the institutional support for the initiative, that the second of the examples here appears to have been more successful than the first in terms of teacher learning and change (it would be worrying if it had not been). What is perhaps more interesting, however, is the teacher commitment to the concepts underpinning lesson study in the second example which emphasise paying attention to all three aspects of mathematical knowledge for teaching as well as planning a lesson collaboratively.

A third example demonstrates an intermediate level of engagement. In this case Teacher 2 (T 2) was the head teacher in the school and leader of the group. He was an avid reader of research into education and particularly about children's learning. He had an egalitarian approach to the leadership and management of his school describing himself as the 'lead learner' in all documentation rather than the head teacher. He had identified lesson study as an approach to professional development amongst his staff that respected their mutual need to develop practice that supported both their individual professional learning journeys and the learning of their students. He gave the rest of the team opportunities to voice their concerns and ideas and appeared not to dominate the group. He saw his role as a facilitator of the

process in that he was able to organise time for meetings and observations but he also expected and got from the participants considerable investment of their free time in the process and most meetings were held after school. This institutional support for the process of involvement in lesson study contributed to the engagement that the participants were able to make and sustain.

CONCLUSIONS

This paper explored teachers' reported learning and changes in practice during and after their engagement in lesson study initiatives. It provided evidence of their learning in terms of three aspects of mathematical knowledge for teaching. It seems that there was learning in all three areas, and we suggest that lesson study is particularly effective in encouraging learning in all three aspects. The paper discussed changes in classroom practice and again it seems that changes in classroom practice were evident and can be seen as effective because they were in line with the changes promoted by the initiatives of professional development. There was evidence of improved student learning and this suggests that the ultimate goal of the professional development was achieved.

However, it seems that not all teachers had equally positive experiences. We examined the ways in which the lesson study initiatives were approached, and suggested that if the teachers' schools are committed to supporting the teachers in taking part in lesson study and if teachers are committed to the ideas underpinning lesson study, then it is likely that the teachers' learning and changes in classroom practice will be deeper and more sustained.

Lesson study focuses on teachers identifying for themselves key issues and objectives that relate to their own context and which are important to them. As a group of colleagues they have an understanding of each other's practice and can move together, in directions that they feel inclined to try, to deal with their own problems. As one of the primary teachers observed:

T 1: it's that traditional CPD you know that we go to and have some sort of, whether its in house or out of house, and we sit and listen and we have things thrown at us and we have initiative this and initiative that. And this is a much more productive form of CPD, it's much more real and it will have a greater impact on learning and teaching.

This conveys a sense that lesson study for this teacher is a real process grounded in her practice as a teacher, something that she has control over and not something that is 'done to her' by some expert outsider with questionable understanding of her working context.

Lesson study is a subtle, complex and difficult process as these accounts suggest. However for those who engage with it at a deep level and develop an understanding of the process, it offers strong support for professional change and learning in all the key areas. Our data gathered from a number of different groups of teachers involved

Working Group 17

in lesson study indicates that changes in practice which the teachers claim to be sustained and significant only occur once they have grasped the key focus of lesson study on students' responses. This focus shifts their reflections on their teaching to a consideration of the learning opportunities they are offering the students and the students' responses to those learning opportunities. It pushes them to create study lessons that make the learning of the students visible to the observers. This is a subtle and difficult concept that necessitates engagement at a deep level with the process of lesson study. We suggest that it is only through sustained involvement that the teachers will develop a deeper understanding of these processes involved in this complex approach to professional development and of the way in which it has the potential to support and sustain their professional development. This deep involvement requires the participants to understand the 'spirit' of lesson study rather than limiting their involvement to the 'letter', or the superficial form, of this way of working. Lesson study involves more than groups of teachers planning lessons together and requires consideration of the mathematics that is the focus of the lesson, the potential ways of teaching it and the ways in which the students are likely to respond to those ways of teaching. Most importantly it involves paying attention to the learning of the students and for teachers to do this they need to create lessons in which that student learning can be observed. As Stigler says: 'The devil (and God!) are in the detail' (p.x) (Fernandez & Yoshida, 2004).

AN ATTEMPT AT DEFINING TEACHERS' MATHEMATICS THROUGH RESEARCH ON MATHEMATICS AT WORK

Nadine Bednarz & Jérôme Proulx

Université du Québec à Montréal, Canada

Through recognizing mathematics teachers as professionals who use mathematics in their workplace, this paper traces a parallel between teachers' professional mathematical and the characteristics of the mathematics used in workplaces found in studies of professionals. This parallel is developed through the five characteristics highlighted in Noss (2002). We use this parallel to help develop further on our conceptualisation about teachers' use of mathematical knowledge in their practice.

There is general recognition in our community of the professional finality of teacher education. One main aim of pre-service teacher education is to develop teachers' capacity to act as professionals. This finality has consequences for all the components of teacher education, in particular the mathematical dimension of their training. It therefore leads to the question of the relevant mathematics needed for the professional practice of teaching mathematics in schools. Our research interest starts from this preoccupation of teachers' professional mathematics (Proulx & Bednarz, 2009), as well as a constant questioning of the presence of a gap between the mathematical experiences lived by teachers through their teacher education and the mathematical practices teacher enact in their classroom (see our review in Proulx & Bednarz, 2008). This questioning led us progressively to the necessity of better understanding the specificity of these mathematical knowings of teachers, so as to be able to think of and develop teacher education approaches better aligned with this professional mathematics in order to prepare them for the demands of their work.

It seemed natural, in that perspective, to be interested in the research studies conducted on the mathematics used in practice by different professional groups; what is often termed "mathematics at work." If teachers are seen as professionals, thus the characteristics of the mathematics used in their practice could be informed by this important corpus of research (see e.g. Noss & Hoyles, 1996; Pozzi, Noss & Hoyles, 1998; Noss, 2002; Noss, Bakker, Hoyles & Kent, 2007). As we began reading this body of literature, we were stunned by the parallel we could trace between their results and analysis and our own data and theorizations on teachers' mathematical practices. We perceived this as an opportunity to continue advancing on our conceptualization of the nature of knowing and using mathematics in teaching (see e.g. Bednarz & Proulx, 2009). This paper is thus centered on exploring this parallel, in an attempt to define better teachers' professional mathematical practices through Noss et al. studies on "mathematics at work." In particular, we draw on Noss's (2002) conceptualization, developed as a result of studies conducted among professional groups in different settings (e.g., engineers, bankers, nurses). We thus document, *for each of the 5 characteristics of this conceptualization*, the parallel we

see with the mathematics used by teachers in practice – supported by illustrations from our data.

BRIEF METHODOLOGICAL CONSIDERATIONS

This parallel is documented through combining two sources of data. The first source comes from collaborative research studies in which teachers and researchers meet to elaborate teaching situations. These studies enable us to describe and analyze the knowledge teachers deploy when designing classroom situations. The second source comes from an in-service research project, in which 3 groups of 8-10 teachers participate, centered on the exploration of mathematics situations *related to teachers' everyday teaching practice*. The exploration of these tasks help gain access to the nature of the mathematical knowledge they mobilise in the action of teaching.

DEVELOPING THE PARALLEL THROUGH NOSS' 5 CHARACTERISTICS

A preliminary remark is necessary before we engage in this parallel. Teachers are a particular professional group, whose profession is to teach mathematics to students. They are in that sense different from other professional groups such as bankers, engineers or nurses whose profession is not directly associated to mathematics. Mathematics teachers are, then, *doubly* associated to mathematics: (1) they teach *mathematics* to students and (2) they enact a certain sort of mathematics in their professional practice (their profession is to teach mathematics and they have developed professional mathematical knowings to do so). Thus, teachers' mathematics at work (our object of analysis) must not be confused and restricted to the mathematics they teach (a certain content linked to the curriculum). The content of school mathematics is seen to act as a structuring resource, in Jean Lave's sense, of this (mathematical) practice of teachers – e.g., in the same way that a drug acts as a structuring resource for the nurses' mathematical practices (the knowledge of the drug structures the mathematical reasoning in the activity of drug's administration to patients) (e.g., Pozzi et al., 1998). But, even if the content teachers teach acts as a structuring resource, the mathematical knowledge enacted within this practice, as we will see in this paper, is considerably more sophisticated and different than the one encountered by their students (the mathematics linked to the curriculum).

The context of teachers' practice is a complex one, both mathematically and socially. As the employees of the bank in Noss et al. study (1996) are concerned with making profits for the bank and benefiting for themselves, rather than learning mathematics for its own sake, schoolteachers are concerned with students' learning. They are concerned with their students' understandings of the mathematics they teach and with their students' success in this learning; teachers are not (necessarily) interested in their own personal learning of mathematics in itself. This finality gives a particular color to the mathematics at work in their practice, as we will see through the documentation of the five characteristics conceptualized in Noss (2002).

Characteristic 1. A fragmentation of the knowledge structure of the workplace

Noss et al. (1996), in an attempt to understand the banker's ways of thinking about quantitative data, put in light the fragmented knowledge structure that characterizes the practice of investment banking: "We encountered departments specializing in the finest detail on one financial instrument, sharing a common wall but no common language with another – essentially similar – department" (Noss, 2002, p. 51). This fragmentation shaped the way bankers saw graphs – conceived as a display of numbers and data in relation to work activities (and not, e.g., as a functional relationship or an indication of a trend about data that permits prediction). This fragmentation of the knowledge structure of the workplace characterizes also in a certain way the one of teachers, e.g. from one grade-level to another or from one order to another (primary to secondary, secondary to post-secondary). Even if practitioners do share a common language for speaking about their practice and referring to it, the knowledge structure of the workplace (by level, by order) shapes their mathematics in use, as we see in the following excerpt.

This excerpt comes from our professional development project (with secondary teachers) and concerns an important part of mathematics-in-use in teaching, that of symbolic notations used in mathematics teaching. After having explored a number of tasks around fractions, a discussion is initiated about an assessment task recently given to grade-8 students where the expression $\frac{(2x+1)}{4}$ played a role. In this discussion, teachers elaborate on their expectations for their students' answers.

Mary (grade-8): I would like to see the division symbol (\div) because I work around the division of polynomial expressions by constants. Hence, I expect my students to do the following, using the division symbol:

$$\frac{(2x+1)}{4} = (2x+1) \div 4 = (2x \div 4) + (1 \div 4)$$
. [She will later say: "I don't want to see $x \div 2$ in a result, but $x/2$." And, as a result of her interaction with other teachers who questioned her on this idea, she will reply: "well, except if I have $\frac{1}{2} \div \frac{1}{3}$ because for students there is the possibility of a confusion with the place where the division stands (e.g., $\frac{2}{3}$ is $\frac{2}{3} \div \frac{1}{4}$ and not $2 \div 3 \div 1 \div 4$)"].

Clara (grade-8 and 10): I would like my students to write $\frac{1}{2}x + \frac{1}{4}$, because I want to prepare my students for the usual notation used for linear functions.

Cathy (grade-7): I would also in that case use the division symbol (even if I don't teach algebra), because my objective is that my students work with operations on natural numbers and their properties like the distributive law: $(2 \times 51 + 1) \div 4$.

Sandra (grade-9): I prefer they continue simplifying this expression from $\frac{2x}{4} + \frac{1}{4}$ to $\frac{x}{2} + \frac{1}{4}$ because I want to make visible the rate of change in this expression.

Jerry (grade-10 and 11): I write it $2(x + \frac{1}{2})$ to draw out parameters and the transformations associated to them [Robert (grade-10 and 11) agrees].

This discussion highlights the subtle ideas engaged by teachers concerning symbolic notations, rooted in the demands of their work activity: e.g., for preventing possible confusion with notation in students; for expressing the results in line with the finality of their work in their classroom (note that both grade-8 teachers did not share the same expectations); for preparing students for the upcoming years and topics. We can see how teachers' mathematical knowledge in use, here about algebraic notations, is finely tuned to their professional activity and its pragmatic demands: it is shaped by the fragmentation of the knowledge structure of the school. A certain rationality guides their choices, putting in evidence different meanings underlying this notation and a diversity of interpretations related to the level where they teach: division of algebraic expressions (the fraction notation has to be seen as a quotient, a division); general expression associated to linear function; seeing the variation rate through the notation; seeing the parameters through the notation and transformations associated.

Characteristic 2. The role of artefacts and tools in mathematics at work

In their ethnographic studies on nurses, Noss et al. show the central role of artefacts in the workplace settings. Artefacts such as notational systems, physical tools, work protocols, etc., act as structuring resources in an ongoing dialectic of producing and being produced by activity in a certain social practice.

For example, in one study on a hospital ward, we found that a seemingly straightforward artefact like a fluid balance chart, contained within it the crystallized activity of the hospital community, shaping in complex – but unnoticed – ways the actions and discourse of those using it. (Noss, 2002, p. 52)

Our data also show the importance of artefacts in the work of teachers. For example, symbolic notations, algorithms and modes of representation to which teachers often refer in their teaching illustrate how these artefacts act as structuring resources in their practice. If, for nurses the fluid balance chart is embedded in the routine of a work protocol for taking care of patients, for teachers a symbolic notation is embedded in their routine of teaching mathematics to students and giving meaning to concepts. These artefacts are so embedded in professional routines that in most cases their underlying structure is hidden: nurses take for granted the explanatory power of the chart, precisely because it is part of their routines; teachers often take for granted the explanatory power of representations, notations or algorithms in their teaching, precisely because it is part of their routine. To understand the complex, but often less visible parts of decision-making related to these artefacts, Pozzi et al. (1998) have noticed that those become more visible through situations involving what they call “breakdowns” in the normal habits of practice, where these oft-hidden meanings are questioned by other practitioners that use or perceive the role of these artefacts in different ways. In that perspective, breakdown situations have a central role to help explicit the mathematics in use within these artefacts, where the models underpinning the artefacts can rise to the surface and become open for observation

by researchers; Pozzi et al. even suggest to provoke situations of breakdown to attain these goals. We can see the potential of such breakdown situations in the next excerpt concerning algebraic notations, where the interactions between teachers around routine practices at each grade level rises to the surface. The notations act here as what Pozzi et al. call a “disputed territory,” which serves both as a breakdown in routines for each teacher and as an opportunity for us as researchers to understand the algebraic notation used.

The symbolic notation is the focus of teachers’ discourse about their practice in this excerpt coming from the professional development research project with secondary teachers. The discussion emerged from an exploration of different students’ solutions to a problem of trigonometry (drawing a point on the trigonometric circle, finding which point is nearer to $\frac{\pi}{6}$). The link that the grade-8 teacher wanted to do with her teaching to prepare the future work of students on trigonometry illustrates the way she works with the circle. She explains that she writes “ $2 \cdot r \cdot \pi$ ” during the process of elaboration of the formula of the circumference of the circle, to help student see the origin of the formula. However at the end of the process, only “ $2 \cdot \pi \cdot r$ ” will be acceptable (a certain written notation corresponding to the convention accepted). She will do the same for $1 \cdot x$, acceptable during the process of mathematization of an algebraic problem, but not at the end (the answer has to be written as x). In the work on the trigonometric circle, the grade-11 teacher will accept a notation like “ $2n \cdot \pi$ ” to show the repetition on the circle of π “ n times” and to help visualize the point associated. But the other teacher (grade-10) reformulates it in “ $2 \pi n$ ” to put the constant before (like the accepted convention). This teacher will also point to the non coherence in the way it is written and explains that the algebraic expressions “ $2n \cdot \pi$ ” means, normally, “ $2n^\pi$ ” to be coherent with the way we usually say and write those expressions (like with “ $pi-r-two$ ” = π^2 or “ $x-two$ ” = x^2).

This discussion shows the invisible relationships buried in these artefacts (and often taken for granted) that a breakdown from routine practices contributed to explicit (in this case the need for teachers to understand the notation in use by other teachers). Teachers had to make sense of what they used, and why, through these discussions. We can also see how these artefacts are shaped by the professional context of the teacher (e.g., teaching at a certain level, making sense of a formula, visualizing the positioning of points on the trigonometric circle) within a broader social system (e.g., answering to certain mathematical school conventions, taking account of the coherence), as well as this practice shapes in return this way of working out these “conventions” by offering new ways of making sense of them and using them.

Characteristic 3. The anchoring of mathematical meanings in practice

The different ethnographic studies conducted by Noss and his team point to the situated nature of the mathematical knowledge of professionals, rooted in the professional activity and context of work. For example, in the case of nurses, their findings show that the different strategies used in relation to drug’s administration would, in the literature on proportional reasoning, be described as lacking meaning.

Working Group 17

However, a fine-grained analysis shows this not to be the case, as the various strategies “was anchored in an intimate knowledge of the drug itself, as well as in the properties of familiar packaging constraints of prescribed doses. The knowledge was mutually constituted and expressed both mathematical relation and culturally-shared situational noise” (Noss, 2002, p. 54). The “situational noise” of a situation is an integral part of professional knowledge at work. In a previous paper (Bednarz & Proulx, 2009), we have brought forth similar findings for mathematics teachers illustrating the anchoring of mathematical meanings in practice produced by the coordination of multiple dimensions (mathematical, didactical, pedagogical, institutional). The “noise of the teaching situations” (e.g. engaging students in the given problem, showing the value of various solutions and not only of the answer, showing how students find it, reacting to some solutions, etc.) appeared to be a key element of teacher’s mathematical knowledge. As a way of illustrating this situated nature of mathematical knowledge rooted in context, we use the following vignettes, taken from a collaborative research study centered on the elaboration of teaching situations (Saboya, 2010). We join Nadia and her students in the following two vignettes as they work with different expressions.

Vignette 1: expression $\frac{10^5 + 10^8 + 10}{10^2}$	Vignette 2: expression $\frac{10^4 + 10^5}{10^2 + 10^3}$
<p>Laura: I am not sure but what I would do ... it is like 10 to the 5, so 5 minus 2 then 8 minus 2 then 10 ... 10 to the 1 minus 2 then after that it would ... then I can't put them together because these are additions, because the law on exponents does not work, so it will be 10 to the 3 plus 10 to the 6 plus 10 to the minus 1.</p> <p>Marc: Is it possible to write 10^{13}?</p> <p>Students: No because it is a “plus.”</p> <p>Nadia: You see there is a plus, and so we say “there is a ‘plus’ which ruins everything.” This ‘plus’ stops me from putting everything together.</p> <p>Brad: Instead of 1/10 could we write “-10”?</p> <p>Mary: Does it mean that it is equal to $\frac{10^5}{10^2} + \frac{10^8}{10^2} + \frac{10}{10^2}$?</p> <p>Nadia: When I have something like that (she shows the second part of the expression, under the line), when I have a sum like that it is as if I have split the fraction in three. So, it is the same principle: $\frac{10^5 + 10^8 + 10}{10^2} = \frac{10^5}{10^2} + \frac{10^8}{10^2} + \frac{10}{10^2}$</p> <p>Brad: Instead of 1/10 could we write “-10”?</p> <p>Nadia: See, some say it's -10 or minus something. This is why I don't want negative exponents because you make errors and it doesn't work.</p>	<p>Nadia: $\frac{10^4 + 10^5}{10^2 + 10^3}$, we cannot do anything with this, we leave it like this.</p> <p>Joe: Why? Can't we separate those?</p> <p>Nadia: No we can't separate this.</p> <p>Joe: Why not?</p> <p>Nadia: if you separate it, it gives $\frac{10^4}{10^2} + \frac{10^5}{10^3}$. It would mean that you add fractions. And do we have the right to add numerators and denominators?</p> <p>Joe: No.</p> <p>Nadia: Ok, no, but when you do as you say, this is what you do.</p> <p>Julie: Couldn't we just do $\frac{10^4}{10^2}$?</p> <p>Nadia: No. What do you do when you separate them like this $\frac{10^4}{10^2} + \frac{10^5}{10^3}$? Is that what you've done?</p> <p>Julie: Yes.</p> <p>Nadia: This does not work because you are adding two fractions and you add numerators together and denominators together. You cannot do that.</p>

As for nurses, where strategies used to calculate drug administration to patients were anchored in an intimate knowledge of the drug itself and varied in relation to the type of drug and the packaging constraints (Pozzi et al., 1998), the previous extracts show similar results in relation to teachers' context. Strategies used in action by Nadia to manipulate algebraic expressions with exponents and simplify them is anchored in an

intimate knowledge of the expression itself and of different types of expressions in relation to students' difficulties (e.g., expressions with additions or not, additions at the denominator, negative exponents). This knowledge is interwoven with her anticipation of her students' difficulties, her sensibility to their errors in such expressions, her intention to prevent these errors, etc. The fact that she does not pursue the simplification in the second case () – even if it is possible – is related to this professional mathematical knowledge intertwined in the context of practice (and unfolded on the spot). The way she mathematically works with the expressions is related to her teaching intentions (prevent errors, working on exponents, using exponents laws, seeing the parallel with fractions), and those shape the way she acts, so that the factorization of a common factor at the numerator and denominator will not be used by students, or that she will not encourage it.

Characteristic 4. Qualitative restructuring of mathematical knowledge

In their studies on nurses and on engineers, Noss and colleagues highlight that a transformation of mathematical knowledge happens within the professional activity at work. For example, a certain meaning of average and variation emerged in nurses' thinking on the ward, in the manipulation and interpretation of quantitative data and relationships related to patients. For a nurse, it is the variation that is crucial, and not the notion of average of a population; the average is considered if it is individually mediated (it is the individual who is the focus of her care). This restructuring and transformation of knowledge in practice is also true for engineers, where they have developed alternative ways of making sense of concepts (e.g., load path); in manners that differ from the "usual" or "formal" way of approaching this concept in traditional mathematics/physics. This transformation of mathematical knowledge *in situ* provides to the engineers a way of thinking more relevant to allow judgments about the validity of the quantitative analysis of the structure.

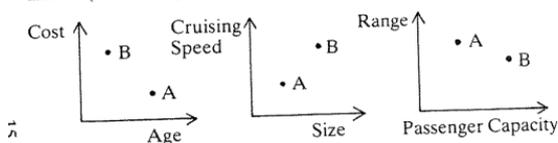

The following excerpt, taken from our professional development project with secondary teachers, highlights similar findings. It concerns an exploration of different graphs and the anticipation of what their students could answer to them, as well as the relevance of giving these sorts of tasks. These tasks were given to teachers (taken from Shell Centre for Mathematical Education, University of Nottingham, 1985).

Working Group 17

2. Two Aircraft

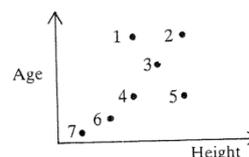

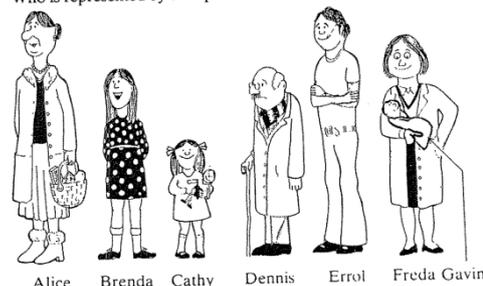

The following quick sketch graphs describe two light aircraft, A and B: (note: the graphs have *not* been drawn accurately)

Interpret the meaning of each graph.

1. The Bus Stop Queue

Who is represented by each point on the scattergraph, below?

The debate on the value of this type of graphical representation is provoked by Mary (grade-8 teacher): “What is the relevance of this type of graph if there is no relation between the magnitudes considered on the two axes? It goes against what we try to develop in students, that is, the idea of independent variable, dependant variable and a relation between the two.” Then, Mary appeared ambivalent about the relevance of using this type of graph: “On one hand, I find these graphs interesting because they force a lecture of the axes by the students, which is one of the difficulties they have and that I observed when they work with graphs. They simply do not read the axes. But, on the other hand, I am not very comfortable with the idea of presenting a graph where there is no relation between the two magnitudes involved on the axes”. This argumentation will be supported by other teachers, like Clara (grade-8 and 10 teacher): “What is the relevance of it if there is no relation between variables? A graph is interesting for seeing if there is a correlation between two variables (e.g., in statistics, to study the behavior of a series of data and its tendency, its correlation) or if it corresponds to a functional relationship. If there is not one and only one value that corresponds to another specific value of the independent variable, we do not have a function, so it is not interesting, since we can’t speak of inverse or reciprocal functions, for example.” Through the discussion, it became clear that all teachers agreed with the fact that in these cases there was no real relevance to use a graph; they raised, e.g., the idea of placing the information available in a table.

This interaction clearly shows a conceptualization of graphs transformed by the professional activity of the teacher, as it was the case for the bankers in the Noss and Hoyles’s (1996) study. For bankers, the graphs were seen as a display of data, as a picture of numbers and as a quick and easy way to display data, and *not* as a medium for expressing relationships (between a certain quantity and time, e.g.). They regarded the shape of the graph as determined by its representational characteristics (number of elements to be displayed, availability of color, target of audience, frequency of variables, scale of axes, etc.) and not in terms of the underlying relationships between those data. On the opposite, for these teachers, the graph was

not seen or accepted as being a simple display of data or of numbers. The central role played by functions in the curriculum they teach influenced their conceptualization of graphs in a very specific way. Teachers regarded graphs as necessarily determining relations between two variables. These two contrasted examples of teachers and bankers concerning the usage/utility of graphs shows how knowledge is transformed within the professional practice.

Characteristic 5. The situativity of abstraction

As we have seen, mathematical knowledge at work is situated. This situativity of knowledge doesn't mean that this knowledge in action is only local. A variety of the observations made on nurses in Noss et al.'s (2002) study reveal, through the different strategies used by nurses to calculate some drug administration to patients, a kind of invariant through a nurses' sense of the quantity of concentration, taking the form of a co-variation constant between the mass and the volume in the drug solution; this invariant is not linked to a particular patient, nor a specific drug's administration. Thus, nurses engage in abstraction, developing abstracted knowledge grounded in their practice. But this abstraction remains to some extent *situated* in that it retains crucial elements of the setting in the ways it is conceptualized. The authors use the expression "situated abstraction" to describe this kind of abstraction at work. It attempts to describe how a conceptualization of mathematical knowledge can be at the same time abstract *and* situated. Finely tuned to their situative constructive development, to their use in professional practice, mathematical invariants are abstracted within that community of practice. The notion of "situated abstraction" confronts the usual way of conceiving abstraction in the mathematics education community, as it is normally thought of as something extracted from a set of situations, essentially de-contextualized. The noise of the context is then perceived in this conception of abstraction as an obstacle to this abstraction: there is a necessity to shift away from the context and from the situation where it was extracted from. The notion of situated abstraction questions this conception, that is, it questions the fact that mathematical abstractions must be separated from the context of their construction or application. On the contrary, situated abstraction suggests that what can be seen as "noise" in the traditional view of abstraction is in fact central to it in a professional context. However, as Noss (2002) explains, this notion of situated abstraction needs to be additionally documented, as it is now more conceived as representing an hypothesis than a finding *per se*.

Our observations through the various sessions with the different groups of teachers show that some aspects of situated abstraction are taking form in teachers' sense of mathematical concepts. For example, an aspect we have explored in depth in Bednarz and Proulx (2010) is the notion of referent in regard to fractions (e.g. $\frac{1}{2}$ of something is different from $\frac{1}{2}$ of another thing). In this case, a conceptualization of fractions in relation to a certain referent emerges within the explorations in the sessions, interwoven with their professional practice concerning issues like

considering their students' possible answers, the possibility to consider or not the relativity of this referent in their teaching, managing this idea in the daily teaching with 27 children, etc.). This notion of referent was also afterwards re-invested in other sessions on other topics (e.g. decimals numbers, area, volume, division and problem solving). This invariant is thus highlighted in various conceptual situations for various concepts, showing that teachers have abstracted within this exploration a specific mathematical knowledge. This abstracted knowledge remains however situated, embedded within teaching and learning contexts for making sense of it: it carries issues of classroom context, of viability of bringing about the referent, of difficulties for students to understand, of their easiness for managing this mathematical openness of the answer, of deception toward their previous teaching or textbooks that did not insist on this powerful idea of referent, of the potential of this idea for students' reasoning and sense making, etc. Those are all "present" in the abstractions teachers develop about the specific notions worked on. However, in the same way that Noss (2002) stresses it, we still are in need of probing further on this issue of situated abstraction in order to get a better and more robust grasp of its meaning and the role it plays in teachers' professional mathematics.

DISCUSSION AND CLOSING REMARKS

This parallel made with these characteristics of teachers' mathematics at work questions and even confronts the usual mathematical preparation of teachers in universities, particularly in regard to the situated nature of this mathematical knowledge and the situated nature of abstraction. Issues like the "noise" of the practice situation is, as we have seen, an essential part of this mathematical knowledge at work for teachers, as it shapes teachers' knowledge as well as the abstractions they draw and how they "restructure" their mathematical understandings in relation to these practices. It therefore calls for a very specific mathematical preparation, precisely in relation to artefacts and their often-hidden meanings in routines, to the de-fragmentation of the workplace, and to the central issue of situativity of professional knowledge – so as to better prepare teachers to act mathematically as professionals in their everyday practice. As Noss (2002) points, the lack of robust connection between both worlds of "mathematics at work" and "mathematical preparation at university" appears to be a central element to take into account for the mathematical preparation of professionals.

[...] the majority of structural engineers do not "use mathematics" of any sophistication in their professional careers [...]: Once you've left university you don't use the maths you learnt there, 'squared' or 'cubed' is the most complex thing you do. For the vast majority of the engineers in this firm, an awful lot of the mathematics they were taught, I won't say learnt, doesn't surface again" (p. 54).

Working Group 17

In that sense, this conceptualization of teachers' mathematical knowledge helps to think about the elaboration of approaches for the professional development of teachers, ones better aligned with the "mathematics at work" of the teaching practice.

ADOPTING AN INQUIRY APPROACH TO TEACHING PRACTICE: THE CASE OF A PRIMARY SCHOOL TEACHER

Claire Vaugelade Berg

University of Agder, Norway

The research reported in this paper is situated within a developmental research project called Teaching Better Mathematics where the collaboration between teachers and researchers is based on the idea of inquiry. The teaching practice of an experienced primary school teacher participating in the project is considered and elements of her practice are conceptualised using the theoretical construct of an inquiry cycle. The analysis shows that the teacher engaged with inquiry at different levels, into the mathematics and into her teaching practice. Possible implications for teacher education are suggested.

INTRODUCTION

The origin of inquiry (Dewey, 1905) can be traced back through the work of Polya in mathematics (Polya, 1945) and his ideas have been developed further during the 1970s and 1980s with an international movement in mathematics learning and teaching aimed at promoting problem-solving and conjecturing in mathematics classrooms (Mason, Burton, & Stacey, 1982; Schoenfeld, 1985). Furthermore, during the last decades, research has been focused on the role played by teachers in their teaching practice in relation to pupils' learning. More specifically, it seems that there is a consensus concerning a possible link between development in teaching and improvement of pupils' mathematics learning in classrooms. In this research report, my aim is to present how professional development for in-service teachers is organised in a developmental research project *Teaching Better Mathematics* (TBM) at the University of Agder (UiA), where the idea of inquiry is fundamental.

This paper addresses the link between theory and practice by referring to the theoretical constructs of teaching cycle, inquiry cycle and developmental research and by exemplifying the idea of an inquiry cycle through the analysis of a primary school teacher's teaching practice. In other words, through this paper I am in a position to link theory, teaching and practice and to address the following research question: what does it mean to follow an inquiry approach to teaching? The structure of this paper is as follows: First I present central aspects of the TBM project and emphasise the theoretical constructs of inquiry, teaching cycle and inquiry cycle, and developmental research. Then I turn to an example from a primary school teacher's practice and show how the theoretical constructs introduced previously are useful in conceptualising different aspects of the teacher's teaching practice. I conclude by discussing possible development of and implications for developmental research for teacher education and especially the importance of the inquiry cycle in the development of mathematics teaching and learning.

CENTRAL ASPECTS OF THE TBM PROJECT

Co-learning agreement with teachers

The aims of the TBM project are as follow: first to promote better understanding and competency in mathematics for pupils in schools, and second to explore better teaching approaches. These aspects are visible in the title of the project depending on the emphasis - Teaching *Better Mathematics* or *Teaching Better Mathematics*. In the project, we collaborate with in-service teachers from 4 kindergarten, 6 primary and lower secondary schools and 3 upper secondary schools. Our collaboration with teachers is organised around workshops and school visits. In the project, we see teachers and didacticians as working together as co-learners (Wagner, 1997). This implies that both teachers and didacticians are engaged in action and reflection, and by working together, each have the opportunity to develop further understandings of the world of the other and of his/her own world. Through our collaboration with teachers, we, as didacticians, might learn about the teachers' teaching practice in schools and, at the same time, about our own research practice. Central to the project activity is the design of mathematical tasks, by the didacticians at the university, as a means for engaging in mathematics. This engagement takes place between teachers and didacticians during the workshops and between teachers and pupils in the classrooms. Teachers often take mathematical tasks, which were presented during the workshops and adapt them to their own teaching practice (Berg, 2010a, 2010b).

Theoretical basis of the TBM project

A fundamental aspect of the TBM project is the idea of inquiry. Inquiry is understood as asking questions and recognising problems, seeking for answers and solutions, and at the same time wondering, exploring and investigating the activity we are engaged in, while looking critically at what we do and what we find (Jaworski & Fuglestad, 2010). In our project we see inquiry at three different levels: at the first level, inquiry into mathematical tasks in relation to pupils' mathematical learning in classrooms; at the second level, inquiry into the developmental process of planning for the classroom and exploring ways of developing better learning environments for pupils in mathematics; and at the third level, inquiry into the research process of systematically exploring the developmental processes involved in the two previous levels (Jaworski, 2007). While the second and the third levels address the collaboration between teachers and didacticians/researchers, the first level addresses the collaboration in classrooms between a teacher and his/her pupils. Due to limitations of space, I focus on just one level, inquiry into the developmental process of planning for the classroom and exploring ways of developing better learning environments for pupils in mathematics. As mentioned earlier, we see our collaboration with teachers as co-learning and we aim at creating and developing a *community of inquiry* where inquiry is used both as a tool in all practices, the teachers' and ours, but also as a way of being, indicating a willingness to becoming or taking the role of an inquirer (Jaworski, 2007). The idea of *community of inquiry*

derives from Wenger's (1998) *community of practice* where the practice refers to the activities in which we, teachers and didacticians, are engaged, and are mainly learning, teaching and didacting. In a community of inquiry, we use inquiry as a tool in all aspects of our practice and aim at developing "inquiry as a way of being" in practice (Jaworski, 2004).

In order to make explicit the processes involved in inquiring into the developmental process of planning for the classroom and exploring ways of developing better learning environments for pupils in mathematics, and to conduct fine grain analysis, I introduce the theoretical constructs of *teaching cycle* and *inquiry cycle* (Jaworski, 2007). A *teaching cycle* is an analytical tool we use to conceptualise teachers' practice: that is, how they usually plan tasks for the classroom, use the designed tasks in class, reflect on his/her own experiences, and then feed back into future planning. However, in a community of inquiry, we are not necessarily satisfied with the normal or usual state of teaching practice and, therefore, our aim in the project is to promote an *inquiry cycle* within which the teachers start to question their practice, explore possibilities and thereby adopt an inquiry approach to their own practice. An inquiry cycle differs from a teaching cycle since it consists of a teacher's planning *and re-planning* tasks for the classroom, using *and observing* the designed tasks in class, reflecting *and analysing* on his/her own experiences, and then feeding back into future planning (Figure 1). Thereby, teachers engage in the process of researching their own teaching practice.

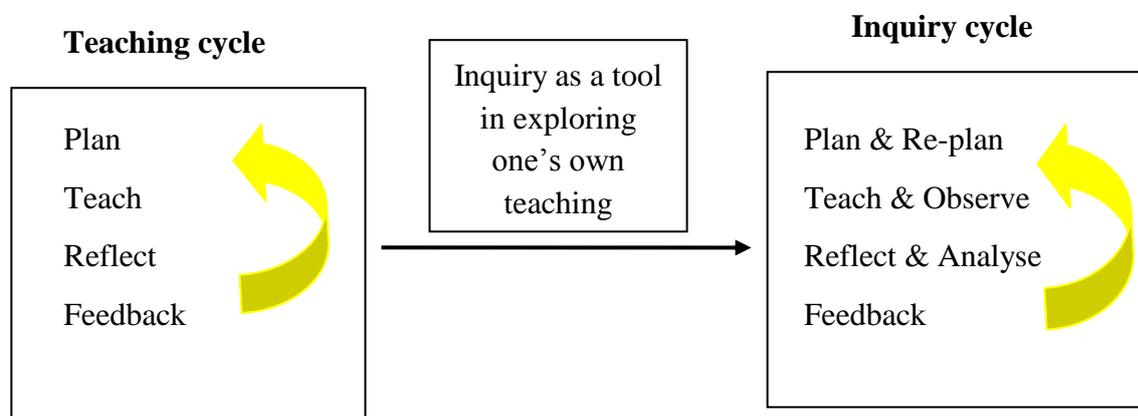

Figure 1: From a teaching cycle to an inquiry cycle

METHODOLOGICAL CONSIDERATIONS AND RESEARCH SETTING

Within the TBM project we follow a developmental research approach. This implies that we, as didacticians, engage in studying, documenting and researching the development of the teachers' practice and, at the same time, our research activity contributes to its development (Goodchild, 2008). Central to developmental research is a *research cycle* and a *development cycle*. The research cycle refers to a cycle between global theories and local theories and, in the TBM project, global theory

refers to community of practice (Wenger, 1998), while local theory refers to community of inquiry (Jaworski, 2007). Furthermore, a development cycle consists of a cyclical process between thought experiment and practical experiment. In other words, the notion of *thought experiment* refers to the preparation of the workshops where we collaborate with teachers, while *practical experiment* refers to the actual realisation of these. Feedback from participants informs the next step of thought experiment. Concerning the development of teachers' teaching practice, I consider that by introducing the idea of *inquiry cycle*, as presented above (see Figure 1), I am in a position to develop and elaborate on the idea of *teaching cycle* further since the dimension of inquiry implies that a teacher is not only engaged with teaching, but teaching *and observing*, and not only reflecting, but reflecting *and analysing*. This theoretical construct is exemplified in the next section.

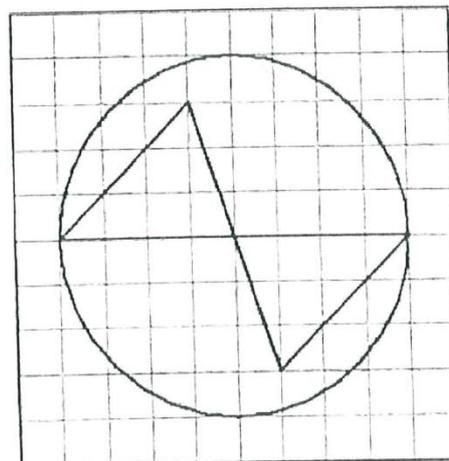

The research setting

The data presented in this paper was collected during a teaching period at a primary school in December 2008. In addition I conducted semi-structured interviews with the teacher both before and after the teaching period. I was invited by the teacher to follow her in her classroom since she was inspired by a particular task that had been introduced during a workshop, which was organised a week earlier. Usually the workshops are organised according to the following pattern: first teachers are invited to present their own reflections concerning the previous workshop, the way they implemented tasks in their own teaching practice and thereby sharing with others their experiences and inviting other participants to comment on their presentations. Next is a plenary presentation, usually by one of the didacticians, on the chosen mathematical theme. After a break, all participants divide into groups, according to the level they teach, and engage with mathematical tasks. Finally, all participants meet again and each group presents the results of their investigation. The aim of the group activity is to offer opportunities to teachers and didacticians to work together and to promote further discussions concerning the use of inquiry-based tasks in classrooms. In addition, the teachers are encouraged to take ideas and tasks presented during the workshop, and to modify and adapt these for their own classes. In the next section, I present the way an experienced primary school teacher modified and adapted a task, which was presented during the workshop. In addition, it is possible to follow how she engaged in teaching and observing her class, and later in reflecting on and analysing the teaching period.

A PRIMARY TEACHER'S INQUIRY CYCLE

The theme of the workshop was "Communication in mathematics: To ask good questions". The team of didacticians at UiA had decided to present the T-shirt task as a means to engage and explore what communication in mathematics might mean. The T-shirt task was previously introduced during a seminar at UiA concerning theoretical perspectives in mathematics teaching and learning through an article

concerning socio-mathematical norms (Tatsis & Koleza, 2008). The task was designed as an imaginary phone call where one person had to explain to another the design of a logo to be reproduced on a T-shirt (Figure 2). In this context the nature of the questions the other person may ask, as a means to reproduce the logo of the T-shirt in an accurate way, was important. Following from this workshop two experienced teachers contacted me, one from a primary school and one from a lower secondary school. Due to limitations of space here, I focus on just one implementation of the T-shirt task by the primary school teacher (Kari) in grade 6. I address implementation in lower secondary school in another article (Berg, 2010a).

Thought experiment: Interview before the teaching period

A week after the workshop I followed Kari in her class (6. grade) and could observe how she modified and implemented the T-shirt task. During the semi-structured interview before classroom observation she explained to me that she had modified and simplified the logo in order to start with an easier figure, a logo with only positive x-coordinates (see Figure 3). In addition, she explained that she introduced the x- and y-axes as a means to facilitate the pupils' engagement with the task (originally the T-shirt logo was represented on a grid, without specification of the axes, see Figure 2). Analysis of the data presented in the next sections shows evidence of the teacher's reflections before teaching period, the way she taught and observed during the teaching period and her reflection and analysis immediately after the lesson.

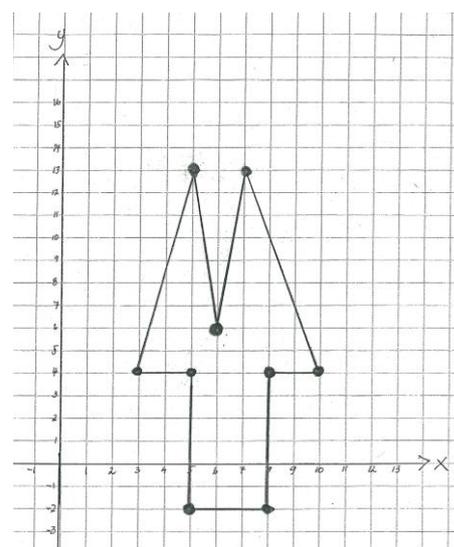

Figure 3

During the interview I also asked Kari the rationale for choosing and adapting the T-shirt task in her class. She explained her choice as follows:

”Yes, it [the task] captured me, and then, when I started to think that it could be about coordinate system, then, then I thought that this is a task I will use.... I relate it [the task] to my teaching and to what I do on that grade.... Pupils will need to use their mathematical language, they can talk about circles, triangles, and several concepts I would like them to have.”

My interpretation of Kari's explanation is that during the workshop where the T-shirt task was introduced (see Figure 2), she engaged in inquiry at two levels. First inquiry

Working Group 17

in mathematics as she explored the mathematics task “it [the task] captured me”, then inquiry in planning for her classroom since, from her knowledge of the task, she could envisage how to modify and adapt the task for her pupils and how to link the task to her current teaching. She refers to the coordinate system and imagines how the T-shirt task could be modified as a means for pupils to engage further with the coordinate system and with mathematical language and terminology. It seems that her aim with this task is that pupils will have the opportunity to use the mathematical notions of circle, and triangle while engaging with the task. I consider that Kari’s explanation illustrates the essence of the “Plan & Re-plan” phase as she was in a position to envision how the teaching-learning process could proceed in her class.

Practical experiment including inquiry: Teaching and observing

The class was organised as following: small groups of two or three pupils sitting together and one of them having the logo on a sheet of paper in the front of them, holding the sheet of paper vertically and describing the logo to the others in the group. The dialogue between two boys (Peter and Jon) refers to the description of the logo as in Figure 3. The dialogue starts when Peter has finished indicating the coordinates of all nine points in the logo (see Figure 3). Jon has drawn all points on his sheet of paper and the issue at stake concerns how to join all points in order to have exactly the same logo as Peter.

Peter: and then line [he starts pointing to Jon’s sheet of paper], down, yes, down [looking at Jon’s drawing and following what his friend is doing]

Teacher [going around in the class and commenting on what Peter just said]: now you have to imagine that you are talking by phone, and then do you know what you are drawing down to?

Peter [not paying attention to what the teacher just said]: and up, yes, on the side [following what his friend is doing], hmm

The teacher leaves the two boys and move to another group

Jon: do I need to go down to this? [pointing to the point 8, -2]

Peter: no, hmm, not now

Jon: just look at what is here [pointing to Peter’s sheet of paper with the logo] so you can see how it should look like

Peter: no, this is wrong, hmm, go to ... the right

Teacher [coming back to the group]: but if you are talking on the phone, can you see where the lines will go? Is there another way to tell?

Peter: yes, ..., hmm, ..., take a line from [the point] 8, 4 to [the point] 8, -2

The teacher is leaving the two boys

Jon: yes, and ...

Working Group 17

Peter: and then from 8, -2 to 5, -2

Jon: yes, like this

Teacher [talking to the whole class with a loud voice]: let me have a little time now, I can hear many similar cases. If you are talking on the phone can you then know if the line should go up, or down, forward or something else?

One pupil: no

Teacher: then how can you explain this [the logo], think about it a little, and try.

Peter was able to indicate to his friend Jon the position of all points using correctly the coordinates of each point. The issue at stake, when the dialogue starts, is related to how to connect all these points together such as the logo on Jon's sheet of paper will be exactly the same as on Peter's sheet of paper. From the video-tape it is possible to see how Peter started to point at Jon's sheet of paper without finishing his gesture. Here it seems that the boys struggled with keeping the imagined context of the task, a phone call, and chose to use indexical expressions as "down". Of course, the meaning of this adverb is clear if one knows the context, in the sense of "down" from which point to which point. It seems that this is the reason why Peter was pointing to Jon's sheet of paper in order to indicate from which point Jon needed to draw a segment down to another point. Kari, who was close to Peter and Jon's group, observed and commented on Peter's explanation and tried to remind the boys of the context of the task within which it is not possible to use adverbs such as "down". It seems that Peter did not pay attention to Kari's interruption as he continued to use adverbs as "up". My interpretation of the fact that Kari left Peter and Jon's group is that she became aware of the boys' way of describing the logo, using indexical expressions, and that she wanted to observe other groups in order to see if they also used similar expressions. The dialogue between Peter and Jon shows that they continued to use pointing and indexical expressions such as "down to this" and "go to the right". It is possible to see a shift when Kari came back and, as she recalled the context of the task, she challenged the boys "can you see where the lines will go?" and encouraged them to find "another way to tell". Now it seems that the boys were in a position to follow her advice as Peter, after a pause, said to Jon "take a line from [the point] 8, 4 to [the point] 8, -2". Compared to his previous utterances, this claim makes sense in a phone call situation. Then Kari chose to interrupt all groups and shared with the whole class her observations "I can hear many similar cases" and, as a result, she emphasised the lack of meaning of indexical expressions in the context of a phone call. I understand her last utterance "then how can you explain this [the logo], think about it a little, and try" as an invitation to inquire in the mathematics and the use of coordinate in order to keep the context of the task and to draw the logo as represented in Figure 3. This implies that, as a result of her observations in class, Kari decided to interrupt the different groups in class and to emphasise the context of the task, a phone call, as a means to avoid indexical expressions and to encourage

pupils to use the coordinates of the points. I consider that this episode offers evidence of how Kari was able to teach *and observe* during the teaching period.

Inquiry cycle: Reflecting and analysing

Immediately after the classroom observation, I had the opportunity to interview Kari. She started by commenting on her pupils' activities:

I was very impressed by what they were doing at the beginning; I was very impressed by that. I think they were very clever, clever and reliable concerning coordinate system. I did not expect it would have gone so nice. I was afraid it would not go so easy.

From Kari's utterance it is possible to follow how she was both reflecting and analysing after the teaching period. She started by recognising the pupils' ability in using the coordinate system. My interpretation is that she was referring to the first part of the drawing of the logo which consisted of placing the different points on a grid using the coordinates of each point. She characterised the pupils' activities as "clever" and "reliable" and it seems that she did not expect that they would be able to reproduce and identify the different points so quickly. However, evidence from the dialogue both with Peter and Jon and with the whole class shows that, during the teaching period, she had to make some comments on the way the pupils engage with the task in order to avoid the use of indexical expressions. Kari commented on this aspect later during the interview:

If I should do it [the T-shirt task] again, just the same [task], then I would have organised them [the pupils] in a way that they could not see each other. Because it was exactly what I said, what can you tell by the phone, I asked them a question about that. By the phone can you say that the line should go down there? Because you can't, and then they must start using the coordinates.

Here Kari developed further both her reflections and her analysis of the teaching situation. She focused on the situation which appeared in class, where pupils used indexical expressions as a means to draw the shape of the logo. She remembered drawing the pupil's awareness on the context of the task "because it was exactly what I said" and asking them "what can you tell in a phone call?" where the "what" was directly oriented to the kind of information and questions one can ask in the context of a phone call. The argument was elaborated further in the last part of her utterance as she emphasised that "during a phone call, can you say that the line should go down there?" The answer to that question was that the particular context of the task implied that one needed to use the coordinate system, not only for identifying the position of the points on a grid, but also for being able to draw segments joining the different points accurately such that the logo will be identical to that in Figure 3. As a result of her reflections and analysis, Kari was in a position to envisage a modified teaching – learning path. She mentioned, right in the beginning of her utterance, that if she were to have the same activity again, she would organise the class differently in order to avoid the possibility that pupils could see each other

and thereby help each other through gestures and indexical expressions. I consider that these two utterances provide evidence of how Kari was able to reflect *and analyse* during the interview after the teaching period.

DISCUSSION

In the beginning of this article I introduced and explained the theoretical constructs of inquiry, teaching cycle and inquiry cycle. My aim, by presenting an example taken from classroom observations in a primary school, was to illustrate how these observations could be conceptualised using the introduced theoretical framework. In addition I consider that the result of data analysis emphasises an important aspect of developmental research which is the didacticians' activity as engaging in researching, studying and documenting the development of the teacher's practice, but also, at the same time, how our research activity contributes to its development. This aspect was visible since I had the opportunity to follow Kari both in her class observing the lesson, and to conduct interviews before and after the lesson. It is in the process of asking questions, trying to find justifications, and comparing learning outcomes together, following a co-learning agreement, that the teacher had opportunities for engaging in the development of her teaching practice. Furthermore the fundamental role of inquiry enabled her to move from a teaching cycle to an inquiry cycle where both observation during teaching and analysis of her own reflections were crucial. Through the analysis it is possible to follow how Kari engaged with inquiry both in the mathematics and in her teaching practice. These aspects were visible as she modified the original T-shirt task, introducing the axes, and choosing a different figure with only positive coordinates. In addition she observed how pupils used indexical expressions such as "up", "down" and "down to this" and thereby did not engage with coordinates both as a means to identify the position of the point on a coordinate system and to make connection between the different points. Her reflections and analysis showed that a change in the organisation of the class is needed in order to keep the imagined context of the T-shirt task. I argue that by following this research approach I am in a position to establish a link between theory, practice and teaching. This recognition begs the following questions: what can we learn from this research that would be relevant for teacher education? And how can the idea of inquiry be introduced in teacher education? In the TBM project teachers and researchers work together as co-learners. A central question would be: what kind of collaboration between teacher students and teacher educators could foster an inquiry approach both to mathematics and to the teacher students' future practice? I consider these issues as fundamental since, in my opinion, one of the aims of teacher education is to encourage teacher students to develop awareness of possible tensions and limitations of their future teaching practice and thereby to support them to look critically at their professional practice.

MATHEMATICAL INVESTIGATIONS IN THE CLASSROOM: A CONTEXT FOR THE DEVELOPMENT OF PROFESSIONAL KNOWLEDGE OF MATHEMATICS TEACHERS

Ana Paula Canavarro

Universidade de Évora, Portugal

Mónica Patrício

E.B.I. André de Resende, Évora, Portugal

This article reports part of a study developed with the purpose of understanding professional knowledge of teachers involved in the development of investigative tasks in the classroom. The study adopted the interpretative paradigm and elaborated a case study of a first-grade teacher. This teacher worked regularly in collaboration with one of the researchers, selecting, planning and developing investigative tasks with her students in the classroom, and also reflecting on her teaching practice with investigations. The analysis of the data allows us to identify several aspects in which the professional knowledge of the teacher was deepened and broadened. It is also possible to identify the main factors contributing to the development of the teacher's professional knowledge.

Keywords: Professional knowledge; investigative tasks; teacher practice and reflection

PURPOSE OF THE STUDY

Investigative tasks promote a rich mathematical experience for the students and provide them with a significant intellectual challenge (NCTM, 2000). These tasks have an open nature and can be approached in very different ways, depending on the work of the solver. This kind of task can contribute to providing students with the mathematical learning experiences recommended by curricular orientations of many countries. In Portugal, they are explicitly suggested in the National Curriculum of Mathematics and in the recent syllabus (2007) of Mathematics for Basic Education.

However, investigative tasks can be very complex and their development in the classroom represents a serious challenge for many mathematics teachers (Oliveira *et al.*, 1999). It is important to understand the professional knowledge of teachers involved in the development of investigative tasks in the classroom, namely for first-grade teachers, since the majority of Portuguese teachers of this grade are not familiar with them. This was the main purpose of the study reported in this article. We investigated the practice of a teacher who participated in a collaborative context with the researcher (second author). Our purpose was to identify the components of professional knowledge she applied to develop investigative tasks in the classroom, and also to identify the influences of that work in the development of her professional knowledge.

THEORETICAL FRAMEWORK

Teachers have particular knowledge they apply in their day to day practices of teaching mathematics (Schön, 1992; Ponte & Chapman, 2006; Sowder, 2007). This professional knowledge is multifaceted and can be organized into different components (Elbaz, 1983; Sowder, 2007). According to Ponte (1995) and Canavarro (2004), there are four interrelated components of professional knowledge that assists the teacher directly when he/she prepares and conducts mathematical lessons: knowledge of mathematics, knowledge of students and their learning processes, knowledge of curriculum and knowledge of instructional process.

The knowledge of mathematics includes knowledge of specific topics, an overview of mathematics, as a science and as a school discipline, the perspective on its nature and its relation to reality (Ponte, 1995). This is essential knowledge for teaching. Having poor mathematical knowledge can inhibit the action of the teacher in the classroom, particularly the mathematical tasks that he/she presents to the students (Leikin & Levav-Waynberg, 2007).

Knowledge of students and their learning processes consists of the knowledge of characteristics of the students, aspects that motivate their learning, and how they develop and acquire knowledge from the learning situations (Canavarro, 2004).

Curricular knowledge includes knowledge of the purpose and guidelines of the curriculum, specific knowledge of the contents of the syllabus that the teacher teaches and of the syllabus of the years before and after, and also includes knowledge about the approaches, strategies and materials proposed (Ponte, 1995).

Finally, the knowledge of instructional process refers to the knowledge directly related to the organization and concretization of classroom practice. It refers to the phases of planning, conducting and evaluating teaching and learning (Canavarro, 2003). This knowledge has a decisive influence on the kind of teaching that the teacher puts into practice (Sowder, 2007).

Research in mathematics education has been explaining how the professional knowledge of the teacher influences the way he/she develops investigative tasks with his/her students (Oliveira *et al.*, 1999). This knowledge is reflected in two aspects of the teacher's work during the development of investigative tasks, which are mutually dependent: the mathematical aspects concerning the investigative task in question – when a teacher assesses the mathematical scope of the task, when he/she is involved in mathematical reasoning in front of the students, when he/she establishes connections between the knowledge present in the task and other mathematical concepts; and the didactical aspects that are fundamental to accomplish the objectives of the investigative activity. These are present when the teacher creates or selects the task, when he/she plans the lesson, when he/she conducts its development, when he/she has to handle unexpected situations of uncertainty, when

he/she has to understand the thought processes of different students and to promote collective reflection of the class (Ponte *et al.*, 1999).

Oliveira *et al.* (1999) stress that the selection and planning of investigative tasks is a complex activity because it requires from the teacher a broad knowledge about their students, their knowledge, interests and abilities. It also requires a solid knowledge of curriculum objectives, materials and resources they have available. The conduct of the class with investigative tasks is also very important, requiring many roles of the teacher (to challenge students, to evaluate their progress, to reason mathematically, to recall or provide relevant information, to support the progress of students and promote their reflection). In addition, the teacher should be aware of the type of interactions he/she has with students in order to promote an investigative ambience (to encourage the discussion of different opinions, the critical sense, reflection and debate). The teacher should also provide, and teach students how to use, technological tools that help them in investigative work (Oliveira *et al.* 1999; Ponte *et al.*, 1999).

The professional knowledge of the teacher is a dynamic knowledge, evolving from teaching practice and the reflection of the teacher about his/her practice. This reflection can be encouraged in the context of the school teacher, through collaborations of the teacher in complicity with colleagues. These collaborations are especially interesting when teachers experiment with the development of new and challenging tasks or new ways of working with students in the classroom (Sowder, 2007).

METHODOLOGY AND CONTEXT OF THE STUDY

As previously explained, this study is intended to contribute to the understanding of the professional knowledge of the teachers involved in the development of investigative tasks in the classroom (Patrício, 2010). The researchers adopted the interpretative paradigm and a qualitative approach, and elaborated case studies of teachers. The option for this design was because the study was intended to provide an explanation of a well-delimited phenomenon, embedded in context, for which we seek a thick description from the standpoint of the subjects being investigated (Erickson, 1986; Merriam, 1991).

The researchers decided to consider a teacher of the first grade because the practice of these teachers is still poorly documented with regard to the development of investigative tasks in classroom. The teacher should be an experienced one and denote propensity for innovation and investment – these conditions offer some guarantee of considerable professional knowledge and a willingness to embark on a new experience. This is the case for the first-grade teacher Petra, who is the focus of this paper. She is a teacher of 40 years, teaching a fourth-grade class (9 year-old students). Petra had never developed investigative tasks in their lessons. The total inexperience of the teacher with these tasks recommended the collaboration with the

Working Group 17

one of the researchers (the second author). That collaboration created conditions to operationalise this study, allowing more reliable and complete data collection, and representing an opportunity for professional development for the teacher.

The collaborative work took about two months. Petra had the opportunity to know and solve several investigative tasks and to discuss their potential with the researcher. The tasks were open and they could be developed in a more or less complete ways by the students. In the next paragraph, we give an example of one investigative task that Petra selected to work on with her students:

Dividing by 11, 111, ...

Look at the figures of the non integer part of the decimal representation of the following fractions:

$3/11$ $9/11$ $18/11$ $47/11$ $52/11$ $125/11$

Can you find any pattern in it?

Is it possible to estimate what the figures are of the non-integer part of the decimal representation of any fraction with denominator 11? Please explain.

And what happens if the denominator is 111? Write your conclusions.

You can also investigate with 1111...

In this collaborative work, Petra also responded to the challenge of the researcher to develop investigative tasks with her students in the classroom. She carried out five two-hour lessons with different investigative tasks, one per lesson.

The role of the researcher was to provide a collection of investigative tasks for the teacher, to support her in selection and in the planning of the lessons, and to promote her reflection on teaching practices. This collaboration emphasized discussion of the plans of the lessons that the teacher elaborated to each class with investigative tasks. The plans were organized according to a script provided by the researcher. The script considers three phases to the development of the lessons: a first phase of presentation of the task to the students; a second phase of autonomous work by the students, individually or in group; and a third phase of a collective discussion of the work done by the students. The script also includes the provision of a list of questions to ask the students in order to promote their mathematical thinking while performing the task.

In the classroom, when the teacher was developing the investigative tasks with her students, the researcher took the role of a non-participant observer and collected data. The teacher's classroom practice was particularly relevant for data collection, considering its different moments (preparation, conduction and reflection). After each lesson with investigative classes, the researcher and the teacher always spent some time reflecting on the teaching practices. They focused on mathematical episodes that took place during the lesson, on the mathematical learning of the

students, and they also tried to identify factors of influence in the way the tasks were developed.

The techniques and instruments used for collecting data were those generally recommended (Merriam, 1991): the interviews (the researcher conducted two formal long interviews at the beginning and at the end of the study; five informal interviews during the preparation of the investigative tasks developed in classroom; five informal interviews at the end of the lessons with investigative tasks – all fully transcribed); the observation of the teacher classroom practice (the researcher observed five classes with the investigative tasks, all audio-recorded and fully transcribed); the documental analysis (the researcher analysed all the lesson plans elaborated by the teacher).

THE TEACHER AND THE INVESTIGATIVE TASKS – RESULTS OF THE STUDY

Petra accepted with great enthusiasm, dedication and responsibility the invitation to participate in the study because she anticipated that she could learn and develop herself professionally. She was teaching a fourth grade class (9 year-old students).

Petra had never developed investigative tasks in her lessons, neither knew their characteristics. From the beginning, she revealed a great appreciation for the nature of the investigative tasks and the work they provide for students in the classroom. This is very consistent with what she valued in the teaching of mathematics: “Mathematics, for me, is to teach to think, is developing the reasoning, is awakening to the problems.”

Her lesson plans were very detailed. She worked hard trying to explore all the mathematical possibilities she could imagine. For each task, she elaborated an extended list of questions she could pose to her students to help them to progress. She explained that she wanted to take full advantage of the potential of the tasks and also to reduce the degree of unpredictability of the work with the students.

The teacher practice with investigative tasks was developed according to the three phases previously described. Her main purpose was to promote the development of students mathematical reasoning, but she tried to establish connections with the concepts emerging from the tasks. For example, for the task *Dividing by 11, 111...*, she wanted the students “to develop confidence in exploring mathematics in an autonomous way; to explore and use patterns on division by 11; to learn about periodic decimal representations.”

In the post-lesson interviews and in the final interview of overall reflection, Petra identified several aspects that she considered gains in her experience with the investigative tasks. In the following sections, we synthesize these aspects, organized by the four components of professional knowledge that we adopted, despite the fact that some of them could be included in more than one component.

Mathematical knowledge

Petra acknowledges having learned mathematical knowledge. When planning for the lessons, she forced herself to get into deep mathematical exploration of the tasks and she involved herself in investigative work.

I spent the weekends searching... and studying for the mathematical knowledge to tackle the tasks... And then I interrogate myself: "what can you investigate more on this?" And I get deeper but I never find everything, of course! (...)

This work revealed some “gaps” in her mathematical knowledge. She consulted some books, colleagues and the researcher trying to overcome the difficulties:

I learned a lot of mathematical knowledge, is true... Because I had to search for things I didn't know at all and others I was not sure... I also asked other colleagues, I asked you ... Because sometimes I had some doubts... the investigation of the rational numbers, for example. I had never worked with infinite decimals, with periodic decimals, my decimals were always finite! And exploring their period, hum... when I was solving the task myself with the calculator, I was not sure about the numbers it was showing me... that's when I called you!”

Petra also experienced some difficulties with a task in the domain of probability. She considered that her knowledge was too informal to explore the task correctly. She had to learn how to count all the possible cases in a complex situation – for example, how to differentiate between 1-6 and 6-1 when throwing two dice.

Curricular knowledge

Petra said that she has extended her repertoire of the types of tasks that she considers appropriate to work with students in the context of current curriculum guidelines. She confessed that she always liked open tasks and she was a great enthusiast of mathematical problems. But after this experience, she came to privilege the investigative tasks:

Now I'm a fan of investigations, seriously! I am fan! I think they have enormous potential... This year was the unknown, it was my first experience with this kind of task... I also like problems very much, but the investigative tasks are more challenging and have more potential for the learning of the students.

Petra said that the investigative tasks contribute to several aspects of mathematical competence that students should develop:

Because they are complex in nature, mathematical investigations provide a greater intellectual challenge and promote the development of more complex capacities of students, as mathematical reasoning, mathematical communication and critical thinking.

Petra also stressed that the investigative tasks, instead of constituting something marginal to the school curriculum, helped to promote compliance with the mathematics syllabus in an interesting way:

Working Group 17

With the investigative tasks you facilitate the achievement of the curriculum and of the mathematics syllabus, one thing is inseparable from the other... I think it only helps! You're not compromising anything... You are addressing mathematics in a much more interesting way and this is how it is expected to be addressed.

Students and learning process knowledge

Petra considered that investigative tasks have great potential to motivate the students to the learning of mathematics because they provide contexts for meaningful learning. The teacher also recognised that students may have an important role as creators of knowledge when developing investigative tasks:

And I think the investigative tasks have great power to motivate the students to mathematics – they like, they get involved and the knowledge that comes from this involvement is great. I'm sure they made significant learning. And they are creating knowledge, they are learning - and this is great!

Instructional process knowledge

The planning of investigative tasks allowed Petra to acquire a new vision about what makes a lesson plan effective: to consider other aspects besides the content, such as ideas of how to conduct the class or of the good mathematical questions to pose to the students. Petra concluded that a careful plan is essential to explore and conduct the lesson in order to take full advantage of all the potential of the tasks:

I learned so much! Look, I learned to plan properly, because I think this is the right way (...) It was ideal that we could always do so but it is too time consuming... When you have a major concern in planning – in the choice of tasks, the choice of materials, the good questions to make them think, the knowledge that could result from the task... – it is obvious that the development of the task is much better and the results can be very positive.

The experience with the investigative tasks in the classroom allowed Petra to rethink various aspects of her practice, although the teacher was used to adopting methodologies that value the role of students and was familiar with students working in groups. The idea that it is very important to limit the support that the teacher provides to students while they are working on the tasks was strengthened. During the developmental phase of investigative tasks, Petra began to avoid giving answers and/or validating the assumptions of the students – otherwise she would prevent the development of mathematical communication and reasoning:

But... I think I can do it better, I still have the tendency to give them the answer... I need to still my tongue... I can not tell them everything, I just can tell a small part of what I am used to...

The ideas of Petra, related to the final lesson phase of discussion, also seem to have changed. The teacher began to attribute more importance to discussion and she reviewed her role in its conduct. She decided to try not to summarize, during that

Working Group 17

phase, as each student disclosed the work they had done. Instead, she became aware of the importance of promoting the discussion and reflection of all students:

You know another thing I have come to notice? Is that when they pass to the communication phase, they reveal some lack of interest... this is because I validate all the assumptions that they ask me during the work group... So, when they present their work to the class, they are already quite sure of what they say... and the others also know that everything is ok, so... there is no discussion among the groups! The next task, I would like to do something different: I will not validate anything. I will give them the task, I will ask them to do all the work and after that the class will validate... or not... I want to bring the discussion to class. They will present and after... "So, what do others think about this? Is it right, is it wrong? Why?"

THE DEVELOPMENT OF PROFESSIONAL KNOWLEDGE – FINAL CONCLUSIONS

This study shows how professional knowledge of a first-grade teacher was revealed in the development of investigative tasks in the classroom. It also shows the contributions that the teacher took through this experience to deepen and broaden her professional knowledge in various components.

It is noteworthy that this experience involved the teacher in the search for a greater understanding and deepening of her mathematical knowledge. The exploration of the investigative tasks was quite demanding for the teacher, because she wanted to be prepared to deal with the multiple assumptions that students could propose and that do not always appear so obvious to the teacher. The teacher's mathematical preparation is crucial to the development of his/her teaching practices (Leikin & Levav-Waynberg, 2007). And, the more demanding these practices are, the more complete and deep the mathematical knowledge needs to be.

This study also emphasizes that this experience provided the teacher the opportunity for reflection on some aspects of her knowledge of the instructional process. On the one hand, the teacher recognized the value of careful planning, referring to it as crucial when exploring open tasks and promoting the discussion of students in the mathematics classroom (Franke, Kazemi & Battey, 2007). On the other hand, the teacher acknowledged the advantage of introducing changes in the way she conducted the class, either at the phase of the development of the tasks by the students, or at the final phase of collective discussion. She considered it to be necessary to moderate the intervention of the groups in order to achieve more shared discussions and challenge the students to validate genuine conjectures and conclusions of other colleagues (Oliveira *et al.*, 1999).

Three main factors contributed to the development of teacher professional knowledge. One was the contact and work with challenging and powerful mathematical tasks with great potential for the mathematical experience of the teacher herself and of her students, with consequences in the way she usually

conducted the classroom (Stein & Smith, 1998). Another factor was the teacher's perception of the acceptance of the investigative tasks by the students, and of the mathematical experience and mathematical learning that they revealed – a factor of great influence in the professional development of teachers (Canavarro & Rocha, 2008; Sowder, 2007). A third factor was the focus on the teacher's teaching practice provided by the opportunity of collaborative work with the researcher, who introduced the tasks, discussed the plans of the lessons, supported implementation in the classroom and encouraged reflection on practice, based on the analysis of the episodes from the classroom (Canavarro & Rocha, 2008; Sowder, 2007).

WHY DO SOME FRENCH TEACHERS PROPOSE « *PROBLÈMES OUVERTS* » IN MATHEMATICS TO THEIR PUPILS IN PRIMARY SCHOOL ?

Christine Choquet,

IUFM des Pays de La Loire, Ph.D Cren, University of Nantes, France.

“Problèmes ouverts” in France (Arsac, Germain & Mante, 1988), literally “open problems”, they can be defined as non classical problems which aim is to develop capacities of research and argumentation. This paper analyses, using a case study, why Xavier, a mathematics teacher in primary school, proposes such a problem and how he organizes his session. It reports also a study on the knowledge which is approached during this session. Our results show that, even if the knowledge can be specified, it is still difficult to conclude on the real learning of pupils. According to us, these results become concrete subjects of reflection during teachers’ training.

Key-words : teacher’s activity, mathematics, open problem, primary school.

INTRODUCTION

Some teachers in France, in primary school, choose to propose “problèmes ouverts” (Arsac, Germain & Mante, 1988) to their pupils in their mathematics’ teaching. These non classical problems would like to develop capacities of research and to discover proofs in mathematics. Different researchers in France have worked on this subject and the studies are not ended. Differences persist, concerning the knowledge boarded in these problems or concerning the real utility for the pupils to learn to resolve them in the classroom. Arsac & al. (1988) propose a characterization of « problèmes ouverts » and insist on the implementation of these in the classroom. Glaeser (1973) proposes a classification of statements to help teachers to make the best choices for their class. Douaire (1999) shows that these problems could be the occasion to teach different forms of reasoning. Hersant (2008) proves that, when pupils study open problems, they work on mathematic objects but they study also methodologic knowledge linked to problem solving. Houdement (2009) establishes a classification of open problems, in order to explain that, if the teachers think about the choice of the problems which they propose, their pupils could develop different capacities of reasoning and also capacities to argue about their results. In our work, using a qualitative case study, we analyse the place which is reserved to these problems, in primary school. We search to understand how and why a teacher uses this type of problems and also to determine the impact of such problems on the short-term learning of pupils. In this paper, with the analysis of one session, we show the choices made by the teacher : why does he propose this problem and how does he

decide to organize the session ? We think also about the knowledge which is boarded : what could be learnt by pupils during this session, with the chosen problem ?

THEORETICAL FRAMEWORK

To answer our questions concerning the choices that the teacher makes for his/her class when he/she proposes an open problem and concerning the pupil's learning during the observed session, we use elements of the theoretical framework "double approach" (Rogalski & Robert, 2008). First, this theoretical framework suggests to consider the teacher in his/her class, with objectives of learning for the pupils and to study his/her practice in connection with the knowledge approached on the session. Secondly, this model considers teaching as a professional exercise, a job trying to reach professional purposes, with specific constraints. Like Rogalski and Robert, we take into account all the elements which constitute the practice of the teacher and we analyze these elements according to five dimensions (cognitive, mediative, social, personal and institutional). Both dimensions, cognitive and mediative, allow to characterize the practice of the teacher during his/her work of preparation before a session and during the effective progress of the session. The social and institutional dimensions allow to define the internal and external constraints of the class. With the personal dimension, we can obtain more precise answers concerning the teacher (for example, personal competencies or personal representations of mathematical notions and their teaching).

METHODOLOGY

Methodology of data collection

Xavier is a forty-year-old teacher, he has been teaching for about fifteen years and this is his fifth year in the school where the observation takes place, with classes of 9-10-year-old children ("CM2" in France). This class level is the last one in the primary school ; after this, pupils enter the secondary school ("*collège*" in France). We take this example in this paper on the one hand because Xavier has experience and is not a beginner in the concerned class level, because we have been observing him for three years (2007-2010), which allows us to have access to numerous information concerning him. On the other hand, we choose this school level because the problems which can be proposed to the pupils, seem to us to be more interesting for our study concerning the knowledge which may be learned.

The observation is led in a natural way, in the sense that we do not intervene either in the choice of the problem, or in the preparation of the session. The session is observed, filmed and transcribed. The exchanges between the pupils, and between the pupils and the teacher in working groups are recorded, to have as much information as possible on these interactions. The pupil's written tasks (drafts, posters) are collected. Conversations at the beginning of our study, then before and

after the session are also transcribed to have the teacher's opinion on what the pupils are learning during the session.

Methodology of data analysis

In the following paragraph, we will present an *a priori* analysis of the problem chosen by the teacher. We check if the problem is really a "problème ouvert" using back the characterization of Arsac, Mante & Germain (1988). We look for all the possible procedures to solve it and we determine which procedures can be used by 9-10-year-old pupils. To answer the questions concerning the knowledge which the pupils build or will have been able to build, we determine those which can be the object of synthesis, the object of institutionalization ^[1]. Concerning the practice of the teacher and the questions about his choices, we inform one by one the five dimensions to obtain more and more precise answers.

OUR HYPOTHESES ABOUT THE TEACHER

Why does he propose open problems ?

First, one hypothesis is that the official instructions in France (2008) insist on the fact that the situations of exploration, discovery or research on problems have to "*develop the pleasure of searching, the reasoning, the imagination, the capacities of abstraction, the rigor and the precision*". Other hypotheses, according to the work which were already made on the subject (Douaire, 1999 ; Hersant & Thomas, 2008 ; Houdement, 2009), can explain the reasons for the teacher's choice. And with our analysis of different open problems, we wondered which objective of learning could have a teacher with this class level. It can be a question of reinvesting simple mathematics notions. It can be also a question of discovering and learning methodologic notions useful to resolve problems (Hersant & Thomas, 2008). The teacher can have the objective to explain pupils that they can use an experimental reasoning, he can also have the objective to go farther than this experimental reasoning, to begin to use a deductive reasoning to validate their answers (Douaire, 1999 ; Houdement, 2009). Another objective put in evidence by Houdement (2009) and also by our analyses, is to teach pupils how to check their results. Finally, the proposition of an open problem during a session of mathematics can be the opportunity to develop more interdisciplinary knowledge (for example to read a poster and to expose results in front of the class, Douaire, 1999).

Hypotheses on which problems are chosen, in which resources ?

Here we do not develop the analysis made on these resources, we only specify that we are trying in particular to determine the legitimacy of the authors in the educational environment, to explain why a teacher uses such or such type of resources. According to our analysis, we conclude that the reasonable and available resources for a teacher in France are different textbooks, (*Capmaths, Euromaths, Ermel ...*),

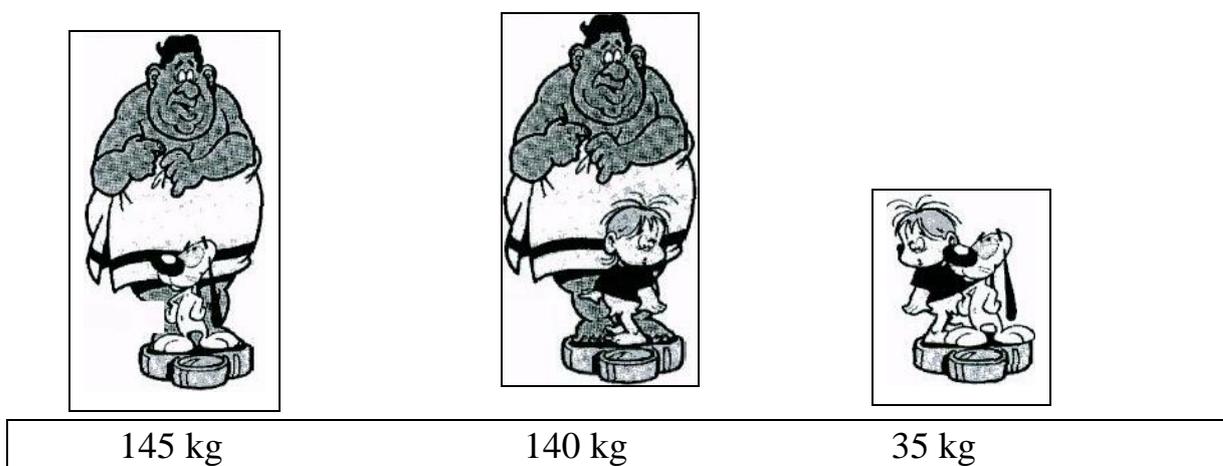

pedagogical reviews (*Grand N*) but also web sites and pre-service or in-service teachers' training.

Hypotheses on the implementation in the classroom

In the official instructions (2008), the educational freedom of the teacher is quoted. Concerning a progress or concerning the number of open problems that the teachers have to propose along the school year, nothing is specified explicitly either in the official instructions, or in the various textbooks. However, considering Xavier's age, we suppose that he worked with a document linked to the last official programs (2003) and we make the hypothesis that he keeps in memory the model of implementation which was presented in this document and that Xavier's choices in this domain are inspired by it.

AN A PRIORI ANALYSIS OF THE PROBLEM

To check a part of these hypotheses and to answer our questions, we have chosen to present the analysis of one among six sessions which Xavier proposed during the school year. The problem, which aim is to determine the weight of the dog, the child and the man, is the following one :

En utilisant les informations données par ces trois dessins, détermine combien pèsent le gros Dédé, le petit Francis et le chien Boudin.

Why is this problem a real “problème ouvert” ?

According to the characterization of Arzac & al. (1988), this problem is for Xavier's pupils a open problem. The statement of the problem is short, in the form of a drawing and an only question using a simple vocabulary for 9-10-year-old children. The situation has a concrete, daily character. It can be extracted from the everyday life. This problem can be understood by the whole class, every pupil can appropriate the situation quickly and can understand why he/she is asked to search from the first individual readings. Furthermore, the necessary mathematical

knowledge being elementary, every pupil can easily begin a research. The problem is nevertheless substantial. The answer is not immediate and asks for a research from all pupils in this classroom. Checking the result seems also possible for the pupils whatever the moment of their research. As soon as a solution appears, they can confirm it or not.

The different procedures

To resolve this problem, five procedures exist. A procedure, noted A, consists in putting in equation the problem and in resolving a system of three simple equations with three unknowns. Another procedure, B, without using the algebraic domain, consists in adding the weight of two scales and, in subtracting the weight of the third. The third procedure, C, consists in calculating the sum of the weight of the three scales, in dividing by two then in subtracting the weight registered on one of the scales. A procedure, D, is based on essays and adjustments, on experimentations. The fifth procedure, E, takes into account a five-kilogram difference between the first two scales, which allow to end after some essays and adjustments. The procedures A and B are not possible by pupils of this class level. The procedures C, D and E are possible.

Knowledge in this problem for 9-10-year-old pupils

When we determined the knowledge which can be the object of institutionalization, in this school level (“CM2” in France), the resolution of this problem especially appeals to the notion of addition, subtraction or division by two. This mathematical knowledge is not new for these pupils, this problem can be the opportunity to reuse it.

During this session, we suppose that a pupil can discover two types of reasoning : one is experimental (using essays and adjustments, corresponding to the procedure D) and the other one is deductive (a reflection on the numbers present in the statement helps to deduce elements allowing to end more quickly, corresponding to the procedures C and E). A pupil of primary school can learn also that at any time of his/her research, he/she is able to check his/her result by himself/herself (by some simple calculations and coherently with the statement’s data), without the teacher’s help.

IN XAVIER’S CLASSROOM

Throughout the analysis of the session, we inform the five dimensions of the theoretical framework of the “double approach”. The mediative and cognitive dimensions allow us to reconstitute the progress of the session proposed to the pupils. With the institutional and social dimensions, we clarify the constraints linked to mathematics teaching in primary school. The personal dimension completes the results, it allows us to answer questions concerning Xavier’s representation of mathematics teaching and it can explain some of his choices.

Xavier's choices

The analysis of this session and conversations with Xavier on this problem before and after the session, explain why he goes on proposing to his pupils this type of problems. He thus responds to the official instructions, he also convinces us that : “[...] *to make mathematics in primary school especially then in secondary school, means to try to solve problems.*”. The problem presented here is an answer to his personal representation of mathematics and representation of mathematics teaching. With such problems, Xavier wants to prepare pupils for their entry to secondary school, by teaching them to search alone or in small groups, without the intervention of the teacher. Furthermore, with previous official instructions (2003), Xavier kept in mind that the problems have to allow pupils “*to take some pleasure in searching*”. He thus chooses this funny, atypical problem which is susceptible to develop the child's curiosity and to lead them to search. The resources which he uses, illustrate this aspect. Xavier does not use either textbooks or pedagogical reviews to find problems. He just consults Web sites (discovered with the keywords like “problems to search, CM2” or “mathematical problems, CM2”) and chooses generally the most playful statements.

Implementation in the class

To precise the analysis of the session, we share it in 3 different steps ; every step corresponds to a different task asked the pupils, by the teacher.

During step 1, Xavier gives briefly some instructions (2 min). He asks the pupils to read the statement and to search individually for an answer. For a couple of minutes, the teacher pushes the resolution of the problem to become the responsibility of each of the pupils. In this case, we observe that the process of devolution^[2] on the individual level is successful.

During the longer step 2 (30 min), pupils search in small groups (four pupils) and have to draft a poster giving their answer and their explanations. The teacher is standing back, he does not intervene in the groups.

Step 3 (10 min) is dedicated to the presentation of the procedures and to the synthesis.

The pupil's activity

We also study the pupil's productions to obtain elements concerning the teacher's practice. Indeed, as C. Orange (2005) puts it, “*The productions are considered as revealing of the pupil's intellectual activity,[...] I mean “productions” in the broad sense : diverse linguistic productions, gestures, material productions [...]*”. Their personal work is going to be more easily approachable through their various productions ; it deals for our study, with linguistic productions (the explanations for example within a small group), intermediate individual productions (considered here as drafts) and final productions (here, a poster by a group of four pupils). The fact of wondering about the intellectual activity of the pupils is to have informations on the

teacher's practice (Orange, 2005). It's possible then, to establish links between this practice and the pupils' learning.

Resuming the poster of each of five groups (numbered from 1 to 5) and the individual productions of each pupil, we redraw the history of these posters ; this gives us the most likely possible idea of the reasoning which took place in every group. Having to identify the procedures of resolution, we try to organize them into a hierarchy. We find :

- Procedures which are partially mathematics (noted PMv) : a five-kilogram difference is found between the weight of the child and the dog. After chosen which one of the dog or the child is the heaviest, a subtraction gives the man's weight (groups 2 and 5).
- Procedures which touch especially other domain of rationality, the everyday life for example (noted PVm) : evaluation of a weight, essays and adaptations (groups 1, 3, 4).

A heterogeneousness of procedures appears with a majority of more or less effective PVm. Group 2 mobilizes a PMv. These pupils don't have difficulties with mathematics. They justify the five-kilogram difference mathematically but then, to justify that Francis is the heaviest, they appeal to their everyday life. Group 5 also uses a PMv, which is different from the previous one. They reflect on the numbers, the decompositions of the numbers which they find (for example, a pupil said : "35, it's 20 and 15 or 25 and 10 [...]"), which allows them to advance in their reasoning. Group 3 uses a PVm instead. Even if they find the five-kilogram difference, they do not justify it clearly and appeal then to the everyday life : "*Big person may be weigh about 100 kilograms*". This assertion directs their essays and they find the answer rather quickly. Groups 1 and 4 use a more or less effective PVm. They don't remark the five kilograms difference, they try some weights for the child, the man or the dog inspired by their everyday life (between 5 and 30 kilograms), then they just check the hypothesis made on Francis and the dog. For group 1, this check is enough but not for group 4 which does not succeed in resolving the problem correctly.

Interactions between the teacher and the pupils.

We study how these interactions are evolving to understand better how the responsibility of the learning during this session is distributed.

During step 2, Xavier is standing back, the pupils can count only on their small group to solve the problem, to exchange on their researches and their possible difficulties. Nobody asks Xavier questions about the problem and he stays behind his desk, "*to avoid the questions*" (he says). This attitude is commented by G. Brousseau (1986) who writes that the teacher "*has to, by his/her attitude, convince the children of his/her neutrality [...] so that they give up asking for the information and the help which they need, to count only on themselves*". Xavier knows, by experience that if he moves in the class, he would have difficulty not to answer a pupil and that his answer could guide too much this pupil.

Working Group 17

Xavier comes back to lead the class when step 3 begins, the step which is dedicated to the presentations of the results and the procedures. Every group exposes the answer to the class. When the answer is correct, the teacher asks the other pupils if they understood the procedure (it's resumed if needed). When the answer is erroneous, Xavier turns to the class to ask : "*Comments ? Is it correct ?*". By this attitude and this questioning, he does not leave the pupils to have the responsibility to validate or not the results that are proposed by the others, he is in fact just the person who shows what is correct or not.

DISCUSSION AND CONCLUSION

The analysis of this session allows us to clarify the choices made by Xavier when he proposes a "problème ouvert" in his class. We obtain elements to understand these choices but we think that there are certain points which must be still studied.

First, we have to continue to fathom out what pupils could learn during a session like this one and how they can learn it. We can think that Xavier's synthesis is not complete, it does not completely return on reasoning which enables to solve a problem and to check the result. So, we wonder about the capacities of the pupils to reuse the methods which they have discovered. French researchers (Robert & Robinet, 1996 ; Sarrazy, 1997) show themselves the ambiguity of the situation because of their difference of points of view. Robert & Robinet would maybe take the opportunity of this problem to specify the pupils methods and tools to solve them better : "*It's on the occasion of an activity that we can hope to teach knowledge [...] Teacher tries to offer pupils the opportunities to build and to put on a part of this knowledge.*". However, Sarrazy thinks that even if the teacher gives the pupils these methods, these tools to solve a problem, the pupils will not necessarily know how to reuse them in another situation of research. "*[...] the conditions of the use of rules and the field of application cannot be defined before, that's why it is erroneous to believe that the pupil can control himself/herself the relevance of the use he/she makes of these rules.*". So, like Sarrazy, we can also suppose that, even if the synthesis is very detailed, pupils will not know necessarily how to reuse this knowledge to solve new open problems.

Secondly, the model of the "double approach" is an effective tool for our study, to describe and understand the observed phenomena. With the study of the cognitive and mediative dimensions but also with the institutional and social dimensions, we obtain answers to our questions. However, throughout our analysis, it seems that the personal dimension holds a particular place in this kind of activity linked to open problems. This last dimension gives us important elements to explain Xavier's choices. We note that the personal dimension has a real influence on the cognitive and mediative dimensions. Indeed, the choice of the statement, of the implementation in the class, the choices made by Xavier concerning the synthesis are largely linked to Xavier's personal representation of mathematics teaching. We continue to think

Working Group 17

about the influence of the personal dimension on the cognitive and mediative dimensions to understand better teachers' practices and also in the objective to improve teachers' training.

NOTES

1. Brousseau characterizes the process of institutionalization by the fact that “*there must be somebody outside (the teacher) to come and time the activities (of the pupils) and identify those who have an interest [...]*”, Brousseau G. (2004), *Théorie des situations didactiques*, La pensée sauvage, p.282.
2. By the process of devolution, G. Brousseau wants to notice the fact that “*the teacher would like the pupil to feel like holding the answer only by himself*”, Brousseau G. (2004), *Théorie des situations didactiques*, La Pensée sauvage, p.303.

THE NEED TO MAKE ‘BOUNDARY OBJECTS’ MEANINGFUL: A LEARNING OUTCOME FROM LESSON STUDY RESEARCH

Dolores Corcoran

St Patrick’s College, Dublin City University

In this paper I examine how three student teachers used ‘ready prepared’ lesson plans as a teaching resource. These might be considered ‘boundary objects’ since they were developed in one practice, for possible use in others. The paper draws on a yearlong study of student teachers that opted to take a course called Learning to Teach Mathematics Using Lesson Study. The students and myself as course tutor and researcher sought to develop a research-based approach to designing and implementing problem-based mathematics lessons. Findings were that ‘boundary objects’ were not always used as intended and successful participation in the practice of lesson study focusing on children’s responses to the mathematics to be taught depended on negotiating shared meanings for specific curricular objectives and teaching materials.

Key words: boundary objects; community of practice; lesson study; student teachers

INTRODUCTION

As public interest in mathematics teaching and learning has increased over the past twenty years, so has the output of commercially produced textbooks and teaching resources increased. Of course, the availability of a comprehensive variety of research-based materials to assist in teaching mathematics is to be welcomed. However, the phenomenal communication explosion arising from global access to the internet has resulted in a proliferation of ‘off the-shelf’ mathematics teaching resources, some of which deserve to be used with caution. There is a propensity - particularly among student and novice teachers - to seek out novel and easily accessible teaching aids that they proceed to use in their classrooms without question. This tendency has been encouraged by the electronic publication by some government bodies of such plans (National Numeracy Strategy, 2006). Despite the perception that such materials should be ‘teacher-proof’, their adoption by some teachers can be problematic. Difficulties in implementation are sometimes attributed to deficits in teacher knowledge either of mathematics subject matter or of pedagogical content knowledge (Ball and Cohen, 1996). The study reported here sought to research how third year student teachers would use off-the-shelf resources while engaging in lesson study.

LESSON STUDY

The practice of Japanese lesson study has been gaining acceptance, as a means of developing the teaching of mathematics, particularly in the USA (Fernandez, 2005), the UK and Ireland (Corcoran and Pepperell, 2011) since the practice was identified

by Stigler and Hiebert (1999) as a possible contributory factor in the mathematics achievement of Japanese students where lesson study is integral to the education system in primary and secondary schools and in teacher preparation (Isoda, 2007). In 2006, Lewis, Perry and Murata appealed for further research into how the demonstrable improvements in instruction brought about by participation in lesson study might be explained. They themselves offered two conjectures. One, that participation in lesson study generates “refined lesson plans”; that is, that the *products* - the “actionable artefacts” -created by the lesson study team are the most important contribution, and two, that participation in the *process* of lesson study enhances teachers’ pedagogical content knowledge, teachers’ commitment and community and teaching-learning resources (ibid., p. 287). These scholars appeared to favour conjecture two and suggested that conjecture one might be dismissed as ‘polishing the stone’ a fruitless exercise that did not warrant sustained pursuit. However, there is a resonance with conjecture one to be found in the “teaching-learning resources” element of improved pathways to mathematics teaching through lesson study. Further research among US teachers participating in lesson study to enhance the teaching of mathematics confirmed findings that conjecture two was the more valid *raison d’être* for lesson study where the emphasis on *process* rather than *product* was facilitated by four major changes: (1) increased use of reflection and feedback loops; (2) refinement of protocols and tools; (3) increased use of external knowledge sources; and (4) increased focus on student thinking (Perry and Lewis, 2009). Yet Japanese proponents of lesson study continue to publish detailed annotated lesson plans and regard a sustained and focused period of study of these and other resource materials as an essential element of lesson study (Takahashi, Watanabe and Yoshida, 2006). It appears from this study that sustained engagement in the process of collaborative negotiation of shared meanings is necessary to optimise use of lesson materials and resources.

THE LESSON STUDY PROCESS

Lesson study is a cyclical approach to improving teaching through collaborative planning of a ‘research lesson’, which one person teaches, while observed by others who then review the lesson. It is premised on the Confucian saying that “seeing something once is better than hearing about it one hundred times” (Yoshida, 2005). Its ultimate purpose is to gain new ideas about teaching and learning based on a better understanding of children’s thinking so the observation of actual research lessons is at the core of the lesson study process. The lesson study cycle however encompasses much more than studying children’s responses while observing a research lesson. It requires time dedicated to intensive *kyozai kenkyu*, - a process in which teachers collaboratively investigate all aspects of the content to be taught and instructional materials available – and to *jyugyo kentuikai* – the post lesson review session (Takahashi, Watanabe, Yoshida and Wang-Iverson, 2005). In this paper, I will briefly outline the lesson study research process as practised by six student

Working Group 17

teachers during two cycles. Then I will draw on data which indicate the different uses made of a particular ‘boundary object’ - a unit lesson plan adapted from the English National Numeracy Strategy on-line resources (NNS, 2006) - by Irish student teachers –Teresa and Finola - in the research lesson they each taught concurrently during lesson study cycle one. Next, I will refer briefly to a second boundary object, a recommended lesson plan (Burns, 1987), which was adopted and taught by one of the students, Ethna, in lesson study cycle two. Ethna’s treatment of this ‘ready made’ lesson will be discussed, together with findings from another lesson study group of US teachers who adopted the same lesson as a ‘research lesson’ (Fernandez, 2005). First, I outline what I mean by boundary objects.

THEORETICAL PERSPECTIVE

The term “boundary object” was coined by Star and Griesemer (1989, p. 388) to describe:

objects which are both plastic enough to adapt to local needs and constraints of the several parties employing them, yet robust enough to maintain a common identity across sites ...They may be abstract or concrete ... The creation and management of boundary objects is key in developing and maintaining coherence across intersecting social worlds.

The notion of boundary objects has found particular resonance in computer science where “design continues in usage” (Rabardel and Bourmaud, 2003, p. 666), and “the conceptualisation of instruments [is] an activity distributed between designers and users” (Rabardel and Waern, 2003, p. 643). In such a context “interpretative flexibility” serves a recognised and useful purpose (Ruthven, Hennessy and Deaney, 2008). However, in mathematics education particularly, the fidelity or otherwise in interpretation of textbooks, designed in one community for use by another community has been problematised (Haggarty and Pepin; 2002). In researching communities of practice, Wenger (1998) uses the construct of ‘reification’ to explain the collaborative process of giving ‘thingness’ to inanimate or intangible aspects of practice, which imbues them with negotiable meaning within the practice and renders them portable. Because the products of reification within one practice may be transported to other practices they become “boundary objects”. By such a definition, the mathematics curriculum, mathematics textbooks and ancillary teaching resources all constitute boundary objects, the potential value and actual meaning of which have to be negotiated afresh by the community where they are being used. According to Wenger (ibid.) participation in the practice is synonymous with negotiating shared meanings for each object used within the practice. In this study, which presents an account of pre-service teachers engaging in lesson study, the interplay between participation in the practice of teaching problem-based mathematics lessons and the reification therein of certain understandings of mathematics and of mathematics teaching resulted in a growing respect for boundary objects and their potential value in teaching mathematics.

THE STUDY

This research project – tier three of a larger study into the development of mathematical knowledge for teaching (Corcoran, 2008) – involved forming a community of practice dedicated to learning how to teach primary mathematics from a reform perspective. The differing ways in which a mathematics teachers' community of practice can develop has been reported at CERME 6 (Reinup, 2009) and the community of practice comprising six third year Bachelor of Education students and myself as course tutor and researcher seemed to exhibit the necessary qualities she outlines. We adopted Japanese lesson study as a model for teacher development and three cycles of lesson study were pursued over the course of one academic year. In each lesson study cycle, student teacher participants prepared two mathematics lessons collaboratively. For the research lessons the students divided into two groups and went to different schools. Then, one student taught a research lesson, observed by two other students who studied children's mathematical responses during the lesson. Each research lesson was video-recorded. I was present at one of the research lessons during each lesson study cycle. The research lesson experience was followed by a reflective meeting to analyse the lessons using the Knowledge Quartet (KQ) framework as a means of focusing on different dimensions of the mathematical content of the lesson (Rowland, Huckstep and Thwaites, 2005). Together with serving as an analytic framework for looking at mathematics teaching along its four defining dimensions of *foundation*, *transformation connection* and *contingency*, the language labels of the eighteen contributory codes for the KQ became part of the "shared repertoire of ways of doing things" (Wenger, 1998, pp. 82-84) within the community and helped to focus the student teachers' engagement with the problem-based mathematics teaching enterprise. The potential of lesson study as a means of bridging the gap between planning and pupil learning outcomes was discussed at the first meeting and the possibilities for developing teaching inherent in observing pupils' responses were mooted. I was party to the lesson study process both as researcher and as course tutor/knowledgeable other and was also engaged in negotiating meanings for these roles (Corcoran, 2011).

THE RESEARCH LESSONS IN CYCLE ONE

During the initial preparation meeting of cycle one, the students opted to teach lessons from the Measures strand of the Irish primary curriculum. They chose the strand unit *weight*, because they perceived the teaching of 'weight' as difficult. The lesson study group had two three-hour meetings before this lesson was taught and various realistic contexts for teaching weight were discussed. The fact that 9-10 year old children 'should' and were already likely to know something about standard units of measure and reference to the curriculum objectives led students to adopt a somewhat ambiguous goal for the lesson; "that children would learn about the weight of a kilogramme". After much exploratory discussion a context for engaging children in the mathematics of weight was suggested and discussed; the directive that

Working Group 17

carry-on luggage on a Ryanair flight must not exceed 10kg. Students discussed their goals in approaching the lessons and the learning outcomes they hoped for their pupils, and how these could be recognised. Much discourse focused on the logistics of organising a lesson - time to be spent on pair work, group work and the time and place for teacher talk. These might be termed generic pedagogic concerns. The students organised their lesson plans according to the usual recommended 'introduction', 'development' and 'closure' phases. In one research lesson, Treasa introduced a problem: 'Would you be able to take your school bag on a Ryanair flight where there is a restriction of 10kg on carry-on luggage?' Children, in groups of six, were asked to compare and order their school bags by hefting them from hand to hand and to record their findings on a scale, - a straight line with six equally spaced marks - which Treasa drew on the board.

In the other research lesson, the problem was phrased as: 'How heavy is your schoolbag in relation to your body weight?' As a conclusion to the investigation Finola drew a scale, going from 0 to 3.5kg, on the board and invited children to tell her where to place their school bags on this scale according to their weight. As she talked, Finola began to draw a horizontal line across the middle of the board. This she calibrated with whole numbers from 0 to 3 then a mark midway between 3 and 4 to denote 3.5 and finally 4. She knew Tom's bag was heaviest at 4 kg and recorded his name over the four. She left intervals of less than 30cm in length between the whole numbers. If she had planned to record the weights of schoolbags and names of every one in the class it might have been better to have made the intervals much bigger, but Finola and her lesson study colleagues had not anticipated the complexity of the mathematical task the lesson involved. Finola's hand hovered indecisively between 0 and 1 on the scale and she finally marked a point half way between them as 100g with Sean's name underneath. Quickly she prompted the Joe, "... and yours was 500g?" At this stage Finola rubbed out the 100g and put in 500g, then rubbed out the 500g and put a child's name under the 1kg mark.

Child: One kilo.

Child: Mine weighed four grammes.

Finola: Four grammes? Really?

Finola decided to conclude the recording of school bag weights there, by saying:

Finola: Ye're all good. You've all got safe schoolbags. They're not going to damage your back at all are they? I don't think so. Now ...

While there were many similarities in the two research lessons, there were many differences in how they turned out. Some of the lesson study group's critical reflection on the two lessons focused on where each of the student teachers had modelled the recording of children's details on a scale. Treasa was confident in her teaching that calibrations should be equally spaced to represent the weights of the six school bags per group. She appeared to convey certainty and control in her handling

of the lesson but later expressed doubts about what she had done. In contrast to Treasa's lesson and a tighter approach to planning for teaching, Finola's lesson and approach appears loose, fluid and more dialectical. Finola also had a particular representation of a scale in mind and she was nonplussed when the messy, uncertainties of children's findings were presented. Obviously she was expecting neat, manageable round numbers of kilogrammes and half kilogrammes, instead children offered 900g, 500g 100g, 3g and 4g and her lesson could be challenged along both *connection* and *contingency* dimensions, of the KQ (Rowland, Huckstep and Thwaites, 2005) not because she didn't know the relationship of grammes to kilogrammes but because she couldn't think where they would fit on her scale.

Recording on Scales Revisited

During the post-lesson reflective session on Treasa's research lesson of comparing weights of school bags, the lesson study group did the activity again themselves using their handbags and the purpose of the calibrations on the scale immediately became questionable. This ordering of bags could be matched to the scale but not to the marks where she as teacher had proposed putting the names of children who owned them. As the student teachers began to realise, this was an ordinal scale only and they had no way of knowing at what intervals the school bags should be marked. It was possible that two or more bags could be mapped to the same point on the scale. With regard to Finola's scale, the group explored the possibility of extending it by asking the children to imagine the space between 0 and 1 to be a much longer line and drawing that underneath and calibrating it in hundreds of grammes. It was an exciting discovery for these student teachers to think that they could do exactly the same with space between 0 and 100g and calibrate that space in tens of grammes. This notion of there being no such thing as an exact measure appeared new to the students and they began to think in terms of the arbitrariness of units and instruments, and the pedagogical purpose of the recommended use of a scale for recording weights.

ETHNA'S RESEARCH LESSON IN CYCLE TWO

In lesson study cycle two, the complexity of the boundary object was greater although it was a much more explicit and detailed pre-determined lesson plan that was used. It was the teacher of the research lesson, Ethna, who had strongly advocated the use of a particularly detailed lesson plan she had chosen. Ethna's lesson study group of two other students agreed an already tested lesson script published by Marilyn Burns (1987) and took pains to set the scene and involve the children in hands-on activity manipulating the fraction pieces. Ethna and her two colleagues brought paper cut outs of cookies and had prepared worksheets for the children and enlarged versions to hang on the board as she explained the tasks. Children were to manually divide four, then five, three and seven paper 'cookies' among four children. The lesson concluded with Ethna simply telling children the

meaning of the symbols for a half and a quarter. She drew circles to represent 'wholes' on the board and shaded in the appropriate fractional pieces, finally asking the children to copy these representations into their copybooks.

Burns (1987, p. 40) describes the mathematical potential in the summarizing of the lesson and Ethna's careful preparation of worksheets ensured that she too had provided material for mathematical discussion with each of her three groups. But at the end of her lesson, Ethna chose to revert to an older, more traditional form of teaching which involved children in copying teacher's work and learning mathematics by looking, listening and remembering. Instead of following through with facilitating children's learning about fractions by discussing their solutions to the activities she had so carefully prepared Ethna closed the lesson by returning to routines of teaching mathematics she may have experienced as a child (Cooney, Shaely and Arvold (1998). It may be she felt 'safer' as teacher in this role or it may be that she felt the mathematics could be more 'safely' transmitted by this mode of teaching. When pushed for time Ethna 'forgot' to ask important *connection* questions but 'remembered' to rely on routines. It appeared that Ethna had persuaded her colleagues that this was a suitable lesson, who had explored and resourced its use without question, but when engaged in the actual teaching of the lesson she ignored the fact that by using Burns' lesson she had challenged the children to reason mathematically about fraction pieces, a task they had completed with considerable success. Instead, Ethna treated the Burns' lesson as a boundary object with little meaning for her practice beyond 'going through the paces'. She finished the research lesson with an impromptu and unplanned return to 'teaching by telling'. The pedagogical meaning of the boundary object had not yet been successfully negotiated nor integrated into the lesson study practice.

DISCUSSION

A critical approach to the sparseness of the curriculum guidelines and the class textbooks in terms of important mathematics emerged from lesson study cycle one, and coupled with detailed observation of the children's talk and actions began to be transformative of practice. The idea of the scale had been imported from the National Numeracy Strategy Unit Plan 4, without heeding the significance of differing calibrations of scales on OHT4.3 (NNS, 2006). This document represented a boundary object (Wenger, 1998, p. 107) for the community, and could be said to represent other mathematical material to which the student teachers were exposed but which they did not necessarily make meaningful. Lesson study advocates recommend that teacher participants actually do the mathematics together that they propose to use in the research lesson. Our lesson study community had done so but in a cursory manner that had not accessed mathematics involved in sufficient depth. The NNS unit plan suggestion remained a boundary object to these student teachers until they had studied its use and negotiated its meanings in relation to the two applications of the problem of recording weights of children's school bags in their

actual research lessons. Much of the work of the lesson study community of practice over the following weeks was to critically align their own experiences and beliefs about mathematics teaching with the skeletal list of teaching objectives in the primary curriculum and to flesh out the resultant lessons from available resources in order to maximise the children's learning. In the light of these two lessons, it appears that suggesting contexts and providing resource materials is not support enough for student teachers. Alignment with the aims of the enterprise of learning to teach mathematics requires development of a deeper understanding of the mathematics to be taught, which in these instances were rooted in studying the actual teaching of research lessons.

The same 'off-the-shelf' lesson (Burns, 1987) which Ethna's group chose to teach as a research lesson has also been used by a lesson study group in the US where that group's learning from the process has been documented and studied in relation to two research questions: a) what opportunities to learn about mathematics for teaching does lesson study offer and b) to what extent can participants take advantage of these opportunities when they often bring limited subject matter knowledge to the situation (Fernandez, 2005). Unlike Treasa, Finola and Ethna, the teachers in Fernandez study were practising teachers with some years experience and her work shows evidence of opportunities for learning pedagogical content knowledge afforded to them by engaging with, discussing and adapting Burns lesson for teaching as a research lesson. She argues that the act of sustained and focused engagement in studying and interrogating the pedagogical implications of the lesson itself, despite their limited subject matter knowledge, acted "as a vehicle for teachers to learn about content in a way that directly feeds into their understanding of how best to teach this content and an incentive to learn more" (ibid., p. 282). Similarly, the student teachers in my study benefited from adopting, trialling, interrogating and adapting boundary objects and participation in this *process* resulted over time in meaningful learning of mathematics *in* and *for* teaching.

CONCLUSION

I have chosen the three cases of Treasa, Finola and Ethna because the manner in which these student teachers (and practising teachers in the US) used the boundary objects in the examples cited above might be attributed to their limited knowledge of the potential for mathematical thinking inherent in the objects, but such a conclusion is not helpful, nor does it tell the full story. Subsequent collaborative work - during which the lesson study participants teased out the possible mathematical meanings, children's likely and actual responses to the mathematics and the teachers' explicit teaching and learning objectives - contributed in each case to increased mathematical subject matter knowledge, more focused and refined pedagogical content knowledge and a desire to go on learning through further engagement in lesson study. I conclude that engagement in a sustained, communal and situated, research-oriented approach to mathematics teaching is necessary if the uses of the many valuable resources

available are to be optimised. This finding has implications for the interpretation and implementation of curricula, of prescribed textbooks and ancillary resources and for the continuing professional development of teachers. It could give rise to “intelligent teachers using intelligent curricula intelligently” (Russell, 1997). By recognising ‘new’ resource materials as boundary objects, deeper understandings of mathematics, of curriculum and of teaching become a focus for negotiation of meaning as participants in lesson study engage with their initial interpretations, enact them, then renegotiate and refine them as “a work in progress” (Wenger, 1998, p.158). In this manner, learning to teach mathematics from a reform perspective involves a state of “constant becoming” (ibid, p. 154) and the practice of lesson study itself becomes the curriculum, where both conjectures concerning the power of lesson study to improve the teaching of mathematics complement each other.

ANALYSIS OF THE TEACHER'S ROLE IN AN APPROACH TO ALGEBRA AS A TOOL FOR THINKING: PROBLEMS POINTED OUT DURING LABORATORIAL ACTIVITIES WITH PERSPECTIVE TEACHERS

Annalisa Cusi, Nicolina A. Malara

Università di Modena e Reggio Emilia

In this work we present an activity we carried out with perspective teachers (PTs) during a brief training course aimed at providing them with theoretical and methodological tools useful for the analysis of class processes concerning the development of reasoning through algebraic language. After an outline of the theoretical framework we introduced during the course, we will deal with the problem of the use of theory in the analysis of class processes, highlighting the difficulties faced by PTs.

Keywords: teacher education; algebraic thinking; analysis of class processes; theoretical tools; reflection on practice.

TEACHERS' PROFESSIONAL DEVELOPMENT: THE SIDE OF THE ACTION IN THE CLASS

For reshaping teachers professionalism several scholars stress the importance of a critical reflection by teachers on their own activity in the classroom (Mason 2002; Jaworski 2003). Mason, in particular, claims that the skill of consciously grasping things comes from constant practice, going beyond what happens in the classroom, and recommends the creation of suitable social practices in which teachers might talk-about and share their experience. Also Jaworski (2004) stresses the effectiveness of communities of inquiry, constituted by teachers and researchers, emphasizing how teachers' participation in these groups helps them develop their individual identity through reflective inquiry.

Our research model is framed in these conceptions, but it also stems from the Italian model of research for innovation, which unites both an innovation in teaching and a promotion of teachers' professional development. According to this model the interaction between researchers and teachers plays an important role in the training processes in which teachers are involved before and during the experimentation of innovative didactical paths. The key-idea is that research and practice develop in a dialectical process: theoretical results produced by researchers are supported by teachers' practice and evolve through it (Malara&Zan 2002).

In our work, on the side of teachers' professional development, we study difficulties and effects of practices involving collective reflection, identifying categories of behaviour that may be productive for students' conscious learning (Cusi&Malara 2009). Our research experience with teachers made us aware of the difficulties they

meet in both designing and implementing socio-constructive teaching. Therefore, we set up and experimented instruments and methods to empower their way of managing whole-class discussions (Malara 2008). Our report takes place in this frame and, precisely, it concerns with the analysis of the role played by the teacher during activities aimed at a renewal in the teaching of algebra, in a perspective that will be outlined in the following paragraph.

THE DIDACTIC OF ALGEBRA: OUR MODEL AND THE ROLE OF THE TEACHER

Our vision of the didactic of algebra has developed in a framework in which algebraic language, conceived as a fundamental tool in modelling and in the development of reasoning, is the key-element. Many research studies support an approach to the teaching of algebra aimed at helping students develop an awareness about the role played by algebraic language and the importance of studying it (see for instance Arcavi 1994, Arzarello et Al. 2001, Kieran 2004). Many of them stress the need of devoting more time to activities for which algebra is used as an effective tool but which are not exclusive to algebra (global/meta-level activities according to Kieran's distinction). Referring to the problems related to this particular approach to algebra, Arzarello *et Al.* (2001) stressed that an awareness of the power of algebraic language can be developed only once the student has mastered the handling of some key-aspects that arise in the development of algebraic reasoning. In particular, the authors highlight the use of *conceptual frames* [1] and *changes from a frame to another* and from a knowledge domain to another as fundamental steps in the activation of interpretative processes. Moreover, Boero (2001) argues that *anticipation* [2] is a key-element in producing thought through processes of transformation.

Since we agree with Wheeler's idea (1996) that activities of proof construction through algebraic language could constitute "a counterbalance to all the automating and routinizing that tends to dominate the scene", these kind of activities play a central role in our approach to the teaching of algebra. Therefore we planned and implemented an introductory path to proof in elementary number theory, to be inserted, in coordination with syntactical activities, in the math curriculum of classes of the first biennium of secondary school (grades 9-10). In our experimentations we were able to highlight the difficulties faced by teachers in making their students develop both the fundamental competences for the constructions of proofs through algebraic language and an awareness of the role played by algebraic language during these kind of activities. Therefore we decided to focus on the crucial role played by the teacher during the educational process. Our hypothesis is that teacher's attitudes and behaviours in the class are decisive in fostering (or inhibiting) students' construction of the competences which are necessary for the development of reasoning through algebraic language.

Our research framework about the teaching and learning processes is based on these three fundamental ideas: (1) thanks to the interaction with adults or with more expert peers, the students can activate internal learning processes which help them achieve a higher level of mental development (Vygotsky 1978); (2) one of the main aims of teaching should be fostering, through activities performed in social contexts, a real awareness of the learning process, focussing on the meaning of the actions which are performed in the class (Leont'ev 1977); (3) in order to foster a meaningful learning it is necessary to give students “the opportunity to observe, engage in, and invent or discover expert strategies in context” (model of the *cognitive apprenticeship*, Collins, Brown and Newman, 1989). Giving this opportunity is possible if the teacher is able to bring cognitive and metacognitive tacit processes into the open, trying to make thinking visible. We were inspired by the idea of a teacher who is able to activate in his/her students behavioural processes which are similar to the ones he/she activates in order to identify effective strategies for problem solving. Therefore we decided to focus on one of the possible roles that a teacher could play in the class: the role of model, which is particularly significant especially in the context of activities of proof construction through algebraic language, central in our project. Our research studies made us develop the idea of defining the theoretical construct of *teacher who poses him/herself as a model of aware and effective attitudes and behaviours for students* (Cusi&Malara 2009). In order to make the features of this construct clearly explicit, we will analyze a class discussion, proposed during a laboratorial activity which will be discussed in this report.

THE ANALYSIS OF A CLASS DISCUSSION AND THE CONSTRUCT OF TEACHER AS A MODEL OF AWARE AND EFFECTIVE ATTITUDES AND BEHAVIOURS

The following discussion refers to the second phase of our introductory path to proof through algebraic language. The class (10 grade) has already faced activities of translation from verbal to algebraic language and vice-versa. The problem posed to students is the following: “*how can we justify that, if n is an odd number, n^2 is an odd number too?*”. In this particular phase, the teacher aims at making students understand the limits of a verbal justification and at guiding them to a conscious use of algebraic language, showing them how to face these kind of problems. During the initial phase of the discussion, two students propose to formalize the hypothesis of this implication through the equality $n=2x+1$. The following excerpt refers to the course of the activity.

1. T [3]: (*addressing A, one of the two students who propose the formalization $n=2x+1$*)
How can we convince ourselves that if $n=2x+1$, then n^2 is odd?
2. A: Because an odd number to the second power gives an odd number.
3. T: How can we see this?

Working Group 17

4. A: Because odd times odd is odd!
5. T: So here there is the concept of multiplication. (*Addressing the class*) They say: if I multiply an odd times an odd, where do I find factor 2?
6. B: I don't find it.
7. T: So, it is odd.
8. T: And you, Z, how can you see it?
9. Z: Squaring an even number, you get an even. Adding 1 to an even, you get an odd.
10. T: Hold on. Here I read n^2 . Why are you saying "I add 1"?
11. Z: $2x+1$ squared gives an odd number because: $2x$ squared is $4x^2$, then there is plus 1.
12. T: $(2x)^2$ is $4x^2$.
13. T: You say $(2x)^2=4x^2$. $(2x+1)^2$ is $4x^2+1$?
14. Chorus : No !
15. T: Let's get back to what Z says. I can't say that $(2x+1)^2$ is $4x^2+1$. But if I want to convince you that $(2x+1)^2$ is odd, what can I do?
16. O: Let's solve it! (T writes $(2x+1)^2=4x^2+4x+1$)
17. T: Now there is "+1" ... This quantity here is the problem (*points to $4x^2+4x$*).
18. P: Let's make the total: we take out $4x$.
19. T: Do we really need to take out $4x$?
20. O: It's enough to take out 2.
21. T: Why 2?
22. O: Because then we can highlight an even number, plus 1. (T writes $2(2x^2+2x)+1$)
23. Z: But $4x^2+4x$ is the same as $2(2x^2+2x)$!
24. T: Yes, it's the same thing.
25. Z: Ah, I see why! Because taking out 2 you see you get an even. [4]

Let us analyze this discussion from the point of view of both the different roles played by T and the students-teacher interaction, trying to highlight: (1) weaknesses and strengths of the discussion, with reference to the application of conceptual

Working Group 17

frames and anticipating thoughts and the coordination between different frames; (2) the role played by the teacher as a “stimulus” to foster an approach to algebra as a tool for thinking, and as a “model” and “guide” in the construction of reasoning. The excerpt can be broken down in three distinct moments: (1) phase of verbal argumentation (lines 1-7); (2) towards a formalization of the property (lines 8-14); (3) proof of the property and reflection upon the importance of choosing a certain representation (lines 15-25).

In the first phase of the discussion A enacts the frame “factorization of a number” to make explicit to the class the justification at the basis of her answer (line 4). Despite her attempt to formalise the answer, A only proposes a purely verbal argumentation. The teacher immediately sets herself in the same frame as the pupil and repeats the reasoning proposed by A to the rest of the class, pointing out the relationship between the fact that 2 is not in the factorisation of n and the fact that n^2 is odd (lines 5 and 7). Through the metaphorical question “where do I find factor 2?”, T reminds that 2 is not a factor in the multiplicative representation of an odd number. Though T seems to pose him/herself only on the operative level, neglecting the metacognitive one (there seems to be a lack of an aloud reflection), this particular arithmetical knowledge was already well-established in the class, therefore it can be an implicit assumption in the development of reasoning. T’s third statement (line 7), which reinforces A’ assertion, seems to block a discussion about the need of a formal proof of the property. Actually, because of the particular moment in the class activity (recollection of students’ different point of views), T refrains from intervening in order to pose him/herself as a listener. This fact becomes clear when T invites an other student (Z) to express her reasoning (line 8).

Z’s intervention (line 9) is immediately taken by T as an opportunity to introduce the class to a justification of the property based on algebraic formalization. Z, in fact, refers to the additive representation of odd numbers to justify her answer, trying to co-ordinate the frames “even/odd” and “polynomials” while she is trying to ‘mentally’ manipulate the expression $(2x+1)^2$. Although Z activates a good anticipating thought (she grasps the idea that the objective is to transform the expression until it gets to the form “an even number plus 1”), she faces some difficulties at the level of syntactical transformations, probably because she tries to proceed only verbally. This is a moment in which T must try to foster in students an harmonic balance between semantic and syntactic aspects. When Z makes an evident mistake in calculating the square of a binomial, the teacher poses him/herself as a reflective guide, echoing the student in the form of a question asked to the whole class (lines 12 and 13). Once he/she has amended Z’s mistake, T underlines the objective of the syntactic manipulations carried out (line 15) and asks the class to suggest him/her how to proceed. In this case, T is playing a double role: investigating subject, putting to the class the question of researching a path suitable to reach the prearranged objectives, and activator of anticipating thoughts, clarifying

the aim of the activity in order to foster the activation of the “even-odd” frame and the research of the correct syntactical treatment to be performed.

Following O (line 16), T gets to construct the expression $4x^2+4x+1$. At this point, the teacher decides to guide the activity, playing the role of an investigating subject. She actually remarks that “+1”, Z had mentioned, is in the determined expression, but she points at the remaining binomial $4x^2+4x$ as a “problem to be solved” (line 17). In this way, she lets the class guide the activity, although she remains the point of reference for the discussion. Through this technique, the teacher again acts as an activator of anticipating thoughts. After P shows he has not enacted a correct anticipating thought (line 18), T echoes P’s proposal, sending it back to the class as a question (line 19). At this point, O enacts the correct anticipating thought, suggesting that 2 might be taken out (line 20). T asks her to justify her idea, so that she can make what she has activated explicit to the whole class. The comment by Z (line 23) shows that the pupil has not interpreted the objective of the manipulation within the frame “even-odd”: she actually shows she has not understood the sense of taking out a factor 2 from $4x^2$ and $4x$. T decides to echo her (line 24), simply repeating that the pupil’s statement ($4x^2+4x$ is the same as $2(2x^2+2x)$) is right. At that moment Z realises that taking out 2 is a way to make explicit the fact that the expression $4x^2+4x$ is even (line 25). It is important to stress that T always tries not to impose the moments devoted to reflection: her way of repeating students’ assertion, also if they are erroneous, and of sending back students’ question to the whole class is a clear methodology aimed at stimulating students’ development of reflective attitudes and metacognitive acts.

This analysis can help the reader clarify some of the definitory elements of the construct of *teacher who poses him/herself as a model of aware and effective attitudes and behaviours* (TMAEAB). This kind of teacher must: (a) be able to play the role of an *investigating subject*, stimulating in students an attitude of research on the problem being studied, and acting as an *integral part* of the class in the research work being activated; (b) be able to play the role of a *practical/strategic guide*, *sharing* (rather than transmitting) knowledge with students, and of a *reflective guide in identifying effective practical/strategic models* during class activities; (c) be aware of his/her responsibility in maintaining a *harmonized balance between semantic and syntactic aspects* during the collective construction of thought processes through algebraic language; (d) try to *stimulate and provoke* the enactment of fundamental skills for the development of thought processes through algebraic language, playing the role of both an *activator of interpretative processes* and an *activator of anticipating thoughts*; (e) stimulate and provoke *meta-level attitudes*, acting both as an *activator of reflective attitudes* and as an *activator of meta-cognitive acts*.

LABORATORIAL ACTIVITIES WITH PERSPECTIVE TEACHERS

The activities we refer to in this paper involved a group of 10 new graduates

particularly motivated, who still have not worked in school and, waiting for new rules about teacher training courses from the Ministry of Education, expressly have asked to the Science Faculty to organize a brief course propaedeutic to teacher training. As we stressed previously, the training paths for teachers that we usually propose are characterized by a constant dialectic between theoretical aspects and didactical implementation. In the moment we had to work with PTs who still have not had the opportunity to enter in the classes, neither as observers, we faced the problem of a lack in this dialectical relationship between theory and practice. Therefore our main aim became that of giving them theoretical and methodological tools to learn how to interpret their future actions in the classes. The methodology we adopted during this course is strictly connected with this particular situation, but it is in tune with the framework we outlined before. In fact, the activities we performed with PTs can be considered preparatory to the critical reflection they will have to do when, as teachers, they will have to analytically examine their actions to improve the effects of their practice. The course (20 hours) was subdivided into 5 sessions. The activities started with a session devoted to the presentation of: (1) our theoretical framework for the didactic of algebra; (2) the different activities about this theme we realized in the classes, highlighting in particular the experimental path for the construction of proofs through algebraic language (carried out with 9-10 grades students). During the following sessions PTs were involved (sometimes individually, sometimes in groups) in activities of reflection about class practices: we proposed them to analyse excerpts of both class and small groups discussions (produced during our experimentations). Every activity of reflection was followed by a collective discussion aimed both at activating a comparison between PTs and at introducing, not in a transmissive way, theoretical issues about methodological aspects of teaching-learning processes, in order to gradually outline our framework.

In order to investigate the incidence of PTs' learning of theoretical aspects in their capability of analyzing the role of the teacher during class processes involving the development of reasoning through algebraic language and to highlight the problematical aspects connected with their use of theory in performing this kind of analysis, we devote the last part of this paper on a particular activity of reflection, individually faced by PTs, characterized by the analysis of the previous discussion (see paragraph 3). In the following we will present the task proposed to PTs and our qualitative analysis of their answers. The aim of our analysis is to highlight the difficulties faced PTs: (a) in referring to the theoretical constructs to analyse T's attitudes and behaviours during the discussion and (b) in contextualizing T's actions in tune with the particular didactical moment that the class is living.

PROBLEMATICAL ASPECTS HIGHLIGHTED IN PTS' REFLECTIONS

We asked PTs to highlight: (1) weaknesses and strengths of the discussion, with reference to the activation of conceptual frames, coordination between different

frames and activation of anticipating thoughts; (2) the moments in which T plays the role of a TMAEAB; (3) the moments in which T's approach differs from the approach which characterizes a TMAEAB; (4) the (positive and/or negative) effects of T's work on students during the discussion. The analysis carried out by PTs are prevalently line-by-line. Only one PT was able to rationalize local observations in an objective and argued frame about T's attitudes and behaviours. In this paragraph we will focus, in particular, on the problematical aspects highlighted by our study of PTs' protocols, referring to three main aspects: (1) appropriation of the theoretical constructs of reference and their use in performing the analysis of the discussion; (2) interpretation of T's actions with reference to the context (didactical project, particular didactical moment); (3) highlighting of the interrelation between T's behaviours and students' behaviours.

In regard to (1), the examined protocols can be subdivided, referring in particular to the TMAEAB construct, into the following four categories: (a) the PT has interiorized the theoretical construct and he/she is able to refer to it in a pertinent way; (b) the PT recognizes, within the class process, typical components of a TMAEAB, but he/she is not able to identify the specific actions which characterize the highlighted components; (c) the PT only partially recognizes the components which characterize a TMAEAB and he/she does not conduct a punctual analysis of the discussion, making sometimes improper references to theoretical constructs; (d) the PT proposes a naïve analysis of the class process, without referring to the theoretical constructs or referring to them in an improper way.

Most of the protocols belong to the categories (b) and (c): few PTs were able to always correctly refer to the theoretical aspects and appropriately use the specific terminology. Because of space limitations, we present here only some reflections belonging to categories (c) and (d) because they better reveal the difficulties met by PTs in interiorizing the theoretical constructs. For example, many PTs did not realize that the rhetorical question proposed by T in line 5 is aimed at making A's reasoning (line 4) explicit in order to stimulate a moment of reflection. R, for example, observes: *"When T asks 'where do I find factor 2?', he/she plays the role of a prompter, inhibiting the anticipating thoughts that could have arisen from students' reflections"*. This reflection testifies a widespread approach used by PTs. They, in fact, often do not analyze T's actions in the context, with reference to what the class already knows and to the particular moment in the didactical path. Their inability of contextualizing the discussion makes PTs interpret as a 'didactical mistake' the fact that T considers obvious that 2 is a factor in the multiplicative representation of an even number. Indeed T's attitude is understandable: aiming at focussing students' attention on the way of developing reasoning through algebraic language, he/she prefers not to re-propose, as a problem, syntactic aspects that most of the students already control.

A similar observation can be done referring to T's choice of quickly performing,

without involving students, the syntactic transformation in line 16. The inability of contextualizing this action makes, for example, M assert: *“The teacher is the one who correctly writes the equality $(2x^2+1)^2 = \dots$; again he/she is does not make his/her students reflect on the meaning of algebraic expressions and on the equivalence between the expressions at the two sides of this equality”*.

As regards to (1), other difficulties are related to a lack in recognizing, referring to the particular context, some typical features of a TMAEAB. Some PTs, for example, consider as negative T’s approach in line 15 because they are not able to recognize that he/she is playing the role of investigating subject. R, for example, states: *“T’s attitude of ‘I want to convince you’ clashes against the meaning of the proving activity”*. An other assertion proposed by T that was not correctly interpreted by many PTs was the one in line 17. Instead of recognizing that T is trying to play the double role of investigating subject and activator of anticipating thoughts, some Pts declare that T is posing him/herself as a mere prompter: *“T suggests the frame to refer to and the quantity on which they have to operate. Therefore he/she is not playing the role of an activator of anticipating thoughts”*(S).

Our study has also pointed out that PTs sometimes propose conflicting interpretations of some micro-actions performed by T. Referring to line 19, for example, we highlighted a contraposition between comments that consider T’s approach positive, stressing that T aims at activating a moment of reflection on the meaning of the syntactic transformation to be carried out, and comments that look at T’s approach as completely negative, since *“T immediately interrupts the student’s proposal”* (D). PTs who propose negative comments to line 19 do not understand that students’ bewilderment can be justified because this is one of the first proving activities that the class is facing.

Referring finally to (3), we can observe that only few PTs have tried to highlight the effects of T’s action on his/her students. In particular, those who tried to highlight an interrelation between T’s actions and students’ actions only propose very concise global comments.

BRIEF FINAL REMARKS

The comments we presented in the previous paragraph highlight the difficulties faced by PTs both in using theoretical tools to analyse class processes and, in particular, in proposing an analysis of T’s actions which takes the particular didactical moment that the class is living into account. Many PTs, in fact, showed to be non completely aware that conducting a balanced lesson on this topic means making students autonomously operate, but also guiding them toward a meaningful learning of how to ‘reason’ through algebraic language. We think that the limitation of the period of work with these PTs can justify their incomplete assimilation of the theoretical constructs they studied. At the same time, the complete lack of teaching experiences in their careers can be considered an important reason of their difficulties in correctly

contextualizing T's actions in tune with the theoretical constructs of reference. However we believe that 'clashing' with these kind of problems could represent for PTs the beginning of a process which could lead to a real professional development. This is testified by the fact that, beyond our evaluation of their protocols, during the following discussions with PTs, they turned out to be very interested in these kind of studies and to really need to go on with the analysis of class processes.

NOTES

1. Conceptual frame is defined as an "organized set of notions, which suggests how to reason, manipulate formulas, anticipate results while coping with a problem".
2. Anticipating is defined as "imagining the consequences of some choices operated on algebraic expressions and/or on the variables, and/or through the formalization process".
3. Here, A, B, O, Z, P and G indicate 5 pupils involved in the discussion while T is for the teacher. Chorus means that the sentence was uttered by a group of pupils in the class.
4. The discussion ends with a further moment of reflection upon the importance of choosing a representation.

THE IMPACT OF TEACHING MENTAL CALCULATION STRATEGIES TO PRIMARY PGCE STUDENTS

Sue Davis

University of Leicester

Following a previous study involving five primary Post Graduate Certificate of Education (PGCE) students, which showed that there was short term impact resulting from an intervention (Davis, 2009), I revisited three of these ex-students to consider whether there had been any continued impact in the intervening two years. Using a case study approach I will show how these teachers, with very different experiences in school, have each built upon the skills, techniques and knowledge learned in the initial intervention sessions. I will also consider how this supports or contradicts the findings of other researchers studying the impact of Teacher Education.

Key words: Impact, Mental calculation, Primary, PGCE, Teacher.

INTRODUCTION

One of my strongest memories from primary school is that of completing a mental mathematics test every Friday afternoon, in preparation for the 11+ examination (selection for the local grammar school) during the final year. We were taught no strategies, other than learning multiplication tables by rote. Questions were fired at us and we had to calculate the answers ‘in our heads’ as the Dutch call this type of calculation (Thompson, 1999). For me, this merely meant picturing the formal written calculation and carrying out the formal method, working as quickly as possible, jotting down first the unit part of the answer, then the tens etc. It was not until many years later, as I trained to teach, that I realised that there was more to ‘mental calculations’ than this. The fact that I could choose from a range of strategies and use my knowledge of the number system to calculate much more efficiently was enlightening. Shortly after this, mental calculation became an important feature of the English primary mathematics curriculum when the National Numeracy Strategy was introduced (DfEE, 1999) and strategies were expected to be explicitly taught and regularly rehearsed and discussed. The recent ‘Williams Review’ (DCSF, 2008) has called for a refocusing on oral and mental mathematics in order to particularly benefit under-attaining groups of children.

Two years ago I conducted a study with five Initial Teacher Education (ITE) students (Davis, 2009) to identify what mental calculation strategies they possessed, how confident they were to teach mental strategies to children and whether my teaching of a range of strategies could increase their confidence of teaching this topic. This study involved an intervention which included teaching them a range of mental calculation strategies, offering opportunities for the students to compare these to their own mental methods for different calculations (e.g. $483 + 89$; $58 - 34$) across

all four operations (+, -, \times , \div). This taught session was audio recorded (and later transcribed) and questionnaires were completed before and after. Five weeks later, following the students' final weeks of Teaching Experience, a further questionnaire and short intervention session (based again on activities involving discussion of calculation strategies) provided further data. The results showed that whilst these students knew only a limited range of strategies before my intervention, they became much more confident afterwards and for two of them there was a clear impact on their teaching in school. These students from my study have now successfully completed their first two years of teaching and three of them were willing to allow me to investigate whether there had been any longer term effect of my intervention.

LITERATURE REVIEW

I have considered the literature surrounding the impact of both ITE and Professional Development (PD) courses for teachers as both have the same aim: to develop the teaching skills of the participants and therefore to enhance the learning of their pupils.

A key aspect of successful professional development is the style or nature of the activities. Both Darling-Hammond (1999) and Elliott et al. (2009) found that discussion amongst participants is central to successful PD which is, of course, the basis of many leading theories of education, particularly that of social constructionism. A successful teacher of mathematics has to develop a deep and flexible understanding of subject knowledge and be able to make connections with other aspects of the subject (Darling-Hammond, 1999). Elliott et al., (2009) develop the idea further by specifying that it is Specialised Content Knowledge which has a strong impact on teaching skills. This literature seems to suggest that my intervention should have had a positive impact in the classroom.

However, Larose, Grenon, Morin and Hasni (2009) have discovered that practice observed by students in school often overrides the information given during the university part of ITE. Students have also been found to lose their enthusiasm for their own learning during their Newly Qualified Teacher (NQT) year and tend to focus on behaviour management rather than subject knowledge (Haggarty, Postlethwaite, Diment, Ellins, 2009). Students in their first year of teaching do not appear to gain from the type of PD experiences that Darling-Hammond and Elliott et al. advocate.

The other consideration for my research is whether mental calculation strategies should be taught at all. Thompson (1999; 2000) advocates the teaching of some frequently used strategies for addition and subtraction so that children can develop flexible methods of calculation. Murphy, however, found that explicitly teaching an addition strategy did not mean that the children used this when faced with calculations that would benefit from its use (2004). Torbeyns, De Smedt, Stassens, Ghesquière and Verschaffel's research supports these findings (2009). They found

that there appears to be no difference in whether a particular subtraction strategy is used, whether or not children have been taught it. Threlfal goes a step further, by arguing that there is no need to teach particular strategies, but instead it is essential to develop a stronger understanding of the number system (2002). If we are to enable children to use flexibility in their approach to mental calculation I do not see these as mutually exclusive. Teaching some strategies may indeed support the understanding of the number system, and vice versa.

METHODOLOGY

The main question I wished to answer was: Is there any evidence of long term impact of the teaching of mental calculation strategies to primary Post Graduate Certificate of Education (PGCE) students? These are students who train to teach on a one year programme having already completed an undergraduate degree in any discipline, so may not have received any mathematics teaching for at least five years.

In addition, there were also a number of subsidiary questions which would support me in answering the main question: Did the students teach any mental calculation strategies during their NQT year? Did the students only teach mental calculation strategies when it was already on their school's planning? Is there any evidence that the children are using the strategies taught? Has the confidence of the students been affected by their teaching of mental strategies?

Each teacher held a particular interest for me and I wished to gain a 'rich picture with 'thick description'' (Thomas 2009, p.116) of them. Therefore the flexibility of a case study approach enabled me to study all three teachers in detail. I wished to develop a detailed 'holistic understanding' (Baxter & Jack 2008, p.554) of these new teachers' experiences throughout their first years of teaching. I had no hypothesis at this stage of what the results of gathering this data would show, which also fits in with the idea of a case study approach.

As with any case study, there is no possibility of drawing any generalisations from this research. This does not mean, though, that I cannot use any information that I gather to improve my own practice. As Baxter and Jack report, a case study 'can inform professional practice' (2008, p.544). A particular strength of this research was to build upon the close collaboration and relationship that exists between me as the researcher and the teachers I was researching. In some methodologies this relationship might be seen as a disadvantage, and might be considered a barrier to the authenticity of the data collected. Using this case study approach, though, it can be seen as an advantage as this is the very reason that I am selecting this particular sample. I was very careful to ensure that the teachers understood I wanted to know what really happened, rather than them hoping not to offend me by telling me that my intervention had an impact on their teaching if it did not.

In order to gain as much information as possible for my 'finished story' (Thomas 2009, p.115) and to corroborate the evidence I collected, I used a range of data

collection tools. Using a variety of data sources ensured that I was not exploring ‘through one lens, but rather a variety of lenses’ (Baxter & Jack 2008, p.544) and this is where the case study approach enabled me to build up a particular picture of the teachers which might not have been possible with other methodologies.

I began my study by designing questionnaires. The questions were ‘precise and non-leading, that neither assume nor presume’ (Castle 2010, p.67) and were a combination of closed questions and open questions to allow for comments about their teaching of mental calculations during their first years of teaching (Cohen, Manion & Morrison, 2000). I included some questions about confidence and competence in teaching mental mathematics strategies from the original questionnaires, completed by this group of students nearly two years ago, in order that I could make comparisons. For this reason I used a five-point Likert scale, as that was used in the original study.

In order to establish whether Haggarty et al.’s (2009) findings regarding a strong focus on behaviour management overriding other aspects of teaching were true for my sample, I also included a section where they ordered a range of five statements about areas they felt they developed most during their first year of teaching. These statements included both behaviour management and subject knowledge. Finally, the questionnaires included three open ended questions about the impact of the PGCE year as a whole on their development in their first year of teaching.

Following an initial analysis of the questionnaires I conducted semi-structured interviews with each teacher, which were recorded and transcribed. In particular, this method of data collection enabled me to prompt the teachers to reflect on any impact during their NQT year of my mental calculation strategy intervention and provided an opportunity for them to consider whether any teaching of strategies had any impact on the mental maths skills of the children. Planning and assessment records to support these opinions were collected where available.

CASE STUDIES

Ellie

‘Ellie’ was a mature student who taught across the primary age group in one school as a regular ‘supply’ teacher for a year, before spending two terms in a Year 5/6 class. She has recently returned to the first school to resume regular supply cover, again covering Years 1-6 (ages 5-11).

The data shows that Ellie has taught a range of mental mathematics strategies to children across this age group. In particular, teaching doubling and halving with all age groups was clearly very important to her, as this was mentioned for the first time less than ninety seconds into the interview. Although she initially taught this strategy to Key Stage 1 children (ages 5-7) Ellie also teaches it regularly to 9 to 11 year olds,

Working Group 17

focusing on how this can support a range of other calculations; for example calculating percentages, equivalent fractions or simply using it to divide by 4 easily.

Ellie also teaches rounding and approximating to Year 3 and 4 pupils, to support their mental mathematics, and using Interactive Teaching Programmes (ITPs) (DfE, 2010) and physical resources, such as bead strings, to support the children in understanding and visualising the number system.

Ellie is very keen to encourage children to discuss their mental methods whenever appropriate and this was a topic she frequently returned to during the interview. She believes this is a direct result of my intervention sessions. Her passion for this crucial element of teaching mental strategies can be seen in the following extract:

Ellie: I often, I do, I do ask them about methods a lot now because I remember sitting with you and we all had so many different methods and it might be that there's children in that classroom that just have not worked out a really easy method but by swapping methods, sort of do it this way, have you got a different way so you've counted on, you've rounded, and y'know, added bits on and taken bits off.....

Later in the interview Ellie returned to this topic when she reflected on the fact that until her PGCE course she generally had just one way of tackling any set mathematical problem. The structure of the intervention enabled her to realise that there were other ways of approaching mental calculation and this realisation has altered her own way of teaching, ensuring she teaches a range of methods. She says she has 'a better awareness, which is probably why I now ask the children, 'how did you do that?' and I think oh yeah, 'cause *** (names one of the students) did it differently to the way I did it.'

In contrast to Haggarty et al. (2009), who found that Newly Qualified Teachers (NQTs) did not develop subject knowledge but focused merely on classroom and behaviour management, Ellie had made a conscious effort to continue to develop her subject knowledge throughout her first two years of teaching, attending three mathematics courses in this time. Indeed, improving subject knowledge in core subjects was the area she had most developed in her NQT year.

Whilst Larose et al. (2009) found that practice in school overrode the practice learned during the university part of ITE, it is clear that Ellie had reflected on all of her university based mathematics sessions, including my intervention sessions. Her maths file, containing notes from all the taught sessions, has been in constant use throughout the intervening two years. As she says, 'I know that I have dipped in and out of that file a lot, for resources and, and for bits and pieces no doubt about it.'

Ellie agrees with the findings of Murphy (2004) and Torbeyns et al. (2009), that learning a range of strategies does not necessarily mean that children will use them. However, she also believes that revisiting and rehearsing constantly is a crucial part of children's learning and she found herself going, 'over it and over it and over it'.

She has found that if children are exposed to these strategies regularly, and are encouraged to talk about them regularly, they do begin to select an appropriate strategy more independently.

Donna

‘Donna’ completed her NQT year in a year 1 class (ages 5-6) and has spent the subsequent year teaching Foundation Stage, Year 1 and Year 2 (ages 4-7) children in the same school, where she is now employed to cover other teachers’ classes during their time for other commitments. This has meant that Donna has been in the unusual position of teaching some of the children this year who she taught throughout last year, which has given her the opportunity to see how the children have developed their skills and to judge the longer term impact of her teaching.

Donna has taught and practised a range of strategies to support mental calculation, the first that she mentioned (after only 53 seconds) being doubling and halving. Like Ellie, she was able to explain why she believes this to be an important skill, and she began this with Year 1 children by using counters and other resources to support their learning. As she says, ‘in Key Stage 1 its probably one of the first non-counting operations you do mentally’. Some of these very young children were already able to recall doubles up to 20 by the age of 6 and this year she has seen how they are able to use these skills to support other aspects of mental mathematics. Many others were still learning one to one correspondence, though, and basic counting skills, so by no means were all children able to calculate mentally even in Year 2.

It is interesting to note that Donna encourages the development of mathematical skills across many other areas of the curriculum, and sees this as an important part of their learning. Indeed, this approach is advocated by many leading educationalists, and forms one of the main recommendations of the recent ‘Cambridge Primary Review’ (Alexander, 2010). Donna particularly focuses on these skills in Physical Education (PE) lessons:

Donna: But in PE and in games we used a lot of .. things like counting in twos to score, rather than always counting one point, y’know for getting one thing back in a race or something. Counting in different numbers or thinking about .. playing games with beanbags. How many more beanbags do you need to make 10? ---- and having teams racing against each other... and I found PE was a really good way of, .. kind of incorporating maths...

It was clear from interviewing Donna that she was working in a team who were all keen to encourage children to develop mental skills, combined with a strong level of independence of thought. This made me wonder whether my two intervention sessions had had any impact on her teaching, or whether, as suggested by Larose et al. (2009), practice observed by students (and presumably NQTs) in school overrides

Working Group 17

the information given during the university part of teacher training. Donna acknowledged that she has learned a lot from these new colleagues, and, for that matter, she has always used doubling to support her mathematics since her own school days, but she makes it very clear that despite the two sessions lasting less than two hours in total, they have had a significant impact on her teaching:

Donna: DEFINITELY, definitely probably even more so this year because I've been working more with year 2....trying to get the children to explain to me the different strategies and then explain why they would choose a particular one and why it was better, and picking out the features. It really stuck with me that when we were talking, how useful that was, so I've done that quite a lot with the children in the class. Definitely.

Tutor: And was that something you might have picked up anyway on your TE placement?

Donna: I might have done but I think that really rammed it home, that.., how important it was for the children to find out for themselves which ones work for them and which ones are..are more efficient than, than others, erm and that unless you get them to think about what they're doing and why they're doing it they might not, you know, I think I was just more overt with it than maybe I would have been anyway.

Donna indicated that she had received no professional development in mathematics since completing her PGCE, and I wondered if this might support Haggarty et al.'s view (2009), that behaviour management becomes the main focus for NQTs, with a lack of enthusiasm for development of their own subject knowledge. From the initial questionnaire it was clear that Donna felt that behaviour management was the skill she developed most in her NQT year, but further discussion during the interview revealed that this was because she had two children displaying such challenging behaviour that both the children and Donna received regular specialist support from the local authority throughout the year. This did not mean that Donna had a lack of enthusiasm for developing her own subject knowledge; in fact, she attended three courses and an NQT conference, all of which heavily focused on subject knowledge, albeit not mathematical subject knowledge. Donna would really appreciate the opportunity to receive further training in mathematics, and made it clear that it was not through choice that the courses she attended had different foci.

From her responses in the questionnaire it is clear that Donna is very confident about her own knowledge of mental calculation strategies and she has increased her confidence in her own ability to teach these strategies to children since she was a PGCE student. This was supported by her discussion of the impact of her teaching on

Working Group 17

the children, which was particularly evident when working with one group of children for both years of her teaching career.

Belinda

'Belinda' has spent her first two years in a Foundation Stage class (ages 4-5), although the PGCE course she completed was a Key Stage 1 and Key Stage 2 course (ages 5-11). Children are divided by achievement into maths groups and she teaches the higher achievers.

Once again, teaching doubles was one of the first strategies mentioned by Belinda (less than two minutes into the interview); although despite mentioning this strategy at various points during the interview it is interesting to note that she did not mention the corresponding halves at all. However, the children learn doubles up to 20, using resources such as counters, pencil marks or fingers to initially support this, before they develop as 'known facts'.

Belinda has learned an enormous amount from her colleagues, and readily admits that most of her mathematics teaching is based on their advice and experience rather than on her learning from her PGCE course, which, in contrast to Donna and Ellie, supports the findings of Larose et al (2009). She has not looked at her mathematics file since the day she left the course. Having said this, she still believes that the two intervention sessions have had some impact on her first years of teaching. In particular, these sessions made her realise that 'everybody visualises things differently and they see things very differently and they have to use different ways to work it out'. She thinks this, combined with her colleagues' advice, ensures that she offers children a range of choices throughout their mathematical learning, despite this not being a strategy included in the published scheme that the school generally work from.

When considering developing subject knowledge compared to developing behaviour management skills, Belinda has attended a number of courses during her first two years of teaching and these have all been based on subject knowledge. Bearing in mind that she is teaching in an age phase for which she was not trained, this is probably unsurprising. The courses have taught her knowledge of the Foundation Stage Curriculum and ways to assess children of this age. Behaviour management is something which Belinda feels she has made least progress in as it has not been a problem for her.

CONCLUSION

Considering the main aim of my research, to establish whether or not there is any long term impact of the teaching of mental calculation strategies to PGCE students, there clearly was for all three of these teachers. In particular, all had a strong belief that an ability to quickly mentally double and halve numbers is crucial to mental calculation. I would certainly agree with this and this was a message given

throughout my intervention sessions. It can clearly support multiplication and division by four or eight, but it can also support multiplication by 5 (multiply by ten and halve); division by 5 (double then divide by 10); multiplication by 20 (double and multiply by 10); division by 20 (divide by 10 and halve) and can similarly support multiplication by 50, 25 and so forth. Percentages can also be worked out mentally using the knowledge of doubles and halves; for example to find 25% of a number just halve and halve again; to find 15% just find 10%, halve it and add the two numbers together. Similarly, equivalent fractions can be found by doubling or halving both numerator and denominator.

Whilst this has been a very small scale study and I therefore cannot possibly draw any general conclusions from my data, I have succeeded in answering all of my subsidiary questions. All three teachers taught mental calculation strategies; they taught these even when it was not on the school's planning; they all believed that not only could the children use the strategies, but some children could also select from a range of strategies, even at the age of five. Confidence was a different issue altogether, as only one student had increased her level of confidence in teaching these strategies, and this seems to be entirely down to the individual experiences of the students.

So why might these teachers have been different to those researched by Larose et al (2009) and Haggarty et al. (2009)? Why have they built on the teaching they received on their PGCE course and why have they continued to develop their own subject knowledge? As suggested by Elliott et al. (2009), I am convinced that this is as a result of the type of teaching they received. If suitable consideration is given to the content and delivery of ITE taught sessions, a small amount of input can have long term impact on their teaching. For maximum impact, the subject knowledge related to mental calculation needs to be taught in an environment where students, teachers or children can discuss their methods freely with one another.

RE-DEFINING HCK TO APPROACH TRANSITION

Sáinza Fernández, Lourdes Figueiras, Jordi Deulofeu, Mario Martínez

Universitat Autònoma de Barcelona

Mathematics learning is a continuous process in which students face some abrupt episodes involving many changes of different natures. This work is focused on one of those episodes, transition from primary to secondary school, and targets teachers and their mathematical knowledge. By including expert teachers' views about transition and characterising the mathematical knowledge that they need to smooth transition processes, we aim to highlight their importance in the continuity in mathematics education. The concept of Mathematical Knowledge for Teaching (MKT) developed by Ball among others (Ball, Thames & Phelps, 2008) and, within this framework, the construct Horizon Content Knowledge (HCK) emerge as our theoretical response to the knowledge for teaching mathematics in a continuous way, particularly relevant during transition to secondary school. The enrichment of the idea of HCK and its expression in the teaching practice intends to develop a theoretical tool to approach transition from teachers' mathematical knowledge perspective.

Keywords: Transition; Continuity; Mathematical Knowledge for Teaching; Horizon Content Knowledge.

INTRODUCTION

Mathematics learning is a continuous process in which students face some abrupt episodes which involve many changes of different nature that derive in a variety of alterations in their educational path. This work is focused on one of those episodes, transition from primary to secondary mathematics, a compulsory transition for students that involves many external changes and targets teachers' mathematical knowledge.

An extensive survey let us detect that previous research on transition from primary to secondary school has been mostly focused on its effects in students' academic attainment (McGee, Ward, Gibbons & Harlow, 2003) whereas a focus on teachers and their perspectives has been mostly absent. Considering specifically transition in mathematics, the following questions arise immediately: which characteristics describe it? Looking at previous research foci of attention and conclusions the mathematical content emerges as a determinant factor: the step from arithmetic to algebra (Boulton-Lewis et al., 1997; Boulton-Lewis, Cooper, Atweh, Pillay & Wilss, 1998; Cooper et al., 1997; Flores, 2002; Gonzales & Ruiz Lopez, 2003), the learning of integer numbers (Gallardo, 2002; Pujol, 2006) or the development of the need of proofs in geometry (Berthelot & Salin, 2000-2001; Sdrolas & Triandafillidis, 2008) and other fields appear as particular well-known problems embedded in the teaching and learning of mathematics that involve transition to secondary school. Since

teachers shape the access of students to this content, we consider their role in transition as crucial.

In conclusion, albeit transitions are processes with a broad range of effects and consequences in the whole students' educational experience, we believe that it is necessary to investigate the specificity of mathematics in transition and particularly, the role of the teacher and his/her professional knowledge during this process. More specifically, the objectives of our investigation are:

O1. Find out mathematics teachers' views about transition.

O2. Characterise the mathematical knowledge that teachers need to smooth transition processes.

With regard to O1, we believe that teachers' opinions and practical everyday experience on transition must be taken into consideration in order to broaden our understanding of transition in mathematics, since they are the only professionals that experience the process of transition along with the students in the classroom. By involving the views of *expert* mathematics teachers we want to enlarge the multiple perspectives from which transition to secondary school can be considered and thus gain a better comprehension of it. Experts' responses will constitute the justification of the appropriateness of the theoretical perspective adopted in O2.

In order to accomplish O2 we require a solid theoretical frame that suits our purpose of focusing on the role of the teacher and, particularly, on the relationship of his or her mathematical knowledge and practice with primary to secondary transition. The concept of Mathematical Knowledge for Teaching (MKT) (Ball, Thames & Phelps, 2008; Hill, Rowan & Ball, 2005; Hill et al., 2008) and its division in different domains and sub-domains appears as a suitable framework for this part of our investigation. Within this theory, the construct Horizon Content Knowledge (HCK) emerges as our theoretical response to the knowledge for teaching mathematics in a continuous way, particularly relevant during transition to secondary school. Hence, our research focus in this part of the investigation is the enrichment of the idea of HCK in order to use it as a theoretical tool to approach transition.

EXPERTS' VIEWS

We aim to find out experts' opinions about transition to secondary mathematics regarding the following questions: which elements affect in a determinant way the transition to secondary mathematics? And which of these refer to the teaching practice? Moreover, not only we want to collect judgements of individual experts but we also want to offer a scenario of group decision, where participants are capable of interact anonymously and reach a consensus. In the following, we will consider an *expert* a mathematics teacher that has taught in both levels and has shown a particular concern about transition issues.

In order to create an experts' group discussion we use the classical Delphi method, which allows us to create a scenario of group decision where experts feel free to

express their opinions and interact anonymously in a very efficient way, ensuring that the information obtained is of “good quality” and reliable (Plans & León, 2010). The versatility of the Delphi method seems particularly appropriate for our research, since it includes open and closed questions as well as qualitative and quantitative analysis. Figure 1 shows the steps included in a typical three round classical Delphi method (Skulmoski, Hartman & Krahn, 2007, p3) which guides the design of this part of our work.

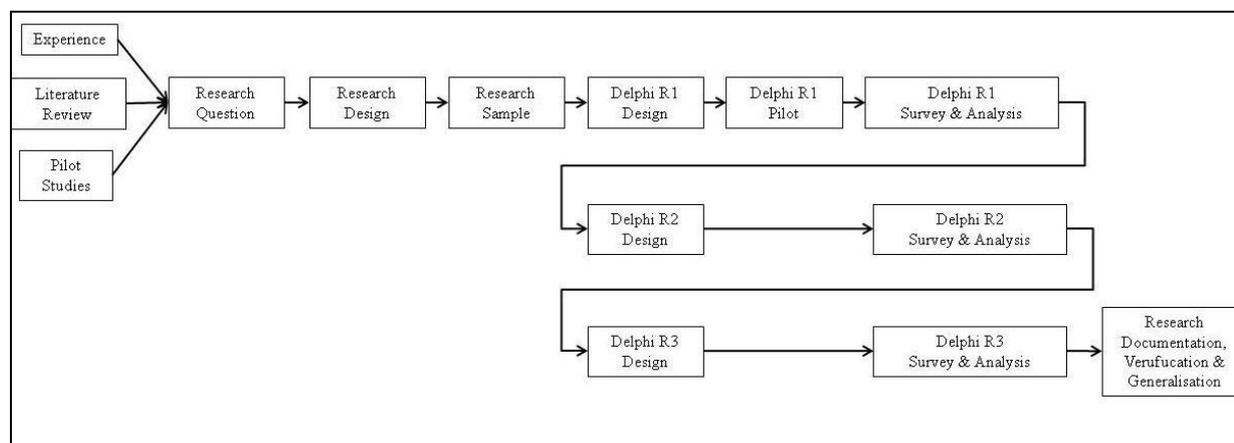

Figure 1: Classical three round Delphi method (Skulmoski, Hartman & Krahn, 2007, p3)

Delphi study

Our own teaching experience led to the problem of transition to secondary school and a previous survey detected a theoretical gap in transition research focused on teachers. Our uncertainty involves expert teachers’ opinions on the elements that affect transition and particularly those related to the teaching practice in both levels.

In the study 15 experts answered our open questionnaire, which included three questions: What factors affect students’ mathematical learning during transition to secondary school? Which qualities should primary teachers have in order to smooth students’ transition to secondary mathematics? Which qualities should secondary mathematics teachers have in order to smooth students’ transition from primary school? Among the factors that affect student’ learning they identified methodological issues and the influence of teachers’ initial training as especially remarkable. For example, scarce use of manipulatives or group work in secondary school, and no balance between teachers’ pedagogical and mathematical knowledge. Experts pointed out that in order to manage transition, teachers must have a set of skills, attitudes and knowledge related to general education such as preparing primary students for a greater autonomy, valuing diversity, managing the interaction, using active and constructive methodologies or encouraging participation. We can infer from data that they refer to those skills from a theoretical framework that conceives a pure pedagogical knowledge. Experts also refer to a specific mathematical knowledge for teaching, which, in terms of Ball, Thames and Phelps

(2008) we call Mathematical Knowledge for Teaching. For example, they refer to manage with different degree of mathematical rigor, know the mathematics taught at both levels and have a global vision of the contents. Some kind of experience connecting the two levels appears essential, as the need to know about the previous and/or forthcoming stages. Following Ball et al. (op cit.), we find that experts refer to characteristics that describe the long-term perspective embedded in the idea of Horizon Content Knowledge. This way, experts' responses become our way in and justify the second part of our investigation, in which the framework of the Horizon Content Knowledge appears crucial to approach teachers' role in transition.

MKT AND HCK

In this part of the investigation we explore the concepts of MKT and HCK in order to clarify the latter's place in the diagram and introduce a different approach to the MKT's organisation above that concludes with the refinement and placement of HCK in this framework and thus, with the inclusion of the notion of continuity in MKT's theory.

Mathematical Knowledge for Teaching overview

Ball, Thames and Phelps (2008) distinguish two domains within the MKT, namely Pedagogical Content Knowledge and Subject Matter Knowledge (see Figure 2). These are not independent from each other, but it is their combination which defines the knowledge needed for teaching mathematics.

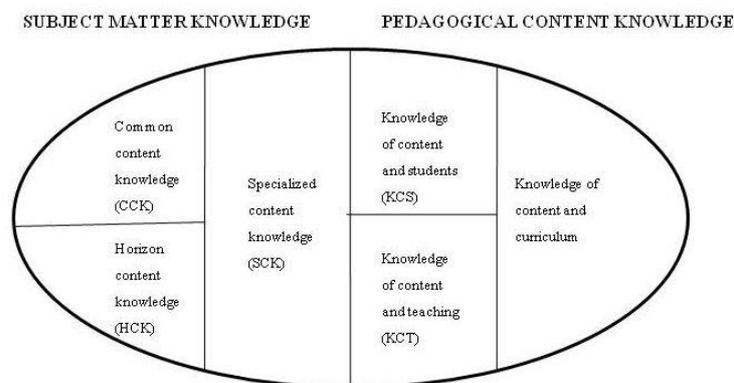

Figure 2: Categories of Mathematical Knowledge for teaching (Ball, Thames & Phelps, 2008, p.403)

Pedagogical content knowledge is subdivided attending three foci of attention within the teaching practice: students, methodology and curriculum. Knowledge of content and students (KCS) involves students' expected difficulties, questions, motivations, etc. and teacher's preparation and responses to those. Knowledge of content and teaching (KCT) concerns methodology issues such as the design of the sequence of a topic or the use of appropriate tasks, representations and examples, etc. Finally,

knowledge of content and curriculum (KCC) is the curricular knowledge needed for teaching. This includes not only the knowledge of the mathematical topics that are included in a particular curriculum, but also the specific moments when they have to be taught and how they are developed in the educational path. Subject matter knowledge is sub-divided in three categories: common content knowledge (CCK), which is the mathematical knowledge that is common to other professions and specialised content knowledge (SCK), which is the specific mathematical knowledge needed for the teaching practice (Ball, Thames & Phelps, 2008).

Before centring our attention on the last sub-domain, the HCK, we detect that KCS, KCT and SCK arise and are expressed only during the teaching practice in mathematics or in the observation of other's teaching practice, while the KCC and the CCK are not necessarily linked to the teaching practice. We highlight this observation by considering KCC and CCK as *foundation* knowledge and KCS, KCT and SCK as having an *in-action* nature. It is important to remark here that the word *foundation* denotes our idea of this theoretical knowledge being the basis and it is not related to the more complex construct of Foundation knowledge included in the Knowledge Quartet of Mathematical Knowledge in Teaching (MKiT) framework (Rowland, Huckstep & Thwaites, 2005). Figure 3 shows our interpretation of the categories of MKT from this approach, not considering yet HCK.

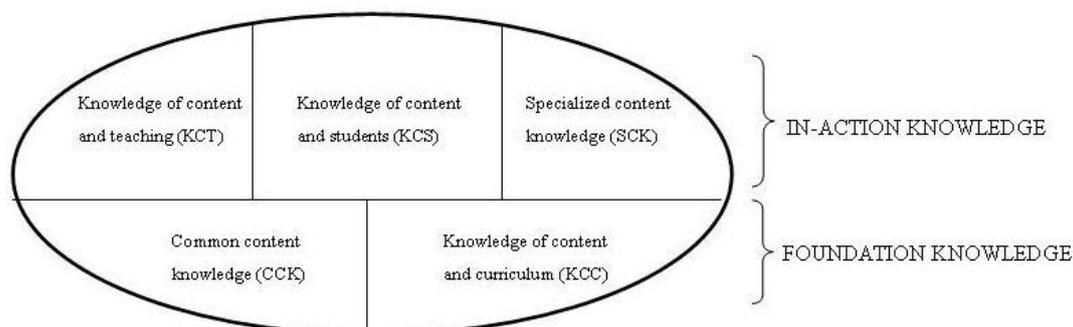

Figure 3: Categories of Mathematical Knowledge for teaching without the HCK

Horizon Content Knowledge

Our main interest is focused on the Horizon Content Knowledge (HCK), provisionally included within subject matter knowledge. About HCK the authors say

We are not sure whether this category is part of subject matter knowledge or whether it may run across the other categories. (Ball, Thames & Phelps, 2008, p.403)

HCK refers to the general awareness of the previous and the forthcoming, and requires an overview of students' mathematical education so that it can be applied to the mathematics taught in the classroom (Ball, Thames & Phelps, 2008). Teachers' consciousness of the past and the future within their subject is actually very closely related to continuity in mathematics education and thus, our view of HCK comprises

this teacher's longitudinal perspective required for continuity. However, this longitudinal view that we understand as HCK encompasses a complex combination of pedagogical and mathematical knowledge, skills and experience that must be clarified in order to successfully approach transition issues in mathematics from this framework.

Firstly, despite the fact that the HCK may be related to the knowledge of the curriculum (KCC), it is independent from the curriculum itself. HCK is not only an awareness of how mathematical topics are related over the span of mathematics included in the curriculum but also refers to the global knowledge of the evolution of the mathematical content and the relationship among its different areas needed for the teaching practice. This general knowledge does not depend on the curriculum context and it is different to the curriculum awareness that a teacher must have in order to teach the appropriate topics at a particular grade. In other words, a teacher could have good level on KCC but fail on approaching this knowledge from a *long-term* perspective.

Secondly, HCK influences the KCS, the KCT and the SCK. For example, HCK must include the ability of the teacher to find out students' previous mathematical ideas and to prepare them for the future. This ability involves KCS (knowledge of previous, current and future students' difficulties, misconceptions or questions) and KCT (different ways students might have seen that represent the same idea or types of tasks that facilitate students' learning in the future). Also, the SCK of a teacher for a particular grade depends on whether that teacher currently teaches in that level. If so, his/her SCK for that grade will be obviously greater than for the other grades. The inclusion of HCK in the framework implies the extension of the SCK to those topics that may really have an effect in what students are learning at the moment or to those future topics for which a teacher is setting up the basis.

Thirdly, HCK has a different nature than the other sub-domains since it does not seem sensible to find the presence of HCK in a particular teaching situation if there is a previous absence of KCS, KCT or SCK. In fact, these are the required bases that allow the posterior gradual inclusion of HCK in the professional practice. From this perspective HCK is not another category in the diagram but it adds a more *sophisticated* (continuous) perspective to the teaching practice. For instance, we would not expect to observe a teacher recognising previous misconceptions in a particular topic, dealing with students' difficulties or conveying a prospective mathematical view of the future if that teacher does not know the topic and its methodological issues at first.

The previous ideas lead us to consider HCK, not as another sub-domain of MKT, but as a mathematical knowledge that actually *shapes* the MKT from a continuous mathematical education point of view since it must be present in every *in-action* category in order to attend transition. Figure 4 shows our interpretation of the framework with the inclusion of the HCK. The idea of *opening* the previous diagram

(Figure 3) and *shaping* it when including the HCK intends to indicate: a) the difference in the expression of each *in-action* category in the teaching practice with or without HCK; b) the connection with past and future mathematical levels, particularly important from a transition (or a continuous) point of view and c) the fact that HCK has a different nature than the rest of categories since it does not appear in the diagram but its presence modifies the teaching practice.

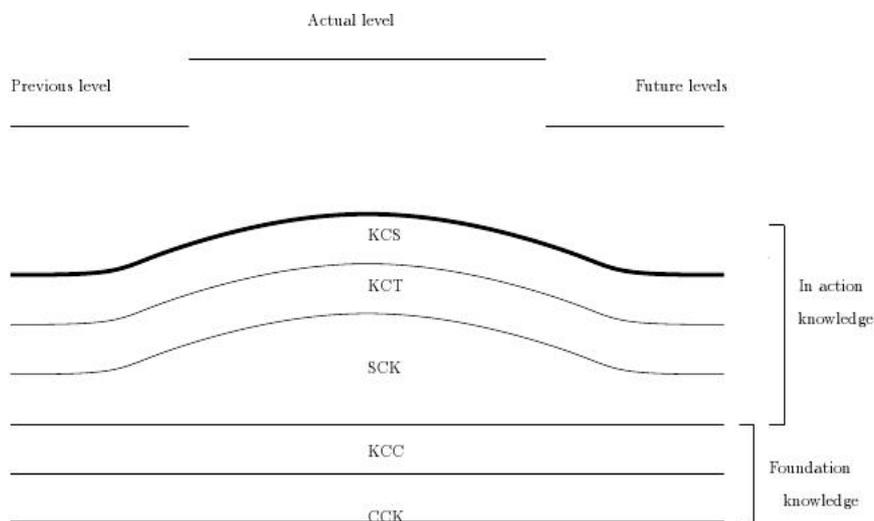

Figure 4: HCK shapes MKT and outlines its nature

Characterisation of HCK

At this point, our consequent aim now is to characterise more specifically our idea of HCK. Hill et al (2008) highlight the need of clarifying how teachers' knowledge affects classroom instruction by carrying out an investigation in which the relationship between teachers' MKT and the quality of their practice is analysed. We follow this idea for the particular case of refining the construct of HCK. Since we do not consider HCK as a theoretical cluster itself but a type of knowledge that shapes the *in-action* knowledge needed for teaching and also because our purpose is to obtain a useful tool for future research on transition, we adopt a practical perspective from which the following question emerges immediately: how does HCK get expressed in teaching practice?

In order to obtain an answer to this question, a series of non-participant observations were carried out. Mathematics lessons in the last year of primary school as well as the first year of secondary school were observed during three months. Participating schools were city centre comprehensive schools that were chosen in order to cover the different possibilities in transition: schools with transitional programs and links among primary and secondary teachers, schools with transitional programs but no communication among teachers and schools without transitional programs. The observation and analysis of these mathematics lessons allowed us to identify classroom episodes in which students' and teacher's interventions offered a good potential in terms of achieving a more specific characterisation of the HCK. We

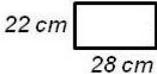

Working Group 17

identified the episodes in which there is a clear opportunity for the teacher to express the HCK. Despite the fact that, on the contrary, its absence or weak presence is evident in the real situations observed, these episodes have proved to be very rich as objects of our investigation, since they let us reflect about the different possibilities of reaction that the teacher could have. Hence, the following question arose: what could have happened, had the HCK been present?

The episode shown in Figure 5 exemplifies these ideas by targeting, in this case, the well documented misconception between area and perimeter.

The teacher poses this problem from the textbook:

Calculate the perimeter and the area of the following rectangle:

The teacher starts solving the problem on the board: $2 \cdot 22 + 2 \cdot 28 = 100$

The following dialogue occurs:

Student1: Why 100?
Teacher: To calculate the perimeter you do this operation and it gives 100
Student2: It's like giving 3 from the 28 to the 22 and you get four sides of 25. Si it's 100.
Teacher: Ok. And now, how do you calculate the area?
Student2: 25 times 25

Figure 5: Example of a real classroom situation in which HCK may get expressed

Two critical moments can be observed in this episode. The first one occurs when Student1 asks the reason of obtaining 100. The second one arises from Student2's misconception of considering that two shapes with the same perimeter should also have the same area.

Student1's question about the result points out at the operation that the teacher has used to calculate the perimeter of the rectangle: if the perimeter is the sum of all sides, why do we double them and add the results in this case? With the aim of clarifying Student1's confusion, the teacher could show how both calculations are equivalent. Moreover, the teacher could make the *connection* with algebra and generalise by reminding/showing that $a+a+b+b=2a+2b$. We observe that the ability of the teacher to make this connection is a pre-requisite for this possibility to occur. In this case, the connection required refers to the concept of perimeter itself and its relationship with algebra. We generally name this level of connection as *intraconceptual connection*, since it is in the essence of the particular mathematical concept.

Student2's ingenious proposal of transforming the rectangle into a square to calculate the perimeter in a more simple way offers an excellent opportunity to attend the common (and broadly studied by research) misconception that follows in the

episode: two shapes with equal perimeter have also the same area. One way the teacher could proceed would be to return the mistake to the student or the classroom by posing a series of questions that target the origin of Student2's mistake: do two rectangles with the same perimeter have always the same area? With the help of the teacher (questions, counterexamples, etc) and/or the rest of the class, the responsibility of correcting the mistake would be returned to the student or the class. As in the previous critical moment, it is necessary that the teacher makes a connection between the notions of area and perimeter in order to attend the misconception arisen. This is the next level of connection since it links two mathematical concepts and thus, we regard it as an *interconceptual connection*. Moreover, with an eye on the future and in order to strength the basis for the future learning of more complex geometry concepts, the teacher could also extend these ideas to other 2D shapes or even 3D solids by comparing surface and volume. This *temporal connection* with future (or past) topics of students' mathematics educational path is the third level of connection required for the teacher to attend these types of situations with a continuity perspective.

FINAL REMARKS

This work intends to move towards a better understanding of continuity in mathematics education. HCK emerges as a noteworthy construct within MKT framework that allows the researcher to approach continuity questions in mathematical education by looking at teachers' professional knowledge. Identifying real practice situations in which an opportunity of attending continuity in the classroom is missed, leads to the detection of the connections required for the potential expression of the HCK. The future systematic investigation of HCK's expression in the teaching practice and its consequences on transition shows a path to the potential inclusion of this mathematical knowledge as part of teacher training programs designed to smooth transition. Moreover, proposing examples like the one described in this work and discussing them in teacher training programs could be a future way in to attend continuity in mathematics education.

NOTE

This study is conducted under the auspices of Ministerio de Ciencia e Innovación (grant EDU2009-07298).

CONCEPTIONS AND PRACTICES OF MATHEMATICAL COMMUNICATION

António Guerreiro¹ and Lurdes Serrazina²

¹School of Education and Communication, University of Algarve (Portugal) and

²School of Education, Instituto Politécnico de Lisboa (Portugal)

This paper reports the evolution of a primary school teacher's conceptions and practices of mathematical communication, during a study supported by a collaborative work among three teachers and the first co-author. It is part of a large research which intends to study the evolution of the conceptions and practices of mathematical communication and interaction in the primary school classroom. This paper focuses on the need for training teachers in mathematical communication and mathematical knowledge for teaching.

Key-words: mathematical communication; conceptions about communication; teaching practices; mathematical knowledge for teaching; collaborative work

INTRODUCTION

The curriculum guidelines on mathematical communication emphasises the representation of mathematical ideas in the speaking, the writing and the reading *of* and *about* mathematics, in abstract and symbolic language and in the social interactions in classroom. The value given to student-student and student-teacher interactions in constructing a significant mathematics learning (ME, 2001, 2007, NCTM, 1991, 2007) hinges on the notion of communication as social interaction, as opposed to the traditional view of communication as a process of transmission of information and knowledge.

The first co-author of this paper conducted a research about the evolution of conceptions and practices of mathematical communication, during a collaborative work focused on the analysis and the reflection of the teacher's communicative practices in the classroom, with three primary school teachers. This research was supervised by the second co-author.

The research problem was specified the following questions: (i) How do the teacher's conceptions concerning mathematical communication, in the classroom, evolve? (ii) How do the teacher's communication practices value the students' acquisition of mathematical knowledge? (iii) How are teacher-students communication and interaction patterns related to the negotiation of mathematical meanings? (iv) What is the relation between the moments of reflection about the teacher's communication practices in the classroom and the evolution of such practices?

In this paper we present a theoretical synthesis about mathematical communication framed in theories of communication, emphasizing the role of mathematical

communication as social interaction in classroom. We present a summary of methodological options, where we stress the methodological challenges of the collaborative work among three primary school teachers and the first co-author.

This paper proposes to explore the role of teachers in the development of mathematical communication and of the student-student and student-teacher interactions. It further intends to highlight the evolution of the teacher's conceptions and communicative practices in the mathematical classroom. We seek to reflect on the increment of mathematical communication in class and the teacher's mathematical knowledge for teaching (Ball, 2003). It results from the work undertaken with one of the teachers who participated in the study – Laura.

MATHEMATICAL COMMUNICATION

The curriculum guidelines for mathematics teaching advocate mathematical communication as a process of social interaction, which differs from others views of communication as transmission of information and knowledge. The greater value given to the role of dialogue and the sharing of information are opposed to a more traditional form of communication based on an one-way process. Brendefur and Frykholm (2000) refer to the existence of *unidirectional communication* and of *contributive communication* in the teacher-oriented classroom discourse, where the student limits himself to attend the class with few interventions. It exists in opposition to the *reflective communication* and the *instructive communication*, where the students use mathematical conversations to share their ideas, strategies, and solutions with peers and teachers.

Interactions between teacher and students generate interaction patterns (Godino & Linares 2000; Wood 1994, 1998), which can be typical either of a teaching process based on memorization, questioning and reproduction, grounded on the teacher's mathematical knowledge – patterns of reciting, funneling and focusing –, or of a learning process grounded on the personal contribution of the learner, making room for an evaluation and reflection on the mathematical activities and on mathematical knowledge constructed in the classroom – patterns of extraction and discussion. From a communication standpoint, the role of teacher and students acquire substantially different meanings, in line with the conceptions and practices of mathematics teaching (Thompson, 1984, 1992).

Mathematical communication as a process of social interaction results from the sharing of meanings constructed and reconstructed by individuals, where the subject identifies himself/herself with the other, and at the same time, expresses and affirms his/her singularity (Belchior 2003). The communicative function is to create and maintain understanding through the negotiation and reconstruction of meaning between individuals (Godino & Linares, 2000; Yackel, 2000). This communicative action is characterized as a process in which the subject affirms his/her view of world and understands the points of view of the others (Habermas, 2004, 2006).

Mathematical learning on the part of the subjects arises from the interactions between the individual and the culture (Sierpinska, 1998), including the interactions between students and the teacher. Mathematical learning results from the students-teacher-mathematics interactions, where the discourse is understood as a language in action, thinking with words with the others and for the others (Godino & Llinares, 2000; Sierpinska, 1998). The practices of communication, based on the process of interaction between the subjects, seem to be linked with a mathematical learning based on the value given to the students' mathematical ideas and meanings (Thompson, 1984, 1992).

METODOLOGICAL OPTIONS

The background investigation for this study fits into a qualitative methodology (Bogdan & Biklen, 1994), which adopts the interpretative paradigm and follows the design of a case study (Stake, 1994; Yin, 1989). Three teachers from the same primary school – Alexandra, Carolina and Laura – participated in this study, in a context of collaborative work with the first co-author, the point of which being the reflection on their professional practices concerning mathematical communication, for two year (from December 2006 to February 2009). The selection of the teachers resulted from the first author acquaintance with them and their willingness to work on the mathematical communication in the context of the primary school classroom.

The data collection consisted of initial and final audio-taped interviews with the teachers, audio-taped descriptions of the collaborative meetings between the first co-author and the teachers (both collectively and individually), and audio and video-taped classroom reports. The multiplicity of instruments for data collection did not depend on the triangulation of data, but on the need to clarify, supplement the meaning of information and identify different ways of seeing the events (Stake, 2000).

The data analysis was organized in case studies: the characterization of the collaborative work between the first co-author and three primary school teachers, and the evolution of the teacher's mathematical communication conceptions and practices. The procedures for data analysis involve various stages until the construction of the interpretative text of the case. The data were reduced and transcribed to expressive episodes, incorporating the complexity of the phenomena and contexts, which allowed reconstructing the experiences of participants (Goetz & LeCompte, 1984).

CONCEPTIONS AND PRACTICES

Conceptions

Laura's conceptions about mathematical communication seem to have evolved from the perspective of mathematical communication as transmission of information and knowledge – "They are small and we are transmitting a lot of things" [2006

Working Group 17

december _ initial interview] – to mathematical communication as social interaction, in an attempt to reach a better understanding between all the students involved – "When they [students] do not understand anything, I always say «please, ask us, don't keep the questions to yourselves»" [2009 february _ final interview].

Laura integrated in her conceptions about mathematical communications and mathematical teaching and learning aspects related to social interaction like the students' knowledge and their cognitive ability to learn:

I let them think. (...) They would come to me and I would say «It is wrong». (...) I would say it was wrong and I wouldn't be expecting their thinking. Not anymore. It's different. I was expecting: «So, clear it up for me. So, why did you do this? How was it?»

[2009 february _ final interview]

Laura acknowledged the close proximity that existed between the processes of interaction in classroom and the mathematical learning. She had given priority to the students' personal knowledge and the moments of communicative interaction. This modification in the teacher's practices seems to have caused a change in the discourse and in the teacher's conceptions, in such a way that the students were now seen as communicative partners in mathematical teaching and learning. This recognition of the student as a knower was also reflected in her personal and professional knowledge for mathematical teaching. The existence of these conceptions seems to confirm the dichotomy between the transmission of information and the construction of knowledge through social interaction.

Practices

Kind of communication. At the beginning of the collaborative work, the teacher's communicative practices in classroom valued the contribution of students – *contributive communication* – with short interventions, used by the teacher (Laura) to assess their knowledge:

Laura: Today, we will go to do an activity about shapes. Do you remember? We talked about squares, more...

Students: Triangles, Rectangles...

Laura: Squares, Triangles, Rectangles and...

Students: Circles.

[2007 june _ lesson _ first year of primary school]

Laura has begun to encourage the students' participation, particularly in discourse in mathematics classroom, and the interactions between the students in the discussion of different perspectives of mathematical resolutions. In the problem of the River Crossing [1], the teacher opted to begin the discussion with a solution that was incongruent with the conditions of the problem.

The student Monica presented the solution of her group, writing:

Working Group 17

Little Johnny takes the rabbit in the boat. Little Johnny takes the cabbage in his lap and the dog on one side, and they go on their way

While the student was writing on the board, some students were waiting with their hands up, as a sign that they wanted to question their colleague.

Teacher: There are hands up.

[2008 march _ lesson _ second year of primary school]

The teacher alerted Monica to the questions of her colleagues and she ended her presentation and chose one of the other students to ask her a question. Following the conclusion about the impossibility of more than two *passengers* in the boat, one of the members of this same group – Tiago – presented a new proposal for the solution, writing:

First goes the dog [the students became agitated because they consider that what their colleagues wrote was wrong]. Second goes the cabbage. And last goes the rabbit.

Gonçalo, observing the solution written by Tiago, said:

Gonçalo: I know what's wrong.

Teacher: So go up there Gonçalo. Go to the blackboard and say what's wrong.

Gonçalo went up to the blackboard and explained his reasons to Tiago.

Teacher: Tiago, stay there to defend yourself.

[2008 march _ lesson _ second year of primary school]

The comments of the teacher were intended to promote the interaction between the students – “*There are hands up*” – and to encourage the justification of student's reasons – “*Stay there to defend yourself*”. This attitude of this teacher promoted a greater interaction between the students in the classroom. The exploration of the incomplete or incorrect resolutions by the teacher resulted from the collaborative work. Usually, Laura would say: «This is wrong. What do you think? What is it saying there?» [2008 april _ collaborative meeting with teacher]

The participation of the students in the classroom discourse went beyond the routines of *contributive* communication. The emergence of *reflexive* communication resulted from the value given to the students' mathematical ideas and knowledge:

Laura: What do you make of these two tables? (Each table was paved with equal squares but different from one table to the other)

Marcia: The biggest pave more and the smallest pave less.

Laura: Stop, what did you say?

Marcia: The biggest pave more and the smallest pave less. The biggest are less used and the smallest are more used.

[2008 april _ lesson _ second year of primary school]

Working Group 17

The increase in mathematical communication resulted in the need for training in mathematics knowledge for teaching as a way to support and to value the students' mathematical ideas and strategies:

If I don't understand how can I explain? (...) My fear is what will happen if one day I will face a situation I do not know and I think «So what now, how do I use this? What should I do? ». (...) This is true, sometimes I think about this. [2008 april _ collaborative meeting with teacher]

The collaborative work seems to contribute to the evolution of mathematical communication as social interaction in the primary school classroom and to the teachers' awareness that they should become more involved in getting more mathematical knowledge.

Patterns of interaction. The centrality of the lesson around the teacher's mathematical knowledge seems to discourage the student's questioning about his own learning. This kind of approach seems to result in the existence of the pattern of reciting, characterised by questions related to the checking of knowledge addressed to the students. Collective or individual answers are validated by the teacher as she repeats the answer:

Teacher: Why do you say this is a square?

Students: It has four equal sides.

Teacher: It has four equal sides.

[2007 june _ lesson _ first year of primary school]

A strategy often used by the teacher aiming to overcome the students difficulties is asking simple and straightforward questions that will direct them to the intended answer or to the resolution of the proposed task, generating an interaction characterised by funnel and focus patterns. At different key moments in the lesson, Laura resorts to this sort of strategy right after wrong solutions have been given. In one of the lessons we observed, the students were supposed to write consecutive natural numbers starting at a given number. Miguel, one of the students, went to the blackboard to fill in the gaps with the predecessor and the successor of 300. Faced with the student's difficulty in determining the predecessor of 300, Laura pointed him towards the solution by means of a dialogue that could be said to be characteristic of the funnel pattern:

Teacher: What is the one before that? Is it 300?

Miguel: No.

Teacher: What is it? What is the order that we should follow? What is it?

[The Student remains silent.]

Teacher: Is the number that comes before that one three hundred and something? Is it?

Miguel: No.

Teacher: So what is it? If it isn't three hundred, what is the hundred before three hundred?

Working Group 17

[Student falls back into silence.]

Teacher: What is the hundred before three?

Miguel: Two.

Teacher: So that other number has to begin with...

Miguel: Two hundred.

[2008 february _ lesson _ second year of primary school]

Laura feels powerless to change this sort of patterns because she believes that she lacks enough knowledge and creativity to take her students on a different path: ‘Many times, when I’m trying to help them out, I’m already providing the answer unwittingly. Sometimes I also lack some imagination to fetch other examples, to pursue different paths’ [2008 april _collaborative meeting with the teacher]. Such lack of imagination and creativity, along with a superficial mathematical knowledge may explain traditional interaction patters based on questions of knowledge validation and focusing on procedures.

However, the *discussion* pattern emerged with the increasing number of interactions among the students and between the teacher and them. In the presentation of resolution strategies concerning a problem on height [2], Laura helped the students to clarify their presentation, following a scheme similar to the pattern of discussion:

Student: 180 is her height standing on the stool and 45. And now we subtracted 45 from 180.

Teacher: Which is...?

Student: Which is her height standing on the stool.

Teacher: 45?

Student: No, 180.

Teacher: So 45 refers to what?

Student: To the stool.

Teacher: So what do we have to do to figure out her height only?

Student: We have to subtract 45 from 180

[2008 may _ lesson _ second year of primary school]

Traditional interaction patterns, such as reciting, are now practically nonexistent, despite the teacher’s omnipresence. The increase in the number of interventions of the students and a growing command of mathematical discourse resulted in the emergence of patterns other than funneling and focusing, such as patterns of discussion, where the students themselves assumed the explanation of resolutions and strategies, with the help of the teacher in the clarification of procedures and learning processes.

SOME FINAL CONSIDERATIONS

Laura’s conceptions and practices about mathematical communication evolved from the transmission of information and knowledge to mathematical communication as social interaction. Mathematical knowledge was socially constructed in the

Working Group 17

classroom as a result of the value given to mathematical ideas, strategies and knowledge of the students.

The increase of social interaction in the classroom among students and among students and teacher contributed to intensify the role of Laura in encouraging the participation of her students in collective talk in the classroom. It also contributed to increase the interaction between students, either mediated by teachers or not and to value the students' mathematical knowledge and individual strategies.

The interactions between the students played a major role in the presentation and discussion of strategies and results of mathematical tasks. The interactions between students were intentionally fostered by the teacher to encourage students in the collective discourse of the classroom. These interactions originated a growing respect among students as they shared their mathematical knowledge and ideas.

Social interaction appears to lead to a change from a mathematical communication centered on the teacher to a mathematical communication centered in the classroom – students and teacher – based on the singular knowledge of each student as a structural component of mathematics learning. In this perspective, the mathematical communication conceptions and practices of the teacher seem to adjust to mathematical communication as social interaction, resulting in value being given to the students' knowledge and strategies: all of this due to reflective communication based on inquiring questions and the discussion in the mathematics classroom.

NOTE

[1] River Crossing - The hunting dog, the rabbit and the cabbage

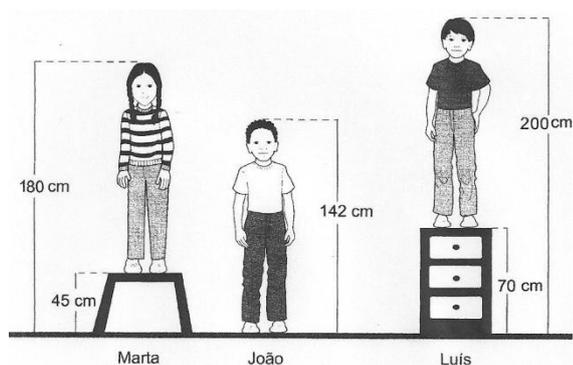

Little Johnny was crossing a dry, unshaded field on the way to his grandfather's house. He was taking with him a hunting dog to go with his grandfather on the hunt, a jack rabbit for his grandmother to put in her rabbit hutch with a pretty female rabbit and a nice cabbage for lunch.

All along the way, the dog wanted to eat the rabbit and the rabbit to eat the cabbage. Little Johnny had to be very careful as he walked along to avoid anything going wrong. After a while Johnny came to a river he had to cross.

In order to cross the river there was a small boat which he could use, but it was so small that he could only take with him one passenger at a time: the dog or the rabbit or the cabbage. He could never leave the dog alone with the rabbit or the rabbit alone with the cabbage, so how can he get all of them across without any problem? You are going to help to resolve this problem.

[2] Luís and his two friends were playing heights as you can see in this picture. Each of the three friends has a different height.

Working Group 17

Considering only the measurements in the picture, write the name of each of the three friends, from the shortest to the tallest.

LESSON STUDY IN TEACHER EDUCATION: A TOOL TO ESTABLISH A LEARNING COMMUNITY

Guðný Helga Gunnarsdóttir and Guðbjörg Pálsdóttir

University of Iceland, School of Education

This paper presents a study on the use of lesson study in teacher education. Teacher education in Iceland has been under constant development and the authors of this paper have taken part in developing mathematics teacher education based on recent research on teacher education. The study shows that lesson study can create a learning community where teacher students can develop their professional language and collaborative competence which are considered to be important issues in teacher education. Lesson study also helps teacher students to put focus on pupils learning and content when planning lessons together. Lesson study with teacher students seems to be a good way for them to learn to teach and to develop as professionals.

Key words: lesson study, mathematics teacher education, learning community

INTRODUCTION

Mathematics teacher education in Iceland has been changing and developing during the last decades. From 1971 teacher education for teachers in compulsory school (grades 1-10) has been a three year B. Ed. degree⁸⁵. The structure has varied but teacher students have always specialized in one or two subjects. From 2007 the B. Ed. degree has consisted of 80 ECTS⁸⁶ in pedagogy and didactics, 80 ECTS in specialization and 20 ECTS for studies of own choice (Stefnumótun Kennaraháskóla Íslands 2005-2010). In their specialization the mathematics teacher students study mathematics and mathematics education. In some courses they study either mathematics or mathematics education while in others the study is combined. For their teaching practice (12 weeks) the teacher students have a home-school.

The authors of this paper have taught different mathematics education courses for more than 20 years and have taken part in developing the studies in cooperation with colleagues. In choosing a structure and content for our mathematics education courses we have put an emphasis on creating a learning community among the teacher students. We play an active role in this community as participants in discussions and as group leaders or experts. The teacher students are to be active and bring in their knowledge, views, and thoughts about mathematics education. We have chosen to introduce our students to lesson study (Lewis, 2002) to establish

⁸⁵ In 2011 a five years M. Ed. degree will be required to qualify as compulsory school teacher.

⁸⁶ European Credit Transfer System – A full academic year of studies is 60 ECTS

learning communities within the frame of the courses. This is based on the belief that the creation of learning communities in teacher education it gives the students good learning opportunities for developing a professional language and a collaboration competency. Our aim is also to introduce a professional learning strategy to our students they can use in different contexts when they enter the teaching profession.

In this study we explore the effectiveness of using lesson study to develop a learning community within our courses. Our research questions are:

- How does the learning community develop during the lesson study process?
- What characterizes the learning community?

THEORETICAL BACKGROUND

Mathematics teacher education has become an important field of study among researchers in mathematics education during the last 20 years. The increased interest was marked by the publication of the first issue of the *Journal of Mathematics Teacher Education* in 1998 and the publication of the first *International Handbook of Mathematics Teacher Education* in 2008 (Krainer & Llinares, 2010). The collaboration of teachers, teacher educators and pupils seems to be a central issue in many of the research studies. Team work, learning communities, networks and design research are often suggested as ways to help teachers to tackle and meet the complexity of teaching mathematics and to support them in their lifelong learning process. (Jaworski, 2005, 2006, 2007; Krainer, 2003; Wood, 2002; Wood & Berry, 2003).

Many researchers have tried to identify a knowledge base for mathematics teaching or important competencies for mathematics teachers. A professional learning competency is considered to be an important factor and teacher students need to learn to create professional learning opportunities during their pre-service teacher education. They also have to learn to collaborate with others and to create learning communities that will support their learning as teachers (Grevholm, 2006; Hiebert, Morris, & Glass, 2003). Teacher students have to realize that they are only starting to create a knowledge base and that they are entering a profession where lifelong learning is essential.

Hiebert, Morris, & Glass (2003) describe learning environments prospective teachers must learn to create in order to sustain their own and other teachers learning. In these environments teacher students need to learn to learn from their teaching in collaboration with others. They mention lesson study as an example of such a learning environment.

According to Darling-Hammond (1998) the best learning environment for teacher students is when they are given the opportunity to teach, study and reflect in collaboration with others and by looking closely at the pupils and their work and share what they see with others. This requires a close connection to schools and

teaching practices. Teacher students need both opportunities to try out their ideas in practice and support to reflect upon and interpret practice (Darling-Hammond, 1998).

Professional learning communities seem to play an important role in supporting teachers in continuously improving their teaching and sustaining their professional learning. Trends in teachers' professional development show increased attention to professional learning strategies grounded in classroom practice. (Fernandez, 2002; Loucks-Horsley, Stiles, Mundry, Hewson, & Love, 2010). Professional learning communities where teachers share understandings about the nature of good teaching and work together on planning and improving teaching seem to provide particularly conducive settings for learning to teach (Hammerness, Darling-Hammond, & Bransford, 2005).

Lesson study is often referred to as an example of a professional development strategy that creates a learning environment in which teachers engage in learning with their peers (Lewis & Perry, 2009). It is also a strategy that aims to achieve all of the four outcomes that according to Loucks-Horsley and her colleagues characterise effective professional development. They are; enhancing teachers' knowledge, enhancing quality teaching, developing leadership capacity, and building professional learning communities (Loucks-Horsley, et al., 2010)

Lesson study is mentioned as an example of a pedagogy for preparing teachers for teaching as a lifelong learning process (Hammerness & Darling-Hammond, 2005). Several research studies report on successful use of lesson study with teacher students (Burroughs & Luebeck, 2010; Tsui & Law, 2007) and teacher educators have shared their experiences of using lesson study with teacher students in journals like NCTM's *Mathematics Teacher*.

The Lesson Study Process

The main idea of lesson study is that a group of teachers, develop a teaching plan for one lesson. The structure of the lesson, the role of the teacher and pupils learning are in focus. The lesson study process can be described as a cycle, a process where the group of teachers repeatedly goes through the phases, discussion, goal-setting and planning, research lesson.

In the first phase, the group has to discuss the aim and the content of the lesson.. Then the participants explore the content, both what it means to acquire understanding of the content it and how it can be approached in teaching. The participants are in control, and make decisions about the process. The participants often deepen their knowledge of the content and possible teaching approaches. They communicate, do research, work together, make decisions, plan teaching, and experience the advantages of participating in a learning community. The research lesson is taught by one of the participants and the other participants are present and take notes. Some times an outside expert is invited to observe the research lesson

Working Group 17

and take part in the post lesson discussions. On basis of observations during the research lessons og the post lessons discussions the lesson plan is revised and the lesson taught again for a similar group. The cycle can be repeated several times (Lewis, 2002)..

In organizing our courses we have focused on establishing a learning community with our teacher students. A learning community where teacher educators and teacher students share ideas, discuss and work together on planning good teaching. Such an environment gives opportunity to develop professional language and collaborative skills. By engaging in the lesson study process the teacher students take part in creating a learning community where the focus is on the pupils learning of a specific content.

METHOD

This research-study focuses on two 10 ECTS courses in mathematics education. The teacher students attend them in their second year and are at the same time attending courses on geometry and number theory. Teaching practice in grades 7-10 is an important part of the mathematics education courses. In the fall they follow the course: *Mathematics teaching and learning in lower secondary school* where they are introduced to mathematics education as a field of study. They learn about lesson study, discuss and study various resources for lesson study (<http://www.lessonresearch.net/>),. Lesson study is introduced as a tool to use in a professional development. The focus in on how being a part of a learning community gives teachers the supporting environment to develop their teaching collaboratively. In the spring term the teacher students attend the course: *Mathematics teaching and learning for all*. Then they try out the ideas of lesson study. All the students, around 15, work as one lesson study group. They start with discussing the aim and the content of the lesson. They focus on what could be relevant for 8th and 9th grade in their home-school and use the curriculum guide and their own analysis and interest in their considerations. The teacher students plan the lesson in collaboration with their teacher educators and make use of different literature and teaching materials as well as their own experiences. In the making of the lesson plan they use a four-column lesson plan (Matthews, Hlas, & Finken, 2009). The columns are: Steps of the lesson: Learning activities and key questions (1), expected pupils reactions and responses (2), teacher's response to pupils reactions/things to remember (3) and goals and method(s) of evaluation (4).

Some of the teacher students are distance learners and all students share a digital learning environment (Blackboard). The students on campus work together in class and records of the work in progress are shared with the distance students in Blackboard. The distance students contribute to the process by communicating their ideas, thinking and reflections the same way. Three or four weeks are used for the preparation of the lesson. Then the teaching plan is introduced to the practice-

Working Group 17

teachers in the home-schools. They can make comments to the lesson plan and share their experiences with the group. Groups are created for teaching and observing research lessons. In each groups there is a teacher educator, practice teachers and teacher students from two home schools if possible. The groups adjust the lesson plan to the actual situations in the school and make practical decisions regarding the research lesson. All groups teach the lesson two times. After the research lesson there is a short evaluation meeting. When all groups have taught the lesson once the teacher students and teacher educators meet at campus to discuss the experience and make revision of the lesson plan. The reasons for different adjustments of the lesson plan in each home school are also discussed. When the teacher students are back at the university time is taken to discuss the lesson study project and this way of planning and collaborating as a tool for professional growth.

The lesson study process reported on in this study has been conducted with two groups of teacher students in total 30 students. Both groups developed lesson plans around prime numbers. The students were attending a course in number theory and the teaching of numbers and number theory was a topic in the math education course. The overarching aim for the teacher students was to find ways to make the mathematics teaching and learning interesting and fun for the pupils. They also found it challenging to make this particular topic, prime numbers, interesting and purposeful for their pupils. The first group developed a lesson plan around the question: What use can be made of prime factorization? They developed six different tasks that could be worked on in groups and then discussed in the whole class. The second group developed a game where the pupils were supposed to find out whether a number was a prime number or a composite number and how they could argue for their categorization.

DATA

In this research-study the data was gathered during the school-years, 2008-2010. This study builds on prior studies on teaching teacher students similar courses. There the focus was on how research on mathematics teacher educations has influenced the structure, content and teaching approach in the courses (Gunnarsdóttir, Kristinsdóttir, & Pálsdóttir, 2008; Gunnarsdóttir & Pálsdóttir, 2010). The data in this study consists of two lesson plans, teacher educators' notes, an interview with two teacher students, audiotapes from planning meetings, correspondence between the teacher students at campus and the distance students, notes from evaluation meetings, a video tape from the evaluation meeting at campus and notes from discussion after the teaching practice period. We also have an audiotape from the oral presentation of the final course assignment where the teacher student presented their ideas about ideal mathematics teaching.

The data was analysed with our goal for using lesson study, to create learning communities, in mind. When reading and listening to the data our attention was

drawn to four main themes that are all important in a learning community. The four main themes; professional language, collaboration competence, focus on pupils learning and teacher students elaboration of the content are evident in all our data. The development of a professional language and collaborative competency are often mentioned as the main goals for establishing learning communities (Hammerness, et al., 2005; Jaworski, 2007). A learning community based on a lesson study process puts focus on pupils learning and mathematical content. We will provide some examples of how these four themes emerge from the data.

Professional language

In the beginning of the lesson study process the teacher students found it hard to understand how you could use several weeks to plan one lesson. It took one session to discuss the approach and decide on content. But when they started to work on the content in more details they realized that there were many things to consider and many different ways to go. They felt the need to understand each other's ideas and they needed to be more precise in their use of language and had to support their arguments by referring to prior readings and common course literature in mathematics education. They also had to refine their shared understanding of concepts from general didactics and mathematics. The discussions became longer and more intense. They were developing their ideas in collaboration and trying to consider the teaching of the content from all points of view. Because of the distance students a part of the dialog was in written format and that demanded a more precise use of professional language. All the teacher students were going to teach the lesson at some point so they felt the need to understand and agree with the lesson plan. Despite of the assumed shared understanding written in the lesson plan the students realized that the lesson turned out differently in the schools when they met after the first round of teaching. The teacher students' use of professional language developed considerably during the process, they used more professional concepts, their discussions lasted longer and they referred more often to literature connecting theory and practice In her final assignment Elsa refers to the book *Adding it up* and that she wants to establish communities of learners in her ideal school. When she introduces her idea to her fellow students they elaborate on the idea and discuss it in a professional way with reference to their shared experiences during the lesson study process.

Collaborative competence

When using lesson study the challenge is to develop an effective way to teach a certain content or concept with some long term educational goals in mind. This is done in collaboration and participants have to present their ideas, discuss them and take joint responsibility for the planning of the lesson. They have to reason with each other and build on their previous experiences. They come to realize how important it is to collaborate, think and plan together. There are many things to consider when

Working Group 17

planning a lesson and when it is done in collaboration more details are discussed and from different points of view.

Kristin: It was fun and rewarding to plan this together. We all thought we understood the plan the same way but it turned out differently.

It also encourages and gives the teacher students opportunity to try out things they otherwise would hesitate to do. They experience what to collaborate about in a learning community and what teacher collaboration can mean. The teacher students' collaborative competence strengthens during the lesson study process. It is evident they have more to discuss and they experience the benefit of having colleagues and common experiences to relate to. They feel it is important for their future development as mathematics teachers to be a part of a learning community and that they themselves have a responsibility in creating such a community. In their final assignment almost all the teacher students see themselves as a part of learning community planning and reflecting on teaching.

Focus on pupils' learning

In the lesson study process the teacher students discuss possible teaching approaches. In choosing an approach they use their knowledge of pupils, their situations and different learning needs. The teacher students try finding an approach that many pupils will find appealing and is at the same time challenging to themselves. In the lesson plan they focus on what the pupils should do but they often fail to anticipate pupils' responses and how they as teachers should react to them. During the teaching of the lesson there is always at least one teacher student in the role of an observer. The teaching approach is well known to the observers and therefore it does not become the main object of study even though they have an interest in how the teaching develops. Instead the observers focus more on the pupils and their reactions and learning. In the evaluation meeting the teacher students often refer to particular pupils responses and become fascinated of how the different pupils deal with the content. Changes in the lesson plan are based on their analysis of the pupils' responses. Their main focus is on making the lesson a positive learning experience for the pupils. The teacher students feel that by choosing approaches like games and group work they succeed in creating good conditions for pupils learning. During the preparation of the lesson the teacher students express their ideas on what is important for the pupils' learning.

Elsa: We need to make use of their interests.

Anna: They have to be able move around.

Karen: It has to be fun and it should be hands on.

Berta: Pupils show more interest when they can work together and decide what to do.

When discussing their future teaching the teacher students point out the importance of getting to know the pupils ideas about mathematics and mathematics learning and base their teaching on that knowledge.

Focus on mathematical content

The choice of content is influenced by what the teacher students are learning in mathematics courses. They have some prior knowledge of prime numbers, rules for finding prime factors and whether a number is a prime or not and rules for divisibility of numbers. But there are some shortcomings in their understanding that become obvious during their initial discussions. They make use of each other's knowledge, make connections and refine their understanding through common discussions. They become more aware of what it means to understand prime numbers and composite numbers.

Tina: The pupils know about prime numbers and ways to find them. They have also worked with divisibility, square roots and composite numbers. We need to discuss with them how to use this when finding out whether a number is a prime number or composite number.

Through the discussion the teacher students also better understand the importance of a good content knowledge for a teacher. They experience that good content knowledge gives you more power and flexibility when designing a lesson process. During the process all the teacher students become better in expressing their knowledge and for many their basic understanding of the content improves a lot. They realize that there are many things to consider if you want to teach this content with understanding.

CONCLUSION

During the lesson study process the teacher students have developed their professional identity. They have realized the complexity of teaching but they have also become more eager and stronger in dealing with the complexity. In the beginning the teacher students focused on the teaching plan as a platform for collaboration. But during the process they realized that they needed to collaborate more closely regarding other aspects of the teaching and the learning of the content. They also felt how rewarding these collaborations were. They felt the need to verbalize their ideas and thinking, ask into others thinking and reflect on that. More and more teacher students became active and they became more able to dwell on things and discuss them in details. Both the distance students and the students on campus became more willing to collaborate and share ideas and they developed a community of learners where everyone had a voice. It was noticeable in the discussions that the teacher students were also ready to take risks and could provide some strong arguments for their ideas. They became more convinced that they could learn a lot from others and by trying out things in collaboration with others.

Trust and openness characterized the learning communities that were established. The fact that it was only a short term commitment and the teacher students had to take part in the project as a part of their study influenced their participation. Because it was not a long term commitment it did not involve much risk for them. It became a

Working Group 17

positive experience that they can use and learn from when they enter into teaching. But trying to establish a learning community in school can become much more risky because it is more long term and there are other expectations and power structures in place. Because the teacher educators were a part of the learning community the teacher students did not have to take full responsibility for the process or the outcome of the process, the lesson plan.

The lesson study process is an important venue to connect theory and practice and it also gives the teacher educators an opportunity to enter the practice field more in the role of a partner than an evaluator. The focus was more on making the learning opportunities for the pupils learning better than on the teacher students' performance. Lesson study has a potential for changing the focus in teaching practice and puts the collaboration between the teacher educators, teacher students and practice teachers in a different context. Many teacher educators are trying to use and develop lesson study with teacher students and here there are many opportunities for further research and development. It is a future challenge to establish learning communities with all three partners, teacher students, teacher educators and practice teachers that could strengthen professional learning communities in schools

THE USE OF THE EMPTY NUMBER LINE TO DEVELOP A PROGRAMME OF MENTAL MATHEMATICS FOR PRIMARY TRAINEE TEACHERS

Gwen Ineson

Brunel University, UK

In England and Wales, mental mathematics has been emphasised in the primary school curriculum for over a decade but little has been done to prepare trainee teachers faced with the task of delivering this curriculum. The Williams Review (2008) recommends that this is an area which should receive 'careful attention' on initial teacher training programmes. Design-based research sought to use conceptual pedagogy to develop an effective programme for trainee teachers to develop their mental mathematics knowledge for teaching. This paper describes the use of the empty number line within the intervention programme for 129 trainee teachers on a one year post graduate training programme.

Key words: Mental mathematics, subject knowledge, conceptual pedagogy

INTRODUCTION

The mathematics curriculum in England and Wales has changed dramatically over the last ten years since the introduction of the National Numeracy Strategy (NNS) in 1998. Pupils in primary schools are expected to be competent in adding and subtracting any pair of two digit numbers before they are taught formal written calculation strategies. As a result, mental calculation has attained a dominant position in the primary curriculum and teacher education programmes in the UK have required adaptation to reflect these changes.

Teachers' Subject knowledge

Until the 1970s, little research had been carried out to determine what sort of mathematics teaching made for effective pupil progress (Ball, 1990). However, during the next few decades, mathematics education theorists and researchers began to consider the implications of Shulman's (1986) general categories of subject knowledge for the specification of the mathematics knowledge requirements for teaching and the construct was appropriated and refined for the purpose of mathematics research and practice.

In attending to mathematics content for teaching, some researchers concentrated on subject matter knowledge and delved deeply into the nature and purpose of the discipline to illuminate the task of ascertaining the mathematics knowledge required of teachers of mathematics (Goulding, Rowland & Barber, 2002). Further research was inspired by respect for the discipline of mathematics. It reflected research studies conducted in the USA, for example Ma (1999) who was specifically concerned with discipline-specific knowledge for teaching mathematics in its content

(substantive and syntactical) and pedagogical forms, and in the UK, for example Askew, Brown, Rhodes, Wiliam, & Johnson (1997), McNamara, Jaworski, Rowland, Hodgen, and Prestage (2002) and Rowland and Turner (2008) who sought to relate subject knowledge to effective teaching.

Ma's work (1999) explored the relationship between discipline-specific knowledge for teaching and pedagogy. Her results showed that American teachers had limited knowledge of mathematics and that their knowledge was often faulty. These findings were not new to American researchers (Ball, 1990) but what was novel was the comparison with Chinese teachers. This and other similar examples led Ma (1999) to contend that Chinese teachers identified and encouraged the specific conceptual understanding which was of importance in covering these types of problems. She described it as a profound understanding of fundamental mathematics (PUFM) – teachers' recognition, within their teaching of:

- the connectedness of the simple but powerful ideas at the core of mathematics;
- the capacity of these ideas to sustain multiple perspectives and flexibility;
- the location of the ideas within a coherent and holistic disciplinary structure.

Crucially, within this specification, there was no differentiation between conceptual subject matter knowledge and pedagogical content (or specialist) knowledge. The conceptual foundation for PUFM was teachers' sense of the connectedness of mathematics ideas; in pedagogical terms it meant that they formed knowledge packages around a central core. Conceptually, teachers had an awareness of the importance of simple but powerful ideas, which were especially stressed and developed through pedagogy. Conceptually, teachers were able to entertain multiple perspectives; pedagogically this meant that, as teachers, they could analyze their advantages and disadvantages and lead students to a flexible understanding. The coherence of their teaching over time reflected teachers' conceptual sense of the primary mathematics curriculum as a whole. Pedagogically, it meant that they could exploit what pupils had already studied and create foundations for what was to follow.

Mental mathematics

A new curriculum for mathematics was established in England and Wales in 1998 (DfEE, 1998) in order to raise mathematical achievement (Brown, Askew, Baker, Denvir & Millet, 1998). This new curriculum – the National Numeracy Strategy (NNS) emphasised the development of mental calculation, which was in line with research in mathematics education in the Netherlands, where mental calculation and, in particular, informal strategies, had been a key component of the Realistic Mathematics Education (RME) programme.

The hundred-square, commonly found in primary classrooms in England and Wales, and used in the Netherlands prior to the introduction of the Realistic Mathematics

Working Group 17

Education programme, was seen as restricting, particularly in terms of mental calculation. The Empty Number Line (ENL) was introduced as a model in schools in the Netherlands, which helped pupils visualise the ‘quantity value’ of numbers. It replaced the practice of partitioning using base ten that encouraged pupils to concentrate on the ‘column value’ (Thompson, 1999) of numbers. Beishuizen (1999) emphasised the benefits of the approach taken in the Netherlands in terms of general mathematics competence:

‘dealing with whole numbers supports pupils’ understanding and insight into number and number operations much more than the early introduction of vertical algorithms dealing with isolated digits’ (p.159).

Furthermore, Klein, Beishuizen and Treffers (1998) suggested that other benefits accrued from the action of replacing the hundred-square with the ENL, such as ‘enhancing the flexibility of mental strategies’ (p.427).

Mental Mathematics and Teachers

The new mathematics curriculum left university teacher educators charged with the need to make provision within their courses and programmes for opportunities to promote and assess the development of trainee teachers’ mental mathematics teaching competence.

So what were the knowledge requirements of teachers training to teach mental mathematics in primary schools? What did an understanding of mental mathematics mean for a primary trainee teacher charged with developing pupils’ ‘with the head’ (Beishuizen, 1997) use of mental mathematics, as opposed to the ‘in the head’ notion of rote learning? These problems were formulated into the following research questions: What are the most effective interventions to enable trainee teachers to enhance their mental mathematics subject knowledge for teaching and how can these be implemented during the university-based element in a one-year postgraduate primary teacher education programme?

THE PROJECT

The project involved the formulation of an innovative intervention programme to develop mental mathematics for teaching. Design-based research, through various diverse methods, involves accumulate a body of evidence that supports and enriches the theoretical principles underpinning a specific intervention and leads to the refinement of the intervention in situ. In their definition of design studies Wang and Hannafin (2005) argue that design-based studies provided access to:

...a systematic but flexible methodology aimed to improve educational practices through iterative analysis, design, development and implementation (p. 6).

The purpose of design-based research is the development of contextually sensitive theories in real-world settings and for these reasons, they offer a methodological

option which met the specific needs of this study manifested in its research question and underlying commitment to theory development.

Theoretical principles for designing the intervention

The design study was predicated on the belief that, in the context of teacher education, a knowledge-framed curriculum was an appropriate object for the study and development of trainee teachers' mental mathematics subject knowledge for teaching. Furthermore, the knowledge-framed curriculum was driven by two theoretical principles, one discipline specific, relating to the conceptual foundations of mental mathematics and the other context specific, relating to the embedding of the conceptual within teaching.

The first principle was that the conceptual foundations of mental mathematics knowledge for teaching implied a commitment to working with numbers as wholes, an understanding of the reciprocal nature of mathematical operations as well as a strategic approach to calculation.

The second theoretical principle was that, in order to extend and realise these conceptual features within their teaching, trainee teachers required access, through conceptual pedagogy - the integration of conceptual and pedagogic knowledge into a bigger whole - to a connected, flexible, coherent approach to subject knowledge for teaching. In other words, the course needed to make provision for the development of what Ma (1999) described as profound knowledge.

The design of curricular activities in the study was based on design principles created by the contextualisation of these theoretical principles within the context of teacher education. Activities were designed to:

- Connect the three conceptual features – whole numbers, interchangeable operations and strategic approaches; provide the means to generate data for review of the effectiveness of the activities by inviting trainees to model pupil behaviour
- Focus on the simple and powerful ideas of mathematics (such as number structure, the laws of arithmetic, principles of counting, equations); re-visit and provide opportunities for their identification
- Nurture flexibility through comparisons by trainees, individually and in groups, with others' perspectives, with their own previously held views and habits and through the application of mathematical ideas within discussions of 'best' strategies
- Reinforce the coherence of mental mathematics in relation to the primary curriculum

The process of design of activities and materials for use with a cohort of 129 primary trainee teachers during a year-long programme of teacher education was based on

these principles. Micro-analyses of trainee teachers' interactions with the designed activities - individually, through group work within the university and in teaching placement contexts – led to review and modification of activities while offering a theoretically-informed commentary on their effectiveness.

Two strategies were adopted to improve validity and reliability: the use of data collection methods that captured the complexity of trainees' interactions with materials and activities in as full a range of contexts as possible; and the creation of a partnership between a small group of trainees and the researcher as a means to challenge tacitly held assumptions and to establish consensus.

The intervention

During the programme, interventions, both planned and reactive, gave recognition to the importance of the principles outlined above. Each of them permeated the mathematics programme's interventions, and specific activities were also planned to target particular areas.

The principles underlying the simultaneous presentation of the four number operations (addition, subtraction, multiplication and division) were derived from the requirements of mental mathematics – the reciprocity of the operations – and of conceptual pedagogy – in this case, connectedness and coherence.

Materials were prepared to highlight the way in which the empty number line could be used in teaching to model and, therefore connect, each of the four number operations. The intention during the initial stages of the session was to provide a stimulus for discussion within small groups in the form of: an explanation of the structure of the empty number line; a brief description of its introduction and use in the Netherlands; and an account of the way in which it was incorporated into the mathematics curriculum in the UK. At this stage group activity would involve the further exploration of the concept and the framing of questions for whole group discussion.

A variety of problems were chosen for use during the next stages of the session, with the specific aim of connecting the four operations. Once again, trainees were to be asked to participate in a group activity and to use the empty number line to find solutions to the problems. Pre-designed materials included the use of the empty number line to tackle, for example, division problems through the repeated subtraction of 'chunks'. Finally trainees were to be asked, in a group activity, to reflect on the appropriateness of the empty number line in the context of their own preparation for teaching and to reveal their thinking.

During the year, qualitative data on trainees' responses were gathered continuously during normal teaching sessions. This was achieved by creating opportunities for trainees to record the detail of the processes used individually and during group discussions and, where appropriate, to justify their responses in writing or verbally, in the whole group public arena.

Working Group 17

Each mathematics session in the programme was planned to focus on progressing trainees' mental mathematics knowledge for teaching by providing access, through conceptual pedagogy, to a flexible, connected and coherent approach to subject knowledge for teaching. This involved a commitment to working with whole numbers, the relationship between mathematical operations and a strategic approach to calculation over a number of weeks and environments (university and school placement) during the one-year programme.

Following the ENL activities described above, some trainees queried the effectiveness of the use of the empty number line. They were directed to research about alternative approaches to partitioning when calculating and critiques of these approaches (Thompson, 1999). After considering the research, trainees in six seminar groups, each of between 25 – 30 trainees, discussed the possible effects of focusing on one approach rather than the other. Initially, three groups reported in the feedback sessions that some members could not understand the need for such a tool because they had learnt strategies for each of the operations which 'worked for them'. One group reported that this tool could become too much of a prop for pupils, encouraging counting in ones. For another group, the notion of using a number line was alien, as the experience of group members, prior to the course had tended to focus on a more formal approach to calculation. One member, commented that 'the empty number line is an interesting concept, but perhaps one of the most challenging methods for me to grasp'. It also became apparent that some trainees were developing an algorithmic approach when using the empty number line. During workshop sessions where trainees were looking at subtraction by counting back or counting on, one trainee commented 'I'm confused, which numbers do I write on the line?' The response by other trainees was that, 'you put the largest number on the right, then the other number at the other end'.

Such data led to the adaption of the intervention programme. Specific examples were introduced which allowed trainees to consider whether counting on or counting back was more appropriate. Trainees commented that specific examples also made them realise the importance of stopping to consider the numbers involved, which enabled them to assess the most appropriate calculation approach. The intervention was adapted further to provide opportunities for trainees to make use of individual whiteboards (similar to those used in primary schools) in order to do rough jottings using the empty number line. One trainee noted that the process of actually using the empty number line for her own calculations had enabled her to become more 'flexible and confident in the use of the empty number line for teaching'.

The comment made, by one trainee, that she had found the empty number line to be a 'revelation' in the classroom, generated overwhelming agreement. The following comments are representative of the group's views about the usefulness of the empty number line:

Trainee 1: The empty number line is a very important visual resource for pupils.

Working Group 17

Trainee 2: I agree... that drawing jumps on the line works well as a natural way of keeping track and recording mental solution steps.

Trainee 1 described a scenario from her classroom, where a group of pupils were using the rounding and adjusting strategy. The example was $98 + 137$. The pupils rounded the 98 to 100, but were then unsure whether to add or subtract the 2 which had been rounded. She demonstrated to the group how she had used the empty number line to encourage the pupils to consider the whole numbers involved. She reported that the pupils went on to complete the examples successfully, and claimed that although the pupils did not continue to draw the empty number line, they said that they were visualising it. Trainee 1 was challenged about whether the method had become an algorithm, but she was confident that the empty number line was used in quite a different way, as a means for visualising the relative sizes of the numbers.

At this stage the opportunity to broaden the cohort's discussion was used to compare the whole numbers approach with alternative approaches in the form of formal written strategies or algorithms. A particular example was selected from an audit which had been used at the beginning of the year ($199 + 174$). Data from this audit revealed that over half of the cohort had used a formal written strategy at the beginning of the year. A number of the cohort described this as an unacceptable use of a formal written strategy. A quick paper survey was undertaken to establish how many of the cohort agreed with this 'unacceptable' use of the formal strategy and it was found that 93% of the group (106 trainees) agreed with this description for this particular item. Some trainees reported that they had not considered an alternative strategy at the beginning of the programme because they were using what they described as their security blanket - those algorithms which were quick to administer and gave reliable results. One group admitted that its members had not considered the numbers involved before diving in to carry out a procedure. A few trainees from other groups said that they were reluctant to move away from the strategies with which they felt comfortable. They could not appreciate why pupils should be introduced to so many different strategies as they felt this could cause confusion. All other groups, however, concluded that while formal algorithms may be effective and, ultimately, be the most efficient strategy, the 'stop and think' approach would encourage thinking about the numbers involved, before making a strategy choice and that this was of greater importance. This reference to a 'stop and think' approach was re-visited throughout the programme in order for trainees to consider alternative approaches.

The empty number line was further developed during discussion regarding problems involving decimals, where trainees reported that they made use of the empty number line for these types of problems purely as a visual image, to consider the relative sizes of the numbers involved. In this context, one trainee noted that the empty number line had helped her to appreciate the structure of the number system. She wondered why she had been 'so concerned about working with decimals, because if

you just think about them on the number line, they are just normal numbers, but zoomed in'. The commitment to focusing on numbers as wholes was an indication of the success of the use of the ENL as a model for developing mental mathematics for teaching.

CONCLUSIONS

As noted above, some trainees were initially sceptical about the value of the empty number line, but for many, this perception changed over the course of the intervention. After spending time in the classroom, trainees began to change their views as they saw the potential benefit of this approach. One trainee observed, during school experience, what was seen as the benefit of planning activities to emphasise connectedness using the ENL 'these children were slowly beginning to make some creative connections between numbers that they could use to help them solve a variety of calculations.'

Although most trainees concluded that a flexible approach to calculation was what they would strive for in their teaching, this commitment was not always evident in their own calculations. The following is one trainee's explanation of her initial response to $199 + 174$, where she had used a formal written method:

'When I look down I think 199 and I know automatically that you should see this as 200.... But when it is written down like that it's not, to me, it's not obvious that it would relate to 200....I definitely only see the digits.'

During review the data which had been collected throughout the programme was referred to and used to provide some insight into these contrasting experiences. A minority of trainees had routinely reported during the first workshops that they found the standard formal written methods efficient and straight forward to apply, and that it was difficult to understand why any other methods were taught in school. When invited to reflect on their experiences during seminars and in schools, there was general agreement that it felt as if they were 'learning backwards'.

Such comments indicate the potential of conceptual pedagogy for change. Even in a generally negative example there is evidence that a trainee was enabled to analyse and identify a lack of coherence as the source of the insecurity of her knowledge of mental mathematics:

'See this is the problem that I have got, I've got all these little facts and they are all over the place. So that, so somehow I know that obviously three quarters is 0.75 and then you times it by 10 and it's 75, I've got all these useless, they are not useless, but, well, they are useless unless I can apply them.....See that's the thing, I've got all these jumbled up facts and I know all these silly little things, that that needs to be that but I don't know why, there is no sense to it.'

This clearly showed that there had been insufficient time for this particular trainee to come to terms with her early experience of mental mathematics, which was

sufficiently strong to resist the coherence promoted in the programme. However, the statement shows that the trainee does appreciate the need for integration and for meaning in the knowledge possessed by teachers of mental mathematics.

Others had been able to use experience of the programme to come to terms with their own knowledge base. One trainee explained how the programme had affected her mathematics knowledge:

'Like most students I would instinctively choose the column method and (abbreviated) long division for these problems, but I would have great trouble teaching them and this brought home the requirements that I must in a sense *ignore* my own knowledge and capabilities.'

This comment is yet further evidence of the recognition that teachers have a different requirement in terms of mathematics knowledge. It is not sufficient to know mathematics, what is significant is the way in which mathematics is known for teaching. These types of comments suggested that, even if they were not fully successful in terms of their own facility with mental mathematics, trainees were able to appreciate the significance of the different approach to mental mathematics that is required of teachers.

Although some trainees had not found a way to resolve their deficiencies in their own mental mathematics through engagement in the programme, for the overwhelming majority of participants, who claimed that they now recognised the negative and lasting effects of embedded routines and practices learnt while they were at school, the situation was acceptable, since they argued that they could operate differently in their teaching. Further speculation about the intellectual significance of the way trainees dealt with the dissonance created by their own development would not be warranted on the basis of this study's data. However, the study has provided legitimate grounds for seeking answers to questions about the limits, durability and architecture of this way of holding knowledge.

At this stage it is possible to conclude that the evolving behaviours of trainees fuelled the development and refinement of an intervention that was based on conceptual pedagogy as applied within the context of mental mathematics knowledge for teaching. Successful outcomes include the illumination and exemplification of existing theoretical constructs such as coherence and connectedness over a range of mental mathematics content involving the use of the empty number line.

READINGS OF THE MATHEMATICAL MEANING SHAPED IN THE CLASSROOM: EXPLOITING DIFFERENT LENSES

Maria Kaldrimidou, Haralambos Sakonidis, Marianna Tzekaki

University of Ioannina, Democritus University of Thrace, Aristotle University of Thessaloniki

Research literature indicates that the mathematical knowledge interactively constructed in the classroom is closely related to teachers' management of the epistemological features of mathematics. In this study, we focus on teacher-students' classroom interactions, adopting a learning and a teaching perspective to examine the mathematical status of the knowledge emerging in the context of two primary teachers' lessons. The results indicate the limits of these two perspectives and the need for multiple lenses in order to adequately capture the complexity of this knowledge.

Keywords: mathematical meaning, epistemological features, teaching practices

INTRODUCTION

Several studies attempted to examine the 'quality' of the mathematical knowledge shaped in the classroom (e.g., Steinbring 1998). The theoretical frameworks adopted in these studies allowed the identification of limitations and deficiencies in teachers' classroom practices but do not appear to have provided powerful lenses for judging the actual nature of the mathematical meaning constructed by the pupils (Kaldrimidou et al. 2008). In the present paper we adopt a learning and a predominately didactical perspective to pursue further the search for analytical tools that enable us to effectively examine the epistemological status of the mathematical knowledge interactively constructed in the classroom.

THEORETICAL ISSUES

Recent developments suggest that socio-cultural factors cannot be ignored in teaching and learning mathematics, thus directing attention to the adult-learner interactions taking place in the classroom (Lerman, 2006). Two distinct patterns of these interactions have been indicated early on by Wood (1994): funnelling (pupils are provided with leading questions which aim at guiding them to a pre-determined answer) and focusing (students' attention is drawn to the critical aspects of the problem through questioning and summarizing what is taken as shared knowledge).

Anghileri (2006), in an attempt to "identify a hierarchy of interactions which relate to teaching practices that can enhance mathematics learning" (p. 33), re-visited the

metaphor of ‘scaffolding’ introduced by Wood et al. (1976) and suggested the notion of three levels scaffold. At level 1, environmental provisions of tasks and resources enable learning to take place without the direct intervention of the teacher. Such provisions include artefacts (e.g., manipulatives) and classroom organization (e.g., peer collaboration), sequencing and pacing events, structuring tasks, etc. The subsequent two levels are related to teacher interactions that are increasingly directed to enriching the support of the mathematical learning.

Level 2 concerns three types of direct scaffolding interactions between teacher and students related specifically to mathematics: showing and explaining the ideas to be learned (limited attention to pupils’ contributions), reviewing and restructuring (responsiveness to the learner). Reviewing is about encouraging students’ reflections and concerns five types of interaction: getting students to look, touch and verbalize, getting students to explain and justify, interpreting students’ actions and talk, using prompting and probing questions and parallel modelling (solving auxiliary tasks). Restructuring, on the other hand, is about altering students’ understandings and regards interactions like providing meaningful contexts to abstract situations, simplifying the problem, rephrasing students’ talk and negotiating meaning.

At level 3, interactions address developing conceptual thinking through specialized processes such as generalization, extrapolation and abstraction. Interactions at this level include making connections, developing a range of representational tools and generating conceptual discourse (initiating reflective shifts and accentuating mathematically valued ways of thinking).

Anghileri’s notion of the three levels scaffold appears to offer a challenging socio-cultural lens to explore the mathematical meaning constructed as a result of classroom interactions, allowing for students’ creativity and teachers’ responsiveness to individuals to be taken into account in the shaping of this meaning.

The quality of the mathematical meaning constructed in the classroom came under scrutiny also in studies inquiring into the relationship between the mathematical knowledge for teaching (MKT - the subject matter knowledge both common to diverse professions and supporting teaching) and the mathematical quality of instruction (MQI – determined by features characterizing the rigor and the richness of the mathematics of the lesson, e.g., the mathematical justifications exploited).

Early studies in this area identified certain deficits in the mathematics teaching: significant mathematical inaccuracies, e.g., definitions missing key elements, as well as mathematically poor teaching patterns, e.g., the use of material that does not support further development (e.g., Cohen 1990). Follow-up studies focused on the practices of teachers involved in reform initiatives, indicating their tendency to adopt practices enriching the mathematics available to the learner: open-ended questioning, careful work with definitions, linking representations, probing for students explanations, and so on (e.g., Lampert 2001).

Hill et al. (2008) lately attempted to carefully test the relationship between MKT and MQI. To this purpose, they pointed out to five determinants of the mathematical quality of instruction: mathematical errors (computational, conceptual, representational or other), responding to students appropriately or inappropriately (addressing successfully or unsuccessfully their mathematical utterances or misunderstandings), connecting classroom practice to mathematics (relating the work done to significant mathematical ideas), richness of mathematics (effective use of multiple representations, provision of mathematical explanation and justification, explicitness about mathematical practices like proof and reasoning) and mathematical language (coherent and accurate language to present mathematical ideas).

The approach suggested by Hill et al. (2008) allows for concretely defined features of the mathematical knowledge to be traced in specific mathematics teaching practices, thus constituting a promising candidate for examining the mathematical knowledge shaped in the classroom.

On the basis of the above, it could be argued, Anghileri (2006) and Hill et al. (2008) offer two challenging but rather distinct frameworks for inquiring into the mathematical outcome of the teacher-learners interactions in the classroom. In both perspectives, these interactions are seen in the context of the instructional practices employed by the teachers. However, the status of the mathematical outcome is examined through the learning process from within Anghileri's framework and via the instructional process from within Hill and colleagues' perspective.

In previous studies we adopted successively socio-constructivist, interactionist and epistemological perspectives to examine the mathematical meaning shaped in the classroom, concluding that they all offer partial readings of its nature (Kaldrimidou, et al. 2008). Moving forward, in the present study we exploit comparatively the lenses provided by Anghileri and Hill et al. in yet another search of analytical tools that allow for a satisfactory identification of the epistemological status of the meaning constructed in the mathematics classroom.

THE STUDY

The aim of the study was to explore the degree to which each of the two perspectives allow for the identification of a) the mathematical status of the meaning shaped in the classroom and b) the task management efficiency (i.e., how students' productions were dealt with) in relation to a).

Two primary teachers, a young male (A) and a more experienced female (B), both professionally well developed, participated in the study. The teachers were asked to teach a lesson on the properties of symmetry designed for 5th grade students. The central task required from the students to work in groups and to decide whether eight pairs of triangles were symmetrical or not and why. The students were expected to eventually note that, in order for the triangles to be symmetrical, they should be

equal, to the same distance from the axis and reverted. The teachers discussed the task and issues related to its management with one of the researchers thoroughly. In particular, they were encouraged to let students experiment and to support them in their search of the properties of symmetrical figures, intervening only when it was absolutely necessary.

The teaching session devoted to the task by each of the two teachers was audio-taped, transcribed and carefully examined, in search for episodes that would exemplify and substantiate the categories suggested by Anghileri (2006) and Hill et al. (2008).

(a) Results I: Anghileri's framework

The analysis of the data showed that, in general, the two lessons were very much alike, sharing a central characteristic: the students were allowed to work on their own and to develop their own ideas, but they were not encouraged to present them synthetically to the class, thus missing opportunities for negotiation of meaning and connecting ideas, that is, for systematizing the properties of symmetrical shapes.

More specifically, the students in teacher A's class came up with all the required criteria simultaneously, while in teacher B's class each group ended up with a different criterion of symmetry. The quotes below provide an idea of how teachers A and B attempted to prompt their students' work respectively (Extract 1):

Teacher A: We must find something, so that we can say whether a shape is symmetrical to another or not. The easy solution is folding, but we cannot always fold ... If it is drawn on the blackboard, how will you tell me whether it is symmetrical? We need to find ways that will allow us, when we see two shapes, to be able to say whether they are symmetrical about an axis or not.

Student in teacher's B class: In order for the two shapes to be symmetrical, they have to have the same shape ...

Teacher B: Fine! Is it only then? Have you observed something else? Look at the cases one by one. See if you agree that, indeed, there is symmetry What things should be happening, what should be in effect?

The two teachers' scaffolding practices indicate that they mainly function at level 2 (Restructuring & Reviewing). Initially, they appear to adopt mostly *reviewing* strategies, as they often invite students to verbalize or explain (Extract 2):

Teacher A: What does the (symmetry) axis do to the two shapes? ... What is the first thing we ended up with? The first result in relation to the two shapes? ...What do we mean when we say that it makes them the same?

Teacher B: Fine, and what is the problem in the first case, why there is no symmetry? ... Does it matter where the (symmetry) axis is or what matters is where the

Working Group 17

two shapes are? ...Since what matters is where the (symmetry) axis is, where should this line be then, in order to have symmetry?

Also, the two teachers tend to often *prompt* children via questioning (Extract 3):

Teacher A: The one (shape) should look right and the other left? ...Can it also be something else?... Initially, are they (symmetrical) or not? Why they are not? Which are the three elements that we mentioned?

Teacher B: Before we get to the shapes, have you something to complete in the axis? ...
... Since we agree for case 5, let's move to case 6. What happens here?

The restructuring practices followed by the two teachers are limited and mainly related to *rephrasing* occasionally students' thoughts (Extract 4):

Student A_A: The fourth case is not (a symmetry case), because, first of all, they are different shapes ...

Teacher A: It is not, Tasos says, because they are different shapes, one is small and one is large, so it goes. And the other two? Are they the same?

Student B_B: It should be the same...

Teacher B: The same shape! There should be the same shape on both sides of the axis! Do you agree with this?

Possibly the most interesting but not frequent scaffolding strategies are those bearing characteristics similar to the ones present in *negotiation of meaning* situations (Extract 5):

Student C_A: One (shape) should look to the right and the other to the left ...

Teacher A: The one should look to the right and the other to the left? Can it also be something else?

Student C_A: Yes, one of the two should look to the opposite side

Teacher A: It is not only right-left. I have above-below, northern-southern, eastern-western ...

Student C_A: The one should look at the opposite side compared to the other

Teacher A: That is, when someone wishes to go somewhere, how would you explain to him? Are you going to only tell him right-left? How do we call all this?

Student D_B: The one shape shouldn't be like the other, because they are opposite to one another

Teacher B: They should be the same, but not exactly the same, they should be opposite to one another! I would like you to explain this "opposite" to me ...What is the meaning of this "opposite"?

Student E_B: They should be equal but from the other edge, the edges should be opposite to one another.

Working Group 17

Student F_B: They should be opposite to one another, that is, they shouldn't be...

Teacher B: I heard a word before, what does this "opposite" you are trying to explain to me mean?

Despite their common way of dealing with pupils' ideas, some distinct differences are also noticeable. In particular, the language employed by teacher A to express mathematical meanings appears to maintain a certain level of accuracy, while teacher B is more tolerant to the adoption of a vernacular, everyday language to this purpose.

Also, despite the fact that both teachers' practices remained at level 2, teacher A tended to be more exploratory than teacher B in utilizing pupils' ideas. For example, he attempted to exploit a counter-example related to representational aspects, initiated by one student's suggestion (Extract 6):

Student G_A: Two shapes, in order to be symmetrical, they have to be exactly the same.

Teacher A: (He draws on the board). Are these symmetrical?

Student G_A: (Tries to explain) ... the triangle should be like this
(he rotates)

Teacher A: We rotate it (he rotates the right-hand shape).

This one?

Student G_A: Ah, no! (they carry on looking for a way to say it)

Thus, teacher A tried to summarize the symmetry criteria identified by the pupils within a new representational framework, unlike teacher B, who maintained a rather funneling approach until the end.

Based on the above, it could be argued that Anghileri's approach appears to offer a useful reading of teachers' exploitation of their pupils' ideas but does not help in making sense of the mathematical meaning emerging in the classroom. In particular, it provides a rather limited tracing of the students' approach to the task and also of their actual understanding of the properties of symmetrical shapes.

(b) *Results II: Hill and colleagues' lenses*

Unlike Anghileri's approach, which makes possible the exploration of the mathematical meaning constructed in the classroom from within a learning perspective, the framework by Hill et al. (2008) turns the lenses on the teacher and his/her teaching actions, trying to identify how these actions affect the final mathematical outcome.

To this direction, the analysis showed that both teachers made very few *mathematical errors*. In fact, the only ones identified were related to mathematical justifications and explanations provided by them and, on the whole, concerned no or incomplete explanations. For example, in the extract below, the term 'symmetry' is incompletely described by teacher A, whereas in an incomplete, if not problematic,

Working Group 17

justification is provided with respect to the meaning of each of the words ‘next’, ‘opposite’ and ‘same’ and their interrelationship by teacher B (Extract 7):

Teacher A: What does the symmetry axis do to the two shapes?

Student H_A: It makes them the same

Teacher A: When we say it makes them the same, what do we mean?

Student H_A: Symmetrical

Teacher A: Symmetrical! Our triangles can be similar but not symmetrical. It is another thing to be ‘similar’ and another to be ‘symmetrical’! Symmetrical are two things separated by this axis of symmetry, the way it is on the one side, it is also on the other side.

Teacher B: Finally, the shapes are next or opposite to one another? I want you to tell me a little better what do you mean by ‘opposite’.

Student I_B: The axis of symmetry separates the shapes

Student J_B: You can say that they are both opposite and next to one another

Teacher B: Mmmm... They are the same

As for *connecting classroom practice to mathematics*, teacher A appears to occasionally try to accentuate mathematical elements in the work carried out in the classroom by linking this work with mathematical ideas and procedures. Thus, in the introduction of the lesson, he explicitly stresses the necessity of identifying criteria for deciding whether two shapes are symmetrical or not (see Extract 1).

Closing the session, teacher A brings forward the most critical question, that is, whether the three criteria should be fulfilled at the same time, in order for the plane shapes to be symmetrical (Extract 8):

Teacher A: Fine! K_A says that we know that these shapes are not symmetrical, because they are different! Therefore, in order to examine if two shapes are symmetrical, we need to examine all three criteria or only one?... I must check all three or only one of the criteria, as your schoolmate argued?

Student K_A: If one of the criteria does not apply, you do not need to look for the rest.

However, this behavior of teacher A is not stable, as he occasionally slips to contradictory actions. In particular, while he resorts to the constructivist exploitation of counter-examples, in order to help students identify the criteria for symmetry, he simultaneously deters them from using folding to realize its presence (providing practical but not mathematical reasons for this). Folding might not be a mathematical procedure, but it is the only available to the students at the time being, in order to process this mathematically significant checking. Thus, students are left with no choice but to judge holistically by visual means (see Extract 1).

There is not much connecting of classroom practice to mathematics in teacher B’s lesson. The only action that could be seen as contributing to this direction is the

Working Group 17

emphasis he places upon checking, allowing the use of folding but without explicit reference to the mathematical necessity of it.

On the whole, both teachers appear to be effectively *responding to pupils* by encouraging them to reflect on their sayings. There are very few cases where this is done inappropriately (Extract 9 – see also extract 1):

Teacher A: You say that the two triangles, when joint, should make up one what ...?

Student L_A: When you will join the two shapes, you should have either a square or a rectangle or a rhombus.

Teacher A: Two shapes are symmetrical about an axis, when ...? We need to bring together these three things, eh? ‘Separate’, ‘share’ and ‘two symmetrical shapes’ indicate different things, eh? Forget folding! How should it be?

Teacher B: What do you mean by this ‘opposite’, because I do not understand. Can you explain using more mathematical terms?

Student K_B: They look each other ... The two ‘points/noses’ of the shapes are different, but is like when two people look at each other...

Teacher B: So, which points should be opposite to each other?

Both teaching sessions appear weak with respect to the *richness of the mathematics* and, in particular, of the mathematical explanations and justifications. Even teacher A, who makes explicit references to practices and ways of reasoning does not invoke mathematical necessity or does not explain why.

Finally, with respect to the *mathematical language*, both teachers tend to question the meaning of the mathematical terms used by the pupils, but the descriptions provided remain often incomplete. Also, terms with double meaning are utilized without clarifications and self-evident notions and relationships are presented in confusing ways (e.g., below, the equality of shapes turns to equality of sizes, a necessary but not sufficient condition for the former).

Teacher A: We have two shapes; the distance from the axis should be the same! ... So, the first is that the distance of my shapes must be the same, I do this. Are they symmetrical now?

Student L_A: They are not, because they have different size.

Teacher B: They should be reverse ... the same sides of the shape should be the one opposite to the other...(A little later on, talking about the axis of symmetry)

Teacher B: Mmm... what should be to equal distance from the axis? When we say ‘in the middle’, what should be equal?

Student M_B: The shapes?

Teacher B: The shapes should be what, equal with respect to what?

Student M_B: Size.

Based on the above, Hill et al. perspective allows for the identification of some but not of other significant aspects of the two teachers' teaching actions closely related to the quality of the emerging mathematical knowledge. For example, teacher A pays attention to the use of mathematically 'legitimate' processes, thus reinforcing the mathematically unacceptable visual means of judging whether two shapes are symmetrical. Teacher B, on the other hand, encourages the exploitation of not mathematically 'legitimate' processes (folding), attributing to checking special mathematical value. These contradictions in the two teachers teaching practices are poorly addressed by this particular perspective. The same is true for issues related to the epistemological nature of the enacted argumentation. For example, in both classes, the development of a definition turns to applying the definition (symmetry), giving rise to a distorted meaning for symmetry (e.g., that the line joining a point and its symmetrical should be vertical to the axis of symmetry is neither addressed nor identified).

CONCLUDING REMARKS

The classroom management of the same task carried out by different teachers offers a fruitful occasion to examine the emerging mathematical meaning. This is because the fixed mathematical content allows for the identification of the impact of specific learning and teaching issues on the mathematical outcome. To this direction, the present study adopted two distinct analytical tools, one focusing on the learning and the other on the instructional management of two teachers, in order to examine the quality of the mathematical knowledge given rise in their classrooms.

The two approaches utilized highlighted different aspects of the teaching process. Anghileri's perspective essentially indicated the ways in which the teachers interacted with their students and dealt with their ideas, revealing a moderate effort to exploit these ideas in supporting the mathematics learning. On the other hand, the lenses offered by Hill and her colleagues related the two teachers' management of their pupils thinking with only certain mathematical features. An especially interesting issue within this context was the use of language, one of the differentiating characteristics of the two lessons.

Bearing in mind the central research question of the study, that is, what is the mathematical meaning shaped by the two teachers' actions in the classroom, as they deal with the same task, it appears that both approaches provide some useful insights into this shaping, without though allowing a satisfactory access to the status of the mathematics constructed by the pupils. In particular, Anghileri's analytical lenses showed that both teachers dealt with pupils' ideas in a funneling mode, with the exception of teacher A, who was functioning predominately at level 2, moving only occasionally to level 3. Hill et al perspective, on the other hand, indicated how concrete aspects of the two teachers practices affected particular features of the mathematics emerging in the classroom.

The analysis of the two teachers' transcripts identified some common characteristics of the two lessons in relation to the mathematical errors and the management of the students' thinking carried out by the teachers. However, some differences concerning the connection of the teaching practices to the corresponding mathematical concepts were also apparent. Thus, both perspectives seem to constitute valuable tools for analyzing mathematics teaching as far as the orientation followed by the management of the tasks in the classroom is concerned. This is an issue of great interest for mathematics education in general and for mathematics teachers' education in particular, because, as Wood (1994) argues, passing from funneling (dominating traditional teaching) to focusing (characterizing constructivist teaching) requires a clear understanding of the essential changes in process.

Beyond this, however, the question of what mathematical meaning is constructed in the classroom is an extremely complex issue requiring the combination of approaches in order to be captured.

THE NATURE OF PRESERVICE TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE

Hulya Kilic

Yeditepe University

The focus of this paper is to present some of the findings emerged from a study investigating the development of preservice mathematics teachers' pedagogical content knowledge (PCK) in a methods course and its associated field experience. Six preservice teachers participated in the study and the data were collected in the forms of observations, interviews and written documents. The analysis of data revealed that preservice teachers' knowledge of subject matter was influential on the development of their PCK.

Keywords: pedagogical content knowledge, preservice, mathematics, secondary

INTRODUCTION

The major goal of teaching is to enhance students' understanding and learning. Teachers need to be equipped with various knowledge and skills to establish and maintain effective teaching environments that enable them to achieve that goal. Shulman (1986) used the term pedagogical content knowledge (PCK) to name a special knowledge base that involves interweaving such various knowledge and skills. He defined PCK as "the ways of representing and formulating the subject that make it comprehensible to others" (p. 9). He stated that PCK includes teachers' knowledge about specific topics that might be easy or difficult for students and possible conceptions or misconceptions that student might have related to the topic.

Many scholars accept PCK as a distinct knowledge domain for teachers but there is no single definition of PCK due to ambiguity of what constitutes PCK (e.g., Ball, Thames, & Phelps, 2008). Because PCK is perceived as knowledge of how to teach a particular subject matter (An, Kulm, & Wu, 2004), viewing PCK as the integration of content and pedagogy would not address all requirements needed for effective teaching. Teachers not only need to possess knowledge of subject matter and pedagogy but also they need to know about students, curriculum, educational goals, and instructional materials to promote students' understanding as well as to achieve learning goals identified in the curriculum. Therefore, some scholars (e.g., An, Kulm, & Wu, 2004; Marks, 1990) accept knowledge of subject matter, knowledge of pedagogy, knowledge of students, and knowledge of curriculum are the components of PCK. Teachers need to know characteristics and needs of a particular group of students, and their conceptions and misconceptions about a particular topic that will be taught. They also need to know the arrangement of the topics covered in a particular grade level and how to use curriculum materials to achieve the learning goals identified in the written curriculum.

Pedagogical content knowledge is assumed to be developed as teachers gain more experience in teaching because it is directly related to the act of teaching (Borko & Putnam, 1996). However, studies of preservice mathematics teachers' knowledge and skills related to teaching have revealed that methods courses and field experiences are likely to contribute to the development of PCK to some extent (e.g., Tirosh, 2000). Although there is no widely accepted standardized instrument specifically developed to measure teachers' PCK or the development of their PCK, researchers could learn about the nature of teachers' PCK by using different methods such as classroom observations, structured interviews, questionnaires, and journals (e.g., An, Kulm, & Wu, 2004). A methods course for mathematics teachers could be designed in a way that preservice teachers would have various opportunities such as analyzing students' error, developing a task, and microteaching to improve their PCK (e.g., Ball, 1988). Therefore, I aimed to investigate what components of preservice secondary mathematics teachers' PCK developed in a methods course and its associated field experiences.

THEORETICAL FRAMEWORK

Based on my review of the literature of which I could only discuss very limited part of it above, I accepted that PCK involved four aspects of knowledge; subject matter, pedagogy, students, and curriculum, and there exists reciprocal relationships between them. In my definition of PCK, knowledge of subject matter refers to both teachers' procedural knowledge and conceptual understanding of mathematics. Knowledge of pedagogy refers to teachers' ability to choose appropriate tasks, examples and representations for a particular group of students and their repertoire of teaching strategies. Knowledge of students involves teachers' knowledge of students' conceptions, misconceptions, and possible difficulties about a particular topic and their ability to diagnose and eliminate such misconceptions and difficulties effectively. Finally, knowledge of curriculum includes knowledge of learning goals for different grade levels and knowledge of instructional materials. Although Ball et al. (2008) separate knowledge of subject matter from PCK in their model of Mathematical Knowledge for Teaching (MKT), they accept that teachers should know the content to teach, to help the students and to understand and apply the curriculum. Therefore, I accept knowledge of subject matter as one of the aspects of PCK.

METHODOLOGY

I conducted a qualitative study to investigate what aspects of secondary mathematics preservice teachers' PCK developed in a methods course and its associated field experience in fall 2008 at a large public university in the southeastern U.S. I wanted to understand the variety and the extent of the issues discussed in these courses and how preservice teachers could benefit from those discussions and field experiences.

Working Group 17

There were 29 preservice teachers taking both courses. I administered a questionnaire at the beginning of the semester to learn how they perceived their level of PCK. The questionnaire consisted of 13 items; eight of them were multiple-choice, one was Likert-type and four were short-answer question. Based on their overall scores, I formed a representative group consisting of six preservice teachers varying degree of perceived level of PCK (low, medium, high).

I was a participant-observer in all class sessions in both classes and I took some notes and collected any written documents given in the courses. I also conducted three interviews with each participant during the semester. At the beginning of the interviews, I asked them to reflect on the issues discussed in the methods and the field experience courses and how they contributed to each aspect of their PCK. Then I gave them some content-specific questions to understand the nature of their PCK. Although the methods course and its associated field experiences were not designed with an intention of developing preservice teachers' PCK, in each session, the preservice teachers were discussing how to teach a particular mathematical concept that was determined by the instructor. Therefore, I used my field notes to prepare content-specific tasks that I asked during the interviews. I also wanted the preservice teachers to reflect on their field experiences. I looked at the students' assignments to gain a better understanding of the course topics and students' thoughts and reflections about those topics. During the last interview, I gave them a shortened version of questionnaire to see how they perceived their knowledge levels at the end of the semester. Furthermore, I asked them to make an overall evaluation of the methods and field experience course in terms of their gains from these courses. Then, I transcribed all interviews and coded them according to the PCK framework developed for this study. I compared the answers to similar types of questions to determine the similarities and differences between the explanations and also to detect any change, if there was one, in their knowledge level of that particular knowledge domain. I discussed my decisions about each participant's responses to the interview questions with a member of faculty from the mathematics education department and we agreed on almost all of them.

RESULTS

I identified four salient features of the nature and the development of preservice teachers' PCK: 1) knowledge of subject matter is a crucial aspect of PCK and influences the quality of the other aspects of PCK, 2) the course practices and field experiences raised preservice teachers' awareness of some issues of teaching and learning mathematics; however, they were not able to apply this knowledge, 3) the preservice teachers benefited from the course practices and field experiences to varying degrees, and 4) the preservice teachers generally overestimated the level of their knowledge of each aspect of PCK. Because of space limitation, I will not discuss the findings in detail, but give examples from interview data to support only the first bullet.

Choice of Teaching Activities, Tasks, and Examples

The preservice teachers' knowledge of pedagogy was investigated in terms of their choices of tasks, examples, and teaching activities and their repertoire of teaching strategies. The findings revealed that the preservice teachers' choices of teaching activities, tasks, and examples depended on their views of teaching and learning mathematics. Collectively, the preservice teachers viewed mathematics as the set of rules, procedures, and facts. When asked to teach a particular topic, they mostly stated mathematical facts and described how to carry out the procedures or apply a rule. Given a set of examples and asked to place them in the order in which they would solve them, some of the preservice teachers looked at their surface features such as the number of terms involved in a given equation or number of steps to solve that equation rather than paying attention to how the examples would facilitate students' understanding. For instance, given the task shown in Figure 1, four of the preservice teachers preferred to begin with the fourth example because it seems easier. One of them reported that she would begin with the second one because she would get a linear equation when cross multiplying the terms and it is easier to solve a linear equation. The other one would begin with the third example because students are familiar with adding fractions with unlike denominators so they would solve it easily.

Similarly, during the second interview I asked them put given linear equations in an order to teach how to graph linear equations. Two of the preservice teachers preferred to begin with line $y = 5$ because it is horizontal line and there is nothing to think about. Although drawing horizontal line is easier than drawing the graph of $y = x + 5$, students usually fail to recognize that $y = 5$ is a line not a point. Therefore, teachers should make sure that students know the difference between a line and a point.

In which order would you like to use the equations to introduce rational equations?			
$\frac{2}{x(x-2)} = \frac{1}{x-2}$	$\frac{1}{x-4} = \frac{2}{3x+1}$	$\frac{5}{x} + \frac{x}{x-1} = 1$	$\frac{3}{x+1} = \frac{x}{2}$

Figure 1. The solving rational equations task.

Identification of Source of Students' Difficulties and Errors

The nature of preservice teachers' mathematical knowledge and their views about mathematics reflected on how they would help students when the students had misconceptions about or difficulties in understanding of a particular topic. The preservice teachers thought that the students fail in mathematics because they do not know the mathematical rules or procedures or they apply them wrongly. They did not state how flaws in students' conceptual understanding would likely lead to failure in

generating a correct solution. Therefore, when they were asked to address students' errors they inclined to tell how to apply the rules or carry out the algorithms correctly. They did not attempt to justify the reasoning underlying those rules or algorithms.

During the third interview, I asked the preservice teachers how they could help a student who made a mistake when solving inequalities such that the student did not change the direction of the inequality after dividing the coefficient of the x term by a negative number. All participants stated that they would tell the student that when dividing by a negative number you need to flip the inequality sign. To convince the student that the answer was incorrect they would ask her to check the reasonableness of the result by assigning a value from the solution set to x . Furthermore, all of them were aware of that there was a mathematical explanation for why they need to change the inequality sign; however except one preservice teacher they failed to state it clearly.

Conceptual Understanding of Mathematics

The preservice teachers' answers to the content-specific questions revealed that their knowledge of subject matter is mostly procedural and they did not know the conceptual foundations of some topics such as ellipses, polynomial equations, permutation and combination. For instance, none of the preservice teachers were able to define what ellipse is. They knew what it looks like but they had no idea what is used for in mathematics. Two of them told that you could form an ellipse by combining two parabolas. Although an ellipse could be visualized as a combination of two parabolas, it is a mathematically invalid argument. They also failed to remember the expressions for $P(n,r)$ or $C(n,r)$ even though they knew that permutation refers to ordering objects while combination is finding different combinations of given objects.

The weakness of preservice teachers' conceptual knowledge of mathematics was evident when answering other type of content-specific tasks such as identification of the source of students' errors. Because they did not know the reasoning for flipping the inequality sign when dividing or multiplying inequality with a negative number, they would tell their students that it is a rule. Furthermore, some of them said that they had not been taught some of the concepts such as ellipses in depth in high school nor studied on them in the college. Therefore, they did not have any idea about them.

DISCUSSION

The findings of this study supported the findings that PCK involves various knowledge and skills which are highly interrelated to each other (e.g., Even & Tirosh, 1995). A teacher should possess in-depth knowledge of subject matter, have a rich repertoire of teaching strategies, and be able to critically select tasks, examples, representations, and instructional materials to promote students'

Working Group 17

understanding of a particular topic, and to diagnose and eliminate students' errors and misconceptions effectively. Moreover, among the other components of PCK, knowledge of subject matter needs specific attention because a teacher should have strong knowledge of the subject matter s/he would teach in order to be able to develop effective teaching strategies that are appropriate for a particular group of students, to choose appropriate tasks for them, and to identify the reasons underlying their errors and address them effectively.

The findings of this study supported the fact that preservice teachers lack knowledge of pedagogy (e.g., Ball, 1990) and knowledge of students (e.g., Morris, Hiebert, & Spitzer, 2009). For instance, when the preservice teachers were asked to order given examples of linear equations, some of them preferred to start with " $y=5$ " because they thought that it was the simplest one. They disregarded the fact that some students might fail to distinguish between a line and a point, therefore " $y=5$ " might not be easily understood by students as they assumed to be so. As indicated in the solving inequality task, the preservice teachers perceive teaching as telling the rules, showing students how to use them, and then having students practice them (e.g., Kinach, 2002). Furthermore, preservice teachers' pedagogical decisions are influenced by their knowledge of subject matter (e.g., Borko & Putnam, 1996). When they were not sure about the reasoning underlying the algorithms as in the case of solving inequalities, they just preferred telling rules.

Although the purpose of this study was to investigate the development of preservice teachers' PCK in a methods course and its associated field experience, I was not able to detect improvement in their PCK, because their knowledge of subject matter was the overriding determinant of their success in answering the questions. I used various tasks involved secondary school mathematics content for the questionnaire and interviews, and I used different items in each interview. This was problematic because if the preservice teachers did not have a strong conceptual understanding of the subject matter involved in an item, the item revealed their knowledge of subject matter rather than another aspect of their PCK. For instance, at the beginning of the semester some of the preservice teachers were able to provide conceptual foundations underlying mathematical facts because they knew the subject matter involved, but at the end of the semester they performed poorly on a similar item involving different subject matter because they did not know much about it.

LITERACY IN MATHEMATICS – A CHALLENGE FOR TEACHERS IN THEIR WORK WITH PUPILS

Bodil Kleve

Oslo University College

This paper focuses upon the importance of aspects of teachers' mathematical knowledge in their work in making mathematics available for pupils. As theoretical background, Bruner's theory about two modes of thought, syntagmatic and paradigmatic, is presented. The Knowledge Quartet is used as an analytical tool in analysing transcripts from classroom observations before discussing the episodes from a literacy perspective. Finally, suggestions are made to put more weight on mediating tools, rather than on basic skills, in the learning process.

Keywords: Teacher Knowledge in Mathematics, Mathematics Literacy, Knowledge Quartet, Paradigmatic and Syntagmatic Thinking

BACKGROUND

Our project, "The Didactic Challenge of New Literacies in School and Teacher Education", focuses on literacy both in classrooms and teacher education from the perspective of didactics in several subjects. In Kleve & Penne (2010), which was a joint presentation in two subjects, Norwegian and mathematics, we explored the expression "Knowledge is made, not found" (Olson, 2001, p. 104), and discussed how meaning is constructed. Drawing on Vygotsky and particularly on Bruner's distinction between syntagmatic and paradigmatic modes of thinking (Bruner, 1986), we suggested some didactical perspectives that we claim have been obscured and ignored in recent years' focus on basic skills. Also, in Norway, student-centred pedagogy with the slogan 'responsibility for own learning' has been a focus over time. Thus, teachers' expertise and knowledge have been taken less into account.

In this paper, I will follow this approach and discuss the importance of the two modes of thought in teaching and learning mathematics, and how a teacher Cecilie, took her pupils with her in using these modes of thought in the mathematics classroom. To emphasise the importance of teachers' expertise and knowledge, I have used the Knowledge Quartet (Rowland, Huckstep, & Thwaites, 2005) as an analytical tool to find out how aspects of Cecilie's mathematical knowledge surfaced in her work in taking her pupils with her in using the two modes of thought in mathematics. The importance of these aspects of a teacher's knowledge is discussed and implications for teacher education are suggested.

The Knowledge Quartet has four broad dimensions; Foundation, Transformation, Connection and Contingency. *Foundation* is the mathematical knowledge the teacher has gained through his/her own education, it is knowledge possessed, which can inform pedagogical choices and strategies. It is the reservoir of pedagogical content

knowledge you draw from in planning and carrying out a lesson and thus informs pedagogical choices and strategies. *Transformation* focuses on the teacher's capacity to transform his or her foundational knowledge into forms that can help someone else to learn it. It is about examples and representations the teacher chooses to use. The third category, *Connection*, binds together distinct parts of the mathematics and concerns the coherence in the teacher's planning of lessons and teaching over time and also coherence across single lessons. *Contingency* is the category that concerns situations in mathematics classrooms that are impossible for the teacher to plan for; the teacher's ability to deviate from what s/he had planned and the teacher's readiness to respond to pupils' ideas are important classroom events within this category.

TWO MODES OF THOUGHT

Vygotsky made a strict distinction between two levels of mental functioning:

The lower level he characterized as natural, biological, causal and shared with nonhuman animals. The higher mental processes he portrayed as representational, sociohistorical, linguistic, voluntary, conscious and distinctively human (Olson 2001, p. 107).

As a development of Vygotsky's distinction between "lower" or natural mental functions and "higher" or cultural functions, Bruner (1986) introduced the *paradigmatic mode* and *syntagmatic mode* as "two modes of cognitive functioning, two modes of thought, each providing distinctive ways of ordering experience, of constructing reality" (p. 11). The syntagmatic mode of thought is basically related to linear time, and has primarily a narrative character. It is told from a subjective point of view and does not require truth, but rather a general probability or verisimilitude, referring to life in culture. This everyday thinking communicates an experienced world, and communicating in this mode means that the narrative structure is the most pervasive cognitive structure. It is merely based on tacit knowledge and acquired as part of communication in the family and in our everyday life, and thus slips easily into the mind. We all live in an "obvious" discursive world and we are linked together in communities through common discourses. Syntagmatic thinking is useful and necessary in our lives. From a didactical perspective however, this way of thinking can lead us only into obvious and tautological reasoning. We therefore need something more which can make us more conscious of other opportunities than what is obvious.

The paradigmatic mode of thought is different. The mind is more resistant to this way of thinking, reasoning about universal aspects of meaning and conclusions valid beyond time and context. Bruner (1986) writes:

[It] attempts to fulfil the ideal of a formal, mathematical system of description and explanation. It employs categorization or conceptualization and the operations by which categories are established, instantiated, idealized, and related one to the other to form a system (p. 12).

Working Group 17

The paradigmatic mode deals in general cases and uses procedures in testing for empirical truth. Consistency and non-contradiction are required.

According to Bruner, the narrative structure acts as a mediating tool in the syntagmatic mode whereas in the paradigmatic mode concepts and metaphors are important mediating tools.

For mathematics, this means that exercising skills and methods (procedural knowledge) takes place in a syntagmatic mode of thinking, whereas generalisations, reasoning beyond time and context and building concepts (conceptual knowledge) takes place in a paradigmatic mode of thinking.

Bruner emphasised that the two modes of thought will never act “alone”. We all use them both continuously, however to different extents depending on the context. Science has often started out as hypotheses in everyday discourse and then been developed scientifically through a paradigmatic effort, a perspective which actively and consciously strives to transcend the narrative structure in the syntagmatic discourse. We therefore need continuous interaction between the two modes of thought to understand both everyday life and science. Bruner (1986) put it this way:

We all know by now that many scientific and mathematical hypotheses start their lives as little stories or metaphors, but they can reach scientific maturity by a process of conversion into verifiability, formal and empirical, and their power at maturity does not rest on their dramatic origins (p. 12).

As an example of the importance of both ways of thinking in the process of constructing concepts, Olson (2001) used a child’s learning to represent nothing with something, a zero. He claimed that concepts cannot pass smoothly from culture to mind, and, therefore, for a child to compare what is in his consciousness, “no cats”, with what is in the culture, “the zero”, is problematic. Olson suggested that both the knowledge of absence and the knowledge of a sequence of numerals (learned by rote?) have to be available in the child’s consciousness.

Learning then, consists of applying the memorized sequence of the numerals to the prior knowledge of absence. In so doing the child is not merely making explicit the known but forming a concept applicable to all sorts of nothings (Olson, 2001, p. 113).

According to Bruner, knowledge is made and not found, even for scientists. Olson (2001) put it this way: “Children, like adults, make what they find” (p.113). For teaching this means that teaching defines the problem space from which knowledge is constructed by the children and constructivism makes competent teaching significant. Competent teachers are needed to determine what children have found from which knowledge can be made rather than to “cover” a settled curriculum.

Mediational means are central in Vygotsky’s (1986) theory. The task for the competent or expert teacher is to make sure that pupils get access to the language or mediational means that can open up new aspects of the world, and develop their

thought. But how does transformation from mediational means to inner thoughts take place, given that children do not find new knowledge, they make it? Discussing this question, Olson (2001) elaborated how knowledge construction takes place:

Knowledge is constructed I have suggested, when the learner can take one set of concepts and use them as a model for thinking about some other sets of events. My example was seeing [] nothing [no cats] in terms of a numeral [zero]. The basic mode is metaphor, abduction, narrative construal, inference to the best representations rather than things. These representations, accumulated archivally in maps, charts, books and computer programs provide many of these most important models (p.113).

Thus importance is put on metaphors; through the metaphor, zero became a part of the child's thinking. According to Olson, it is easier to understand Vygotsky through metaphor theory.

In her book, *Thinking as Communication*, Sfard (2010) discussed the same aspects from Bruner's theory and she put weight on discourse and metaphors in science and everyday life:

Jerome Bruner describes the transition from a metaphor to its operationalized, "scientific" version in a beautifully metaphorical way. After stating that metaphors are "Crutches to help us get up the abstract mountain," The author notes: Once up, we throw them away (even hide them) in favor of a formal logically consistent theory that (with luck) can be stated in mathematical or near-mathematical terms (p.41).

How do teachers 're-present' their mathematical knowledge to pupils in terms of examples, demonstrations, illustrations, activities and questions? What crutches are the pupils given which they can throw away? In the next section of this paper, *I will present examples from mathematics classrooms and discuss the importance of aspects of the teacher's mathematical knowledge, with emphasis on the transformation aspect, in encouraging pupils to think in both modes of thought, syntagmatic and paradigmatic*. For pupils to learn to think in a paradigmatic mode, to form new mathematical concepts on which they can perform operations, their interaction with more knowledgeable peers (the teacher), who can use the concept in a paradigmatic mode, is of decisive importance.

This stresses the importance of both modes of thinking, syntagmatic and paradigmatic, in pupils' learning process. In our curriculum, LK06 (Kunnskapsdepartementet, 2006) "basic skills" are emphasised. From a literacy perspective, it is even more important for the pupils to learn how to use mediating tools to understand and develop new insight and to form new mathematical concepts. They need tools of the mind to extend mental abilities. In this work, aspects of the teacher's mathematical knowledge play a crucial role.

EXAMPLES FROM THE MATHEMATICS CLASSROOM

I will now present extracts from two mathematics lessons in 10th grade with a teacher, here called Cecilie. The data are taken from Kleve (2007), a study in which I investigated how mathematics teachers in lower secondary school implemented a curriculum reform in Norway. Four mathematics teachers were observed over a period of three months, and the mathematics lessons were audio recorded and transcribed. The two episodes, which I present below, are selected because they illustrate how shifts between syntagmatic and paradigmatic modes of thought took place in Cecilie's lessons.

Episode 1

Cecilie had drawn a right-angled triangle on the board and asked the pupils to have their calculators ready:

- 1 Cecilie: What kind of a triangle do we have there, Mikkel?
- 2 Mikkel: Right-angled triangle
- 3 Cecilie: Then we know the lengths of the two sides. []. How can I find the third side, Leif?
- 4 Leif: You have to use Pythagoras
- 5 Cecilie: Yes, have to use Pythagoras. Let us try to do that with this triangle. If we call this side for x, Leif?
- 6 Leif: Must take $x^2 = 3.6^2 + 4.8^2$
(Cecilie wrote it on the board)
- 7 Cecilie: Yes, let us calculate that. Three point six squared is?
- 8 studs: Twelve point ninety six
- 9 Cecilie: Four point eight squared is?
- 10 pupils: twenty-three point o four
- 11 Cecilie: Twenty-three point o four (wrote it on the board). The sum of these numbers is?
- 12 Pupil: Thirty-six
- 13 Cecilie: It is thirty-six
- 14 Pupil: It makes six
- 15 Cecilie: Yes okay it became six long. This was lots of calculations. If we look at the numbers here, we could have simplified it. Is it like, here I have added one point two, and if I add another one point two I'll get the third side? *Is that a rule which always works?* Let us take another example. New triangle (She drew a new triangle on the board with sides like 7.5 and 10). If that is seven point five and that is ten, will that one (the hypotenuse) be twelve point five? Can you check if it works?
- 16 Baard: Yes
- 17 Cecilie: That worked as well. Your exploratory task is now: Does it always work? Does it work for any length?

Working Group 17

Later in the lesson, when the pupils had found counterexamples to the teacher's "rule", that in a right angled triangle, you can add the difference between the two smaller sides to get the hypotenuse, Cecilie said:

If it had been that easy in all cases, we wouldn't have had this rule (Pythagoras' sentence). Then I'd tricked you to calculate a lot. Next question is then: why does it work on these sides? What is special with the numbers here? Why does it work with my examples? Take a look at the lengths of the sides.

Towards the end of the lesson, when they had worked out that the ratio between the smaller sides had to be $\frac{3}{4}$, they investigated further. They went on to Pythagorean Triples, taking 3-4-5 as a starting point and Cecilie presented Euclid's formula $p^2 - q^2$, $2pq$, $p^2 + q^2$, which makes Pythagorean triples when p and q are whole numbers, and makes the special 3-4-5 triple when $p=2$ and $q=1$.

Before discussing this episode from a literacy perspective, I will investigate aspects in the KQ of the teacher's mathematical knowledge which became evident in the episode and especially when Cecilie took her pupils with her in what I see as a shift from a syntagmatic to a paradigmatic mode of thought. Since there were no contingent moments in this episode, (which may be because she was not open to it), I will focus on the three other aspects, Foundation, Transformation and Connection of the KQ.

I will start with the teacher's *foundational knowledge*, the knowledge from which she chose examples, illustrations and kinds of questions asked. First of all, Cecilie demonstrated knowledge of Pythagoras' Theorem and the sentence to be investigated: 'In right angled triangles where the ratio between the two smaller sides is $\frac{3}{4}$, you can take the difference between the two smaller sides and add to the largest to get the length of the hypotenuse'. Also the teacher's knowledge of Euclid's formula was demonstrated. This shows that the teacher in this case had the foundational knowledge required for the topic of this lesson.

How did Cecilie make this knowledge accessible for her pupils? A feature of the *transformation aspect* of Cecilie's knowledge was that she related what was new to something well known. She started off with a right-angled triangle and Pythagoras' Theorem. That way she used for the pupils a well-known theorem to explore a new sentence. From her knowledge of the sentence to be proved (which was part of her foundational knowledge), Cecilie chose examples which made the sentence true. Also, when introducing Euclid's Formula, she used the, for the pupils, now familiar 3-4-5 triple to exemplify. To incorporate the pupils in this episode, she asked questions for them to answer.

In this episode, there was a *connection* from the start through calculating the hypotenuse in one triangle then in another triangle, then finding a counterexample to explore in which cases the sentence was true. Cecilie then made the link to Euclid's formula, which shows that she was in a position that made her able to make

Working Group 17

connections between Pythagoras' Theorem, the sentence to be explored and Euclid's formula.

Looking at this episode from a literacy perspective, we will see that the course of the lesson was in a syntagmatic mode until turn 15. Throughout turns 1-14 the teacher had funnelled the pupils through calculations, stage by stage, using a well-known theorem (Pythagoras). Pythagoras' Theorem was used in calculating the hypotenuse in a triangle with the shorter sides being 3.6 and 4.8, and in another triangle with sides like 7.5 and 10. Then, in turn 15, she shifted to: "Is that a rule which always works?" And the question was restated in turn 17: "Does it always work? Does it work for any length?" All of a sudden they were challenged with the word *why*. And she gave them a hint in saying: "Take a look at the lengths of the sides". One strategy was to find a counterexample, which is a well-known way of proving that something is not true. The next stage was to investigate in which cases the "rule" worked. That way, the teacher took her pupils with her towards a paradigmatic mode of thinking which, in mathematics, incorporates generalisations. In which cases does it always work? To prove that something works, it is not sufficient to find many, thousands, examples with numbers in which it works. Using algebra is a way of proving, generalising and reasoning beyond time and context.

In recent curricula in Norway, the algebra content is reduced, and more weight is put on "basic skills". Thus mathematics in school has moved towards a more linear discourse or syntagmatic mode. Less weight has been put on vertical generalisations and paradigmatic thinking. In turn 17 above, "does it always work?" the pupils were challenged into another mode of thought, the paradigmatic, from the one in which they had so far been working. Until now, they had only carried out simple calculations on their calculators and answered the teacher's closed questions. The examples the teacher used, the questions she asked, and the connections she made acted as mediating tools for the pupils.

Episode 2

Let us take a look at a similar episode from a mathematics lesson with the same teacher two weeks later. The starting point was a task from a test. Like in episode 1, there was a sudden break in discourse, or a shift in mode of thinking, from syntagmatic to paradigmatic. The generalisation question was in the text. However, on the test, the pupils had worked out the task with concrete examples. The teacher took those examples as a starting point and thus offered the pupils mediating tools to solve the task which was: "The length of a rectangle is increased by 15% and the breadth is reduced by 20%. How many percent does the area of the rectangle change?" Thus, the relation to something known for the pupils, a reified object, was established, before a similar break or shift in discourse (like in episode 1, turn 17) took place.

- 1 Cecilie: The length in a rectangle is increased by 15% and the breadth is reduced by 20% how many percent does the area of the rectangle

Working Group 17

change? And the way everybody who answered that task did it, was that you chose a rectangle. Let us take this rectangle in which the length is 20 and the breadth is 5 (she drew it on the board). How big is the area of the rectangle?

- 2 pupils: Hundred
- 3 Cecilie: It is hundred. The area is hundred. And then the task was: The length is increased by 15%, how much will the new length be?
- 4 Leif: Twenty-three
- 5 Cecilie: Very good, Leif, very good mental calculation. The new length becomes twenty-three, and when the breadth is reduced by 20 %, what is the new breadth then?
- 6 Baard: Four
- 7 Cecilie: Yes, and what is the area?
- 8 Baard: It is ninety-two, right? It's a guess.
- 9 Cecilie: Right. It is not a guess, it is a mental calculation. How many percent is the area reduced?
- 10 Baard: Eight percent
- 11 Cecilie: Yes, it is. If it was hundred percent earlier, then it is ninety-two percent now, an eight percent reduction. Then the question is: are you sure it is applicable for other rectangles as well? This was for one special rectangle.

Also, here, I will discuss aspects of the KQ before studying the episode from a literacy perspective. In this episode, Cecilie demonstrated that she knew that length 20 and breadth 5 would make the area 100, that the change in area and the change in percent then would be the same. Also, 15% of 20 and 20% of 5 giving two whole numbers (3 and 1), which again gave them two whole numbers with which to calculate further, is worth noticing. This knowledge, which is a feature of the foundation aspect of the teacher's mathematical knowledge, informed her choice of measures in the example in this episode. Her *choice* of using a 100 rectangle was informed by her foundational knowledge, which included that the change in area and percentage change would have the same value. This demonstrates the transformation aspect of her knowledge. Also taking the pupils' answers to the task as a starting point, which had been choosing a concrete rectangle, demonstrates how she transformed or "re-presented" her knowledge of percentage change to be available for the pupils. She offered the pupils a 100 rectangle as a mediational means to percentage change. Thus a relation within mathematics was used, which demonstrated the KQ's connection aspect of Cecilie's knowledge.

In this episode, like in episode 1, they started in a syntagmatic mode, working with concrete examples, and as in episode 1 (is that a rule which always works?), we can see a shift in discourse, a shift in thinking: *Is it applicable for other rectangles?* A move to the paradigmatic mode of thought was initiated. After this episode, later in the lesson, the teacher emphasised that, on the test, it had not been sufficient to show the percentage change for concrete rectangles. She required a way to find out if it

applied to all rectangles. A shift to a paradigmatic mode was taken. In mathematics, generalisations play a crucial role in this mode, and use of algebra is a way of carrying out generalisations. After the episode presented above, a pupil suggested using algebra: $1.15a \cdot 0.8b = 0.92a \cdot b$, which is $0.08 = 8\%$ change related to $a \cdot b$. That way they had proved that the change was 8% for all rectangles.

In this lesson, Cecilie referred to the lesson two weeks earlier in which they concluded that $\left(\frac{4}{3}a\right)^2 + \left(\frac{3}{4}b\right)^2 = \left(\frac{5}{3}a\right)^2$. This elucidates another feature of the connection aspect of Cecilie's mathematical knowledge. There was a connection, a relation, between the two lessons, a relation the teacher made the pupils aware of. Such connections can act as mediational means in pupils' learning, and are important in strengthening their paradigmatic thinking.

DISCUSSION

In this paper, I have shown how Cecilie, in two lessons, took concrete examples as a starting point, and the examples she used acted as mediational means for the pupils to generalize and to move from a syntagmatic mode to a paradigmatic mode of thinking. I have used the Knowledge Quartet as an analytical tool and suggest that aspects of teachers' knowledge, with emphasis on transformation and connection are of crucial importance in the work with pupils in both modes, syntagmatic and paradigmatic, of thinking. In episode 1, the well known Pythagoras' Theorem was used as a crutch to find lengths of sides. In episode 2, a 100-rectangle was used as crutches to find percentage change. This implies that there is "something" needed which can serve as mediational means to make pupils more conscious for other opportunities than the obvious. Based on how they had solved the task on test, I suggest that it was obvious for the pupils how big the percentage change was in concrete rectangles. In solving the task on the test, they had been in a syntagmatic mode of thinking. However, for the pupils it was not obvious that the percentage change was the same for all rectangles; that the change was valid beyond concrete rectangles.

In earlier research, I have discussed how pupils' difficulties, which surfaced in contingent moments, in the conceptual understanding of fractions greater than one can be traced back to the transformation aspect of the teacher's mathematical knowledge (Kleve, 2009, 2010). From a literacy perspective, I suggest that the examples and illustrations the teacher used in that lesson was more of a hindrance than a help for the students to think in a paradigmatic mode. They failed in serving as mediational means between concrete conceptions of something more than one and improper fractions. In Kleve (2009b), I discussed the teacher's difficulties in illustrating improper fraction, and suggested that the focus on fractions as part of a whole, the "easiest" way for pupils to understand a proper fraction, also acted as a

hindrance in illustrating an improper fraction. They were stuck in the syntagmatic mode of thinking.

Based on this, I suggest that aspects of teachers' mathematical knowledge are crucial factors and therefore important to focus upon in teacher education. What are student teachers' choices of examples and illustrations and questions informed by? How do questions, examples and connections they choose influence pupils' thinking and learning in mathematics? For teachers, it is of great importance to be conscious of the two modes of thinking and consequently not let that work be overshadowed by "responsibility for own learning" and focus on basic skills.

HELPING IN-SERVICE TEACHERS ANALYZE AND CONSTRUCT MATHEMATICAL TASKS ACCORDING TO THEIR COGNITIVE DEMAND

Eugenia Koleza, Christos Markopoulos, Stella Nika

Department of Primary Education, University of Patras, Greece

The focus of this study is on the investigation of seven teachers' conceptions concerning the cognitive demands of the mathematical task. This study is part of an ongoing research on elementary teachers' professional development concerning their ability in designing goal oriented activities for mathematics teaching. Through our research, we tried to investigate precise components of teachers' Mathematical Knowledge for Teaching and Pedagogical Content Knowledge. Teachers collaborated as members of a Community of Practice in order to design, comment and reevaluate mathematical activities, concerning mainly their cognitive demand.

Keywords: mathematical task, cognitive demand, professional development

INTRODUCTION

In our ongoing research we investigate ways to support elementary pre service and practicing teachers in developing a much deeper understanding of mathematics curriculum via problem posing activities.

Research indicates that success of any educational reform depends mainly on teachers. Teachers use textbooks in different ways. Some tend to follow the textbook almost as a script for instruction (Remillard, 1992), whereas others adapt textbook activities and instructional suggestions to the needs of their classroom (Stake & Easley 1978). Researchers, point on these different attitudes drawing the distinction between designed and enacted curricula (Ball & Cohen, 1996). Many teachers function as designers of curricula that are enacted in their classrooms. Nevertheless, traditional use of textbook and teacher-directed approaches dominate (Jaworski & Gellert, 2003), because of a number of socio-cultural issues relating to classroom culture, teachers working individually, textbooks' structure in discrete lessons, teaching for exams and grading, teachers personal epistemologies, and teachers lack of knowledge. Designing a mathematical unit of study, teachers must first clearly understand the interrelationships of the various ideas within the unit, and second be able to choose or to construct learning activities in order to help students see and appreciate these connections.

In order for teachers to be able to act creatively concerning curriculum, they need support on a conceptual and on an attitude level. To change the way they teach mathematics, teachers must have opportunities to learn mathematical content and pedagogy in new ways, and believe to their capacity to implement the changes.

Working Group 17

Concerning knowledge teachers need to teach mathematics, recent research has specified Shulman's categories (1987) of content knowledge and pedagogical content knowledge subdividing them into *common content knowledge* and *specialized content knowledge*, on the one hand, and knowledge of content and students and *knowledge of content and teaching*, on the other (Hill and Ball, 2004; Ball, Thames & Phelps, 2008). Ma (1999) in her study of the differences between U.S and Chinese teachers pointed to four aspects of knowledge-for-teaching. These are:

- knowledge of basic mathematical ideas
- the ability to make connections between these ideas
- the capacity to create and use multiple representations of these ideas in teaching
- deep knowledge of the curriculum continuum.

Second and third aspect of Ma's knowledge taxonomy, is similar to specialized content knowledge (SCK). "*Perhaps of most interest to us is evidence of the second category — specialized content knowledge. Like pedagogical content knowledge it is closely related to practice, but unlike pedagogical content knowledge it does not require additional knowledge of students or teaching. It is distinctly mathematical knowledge, but is not necessarily mathematical knowledge familiar to mathematicians*" (Ball et al. 2008, p.394). This kind of knowledge is of special interest if we want teachers not only to apply but also to be able to choose or construct mathematical learning tasks with high cognitive demand. By cognitive demand we mean the kind and level of thinking required of students in order to successfully engage with and solve the task. For example, tasks as Martha's Carpeting Task and Fencing Task (Stein et al., 2000) may help students think of fractions, decimals, and percents as different but equivalent representations of rational numbers, but are tasks of different cognitive load. At the heart of SCK lies the skills and knowledge required to unpack, to "decompress" a mathematical concept or skill into its sub concepts. And "decompression" of mathematical knowledge is a prerequisite of specifying and formulating curricular goals and designing corresponding learning activities (Ball et al., 2008; Hill et al., 2008).

OUR RESEARCH

Our research, deals with the professional development of elementary and middle-schoolteachers. The whole project foresee two phases: Design/Teachers' Formation, and Implementation. In the present paper we are referring to the first one.

Having in mind that the effectiveness of a lesson depends significantly on the care with which the lesson plan is prepared, during first phase we designed a seminar in order to support elementary teachers on formulating instructional goals and on assessing and constructing mathematical tasks in terms of their cognitive demands.

Working Group 17

Planning phase is the most important moment of instruction, because it is during this phase that “*teachers make decisions that affect instruction dramatically. They decide what to teach, how they are going to teach, how to organize the classroom, what routines to use, and how to adapt instruction for individuals*” (Fennema & Franke, 1992, p. 156).

The main question guiding our seminar’s planning was: *How can we help teachers improve their capacity to plan (and enact) lessons that support students’ learning?*

Four main competences we anticipated that teachers acquire through seminar. These competences are referred as important for teachers’ professional development by a number of researchers (Stigler & Hiebert, 1997):

- Designing and assessing mathematical tasks of different cognitive demands
- Connecting mathematical tasks with learning goals
- Generating questions that could be asked to promote student thinking during the lesson, and considering the kinds of guidance that could be given to students who showed one or another types of misconception in their thinking
- Anticipating solutions, thoughts, and responses that students might develop as they struggle with the problem

Researchers (Stein et al. 1996; Stein et al., 2000) distinguished four categories of tasks related to cognitive demand: memorization tasks, procedures without connections, procedures with connections, and doing mathematics. They characterized the first two categories as Math Tasks of Low Level Cognitive Demand (LLCD), whereas the last two as Math Tasks of High Level Cognitive Demand (HLCD). The kind of tasks teachers use, largely define what students learn (Hiebert & Wearne, 1993). But, between designing mathematics tasks and implementing them in the classroom intervene many parameters. Further research on cognitive demand of mathematical tasks has shown that mathematical tasks alone do not guarantee students’ learning because teachers often may not implement challenging tasks as they were intended. Stein et al. (1996) found that only half of HLCD tasks are treated as such in the classroom. Investigation of parameters that influence teachers’ decision to maintain or change the cognitive demand of an activity was one of the main goals of the second phase of our research.

In this paper we present instances from the seminar. More precisely, we comment teachers’ difficulties in assessing mathematical tasks, focusing on the investigation of their conceptions concerning the cognitive demands of mathematical tasks

METHODOLOGY

Eight in service elementary teachers (2 men and 6 women) participated in the course. Helen, Marianna, and Martha have 20, 22 and 23 years teaching experience in primary schools, Vaso and Despina have 14 and 16 years teaching experience and

Maria, Nikolas and Dionisis have 7 years teaching experience each.

Teachers participated on a volunteer basis, and thus, this is not a random sample and may not be representative of the population of in service elementary teachers. Nevertheless, as mentioned before we tried to engage teachers from three different groups concerning their teaching experience. Although all were graduated from a University Department of Primary Education they were not familiar with the ‘philosophy’ of new mathematics textbooks. For example discussing during seminar about tasks involving critical thinking, most of them considered that the request for justification is just enough to raise the cognitive load of a task even in the case that the task is an algorithmic routine one. i.e. “*Are the fractions $1/2$ and $5/10$ equivalent? Justify your answer.*”

For seminar’s design, we used (lightly modified) the 4-I Model (Teacher-Innovator Model) (Yeap 2006), a teacher -development model for good practices. The model comprises four stages: Ignoring, Imitating, Integrating and Internalizing.

At **Level 0 (Ignoring)** during three approximately two-hours meetings we presented and discussed with the team of teachers three theoretical Frameworks concerning Instructional Design: The “Understanding by Design” (Wiggins & Tighe, 2005), The “Learning by Design” (Kalantzis & Cope, 2005) and “The Implementing Standards-based Mathematics Instruction: A Casebook for Professional Development Ways of Knowing in Science Series” (Stein et al, 2000).

Wiggins & Tighe (2005) describe an approach of designing the teaching unit, focusing on Understanding. They have developed a theory, presenting a multifaceted view of what makes up a mature understanding, the «six facets of understanding»: explanation, interpretation, application, perspective, empathy, and self-knowledge.

Kalantzis & Cope (2005) describe eight «knowledge processes» which represent a range of different ways of making knowledge. Each knowledge process means something different in the structuring of the learning activities. These knowledge processes are: Experiencing the known—or reflecting on our own experiences, interests and perspectives. Experiencing the new—or observation of the unfamiliar, immersion in new situations, reading and recording new facts and data. Conceptualising by naming,—or developing categories and defining terms. Conceptualising with theory—or making generalisations and putting the key terms together into theories. Analysing functionally—or analysing logical connections, cause and effect, structure and function. Analysing critically—or evaluating critically your own and other people’s perspectives, interests and motives. Applying appropriately—or applying insights to real-world situations and testing their validity. Applying creatively—or making an intervention in the world that is truly innovative and creative and that brings to bear your life’s interests, experiences and aspirations.

Neither of these two Frameworks is especially designed for mathematics classroom.

Working Group 17

Nevertheless, we considered them as important knowledge source for the seminar, because of their emphasis on teaching and learning by understanding.

Level 1 (Imitating): “The Implementing Standards-based Mathematics Instruction”, framework was the main tool of our formatting process. More precisely, after presenting and discussing with teachers the Task Analysis Guide (Stein et al, 2000), we spent one three-hours meeting in commenting and sorting mathematical tasks as of their cognitive demand. At the end, we gave them for reflection the following activity: Choose five activities from your class textbook (or from any other mathematics textbook you wish): 2 of LLCD and 3 of HLCD. For each one of these activities, try to answer the following questions:

1. **Do the activity.** What are all the ways the task can be solved?
2. **What is the cognitive demand of the activity?** (Choose one of five categories of the Task Analysis Guide). Justify your response: In what kind of thinking processes does the activity engage students?
3. **Identify the mathematical goal(s) of the activity.**
4. **What mathematical ideas does the activity develop?**
5. What misconceptions might students have? What errors might students make?
6. **What are the possible difficulties** students may be confronted? Could you anticipate their possible errors?
7. What questions will you ask to focus their thinking? **Identify specific questions through which you could activate students thinking process** concerning the activity (especially in case they are stuck)
8. (In case you think it is necessary) **How you would modify this textbook activity?**
9. **Design, you yourself, an activity of HLCD with the same mathematical goal.**
10. **Write anything else you think as important about this activity**

They had at their disposition one week to reflect and react.

At **Level 2** (Commenting/Integrating) teachers’ reaction to previous questions became the object of a team-discussion during one three-hours meeting. During this phase we tried to apply in our community of practice the six elements of a “Learning by Inquiry Process” as it is described in (Grevholm, 2009), i.e. Teachers are encouraged to ask questions (Questioning), to investigate each others ideas and collect information in order to reformulate their own ideas (Investigation). In this way new knowledge is created (Creation). Teachers, as members of the community discuss the new knowledge (Discussion), and reflect on their old knowledge and practices (Reflection) Discussion and reflections leads to wondering, which raises new questions (Wondering).

At Level 3 (Internalizing) we asked teachers to design a teaching unit following the preceding theoretical framework.

In what follows, we focus on the teachers' responses to the given activity (Level 1) as well as their interaction trying to justify their choices within the team (Level 2). The data consists of the three-hour meeting's transcribed audio, the researchers' field notes and the teachers' written responses to the given tasks. During interaction, each teacher in his turn spoke and argued for every question or subject that emerged during the talks, explaining and illustrating his point of view. One could interrupt the flow of the conversation to add something, to express a different or contrasting view or to ask for a clarification.

ANALYSIS

Through the analysis, a number of interesting issues concerning the way that the teachers conceive the mathematical task and its cognitive load emerged.

Defining the cognitive demand of a mathematical task

The distinction between mathematical tasks of Low Level Cognitive Demand (LLCD) and High Level Cognitive Demand seemed to be a difficult activity for the teachers. We observed that often there were disagreements about the characterization of an active as a LLCD or a HLCD.

Most of them considered that the discrimination of the level of the cognitive demand of a task depends mainly on the complexity of the involved arithmetical operations. The case of Vaso, who tried to justify her decision of a HLCD task, was representative of the teachers' tension to focus mainly on the arithmetical operations that the task involves. She argues that "*...division between large numbers is very difficult for them (students)*". Particularly, she proposed the following task:

(Task 1) *In a summer camp there are 60 scouts. The scouts are divided into groups of 15 people and form circles to play games.*

a) How many circles are going to form? The scouts will form circles.

b) In each circle there are 3 guides. How many guides are all together?

c) How many people are together scouts and guides?

Vaso argues that the fact that there is a number of arithmetical operations that students are asked to carried out transforms the task to HLCD. On the contrary, Maria, another member of the team, considers this particular task as a LLCD arguing that "*...the solution path is predefined. There is no doubt about the solution approach.*"

Teachers' inadequacy in providing all the possible solutions of the mathematical task prompted them to underestimate its "cognitive load". An illustrative example was the case of Despina who considered that a task involving percents is a LLCD one, as it can be solved applying the specific algorithmic routine that students have already taught. She focused only on one possible solution, ignoring a number of interesting approaches, which involve proportions, rates, fractions, and even the use of the

number line representations. In particular, the task she proposed as an LLCDC was the following:

(Task 2) *The director of a movie theatre, notice that the usual number of the audience on Mondays is about 70 persons. In order to increase the number of the audience he announced that every Monday for each one of the first 45 tickets a movie poster will be provided free of charge. Next Monday he calculated that the 45 persons who won the movie poster were the 60 percent of the audience.*

a) *Find out how many persons watch the movie that Monday.*

b) *The cost of each poster is 2€ and the profit of each ticket is 6€. Comparing the total income of that particular Monday with the income of the preceding Mondays, does it worth continuing this particular promotion for the next Mondays?*

Through the interaction with the members of the team Despina figured out that, in fact, there are a number of interesting approaches to the task. Moreover, the members of the team realized that the level of the cognitive load of a task could be raised by the investigation-during teaching- of a range of possible solutions. In other words, they concluded that the “openness” of a task is a factor that possibly defines the level of its cognitive load. Another factor they also considered was that the placement of the task in the teaching sequence. For example, they argued, the summer scouts camp could be a HLCD one, if it had been used as an introductory to the concept of division. Marianna, referring to the specific textbook, asserted: “actually this is the first mathematical problem involving division that students confronted in the textbook of the third grade”.

Modifying the level of the cognitive load

Teachers’ responses to the inquiry of finding ways of “raising” the cognitive load of a task were initially limited to the creation of more difficult/complex arithmetical operations. For example, Maria suggested in the case of the summer scouts camp task to modify the number of the scouts or the number of people in a group so as to provide a division with a remainder. Nikolas transformed that task by involving a reverse arithmetical operation. An interesting case was Martha who argued that giving students –through task 2- a general rule of finding percents applicable to a great number of similar tasks, could make task 2 a HLCD one. Actually, she combined cognitive demand and range of applicability. Martha suggested that in order to rise the cognitive demand of task “*I should ask students to explore all the possible solutions, present them in class and justify which one is the best*”. Nikolas questioned the term “*best*” for a solution. He argued that it is appropriate to define the criteria under which students will choose a solution. He claimed that the “*easiest*” solution is eventually the “*best*” for the students.

The use of multiple representations and connections between different mathematical concepts in order that the task evolves into a “*more advanced mode*” was also an

idea that teachers discussed. For example, Despina suggested asking students represent the data of the “movie theatre task” in an empty number line and make estimations about the possible solutions. In her opinion, such an intervention may encourage students to make connections between the different representations of the quantities and possibly conceive the interrelations between percents, ratio and proportions and fractions.

DISCUSSION - Concluding Remarks

The project created opportunities for in-service teachers to learn and participate with their textbooks in professional development and provided them with opportunities to change their notions of learning and teaching mathematics. The project also offered the opportunity for collaboration between primary school teachers and university researchers, under the main goal to develop knowledge and practice in the teaching and learning of mathematics, so that teachers in schools have better teaching experiences and achieve better conceptual understandings of mathematics with their students.

The analysis of our data provides interesting issues concerning teachers’ ability to characterize mathematical tasks according to their cognitive load as well as their efficiency to reconstruct/redesign tasks, raising their cognitive demands. In almost all cases, the mathematical content of the tasks as well as their cognitive load were not so obvious for the teachers who restricted themselves to school practices reproducing “well known” techniques. For the teachers we worked with during this project, cognitive demand of a task is not independent of the activity’s goal as it is described in textbook’s instruction. More specifically, the position of the task in the unit is a parameter that influences its cognitive demand. A task that is placed in the start of the instruction in order to introduce the students (for example) to the concept of division can be characterized as high -level demand task. The same task could be considered as a low-level task demanding practice if it is placed in the end of a lesson plan.

Concerning the “raising” of the cognitive level of a task, teachers initially confronted difficulties. Their first suggestions were limited to the creation of more difficult/complex arithmetical operations, modifying an arithmetic/numerical element (data) of the problem. But during the progress of the meeting and with the growing discussion and the interactions within the team, teachers orientated towards more effective ways to manage and organize the task. I.e. they referred to the exploration, presentation and discussion of all possible solutions of a task, the use of multiple representations and connections between different mathematical concepts such as the use of a blank number line and estimations of the solutions.

The goal in this research was not to achieve complete agreement between the team but to provide teachers the opportunity to participate in a thoughtful analysis of the tasks, to emerge their shared interest for discussing the characteristics of the tasks

and to raise the level of discussion among participants toward a deeper analysis of the sorting of the tasks. The point was to encourage teachers to dig beneath the surface in determining the level of thinking required to complete a task, based on the point of researchers (Stein, Smith, Henningsen, & Silver, 2000) who claim that when teachers take the opportunity to analyze the tasks, they become more alert to the potential for slippage between intentions and actions in their teaching.

Specific issues generated lively discussion on topics such as the difference between “level of cognitive demand” and “difficulty” of a task, the factors associated with the decline or maintenance of the level of cognitive demands of mathematical tasks during the implementation phase in the classroom, and construction of goal-oriented high-level mathematical tasks.

Hopefully, the results of this study will provide insight into some substantial issues that form the instruction of mathematics. Understanding the cognitive demand level of the mathematical tasks and the ways to “rise” this level will have potential benefits for teachers in acquiring the competencies needed for a better design and implementation of an effective instruction.

PROFESSIONAL KNOWLEDGE RELATED TO BIG IDEAS IN MATHEMATICS – AN EMPIRICAL STUDY WITH PRE-SERVICE TEACHERS

Sebastian Kuntze¹, Stephen Lerman², Bernard Murphy³, Elke Kurz-Milcke¹, Hans-Stefan Siller⁴, Peter Winbourne²

¹Ludwigsburg University of Education, Germany; ²London South Bank University;
³Mathematics in Education and Industry, U.K.; ⁴University of Klagenfurt, Austria

Professional knowledge of mathematics teachers related to big ideas in mathematics and mathematics instruction can enhance teachers' competencies of designing rich learning opportunities in the mathematics classroom. Responding to a need of empirical research on professional knowledge connected with big ideas in mathematics, this study presents results of a test administered to more than 100 German pre-service teachers. The results indicate that the pre-service teachers often were unable to discern big ideas behind mathematical contents and to link elements of content matter according to these big ideas. The results call for an emphasis in teacher education not only on a solid content matter knowledge base, but also on overarching concepts and meta-mathematical ideas.

Keywords: Professional knowledge, big ideas, connecting PCK/CK components

INTRODUCTION

There is a consensus that designing rich learning opportunities in the mathematics classroom can be supported by an emphasis on big ideas associated with mathematics and mathematics instruction. Awareness of such big ideas requires professional knowledge of teachers, especially in the areas of content knowledge (CK) and pedagogical content knowledge (PCK). However, empirical research on professional knowledge connected with big ideas in mathematics is scarce, even though evidence is needed, e. g. for designing teacher education programs on an empirical base.

Consequently, this study concentrates on components of professional knowledge linked to big ideas. A test and questionnaire instrument has been developed in the EU-funded teacher education and research project ABCmaths (“Awareness of Big Ideas in Mathematics Classrooms”) for this purpose and has been used in a first approach to assess the knowledge of 117 pre-service teachers. The results show that the pre-service teachers were often not able to link mathematical contents according to selected big ideas and to communicate about these ideas. There is hence a need of supporting reflective competencies of teachers with respect to mathematics-related overarching concepts like big ideas.

In the following first section we give an overview on the theoretical background, presenting both a working definition of big ideas and an outline of the theoretical

model of professional knowledge components used in this study. The second section leads to the research interest of the study. After having given information about research design and sample in the third section, we report on results in the fourth section of this paper. The fifth section concludes with a short discussion of the evidence and of its implications.

THEORETICAL BACKGROUND

Big ideas related to mathematics and mathematics instruction

Providing rich learning opportunities in the mathematics classroom is essential for instructional quality and the development of competencies of students. Many researchers have emphasised the role of overarching concepts or fundamental ideas in mathematics and its teaching and learning for creating conceptually rich learning opportunities (e.g. Schweiger, 1992, 2006; Bishop, 1988). Supporting these goals, the aims of national standards in many countries (e.g. Office of Qualifications and Examinations Regulation, 2002; KMK, 2003; NCTM, 2000) can be associated with such implicitly shared underlying “big ideas”. According to the working definition of *big ideas* in the teacher education project ABCmaths, *big ideas associated with mathematics in the classroom* anchor, link and constitute mathematical knowledge in contexts (within maths, the curriculum and/or beyond maths) and foster making sense of and communicating this knowledge in a more general way. Following a pragmatic approach, which aims above all at encouraging teachers’ reflection on overarching concepts in mathematics and on their potential for learning, four important aspects have been collected that may help to identify big ideas (ABCmaths team, in preparation). Big ideas can be characterised as:

- Ideas that should have a high mathematics-related potential of encouraging learning with understanding of conceptual knowledge (including orientation, linking and anchoring of knowledge)
- Ideas that should have a high relevance for building up meta-knowledge about mathematics as a science (adapted to the target group of learners) including knowledge necessary for interdisciplinary comparisons
- Ideas that should support abilities of communicating meaningfully about mathematics and providing mathematics-related arguments
- Ideas that should also encourage reflection processes of teachers connected with designing rich and cognitively activating learning opportunities as well as with accompanying and supporting learning processes of students.

These aspects can be seen as a pragmatic answer to a partly divergent discussion of multiple approaches in the area of big ideas: In the German-speaking discussion for example, the diversity of the notions of “fundamental ideas” (e.g. Schweiger, 1982, 2006), “central ideas” (Schreiber, 1983), “universal ideas” (Schreiber, 1983), “core ideas” (Gallin & Ruf, 1993), “leading ideas” (e.g. Vollrath, 1978) and “basic

ideas/basic conceptions” (“Grundvorstellungen”, e.g. v. Hofe, 1995) give a heterogeneous picture and call for an integrative and sufficiently open perspective like suggested by the criteria given above.

Three examples of big ideas are the following:

- *Using multiple representations*: This big idea reflects strategies used and required in many mathematical domains that have to do with the use of different ways of representing mathematical facts or concepts as well as with changing representations and linking them.
- *Giving arguments/proving*: Mathematics as a science can be characterised by the forms of argumentation and proof used in this discipline (cf. Heinze & Reiss, 2003). As a consequence, argumentation plays an important role in all domains of mathematics.
- *Dealing with infinity*: This big idea highlights the significance of exploring phenomena linked with infinity in mathematics, strategies of maintaining generality in thoughts in order to include an arbitrary, often infinite number of cases as well as patterns and structures that bear infinity often in themselves.

Big ideas associated with pedagogical content knowledge (PCK) support teachers when designing rich conceptual learning opportunities for encouraging mathematical thinking. More detailed considerations about these big ideas and examples are provided in (ABCmaths team, in preparation). The big ideas “using multiple representations” and “giving arguments/proving” appear both in the domains of CK, i.e. as mathematics-related big ideas, and PCK.

Professional knowledge related to big ideas

Professional knowledge about big ideas is not only “horizon knowledge” (Ball, Thames, & Phelps, 2008; Ball & Bass, 2009) – it has strong links to different areas of CK and PCK (Shulman, 1986). For example, using multiple representations requires CK in various domains. This can be seen e.g. when looking at a sample task published by the group of D. Ball (s. Ball & Bass, 2009) which relates to professional knowledge about the idea of multiple representations, clearly requires CK and which focuses on knowledge relevant for teaching in the mathematics classroom (Figure 1).

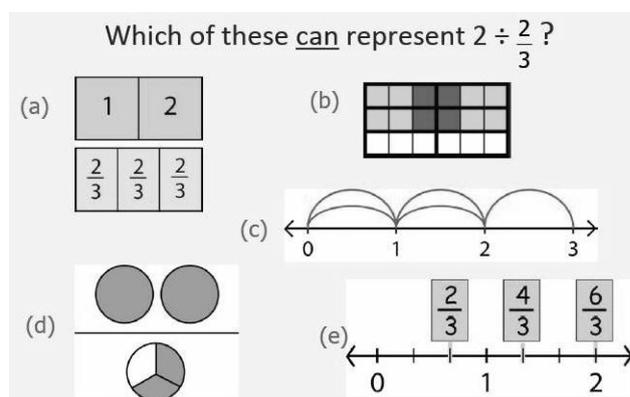

Fig. 1: Sample item in Ball & Bass (2009)

Hence, knowledge about big ideas is central for many components of professional knowledge and potentially links different components. For this reason, the teachers’ awareness of big ideas in mathematics and mathematics instruction appears to be

crucial not only for designing learning opportunities, but also for the ongoing professional learning of teachers.

As a base of reference for this study, we refer to a framework for the description of components of professional knowledge (shown in Figure 2) that includes instruction-related views held by individual mathematics teachers (Kuntze, submitted; Kuntze & Kurz-Milcke, 2010). This model of professional knowledge integrates the spectrum between knowledge on the one hand and convictions/beliefs on the other, because a dichotomous theoretical distinction between knowledge and beliefs is impossible (cf. Pajares, 1992). Hence, both are considered as being contained in the notion of professional knowledge. The distinction between different domains of professional knowledge as suggested by Shulman (1986) appears in the vertical columns (see Ball, Thames, & Phelps, 2008, for the possibility of further refinement into domains). Taking into account that individual professional knowledge is often organised in an episodic structure (Leinhardt & Greeno, 1986; Bromme, 1992), we consider furthermore different levels of globality (Törner, 2002; Lerman, 1990; Kuntze & Reiss, 2005). Besides global components of professional teacher knowledge, e.g., a general cognitive constructivist view of mathematics teaching and learning (Staub & Stern, 2002), content domain-related components are considered relevant, e.g., views linked with content domains like geometry or decimals. Further, studies by Biza, Nardi and Zachariades (2007) as well as by Kuntze (accepted) focus on views of teachers related to concrete tasks, hence are specific to a particular content. Finally, views of teachers concerning (videotaped) instructional situations have also been included in empirical studies (e.g. Lerman, 1990; Kuntze & Reiss, 2005). Professional knowledge related to big ideas is relevant for different levels of globality, as they are important for mathematics and mathematics instruction as a whole but also relevant for many specific contents and instructional situations.

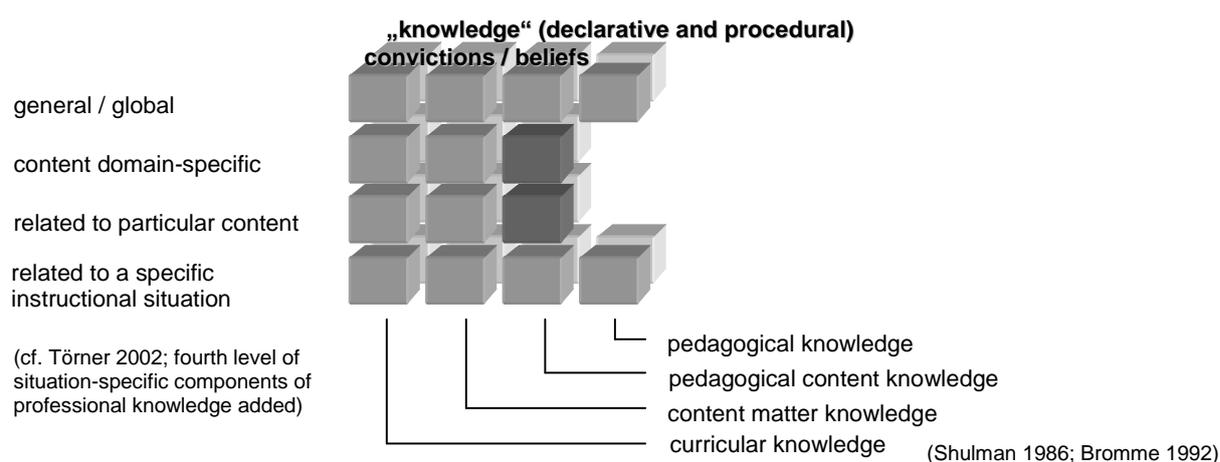

Figure 2: Model for components of professional knowledge (Kuntze, submitted)

Together these components of professional knowledge are likely to influence instruction and hence learning opportunities for students in mathematics classrooms.

Thus, evidence about teachers' professional knowledge can help to design teacher education programmes with the aim of helping teachers to improve their teaching.

RESEARCH INTEREST

Against this theoretical background, the project ABCmaths ("Awareness of Big Ideas in Mathematics Classrooms", www.abcmaths.net) aims at investigating professional knowledge of mathematics teachers related to big ideas as those introduced above and at its further development through both pre-service and in-service teacher professionalisation programmes at the level of CK and PCK. For this purpose it is necessary to explore the status quo of professional knowledge in this area in so-called analysis of needs studies. Moreover, new test and questionnaire instruments had to be developed and piloted.

This paper presents an analysis of needs study with pre-service teachers. Further research in ABCmaths will include in-service teachers and evaluation research on effects of teacher professionalisation programmes. In order to get insights into the professional knowledge of pre-service teachers, we focus on the three mathematics-related big ideas introduced above, namely "using multiple representations", "giving arguments/proving", and "dealing with infinity". At later stages of ABCmaths, the research will be extended to further big ideas. Hence, this study aims at providing evidence for the following research question: *What professional knowledge related to the big ideas "using multiple representations", "giving arguments/proving" and "dealing with infinity" do German pre-service teachers have?*

More explicitly, the study focuses on professional knowledge about big ideas related to linking contents and examples of subject matter with big ideas, as well as analysing them against the background of specific big ideas. This component of professional knowledge is likely to play a key role for competencies of designing rich learning opportunities in the classroom and it requires also mathematics-related meta-knowledge about specific big ideas.

SAMPLE AND METHODS

In order to find out about the research question above, a test was administered to 117 German pre-service teachers (78 female, 35 male, 4 without data) before the beginning of a university course. The pre-service teachers had a mean age of 22.33 years ($SD = 3.56$ years) and had been studying on average for 2.19 semesters ($SD = 1.12$). 61 pre-service teachers were preparing for being teachers in primary schools, 35 in secondary schools for lower-attaining students, and 15 for working in schools for students with special needs.

Corresponding to the aspects emphasised in the previous section, the test focused especially on analysing contents and perceiving links across contents according to big ideas. The test instrument concentrated on the ideas, "dealing with infinity", "giving arguments/proving", and "using multiple representations".

Working Group 17

A sample task related to the idea “using multiple representations” is shown in Figure 3. In this task, the pre-service teachers were given an example of two representations of the definition of square numbers and asked to give other examples of mathematical contents where definitions can be based on different representations.

On the right, there is a graphical representation of the definition of “square number”. This representation affords an additional access compared to the symbolic definition (“if $q=n^2$ for a positive integer n , the q is called a square number”).

Can you think of other mathematical concepts, for which a symbolic definition can complement with a non-symbolic representation in a similar way?

Please give as many examples as possible.

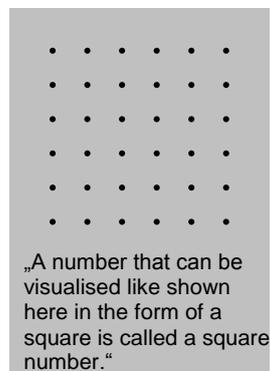

Figure 3: Sample task related to the idea “multiple representations” (task 6)

The answers of the pre-service teachers were collected in an open format. There were two tasks related to the big idea of “dealing with infinity”, and three tasks for the ideas “using multiple representations” and “giving arguments/proving”, respectively. The pre-service teachers were given as much time as they liked to devote to answering the test.

For gaining an overview of the quality of the answers of the 117 pre-service teachers, a top-down coding method was used. The coding categories concentrated on the aspects of existence of a codable answer, the quality and transfer level related to the examples provided, and the embedding of these examples. For an easier understanding, more details about the codes are reported together with the corresponding results in the following section.

RESULTS

In order to get an overview of the number of codably answered tasks, an initial coding assigned the answers to the categories “no answer given to the task”, “irrelevant answer given, i.e. no detectable semantic relationship between answer and the task” and “codable answer with respect to quality codes”. The frequencies of codes for this initial coding are displayed in Figure 4. An over-all observation is that the frequencies of codable answers were low: For almost all tasks, more than a third up to about two thirds of the pre-service teachers could not give an answer at all.

For task 6, which is the sample task given in Figure 3, we give a more detailed picture of the findings, in order to provide more in-depth information about the professional knowledge of the pre-service teachers.

Working Group 17

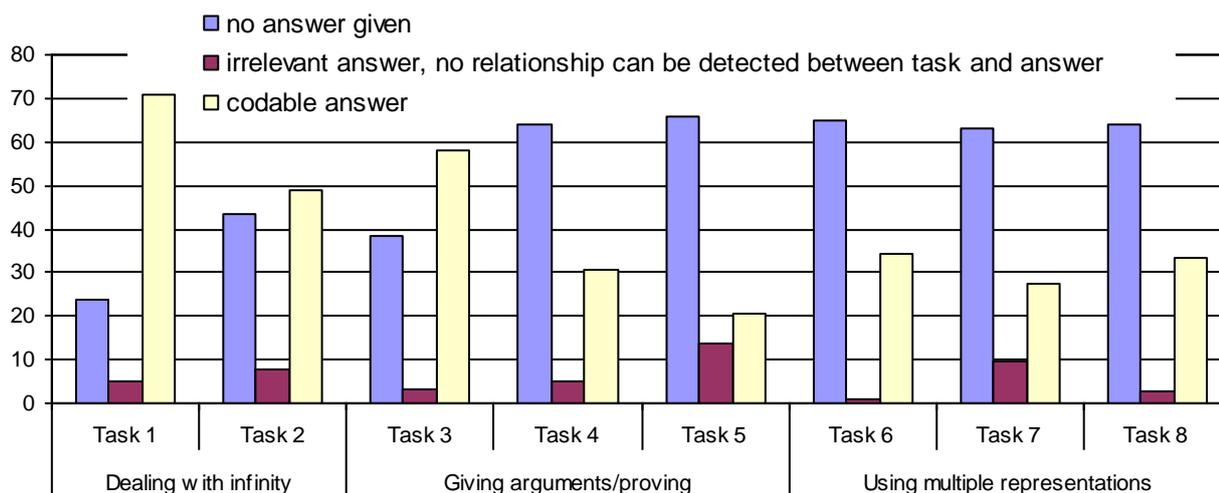

Figure 4: Frequencies of answers to tasks

In the task, the participants were asked to provide other examples related to multiple representations. In a corresponding coding of the quality of these examples provided, 65.8% of the answers were classified in the code “no example given”, 17.1% of the answers were coded as “ ‘peripheral’ relationship of example with big idea visible, but substantial gaps or disruptions / inadequate character of the example given” (an example of an answer classified in this code is presented in Fig. 4), 10.3% of the pre-service teachers gave one adequate example, 6.0% provided two adequate examples and 0.9% gave more than two adequate examples.

An additional coding relating to the quality of the answers focused on their *transfer level*. As an example was given in the task, the coding distinguished whether the pre-service teachers gave adequate examples in other content domains which were not ‘close’ to the given example – an indicator whether teachers are able to link contents according to big ideas across content domains. In case of more than one example provided in the answer, the highest category was coded. Out of the 17.2% of answers with at least one adequate example, a majority of 89.5% gave at least one adequate example from another content domain, which is 15.4% of all pre-service teachers.

Finally, the level of embedding or argumentation linked with the examples given was coded for the 17.2% of answers with at least one adequate example. Out of these answers, 55% did not have any embedding or reflecting comments on the examples provided, whereas in the remaining 45% of the answers, embedding comments for the examples were given. The category of “adequate argumentational embeddings/justifications/analysing comments e.g. about how the example fits to the big idea” turned out to be hypothetical for this sample of pre-service teachers, as 0% of the answers fulfilled this criterion.

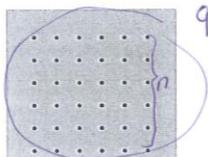

Figure 5 shows some sample answers. The first answer was coded as an appropriate example close to the given example, as the given example is just modified. In the

second example, possibilities of representing fractions graphically or as partitions of a cake are used as an example, which was still coded as an appropriate example, even though the example seems neither completely developed, nor linked or embedded by explanatory terms.

The last answer in Figure 5 was coded not to be an appropriate answer, because the representations can not replace each other but one might be used as an illustration or specification only, even if a correct and complete diagram of the geometrical situation had been given. Beyond the findings related to the coding, all examples are relatively short and seem not to correspond to high skills of mathematics-related communication.

Rechts ist eine graphische Darstellung der Definition von "Quadratzahl" gegeben. Diese Darstellung bietet im Vergleich zur symbolischen Definition („wenn $q=n^2$ für eine natürliche Zahl n , dann heißt q Quadratzahl“) einen zusätzlichen Zugang.

Fallen Ihnen andere mathematische Begriffe ein, bei denen die symbolische Definition in ähnlicher Weise einer nicht-symbolischen Darstellung gegenübergestellt werden kann? Bitte schreiben Sie möglichst viele Beispiele auf.

„Eine Zahl, die wie hier gezeigt in Form eines Quadrats veranschaulicht werden kann, heißt Quadratzahl.“

 $a^2 + b^2 = c^2$ 

Figure 5: Sample answers

DISCUSSION AND CONCLUSIONS

The results suggest that pre-service teachers were not able to give a lot of examples for mathematical contents linked to the big ideas considered in the test instrument. As answers referring to relatively simple mathematical contents were possible, this can be interpreted as a lack of awareness of big ideas in the professional knowledge of the pre-service teachers.

The results seem to suggest that the tasks were too difficult for the pre-service teachers. Indeed, the tasks were also designed to be used with in-service teachers, which raises research questions about the role of instructional experience for professional knowledge related to big ideas. However, from a theoretical viewpoint, the tasks focus on knowledge that teachers really should have – ideally already as a consequence of their school mathematics experience, which should have provided them with a base of examples and networking knowledge linking these contents to ideas. The results however indicate that there is a need for professional development in this area, potentially both for a content knowledge base of examples and networking skills or reflection knowledge related to big ideas that can organise knowledge and help to develop rich learning opportunities.

Further attention should be devoted to research questions concerning the knowledge of in-service teachers, possibilities of developing professional knowledge by teacher education programs, extensions to other big ideas, and the role of culture.

ACKNOWLEDGEMENTS

THE ROLE OF VIDEO-BASED EXPERIENCES IN THE TEACHER EDUCATION OF PRE-SERVICE MATHEMATICS TEACHERS

Miriam Liston* and Olivia Gill†

*National Centre for Excellence in Mathematics and Science Teaching and Learning

† Department of Mathematics and Statistics, University of Limerick

This paper will report on the role of video-based experiences and reflection among pre-service secondary school mathematics teachers as the drive towards a more constructivist approach to teaching and learning mathematics strengthens in Ireland through the introduction of a new initiative called 'Project Maths'. This study uses the critical analysis and reflection of video recordings to examine pre-service mathematics teachers' subject content knowledge. 29 pre-service teachers were video-taped teaching a mathematics class to mature students at the University of Limerick (UL) from January to May 2010. Rowland's (2008) Knowledge Quartet was the framework used for reflection of this teaching. The findings are discussed and implications for mathematics teacher education are highlighted.

Keywords: Mathematics Teacher Education, Pre-Service Mathematics Teachers, Video-Based Experiences, Subject Content Knowledge and Pedagogical Content Knowledge

INTRODUCTION

The low uptake of Higher Level¹ mathematics (16% of total cohort in 2011) and the large failure rate of mathematics at Leaving Certificate² has highlighted the need for reform of mathematics education in Ireland. A move towards addressing the teaching and learning of mathematics is currently being implemented under a new initiative called 'Project Maths' which will see much greater emphasis placed on student understanding of mathematics concepts and applications.

However, there is also need for change to occur in the training of our mathematics teachers. Recent PhD work by the first author (ML) suggests that first year pre-service mathematics teachers (studying Physical Education and Mathematics at UL) have a fragmented, disjointed view of mathematics and the approaches that they adopt to learning mathematics are mainly of a procedural nature. There has been similar research internationally portraying the poor conceptual understanding that often exists among pre-service mathematics teachers (e.g. Nicol, 1999). This study was undertaken in order to link the research to a current teacher education programme by critically assessing, reflecting and most importantly, developing pre-service mathematics teachers' awareness of their subject content knowledge, as well as their pedagogical content knowledge, through the use of video-based experiences. The study is predominantly exploratory in nature since it aims to identify and create

awareness among pre-service mathematics teachers' in relation to their subject and pedagogical content knowledge. Although not analysed in this study, it is also hoped that in light of their Knowledge Quartet (KQ) training outlined in the methodology below, pre-service teachers will develop their knowledge in preparation for their video-based teaching experience and indeed after this experience. Shulman (1986) clarified subject matter knowledge as knowledge of the content of the discipline such as facts and concepts. He described pedagogical content knowledge as the manner in which a teacher can represent the subject in a way that others can comprehend and an understanding of what makes the learning of the subject easy or difficult.

There has been much research carried out on the use of video-based experiences in the training of prospective teachers as a tool to critically observe and reflect on their own teaching and the teaching of others. Alsawaie and Alghazo (2010) concluded from their study that video-based experiences increased pre-service teachers' knowledge about problems in practice, developed their sensitivity toward student learning and lead to them to think in depth about efficient instructional strategies. In addition, Maher (2008) claims that it provides students with an opportunity to reflect and review theirs, and others, mathematics teaching, helping them to become aware of their practice as well as assisting them to grow in their pedagogical content knowledge.

For these reasons, one focus of the paper is on pre-service teachers' reflection of their own teaching. The authors also believe that the use of video-based experiences in mathematics teacher education pedagogy classes are beneficial to teacher educators by enabling them to observe and evaluate their students' subject and pedagogical content knowledge. Therefore, this study also focuses on the researchers' critical observation and reflection of the pre-service teachers. Due to constraints to the length of this paper, as well as the need for further analysis of the data collected, pre-service teachers' critical observation and reflection of their peers is not reported on here.

THEORETICAL FRAMEWORK

The theoretical framework employed in this study for investigating pre-service mathematics teachers' subject content knowledge and to a lesser extent, their pedagogical content knowledge, is now discussed.

The Knowledge Quartet (KQ) devised by Rowland, Huckstep & Thwaites (2005) was the framework upon which this study was conducted. Rowland and his colleagues created this framework for the observation and review of mathematics teaching. It consists of four units: foundation; transformation; connection and contingency. Each unit is subdivided into smaller sub codes of which there are 17 in total. The framework used in this study is a slight adaptation to Rowland et al.'s (2005) KQ since one or two of the sub codes are not identical to the original version e.g. "depth of mathematical knowledge" was not a code in the original KQ. Rowland

Working Group 17

(2008) describes foundation as trainees’ knowledge, beliefs and understanding acquired in preparation for their role in the classroom. Transformation concerns “knowledge-in-action as demonstrated both in the planning to teach and in the act of teaching itself” (Rowland, 2008, p.289). Connection, the third category, links together choices and decisions for the more discrete parts of mathematical content. It includes making connections between concepts and procedures as well as sequencing of subject matter. The final category, contingency, incorporates the pre-service teachers’ ability to respond to students’ ideas and think on one’s feet. Table 1 below summarises the Knowledge Quartet framework adapted from Rowland and his colleagues for use in this study.

Foundation	Transformation	Connection	Contingency
<ul style="list-style-type: none"> - Depth of mathematical knowledge. - Use of terminology - Use of textbooks - Reliance on procedures 	<ul style="list-style-type: none"> -How the mathematics is communicated to the learner (the difference between someone who knows mathematics and someone who knows how to teach mathematics - Example Choice (real-life examples, other subject areas etc.) - Analogy - Demonstration - Representation - Illustrations 	<ul style="list-style-type: none"> - Making connections between mathematical concepts - Making connections between mathematical procedures - Sequencing of subject matter (order in which the mathematic concepts are taught) - Anticipation of complexity (knowledge/awareness of areas which students will find difficult) 	<ul style="list-style-type: none"> - Ability to think one one’s feet - Response to unexpected - Deviate from lesson plan if advantageous

Table 1: The Knowledge Quartet (adapted from Rowland, 2008 and Rowland et al., 2005)

METHODOLOGY

Research Design

The research was carried out in two main stages. In stage one both authors separately watched and compared three extracts from a TIMSS video study and analysed them according to the KQ identifying aspects of each of the four units that impacted on the lesson. Following this pre-service teachers were provided with KQ training in the form of two workshops. The first workshop included a 20 minute lecture and discussion of the KQ. They then observed and analysed one extract from the TIMSS video study (selected by both authors) in the same manner as that previously done by the authors. This was done individually firstly, following by paired and whole class discussion on findings. Finally, the pre-service teachers were provided with a copy of the researchers’ analysis to compare and contrast their own analysis with. The pre-service teachers had one further workshop where they again observed and reflected

on a 30 minute extract from another TIMSS video and in pairs/groups they discussed what they had observed and reported on based on the KQ units and sub codes.

In the second stage of this research, the pre-service mathematics teachers were split into pairs for teaching a 50 minute support tutorial (25 minutes each) to “Access” mature students. As the name suggests, these tutorials support the work done in lectures and in the students’ regular tutorials provided by the University. Each pre-service teacher was required to teach a support tutorial and reflect on it once provided with the DVD of the lesson. They were also required to attend two other lessons observing and reflecting on their peers’ teaching although this is not reported on in this paper as explained earlier. The KQ is the basis for all observation and reflection. Pre-service teachers were provided with a copy of the KQ table and a critical observation and reflection report form devised by the authors for this analysis (available from the first author). Prior to teaching, each pre-service teacher was provided with a tutorial sheet from the lecturer of the Access Mathematics or Access Statistics course with specific questions to follow. The first author also attended all support tutorials and observed and reflected on each pre-service teaching session.

Research Sample, Data Collection and Data Analysis

The sample included 29 pre-service secondary school mathematics teachers studying Physical Education and Mathematics at UL. Access to the sample was not a problem since their mathematics pedagogy module from January 2010 to May 2010 was taught by the second author (OL). Olivia Gill is also manager of the Mathematics Learning Centre in UL and assigns tutors for all support tutorials. This provided us with the sample to teach – mature students studying an access certificate course designed to refresh students’ skills in areas such as basic mathematics and statistics. Many of these mature students have not studied any form of mathematics in a number of years and are returning to education in the form of this Access course which provides a means of entry to third level undergraduate courses in the future.

Prior to data collection, consent was obtained from all mature students and pre-service teachers for recording the lessons. The participants were informed that all data was anonymous and that it would be stored securely for the authors’ use only. Four pre-service teachers taught per week, two at the mathematics support tutorial and two at the statistics support tutorial with exception of one pre-service teacher who taught a full lesson on his own due to odd numbers. All lessons were recorded and DVDs developed of each lesson. Each pre-service teacher was given the DVD of their teaching only. The authors also had a copy of the DVD of each lesson.

This paper reports firstly on the researchers’ analysis of the 29 pre-service teachers’ teaching. The first author attended each lesson and at a later date she again reflected on all video-recordings in more detail. Again, the KQ and the codes designed by Rowland et al. (2005) was the framework for this analysis. On completion of this stage of analysis, the authors determined the main themes or findings that emerged

from the data under each of the four units. The findings coming from the data were compared by the two researchers for consistency.

The pre-service teachers' own critical observation and reflection reports are also analysed and discussed in this paper. These reports were completed in the same manner as the authors in that each pre-service teacher watched the DVD of their own teaching and reflected on it by identifying aspects of each of the four units of the KQ that impacted on their lesson. The reports were then submitted to the first author. One pre-service teacher failed to submit his report so analysis is based on 28 pre-service teachers. Again, the first author determined the main themes/findings emerging from the pre-service teachers' reports in terms of pre-service teachers' awareness, or otherwise, of aspects of the KQ that impacted in any way on their lesson.

FINDINGS AND DISCUSSION

The findings and discussion in terms of both the researchers' critical observation and reflection of the pre-service teachers and in terms of the pre-service teachers' critical observation and reflection on their own teaching are now presented and discussed under the four main categories of the KQ; foundation, transformation, connection and contingency. The KQ sub codes as in Table 1 are in italics for clarity.

Researchers' critical observation and reflection of the pre-service teachers

Foundation

The *depth of mathematical knowledge* demonstrated by the pre-service teachers was poor with only six teachers displaying a good depth of knowledge. In general, the pre-service teachers *relied on procedural knowledge* (19 out of 29), described by Skemp (1978) as instrumental understanding or knowing the 'how' rather than knowing the 'why'. For example, one pre-service teacher did not relate to students' method for calculating the median as it differed from her method. She was confused stating that

“5.5 is the median because it is the right middle number. I don't know why the formula isn't working”.

Many explanations were also focussed at a procedural level. When explaining the basic laws of probability one teacher reinforced the idea that students should multiply when they see the word 'and' and add when they see the word 'or'. Mason & Spence (1999) stress the failings of rehearsal and practice of techniques. While a mixture of both procedural and conceptual understanding is important, an overreliance on procedural understanding can be damaging. A concluding remark from one teacher was that

“If you can learn off the formulas you'll be fine”.

Working Group 17

This may have been the manner in which this pre-service was taught himself in school. Developing subject matter knowledge is essential for these pre-service teachers since improvements in particular kinds of subject matter competence contribute to better analysis of practice thus improve teaching (Hiebert, Morris, Berk & Jansen, 2007).

In addition, 25 out of the 29 pre-service teachers frequently used *poor mathematical language* or failed to introduce *terminologies* in their teaching.

Transformation

Communicating the mathematics to the learner is one of the sub codes under this category. 8 out of the 29 pre-service teachers were categorised as good transformers or communicators of knowledge, 14 categorised as poor transformers of knowledge and 7 as average. The pre-service teachers were categorised according to the way in which the teacher transformed his or her own meanings and descriptions of the content. An example of where knowledge was transformed effectively through *representation* and indeed by using a *real-life example* was where a pre-service teacher used a You Tube video of a car overtaking another car to introduce the concepts of velocity and acceleration. While the first author is not suggesting that real world contexts are the only effective way to transform the mathematics to the learner, she is in agreement with researchers such as De Lange (1996) that some real world connections develop students' understanding of mathematical concepts.

While pre-service teachers were provided with specific questions to follow, they were given scope and encouraged to provide their own examples and vary their teaching strategies throughout the lesson. 5 out of the 29 pre-service teachers used *real-life examples* more than once in the lesson, while 7 out of the 29 made one attempt to put some concepts in context, and the remaining 17 used no real-life contexts. Boaler (1994) explains that teaching in context motivates students and builds their confidence and interest in mathematics so long as a realistic view of mathematics is given which makes sense both in the classroom and in the real world. There was some varied use of *demonstrations and analogies* but at times these were incorporated in the lesson to little effect e.g. one teacher used the interactive software package 'GeoGebra' to introduce the meaning of differentiation but she struggled to explain what was happening on the diagram. The importance of foundation knowledge is again to the fore here.

Connection

The main finding to emerge from this category in terms of *making connections between concepts or procedures* was that many of the pre-service teachers lacked the knowledge to do just that. In a number of lessons, in particular the statistics lessons, no link was made between the answer obtained and the actual concept involved. Ball, Lubienski & Mewborn (2001, p. 433) report on a lack of understanding of the mathematical knowledge necessary to teach well.

Sequencing of subject matter is another sub code within this category but as students were provided with tutorial sheets prior to the lesson the code was less relevant to this study. It was interesting to note however, that only four of the 29 pre-service teachers re-ordered the sequence of exercises or topics according to what they felt would most benefit the students' learning. There were eight incidents observed where the pre-service teachers *anticipated difficulties* their students may have with a particular concept.

Contingency

The final category in the KQ is contingency which is determined by the pre-service teachers' *ability to think on his or her feet, respond to the students and deviate from the lesson* where he or she feels it would be beneficial for one or all learners. These three codes are discussed together since they are very much interlinked. The main findings emerging from this category were that most pre-service teachers (21 out of the 29) appeared to lack the content knowledge necessary to interpret students' questions and misconceptions and to confidently deviate from the lesson plan to explain such misconceptions. For example, in a lesson on integration a number of students were confused when the pre-service teacher removed the integral sign when he had not in fact integrated yet. The pre-service teacher was unaware and struggled to correct his error. The importance of subject content knowledge has been reported many times throughout this paper.

There was however, some evidence of good *responses and ability to deviate from lesson plan* where appropriate and beneficial for students (6 out of the 29).

Pre-service teachers' critical observation and reflection on their own teaching

Foundation

There was a mix of awareness among the pre-service teachers when reflecting on their foundation knowledge. 10 of the 28 pre-service teachers recognised their strengths or weaknesses in terms of *depth of mathematical knowledge*, use of *mathematical terminology* and *reliance on procedures*. One pre-service teacher who was categorised by the authors as having poor foundation knowledge recognises this to be the case and reflected that he

“Doubts own knowledge of the content while explaining (solve $64^{\frac{2}{3}}$) to the class, thus creating confusion for the pupils”.

A further 9 pre-service teachers displayed a poor ability to critically reflect on the aspects of foundation failing to recognise a *reliance on procedures* and unaware of their poor content knowledge. One pre-service teacher stated that she had a 'comprehensive knowledge of the topic' despite the fact that she struggled to calculate the median. This would suggest that her beliefs about her knowledge do not match her actual content knowledge. Sullivan (2008) talks about the importance of teachers understanding the relevant mathematics needed to appreciate the work that

Working Group 17

their students are expected to do. The remaining four pre-service teachers submitted vague reflection reports suggesting that perhaps their interpretation and understanding of the KQ was not as the authors would have hoped.

Transformation

The authors categorised 11 of the 28 pre-service teachers as demonstrating good critical reflection skills in terms of transformation of knowledge. These pre-service teachers were very much aware of the way in which the knowledge was *communicated* be it in an effective way or otherwise. One pre-service teacher recognises the effective transformation of Pythagoras' Theorem through use of YouTube video while also noting that her explanation of angles of elevation was unclear. Similar findings were noted in the authors' analysis. There was also some poor understanding of transformation (9 out of the 28 pre-service teachers). The pre-service teachers whose reports highlighted both good and poor critical awareness and reflection were categorised as mixed transformation reflections. One such pre-service teacher reflected on the many effective aspects to his lesson but also maintained that he used pair and group work to encourage peer learning. This was not evident to the authors and perhaps the pre-service teachers need more guidance in terms of how to implement group and pair work effectively.

Connection

This category was the most poorly reflected on by the pre-service teachers. 16 out of the 28 demonstrated very poor critical analysis and reflection here and it seemed they were unaware of what 'connection' means. Another possible reason for the poor reflection was the focus of some pre-service teachers on procedural knowledge. According to one student he had linked and made *connections between the mathematical procedures* because he had "*Reiterated to pupils the importance of showing all workings in case you make a mistake*".

The importance of teachers' beliefs comes into play again here and the author is in agreement with Grootenboer's (2008) suggestion that there is a strong case for considering the development of reform of prospective teacher's beliefs.

Contingency

There were once again varied critical reflections for this category with 11 out of the 28 pre-service teachers demonstrating good critical awareness of where contingency was in action or where it could have been improved upon. 8 of these 11 pre-service teachers admitted that they lacked the content knowledge to *deviate from their lesson plan* or respond effectively to students' questions. According to Shriki (2010), many teachers do not possess the abilities needed to foster their students' creativity in mathematics, mostly due to lack of prior experience or proper college preparation. In the authors' reflections, it was noted that foundation knowledge seemed to impact on the pre-service teachers' contingency. Of the 9 pre-service teachers who reflected

poorly on contingency, 6 were not aware that insufficient foundation or content knowledge hindered their ability to *respond to the unexpected*.

CONCLUSIONS

The above findings offer an insight into pre-service teachers' subject and pedagogical content knowledge from the researchers' perspective and from the pre-service teachers' own perspective. Some findings suggest that pre-service mathematics teachers may not have sufficient subject matter knowledge to alter their teaching strategies and ultimately teach for understanding. There is an onus on mathematics teacher educators to develop pre-service teachers' ability to move away from traditional approaches to teaching and create an awareness of the benefits of doing so. Video-based experiences are one way of doing that and this is one of the main reasons as to why the data was firstly analysed from the researchers' perspective. It offers a challenge to teacher educators to create awareness among pre-service teachers of the need to develop their subject and pedagogical content knowledge which was the focus of this study. From their own reflections and the findings reported above, it is clear that there is a mixed awareness among the pre-service teachers about the need for them to develop these essential tools for effective mathematics teaching. This offers a major challenge for teacher educators.

Video-based experiences also provide trainee teachers with the opportunity to develop critical reflection skills in terms of their own teaching which is why this study included analysis from the pre-service teachers' perspective. Evidence from the paper highlights the further need to enhance pre-service teachers' reflective skills and develop their awareness of how to do so effectively. The process of mathematics teachers' reflecting on teaching situations is described by Garcia, Sanchez & Escudero (2006, p. 2) as "an important process providing information that contributes to our understanding of their professional knowledge".

NOTES

1. There are three levels of mathematics in the Irish examination system with the highest level referred to as Higher.
2. The Leaving Certificate, commonly referred to as the Leaving Cert., is the final course in the Irish secondary school system and culminates with the Leaving Certificate Examination.

MULTICOMMENTED TRANSCRIPTS METHODOLOGY AS AN EDUCATIONAL TOOL FOR TEACHERS INVOLVED IN CONSTRUCTIVE DIDACTICAL PROJECTS IN EARLY ALGEBRA

Nicolina A. Malara – Giancarlo Navarra

University of Modena and Reggio Emilia (Italy)

This paper presents results regarding the Multicommented Transcripts Methodology (MTM) we have enacted to promote in teachers of primary school and secondary school awareness of their own ways of being in the class and to guide them in managing mathematical discussions. After a brief overview of the theoretical framework and the methodological structure of MTM, two multicommented classroom-based episodes are proposed, with the aim of highlighting the MTM educational potentialities. Some final remarks concerning the formative, cultural, educational and methodological principles of MTM are made.

Keywords: Early algebra, Metacognition, Multicommented Transcripts Methodology, Reflective Teaching, Teacher Education

INTRODUCTION

Early algebra is proving to be an appropriate approach to algebra for 5 to 14 years-old pupils, which allows them to achieve a better control over the meaning of the algebraic objects as well as of their generative processes. This achievement may occur in different ways depending on the age of exposure to early algebra, either in the first years of primary school or after several years of traditional teaching. In the first case, arithmetic should be *introduced* in a *pre-algebraic* perspective, whereas in the second one it should be *revisited from a relational and structural point of view* overcoming the traditional focus on algorithms execution. This entails a re-framing of teaching in the arithmetic-algebraic area requiring a greater attention to the construction of algebraic language as an instrument for representing relations and properties. This change of perspective leads teachers to revise their own knowledge, beliefs, attitudes, working styles.

The MTM, on which we report here, was born for this aim. It developed within our ArAl Project, which involves in-service teachers in long term educational process. In the project the teachers deal with basic theoretical issues in early algebra together with the development of teaching sequences across the school grades: from algebraic generational activities to meta level activities (Kieran 1996), such as modeling and proof 1. This led us to design ways and tools to study the behavior of teachers involved in our project and engaged in early algebra teaching sequences, with the aim to lead them to reflect on their actions in the classroom and understand how these may be improved. (Malara & Navarra 2009, Cusi & Al. and related references).

SOME THEORETICAL INDICATIONS

Several studies highlight how teacher's knowledge, beliefs, emotions and attitudes are intertwined and determinant components of teaching and learning processes (see Malara & Zan 2008 and related references). They underline that the study of these relationships is crucial to provide teachers with useful suggestions in their professional development. In this respect, the analysis of interactive and discursive practices, the awareness of the variables that influence the classroom process and self-observation during action are fundamental. The value of the teacher's *critical reflection* is a well known fact in the achievement and empowerment of the above mentioned skills (see for example Mason 2002, Jaworski 2003). In Jaworski's view, the essence of the reflective practice consists of making explicit teaching approaches and processes, so that they become the object of a detailed critical examination. She promotes the usefulness of *communities of inquiry in teaching*, discussion groups composed of teachers and researchers, in which the teacher has the opportunity to develop a specific identity.

Our teacher training model follows these conceptions and modalities. But it represents the outcome of research and training practices developed in Italy since the 1970's. Our hypothesis is that by critically reflecting on socio-constructive teaching/learning processes, the teacher is led to become aware of the different roles he/she is supposed to play in the classroom, of the best modalities to interpret them and can also get useful suggestions about how to behave in the classroom. Moreover, it is crucial for teachers to approach research results that can be useful for practice and become aware of the importance of studying them for their own professional development.

The focus of our research is on the analysis of classroom-based processes that develop along teaching sequences planned with the teacher. These studies aim at: showing teachers the micro-situations which compose a process and the higher or lower effectiveness of the micro-decisions made; favoring the achievement of control over their own behavior and communication styles, as well as noticing the impact the latter have on pupils' behavior and learning. More in general they aim at gathering both theoretical and practical tools for pre-service and distance teacher training.

THE METHODOLOGY

In our project teachers are involved for at least two years in training activities. After planning and implementing lesson units together with the researchers, the teachers carefully record some lessons they choose, transcribe them according to a predefined format, add details coming from the notes they have taken during the lessons (gestures, expressions, etc.) and include reflections and comments. The teachers then engage themselves in a network exchange of e-mails with their mentors and sometimes with other teachers. The exchange consists mainly of reflections and comments regarding the classroom transcripts, through which the mentor infers the teachers' interpretation of their theoretical frame and the developed cultural values,

as well as their progressive harmonization with the background and the previous attitudes. This is the core of MTM.

There are two different ways of implementing MTM. One way takes place in a university environment as part of a national or international research and training programs. It involves a small number of researchers and teachers who strictly interact with specific research proposals. The other way is implemented in schools, from different Italian regions and organized in networks, by teachers who take part into the ArAl Project. It is characterized by a few meetings with researchers and teachers and several long distance interactions, conducted via e-mail. A high number of teachers are involved (in the year 2010 nearly 150), organized in small groups of work. Each group is coordinated by a researcher, who plays the fundamental role of E-tutor. This latter type of intervention is mainly aimed at training although with important spin-offs for research.

As first step, teachers are required of including in their transcripts of class session, either positive or negative comments concerning mathematical issues or critical points in the development of the discussion, possibly attaching some class material. The transcript of each session is sent by e-mail to the E-tutor, who makes comments and sends it to other teachers and researchers involved for further comments. Each of them can intervene again in the cycle with further meta-comments. So, the multicommented transcripts (MT) reify. They become an important object of study for the teachers through sharing with colleagues within the school and during meetings with the E-tutors. They are also published in the schools websites, in some cases included in www.aralweb.unimore.it as ‘good practices’. In the following we wish to highlight their educational potentialities through some excerpts.

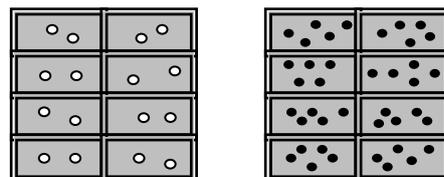

ANALYSIS OF CLASSROOM EPISODES: TRANSCRIPTS AND COMMENTS

Here, two MT excerpts, which document both the interactions among the actors and the variety of the faced themes, are presented. The order of their presentation is: (a) context; (b) transcript of session; (c) comments. In the comments, the words written in *Italic* indicate key elements of the ArAl Project theoretical framework, which are described in its Glossary 2 (some examples can be seen in <http://www.aralweb.unimore.it/on-line/Home/ArAlProject/Glossary.html>).

Episode 1 (year 3 primary, 8-9 years old)

The teacher is participating in the project for the second year and she is working on the distributive law, already discovered by the class in simpler cases.

She shows two boxes, divided in eight parts, containing two types of marbles, as shown above. She

says they belong to Marina’s collection who has organized them in a very orderly

Working Group 17

way. Then the teacher formulates the task: “Represent the situation in mathematical language so that Brioshi 3 may find the total number of marbles in the two boxes”. Pupils work and their proposals are written on the blackboard. Many of them formulate more than one proposal.

Andreina, Danilo, Francesca, Martina	$16 \times 40 = n$ $40 \times 16 = n$ $n = 16 \times 40$ $n = 40 \times 16$
Andrea	$(5 \times 2) + (4 \times 2) = n$ $n = (5 \times 2) + (4 \times 2)$
Maria	$2 \times 8 = n$ $5 \times 8 = n$ $n = 2 \times 8 + 5 \times 8$
Bruno	$(2 \times 8) + (5 \times 8) = n$
Melania	$4 \times 2 + 4 \times 5$
Sara, Elena, Giovanna	$5 \times 8 = n$ $2 \times 8 = n$ $n = 5 \times 8$ $n = 2 \times 8$
Francesco	$(2 \times 8) + (5 \times 8) = n$
Chiara	$2 \times 2 + 5 \times 2 = n$ $n = (2 \times 8) + (5 \times 8)$ $n = 4 + 10$

Teacher: Good! Now, as usual, let's open up the discussion. [Comm 1]

Andreina: Teacher, we were wrong because 16 is not repeated 40 times.

Teacher: Explain it better.

Andreina: I understood that we didn't have to multiply red marbles and green marbles, but rather put them together.

Teacher: What do you mean by 'put together', try to use mathematical language better.

Andreina: United...

Teacher: Do you know a more suitable term to explain what Andreina means?

Francesco: You must add.

Teacher: Yes, this sounds clearer... Any other remark?

Melania: In my opinion the translations made by Andreina's group are *opaque*.

Teacher: What do you mean?

Bruno: They are *opaque* because they have already found the number of marbles.

Chiara: It was not up to us to find 16 and 40, but rather write the translation to be sent to Brioshi. They have nearly solved the problem.

Bruno: It's true, they found the *product and not the process*.

Teacher: What do you think about Andrea's representation?

Andrea: Miss, I got wrong too... erase, erase.

Teacher: Hold on, explain what you wrote (*Andrea can't explain*).

Melania: I also realize that I forgot to write something. I wrote 4×2 and 4×5 because I saw separate columns, but now I understood that my representation is not complete, I must add ' $\times 2$ '.

Working Group 17

Teacher Tell me which changes I should make.

Melania: $4 \times 2 \times 2 + 4 \times 5 \times 2 = n$.

Francesco: But she wrote like me... like Bruno... and like Maria Giovanna, because 4×2 equals 8.

Andrea: Melania factorized eight!

The expression by Francesco is chosen to be sent out to Brioshi: $n = 2 \times 8 + 5 \times 8$.
[Comm 2] [Comm 3]

1. Comment by the E-tutor: Regardless how correct the expressions are, the pupils show they use the *letter* as indicator of a number to be found. It is a naive and sometimes not pure use of the letter, like in the cases of Maria, Sara, Giovanna, Elena and Chiara, where the same letter stands for different quantities. Pupils should be led to reflect upon this from the beginning.

2. Comment by the E-tutor: The transcript shows how the class is familiar with *mathematical discussion*. Also, it shows the good argumentative skills of the pupils and the fact that they draw on important theoretical constructs such as the distinction between *opaque* and *transparent* representations and between *process* and *product* of a calculation. It would be appropriate not to overlook a collective investigation on expressions like Melania's, which are incorrect but revealing her initial vision of the situation. How do they get to decide that Francesco's expression should be sent out to Brioshi?

3. Comment by the coordinator: The iconic representation proposed by the teacher for translation into mathematical language is problematic and deserves reflection. Its negative influences can be detected in the translations made by Andrea or Melania. Many pupils use the (correct) representations 2×8 e 5×8 . But the numerical representation consistent with the given representation is: $2 \times 4 + 2 \times 4 + 5 \times 4 + 5 \times 4$. Moreover, reading by rows, one may be led to the representation $(2+2+5+5) \times 4$, changeable into $(2 \times 2 + 5 \times 2) \times 4$, for the meaning of multiplication as repeated addition, an expression which can be, in turn, modified into $(2+5) \times 2 \times 4$, for the distributive law they just met. The latter expression permits a link with representations 'perceived' by many pupils: $(2+5) \times 8$ e $2 \times 8 + 5 \times 8$. These steps are certainly very sophisticated for pupils aged 8-9 and require control over parentheses and the property itself. The teacher should appropriately make hypotheses about the possible interpretations induced by an iconic representation and constructs a discussion sketch for each of them, in case some pupils propose it or even to show how a representation can be viewed in more different ways. A general point must be highlighted: the need to favor the interpretation of paraphrases in mathematical language contributing to the construction of meaningful skills in pupils.

Episode 2 (grade 9, pupils aged 11-12)

A general representation of the sequence 4, 11, 18, 25, 32, ... is sought for. The table reported below is constructed on the blackboard to identify the link between place number and term of the sequence.

Place [Comm 4]	Term	Rule
1	4	$7 \times 2 - 10$
2	11	$7 \times 3 - 10$
3	18	$7 \times 4 - 10$
...
8	53	?

Pupils find various rules, but they are focused on one in this case. The teacher is encouraging reflection upon relationships between numbers of the first and the third columns.

Teacher: You have discovered that “the place equals the term preceding the second factor of the multiplication”. So, for instance, what is the rule at place 8? [Comm 5]

Serena: You must do $7 \times 9 - 10$.

Teacher: Do we all agree? [Comm 6]

Many: Yes.

Teacher: And is it 53? [Comm 7A] [Comm 7B]

Many: Yes.

4. Comment by the E-tutor: ‘place’ is used instead of ‘place number’. It is appropriate to be precise not to induce pupils to identify quality and quantity.

5 Comment by the E-tutor: Pay attention to the abbreviations (see Comm 4). The fact that pupils know the meaning of ‘preceding’ in Italian is not enough for a *translation* in algebraic language. They must learn to express ‘preceding’ in relation to the number that follows. If they are able to paraphrase it only with ‘that precedes’ (as in the transcript), they get stuck, because these *paraphrases* are *opaque*. They should rather be induced to make explicit the link between the two numbers and express the preceding number as a function of the subsequent. Natural language supports the achievement of this expression. In a grade 8 class, for instance, the proposal made by a pupil: ‘the preceding number is always one unit smaller than the number that follows’ turned out to be very effective and decisive for translation.

6. Comment by the E-tutor: There should be a *shared didactical contract* according to which monosyllabic answers are not acceptable. They do not help the teacher understand how the topic has actually been understood and do not help classmates either. Questions that require only ‘Yes’ or ‘No’ answers are not productive as well. Pupils do not *argue*,

they only answer the teacher's questions and let her guide them towards her objective. Requests like 'Explain what you mean' make the pupil himself define the objective of his reasoning, and construct the related explanation. In these cases, the teacher should only evaluate the quality of the discussion, *sorting out the argumentative traffic* by intervening mainly on the methodological plane, thus favoring the *social construction of knowledge* through *negotiation, sharing* and *stabilization* of meanings. A teacher should become aware that control over natural *language* and implementation of *social practices* are basic elements for the understanding of mathematical language and therefore of mathematical concepts.

7A. Comment by the teacher: At this point (I refer to Serena's 'You must do' and to my 'it is', but this also occurs elsewhere in the transcript), I realize how imprecise my language is. I could have said "Does $7 \times 9 - 10$ 'represent' number 53?" or "Does it 'correspond' to 53?"

7B. Comment linked to the previous one by the E-tutor: Ok, right. But it is not only a matter of language, I think this reveals rooted attitudes which reflect hidden convictions. Very often teachers' algorithmic approach is 'dominant' (referring to: operations, result, calculate, solve, 'how much is', 'it is', ...), the relational one is 'recessive' (mainly focusing on: *relations, structure, representation, ...*). These activities in an early algebra environment aim to induce teachers to reflect on this point.

REFLECTION ON EPISODES AND COMMENTS

Comments in the transcripts are valuable for training in several aspects. Some of the most meaningful are reported below.

Socio-linguistic aspects. We underlined how important linguistic aspects are in the construction of mathematical knowledge and how central they are in mathematical discussions. Pre-requisite for teachers to be able to make the discussion a shared instrument for the class is that they acquire many skills: to create a good context for interaction, to enact socio-mathematical norms that lead to compare different solutions, evaluate if a solution is acceptable or of a good quality, to steer the direction of the discussion in the different phases, to involve pupils in meta cognitive acts and so on.

The relationship theory-practice. Another aspect emerging from comments is reference to the theoretical framework and to the glossary of the project not only shared by researchers and teachers but also – with appropriate adjustments - by teachers and pupils. Sharing is extremely important in both cases, because teachers and above all pupils are enabled to understand how aspects apparently far from mathematics, such as: 1) competence in using languages, mainly natural language, and control of their semantics and syntax; 2) being able to translate from one language to another; 3) difference between representing and solving a problem situation; 4) distinction between process and product; 5) recognizing the meanings of the equal sign; ... *are the foundations of a meaningful construction of mathematical knowledge.*

Mathematical aspects: an example, the conquest of the letter. In the first episode the letter is used in a very naïve way, in the second one it represents a high-level goal (in the next step the variable ‘n’ is introduced as place number and to represent $7 \times (n-1) - 10$ by t_n as the n-th term of the sequence). *Algebraic babbling* (a theoretical constructs of the ArAl project, which compares modalities of construction of algebraic language to those of construction of natural language) emerges throughout exploration, discovery, conjectures, failed attempts which entail the introduction and use of the letter with various meanings (generic number, unknown, variable). Through transcripts and the analysis of comments, teachers become aware that the main difficulty for pupils is *to get to understand that a letter can represent a number*. It is an epistemological jump, fundamental for algebraic thinking, which may become a block if the pupil is not guided enough.

The use of comments in the training process aims to make the teacher sensitive to basic general issues, such as: are students aware they are *communicating* through mathematical language? What kind of relationship do they have with the *semantics* and *syntax* of mathematical language? Which environment (situation, contest) can improve algebraic thinking? How can one detect the awareness of ‘algebraic content’ in pupils’ sentences, intuitions, proposals, representations? These kinds of questions make teachers’ reflections profound, meaningful and productive.

CONCLUDING REMARKS

MTM appears to be an effective instrument in teacher’s training processes involving mathematics.

This methodology has an important pre-requisite: a trusting relationship between teachers and researchers. Moreover, when the teacher edits a transcript, he puts himself on a different level. He detaches himself from the activity he was part of and critically reads what happened in the classroom. His class is no longer his class. His transcript is no longer narrative, it acquires scientific aspect and becomes a training instrument. Comments may bring her/his misconceptions to the surface, touching sensitive points. Many teachers immediately realize that the comments are valuable and accept the remarks. Others see their competence jeopardized; they feel uncomfortable and refuse to accept that their transcripts may become public. Others tend to ‘watch and wait’, they need time to familiarize themselves with the methodology and be convinced before using it. These different types of behavioral patterns are monitored by researchers, who are always trying to make teachers understand that MTM is meaningful and productive only if participants engage in the project with open and sincerely committed minds.

Notes

1. For an overview of the project and related bibliography, see the site www.aralweb.unimore.it.
2. Glossary terms are more than 100 and belong to several categories: theoretical constructs, which are both original or coming from previous studies of mathematics education, terms relating to linguistic or

Working Group 17

psychological aspects. These are interconnected in a network of references, which allows the teacher to build a reticulum of knowledge that led him/her gradually to a new vision of the arithmetical-algebraic area and its teaching.

3. Brioshi is a metaphor from the ArAl Project. He is a virtual Japanese student exchanging messages in mathematical language with pupils. His acknowledged skill in this area, encourages pupils to check the correctness of the mathematical expressions to be sent out to him.

LABORATORY ACTIVITIES IN TEACHER TRAINING

Francesca Martignone

Math Department of the University of Modena and Reggio Emilia, Italy

The Laboratory of Mathematical Machines of Modena, supported by the “Regione Emilia Romagna” (Italy), invested the most recent mathematics education researches in the teacher training project MMLab-ER. The training course was unique both in methodology and focus: teachers joined laboratory activities with mathematical machines analysing the interactions (between peer, experts and also with tools) and the cognitive processes involved. The paper presents examples of these activities where teachers construct, and then analyse, different resolution strategies carried out during ruler and compass constructions.

Keywords: *Mathematical laboratory, teacher training, resolution processes.*

INTRODUCTION

The Project "Laboratory of Mathematical Machines for Emilia-Romagna" (MMLab-ER) [1] aims at facilitating the implementation of a laboratory approach in the teaching and learning of mathematics. The first step of the Project was the set up of a network of math laboratories distributed among five cities in Emilia Romagna region (Italy), followed by the training of in-service teachers (primary, secondary and high school) on laboratory activities with special tools, such as the mathematical machines: reconstructions of tools belonging to the historical phenomenology of mathematics from ancient Greece to 20th century (i.e. curve drawers, pantographs and mechanical calculators) [2]. The training course started with laboratory activities on ruler and compass constructions (the compass is one of the oldest and well known mathematical machines) and continued by introducing other curve drawers and pantographs for geometrical transformations used in history both for mathematical purposes and also for practical purposes. In all these activities it is highlighted how, through appropriate tasks, the mathematical machines laboratory activity can be a suitable environment to develop crucial aspects in the teaching and learning of mathematics: for example the exploration processes, the production and comparison of conjectures and argumentations.

This paper presents some examples of teacher training activities in which teacher educators focus the attention on important learning goals, such as the development of *adaptive reasoning*: “the capacity for logical thought and for reflection on, explanation of, and justification of mathematical arguments” (Kilpatrick, 2001, p. 107).

THEORETICAL FRAMEWORK

MMLab-ER Project is grounded on a laboratory idea that is well expressed by this metaphor: “We can imagine the laboratory environment as a Renaissance workshop,

in which the apprentices learned by doing, seeing, imitating, communicating with each other, in a word: practicing” (Bartolini Bussi et al., 2004, p. 2) [3]. For this reason, the math laboratory should not be conceived only as a physical space in which teaching practices based on the use of specific technologies are developed, but rather as a teaching methodology. This laboratory idea, linked to the tradition of the European cultural history and highlighted by ICMI (International Commission on Mathematical Instruction) since the last century, is suggested by the Italian Commission for the Teaching of Mathematics in the “Mathematics curriculum for the citizen” [4]. During the training, teachers were involved in this type of mathematics laboratory. The hands-on tools used and analysed in these activities are the mathematical machines.

The MMLab-ER Project is based on the experience gained from MMLab in the laboratory activities carried out in school: in particular researches on epistemological and educational aspects involved in activities with mathematical machines (Bartolini Bussi, 2000; Bartolini Bussi & Maschietto, 2006; Maschietto & Martignone, 2008). In recent years the MMLab research analyzed also the cognitive aspects involved during mathematical machines activities. In particular Martignone & Antonini (2009) studied the interaction between a subject and a mathematical machine using Rabardel theory (Rabardel, 1995). According to Rabardel, an instrument is defined as a hybrid entity made up of both artefact-type components and schematic components that are called utilization schemes. Following these ideas, during the interaction with a machine, we have identified artefact exploration processes and different (utilization) schemes carried out to solve a specific task. This study focused our attention on the importance of analysing these aspects and it was also useful to project tasks on the machines explorations dealing with the analysis of artefact components (how is done) and the genesis and development of utilization schemes (how do you use it? What is done?).

The theoretical framework, used to describe and interpret the different phases of laboratory activities with artefact and the role of the teacher, is the construct of semiotic mediation introduced by Mariotti & Bartolini (2008). In this framework

the teacher's main roles are the following: to construct suitable tasks; to create the condition for polyphony, eliciting the polysemic feature of the artefact; to guide the transformation of situated “texts” (signs) into mathematical “texts”. In this way the teacher mediates mathematical meanings, using the artefact as a tool of semiotic mediation. (Bartolini Bussi, 2009, p.125)

The Project has provided the opportunity to rethink on these existing researches bringing some innovations. For example, the study of the potential that the laboratory activities with mathematical machines can offer in the genesis and development of students’ exploratory and argumentative processes. Our attention to the study of these processes is grounded into different studies: e.g. the researches collected in *Theorems in school: From History, Epistemology and Cognition to*

Classroom Practice (Boero, 2007) and the study of exploration processes during problem solving activities (Martignone 2007).

The training project has also taken into account international researches in the field of teacher education, many of which were presented in *The International Handbook of Mathematics Teacher Education* [5]. In particular, we are in agreement with Watson & Sullivan (2008) research because we designed *tasks for teachers* that focused on important aspects of mathematical activity “to provide insight in to the nature of mathematical activity” (Watson & Sullivan, 2008, p. 110) and we worked with teachers who faced these tasks reflecting on what they are doing and on what way they could make something similar for their students (*classroom tasks*).

“We use classroom tasks to refer to questions, situations and instructions that teachers might use when teaching students and task for teachers to include the mathematical prompts many of which may be classroom tasks, that are used as part of teacher learning” (Watson & Sullivan, 2008, p. 109)

LABORATORY ACTIVITIES WITH TEACHERS

Teacher training features

The MMLab-ER involved primary, secondary and high school math teachers [6]. For this reason, it was an important opportunity to foster a dialogue and a discussion between teachers from different school levels. Teachers could share ideas and thoughts about the role of the teacher and the different cultural aspects and contents that emerged from the laboratory experiences with mathematical machines. The training course, designed and managed by the author, exploited this opportunity by offering activities that could be an inspiration to teachers from different types of schools, with the common goal of the acquisition of laboratory methodology, the development of attention on exploration and argumentation processes and on relative verbalization.

One of the purposes of MMLab-ER training was to give room for the dynamic discussion and comparison of solution strategies among peers and experts. In particular we asked to explain the procedures of geometrical constructions in order to understand their roots, motivations and development not only related to the mathematical contents involved, but also to the use of tools. Therefore, the focus is on the analysis of own and others' problem solving processes.

It is important to stress that MMLab-ER training did not wish to give pre-packed worksheets for classroom activities. The working session aimed at providing ideas and guidelines for possible teaching experiments, which were designed during the course according to the needs and the goals of teachers.

Summarizing, the peculiarities of MMLab-ER teacher training are related to:

- The course methodology: during training sessions the teachers are placed, with the obvious differences, in learning situations “acting as students”; they are divided in working groups and joined the discussions orchestrated by a teacher educator. In these activities the tasks are open and the different possible solution strategies are described and discussed with all other colleagues who belong to different schools and grade levels.
- The exploration and use of special hands-on tools coming from the history of mathematics and from everyday life.
- The choice to focus on the verbalization and comparison of problem solving strategies (analysing roots, choices, procedures and arguments of the resolutions).

This article presents an experience carried out during the MMLab teacher training, from individual tasks to collective discussions in which teachers described and analyzed different ruler and compass constructions. It will also shed light on the role of the teacher educator who manages the collective discussion with teachers through specific techniques, such as asking to explain, summarizing and highlighting the implicits of resolutions strategies.

An example: ruler and compass constructions

The first mathematical machines used in the MMLab-ER training is the most known: the compass. We wanted to reassess the importance of ruler and compass constructions in mathematics teaching-learning: the compass, in fact, although widely used for practical purposes (e.g. in technical education), is not often analyzed in its foundational role in the mathematics culture (we just think to Euclid's Elements).

Following Rabardel theory, teachers analysed the compass. At first, the physical object with its specific characteristics, and then the utilization schemes that develop under specific tasks, for example to draw circles and the measurement transfer. This first activity set the protocol of exploration that will be the basis of each machines exploration. After analyzing the artefact components and its utilization schemes (answering to the questions: *how is it done? What it does?*), teachers studied the role of structure and movements in order to justify the machine functioning (*why it does that?*). Obviously, in this particular case, the exploration was carried out very rapidly because the compass is already well known by the teachers. The analysis of instrument finished with a problem solving activity guided by the open question: “*What if it does change...?*”. Teachers explored the possible changes of the compass (e.g. with equal or different rots and with extensions) and the existing different types of compasses (e.g. plane compass and the blackboard compass).

After this instrument analysis the teachers faced this crucial task: *To construct an isosceles triangle using ruler and compass.*

Working Group 17

From the point of view of contents, the choice of the isosceles triangle was made because it is a figure whose definition and properties are known since primary school and therefore suitable to all course participants and reproducible in different classes (with obvious adjustment). Moreover, the request is deliberately left open (we do not ask: to construct an isosceles triangle given the sides) in order to encourage the genesis of different construction strategies. This activity, carried out by all teachers involved in the Project (about a hundred divided into five provinces) was proposed to focus teachers attention on the following aspects: how and why the same final product (in this case, the isosceles triangle) can have different constructions; the importance of analyzing the theoretical and practical reasons grounding the different choices; the role of artefact components and utilization schemes analysis in the planning and development of the resolutions.

Teachers faced the task individually and discussed the possible solutions in small groups and then collectively. This methodology should foster the verbalization of their processes and argumentations. The teacher educator orchestrated the collective discussion using different techniques: calling teacher to play his/her construction, asking to dictate the procedure highlighting the implicits, comparing different constructions and giving suggestions for other possible constructions.

Below we show and analyse some excerpts selected from a collective discussion in which are presented different constructions of the isosceles triangle. The discussion started after the working group session.

Teacher educator: Who can explain to me his construction? Always step by step so we can reproduce it.

Teacher A: I was lazy and I have only drawn a circle with radius at will, then I connected the circle center to two points belonging to the circumference.

The teacher educator performs the procedure on the blackboard (fig. 1).

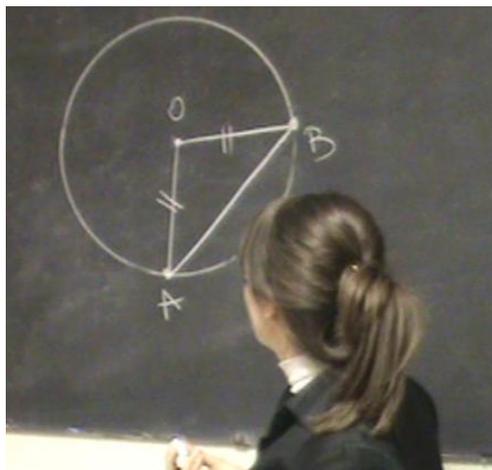

Figure 1: Solution A

Teacher A: I almost chose the sloped side and then I constructed the triangle.

Working Group 17

Teacher educator: Okay, first you gave me a procedure and now, do you want to justify it?
The procedure is correct: I found an isosceles triangle. I know that it is just an isosceles triangle because ...

Teacher A: Because the points I have chosen are on the circumference.

Teacher B: Yes, they are the circumference rays and so they are equal.

Teacher A: But now ... I'm asking myself this question: I said at will, but I had to be careful...

Teacher C: They should not be on opposite sides.

Teacher D: They should not belong to the diameter.

Teacher educator: This is an additional step: asking if...

Teacher A: Then, perhaps in order to be more precise I should have said that I excluded the points diametrically opposite.

Teacher educator: Yes, I should not take B aligned with O and A. The exploration of the limit cases is important. With a dynamic geometry software this exploration could be facilitated [...]

As we can see in this excerpt, the teacher educator orchestrates the discussion asking questions, highlighting the limits and peculiarities of the suggested procedures, raising ideas, and summarizing.

Now we show a second excerpt in which a teacher describes another construction and, as before, the teacher educator reproduces that on the blackboard.

Teacher E: I draw a segment, I open the compass at will and I draw a circumference pointing on the two extremes.

Teacher F: But with the same opening.

Teacher E: Yes, maintaining the same opening.

The teacher educator opens the compass less than half of the segment (selected as triangle base) and she draws the two circumferences while the classroom starts to rumour.

Teacher E: Not in this way.

Teacher educator: You told me "as I will"...

Teacher E: Larger.

Teacher groups: More than half.

Teacher educator: Ok, why? In the meantime, let us ask ourself, what we said before: my construction starts from a definition or a property of the isosceles triangle. What property would you use?

Teacher E: I wanted to use the properties of segment axis.

In this excerpt we notice the attention and the effort involved in highlighting the implicits in teachers' procedures and in the roots of constructions.

The discussion continues analyzing other constructions (see figure 2-3).

Figure 2: Solution B: a construction that uses the segment axis

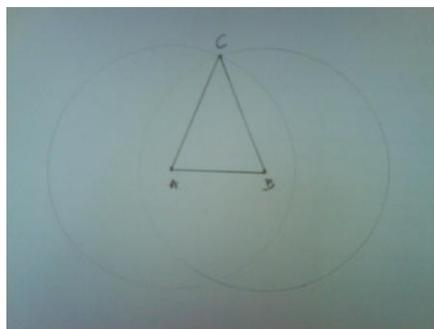

Figure 3: Solution C: a construction of a triangle given three sides when two sides are equal

In these collective discussions the teachers see and listen to procedures (made by colleagues or by teacher educator), by asking questions and focusing more on understanding the reasons behind the single steps in relation to mathematical concepts involved and the role of compass. This work leads teachers to reflect on the formulation of procedures, the limit cases, the roots of the constructions and the argumentations that support them.

The teacher educator notices that nobody has used the isosceles triangle propriety of “having two equal angles” and therefore she suggests this task: *To construct an isosceles triangle given one of the equal angles.*

This task is interesting because not all the teachers remember the procedure and, for this reason, the activity is seen as a challenge that they have to face by collaborating and discussing in small groups.

Here is a brief excerpt from a discussion that followed the explanation of the procedures carried out by a teacher (teacher 1) who made the construction shown in fig.4.

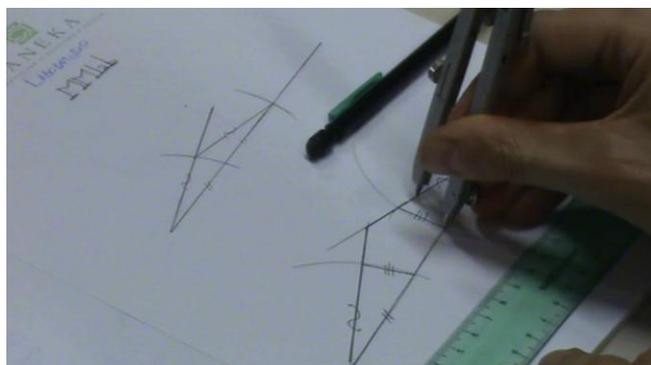

Figure 4: Solution D: a construction of isosceles triangle given one of the equal angles

Working Group 17

The teacher 1 constructs an isosceles triangle cutting the angle with a circle and then re-constructs it as we can see in fig.4.

Teacher 2: But the problem is that...we said it is equal to this (*he indicates the isosceles triangle sides identified by the circumference that cuts the angles sides*). This is equal to this, so these two triangles have equal sides, so they are isosceles.

Teacher educator: The fact is that you have chosen how to cut the angle with the circumference.

Teacher 2: But in this way they are isosceles, did we construct an isosceles triangle using isosceles triangles?

Teacher educator: Yes, they are isosceles triangles, but it could be done also by using the construction of a scalene triangle. The crucial step is when you construct this arc (*she points out the line segment that connects the points of intersection between the circumference and the angle sides*).

Teacher 1: As a matter of fact, I constructed two congruent triangles, so now I have the correspondent angles congruent; the isosceles triangles are made in few steps.

Teacher 2: It is true, what interested me was to construct an angle congruent to another and in order to do that it is sufficient to construct two congruent triangles. Naturally for the construction of an isosceles triangle I have to put them in this way (*he points that out*), if they do not mirror, it does not work.

In the excerpt we see how the construction steps are analyzed and discussed with a teacher who wants some clarification about the key elements that ensure the construction validity.

The whole activity on the isosceles triangle construction (individual task followed by collective discussion) highlights how, even in this simple task, we can use the laboratory approach in order to develop the analysis and the comparison of different solutions, underlining the importance of verbalization and explanation of choices (theoretical knowledge, practices, etc.) and procedures. From the point of view of mathematical contents, teachers realize that even starting from the same definition of isosceles triangle (a triangle that has two equal sides) there are different constructions and cognitive processes involved: i.e. the solutions A and C.

The final discussion dealt with the constructions frequency because more than half of the teachers made constructions like in solutions B and C, few like the solution A, and almost none like the solution D. Teachers thought about these choices and concluded that the first two strategies (B and C) are more frequent because they are used both in technique drawing (*“when you learn the construction of triangles, you do so”*) and when you draw on squared paper (*“these are constructions that we, and our students, usually made using the squared paper: the segment axis are simple and*

fast to do"); while construction D has not occurred because is not used frequently (*“it has not come to my mind because I never do it”*). It should be noted that all these reflections were been useful to teachers in the subsequent phase of teaching experiments design, in particular for the a priori analysis, for the tasks choice and for the management of group discussion.

CONCLUDING REMARKS

The methodology and tasks carried out during the MMLab training course aimed at developing the teacher’s attention to other ways of thinking and awareness of their own resolution processes. The development of this type of competence is not only useful for teachers to analyze the possible solutions of their students (the peculiarities in their thoughts and the possible mistakes or misconceptions), but it opens up the horizons on important mathematics features which are not reduced to symbols manipulation or reproduction of proofs studied on books. The reflection on these processes and on the role of theoretical and practical knowledge was one of the most important guide lines in the laboratory activities designed by trained teachers and developed in teaching experiments during the two years of the Project. Even if the analysis of project results is only at the beginning, because the project ends this year, we already have found a correspondence between the guide lines of the training and the teaching experiments carried out by trained teachers. In these teaching experiments, teachers, fostering individual production and critical observations, have always asked their students to verbalize their solutions, by discussing and sharing their knowledge.

NOTES

1. The MMLab-ER is a two-year project (2008-2010) founded by “Regione Emilia Romagna” and coordinated by M. G. Bartolini Bussi and M. Maschietto. The responsible of the teacher training design and development are F.Martignone and R. Garuti.

PLANNING TEACHING ACTIVITY WITHIN A CONTINUOUS TRAINING PROGRAM

Cristina Martins¹ and Leonor Santos²

¹School of Education, Polytechnic Institute of Bragança (Portugal) and ²Institute of Education, University of Lisbon (Portugal)

The present text is part of a more comprehensive work purporting to study the professional development of primary school teachers within the program for continuous training in mathematics (PCTM). We will present a cross analysis of the case studies of teachers Dora and Aida, focusing on the meaning they confer upon the process of planning a teaching activity, tasks planned and planning development within PCTM. Aida bestows great importance on this process. Dora's participation in PCTM widened her horizon to the necessity of undergoing it.

Key-words: teacher planning, practice, teacher training

FOREWORD

This text is based on a work whose main purpose is to study the professional development of in-service primary school teachers within the program for continuous training in mathematics (PCTM). We specifically wish to ascertain how didactic knowledge relating to teachers planning develops through participating in PCTM. I.e.: what meaning do they confer upon planning? How do they plan? What sorts of tasks do they select?

We consider that professional development is conceived as a permanent, continuous and intentional process, aiming at improving professional knowledge, teaching practices and reflection thereupon, thus contributing towards better students' learning in Mathematics (Guskey, 2002; Sowder, 2007). Participation in training programs is taken to be a tool for professional development (Guskey, 2002; Wu, 1999). One of the goals of PCTM is "to foster the undertaking of curriculum development experiences in mathematics which contemplate class planning, class direction and reflection by the teachers involved, supported by peers and coaches" (Serrazina *et al.* 2005, p. 3), thus foreseeing that in PCTM there will be an intentional investment in the aforementioned components. Thus, this program aims at providing, throughout the academic year, a site for experimentation and joint reflection, between teacher-trainer and trainees, so that one can reflect upon practices and use them to develop a sustained knowledge, which takes into account the characteristics of the students it addresses (students aged 6 to 10).

The activities to be developed within this program, take the form of:

— Group training sessions (GTS), biweekly joint sessions for planning and reflection upon activities associated with the teaching practice, involving the teacher trainer and a group of teachers voluntarily enrolled in PCTM.

— Classroom supervision sessions (CSS), sessions for the development of classroom curriculum activities corresponding to conducting practices materializing the planning detailed in the joint sessions and respective discussion, involving the teacher trainee and the trainer in her role as supervisor;

— A joint work session for the development of other enlivening actions with the teachers.

As far as evaluation is concerned, the elaboration of a portfolio reflecting the professional development resulting from the training is proposed.

In this text we wish to present Aida and Dora's vision of the planning process, trying to perform a cross analysis of these two cases on the basis of the following categories: (i) meaning/importance of planning; (ii) tasks planned under PCTM; (iii) weight of planning undertaken under PCTM; and (IV) collaborative work in performing planning.

THEORETICAL FRAMEWORK

Teaching practice is a key component of a teacher's professional life. Teaching Mathematics, regardless of level, involves students, teachers, administrators and schools in contexts which change on a daily basis making the creation of a formula, "a kind of guide", or even of a set of practices teachers can adopt, difficult (Franke, Kazemi, & Battey, 2007). Within teacher's action three basic stages are usually considered, concerning teaching practice: pre-active, interactive and post-active phase. (Canavarro, 2003; Clark and Peterson, 1986, Santos, 2001; Vale, 2000). Classroom practice begins with planning, this being the phase where the teacher identifies content, materials and teaching methods necessary for the practice. For Yinger and Hendricks-Lee (1995) teachers have, on one hand, daily and yearly, the responsibility of selecting and conceiving learning experiences based on course content and, on the other, must be prepared to take the utmost profit from non-planned teaching opportunities which might arise in the course of educational interactions, and being able to achieve these purposes thus demanding preparation.

Pacheco (2001) sees planning "as a practical activity allowing the organization and contextualization of didactic action taking place at classroom level" (p. 104), presenting two main functions, one being to clarify what one wants to perform in the classroom and the other to predict and modify forecasts, throughout the process in agreement with the didactic situation (Pacheco, 2001). Thus, "the act of planning presents itself as a specific and essential teacher's competence which allows him/her to configure, by means of a mental or written plan, the several didactic elements used as a basis to structure the teaching learning process, providing a reduction of incertitude or insecurity" (Pacheco, 2001, p. 105). Even when written plans are produced, they represent only a small part of the true planning that has been taking place in the teacher's mind (Arends, 2007, p. 100).

According to Yinger and Hendricks-Lee (1995), to be prepared for interactions as dynamic as the ones that take place during class seems to be less a question of prediction and control and more a question of preparation and response ability. Specifically, the teacher must anticipate difficulties and student's resolution procedures, foresee how to monitor them and sequence the possible interventions and connections that might be established (Stein, Engle, Smith, & Hughes, 2008). Within this framework, planning producing more generic charts, more flexible and activity-based, will be more useful than the one producing strictly specified and goal-oriented plans. Likewise, plans will become more useful if not conceived to be implemented as means for interaction control, but rather as framing tools purveying a starting point for educational interactions (Yinger & Hendricks-Lee, 1995).

The selection of tasks to submit to students is envisioned as the main point for planning the teaching/learning process (Fernandes, 2006; Ponte, 2005). It is up to the teacher to be responsible for their preparation and direction, taking three concerns under account: mathematical content, students and their learning paths. It is also important to understand how students and teachers *deal* with the diversity of existing tasks, namely concerning evaluation of work undertaken, progress achieved and difficulties to be faced, and cognitive and metacognitive processes and strategies associated with each range of tasks submitted to them (Fernandes, 2006).

The possibility of performing teaching practice collaborative planning work allows capitalizing energies, to provide extra support, to multiply perspectives, to enrich reflection (Serrazina *et al.*, 2006). Collaborative learning as a professional development strategy (Marcelo, 2002) involves group-oriented formative processes, causing not only that learning activities be performed with others in interactional context but also that goals and results of such learning also present a collaborative aspect. PCTM is presented as a privileged means to perform this task (Serrazina *et al.*, 2006). In the context of teacher's professional development Joubert, Back, De Geest, Hirst and Sutherland (2010) state that there are different models but most of them aim at providing opportunities for teachers to become involved in learning and change processes. They suggest, however, that different teachers, influenced by their work contexts and personal motivation, beliefs, theories and experiences, will perceive different opportunities, and such perceptions may change in the course of time.

INVESTIGATION METHODOLOGY

The undergoing investigation is qualitative/interpretative in nature (Teddlie & Tashakkori, 2003), using case study techniques (Stake, 2007).

The wider study has considered three primary school teachers, Aida, Dora and Sara, belonging to the same training group, who enrolled voluntarily in PCTM. Selection criteria were number of teaching years and academic training. In this text we will only focus on Aida and Dora.

Aida is about 45 years old, and has 25 years experience as a teacher. She underwent one year in PCTM. As academic training she has a primary school teacher's degree (three years course), a specialized course of superior studies in the French teaching area (license degree) and a master's degree in History of Education. Mathematics has always been one of her favorite subjects, although her post-college training has been unconnected with this area. From PCTM she hopes to become up-to-date and try that "children might learn to see mathematics in a different way, as a subject that can be interesting" [Aida, portfolio].

Dora has less than 10 years teaching experience and is about 40 years old. Dora underwent two years of PCTM. She has a license degree (four year course) in Basic Teaching, specialized in visual and technological education, enabling her to teach in primary school. Her life as a student is determined by mathematical failure and a conflictive relationship with it. Dora expects from PCTM "to be able to overcome myths" [Dora, first interview] she has felt since childhood and to learn.

Data gathering started in the academic year 2006/2007 and took place for two consecutive years, through semi-structured interviews (namely one initial, one half-way, one final, one two years after completion of the program and four post-observation interviews conducted with Aida who only took one year of training, the same number with Dora plus 5 post-observation interviews in the second year of training) participant observation of the Group training sessions and of the Classroom supervision sessions, and documental analysis of materials produced by the teachers and field notes and accounts of the teacher-trainer.

Following an interpretative paradigm an analysis of information started at the end of the training year, consisting in organization and interpretation of data, according to *à posteriori* defined categories, taking into account the problem under consideration, theoretical presuppositions and empirical work undertaken. The interpretative paradigm subscribes to a relativistic perspective of reality "envisaging the real lived world as a construction of social actors who, at each moment and place, construct the social meaning of events and phenomena and reinterpret the past" (Santos, 2001, p. 186).

In this text, according to the categories developed, different topics were found characterizing these teachers' vision about the process of planning teaching activity.

AIDA AND DORA: PLANNING TEACHING PRACTICE

Meaning and importance of planning

To Aida, planning teaching activities is a key aspect of the teaching/learning process, assertively stating that she has always planned, specifically noting the prediction relevance of the aspects planning includes:

I really don't know how people manage to teach a course they have not planned beforehand. Although there might be one day when one does not have the time, but

Working Group 17

everything is lined-up in one's mind. As rule I have everything actually written down. [Aida, initial interview].

In her final interview she mentions class preparation, seeing it as a privileged moment to consider the several aspects present in a class, an essential condition for its success:

It is essential because when we are preparing the course we reflect about class content, about the material we are going to bring, about what students know and about how to do it. So, I think one has to go this way. We must prepare every class for it to succeed, although improvisation is important, but only up to a point. I think preparation is essential for every class to take place as we want it. [Aida, final interview]

Dora clearly associates planning task to writing, which she claims not to like: "It is true, I don't like it, I never did" [Dora, initial interview]. She claims she usually prefers to mentally plan tasks, and only organize some ideas on paper, which are often changed when she enters the classroom:

I always think about what to do, but I don't write every step down, every step I must take, that is, I put down some topics for my own guidance, it's my way of organizing myself. Of course I prepare materials, the files I am going to use, and I bring it with me like that. I just get there and I don't follow a script, never, never. [Dora, initial interview]

In her final interview, she talks about planning teaching activities during PCTM clearly reinforcing the importance of the selection of tasks to put forward: "After having had the idea I prepared the material, oh yes... . That part is what's more important. For instances I made up the problem I was going to bring with me. And some of the material I used. If its correctly made up, why not using it, right?" [Dora, final interview].

At the end of the first year of PCTM she assumed the importance of planning, namely referring to planning investigation activities (speech 1) as well as undertaking planning in general (speech 2):

1. I prepared classes, that's obvious, it's just that I did it lightly, and not anymore, I go down to details more. Even because regularities taught me, I must pay more attention to that part, I must be rigorous when I prepare classes, to know whether or nor I am prepared for the answers and questions of students. [Dora, final interview]

2. Useful to know what we are going to do, to have a sequence, to know the steps we have to take, to consider what we are going to do, what must be done, the objectives, to know all those steps. [Dora, 2nd post-observation interview]

Although Aida has always acknowledged planning as an essential part of the teacher's teaching practice, associating it to a written record, Dora became, through participation in PCTM, more sensitive to its necessity, distancing herself from the idea of something exclusively mental and mainly associated with selecting tasks to face the students with.

Tasks planned in PCTM

Ever since the beginning of their training Aida and Dora have decided to experiment in tasks that were not usual in their teaching practice which caused them, for instances, to gain a new vision on the meaning and importance given to problem solving. Although Aida considered that problem solving was part of her classroom strategies, she had seldom presented problems that could not be solved directly through the use of an algorithm and whose resolution was possible using different strategies. This aspect is remarkable in her choice to include this task in the portfolio:

The choice of this task to become a part of the portfolio is due to the fact that it was precisely the first and, as such, was surrounded by larger expectations. Another reason which has defined my option is also related to its content. Introducing a “different” kind of problem from the ones you usually face the students with, which constitutes a challenge regarding my professional practice. [Aida’s portfolio, justification for inclusion of the first task]

Dora also mentions that before the training she already engaged in problem solving, but that she considered them to be different from the problems she currently uses, upon which the student can use different solving strategies:

But they were not problems just like these, sort of games that cause mental reasoning to develop, that make them think, that can be practical, useful for their daily life, less routine. And they do them very gladly and with much more willingness than the others. The others are much more a mathematical task. That is an operation! Is it a sum, a subtraction, or a division? It’s always the same thing. And in these problems they don’t see it, they see them as game, a challenge. [Dora, 1st post-observation interview]

Thus, for both of them, the tasks planned within PCTM have constituted a challenge in setting up a new meaning.

Elaboration of planning within PCTM

Resorting to planning developed within PCTM. Aida followed planning worked out within the training group, but always adding a personal touch to it. For instances, in the first task undertaken, Aida thought about presenting the students with a problem similar to the one worked out in the group, but adapted to a context fitting the Christmas season, stating regarding this in the 4th GTS: “I am going to make the experience” and she went on “I’m thinking about introducing precisely this one for a 4th grade, not the spider, but with Santa Claus, giving it another development”. [Aida, transcript of 4th GTS]

While experimenting with classroom tasks, Dora based herself upon the planning “discussed in the group” but “afterwards did not follow them to the letter” [Dora, final interview]. According to herself, this option his connected to her own way of being; “Besides, if I get stuck to a piece of paper I am less spontaneous, I don’t feel

like myself. I like to improvise, ...” [Dora, final interview]. However, when she talks about not fulfilling the first planning undertaken within PCTM she also grounds her justification in the students:

The fact that I did not lecture everything I had planned to, was my own option, and because, as I already mentioned, the students had perfectly understood the mechanisms for solution. Thus, to continue would only be useful for the students to apply the already mechanized procedure. Besides, I did what I ought to have done, we must not stick to what is written down, in this case in the planning, but, instead, in under what conditions is the activity carried out, what the students needs are, and, unquestionably, their mental availability. This is a factor that has a great weight in my way of living the profession. [Dora’s portfolio, 1st written reflect]

Thus, while Aida when elaborating her planning adapts it to her students, Dora adapts it to herself, although having the students under consideration.

The role of collaborative work. Aida has always been careful to prepare her planning in writing and in detail, and to discuss it within the work group. “We went on to Aida’s planning, who presented in detail the task she intends to explore, an activity of mathematical investigation based upon a multiplication double entry table” [report of the 7th GTS]. In planning classroom tasks she not only profited from and requested collaboration from colleagues, as she gave her own opinion about other people’s work. In the 4th Group Training Session she questioned a colleague about how on long it had taken to perform a problem solving task: “Is is a 3rd or a 4th grade?, How long, more or less, has the task taken?” [transcript from the 4th GTS]. In the same session, faced with the suggestion of a problem put forward by a member of the group for experimentation in a classroom, she mentioned: “It seems to me even more complicated [than the one with the spider]” [report of the 4th GTS].

She also never refrained herself from asking the supervisor for clarification which could help her to sort her ideas out and, simultaneously, in planning tasks:

I was thinking about, this time, a mathematical investigation activity starting from a double entry multiplying table, correct me if I am not using the appropriate terminology, (...) And since we are in a clarifying mood, regarding the 2 multiplying table, is it more correct to say that 1×2 , 2×2 , 3×2 , 4×2 , or, instead, 2×1 , 2×2 , 3×2 , 4×2 , as we were taught. [transcript of the 7th GTS]

In her portfolio, she alludes to and includes the material given by the supervisor in the group training sessions “since these constitute an essential support for the choice and programming of the task”, including “[Internet] research carried out during preparation phase, because I consider that the whole process of teaching and learning presupposes some kind of investigation”, indication of bibliographic research carried out, as “it also turns out to be a legitimation of some of the options taken” [Aida’s portfolio, justification for the inclusion of the material used in the preparation of the first task].

Dora also considers the participation of the other elements of the group and the supervisor in carrying out planning. Thus in the 7th Group Training Session Dora shares some of her concerns regarding time management:

We proceed to Dora's planning, who had previously exchanged some ideas with me through e-mail. Her task consist in finding regularities in the 2, 5 and 9 multiplying tables, with the students grouped in pairs.

Dora: Do you think I can use up the whole time just with this?

Reseacher: I think so, if you let them air their discoveries.

Dora: Aida has got so much here! (...) [Report of the 7th GTS]

Dora mentions in particular the importance of the supervisor in preparing the tasks to experiment. Specifically about the second task undertaken, she makes it clear that she needed "a lot of help from you, a lot of guidance", which leads her to conclude: "but I also learned from this, it's not just that you helped me, you helped me out with doing the planning and you taught me how to do it" [Dora, 2nd post-observation interview] As a matter of fact, Dora recognized that planning a mathematical investigation activity for the first time constituted a controlled risk, as she was participating in the program and had the support of the supervisor, and also recognized that student's activities and their learning from undertaking this task, overcame all other factors. "I risked it because I had the support of the supervisor, in case it would be needed, and as I liked the theme, I thought it was interesting for students, as they could perform several explorations and, lead them to be interested, in a more attentive way, in the numbers and in the investigation" [Dora's portfolio, justification of the choice of the 2nd task].

To Aida, collaborative work, either with the whole group either with the supervisor, was used in a double perspective, for her own support and for that of the others. It was seem as a multidirectional collaboration. For Dora instead, this working context, relies more upon the supervisor, and in a one way direction. It is a one directional relationship, to learn.

FINAL CONSIDERATIONS

The starting point of these two teachers is clearly different, so it would be expectable that their professional development during PCTM would also be different. Aida starts out from two kinds of expectations for the training, one connected to teaching, one connected to learning, helping out her students, Dora, on the other hand, takes teaching as her strong bet, to learn and to gain confidence in an area with which she has always entertained a conflictive relationship.

Aida identifies the different aspect present in planning, contents, tasks and materials, methodologies and what students already know (Canavarro, 2003; Clark and Peterson, 1986, Santos, 2001), while at first Dora concentrates herself on the materials, seeming that the associated objectives are not determinant for classroom

work orientation. For Aida, one needs to clarify in order to be able to modify (Pacheco, 2001), Dora instead, who stresses the importance of change within the class, does not associate it with a thorough preparation, but rather to her whim of the moment, resorting to the unforeseen. With the course of the training, Dora begins to mention the importance of planning to ascertain the sequence of the task in accordance with the objectives defined and to be prepared to answer students (Stein, Engle, Smith, & Hughes, 2008) and address unforeseen situations of the teaching practice to use them for the better advantage (Yinger & Hendricks-Lee, 1995), recognizing the advantage of resorting to a written record.

The planning undertaken in group during training constitutes the starting point for both teachers. However, once again, one can see that while Aida values from the very beginning the learning component, adapting it to her students, Dora centers herself upon teaching, adjusting it in the classroom to herself, also taking the students under account. The different levels of professional development that both teachers present are also shown in the way they profit from collaborative work undertaken during training, as an asset to all elements involved (Hargreaves, 1994), or as a context for personal learning. However, the tasks carried out during training have constituted a context for professional development for both teachers.

With the analysis of a training program with specific and innovating characteristics we aim to provide answers which contribute to improve initial and continuous teacher training. However, from the evidence gathered from these two cases, the question remains to determine up to what point the same training format can apply to such different teachers. In which way can one foster professional development of teachers starting up from different levels? How to ensure the sustainability of this program?

MATHEMATICS PROBLEM SOLVING PROFESSIONAL LEARNING THROUGH COLLABORATIVE ACTION RESEARCH

Joyce Mgombelo & Kamini Jaipal-Jamani

Faculty of Education, Brock University, Canada

This paper draws from a study that aimed at finding out how teachers' collaborative action research in the Teachers Learning Together (TLT) project promotes professional development in the area of mathematics amongst elementary school teachers. The paper focuses on an analysis of teachers' experiences of teaching and learning of problem solving in a collaborative action research. Qualitative research approach was used to conduct case studies of three teacher-researcher teams. In the two cases analysed in this paper, collaborative action research provided opportunities for teachers to learn about problem solving process, creating an environment that fosters students' learning through problem solving and mathematics knowledge for teaching

Keywords: professional development; problem solving; collaborative action research; mathematics knowledge for teaching

INTRODUCTION

Mathematics education reform movements reflected in documents such as the Ontario Mathematics Curriculum (2005), NCTM Principles and Standards, (2000) call for mathematics teachers and educators to look at different ways of teaching and learning mathematics. One of the elements of these reforms is a focus on problem solving as a key component of effective mathematics teaching and learning. For example, according to the National Council of Teachers of Mathematics (NCTM, 2000), "solving problems is not only a goal of learning mathematics but also a major means of doing so" (p. 52). Recently mathematics education researchers have recognized the importance of mathematics teachers' understandings of the underlying assumptions and theories of teaching and learning of problem solving as reflected in these documents and their practical applications. As such, researchers have argued for the importance of professional development for teachers to enable them to enact, in their classrooms, the teaching and learning of problem solving.

Traditionally teachers' professional development models comprised of one-day training workshops provided by experts who come and go. Researchers have argued that this type of professional development does not result in a change of teachers' practices (Joyce & Showers, 1995). Researchers also contend that professional development that is close to the classroom, collaborative, content focused, and relies on expertise and lived experiences of participating teachers have the potential to affect teaching practices (Kratzer & Teplin, 2007).

Working Group 17

This paper draws from a study that aimed at finding out how teachers' collaborative action research in the Teachers Learning Together (TLT) project promotes professional development in the area of mathematics amongst elementary school teachers (Mgombelo & Jaipal, 2010). The study was guided by the following questions:

- In what ways does collaborative action research, when used as professional development, influence teaching practice?
- In what ways does participation in teacher-designed action research inform teachers' understanding of elementary school mathematics and elementary mathematics teaching and learning?

The paper focuses on an analysis of teaching and learning of problem solving in a collaborative action research. TLT is a professional development initiative of The Elementary Teachers Federation of Ontario (ETFO). ETFO invited and provided support for teacher teams from the same school or in similar roles at different schools to come together to conduct action research projects relevant to their specific professional needs, circumstances and interests. For the 2008 school year, the focus of professional development was on mathematics. Over the course of the year, teams of teacher-researchers were supported by university facilitators as they conducted their own research projects at their schools. As part of this project, ETFO contracted university facilitators to facilitate the professional development and conduct three case studies of some of the teacher teams with whom they were working. In this paper we describe some of the findings from two case studies that we conducted -- these teacher teams investigated problem solving in their action research projects.

THEORETICAL FRAMEWORK

The research was framed by the following ideas: teachers develop knowledge of teaching and learning mathematics in practice by engaging in activities that promote collaboration, reflection and experimentation such as collaborative action research; effective mathematics teaching requires a sound knowledge of mathematics for teaching; and teachers need to learn how to teach through problem solving.

Collaborative Action Research

Action research derives its roots from the work of the German social psychologist Kurt Lewin (Carson, 1992). Lewin was concerned about the gap that existed between theories about society and the dynamics of social practice. In the past two decades action research has emerged as a significant form of research into practice. In education, in-service and pre-service teachers are being engaged in action research as part of professional development and as part of educational reform efforts (Feldman, 1996). Following Lewin, various manifestations of action research have developed. Action research can be individual or collaborative. Collaborative action research can be defined as collaborations between teachers and outsiders, such as university

Working Group 17

researchers (Savoie-Zajc & Descamps-Bednarz, 2007) or collaborations among teachers (Feldman, 1996). In the TLT project, teachers were involved in a collaborative action research. Feldman (1996) defines collaborative action research as research that involves practitioners working together to take actions within their situations in order to improve their practice and to come to a better understanding of that practice. The words “collaborative”, “research” and “action” in collaborative action research might be conceived as:

- Collaborative: group of teachers working together
- Research: systematic, critical inquiry made public
- Action: Understanding the teaching and learning system requires taking action within the system and paying close attention to the results of taking those actions

In their paper “Complexity Science and Educational Action research: toward a pragmatics of transformation” Davis and Sumara (2005) notice a similarity between sensibilities promoted by collaborative action research and those promoted by complexity science. Both collaborative action research and complexity science are concerned with “what one might do to bring together the self interests of autonomous agents into grander collective possibilities” (p. 454). One way that complexity science addresses this question is by elaborating on conditions that are necessary for bringing together a collective learning system. These conditions include making sure that there is redundancy among the participants in a team. Redundancy, understood as commonalities among participants in a team, is necessary to ensure a transition from a collection of me’s to a collective of us (Davis & Simmt, 2003). Another condition that is necessary for the emergence of a collective learning system involves the presence of diversity among the members of the team. Diversity allows novelty; it is the source of a collective’s flexible response—its intelligence.

Mathematics Knowledge for Teaching

The question of the relationship between knowledge of subject matter and knowledge of teaching has been a central concern in teacher education. In practice any mathematics professional development program has to contend with the question of how to integrate knowledge of subject matter (mathematics) and knowledge of teaching. An initial characterization of this integration comes from Shulman’s (1987) work on pedagogical content knowledge. Shulman defined pedagogical content knowledge as a particular form of knowledge that embodies the aspects of content most germane to its teachability. Recently, Ball and Bass (2002) elaborated on pedagogical content knowledge and used the term “mathematics knowledge for teaching” to capture the complex relationship between mathematics content knowledge and teaching. Ball and Bass suggest that any inquiry into teachers’ knowledge of mathematics should begin by analyzing the work of teaching and questioning what mathematics matters for this kind of work; they maintain a

delineation between knowing mathematics and knowing mathematics that is useful for teaching. In addition to knowing mathematics content, knowing mathematics that is useful for teaching involves specialized content knowledge that is not pedagogy but includes for example knowing how to represent fractions and decimals with diagrams.

Teaching through Problem Solving

There is consensus in mathematics education about the importance of problem solving and its potential for increasing students' engagement with mathematics. Consequently, teaching through problem solving has gained prominence in mathematics education over the last two decades. From the student perspective, the experience is one of "learning through problem solving," and NCTM (2000) states that:

Instructional programs should enable all students to build new mathematical knowledge through problem solving; solve problems that arise in mathematics and in other contexts; apply and adapt a variety of appropriate strategies to solve problems; and monitor and reflect on the process of mathematical problem solving. [p. 52]

Although problem solving is regarded as a beneficial approach to teaching mathematics, teachers however, have often found effective teaching of mathematics problem solving to be a major challenge. For example in Finland, Pehkonen (2007) found that teachers who believe problem solving is beneficial still fail to implement it in within their classrooms.

METHODOLOGY

We used qualitative research methodology to conduct case studies of three teacher-researcher teams, focusing on the teachers' learning as they engaged in their own action research activities. Overall, the two Mathematics educators acted as facilitators for nine teacher-researcher teams as part of the Teachers Learning Together project. ETFO held a symposium over two days in August 2008 where participants were introduced to the Teachers Learning Together project and action research methodology. From the nine teacher teams that were assigned to us by ETFO, we selected three groups to be the focus of our case studies. Selection of teams was based on the following aspects:

- The diversity provided by the three teacher-team projects selected according to their home school districts, the grade levels addressed, mathematic topics addressed, the teachers' levels of teaching experience, and their experience with research
- The potential of the each team's plan to address our research questions
- The alignment of the each teacher team's action research project with the Ontario Elementary Mathematics Curriculum (2005).

Data Collection methods

Data sources were:

- 1) Copies of teacher-created artefacts relating to the focus of the teachers' research such as lesson plans, teaching materials, and teachers' post-lesson reflections in journals: These were collected by the teachers on our behalf throughout the school year
- 2) Teacher-created action research project reports: The teachers' final action research reports described and presented findings of how their action research had impacted their professional practice.
- 3) Transcriptions and field notes of teacher-researcher team meetings (selectively audio-recorded).
- 4) Our own researcher journals: Each researcher kept a written record of her own reflections relating to the research project over its duration.
- 5) Transcriptions of one focus group interview per team at the end of the project, audio recorded

DESCRIPTION OF TWO CASES

Case 1: Student Questioning in a Problem Solving Context

This teacher team of four junior division (grade 4-6) teachers were mathematics facilitators from four different schools with a history of engaging in collaborative professional development projects initiated by the Ministry of Education and the District school boards. At the time of the TLT project, the four teachers taught one grade 4/5 class, one grade 5 class and two grade 6 classes respectively, located in two rural and two urban schools. Three schools were K-8 schools and one was a grade 4-8 school. Their research question emerged from observations of students learning during their two-year professional learning in the District School board project that had focussed on teaching through problem solving. Teachers observed that students were not asking mathematically relevant questions and engaging in productive dialogue that furthered their mathematical understandings. They therefore wanted to make math more "visible" to students. For this TLT project, the teachers used instructional strategies that included math congress and gallery walk (Fosnot, 2007; Fosnot & Dolk, 2001; 2002). These instructional strategies involve students in dialogue, conversation, discussion, and questioning of mathematical solutions presented by their peers. After discussions with each other and the researchers, the group narrowed their focus to the role of students' questioning and dialogue during problem solving contexts. Their research question was: How can we enhance productive questioning and dialogue through the implementation of targeted instruction so that classroom conversations make the mathematics more accessible to all students? The goal of their study was to identify strategies that would promote

effective student questioning and dialogue during problem solving to foster mathematical reasoning for all students.

After conducting an extensive literature review, the team observed that most studies on mathematical questioning focused primarily on teacher questioning. The limited literature in the area of student questioning in mathematics meant that the team would have to explore a number of targeted strategies designed to engage students in rich dialogue and effective questioning (by teachers and students), to find out if such strategies made the mathematics accessible to all students. Since they were already familiar with a number of strategies learned in the district school board project, they decided to try out the following strategies: Math Congress , (Fosnot, 2007), Gallery Walk / Post-it-notes, Think/Pair/Share, Modeling, Anchor Charts, Annotation of Key Mathematical Ideas / Student Comments / Questions, Summarizing / Generalizing, Wait Time / Pacing. Their intent was to try out these strategies, observe students, reflect as a group, and adjust the strategy.

Case 2: Students Communicating their Problem Solving Strategies through Bansho

Participants in this case consisted of four Grade 3 teachers from four different schools and one special assignment teacher in mathematics. Similar to the first team, all five teachers had participated as a group in their school boards' professional development initiative, prior to the TLT project. The team had been working on problem solving as the focus on the project. They observed that their students had problems communicating their computational strategies during problem solving. Upon further discussion and dialogue with each other and the researchers, they therefore decided to focus on students' communication of problem solving strategies. Their research question was: "How can we increase our students' ability to communicate their problem solving strategies more effectively by using the strategy of *bansho* in the classroom?" They decided to implement *bansho*, a Japanese strategy where students' problem solving strategies, serving as a public record, is displayed on a board. The teacher organizes the board writing so that the progression of ideas in the entire lesson builds logically and is captured for the duration of the lesson so that students may use the record for their note taking. The public record, or the *bansho*, is the class's collective thinking. The mathematical strand they chose was number sense and operations.

The team initiated the implementation by meeting to familiarize themselves with the mathematical landscape of learning for multiplication (Fosnot, 2007). This was crucial to understanding students' thinking strategies in problem solving. The teachers selected four different problems that involved multiplication concepts. The implementation was organized in a cycle of co-planning and co-teaching and was repeated 4 times. In each cycle, a *bansho* lesson was co-planned for half a day, one classroom was selected for two teachers to co-teach the lesson, three other classes were taught by the respective class teachers independently, and all teachers collected

student work in the form of the *banshos* for a post –lesson debriefing on a second half day. During the post lesson debriefing, the team spent time collaboratively dialoguing about their implementation and students’ learning – specifically discussing the *bansho* strategy and how students’ communicated their learning through the strategy. Based on these post lesson debriefings, they refined how to implement the *bansho* strategy.

FINDINGS

Through a qualitative analysis of data and informed by theoretical framework we identified a number of themes that characterise the experiences of teachers in collaborative action research. In what follows we present some of the themes which resulted from the analysis of two cases of teachers’ experiences about teaching and learning of problem solving in a collaborative action research.

Relation between collaborative action research and problem solving processes

For the teachers the collaborative nature of the action research process enabled them to experience learning environment similar to an environment that promotes learning through problem solving. In other words as teachers engaged in their own learning, they were empowered to foster the same learning environment for their students. For example one teacher felt that her experience in the project empowered her to be able to create a similar collaborative learning environment in her own classrooms to support students to take ownership and risks in learning.

It really is almost a mirror of exactly what is going on here [action research group]. When you get support, and when you get respect, and when you allow people to sort of figure out and talk to each other and find their way, then you get happier learners. You get more committed learners, you get more enthusiastic learners. You get learners who are willing to take risks, which we all are now. It’s almost like this is the mini version and then we take it back to our classroom and we create it.

Another teacher felt that her own learning process that she was engaged in the TLT action research project reflected the learning process that *bansho* strategy for teaching problem solving was promoting for her students. Her awareness of her own learning enabled her to support her students’ learning through problem-solving.

I might say the *bansho* does for the students what the math TLT does for me this year. It validates my opinions, it listens to me, it allows me to show it. The other kind of P.D. we get, is more like the old textbook: “okay, today we’re going to look at pages 1 to 10. Here’s the lesson. I want you to do questions 3 and 4. Take 5 and 6 home for homework. Tomorrow we’ll take it up.” ...whereas, the math TLT we’ve been doing this year is a *bansho*. My opinions are validated. I’m looking at other people’s strategies.

Impact on Students' Learning through Problem Solving

In a couple of instances, teachers noted that their professional learning in the project had positive effects on their students' learning. For instance, one teacher expressed how the targeted instruction on developing questioning skills during collaborative problem solving gave students an awareness of the value of learning by listening to different students' ideas, and engendered respect in students for other students' ideas.

I think one of the biggest things for me is having the kid that is traditionally smart in math, see a child that he or she would assume is in the lower end of the class, giving a strategy, presenting a strategy, explain their strategy...and then that really sharp kid goes "Ah! I never really thought of it like that!" That opens their eyes to the potential of the other kids in the class, which sometimes they just...ignore...

Teachers in the first case reported progress in students' mathematical questioning and dialoguing during problem solving. For instance, teachers described students' growth in mathematical thinking in terms of students' use of mathematical language in their questioning of peers' solutions of problems.

As the year progressed we noticed an improvement in the facility with which students used mathematical language. Comments such as: "How did the open array help you?", "What are the dimensions of the long rectangle?", "Are those equations part of the Venn diagrams? And "Can it work so that the area stays the same and the perimeter change?" show this development.

Learning Mathematics Knowledge for Teaching

It seems that collaborative action research project provided opportunities for teachers to learn mathematics knowledge for teaching. One teacher noted how she was better able to use math resources and know what to look for in the resources in ways that supported her growth in mathematics knowledge for teaching.

My math shelf is constantly [used]...I am constantly taking things off, putting things on, looking things up, making notes, looking for references, figuring out the math, looking at my math dictionary, looking at all my professional resources... and to say, "okay, I want to do this lesson, but what are the strategies that might come out of this problem solving? What might I see on my *bansho*?" It [action research] certainly, it has been more useful as a professional learning tool than many others.

Teachers identified specific aspects of their projects that had an impact on growth of their knowledge of mathematics for teaching. For example teachers reported how mathematics they focused on in the *bansho* strategy was also enhanced through reflection on student's work.

Working Group 17

I think we were all aware of it [*bansho*] before, but having the opportunity to chew it up the way that we did, the depth of our understanding certainly has increased.

By identifying the strategies the students used in our *banshos*, we also looked for the ways that those strategies were connected with respect to the [mathematics] Big Idea. This enriched our pedagogical content knowledge and sometimes even our own understanding of mathematics.

CONCLUSIONS

In the two cases analysed, collaborative action research engaged teachers in ways that enabled them to learn about problem solving process and how to create an environment that fosters students' learning through problem solving. Teachers' participation in the project led to growth of their mathematics knowledge for teaching. Collaborative action research spurred teachers to do their own research into math topics and use a variety of resources to support their planning and teaching. Collaborative analysis of students' work and teaching strategies promoted reflection on how different problem solving strategies supported growth of student mathematical thinking and increased teacher's understanding of how to teach through problem solving.

In conclusion it appears that collaborative action research can lead to the generation of new mathematics knowledge and understanding of problem solving for teachers. This has significance for mathematics professional developers and educational reformers. Professional development for teachers should foster a collaborative environment in which teacher can experiment with new ideas in theory and practice.

A STUDY OF THE DIFFERENCES BETWEEN THE SURFACE AND THE DEEP STRUCTURES OF MATH LESSONS

Edyta Nowińska

The Adam Mickiewicz University of Poznań

There is a consensus that designing rich learning opportunities in the mathematics classes and thus the improvement of the students' mathematical knowledge and skills can be supported by the application of findings about instructional practice. This application is a challenging task for both researchers and teachers. In a study conducted in Germany it was possible to investigate the reasons for the lack of positive effects of the application of theoretical findings about instructional practice on students' mathematical behavior. The results of the investigation and their consequences will be presented in the paper.

Key-words: deep structure, surface structure, teacher's activity, students' activity in the classroom

INTRODUCTION

International studies like TIMSS and PISA show that students face considerable difficulties in reaching well-founded mathematical knowledge and in using it autonomously. Such difficulties point to the need of developing effective instructional methods that have a potential to modify the teaching and learning processes in the classroom and to improve the students' mathematical achievement. Numerous initiatives have been taken in many countries to innovate mathematical classroom practice with new instructional methods (Kramarki & Mevarech, 2003; Depaepe et al., 2010; Gärtner, 2008). In the discussion about the quality of mathematical instruction the role of metacognition (e.g. NCTM 2000) and cognitive activation (e.g. Lipowsky, 2009) are stressed. From the researchers' point of view, it is obvious that those new instructional methods should encourage students to engage with the learning content and thus to develop elaborated knowledge basis. For an effective implementation of any instructional methods, it is important to distinguish between visible and invisible students' activities. For example, if an instructional method involving a cooperative learning form is performed, it can be expected that the student-student interaction around matters of teaching and learning also increases and that the students articulate their thinking, explain their mathematical reasoning and learn critical thinking. In doing that, the diversity in the students' prior knowledge will be used for an internal cognitive process of knowledge construction, carried out by an individual learner. These are some of the factors that make learning in cooperative groups promising (Slavin, 1980). The fact that the students are seated in cooperative working groups does not mean that they are actually working cooperatively and that the cooperative group has an impact on their cognitive activity and on their learning outcomes.

However, the literature on mathematical education change shows that it is difficult to transfer theoretical findings in the instructional practice and thus to reach the aimed positive effects in students' mathematical knowledge and skills. Depaepe et al. (2010) provide one example which highlights this difficulty: A group of researchers conducted a 7-month video-based study in two sixth-grade classes focusing on the teachers' metacognitive and heuristic approaches to problem solving. The researchers investigated the extent to which two teachers focused on metacognitive and heuristics skills in their teaching of mathematical problem solving. They found a positive relationship between the students' spontaneous application of heuristics to solve non-routine word problems and the teachers' references to these skills in their problem-solving lessons. However, increased application of heuristics did not result in students' better performance on those non-routine word problems. It can be supposed that the students didn't use the heuristics for a better understanding of the given problems and their solution ways were incorrect. Depaepe et al. (2010) try to explain the findings, but the explanation is difficult. It needs a more critical and qualitative perspective to appropriately interpret the relationship between the teacher's instructional methods and the students' learning processes and learning outcomes. The results of the study emphasized that it must be questioned and investigated to what extent metacognitive and heuristic skills were mainly done exclusively by the teachers and to what extent their students also internalized these new activities and skills.

The study of Depaepe et al. points to the need for the explanation of the lack of positive effects of the application of some new instructional methods designed to improve the students' metacognitive and heuristic skills and thus their problem-solving skills. Another promising study of a new instructional method (i.e. increasing the use of challenging and cognitively activating mathematical tasks) but without the expected positive effect on students' competencies (i.e. reflection, critical thinking, cooperation, and communication) was conducted by Gärtner (2008). Gärtner supposes that the expected positive effects regarding the students' competencies cannot be achieved within a year. He supposes that more time is needed to gain these positive effects, but there is no precise explanation how they can be achieved later. Moreover, Gärtner investigated classroom practice using teacher and student questionnaires. And he did not verify the results through direct observation.

In my PHD research (Nowińska, 2010) conducted in Germany it was possible to investigate the lack of the positive effects of a project to improve the students' mathematical knowledge. To explain the lack of the effectiveness of the project, I investigated the instructional practice, particularly the teacher and students' activities and the relationship between them, when new instructional methods were being practiced. An in-deep transcript analysis leads to the assumption that mainly the visible structure of the instructional practice itself (visible teachers' and students'

activities) has changed. Consequently, the cognitive potential of the new teaching content, challenging tasks and classroom discourse could not be used effectively by the students. The achieved explanations for the unexpected lack of positive effects of the project will be presented in this article.

In the first section to follow, I give an overview of the background of my study, presenting both the idea of the project to improve the students' mathematical knowledge and skills and the dataset and research question. The second section (Theoretical background) leads to key theoretical ideas used in my study. Information about the result of the investigation will be given in the third section. The fourth section concludes with a short discussion of the results.

A PROJECT TO IMPROVE MATHEMATICAL INSTRUCTION

Project idea

The aim of the project that I analyzed in my PHD research was the application of a learning environment that makes it possible (for students) to reach a deeper understanding of mathematical concepts and a well-founded mathematical knowledge. The project was conducted in Germany, in two six-grade classes (13 years old students, Realschüler). The project was based on some key ideas of *Cognitive Mathematics Education (CME)* (Cohors-Fresenborg & Kaune, 2005). *CME* uses the description of the mathematical knowledge of pupils via the concepts 'frame' and 'procedure', which were introduced to cognitively-oriented mathematics education by Davis and McKnight (1979). *CME* puts the construction of a cognitive mathematical operating system as a priori goal of mathematics lessons. Its most important elements are the 'function frame' and the 'contract frame' with suitable, attached procedures. Both frames use the frame 'formal representation of intuitive knowledge'. The development of the function frame, in students' cognitive mathematical operating systems was the main aim of the learning environment designed for the two six-grade classes in the project that I analyzed. The students involved in the project should develop a certain concept of function with several variables. The function concept makes the organization of the mathematical knowledge in students' minds and the connection between its parts possible. This hinders fragmentation of the knowledge. Conceptual understanding of the mathematical tool 'function' forms the basis for formalizing the intuitively existing knowledge (i.e. when dealing with complex mathematical tasks), for working out the formal aspects of this knowledge and thus for creating more transparency and understanding functional dependence. It makes it possible to work on complex mathematical problems. The conceptual understanding of 'function' constitutes the basis to improve the learners' skills to expose, explain and present functional dependence. For those skills the expressions *thinking in functions* or *functional thinking* will be used. They include an excellent handling of mathematical formalism of functions of several variables as well as the concept 'variable'. In Kaune (1995),

the role of thinking in functions and their formal representations is explained in a more detailed way. The improvement of those students' skills should be supported by the new learning environment with different external representations of the mathematical tool 'function' and by new formats of tasks, exercises and mathematical problems which should be solved by using functions.

What is more, the change in mathematical instruction should be supported by a change of classroom culture. The classroom culture should encourage students to cognitive, metacognitive and discursive activities (Cohors-Fresenborg & Kaune, 2007a, b). The key features of the classroom instruction complement one another to the concept of 'cognitive activation', as explained in Lipowsky (2009, p. 529): "In cognitively activating instruction, the teacher stimulates the students to disclose, explain, share, and compare their thoughts, concepts, and solution methods by presenting them with challenging tasks, cognitive conflicts, and differing ideas, positions, interpretations, and solutions. The likelihood of cognitive activation increases when the teacher calls students' attention to connections between different concepts and ideas, when students reflect on their learning and the underlying ideas, and when the teacher links new content with prior knowledge. Conversely, the likelihood of cognitive activation decreases when (...) the teacher merely expects students to apply known procedures".

There are numerous visible or easy to implement "elements" of the new instructional concept (mathematical tasks, content, some features in teacher behavior). Anyway, the main focus when using or practicing these elements should be on the students' cognitive, metacognitive and discourse activities that are main factors of knowledge acquisition in constructivist view of learning.

The intended changes in the instructional practice were challenging for the teacher involved in the project. Two teachers from one school decided to take part in the project. The teachers had diverse possibilities to improve their content and pedagogical-content knowledge in order to be able to realize the project. Supportive coaching and meetings with the researchers leading the project were realized before and during the project.

Dataset and research question

The dataset includes a video recording of 46 lessons, students' worksheets and written answers to control tasks. The way in which teachers actually put the project idea into practice was investigated through an in-deep analysis of the transcriptions of the lessons. The main focus of the investigation was on the way how the teachers involved students in using the function concept and formal representation and to solve the assigned tasks.

Students' written answers to the tasks designed for the lessons and for control tests during the school year were carefully scrutinised by looking for accuracy of the

application of the function concept and for their argumentations and explanations given to the designed tasks and questions.

The main research problem was to work out the explanations for the unexpected lack of positive effects of the change of the instructional method that had been achieved. A quantitative analysis with a pretest-posttest design at the end of the school year showed no project effect: The students of the project group (N = 29) and a control group (N = 111) have developed – concerning their mathematical achievements – almost identically over one school year. Because of this result the videotaped instructional practice had to be investigated intensively to work out some explanation for that unexpected project result.

THEORETICAL BACKGROUND

In order to work out an explanation for the unexpected project result, a qualitative in-deep analysis of transcription of the lessons was conducted. Thereby, the attention was directed to the students' use of learning opportunities and of the new instructional features. For that purpose, the surface and the deep structures of teaching and learning practice were investigated. The distinction between the surface and the deep structures of teaching and learning practice was introduced by Oser and Baeriswyl (2001). The surface structure means the situation the teacher sets for students (learning topics, methods, social forms, teaching styles), routines and regulation in the teacher's and students' activities observed in the situation and all teacher's activities planned to initiate learning processes and to provide learning opportunities. Observing the surface structure helps to assess the classroom instruction regarding its cognitive potential for meaningful learning processes by students. The deep structure means the quality of the initiated learning processes and, in particular, the internal learning sequences, or operations that students follow to appropriate knowledge, develop socially, solve problems and acquire skills (Oser & Baeriswyl, 2001, p.1041). Any investigation of the deep structure needs to take a closer look at the interplay between the presented mathematical content and its use, at the mediation by the teacher between the mathematical content and at the students' activities and their cognitive, metacognitive and discourse behavior. According to Cobrun (2003, p. 4), the investigation of changes which go beyond the surface structures and procedures of a classroom instruction is important if the success of the implementation of new instructional methods should be evaluated.

The deep structure of teaching and learning practice was investigated by using *the system for categorizing metacognitive and discourse activities during stepwise controlled argumentation in mathematics lessons (CMDA)* (Cohors-Fresenborg & Kaune 2007a,b). When analyzing a transcript with *CMDA*, metacognitive and discourse activities of teachers and students are made transparent in the transcript and thus easy for further analyzing of patterns in practicing these activities in student-student and teacher-student interactions. Using *CMDA* helps to assess if the

instructional features of ‘cognitive activation’ are internalized by a teacher and also by students and to what extent students make use of challenging teachers’ questions, demanding mathematical tasks or classroom discussion for their learning processes.

RESULTS

The first results of the qualitative analysis of instructional practice were promising: the behavior of the participating teachers gave evidence of the intended change in the instructional method. The teachers asked the students to explain misconceptions and errors in argumentations and in internal representations of mathematical terms and concepts. They led their students to check and assess arguments of other students, to explain functional dependencies, to discuss and assess different approaches to mathematical tasks and also to listen carefully in order to have discussions with other students. In so doing, the teachers provide learning opportunities for students. They encouraged students to practice metacognitive activities (like monitoring or reflection) and to engage cognitively in classrooms discussions.

The revealed changes in the teachers’ behavior and in the implemented teaching contents pertain to the survey structure of the teaching and learning practice. They show its cognitive potential to provide meaningful learning opportunities for students. Another positive result of the project was that the learners were able to handle complex modeling tasks and to formalize complex functional dependencies. To investigate how students use the cognitive potential for their own learning activities and how teachers promote these activities, the deep structure of the teaching and learning activities in the classroom was analyzed. The results of the analysis lead to the assumption that exclusively the surface structure of classroom practice has changed as desired. Consequently, the cognitive potential showed to the outside in the visible structure of the teaching and learning practice was only seldom used by the student. The teachers organized what is visible (the surface structure of learning) and neglected to consider if the students actually reflect on what, how and why they are doing when using functions or on benefit they have by using functions. That can be an explanation for the lack of positive learning effects and an explanation for the unexpected results of changes in instructional practice. This phenomenon will be illustrated with the following example.

Transcript, example

Numerous demanding mathematical tasks were designed to be implemented in the classroom practice. When solving these tasks, students’ skills to think in functions and their cognitive activities by using the function concept when precisely stating and formalizing the tasks should form the center of the teacher’s attention. Those activities play an important role in problem-solving and building a mental representation of a given situation.

In the following part of a complex mathematical task a functional dependency between the total price for the holiday in an apartment on the north beach and two

variables should be formalized. It is the first task in which the notation of functional equation with two variables has to be written, so students' explanations, argumentations and interpretation of the situation described in the task should be intensively supported by a teacher. These activities make the learning situation when discussing this task particularly challenging and they should be actually realized by students. This mathematical task as a part of the surface structure presents a cognitive potential of the instructional situation.

By the investigation of the deep structure, attention should be focused on the mediation by the teacher between the mathematical task and the students' activities to understand and solve the task.

Mr. and Mrs. Schulte, their two adult children and their dog, are planning a 14-days holiday trip to the island Borkum. They have to choose between two offers. The first offer states the following:

"Apartments on the north beach": Price per week 504 €, costs for the final cleaning 100 €, pet one-off 55 €. Write down a functional equation that can be used to calculate the total price for the holiday in an apartment on the north beach:

x_1 : number of days

x_2 : number of pets taken with you.

An analysis of a classroom discussion when discussing and solving this task revealed that there are no reflection activities on functional dependency described in this task and on the mathematical tool 'function' which has to be used to formalize this dependency. One student suggested the following equation as a solution for this part of this task: $p(x_1, x_2) = 504 \cdot \frac{x_1}{7} + 55 \cdot x_2 + 100$. However, the student did not explain how he got his functional equation and why this equation is correct. He gives no interpretation of the situation described in this task. As long as the functional equation is formulated, the cognitive potential of this task is not used effectively in the learning situation. The following transcription shows the further classroom situation.

- | | | |
|----|----------|--|
| 1 | Teacher: | Now, I need somebody who can explain the price function in his own words. |
| 3 | Student: | The whole function? |
| 4 | Teacher: | Yes, I'll point at it and you (...) So, the first part stands for? |
| 5 | | [L. pointing at 504 of the functional term.] |
| 6 | Student: | Well, the first part, so 504 stands for what they have to pay for... er... for one week. |
| 8 | | [L. pointing at $x_1/7$ of the functional term.] |
| 9 | Student: | The x_1 divided by seven means that they have to pay it for seven days. |
| 11 | Teacher: | Yes. |
| 12 | | [L. pointing at the functional term $55 \cdot x_2$.] |

Working Group 17

- 13 Student: And the 55 times x_2 means er, that they have to pay 55 Euros for the pet, for one pet.
- 15 [L. nods and points to the functional term 100.]
- 16 Student: 100 Euros, that is the final cleaning, that occurs only once.
- 18 Teacher: Ok. So you have it, the function.

The teacher asks a student to explain the functional equation (line 1). This demand is a part of the surface structure of the instructional situation and has a great cognitive potential. It suggests that the teacher tries to encourage the students to engage cognitively by working on this task.

Now, the deep structure of the situation is to investigate and thereby the focus is on directing the students' activities. Using *CMDA*, the first teacher's intervention (lines 1-2) is to be understood as a demand for the reflection on the suggested formal representation. Nevertheless, there is no correct answer from the student trying to explain the functional equation. No explanation of this equation can be understood as a reflection on the formal representation and on its semantics or syntax. The student gives only fragmented information about the function term and does not take the function name and the arguments into consideration. The student focuses on the formal representation but when interpreting it, he switches to some information about the Schulte family: "*they* have to pay" (lines 6, 9, 13). His remarks on variables x_1 and x_2 are not clear and not correct. The teacher, however, accepts the student's answers by saying "Ok. So you have it, the function".

The transcript shows that neither the cognitive potential of the task nor the cognitive potential of the teacher's demand led to the expected students' activities. Such a situation does not contribute to foster students' skills to *think in function* because there is no possibility to learn how to create more transparency and understanding of functional dependencies and how this dependency can be represented precisely. The teacher leaves no room for students to wonder how to tackle the formal representation for the given task and how to get the solution. Consequently, cognitive activities that meaningfully constitute the use of a function concept cannot be internalized by the students.

There is one more interesting aspect in this classroom situation. The teacher directs students' attention by pointing their finger at selected parts of the functional equation (lines 4, 8, 12, 15). The teacher's intention to react in this way is difficult to interpret. This reaction and the teacher's comment in line 18 lead to the assumption that the teacher has difficulties to use his knowledge about the new instructional methods to support and control students' learning activities. His attention is concentrated more on the surface structure of the teaching and learning situation than on the deep structure. This classroom situation shows that positive changes in the surface instructional structure do not implicate that also the deep structure changes as desired. The presence of specific tasks or the teacher's challenging questions is not a guarantee for the intended change of the ways teachers engage students in using

these tasks and questions and support the internal learning operations that children should follow to gain knowledge or to acquire skills. The students were able to use function to solve the designed mathematical task. Therefore, their knowledge about functional dependency and their skills to explain and formalize functional dependencies were not sustainable. The lack of the intended change in the deep structure can be an explanation for that unexpected result of the project.

DISCUSSION

Our analysis of the surface and the deep structure of lesson suggests that teachers' attention in class was focused on immediate outcomes, that is, on obtaining solutions to given tasks and using functions as mere procedures for calculations rather than on the long-term goal – on developing students' functional thinking. With the teacher's support, students were able to solve even very complex mathematical problems using functions with several variables, but they did not seem to be given the opportunity to internalize the acquired skills, to control their activities and to (re-)organize their knowledge. Teachers' expectations for their students included application of well-known procedures, but not reflection on them. Our findings stress the importance of the qualitative analysis of the deep structure of the instructional practice when the practice is changing through the application of the theoretical findings about effective teaching and learning approaches. Our results are similar to those stressed by Robert and Rogalski (2005), achieved by using their methodology with a twofold analysis of the classroom session dynamic. The findings stress the need to pay more attention to the ways teachers manage the relationship between students and mathematical content, in a 'normal' lesson and also while changing the teaching and learning practice to improve the students' mathematical knowledge and skills.

TEACHERS MANAGING THE CURRICULUM IN THE CONTEXT OF THE MATHEMATICS' SUBJECT GROUP

Cláudia Canha Nunes

Fernando Pessoa School, Lisbon

João Pedro da Ponte

Institute of Education, University of Lisbon

This study addresses the teacher daily practice. The goal is to understand, from the teachers' perspective, the challenges and difficulties that they face when attempting to involve the pupils in mathematics learning. We are particularly interested in issues that arise when teachers assume curriculum management decisions in the context of the school mathematics department. The methodology is qualitative and interpretive, with case studies. The results indicate that curriculum management supported by the collaborative context creates tensions when a teacher makes decisions that diverge from those assumed collectively and also between the collaborative group with an innovative approach to teaching and teacher professional identity.

Key-words: Curriculum management, mathematics teacher, mathematics subject group.

INTRODUCTION

A key element of teachers' professional practice is the way he/she interprets and manages the curriculum, taking into account the students' characteristics and the conditions and resources of the school. This study draws on several fields of knowledge: teachers' professional knowledge and identity, curriculum management in mathematics, and collaboration and leadership in school context. It strives to understand the practice of collaborative curriculum management in the context of a school mathematics department. Particularly, we address two questions: (i) How teachers conduct curriculum management, in this context, as they attempt to diversify students' learning experiences? (ii) What is the potential of collaborative work around curriculum management in the development of a professional culture at the school?

CURRICULUM MANAGEMENT AND TEACHERS IDENTITY

It is usual to distinguish different curriculum levels – e.g., the prescribed (or formal) curriculum of official documents, the available curriculum mediated by school textbooks, the curriculum planned (or shaped) by the teacher, the curriculum in action enacted by the teacher in the classroom, the curriculum learned by the students, and the curriculum evaluated, for example, through national examinations

(Gimeno, 1989; Stein, Remillard & Smith, 2007). Curriculum management refers to the actions of the teacher that contribute to the construction of the curriculum in the classroom (Gimeno, 1989; Ponte, 2005). For the teacher, the focus of the curriculum management process is students' learning, and it is according to this (at least in theory) that he/she takes all the necessary decisions. Therefore, as Ponte (2005) suggests, curriculum management has to do, essentially, with the way the teacher interprets and shapes the curriculum, on two levels: a *macro* level, concerning the overall planning of teaching for an extended period, and a *micro* level, corresponding to the teaching process in the classroom. The teacher makes decisions selecting tasks, strategies, and materials appropriate to the objectives and purposes of mathematics teaching, taking into account his/her students and working conditions. The teacher adjusts the curriculum as he/she evaluates and periodically reflects on his/her professional practices. Nowadays, as a curriculum manager, the teacher faces new challenges: the modern society poses constantly new demands on schools, the student population assumes a cultural diversity never seen before, and curriculum orientations proposes a major change on the role of the teacher, from a "deliverer" of knowledge, to that of a facilitator of learning.

To teach well, the teacher must know teaching techniques, the content of what is taught, the students, and the school context (Shulman, 1986). But, fundamentally, the teacher teaches what he/she is (Elbaz, 1983; Ponte & Chapman, 2008). The teacher's professional identity is an aspect of his/her social identity, which presupposes the existence of a community providing ways to think and act which constitute collective values (Dubar, 2002). Ponte and Chapman (2008) indicate that in the construction of a professional identity, the teacher takes the culture, values and norms of the professional group, but also has the possibility of influencing and thus contributing to the change of the group, mobilizing his/her cultural background and personal experience. Moreover, the socialization process of the teacher at the school and in his/her mathematics department is often complex, sometimes inhibiting the experimentation of new ideas, the involvement in curriculum innovation projects and the establishment of personal relationships and sharing of experiences. This process makes a real the duality that often exists between the model of professional culture devised by the teacher and the reality that the teacher faces in daily practice (Ponte & Oliveira, 2002). In order to schools experience a significant development, the most important element to address is the teachers' professional involvement and collective work (Nunes & Ponte, 2010). These critical dimensions may help understand how teachers develop their work, includes how they manage the mathematics curriculum.

METHODOLOGY

This study follows a qualitative approach (Erickson, 1986), with a case study design (Stake, 1994; Yin, 1989). The study involves a group of 14 mathematics teachers of a secondary school with 12-18 years old students. The mathematics teachers have an extensive experience of working collaboratively and, in recent years, they developed

various projects at the school. Most of these projects emerged from the need that they felt to improve their practice and to help students to overcome their difficulties. During the school year 2007/08 the teachers of the mathematics department developed the project “Investigations, proof and problem solving tasks in textbooks and in curriculum management”, involving all classes from grades 7 to 12. This project aims to diversify tasks in the mathematics classroom, in order to encourage the students’ in learning mathematics.

This study considers the group of teachers involved in the project and within that group, focuses particularly on three teachers: Ana, the coordinator of the mathematics department, Matilde, a teacher that arrived recently to school and to the department, and Simon a teacher at the school for 28 years. These cases provide several contrasts that enable understanding the relationships between professional knowledge and curriculum management, as well as regarding collaboration and leadership at the school. In this article, we present a small glimpse of the cases of the three teachers.

Collection of data was done during the school year 2007/08 and includes participant observation (Jorgensen, 1989) of the teachers’ working sessions and of two classes, with record of field notes in a research journal, two interviews with each of the three teachers selected for case studies, and collection of documents (Adler & Adler, 1994; Patton, 2002; Yin, 1989). According to the research plan, data analysis began simultaneously with data collection, to identify the need for further collection of data. The second level of data analysis involves the development of categories focused on professional knowledge, curriculum management, collaboration, and leadership that may help in noticing interesting relations. The third level of analysis seeks to explain the meaning of the data, in order to provide contributions to the understanding of the phenomenon under study (Merriam, 1988).

RESULTS

The group working sessions

This group of teachers holds a session every week, for three hours, working collaboratively in curriculum management. Usually, they start altogether collectively but to work in a specific school level they splits in subgroups. Collectively,

The group shares their practices experiences, plan and prepares tasks and assessment instruments, defines classroom strategies and questions to help students in their difficulties, and later the group reflects on students work, in particularly in the tasks related to the group project that are realised in all grades [Research journal on Group Working Sessions-GWS].

In subgroups of two or three teachers,

They plan teaching units, using first the textbook and other curriculum materials, particularly the official curriculum documents; construct assessment

Working Group 17

tests; and discuss specific issues related to the school level involved [Research journal on GWS].

Also the purpose of these subgroups is,

To plan lessons and regulate practice, defining common tasks to be developed and classroom strategies with different classes, sharing experiences and difficulties teachers with colleagues [Research journal on 10th grade subgroup work].

During the working sessions all teachers are invited to participate and have the opportunity to share and express their point of view. All work is developed in a supportive environment and there are friendly interpersonal relationships among all teachers. This dynamic is focused on a particular concern of this group of teachers – developing and practicing an effective mathematics teaching that may guarantee students' success in their learning: “We want them prepared for the future, especially those who want to access to higher education” [Ana Interview-INT, 25/10/2007].

Some of these teachers, being aware of the educational changes, strive to be always updating their professional knowledge [Researchers' journal, GWS]. This may explain their frequent participation in professional meetings outside the school. Also, this may clarify why these teachers are invited to share what they learn from those meetings by providing of a workshop based on what they learned for the other colleagues of the group. As an example, a teacher has attended an in-service training course in calculators and he organized a workshop for his colleagues on this topic [Research journal, GWS 2].

There are different statuses and roles assigned to each group member. Since the last ten years, one norm of this group is that there is always a teacher responsible to lead the group of teachers that are teaching classes from grades 7 to 9. One of the teachers, Simon, explains:

This leader is chosen from the group of teachers that belong to this school for more than 15 years. He/she has to teach grades 7 to 9 and has to be replaced every three years. When none of us is there [leading] things go wrong! There are problems with parents, some of the curriculum topics are not achieved... [Simon INT, 16/10/2007].

Simon's words suggest that the group seeks to take into account the expectations of students and parents. This may explain why the teachers manage the curriculum and build the assessment tools in group or subgroups. Doing so, they strive to harmonize them with the views of all teachers and to support the decisions of each teacher about their own students' learning and assessment.

Also, this seems to be a way the group found to support the younger teachers, who are usually responsible for teaching middle school grades, as this allows a stronger regulation of the teaching-learning process to assure the quality of students learning

in these grades. In contrast, older teachers are responsible for teaching grades 10 to 12, but every three years they have to teach one or two classes from grades 7 to 9, keeping in close contact with all the issues of all school grade curriculum goals and eventual changes.

The professional experience of the three teachers

Matilde has 11 years of experience teaching mathematics classes from grades 7 to 12. She is in this school since 2006. She has already worked in seven different schools performing roles as a mathematics teacher and as a class director. She has a degree in mathematics teaching. She says that, outside the school, all her time is dedicated to her family.

Ana is 39 years old. She has been a teacher for 12 years and she has a master's degree in mathematics. Her capacities and work are recognised by all mathematics teachers by the school community. The results get by her students in the national exam are well known and the number of her students who go into university contribute to this social recognition. At the beginning of the school year of 2007/08, she was elected, by her colleagues, the head of the mathematics department. Her colleagues mention that "Ana's first reaction was panic because she felt that she was not prepared to face the challenges and she did not know all the tasks involved in this job" [Research journal, 11/09/2007].

Simon is a teacher with 28 years of experience teaching mathematics classes from grades 7 to 12. Throughout his career he played several roles in his school such as deputy head teacher, in-service teacher education coordinator, department coordinator, and project coordinator (of mathematics projects and of other school projects). He is an in-service teacher educator in professional development courses and belongs to several working groups in and outside his school. Because of his professional experience and the initiatives he promotes in the group, Simon is recognized by his colleagues as the unquestionable leader of the group. This academic year he has only grade 12 classes.

Matilde, Ana and Simon are in different stages of their careers and have a relationship with the school and the mathematics group marked by their personal and professional trajectories.

Managing the curriculum: Individual dimension

Concerning the individual work of the teachers in managing the curriculum, Matilde shows little identification with the perspective of the group. The voices some concern in the decisions that she makes in the classroom when using more open tasks; Ana shows confidence in taking decisions in relation to the work to develop with students; and Simon shows how to articulate the work with the textbook with working on open tasks, diversifying the tasks proposed to students.

Working Group 17

Matilde teaches grades 7 and 8. The way she works with open tasks in the classroom, contradicts the view of the group in relation to mathematics' teaching and learning:

Matilde – I think that I often influence the students' reasoning while they are solving a problem. I say what they should do! (...) I do this because I have to go on!

Simon – That exactly what you should never do!

Sebastian – We have to control our selves! We have to go step by step, questioning the students but wait for their answer. They have to think by themselves. Today you spend some time more, but you will gain tomorrow because your student have learned and achieved the goal. We can help you! [GWS, 20/11/2007].

In this discussion it is possible to understand that Matildes' decision contradicts the perspectives of the group about the way of manage student work with open tasks. It is also perceptive that Sebastian, the leader of the subgroup grade 7 and 8, tries to give Matilde some clues to help her future working, sustained in his large teaching experience (26 years).

Ana teaches grade 12. She follows the planning done in the subgroup and in the classroom she uses the textbook as a central resource. She offers to the students the tasks that are prepared in the context of the grade 12 Subgroup:

I do something that I already did a few years ago, it is not new. I issue students a challenge and I want them to write anything about these issues. They write funny mathematics' reports. [Ana INT, 26/09/2007]

Simon teaches grade 12. He follows the planning done in the subgroup and, in the classroom he also uses the textbook as a central resource. He also offers his students the same tasks as Ana but he proposes solving them in two phases. He argues that classroom work must be focused on the student. The first approach is always the textbook. [GWS, 11/09/2007].

To learn, students have to like what they are doing, and so what I like most is that they solve their own problems. First, I would like them to be able to read a problem and not turn their arms down, not get discouraged, therefore grasping the problem. (...) Achieving that with my classes is to get weapons to grasp and solve the problems which arise. [Simon INT, 16/10/2007]

In summary, the evidence shows us that Matilde has some difficulties to manage students' difficulties while they solve more open tasks and decides to provide them the answers. Simon tries to help his students to be autonomous assuming that students have to reflect on their own work and mistakes to learn.

The three teachers and the mathematics subject group

Working Group 17

In this section we present some of the dimensions of the relationship between the teachers and the group. Matilde does not identify herself with the culture of the group, Ana shows some embarrassment related to her role as head teacher, and Simon appreciates the dynamics and the work that the group develops. As the natural leader of the group, he nurtures his relationship with his colleagues using curriculum management as a focal activity.

Matilde recognizes that she is an outsider regarding the group:

I feel [quite outdated] by people who are here in school for longer than me. (...) I never felt this, but [now] I feel, because I think they [the other teachers] search for professional development training and I do not. [Matilde INT, 15/01/2008]

But at the end of the study, Matilde recognises that she has learned a lot with the teachers of this group:

In this group I felt that we should invest: I saw happy teachers even when difficulties emerge. We felt supported by my colleagues and still have a lot to learn to empower my practice [Matilde Final Reflection - FR, 14/07/2008].

As a mathematics teacher, Ana needs to share her work with her colleagues. As subject leader, she considers this to be a “special” group, where all the work is planned in collaboration and where there is a strong reflexive attitude, all members sharing with each other their own practices and experiences:

This is a special group. We work together for a long time. I hope it will stay like this! This one is the first [school] where the teachers of the mathematics department work in collaboration sharing all the tasks. [Ana INT, 25/10/2007]

I've been a coordinator, in a school much smaller than this one at the beginning of my career. (...) Working with colleagues is sometimes difficult. I have a bit of fear in this task, but I try to be ready. [Ana INT, 08/05/2008]

Ana refers to Simon as the catalyst element of the working processes developed inside the mathematics' subject group, and, in the different projects developed by the group. She refers to him,

He has his own beliefs about how professional and school culture should be – with strong collaborative work and a continuous development and learning attitude – and the entire group follows his vision [Research journal].

Furthermore, and besides the fact of being the subject leader, Ana decided to share the coordination of the school project. She looks at collaboration as a natural working situation of the members of the subject group and as a tool for help, support, and sharing:

Working Group 17

I am always telling what happens in my classes and I like to know my colleagues' experiences, so I can have different opinions on my decisions and classroom strategies [Ana INT, 08/05/2008].

Decisions about assessment provide an interesting episode concerning the relationship of Simon and the group. In fact, the other grade 12 teachers felt that the students should do assessment tasks just in one phase. That is what Ana and Diogo indicate:

Ana – I think that if the task is to assess the students' learning then it has to be done individually. (...) I do not agree to give a second chance, because there are students with private tutoring and already know the task and many of them can provide ready-made answers.

Simon – I think that they perform much better in a second stage. And I do not agree with you [Ana] that the reason is that they have external help and they already know the task.

Diogo – I agree with Ana. In addition, if it counts for assessment, we have to do all in the same way, so that some [students] benefit and others do not. [GWS, 20/11/2007]

However, Simon decided to use a different strategy and gave a second chance to his students to improve their first response to the task, once corrected and commented. This decision was discussed in the following working session, as Simon announced his decision and suggested the group to analyse and reflect on the performance of his students in both phases. There were some negative reactions, especially from Ana and Diogo who have disagreed with Simons' decision [GWS, 4/12/2007]. The issue was taken up later at meetings in which the group built tasks and discussed how to implement them in the classroom [GWS, 15/01/2008; 19/02/2008; 8/04/2008; 6/05/2008]. As a result, some other members of the group began to use Simons' strategy. In particular, at the end of the study Diogo admitted that this strategy can help students improve their learning, as he has verified with his own classes [GWS and FR, 14/07/2008].

Simon says that the discussions that the group has done in the project working sessions have been very "interesting" for him. In particular, he stresses the construction of open tasks and the definition of criteria to assess and reflect on the results of students:

The construction of tasks of proofs, problems and explorations and investigations and their implementation in the classroom, the discussions we had in the group working sessions, has always been very enriching, and the exchange of ideas and clarification of points were a highlight of this project. (...) Discussions on the grading of the students' work and their achievements to give them feedback were undoubtedly very important aspects for my learning.

Working Group 17

The contributions of all colleagues made me to reflect on my practice in these aspects, questioning what we did and discovering ideas and suggestions perfectly workable in practice in the future. [Simon FR, 14/07/2008]

From Simons' words it is evident the importance of teachers' reflect on their own practice and have opportunities to share experiences and doubts about their practice. These are key elements for teachers' professional development and also for the sustainability of a collaborative work culture in school context.

CONCLUSION

Ana, Matilde and Simon are teachers in different phases of their careers, from the same mathematics department that work collaboratively. The results of this study show that the curriculum management made in the context of a collaborative group and the various initiatives of the group in developing innovative practices that involve the development of exploratory tasks are significant changes in educational practice and enable the sustainability of a culture of collaboration (Nunes & Ponte, 2010). There are situations that generate conflicts in the group, especially when most participants support some decision and some individual practices diverge from that, as illustrated by the case of Matilde and Simon.

But this dynamic and working context seem to motivate the involvement of the teachers in teaching and learning. In particular, such dynamic appears to support the professional development the teachers and their capacity to accept new challenges. For example, Ana feels that she still has much to learn. But the context, in which she develops her profession, in particular the subject group she leads, represents an advantage for her. As one of the youngest members of the group, when she was elected subject leader, she chose to have a quiet and learning attitude. Every time she needs help she asks her colleagues and she can count on them for collaboration and experience, mostly from Simon.

One important conclusion that we draw from this analysis is that Simon, the natural leader of the group, bases most of his relationship with his colleagues in the activity of curriculum management. The professional practice of these teachers, supported by this working environment, shows that current curriculum orientations may be implemented not just at an individual or small group level, but by a whole school mathematics department.

Finally, the group culture and collaborative work seems to help in the gradual socialization process of new elements such as Matilde, while fostering a climate of confidence conducive to sharing experiences and difficulties (as showed in the discussion involving Matilde, Simon and Sebastian in the group working sessions), essential elements for the construction of teachers' professional identity development (Ponte & Chapman, 2008). Also, these group culture and collaborative work in the context of a project that involve all the teachers of the mathematics department of a

school shows some important elements for an effective way of promoting sustainable mathematics teachers' professional development (Zehetmeier & Krainer, 2011).

From this study new issues emerge for future research, namely: How teacher's practices and curriculum management influence students' learning of mathematics? What conditions are necessary in schools, and more widely in the social context, so that this kind of collective curriculum management takes place, very much in line with current curriculum orientations? How can we create an effective network between professional development programmes and school mathematic departments in able to promote sustainable collaborative culture and professional development?

PROSPECTIVE MATHEMATICS TEACHERS' NOTICING OF CLASSROOM PRACTICE THROUGH CRITICAL EVENTS

Despina Potari*, Giorgos Psycharis*, Eirini Kouletsi* and Maria Diamantis**

*University of Athens, Greece, ** Southern Connecticut State University, USA

This paper reports on a study conducted to explore prospective mathematics teachers' reflections on teaching practice at the secondary level through noticing key aspects of classroom interactions. The study used critical incidents taken from everyday classroom situations as a means to make the act of noticing more concrete. The participating prospective teachers were engaged in a number of different activities including observing, designing and teaching. The results indicate a progression of prospective teachers' noticing of classroom practice and development of teaching awareness marked by shifts in analysing and interpreting classroom events.

Key words: reflection, noticing, critical incidents, teaching awareness

INTRODUCTION

In this paper we aim to tackle the theory-practice problem in mathematics teacher education (cf. Mason, 2002, Jaworski, 2006) by exploring prospective teachers' reflection on teaching practice through noticing key aspects of everyday classroom situations. Our approach involves the use of critical incidents (Goodell, 2006) as the means by which noticing -and thus reflection on teaching practice- is facilitated to emerge. Our theoretical position towards reflection is based on Jaworski's (1998) interpretation of Dewey's definition of reflective thinking, i.e. "firstly, a recognition of questions to address, identifying some perplexity, making some aspects of teaching problematic; and, secondly, through some processes of enquiry, to seek solutions, or resolutions to, or new ways of understanding, the problems identified." (ibid., p. 7). In resonance with a number of current research approaches (c.f., Scherer & Steinbring, 2006, Jansen & Spitzer, 2009) we see noticing as an activity involving description, analysis and interpretation of teaching practice, thus creating a framework for reflection. A number of research approaches have indicated a number of difficulties that prospective teachers face while engaged in reflection on classroom interactions (eg. collecting evidence about students' learning as well as developing interpretative analysis of classroom instruction (Morris, 2006)). A recent focus on the prospective teachers' reflections on critical incidents taken from classroom situations (Goodell, 2006) supports the idea that critical incidents can be a powerful tool towards promoting prospective teachers' reflective practices to develop. In our study, we used critical incidents as means to engage prospective teachers in reflecting on teaching practice so that they could learn to attend to their students' thinking, interpret classroom phenomena and start to develop ideas of alternative teaching actions. This paper demonstrates how this approach can facilitate

the progression of prospective teachers' noticing of classroom practice and development of teaching awareness marked by shifts in interpreting classroom events.

THEORETICAL FRAMEWORK

Two main bodies of research informed our study: the first, concerns reflective thinking through *noticing* of classroom interactions in teacher education, and the second, *critical incidents* of classroom practice as a concrete basis for reflection and interpretation. In his elaboration of the idea of noticing in teachers' professional development, Mason (2002) pointed out the importance of teachers' attention on the students' learning processes as well as to the teachers' self-observation practices in the classroom. In this view, *noticing* has been related to systematic reflection on acts or issues, leading to shifts in the structure of attention and, through this, to different levels of awareness both in mathematics and in mathematics teaching. In the research reported by Scherer and Steinbring (2006), noticing of students' learning processes was at the core of the joint reflection of teachers and researchers. The analysis suggests that a critical step towards a positive change of teaching activity consists in moving the dominating focus of mathematical interaction in teaching from the teacher to the learning students.

In the domain of preservice teacher education existing research studies suggest that it may be possible to help prospective teachers engage in reflective thinking through noticing so as to enhance their ability to focus on key aspects of teaching practice. Morris (2006) reported that under the condition to form hypothesis about the sources of students' difficulties in a videotaped mathematics lesson, prospective teachers appeared to be able to develop claims and conjectures about the connection between specific instructional activities and students' mathematical understanding. Spitzer et al. (2011) reported that a rather short classroom intervention (2 lessons) involving joint reflection and discussion on written classroom transcripts provided by the researchers, produced substantial improvement in prospective teachers' ability to identify and analyze evidence of student understanding. Similar findings were also reported by research studies in which prospective teachers were engaged in reflecting on their own teaching. The results revealed that reflective activities served as transition mechanisms that promoted prospective teachers' awareness of the need to monitor student understanding during the lesson (Artzt, 1999) and develop hypothesis when interpreting how their teaching affects their students' learning (Jansen & Spitzer, 2009).

Along with a focus on prospective teachers' reflective practices, researchers have been concerned about the introduction of sufficient structures for making the act of inquiry into teaching practice more concrete. A particular example of a structured framework for reflection on classroom episodes are *critical incidents*, i.e. everyday classroom events which are significant for the teachers, make them question their

practice and seem to provide an entry for their better understanding of teaching-learning situations (Hole & McEntee, 1999). Recent research focus on the use of critical incidents in pre-service teacher education (Goodell, 2006) supports the idea that critical incidents can be considered as a means to facilitate prospective teachers' productive engagement in noticing teaching events and critically reflecting on them. In resonance with this approach, in this study we were interested to stimulate prospective teachers' noticing through critical events and see if and how the developing process of selecting and reflecting on critical incidents in different contexts (i.e. observing, designing and teaching) might promote changes in the prospective teachers' stance towards analysing and interpreting classroom events.

METHODOLOGY

Context of the study and participants

The research took place in the context of a 16-week mathematics education undergraduate course (taught in one semester by the first author, mentioned as teacher educator in this paper) at the University of Athens in Greece. The philosophy of the course was to link theory-driven instruction on the teaching and learning of mathematics at the secondary level with realisation of mathematics teaching in real classroom settings. The aim was to engage prospective students in critically consideration of aspects of mathematics teaching as they emerge from the complexity of teaching practice in schools. Every second week (for the entire semester) prospective teachers were asked to participate in a number of field activities such as to observe other teachers' course in cooperating schools, to conduct a didactical intervention in one group of students and to design and implement lessons in the classroom. Each week following the field activities-week included a 3-hour class session taking place at the University. Instructional practice in this session aimed to support prospective teachers' reflective activities on their recent field experience and to link emergent issues with existing mathematics education research. The 22 prospective teachers (9 males, 13 females) who served as participants in this study were divided in pairs and carried out collaboratively the field activities under the supervision of 8 experienced secondary mathematics teachers who served as mentors. Apart from the teacher educator, the research team consisted of two more researchers of mathematics education (the second and fourth author) and an experienced teacher (the third author) who acted as mentor-researcher in the study. Enrolling in the course, prospective teachers had a background of undertaking at least four other mathematics education courses as a part of their teacher education program at the University. Most of them also parallel to their university studies were helping school students on a private base with their mathematical homework.

Research design and data sources

Reflection on teaching practice through noticing of classroom events in the framework of critical incidents was the foundation of our research design. Critical

incidents were considered as a methodological tool for triggering prospective teachers' reflection on teaching practice. In the first class meeting, prospective teachers were introduced to the idea of critical incidents mostly through examples and also by reference to teacher education research. In the next class meeting and in the first half of the third, the groups of prospective teachers completed tasks that required them to identify why some classroom incidents "provided" by the teacher educator (e.g. transcripts of lessons or videotaped teaching episodes) could be considered as critical, discuss the features of those incidents, and finally analyze and interpret them. These incidents were considered as critical by the researchers as they could indicate an important teaching and learning moment (e.g. an unexpected student's response, an "effective" classroom interaction etc.) In the second half of the third class meeting and in all the subsequent ones, the groups of prospective teachers were asked to select and present in the next class session a critical incident that represents an unexpected situation that they had experienced during their fieldwork activities (i.e. observation of lessons, didactical interventions, design and implementation of lesson plans). It was expected that these presentations and the subsequent class discussions would provide a fruitful terrain for studying the development and evolution of prospective teachers' noticing through critical incidents in different contexts. All class sessions (8 in total) were video recorded. The data for this study was conducted over the entire semester, and consisted of: (a) prospective teachers' personal portfolios including their written accounts of critical incidents and material related to the design, implementation and presentation of their field activities in the classroom (e.g. worksheets, lesson plans, presentation files); (b) video recordings of all class sessions at the University; (c) audio-recordings of interviews with some of the prospective teachers regarding their field activities, and (d) researchers' field notes. For the analysis verbatim transcriptions of all recordings were made. The analysis presented in this paper is based only on the video transcripts of the class sessions.

Data analysis

In this study we worked broadly through a grounded theory approach (Strauss & Corbin, 1998) as our goal was rather exploratory. The unit of analysis was the episode, defined as an extract of interactions performed in a continuous period of time around a particular issue. The episodes which are the main means of presenting and discussing the data were selected (a) to involve prospective teachers' interactions on student learning according to an unexpected teaching event and (b) to represent indications of emerging shifts in prospective teachers' noticing of classroom interactions involved in the episode.

RESULTS

The prospective teachers identified a variety of critical incidents throughout the activities of the course. The issues that were addressed by them concerned mainly

students' difficulties; classroom management; curriculum and textbooks, overall educational and social context. In this paper, we report findings indicating the shifts in analysis and interpretations of students' learning that occurred during the university class meetings.

Noticing students' learning in teaching examples provided by the researchers

In the initial class sessions the prospective teachers' comments and interpretations of critical incidents were mostly related to students' misconceptions and to ineffective teacher's strategies. They appeared to attribute these problems either exclusively to students' responsibility or to wider social factors that framed teaching and learning. Moreover, these factors seemed to have been considered in a fragmented way despite of the teacher educator's attempts to encourage prospective teachers to see teaching and learning at its complexity. We provide below some evidence of some of the issues described above by referring to an extract from the second classroom meeting. The teacher educator presented a task related to students' proofs for the statement: "The sum of two consecutive odd numbers is divisible by four". (taken from Boero & Guala, 2008). One 14- year- old student provided the following response:

"By making some trials like for instance, $3+5$, $15+17$, $31+ 33$ I realise that I always get sums made by the first odd number and by the same odd number increased by two, thus I get the double of an odd number plus two. This result is divisible by four because the sum of two equal odd numbers would be (alone) an even number divisible only by two, but if I add two I get the consecutive even number, which is divisible by four because even numbers follow each other with the rule that if one is divisible only by two, the following one is divisible by four (like: 2, 4; 6, 8; 22, 24; etc) because the multiples of four are four units far from each other" (ibid, p.238).

Initially, prospective teachers considered student's reasoning empirical:

"The student makes an attempt to generalise but constructs some rules that hold for small numbers but then he concludes arbitrary that this is true for all." (Lefteris, 2nd class meeting)

Later on in their attempts to develop a better understanding of the student's thinking they started to consider much deeper issues such as the symbols' use in a mathematical proof, what constitutes a mathematical proof, and the distance between curriculum demands and students' mathematical understanding. The following example indicates prospective teachers' initially rather narrow perspective about the nature of mathematical proof:

"It is like another example we had seen in the previous lesson where the student could not use the symbols. Although this student seems to understand what the answer is and how more or less to get it, this is not a mathematical proof... it does not have operations and relations." (Ioanna, 2nd class meeting)

Although in this part of the discussion the teacher educator's intervention was minimal, the prospective teachers started to express different opinions from their

initial ones indicating their appreciation of student's reasoning and their efforts to provide an adequate justification (2nd meeting):

Spirithoula: We need to remember that this student is only in the 9th grade and he does not have yet the experience to write the even number in the form of $2k$ and the odd in the form of $2k+1$, so that to construct an accurate mathematical proof. I think that for a student of that age the whole thinking was very good.

Adriana: I would also agree, let's not forget that it took ages to develop the formalism ...

Oliver: Diofantus also did not use algebraic symbols...

Adriana: How can a student of that age construct such a proof?

Although the class seemed to come to a consensus, one prospective teacher reminded the audience that the mathematics curriculum suggested a formal approach to problems of that kind. This creates some tensions again:

"I completely disagree. It is very good that a student does something different from what he has been taught. Following a problem solving method mechanically is not good for his future mathematical development. It is more important to encourage him to make explorations." (Oliver, 2nd meeting)

Through the above comment, Oliver brought to the foreground the critical role of exploration in students' mathematical development in the long term.

Prospective teachers' attention to students' thinking in this context seemed to have made a number of shifts in the ways they analysed students' understanding. In particular, they started to recognise students' reasoning beyond the formality of the symbols and to view it as an integral part of students' mathematical future development.

Noticing students' learning in classroom observations

In the third, fourth and fifth meeting the prospective teachers commented on critical incidents which they had noticed in the classroom observations. A variety of issues emerged in the discussions such as conceptual and procedural learning, students' difficulties to make connections between different representations, the relation between the nature of teacher's questions and students' answers, curriculum and wider social issues and their impact on learning and teaching, the role of students' prior knowledge in learning and the effectiveness of specific teaching examples and tasks (e.g. the use of paradoxes, the connection among different content areas). In the discussions a central issue was the construction of mathematical meaning. Initially the focus was on students' mistakes that were due to lack of understanding. However, during the discussion the prospective teachers started to link this phenomenon to teachers' choices (examples, tasks, questions) and to research findings. We will try to indicate these shifts by using examples from our data.

A number of critical incidents that the prospective teachers presented were related to the fact that the students often apply a method to solve a mathematical task without understanding the underlying properties. Some examples were the transformation of a fraction to an equivalent one, the solution of a first degree equation, arithmetic or algebraic computations. For example, one critical incident reported by a prospective teacher was about a classroom interaction between two students concerning the transformation of the fraction $\frac{7}{5}$ to its equivalent with 30 as denominator. The first student completed the transformation by multiplying both terms of the fraction by 6. Then the second student wondered why he did not use a faster common technique based on the use of the appropriate factor that is “kept” in a place over the nominator. The prospective teacher interpreted the phenomenon by considering this technique as a “picture” in the student’s mind which might provide a barrier to conceptual understanding:

“The second student seems to have clear in his mind a picture without knowing why this method works, the essence of the method.” (Kostas, 3rd class meeting)

In a subsequent stage of the discussion, the teacher educator attempted to move the class attention on how to deal effectively with the situation in order to make the meaning of this specific technique transparent to the student. Kostas stated that he would ask him to reflect on his actions “What are you actually doing?” “In what way your approach is different from your peer’s?”. Another prospective teacher recalled from his fieldwork observation how another teacher managed a similar situation. Instead of stressing the rule “change side, change sign”, commonly used, in solving algebraic equations, he emphasized the properties involved in the solution process. The prospective teacher found this approach original as it was beyond his own experiences:

“There was not the method of moving it to the other side and change its sign but the teacher was emphasizing that we do the inverse operations. I find this approach very different, more advanced.” (Lefteris, 3rd class meeting)

In a subsequent class meeting, the prospective teachers themselves started to build connections between learning, teaching and research. They had been asked to find and read a research paper that would help them to develop adequate explanations of the fact that students often do things at an operational level without deeper understanding of the underlying properties. In terms of students’ learning they managed to give deeper interpretations by realising the meaning of the variable, the double meaning of the equal sign and the transition that the students needed to make from arithmetic to algebra. In terms of teaching they identified tasks such as a tree diagram that could help students to understand the priority of operations and use it for solving equations or they talked about the emphasis needed to be given on algebraic structures in arithmetic. Some typical comments were:

“The students need to understand that a variable is an element of a set, something like this.” (Ioanna, 5th class meeting)

“We read about a tree diagram that helps students to read and see how the algebraic relation is structured and it also uses a computer program to represent it.” (Lefteris, 5th class meeting)

By summarising, in this context the prospective teachers extended their own examples about mathematics teaching and learning and started to reconsider and evaluate the effectiveness of some of the teaching approaches they experienced as school students. We also noticed deeper interpretations of students’ mathematical contributions by relating them to the research findings. Finally, they started to focus on the role of teaching practices to the development of learning and identify fine elements of teaching.

Noticing students’ learning in prospective teachers’ teaching

In the last three class meetings the prospective teachers presented critical incidents from their own teaching. The critical incidents were related to students’ difficulties or unexpected responses, to the appropriateness of the designed tasks, to epistemological aspects and to classroom management. Almost all the prospective teachers participated in the discussion by presenting and justifying their critical incidents as well as by challenging their peers’ interpretations and claims. In this phase, the main part of the class discussions was based on the prospective teachers’ interactions. Some of the main issues that emerged were: a teacher’s difficulty to notice students’ learning; the problem of time; the connection among different representations; the difference between procedural and conceptual understanding; the management of students’ different mathematical backgrounds and interests; the difficulty to design a mathematically challenging task consistent with students’ cognitive and affective needs; and the epistemological characteristics of geometry.

In terms of students’ learning the prospective teachers’ interpretations focused more on the students’ strategies and thinking processes rather than on their difficulties and errors. Moreover, they often seemed to overtly recognise the critical role of tasks in challenging students’ mathematical thinking. We are giving below some examples from prospective teachers’ reflections.

In the 7th class meeting, Katerina talked about what she learned from her 8th grade students while working on a task she had designed for comparing the areas of three irregular polygonal areas:

“We wanted to see how the students were thinking while they were dividing the areas to regular shapes. We let the students to work on their own. I had expected them to develop three or four different strategies but when I analysed them afterwards I discovered that they were twelve!...What I have understood is that when you let the students to work on themselves they have a lot of different ideas. We can also see how they are thinking... All the students in the class had done something.” (Katerina, 7th class meeting)

Katerina recognised that students' thinking can be very powerful through the analysis of their strategies. Moreover, she acknowledged the importance to provide space to all students to think mathematically during the teaching. In the discussion that followed the other prospective teachers also commented on the added pedagogical value of students' multiple solutions of a mathematical task:

"I think that it has to do with the nature of the tasks. A very specific task does not allow for multiple solutions and answers. So, I do not have to ask questions that have as answer "yes" or "no". We need to ask why." (Spirithoula, 7th class meeting)

In the last class meeting Aggeliki and Maria presented a critical incident from their teaching in a 9th grade class. Their teaching goal was for the students to make sense of the algebraic formula $(a+b)^2 = a^2 + 2ab + b^2$ through a geometrical task they had developed. One student who was engaged in calculating areas in the geometrical context he recalled the formula without connecting it to the problem. The two prospective teachers did not expect this response and they interpreted that the student did not make any connection to the problem but he only recalled the relation without understanding:

"I expected to hear that the area of the total land was the sum of the four rooms and he gave me the algebraic formula." (Aggeliki, 8th class meeting)

"I used to do this when I was at school. The teacher was telling me something and when I did not know it I was giving him the formula I knew." (Maria, 8th class meeting)

In their attempt to interpret student's approach the prospective teachers were trying to go more deeply to student's thinking process. For example Lefteris mentioned the fact that the student worked at the operational level and could not see the relation structurally:

"The student says that the solution of this relation is... he does not see the equivalence of the two quantities, he only sees that he will expand the $(a+b)^2$ and he will find the result. He has acted only procedurally." (Lefteris, 8th class meeting)

Overall, by reflecting on their actual teaching the prospective teachers seemed to focus on key aspects of student's learning and to relate it to features of the tasks (e.g. openness, kind of representations).

CONCLUDING REMARKS

Our purpose in this paper was to illustrate a particular approach to encourage and study prospective teachers' reflection on teaching practice by noticing key aspects of classroom interactions through critical incidents. The results indicate a progression of prospective teachers' noticing of classroom practice marked by shifts in the analysis and interpretation of critical incidents. An initial analysis of students' thinking at a surface level has gradually been moving towards considering salient features of the learning process. Towards the last class sessions prospective teachers seemed to be able to make connections between students' learning with particular

aspects of teaching practice. Finally, this process seemed to be carried out through the integration of different sources of knowledge such as prospective teachers' tacit knowledge about teaching from their experiences as students and private tutors and the academic knowledge they were developing at the University course.

CURRICULAR CHANGES IN PREPARATION OF FUTURE TEACHERS – FINANCIAL MATHEMATICS COURSE

Michaela Regecová, Mária Slavíčková

Department of Algebra, Geometry and Didactics of Mathematics
Faculty of Mathematics, Physics and Informatics
Comenius University in Bratislava, Slovakia

The paper deals with problem of introduction of new mathematics content into secondary school curricula and its influence on changes in curricula for future teachers of mathematics. We are focused on development of content knowledge. We choose area of (everyday) financial mathematics because of the new school reform in year 2008 and the basic financial mathematics is obligatory part of the mathematics education at secondary schools in Slovakia. In our research we observed changes in students' content knowledge from financial mathematics after following the course of financial mathematics for future mathematics teachers. The results imply that their knowledge is not sufficient and therefore there is need to give more courses/lecture of financial mathematics in preparation of future teachers focused on basic financial notions and mechanisms.

Key words: financial mathematics, financial literacy, school reform, preparation of future mathematics' teachers

INTRODUCTION

The importance of financial education has increased in recent years, in particular as a result of developments in the financial market and demographic, economic and strategic changes. Currently, consumers have better access to a whole range of credit and saving structures that differ with regard to fees, interest rates, maturity or other parameters.

“Financial education is the process by which financial consumers/investors improve their understanding of financial products and concepts and, through information, instruction and/or objective advice, develop the skills and concepts and, through information, instruction and/or objective advice, develop the skills and confidence to become aware of (financial) risks and opportunities, to make informed choices, to know where to go for help, and to take other effective actions to improve their financial well-being and protection.” *OECD (2003)*

Ministry of Education of Slovak Republic in compliance with OECD Recommendations How to Improve Financial Literacy (OECD, 2003) prepared National standard of financial literacy (Ministerstvo školstva SR & Ministerstvo financií SR, 2008) in October 2008. The main goal was start with financial education at schools according with new State educational programs (SEP) within new school reform.

New school reform started in September 2008 at primary and secondary schools. This reform innovated content of many subjects, financial education was integrated mostly into mathematics education. Implementation of this reform unfortunately did not count with necessary changes on the universities that prepare future mathematics teachers. The effect of this situation is that universities continue with preparation of future teachers that are not appropriately prepared for teaching according the new State educational programs.

Therefore we suggested study material from financial mathematics (FM) for students – future mathematics teachers. These students were just graduated from secondary schools; they followed the old system of education – it means without the FM course and other changes that are part of the new school reform from 2008.

The aim of our research was to find out if the study material prepared for teaching FM improves knowledge of the students in the 1st year of study on university to be teachers of mathematics. To verify suitability and propriety of suggested course of financial mathematics as a part of the subject Didactical seminar 2 from the standpoint of students understanding of basic terms and mechanism of FM we suggested research in this area.

The research question was if the students' knowledge from financial mathematics after attending the FM course is on the level of institutionalization, it means if they are able to apply obtained knowledge from FM.

Following formulated research question we observed students' ability to apply knowledge from FM in solving the real life problems from financial area that could improve students' attitudes towards mathematics education (Vankúš & Kubicová, 2010).

THEORETICAL FRAMEWORK

We can identify at least three general approaches in didactics of mathematics: cognitive, social and epistemological. Epistemological approach of the research is focus on using of the mathematical knowledge and its spread into educational institutions (Kohanová, 2008). Therefore we choose *Theory of didactic situations* (TDS) for the analysis of students' solutions in our research.

Brousseau (1998) defines the *didactic situation* as a situation for which is possible to describe the social intention of acquirement of student's knowledge. This situation is realized in system called the *didactic system* (didactic triangle) that is composed from three subsystems: learner (student), learning (teacher), information (knowledge) and from relations between them. In didactical situation are subjects confronted with prepared milieu. The *didactic milieu* (Brousseau, 1990) is the basic notion of Theory of didactic situation. Following the Piaget's theory the milieu is source of contradictions and non-steady states of learner (subject) by process of adaptation (by Brousseau (1986) it is assimilation and accommodation). All knowledge has its specific environment in which students are confronted with.

The didactic situation can be described as a game between a (person in the role or position of the) teacher and the student-milieu system. Every game has its rules and strategies. The rules and strategies of the game between the teacher and the student-milieu system, which are specific of the knowledge taught, are called the „*didactic contract*“. The rules of the didactic contract are not explicit and they can be slightly different from classroom to classroom, culture to culture, and they can even change in the history of a single classroom with the same teacher and the same students. (Sierpinska, 2003b)

Analysis of our research was carried out following knowledge building by TDS: action, formulation, validation, and institutionalization according Sierpinska (2003a).

The results followed from research focused on level of financial literacy of university students described in Regecová & Slavičková (2010) indicate that students' knowledge from financial mathematics are mostly on the level of action or formulation. In presented research we were interested also in ability of student to estimate the result of problem. As was written in Brisudová & Slavičková (2006) students are not able to make a guess and their calculation always depend on calculator. The ability of guessing is missing on mathematics lessons.

METHODOLOGY

Following the model of design-based research (DBR) (Wood & Berry, 2003) and in accord with our research question we developed a proposal of proper course of financial mathematics (FM) for student of the 1st year on Faculty Mathematics, Physics and Informatics (FMPI) and Faculty of Natural Sciences (FNS) to be a teachers of mathematics. This curricular change should permit to the students' teachers to be obtaining necessary knowledge from the FM both for usage in real life and notably in their future teacher of mathematics career on secondary school.

The main idea of State Educational Program (SEP) (Ministerstvo školstva SR, 2008) is to know use knowledge from financial mathematics in real life and on secondary school mathematics level. Therefore we tried to suggest tasks, problems and examples in accord with SEP. There were no Slovak text-books for secondary schools that can be used on the lessons corresponding with New Curricular Reform (NCR) in that time. When we were preparing the course of FM for future teachers on our university, we use the text-book from Czech Republic (Odvárko, 2005), in which the educational program focused on FM is very close to the program determine by Slovak SEP. The other reason were similar trends in both countries (from historical, linguistic and socio-cultural point of view) and similar school reform in Czech Republic that was realised in 2007 (one year sooner than in Slovakia). From this textbook we pick up tasks that were in accord with NCR and we change these tasks a little bit (change the names of persons and institutions to made it more attractive).

Working Group 17

Because of not enough space in subject Didactical seminar 2 on bachelor degree of the teacher education program on FMPI and NFS (2 lessons) we pick up 42 tasks and divide them into 2 thematically independent parts. The 1st part was focus on bank accounts, fix deposit, bankbook and different type of save up products. The 2nd one was focus on different type of loans, leasing, and credit. (Regecová, 2009)

Integration of the FM course into 2 lessons in winter 2008 allowed us to start with teaching in summer term 2009. Because of many tasks need a bigger calculating, or more difficult formulas, we realize to teach both - with using of ICT and common way (chalk and blackboard). We used MS Excel and free software GeoGebra.

Before we started with the experimental teaching of FM we prepare didactical test. The test had 4 tasks chosen to cover important areas from financial mathematics taught on secondary school level (2 tasks were focused on saving products and 2 on loans). Therefore content and construct validity of this test was high.

We tested sample of 25 students at university level in the 1st year of study to be a teacher of mathematics (2 groups of students). Pre-test was written in the same week in both groups. Students in the groups were taught by different teachers (one group taught Michaela, the second group taught Maria) and they did not know that they will be involved to the experiment. The teaching/learning process started one week after the pre-test. The innovation of teaching was not only in adding a new topic into the existing subject. The approach to the problem was different. We started to use ICT not only as demonstration tool, but students also had computers to made their own simulation, calculation and modeling, students had possibility to use ICT to made up their home works etc. Using of the ICT was common, individual work of the students was necessary, home works could be prepared by using of ICT.

According to teaching/learning process we would like to specify that every student has one task to solve one week before the lesson. Therefore process of action and formulation of hypothesis was realized at home environment of every student. There was possibility to discuss students' hypothesis among schoolmates whole week. Validation of students' hypothesis started during the presentation of their solutions on the lesson. There was discussion among students themselves and among students and teacher. Institutionalization of new knowledge was up to the teacher.

During the teaching we were doing also observation of the behavior of the students, their attitude and opinion on these changes. It of course differs from student to student. Mostly girls were discouraged because of computers.

Posttest was written approximately 2 weeks after the finishing of the topic financial mathematics. We offer analysis of two chosen tasks from the experiment in this paper.

RESEARCH AND RESULTS

Before the testing of the students we write analysis a priori of all 4 tasks. We point out the aim, terminology and possible models of solving the tasks. In general we can write that the aim of the test was:

- find out which model for solving chooses students to solve standard tasks from financial mathematics, it means, if they know terminology and models of financial mathematics,
- if students are able to guess and count the better alternative, if they know mechanism of loan interest or credit and if they know influence of loan interest or credit on profitability of the loan.

Necessary terminology which had to understand for solving the task was bank account, annual interest, interest rate, interest tax, credit, loan, mortgage, principal, repayment plan.

Models used in solving the test differ according to the aim of the tasks. We assumed also incorrect solving strategies/models. We can divide the strategies into two main categories: M1 – financial mathematics approach, M2 – non-financial mathematics approach.

Detailed a priori analysis of students' solutions is described in Regecová & Slavičková (2010). In this article we would like to focus on analysis of student knowledge improvement and errors in their solutions.

The results from the first part of the research imply that students do not have proper knowledge from FM. The comparing their result before the curricular changes and after is described bellow. We compare level of knowledge of each student before and after the course of financial mathematics.

Task 1

We would like to set up new bank account and deposit 100 EUR (3 012,60 SKK) every month starting at the beginning of the year. The deposit will always be made at the beginning of the month. We know that “our bank“ offers a 2.3% fixed interest rate (the interest rate will not change throughout the year). The interest rate is calculated and deposited *only once (every quarter in post-test)* to our account, and always at the end of the calendar year. How many EUR would have in the account by December 31th with a 2.3% interest rate? How many EUR would we save by the end of the year if we would put 100 EUR every month to our piggy bank?

Pre-test:

There were 23 students who used model M2 to solve the task 1; it means the model without the tools of FM in the pre-test. None of these students achieved the correct answer. Most often mistakes were: 12 students did not think of tax 19 % (missing relation with real life), 2 students made error in the order of number magnitude (missing the guess of possible result), incorrect interest rate (1 student), and not

proper tax (1 student). One student solved this task correctly (model M1) and one student did not solve this task.

Post-test:

All 25 students used model M1 in the post-test, it means after the course of FM. All of them tried to apply their knowledge from FM in solving the task. But correct answer gets only 4 students. The most often error was that students did not think of periodicity of the deposit – 8 students did not count with every month deposit 100 EUR. Similar, 4 students did not think on quarter period, but months', 5 students did not use the proper interest rate (they use months', quarters' instead of the years'), 2 students think of quarter period but in next quarter count only with interest, not whole amount of deposit from the 1st quarter, 1 student think in quarters, but do not think that in the second quarter we have also amount from the 1st one, in the 3rd from the 2nd one etc. The positive result is that every student count with 19% tax.

Comparing pre-test and posttest:

From the results of pre-test and post-test in each students (25) we can see, that all of them tried to use these knowledge to solve the task after the attending the financial mathematics course. The one of possible reasons could be didactical contract (Sierpinska, 2003b) the effort of the students to apply obtained knowledge by any way. But the higher level of the task 1 in post-test comparing to pre-test could be the reason that only 4 students get correct answer to the question. In general we can say that students after the financial mathematics course are able to apply the methods and tools of FM but with some problems. Their knowledge of FM was not institutionalized during courses of FM.

We demonstrate progress in using of solving method by one chosen student in the Table 1 even if presented solutions are not correct.

Pre-test

Sum of deposits: $12 \cdot 100 = 1\,200$ EUR

Counting with tax 19 %: Tax $2.3 \cdot 0.19 = 0.44$ %

Interest rate after taxation: $2.3 - 0.44 = 1.86$ %

Value of the interest add to the account: $1\,200 \cdot 0.0186 = 22.356$ EUR

At the end of year: $1200 + 22.356 = 1222.356$ EUR

Piggy bank money: $12 \cdot 100 = 1200$ EUR

Post- test

Sum of deposit and interest (in EUR) in three months separately, so in one quarter:

January: $100 + 100 \cdot \frac{3}{12} \cdot \frac{2,3}{100} \cdot 0.81 = 100.466$, February: $100 + 100 \cdot \frac{2}{12} \cdot \frac{2,3}{100} \cdot 0.81 = 100.311$,

March: $100 + 100 \cdot \frac{1}{12} \cdot \frac{2,3}{100} \cdot 0.81 = 100.155$, ..., July: $100 + 100 \cdot \frac{6}{12} \cdot \frac{2,3}{100} \cdot 0.81 = 100.932$, ...

Total sum: $12 \cdot 100 + 100 \cdot \frac{2,3}{100} \cdot 0.81 \cdot \left(\frac{1}{12} + \frac{2}{12} + \frac{3}{12} + \frac{4}{12} + \dots + \frac{12}{12} \right) = 1212.11$

Piggy bank money: $12 \cdot 100 = 1200$ EUR

Table 1: Example of student solution in pre-test and post-test.

Task 2

A brokerage firm received a loan for 99 000 EUR with a 13% interest rate over 3 years. According to the contract with the bank, they will start the payments one year from the origination of the loan. Payment is yearly and the bank collects interest once a year. How much would the yearly payment be? Round your answer to the nearest cent.

Pre-test:

There were 4 students who tried to solve this task in model M1 but because of the weak knowledge of FM only 1 got a correct answer in the pre-test. 10 students did not start to solve this task, other students tried to save the fairness in payments and divide the amount into 3 equal parts and use interest rate to get an answer, or they start with counting on the interest rate and the result divide by 3, or 12, or 36. The obtained number they declared as an annuity. The counting was mostly illogical what implies that students did not understand the term annuity and there is again didactical contract present – students tried to count “something”, because it was expected.

Post-test:

In the post-test 23 students used M1 model, but 6 of them obtained correct answer. The rest 2 students did not start to solve this task. The most often errors were: using the formula instead of the logical procedure (13 students), but many students did not use this formula in correct way. One student tried to solve the task by both models, but without any success. Two students who used the formula correct were not sure with the answer, for just in case they multiply this result by 3. Three students used months' interest rate period instead years'.

During the schooling we tried to do not use formula, we tried to lead the students to understand the mechanism of different financial products. The fact that students use formula even that we forbid it implies that students were not able to use mechanism and obtained knowledge was formal. Their knowledge of FM was deformed and not institutionalized during courses of FM.

Comparing pre-test and posttest:

Analysis of pre-test and post-test in every students pointing that after the attending FM course most of the students tried to solve the task by mechanism and knowledge of FM. This fact is necessary to highlight mostly in 10 students who in pre-test did not try to solve this task. In total we can say that students had an effort to use FM tools and mechanism in solving this task, but as we say before, only some of them get correct answer.

We demonstrate progress in using of solving method by one chosen student in the Table 2 even if presented solutions are not correct.

Pre-test

Interest paid in total: $99000 \cdot 0.13 = 12870$ EUR

Interest paid in one month: $12870 : 12 = 1072.5$ EUR

Annuity will be 1072.5 EUR.

Post-test

The end of:	Annuity	Interest	Principal	Debt
	–	–	–	99 000
the 1 st year	x	12 870	$x - 12\,870$	$99\,000 - (x - 12\,870)$
the 2 nd year	x	$99\,000 - (x - 12\,870)$	$x - [99\,000 - (x - 12\,870)] = y$	$99\,000 - (x - 12\,870) - y = z$
the 3 rd year	x	z	$x - z$	0

$$99000 - x - 12870 + [99000 - x - 12870] - x - 0.13 \cdot 99000 - x - 12870 = 99000$$

$$x = 62370 \text{ EUR, but if I use formula, then } a = \frac{99000 \cdot 0.13 \cdot 1}{1 - 1 + 0.13 \cdot 1^{-3}} = 41928.70 \text{ EUR.}$$

Table 2: Example of student solution in pre-test and post-test.

CONCLUSION

The results of our research show that knowledge of the students (graduated secondary school students) from FM is not on sufficient level. We did not noticed progress in solving the tasks by students after attending the FM courses in duration 2 hours. Future teachers are only able to apply their knowledge to problem solving in a superficial way relying on recalling formulate or remembering procedures. One of the possible reasons why deformation of educational process happened is the lack of the teaching hours. Therefore the students were not able to shift their knowledge on level of validation and institutionalization and they obtain only formal knowledge. That indicates that it is necessary to pay attention to this topic in more detailed way and in bigger time donation. The results also indicate that information from the media and everyday life are not sufficient. Therefore the students are not prepared for it and need to learn more at secondary and university/higher school level from this very important area of the life. As we can see, the one of the aim of the teaching mathematics (following NCR) “*develop the analytical thinking and ability to solve the task in real life*” was not reached – students are able to memorize, but they do not understand, they cannot make their own construction; they need to be lead by teacher/tutor. The other ability – make a guess is still not on adequate level.

In our study we focused on development of content knowledge but there should be balance between developing future teachers’ content knowledge and their pedagogic knowledge. The question is, what approaches on the part of teacher educators can help future teachers to develop all aspects of their knowledge for teaching

(knowledge of math, ways of teaching math and ways in which students learn math) at the same time?

KNOWING MATHEMATICS AS A TEACHER

C. Miguel Ribeiro; José Carrillo

Research Centre for Spatial and Organizational Dynamics (CIEO), University of Algarve, Portugal; University of Huelva, Spain

Drawing on the conceptualization of Mathematical Knowledge for Teaching (MKT) this paper considers the knowledge underlying the practice of Maria, a primary school teacher, as evidenced in an episode where she attempts to explain the reason for representing the concept of area with superscript: dm^2 . Through analysis of situations identified as revealing critical gaps in her MKT, we discuss the particularities of the mathematical knowledge required to allow the pupils to achieve a full understanding of the content in question.

Keywords: Mathematical Knowledge for Teaching, teachers' practices, primary school.

INTRODUCTION

The way we approach mathematics and its teaching is intrinsically linked to our knowledge of each topic we are to cover. This knowledge necessarily influences the nature of the tasks we set and how we implement them in the classroom, in particular with respect to regulating the mathematical demands involved (Charalambous, 2008). The teacher's knowledge allows a wealth of factors to be taken into account when devising tasks (in terms of both design and delivery) and contributes to the effective construction of mathematical knowledge on the part of the students. It follows, then, that research into the mathematical knowledge involved in the teaching process is of great importance. We follow the line taken by Stylianides and Stylianides (2010) in which mathematics knowledge is considered an applied knowledge, specifically linked to the nature of education and the "problems" associated with the task of teaching.

Only by being in possession of a solid knowledge of mathematics for teaching (and the mathematics underlying this) can it be possible for us, as teachers, to develop a practice that encourages sustained learning by students, enabling them to create networks of concepts and fruitfully navigate between them (e.g. Ribeiro (accepted)). This paper conceptualises mathematical knowledge according to the proposals of the research group led by Ball (e.g. Ball, Thames and Phelps (2008) and Hill, Rowan and Ball (2005)), and follows their concept of Mathematical Knowledge for Teaching (MKT).

In order to be able to seek improvement in practice and likewise in teacher training, it is essential to know the areas of mathematical knowledge in which teachers find themselves most deficient. Fuller knowledge of these areas, and the situations in which they can be brought to light in the classroom, would (one hopes) lead to a re-

structuring of training programs to focus on these areas, and to teachers becoming more active and reflective professionals, better informed of their own MKT.

This paper considers several aspects/sub-domains of MKT brought to the fore in the practice of Maria (a teacher in the ‘1st Cycle’⁸⁷), during an episode concerning an attempted explanation as to why the unit of area one square decimetre is written as 1dm^2 (i.e., the reason for the ‘2’ in superscript). We chiefly discuss the gaps this incident highlights and the potential impact on the pupils’ learning, both immediate and future. This analysis and discussion aims to achieve a broader understanding of the possible factors leading to these failures, so that we can devise strategies for intervening and supplying the missing knowledge.

THEORETICAL FRAMEWORK

The work of Shulman and his associates (e.g. Shulman (1986) and Wilson, Shulman and Richert (1987)) has provided various perspectives and conceptualisations of the professional knowledge of mathematics teachers. Three of these conceptualisations which have proved to be influential are Mathematics for Teaching (MfT) (Simmt & Davis, 2006), the Knowledge Quartet (KQ) (Rowland, Huckstep & Thwaites, 2005) and Mathematical Knowledge for Teaching (MKT) (Ball et al. 2008). These have in common that they start from practice and take as the key focus the mathematical knowledge that teachers need to perform their teaching duties, although each work takes a different approach.

In MfT, Brent Davis and colleagues (e.g. Davis and Renert (2009) and Davis and Simmt (2006)) focus on the teacher from a theoretical perspective, and bring a systemic interpretation to the complexity of practice, with a view to understanding how teachers learn. The KQ, developed by Tim Rowland and associates, constitutes a theoretical framework grounded in practice and developed inductively (e.g. Rowland, Huckstep & Thwaites, 2005; Rowland, Thwaites & Huckstep, 2003). Their work focuses on “what the teacher actually knows and what he believes and how opportunities to enhance knowledge can be identified” (Rowland et al., 2005, p. 257). The model jointly considers teachers’ knowledge and beliefs about the teaching process. As the name implies, the KQ is composed of four distinct dimensions: *foundation*, *transformation*, *connection* and *contingency*. The group led by Deborah Ball regards the professional knowledge that teachers should possess as the knowledge of mathematics required to develop the various tasks involved in the act of teaching students (tasks of teaching), which it denominates MKT. Once again theory is very much rooted in practice (Ball & Bass, 2003), with their

⁸⁷ Education in Portugal is divided into four cycles: the 1st Cycle covers the first four years at school (pupils aged between 6 and 9), with the class teacher covering all the curricular areas; the 2nd Cycle stretches over just two years (5th and 6th years of primary) with pupils aged from 10 to 11; the 3rd and 4th Cycles, at Secondary level, each cover three years and complete the 12 years of compulsory education.

multidimensional model of the mathematical knowledge involved in the task of teaching emerging from the analysis performed and relationships obtained.

For the analysis of practice presented here, and consideration of the mathematical knowledge involved (applied mathematics), we chose to employ the conceptualization of MKT, with its various sub-domains. The choice of this conceptualization over the others mentioned above (MfT or KQ), or indeed any other, was due to the fact that our aim was to identify, from observed practice, what knowledge the teachers were deploying at each specific moment, and hence the system for making this identification played a key role⁸⁸. In addition, this conceptualisation attributed a very specific orientation to the teacher's mathematical knowledge, placing emphasis on the mathematical reasoning they are immersed in during the course of their work (understood as more than correcting mistakes and evaluating students' answers). While the KQ focuses, originally, on pre-service teachers' knowledge in action, and MfT deals with the mathematical domain mainly, the MKT embraces the focus of knowledge in action from the perspective of the mathematical knowledge teachers' show in relation to teaching.

Ball and her associates introduced the notion of MKT, a specific type of mathematical knowledge in relation to teaching which is not necessarily picked up or increased through the attendance on mathematics courses of a purely scientific bent. This mathematical knowledge must be related to the kind of mathematics they are going to teach, and concerns the ability to make the content comprehensible to their students, being aware of the students' mathematical background, and knowing how to relate previous knowledge to the learning opportunities to come (Hill et al., 2005). In their words MKT can be defined as

the mathematical knowledge used to carry out the work of teaching mathematics. Examples of this "work of teaching" include explaining terms and concepts to students, interpreting students' statements and solutions, judging and correcting textbooks treatments of particular topics, using representations accurately in the classroom, and providing students with examples of mathematical concepts, algorithms and proofs. (p. 373)

In the multidimensional model which has been developed by the group, Content Knowledge and Pedagogical Content Knowledge (following Shulman) are each divided into three sub-domains. They consider Content Knowledge to be formed by Common Content Knowledge (CCK), i.e., typical 'schoolboy' mathematics,

⁸⁸ This process of identification should not be understood as referring to a limited number of dimensions, but should be understood in a broader perspective that takes into account future research projects involving teachers and trainee teachers in which one of the points of focus is the mathematical knowledge that they have/ require to teach different contents in order to improve their own performance and the type and focus of the training available to mathematics teachers (current or future).

Specialised Content Knowledge (SCK) and Horizon Content Knowledge (HCK). Pedagogical Content Knowledge they likewise divide into three types, each a variant of Knowledge of Content and: Teaching (KCT), Student (KCS), and the Curriculum (KCC). Teachers should have a specific professional knowledge, so that in addition to knowing ‘how to do’, considered in CCK, they should also have a knowledge of ‘how to teach to do’ (how to teach to understand), which corresponds to SCK. SCK is seen as the knowledge required by the teacher who genuinely wishes their students to understand what they do and not merely run blindly through a set of given procedures. This component is not limited to knowledge regarding procedures, but has a broader meaning which includes the necessary concepts. The teachers should also be familiar with the way that each the various mathematical topics relates to the others and the way in which the learning of a particular topic develops as one moves up the school (HCK). In relation to the situation presented below (cf. the section ‘Applying the analysis to practice’), knowing how to write the area of measurement 1dm^2 is considered CCK, whilst understanding and being able to explain why the unit is written in this particular way corresponds to SCK (ie, the reason for the superscripted ‘2’ in the written representation – what it means and represents within the mathematical domain).

In addition to knowledge of content, teachers should also have a thorough knowledge of the curriculum and pedagogy. Knowledge of Content and Teaching (KCT) corresponds to the type of knowledge which the teacher draws on in order to organise the different ways the students explore mathematical contents, such as determining the sequencing of tasks, choosing examples, and selecting the most appropriate representations for each situation. Regarding Knowledge of Content and Students (KCS), Ball et al. (2008) relates it to the need for the teacher to anticipate what the students are likely to think, their difficulties and motivations as well as listening to and interpreting their comments. The teacher must be aware of the students’ capacity to understand in such a way that it could allow him/her to go further in deepening the students’ knowledge. With respect to Knowledge of Content and Curriculum (KCC), the authors agree entirely with Shulman (1986, p. 10) that teachers should have a complete picture of the diversity of programs for teaching certain subjects and topics at a particular level/year group, and a variety of educational materials they can draw on. They should also be able to recognise the varying circumstances which suggest the adoption of one approach over another. In general terms, their curricular knowledge should be what can be termed both vertical and horizontal in its scope.

DESCRIPTION OF THE STUDY AND CHOICES MADE

This paper is part of a broader study (involving two primary teachers) focusing on teachers’ professional development in which the MKT is one of the dimensions under consideration. To facilitate the identification of this knowledge we chose a case study approach combined with a qualitative methodology. Here, we shall analyse and

discuss various aspects of the MKT that was in evidence on the part of a teacher (Maria) teaching year 4 (9 year-olds). Maria was a teacher of 18 years' experience and had been with her class since their first year. Amongst several volunteers to work on such project⁸⁹, Maria revealed a clear will to improve her practice, not being "afraid" to recognize gaps in her knowledge, intending to learn to be able to fulfil them.

Data collection consisted of audio and video recordings of the teacher in action, supplemented by informational talks before and after each lesson (to gather lesson previews – lesson image – and to clarify certain inferences). All the audio recordings were transcribed and complemented with the information from the video, which allowed us to capture the greater part of the teacher's actions and her interactions with the pupils (Brophy, 2004). The transcripts were then used to divide each lesson into episodes (associated with the immediate goals of the teacher). The identification of each of the sub-domains of MKT was then made for each of these episodes. Such identification allows an in-depth analysis of the teachers practice.

Our primary interest has been in instances where a lack of knowledge on the part of the teacher becomes evident, as these represent an opportunity to learn (Hiebert & Grouws, 2007). We explore possible causes for such occurrences and consider various means of supplying the lacking knowledge (as part of teacher training).

APPLYING THE ANALYSIS TO PRACTICE

Here we present a brief contextualisation, description, and subsequent analysis, of an episode previously considered by Maria as part of her lesson image. Prior to this episode the students had performed various activities for measuring the area of a surface (table top) using triangles, rectangles and squares with a ratio of 2 and 4 between them (there were not enough units available to cover the surface because Maria intended to use the task to remind students of the rectangular model of multiplication). The pupils measured the sides of one of these squares after which the teacher told them that "because it had these special measurements", it was known as a square decimetre.

Illustration 1 – Transcript of an episode were the teacher aims to present how to write $1dm^2$ (T: Teacher; S: student)

Later in the lesson a second student again questioned the teacher about the reason for that "way of writing it", suggesting that it would be better to put a square "up there" (instead of a '2'). Maria answered as before, adding that they were always "written" in this way. This environment informs us about some of the sub-domains of the MKT, as well as some gaps in these components, but also provides access to information regarding beliefs about school mathematics. (Following Climent (2005), Maria reveals beliefs concerning such school mathematics to coincide precisely with what the textbook says; it is precise and polished, and has the objective of equipping pupils with the basic skills for everyday life.)

Concerning subject matter knowledge, Maria demonstrates that she knows how to write a square decimetre ($1dm^2$), an item of knowledge pertaining to CCK. But despite having given thought to the situation previously, she had not anticipated the question raised by the student (line 881) because she was not in possession herself of the knowledge that might have made her ponder the convention – beyond assimilating it as one more "rule". It reveals an understanding of the contents themselves, but without questioning their origin and mathematical explanation.

Maria reveals a lack of SCK in that she was unable to explain why units of area are written with a '2' in superscript, conflating the exponential notation (for powers) with the geometric shape for measuring area (a square of 1dm). She showed that she lacked the knowledge that would have allowed her to give a mathematically valid explanation for the role the symbol takes in this position.⁹⁰ This association of the two notations (with natural base and exponent) might result in students assuming, later in their school life when they cover the topic (on the curriculum for the 2nd cycle (Ponte, Serrazina, Guimarães, Breda, Guimarães Sousa Menezes, Martins & Oliveira, 2007)) that powers correspond to analogous concepts/representations, impeding a full understanding of this subject content.

Such gaps in terms of MKT frequently prevented her, among other things, from providing appropriate and rich mathematical explanations in order to make the

⁹⁰ This lack of knowledge was acknowledged by Maria in the discussions after class, saying that she had *never questioned herself about that, she supposed it was just another math convention.*

contents comprehensible to students. She provided examples which did not allow the mathematical exploration of doubts raised by the students – it revealed not knowing herself the reason for the use of the ‘2’, so that she was unable to distinguish its use for dimensions from that of exponent, which could lead to students then assuming that dm^2 is obtained by performing $dm \times dm$ (as if it were two variables).

These shortcomings led us to reflect on what mathematics underpins a mathematically adequate and comprehensible explanation for students in year 4. The explanation of the role/meaning of the superscript ‘2’ would perhaps be much simpler (from a mathematical perspective) if the question were posed by students in higher year groups to their mathematics teacher. This leads us to agree with Rowland’s (2009) observation that much elementary mathematics teaching is ‘difficult’ compared with teaching in the secondary grades and beyond, because the very concepts being taught lie somewhere beneath our conscious awareness, and our ability to pedagogically analyse in useful ways. It is therefore also difficult to provide a more detailed specification of the distinct aspects of mathematical knowledge that could be included in the specific and necessary knowledge required by the teacher (in terms of knowledge content such as PCK).

SOME FINAL NOTES

The analysis we undertook allowed us to discern some aspects of the teacher's MKT and, from there, look to different approaches and perspectives for facilitating improvement (with respect to this teacher in particular, but also to teachers generally during the course of their training). The identification of sub-domains in the conceptualization of MKT served as a starting point for a fuller discussion of the mathematics involved in this specific situation, and/or what should underlie this for optimal learning – this was one of the reasons why we adopted this conceptualization and not the MfT or the KQ. Hence, our approach to this teacher's knowledge took a general form, without intending to suggest the supremacy of one dimension over another, but rather considering (clearly) all sub-domains interconnected and interdependent.

The MKT revealed by Maria, as with the shortcomings identified, are applicable only to each individual situation and cannot be extrapolated to other contexts (Delaney, Ball, Hill, Schilling & Zopf, 2008). However, this information (and knowledge of gaps) allows us to focus attention on mathematically critical hypothetical situations for teachers (current or future) which could lead to poor (or even inaccurate) learning by the students and hence limit the opportunities for learning provided in the classroom (Hiebert & Grouws, 2007). Even in those situations in which Maria shows a lack of knowledge, the constituents of the dimensions of the MKT are in harmony (in the sense understood by Potari and Jaworski (2002)) even though these cases correspond to instances in which the students' learning may not reflect correct

mathematical constructions/concepts, being based on somewhat incorrect assumptions on the part of the teacher.

The analysis and study of this teacher's MKT (through her practice) aimed chiefly to provide a richer understanding of certain critical features which emerge from practice, as a means of contributing to the improvement of this practice, and not merely to identify potential gaps. So that in future studies the analysis does not remain at the level of identification/attribution (or is applied simply to highlight teachers' lack of "pure" mathematical knowledge, which in this conceptualisation concerns only CCK), it is necessary that the practice and specific situations identified be subsequently discussed with the teachers, so that they can reflect on them and convert them to mathematically correct ones (considering the various dimensions involved).

Initial and in-service training could also benefit from this system of analysis as a bridge between theory and practice, hence promoting a dialogue based on a common language and a shared understanding.

We consider it essential that training should be based on practice and in particular on any gaps in knowledge which come to light in this practice, with the aim of enabling teachers to respond "with understanding" to all situations that come up in their day-to-day work. This point of departure is important, too, as we believe that learning is circular – we teach what we are, what we know, and how we know it. Each of us learns by facing situations designed to stimulate this learning. So despite being constantly faced with different situations demanding our immediate response, it is only through "outside" help that it is possible to focus attention on what we don't know (some gap in our knowledge brought to light) and we are able to learn.

SECONDARY MATHEMATICS TEACHERS' CONTENT KNOWLEDGE: THE CASE OF HEIDI

Tim Rowland, Libby Jared and Anne Thwaites

University of Cambridge, UK

The Knowledge Quartet (KQ) is a theoretical framework for the analysis and development of mathematics teaching. It focuses attention on classroom situations when the teacher's knowledge of mathematics and of mathematics-related professional knowledge comes to the fore. This focus for analysis and reflection is a stimulus to the enhancement of teacher knowledge and the improvement of teaching. The KQ has been developed in empirical research since 2002 in the context of elementary mathematics teaching: the purpose of this paper is to demonstrate the application of the KQ in a secondary school mathematics context.

Keywords: teacher knowledge, secondary, novice teacher, Knowledge Quartet

INTRODUCTION

A programme of research at the University of Cambridge (*SKIMA*: subject knowledge in mathematics) from 2002 to the present has investigated the mathematics content knowledge of novice teachers, and the ways that this knowledge becomes visible in planning for teaching and within classroom instruction itself. Aspects of this research programme have been reported at each CERME conference since 2003 (e.g. Huckstep, Rowland & Thwaites, 2006). A significant outcome has been the identification of a framework for the observation, analysis and development of mathematics teaching, with a focus on the contribution of the teacher's mathematical content knowledge. The framework in question, called the *Knowledge Quartet*, categorises events in mathematics lessons with particular reference to the subject matter being taught, and the mathematics-related knowledge that teachers bring to bear on their work in classrooms, as opposed to more generic features of the lesson. While Shulman's distinction between subject matter knowledge and pedagogical knowledge underpins this 'theory' of mathematics teaching, the Knowledge Quartet (KQ) is more interested in the situations in which such knowledge comes into play than in categorising the different 'kinds' of mathematics teacher knowledge. The origins of the KQ were in observations of elementary mathematics teaching, and grounded theory methodology (Glaser and Strauss, 1967), in the context of one-year graduate elementary teacher preparation.

The Knowledge Quartet

According to the KQ, the knowledge and beliefs evidenced in mathematics teaching are conceived in four categories, or dimensions, named *foundation*, *transformation*, *connection* and *contingency*. The application of subject knowledge in the classroom always rests on *foundation* knowledge. This first category consists of knowledge and

understanding of mathematics per se and of mathematics-specific pedagogy, as well as beliefs concerning the nature of mathematics, the purposes of mathematics education, and the conditions under which students will best learn mathematics. The second category, *transformation*, concerns the presentation of ideas to learners in the form of analogies, illustrations, examples, explanations and demonstrations. The third category, *connection*, includes the sequencing of material for instruction, and an awareness of the relative cognitive demands of different topics and tasks. The final category, *contingency*, is the ability to make cogent, reasoned and well-informed responses to unanticipated and unplanned events. This conceptualisation of each of the four dimensions of the KQ is the synthesis of a set of codes which emerged from grounded analysis of the primary mathematics classroom data. Each dimension is composed of a small number of subcategories that we judged, after extended discussion, to be of the same or a similar nature. Table 1 shows the codes contributing to each of the four dimensions.

Dimension	Contributory codes
<i>Foundation:</i>	awareness of purpose; adheres to textbook; concentration on procedures; identifying errors; overt display of subject knowledge; theoretical underpinning of pedagogy; use of mathematical terminology.
<i>Transformation:</i>	choice and use of examples; choice and use of representation; use of instructional materials; teacher demonstration (to explain a procedure).
<i>Connection:</i>	anticipation of complexity; decisions about sequencing; making connections between procedures; making connections between concepts; recognition of conceptual appropriateness.
<i>Contingency:</i>	deviation from agenda; responding to students' ideas; use of opportunities; teacher insight during instruction.

Table 1: The Knowledge Quartet – dimensions and contributory codes

Further details are given e.g. in, Huckstep, Rowland & Thwaites (2006), and in Rowland, Turner, Thwaites & Huckstep (2009). We emphasise that the conceptualisation of the KQ has been refined, and the constituent codes enhanced, in an iterative response since 2003 to additional classroom data, in the process of application. This paper is best understood in the context of that process of theory evolution.

Rationale

From time to time questions have arisen about the adequacy and relevance of the KQ to analyses of mathematics teaching in secondary schools, and even to subjects other than mathematics. While we could not comment on the second of these questions, we believed that it would be meaningful and productive to test the application of the KQ to mathematics teaching beyond the primary years, and began to do so systematically in 2010. We began unsure about how well the KQ might ‘fit’ secondary teaching –

and the work of trainee secondary mathematics teachers in particular – on account of certain characteristics of both the teachers and the subject matter being taught, when compared with their primary mathematics counterparts. In particular, these secondary trainees are all *specialist* mathematics teachers, with evidence of recent success in their own study of mathematics, and their teaching is supported by mathematics specialists throughout their *practicum* placements. By contrast, generalist primary teachers, who have typically specialised in the arts and humanities in their own education, often lack confidence in their own mathematical ability (e.g. Green & Ollerton, 1999). From the mathematical point of view, the subject matter under consideration in secondary classrooms becomes significantly more abstract and complex than that in the primary school. As Potari and her colleagues indicated at CERME5, “teachers’ knowledge in upper secondary or higher education has a special meaning as the mathematical knowledge becomes more multifaceted and the integration of mathematics and pedagogy is more difficult to be achieved” (Potari et al., 2007, p. 1955). The purpose of this paper is to test, and to illustrate, the application of the KQ as an analytical and developmental tool in the context of novice secondary mathematics teaching. One could expect that the secondary context could necessitate annexing additional codes to those which emerged earlier in the analysis of primary mathematics teaching (Table 1).

METHODS

UK teacher education context

In the UK, the majority of pre-service secondary teacher education takes place under the auspices of university education departments. Trainee mathematics teachers are required to have at least half of their undergraduate study in mathematics, and expected to have achieved at least an “upper second” class bachelor’s degree, before following a one-year, full-time course leading to a Postgraduate Certificate in Education (PGCE). In order to achieve a good theory/practice balance in the PGCE, for the last 20 years the programme has been conceived as a ‘partnership’ between the university and several collaborating schools, and two-thirds of the 36-week course is spent working in two schools under the guidance of mathematics specialist, school-based mentors.

Participants

The project participants were three volunteer trainee teachers from one secondary mathematics PGCE cohort at our university. Their professional placements were in different schools, all within a half-hour commute from the university.

Data Collection

The trainee participant in each school taught two ‘project’ lessons to the same class. These lessons took place in May, towards the end of the trainees’ second school-based placement, which had begun in January of the same year, so that the

participants were familiar with their schools and with the pupils in their classes. One or two members of the research team (the authors) observed and videotaped each lesson. One tripod-mounted camera, operated manually, was placed at the rear of the classroom. Sound recording was via a radio microphone worn by the trainee-teacher. Trainees were asked to provide a copy of their lesson plan, for reference in later analysis. As soon as possible after the lesson, the research team met to undertake preliminary analysis of the videotaped lesson, and to identify some key episodes in it by reference to the KQ framework. These were fragments, typically 5-10 minutes long, in which two or more of the four KQ dimensions were particularly salient, according to our preliminary analysis. Then, again with minimum delay, one team member met with the trainee to view a selection, typically two, of these episodes¹ from the lesson and to discuss them, in the spirit of stimulated-recall (Calderhead, 1981). These interview-discussions addressed some of the issues that had come to light in the earlier KQ-structured preliminary analysis of the lesson. An audio recording was made of this discussion, to be transcribed later. In some cases the observation, preliminary analysis and stimulated-recall interview all took place on the same day. In the case of Heidi, the trainee featured in this paper, the delay between observation and interview was nearer 20 days for both lessons, on account of her prior commitments and those of the researchers.

Data analysis

The data analysis consisted mainly of fine-grained analyses of each of the lessons, both before and after the stimulated-recall interview, against the theoretical framework of the KQ. In this sense, in contrast with the earlier *SKIMA* research, analysis was primarily theory-driven as opposed to data-driven. Initially, we identified in the video-taped lessons aspects of trainees' actions in the classroom that could be construed to be informed by their mathematics content knowledge (including their pedagogical content knowledge). In addition, when possible, our interpretation of the trainees' mathematical and pedagogical purposes and intentions was further assisted by reference to their lesson plans and the post-lesson interviews. These actions were, where possible, coded in accordance with the KQ and its 20 constituent codes, thereby testing the adequacy of the theoretical framework, developed in the context of elementary mathematics teaching, in this secondary school context. Therefore, this research phase entailed 'theoretical sampling' (Glaser and Strauss, 1967), whereby the application of a theory has the potential to expose its shortcomings, laying it open to refinement, modification and possible improvement.

THE CASE OF HEIDI

We come now to our case study. Heidi was, in many respects, a 'typical' secondary PGCE student, having come to the course direct from undergraduate study in Mathematics and Statistics at a well-regarded UK university. Her placement school was state-funded, for pupils aged 11-16. The school was 'comprehensive', providing

for some 1400 pupils across the attainment range. In keeping with almost all secondary schools in England, pupils were ‘setted’ by attainment in mathematics, with 10 or 11 sets in most years.

We offer Heidi’s lesson as a ‘case’ in the following sense: it is used to illustrate, and to test in the secondary context, how the KQ can be used to identify, for discussion, matters that arise from lesson observation, and to structure reflection on the lesson.

Heidi’s lesson

This was Heidi’s second videotaped lesson. Her class was one of two parallel ‘top’ mathematics sets in Year 8 (pupil age 12-13), and these pupils would be expected to be successful both now and in the high-stakes public examinations in the years ahead. According to the observation notes, there were 30 pupils in the class, 17 boys and 13 girls. They were seated at tables facing an interactive white board (IWB)² located at the front of the room. Heidi stood alongside the IWB for the whole of this lesson, and the video camera was trained on her and/or the board. The objectives stated in Heidi’s lesson plan were to “Go over questions from their most recent test, and then introduce direct proportion”.

As soon as the pupils were settled at their tables, Heidi returned test papers to them, from a previous lesson, and proceeded to review selected test questions with the whole class. These questions included two on simultaneous linear equations. Several pupils offered solution methods, and these were noted on the IWB. Nearly 30 minutes of the 45-minute lesson had elapsed before Heidi moved on to the topic of direct proportion. She began by displaying images of three similar cuboids on the IWB: she explained that the cuboids were boxes, produced in the same factory, and that the dimensions were in the same proportions. The linear scale factor between the first and second cuboids was 2 [Heidi writes $\times 2$], and the third was three times the linear dimensions of second [$\times 3$]. Heidi identified one rectangular face, and asked what would happen to the area of this face as the dimensions increased. They calculated the areas, and three pupils made various conjectures about the relationship between them. The third of these said “I think it is that number [the linear scale factor] squared”. Heidi then introduced two straightforward direct proportion word problems, such as “6 tubes of toothpaste have a mass of 900g. What is the mass of 10 tubes?” Different approaches were offered and discussed.

THE KNOWLEDGE QUARTET: HEIDI’S LESSON

Earlier, we introduced the four dimensions of the KQ, and gave a general account of the characteristics of each of them. We now offer our interpretation of some ways in which we have observed, or inferred *foundation*, *transformation*, *connection* and *contingency* (but not in that order) in Heidi’s second videotaped lesson. It will become apparent that many moments or episodes within a lesson can be understood in terms of two or more of the four dimensions. We also draw upon her lesson plan,

and upon her contributions to the post-lesson, stimulated-recall discussion with a researcher (Anne, in this case). This discussion had homed in on two fragments³ of the lesson that had been selected at the preliminary analysis session a few days earlier. The first of these fragments was Heidi's review of the first of the two test questions on simultaneous equations; the second was the introduction of the proportion topic using the IWB-images of the three cuboids.

Transformation

Heidi had little or no influence regarding the **choice of examples** (a key component of this KQ dimension) in her test review, since the test had been set by a colleague. However, the stimulated-recall interview gave an opportunity and a motive for her to reflect on the test items. There had been two questions (7 and 8) on simultaneous equations, and the related pairs of equations were

$$\text{Q7: } 2x + 3y = 16, 2x + 5y = 20 \quad \text{Q8: } 3b - 2c = 30, 2b + 5c = 1$$

In response to an interview question, Heidi thought the sequencing appropriate. In particular (regarding Q7) she said "They could do it the way it was", seeming to refer to the fact that one variable (x) could be eliminated by subtraction, without the need for scaling either equation. In fact, the pupils' response to Heidi's invitation to offer solution methods suggested that this opportunity was not recognised, or not welcomed. The first volunteer, Matthew, proposed multiplying the first equation by 10, and the second by 6, suggesting a desire on his part to eliminate y , not x . (We shall consider Heidi's response to this under *Contingency*). Heidi was able to explain this in her answer to Anne's question "What if the y -coefficients were the same". Heidi's first response was "That would be less difficult because they tended to want to get rid of the y . I don't know why".

In fact, in this lesson segment, when eliminating one variable by adding or subtracting two equations, Heidi reminds the class several times about a 'rule', namely: if the signs are the same, then subtract; if they are different then add. Heidi suggests, later in the interview, that the pupils tend to want to make the y -coefficients equal, as Matthew did, because their signs are *explicit* in both equations. This can be seen, in both Q7 and Q8, where the coefficient of the first variable is positive in both equations, and the sign left implicit, whereas $+$ or $-$ is explicit in the coefficient of the second variable. This insight of Heidi's is typical of the way that focused reflection on the disciplinary *content* of mathematics teaching, structured by the KQ, has been found to provoke valuable insights on how to improve it (Turner & Rowland, 2010). Heidi's observation is that restricting the x -coefficients to positive values (and emphasising the 'rule') has somehow imposed unintended limitations on student solution methods, with a preference for eliminating y even when "they could do it the way it was" by eliminating x .

Turning to **choice of representation**, and Heidi's introduction of the direct proportion topic, we note that we misinterpreted Heidi's use of the three cuboids in

our preliminary lesson analysis. Her lesson plan included: “Discussion point: What happens to the area of the rectangular face as the dimensions increase? What happens to the volumes of the cuboids as the dimensions increase?”. We took this to mean that she intended to investigate the relationship between linear scale factor (between similar figures) and the scale factors for area and volume. In the event she was drawn into this topic, but this had not been her intention, and the subsequent word problems make this clear. In the event, there is discussion of the area of one rectangular face of the cuboid, and how its area increases as the cuboids grow larger: there is not time to consider the volumes. When probed about her choice of context for the introduction of the direct proportion topic, Heidi said that she had chosen the cuboids because it was “a nice visual” which contrasted with the “wordy” presentation of the other problems. In fact she drew on her IWB expertise by unveiling the images of the cuboids, one by one, as if drawing back electronic curtains. She responded to appreciative ‘Wow’s from the pupils with modesty, saying “It’s not all that impressive is it?” In the interview when asked whether she agreed that she could have done the work on area comparison with rectangles, she replied “You’re absolutely right, rectangles would be enough ... but I did like my box factory”. Here we see an example of trainees’ propensity to choose representations in mathematics teaching on the basis of their superficial attractiveness at the expense of their mathematical relevance (Turner, 2008). In this instance, the preference for these ‘visuals’ took Heidi into mathematical territory for which she was not mathematically prepared (see *Contingency*).

Contingency

Analysis of this dimension of the KQ in Heidi’s lesson intertwines with the component of *foundation* concerned with teachers’ beliefs about mathematics and mathematics teaching. Here, we begin by taking up the story of Matthew’s suggestion to solve Q7 by multiplying the first equation by 10, and the second by 6. Heidi responded to Matthew (**responding to students’ ideas**) with “Excellent, you could do that”, and talks it through (without writing on the board), saying that Matthew is trying to “make the number in front of the y , which we call the coefficient, the same”, so that both will be 30. She does point out that “You wouldn’t have to do quite as much timesing as that, quite big numbers, if you didn’t want to”, and there might be “other multiples” which could be used.

Given Heidi’s earlier comment that, with the equal x -coefficients, “they could do it the way it was”, Anne asked her why she had “run with” Matthew’s suggestion⁴. Heidi replied “Because it would work. You’re trying to find the lowest common denominator but it would work. Like adding fractions, it would work with any common multiple. I didn’t want him to think he was wrong”. This kind of openness to pupils’ suggestions, and ability to anticipate where they would lead, was very characteristic of Heidi’s teaching, and several examples of it can be found in our

data, although there are occasions when her prior expectations blinker her reading of events as they unfold.

Within the class discussion which followed Heidi's introduction of the three cuboids, the pupils calculated (in cm^2) the areas of the rectangles with sides (respectively) 2×3 , 4×6 , 12×18 (all cm) viz. 6, 24, 216 (in cm^2). Heidi had annotated $x2$, $x3$, as we noted earlier. The first pupil contribution about the relationship between the areas conjectured that cubes (unspecified) were involved. Heidi acknowledged this suggestion, but set it aside. Now, it just so happens that the third area is the cube of the first ($6^3=216$). This is, admittedly, a coincidence, and we are in no position to know whether it is what the pupil had discovered. A second pupil suggested that the relationships were "timesed by 4 and timesed by 6". Heidi made it clear that she was not checking these calculations numerically ("I'm going to take your word for that"), recorded this second proposal on the IWB (writing $x4$ and $x6$) and said "So two times what this has been timesed by [*pointing to the linear scale factors*]. Good observations". This seemed to be the end of the matter, until a third pupil, Lucas, said "I think it is that number squared". Heidi paused, then changed the second factor to $x9$ and emphasised the squares.

Now, this length/area relationship in similar figures was not what Heidi had set out to teach, and it became clear at the interview that Heidi (unlike Lucas) did not know in advance about "that number squared". In the interview, the discussion proceeded:

Anne: Then you go on to areas. They give a range of options. Now, you take all these responses and give value to all of them. But this was different, in that two of these responses were not correct.

Heidi: I want to take everyone's ideas on board. When you do put something on the board they correct each other rather than me being the authority. In that case I had a bit of a brain freeze, I hadn't worked out how many times 24 goes into 216, but they're used to me putting up everything.

We see here, paradoxically, a situation – by no means the only one – in this secondary teaching data in which some subject-matter in the school curriculum lies outside the scope of the content knowledge of the trainee at that moment in time. This should come as no great surprise. For all their university education in mathematics, and their knowledge of topics such as analysis, abstract algebra and statistics, there remain facts from the secondary curriculum that they will have had no good reason to revisit since they left school. This is no disgrace, and they will have cause to remember soon enough. What is significant, however, exemplified by Heidi but more-or-less absent in our observations of primary mathematics classrooms, is a teacher with the confidence to negotiate and make sense of mathematical situations such as this (the length/area relationship) 'on the fly', as they arise.

We noted earlier Heidi's response to Matthew: "Excellent, you *could* do that", in a situation when his method differed from the one she had in mind. She used versions of this formula (praise, followed by an implied caution) on two other occasions in the lesson. In an earlier test item, it was given that £36 is 75% of some quantity (x). Heidi had in mind solutions such as $x = 36 \times \frac{100}{75}$, but Adrian suggested finding a third of 36 and adding it to 36. Heidi responded "That's a perfectly acceptable way, Adrian. Yes, you *can* do it that way ...". Later, in the dog-walker proportionality problem (a dog walker walks 7 dogs in 2 days, how many dogs in 10 days; 5 days?) a pupil suggests a unitary approach (how many dogs in one day) some way into the discussion. Heidi responds "Lovely, you *can* do that", and in fact she subsequently emphasises the $\times 3.5$ scaling. These responses suggest a tension in Heidi's mind, when **responding to students' ideas**, between acknowledging and valuing flexible, idiosyncratic solution methods and promoting standard methods that will 'work' for them now, and in the high-stakes tests to come. This tension is probably not lost on her pupils either, and is conveyed in her language, in the modal ambiguity between possibility and permission ('can' and 'could').

Foundation

This lesson does raise a few issues about Heidi's content knowledge that might be brought to her attention, and some of them were raised in the interview. Briefly, these include: her **use of mathematical terminology**, which is either very careful and correct (e.g. 'coefficient'), or quite the opposite (e.g. 'timesing'); her lack of fluency and efficiency in mental calculation, such that she did not question the suggestion that $6 \times 24 = 216$ herself in the cuboids situation: on occasion it appeared that she was puzzled by some of the pupils' mental calculations; thirdly, she was not aware of the length/area/volume scale-factor relationships referred to earlier.

But, after many hours spent scrutinising the recording of this lesson, and that of the post-lesson interview, our lasting impression relates to the **beliefs component** of the *Foundation* dimension. In particular Heidi's beliefs about her role in the classroom in bringing pupils' ideas and solution strategies into the light, even – as we remarked earlier – when she believed that 'her way' would, in some sense, be better. As she told Anne, "I want to take everyone's ideas on board. When you do put something on the board they correct each other rather than me being the authority". Her perception of this aspect of her role, as teacher, and the possibility of the pupils themselves contributing to pupil learning, is resonant of various constructivist and fallibilist manifestos. Balacheff, for example, advised that "[the] transfer of the responsibility for truth from teacher to pupils must occur in order to allow the construction of meaning" (1990, p. 259), and identified classroom discussion as a context in which this transfer can take place. Heidi constantly assists this 'letting go' by acknowledging pupils' suggestions, and making them available for scrutiny by

writing them on the board. Occasionally she finds herself in deep water as a consequence, but she never seems to doubt her [mathematical] ability to stay afloat.

Connection

We identified a few events in this lesson under *connection*. For example, Heidi's introduction to direct proportionality with the cuboids seemed quite unrelated to the word problems which followed. In any case, the rather diverse objectives for the lesson were likely to make it somewhat fragmented, and we omit further analysis of this KQ dimension from the present narrative.

CONCLUSION

The purpose of this phase of our *SKIMA* research was to test the 'fit' of the Knowledge Quartet to secondary mathematics teaching. The indicative analysis of Heidi's second lesson in this paper indicates the potential of KQ as an analytical and (potentially) developmental tool in the context of novice secondary mathematics teaching. In this lesson, there were no moments or events, in which Heidi's mathematical content knowledge became a significant and/or influential factor in the proceedings, that could not be accommodated by one or more of the four dimensions of the KQ and the existing 20 codes. There are, however, such events in the data, as a whole, that may cause us later to want to supplement the codes within existing KQ dimensions. For example, the existing four *transformation* codes might not adequately capture the kinds of extended explanations, or the imaginative task design, that we saw in some other lessons. In other cases, such as Heidi's commitment to valuing student ideas and conjectures, the difference between these data and those from our novice primary teachers is more one of degree than of kind, from a KQ perspective. In our role as mathematics teacher educators, our analysis (as researchers) of the six lessons taught by these three volunteer participants now encourages us to pilot the use of the KQ as a developmental framework for the observation and review of lessons taught by secondary PGCE trainees during their school-based placements. This, in turn, will create yet more opportunities for testing and refining the KQ in the field.

Notes

¹ A DVD of the full lesson was given to the trainee soon afterwards, as a token of our appreciation, but their reflections on viewing this DVD in their own time are not part of our data.

² Interactive whiteboards, with associated projection technology, are now more-or-less universal in secondary classrooms in England.

³ The two corresponding video clips were each about four and a half minutes.

⁴ Our earlier KQ research had identified three kinds of responses to unexpected ideas and suggestions from pupils: to ignore, to acknowledge but put aside, and to acknowledge and incorporate.

PRE-SERVICE TEACHERS LEARNING TO ASSESS MATHEMATICAL COMPETENCIES

Norma Rubio*, Vicenç Font**, Joaquim Giménez**, Uldarico Malaspina*

*Pontificia Universidad Católica del Perú, **Universitat de Barcelona

This study investigates the professional competence of a group of pre-service secondary-school mathematics teachers with respect to assessing the mathematical competencies set out in the PISA 2003 report. It considers only those theoretical constructs proposed by this report. The research is descriptive in nature and includes a case study. The results were: 1) pre-service teachers do not recognize the level of complexity (reproduction, connections or reflection) of the competencies needed to solve a given problem; and 2) neither do they recognize when it comes to assessing the mathematical competencies that can be inferred from the solution given to a problem.

Key words: pre-service teachers, mathematical competencies, assessment, PISA 2003, professional competency

INTRODUCTION

The competencies set out in the PISA 2003 report are inspiring competency-based curricula in several countries. An inherent problem with this type of curriculum is how to ensure that teachers have the professional competency required to assess the mathematical competencies established by such curricula. This, in turn, is related to the problem of determining the mathematical and educational knowledge which pre-service teachers need to acquire (Ball, Lubienski & Mewborn, 2001; Hill, Schilling & Ball, 2004; Sowder, 2007; Hill, Ball & Schilling, 2008; Wood, 2008; Font, Rubio, Giménez and Planas, 2009; Godino, 2009).

Assessment is the process of obtaining information that is used to make educational decisions about students, to give feedback to the student about his or her progress, strengths, and weaknesses. The professional competency about knowing how to assess the students is considered in recent literature of mathematics education for many reasons. For instance, the impact of evaluations on the work of students is very important (Romainville, 2002). Researchers, such as Brown and Coles (2000), relate this competency to the need for developing a teacher's ability to make complex decisions, and others talk about the need to develop professional formative assessment competency (Hodgen, 2007).

The present study forms part of a more general research project (EDUC2009-08120: "Assessment and development of professional competencies in mathematics and how to teach them during the initial training of secondary and high-school teachers"), which aims to determine how to ensure that pre-service secondary-school teachers develop, during their initial training, the professional competency required to assess

the mathematical competencies of pupils and their metacognitive support (Niss, 2002).

The main aim of this paper is to determine the initial competency level of pre-service secondary-school teachers with respect to assessing the mathematical competencies set out in the PISA 2003 report when using their proposed theoretical framework. As a result, the research presented here is descriptive in nature. The regional government of Catalonia (Spain) had just approved a proposal for a competency-based curriculum that differs only slightly from the PISA 2003 competencies. We therefore opted to use the PISA 2003 competencies as the benchmark for this study.

The starting hypothesis was that pre-service teachers, who have mathematical but not professional competency, will not find it easy to assess mathematical competencies purely on the basis of the information provided by PISA 2003 tests, i.e. using the constructs ‘competency clusters’ (which can be used to determine three levels of complexity: reproduction, connections and reflection) and the list of ‘competencies and their components’ set out in the PISA 2003 report (OECD, 2003).

PISA 2003 considers eight competencies (thinking and reasoning, argumentation, communication, modelling, problem posing and solving, representation, using symbolic, formal and technical language and operations, use of aids and tools), which, taken together, can be seen as constituting comprehensive mathematical competency. Each of these competencies can be possessed at different levels of mastery (OCDE, 2003). In order to assess students’ capabilities, as well as their strengths and weaknesses, PISA 2003 also uses the construct competency clusters (reproduction, connection, reflection). Such constructs had been used to build tasks for summative assessment of students’ mathematical competences. Nevertheless, such a framework does not consider formative assessment of competences as explicitly needed for several authors (Hodgen, 2007). Thus, competences manifested by the students and the degree of intensity were not indicated in a way possible to permit regulated feedback. Therefore, the teacher needs to have such artifacts in a way to promote and develop mathematical competence (Wiliam, 2007).

In our theoretical perspective, we assume that the development of teacher competence in the analysis of mathematical objects and processes activated in mathematical practices is a necessary step to develop the expertise needed to assess the mathematical competencies of students. According to the theoretical model proposed by an onto-semiotic approach (Font, Planas & Godino, 2010), the competence in the analysis of mathematical objects and processes is a component of didactical analysis for instructive processes to be developed for pre-service teachers.

DATA COLLECTION

To identify the initial level of prospective teachers, we observed and analyzed two classes given in the Faculty of Mathematics of the University of Barcelona as part of the module ‘Teaching Mathematics’. Both classes addressed the topic ‘PISA 2003

competencies'. With the course tutor's agreement, the second class was modified slightly compared to what had been taught in previous academic years. The class content included an introduction to the PISA 2003 report by the tutor and individual work by students. The first class involved information about and reflection upon the 'competency clusters' (levels of complexity) and the list of 'competencies and their components' from the PISA 2003 report. Some of the problems proposed in the PISA tests were used as examples. In the second class, students responded to a questionnaire designed to assess their initial competence in assessing mathematical competencies.

The 22 students who participated in these classes were in their final year of a mathematics degree. This ensured that they would have mathematical competence but very little competence in assessing mathematical competencies, due to their lack of previous training in teaching mathematics. These final-year students from the Faculty of Mathematics were aspiring to be secondary-school teachers and were studying their first module in 'Teaching Mathematics'. The two classes took place during the third week of the academic year, which meant that students had already discussed and analyzed (during the first four classes of the term) the secondary-level curriculum drawn up by the regional government of Catalonia (Spain). As mentioned earlier, this curriculum was based on competencies that were very similar to those set out in the PISA 2003 report and the principles and standards of the NCTM.

The data collected were as follows: 1) prospective teachers' responses to a questionnaire; 2) information obtained from interviews (pre- and post-) with the tutor imparting the 'Teaching Mathematics' module; and 3) responses to a second questionnaire in which they were asked about their responses to the first one. Before giving the first questionnaire, the pre-service teachers received information about PISA 2003 constructs (the 'overarching ideas' to which the problem referred; the types of situation and context; a description of the competency clusters that serve to characterize three levels of complexity; and a list of the eight main competencies, along with a description of each one).

The first questionnaire was structured as follows: first let's observe several PISA problems, so called "CO2 levels" (OECD, 2009, p. 144-145) and "Internet relay chat" (OECD, 2009, p. 112), as well as a pupil's solution to a slightly modified version of the carpenter problem (Figure 1).

The modification merely involved asking for an open rather than a closed answer, in which students were also asked to justify their answer of the "carpenter" problem (OECD, 2009, p. 111), which is shown below (Figure 2). After solving the problems as secondary school students, two professional questions were proposed: (a) Classify the three problems according the type of clusters; (b) Which competences can you infer looking at the student's answers for the carpenter-adapted problem? To consolidate the data, the research team interviewed the tutor. After knowing their

answers, in a subsequent class, a second questionnaire was proposed to the sample of students. Let us say now, as examples, only two of the questions proposed in this

Figure 1: Statement of the carpenter problem (adapted)

CARPENTER (ADAPTED) PROBLEM:
A carpenter has 32 meters of timber and wants to make a border around a garden bed. He is considering the following designs for the garden bed. For each design, say whether the garden bed can be made with 32 meters of timber. You must answer yes or no, and explain why.

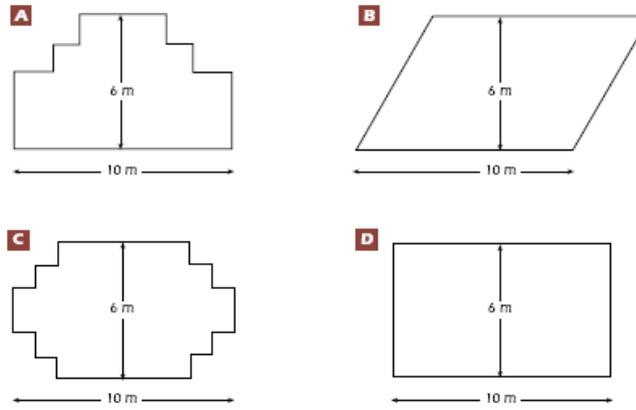

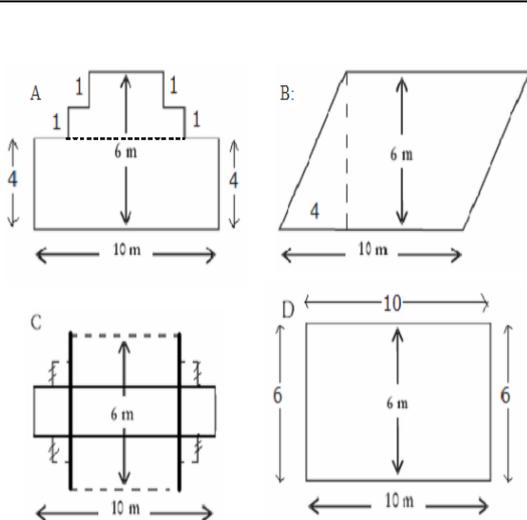

Figure 2: Reproduction of a student's solution

The different garden beds (A, B, C, D) that could be enclosed with 32 m of timber:

A: First I calculated ~~the area~~ the perimeter of the main rectangle ($4 \times 2 + 10 \times 2$), since although this figure has raised sections the horizontal lines complete the inner rectangle.

Then I added the four metres of vertical borders, which account for the breakdown of the rectangle as $28 + 4 = 32m$.

B: In this case it wouldn't be possible as there isn't enough for the diagonals... you would need more than the available timber to enclose $\sqrt{6^2 + 4^2} = 8.4m = 7.2m$.

The 8.4m added to the 10 of the length would give 37 ($7.2 \times 2 + 10 \times 2$).

7.2m

34m

C: Here I'm going to apply the same system as in Figure A. In this case it would be with 2 different rectangles, so I take the longest one and add 10 m twice, and then from what's left I take the verticals, the 6 m, 32 m.

D: This is just adding the lengths of the sides (perimeter) $6 + 6 + 10 + 10 = 32m$.

questionnaire: (a) If you remarked that one of the competences present in the solution was modelling, tell us why. (b) If you consider one of the competences (argumentation, communication) but not both of them, do you feel they are independent one from the other? Some other questions, proposed to understand students' justifications of previous answers, are not included in this text.

ANALYSIS OF RESPONSES

The data were analyzed by means of a triangulation process. The first step involved two researchers analyzing the responses to the first questionnaire. Thus, the tutor participated in a second analysis with the research team, in order to gather his views on the initial analysis for refining the observations.

Analysis of responses to the first questionnaire

With respect to the competency clusters, it was expected that pre-service teachers would not find these easy to apply. The analysis of their responses suggested that they did indeed have difficulties in distinguishing between levels. For example, 12 of the 22 pre-service teachers did not consider the adapted carpenter problem to be a problem of connections (even though it remains so).

Given the type of training received by students in the Faculty of Mathematics our initial hypothesis was that those students who classified the problem as one of reproduction did so basically because they considered it to be an easy problem (an exercise) and failed to put themselves in the pupil's shoes. The pre-service teachers were asked about this issue in the second questionnaire.

As regards competency in 'thinking and reasoning', it was expected that this would be mentioned in the response of all the pre-service teachers, since it would follow from the correct response of a pupil to the carpenter problem. In other words, in order to answer a problem correctly a pupil would have to be capable of 'thinking and reasoning'. The analysis revealed this to be the case, since pre-service teachers indicated the 'thinking and reasoning' competency at all three levels of complexity (reproduction, connections and reflection).

Another expected result was that the competencies 'argumentation' and 'communication' would both be present in the responses of pre-service teachers, because the solution analyzed was correctly argued and communicated. However, this expectation was not fulfilled, since a group of 11 pre-service teachers (50% of the total number of students) considered only one of these competencies. It thus appears that they did not regard these competencies as sharing a common ground. They were asked more about this issue in the second questionnaire.

It was also expected that the 'modelling' competency would appear in few responses of pre-service teachers, however this competency appeared in eight of them. Given this relatively high number of pre-service teachers who did consider this competency to be present it was decided to ask them more about the reasoning behind their response in the second questionnaire.

The 'problem-solving' competency was expected to feature in the majority of responses, unless the problem was regarded as trivial or an exercise. Of the 17 students who considered the problem on the level of connections or reflection only two failed to consider the 'problem-solving' competency. Of the five who considered

the problem on the level of reproduction, two said that the ‘problem-solving’ competency could be inferred from the pupil’s answer. These latter two students were asked about their responses in the second questionnaire.

The ‘representation’ competency was also expected to be present in almost all the pre-service teachers’ responses. However, given that a significant number of them (7) did not mention it, it was decided to ask them about the reasoning behind their response in the second questionnaire.

Given the type of training received by students in the Faculty of Mathematics, it was also expected that the competency ‘using symbolic language’ would not feature widely in the students’ responses, since the pupil’s solution they were asked to analyse contained a lot of written text in natural language and very few mathematical symbols. However, only three of the 22 students fulfilled this expectation so it was decided to ask them about the reasoning behind their responses in the second questionnaire.

The final competency ‘using aids and tools’ was not considered when evaluating the competencies that could be inferred from the pupil’s response to the carpenter problem, since only pen and paper were used to solve the problem.

Interview with the tutor

The tutor was in complete agreement regarding the ambiguity of the levels of complexity, and said he was not surprised that students had difficulties in applying them correctly; indeed, he added that he himself found it difficult. He also stated that the reason why some students considered the problem to be one of reproduction was because they regarded it as easy and failed to put themselves in the pupil’s shoes.

The tutor was not surprised that the ‘thinking and reasoning’ competency appeared in the response of all his students, and added that in his view it was not a very useful competency for discriminating between responses, since one could always consider it to be present, even if the answer given by a pupil was incorrect.

In contrast, the tutor was surprised that 11 of the 22 students considered that the pupil’s solution showed argumentation but not communication. He attributed this to the fact that for pre-service teachers, argumentation is associated with formalism, whereas they associate communication with oral or written expression.

The tutor agreed that the ‘modelling’ competency should not be considered as present in the solution to the carpenter problem. In his view, those students who had inferred its presence had simply responded without too much thought. He suggested asking them more about their reasoning. With respect to the ‘problem-solving’ competency the tutor’s view was that pre-service teachers did not consider this because they regarded the problem to be an exercise.

The tutor was also surprised that his students had not mentioned the competency 'representation', since this had come up in previous classes when discussing the secondary-school curriculum drawn up by the regional government of Catalonia.

The tutor agreed that the reason why pre-service teachers did not consider the competency 'using symbolic language' to be present was that the problem-solution analysed contained very few mathematical symbols. In his opinion, the profile of pre-service teachers was such that this idea was sometimes taken to extremes. i.e. if they saw a meaningless series of mathematical symbols they might say that "this is mathematics", whereas when presented with graphs and verbal expressions they would say "this isn't mathematics".

The tutor was told that the present research sought to corroborate that a pre-service teacher, with good mathematical skills but very little training in mathematics education, would find it hard to assess the mathematical competencies of pupils solely on the basis of the theoretical constructs set out in the PISA 2003 report. It was also pointed out to him that one possible objection to this hypothesis could be that the same students might perform better with these theoretical tools once they had gained more experience. However, the tutor was sceptical about this latter possibility, as he considered that tools other than the theoretical constructs set out in the PISA 2003 report were required.

Analysis of pre-service teachers' responses to the second questionnaire

The pre-service teachers who regarded the problem as one of reproduction did so because they considered it to be a familiar and simple problem. Examples of their responses included: "It involves calculating the perimeter of different shapes, in other words, the reiteration of a known and familiar algorithm which only requires dealing with simple expressions and formulas"; "Because for the possible garden beds you always need to calculate the perimeter, a familiar formula"; "Because he uses the perimeter formula"; "It is conceptually very simple... a very general exercise"; "The problem is simple and can be solved with routine procedures".

The pre-service teachers who considered that only the argumentation, not the communication, competency was present stated that this was because communication implies transmitting a message or information, whereas arguing requires robust explanation. Their responses included: "Communicating means transmitting information, whereas arguing implies giving more reasons why, it's more than just transmitting something or making it known"; "Communicating means expressing something that you think, whereas arguing involves doing something that you propose and have to resolve"; "I don't think the two are totally independent, because when you communicate you have to argue what is communicated. However, on this occasion good argumentation is considered more important"; "I don't think they are independent of one another, because in order to argue it is very important to communicate beforehand"; "They are independent here, because the pupil explains in

his own way how he solved the problem, but he doesn't communicate". The pre-service teacher who inferred the presence of the communication but not the argumentation competency said that in his view "communicating knows how to transmit a message whereas arguing implies that the arguments used must be robust and not contradictory".

The pre-service teachers who considered that the 'modelling' competency was present based this view on the fact that the pupil translates figures into mathematical structures. Their responses included: "The solution to the problem presented here begins with the model of the garden bed that the pupil makes in order to solve the problem"; "The problem makes you translate the figures into a mathematical structure"; "Because the pupil uses a system to find the perimeter, in other words, he makes an algorithmic model"; "Because the figures in the problem can be broken down into parts or other more simple figures and this makes it easier to solve the problem".

The two pre-service teachers who considered the problem to be one of reproduction and felt that the pupil's solution illustrated the 'problem-solving' competency gave responses such as: "You need to propose what you can use and then find the solution"; "Solving the carpenter problem obviously requires the problem-solving competency, even if the answer is a mere reproduction".

The pre-service teachers who did not consider the 'representation' competency to be present said that in this problem there was nothing to represent. Their responses included: "The representation is already given in the problem statement, you only have to make calculations"; "To calculate the perimeter, which is necessary, you don't have to interpret the different representations"; "Nothing is represented here, and nothing is drawn".

The pre-service teachers who considered that the competency 'using symbolic language' was not present in the pupil's solution did so because there is no formalism (e.g., use of symbols, variables, algebraic operations) in the solution given. Their responses included: "I think there are several sentences that could have been written mathematically"; "There are only a few common operations"; "It is not necessary to use any algebraic or formal tool to solve the problem".

final considerations

This study has highlighted a number of preconceived ideas held by pre-service mathematics teachers that derive from their previous training. For example, in determining the level of complexity they take into account, above all, their personal appreciation of the problem's difficulty. Furthermore, they consider argumentation and communication to be two competencies without common ground. Finally, they do not contemplate the competency 'using symbolic, formal and technical language and operations' when graphs and natural language, for example, are present.

The pre-service teachers do not use the theoretical constructs properly as set out in the PISA 2003 report in order to determine the level of complexity of the competencies required by a given problem. Nor do they recognize when it comes to assessing each one of the competencies that can be inferred from the response given to a problem.

There are at least two possible explanations for these findings. One would be that the pre-service teachers need more practice in using these theoretical constructs before they reach a level of competence similar to that of the experts who evaluated the PISA 2003 tests (this is to be considered in future studies). The other would be that the problem lies not in the lack of practice but, rather, in the ambiguity of the theoretical constructs used in the PISA 2003 report (for example, the different ways of understanding competency; the relationship between the notions of ‘process’ and ‘competency’, which appear as closely related and, in some cases, are even used as analogous terms; the overlap between competencies, almost all of which have a common ground, and the fact that two of them (i.e., problem-solving and modelling) are more akin to ‘meta-competencies’).

Such analysis allows us to reflect (in the wide project) about the variables influencing development of professionals in assessing competence, by means of successive observations during the pre-service training process. We found that the question that remains to be answered is what theoretical tools would be required by pre-service teachers to enable them to be aware of assessing students’ competences in a formative way. We also found that (1) to reflect about assessing realistic mathematical projects formatively, and (2) the use of suitable criteria for analysing their own practices as teachers were two crucial tools for having indicators about their developing professional competences.

Acknowledgment

The research work reported in this paper was carried out as part of the project: “Evaluation and development of professional competencies in mathematics education for pre-service teacher training for Secondary School”, EDU 2009-08120.

MOVING BEYOND AN EVALUATIVE TEACHING MODE: THE CASE OF DIANA

Rosa Antónia Tomás Ferreira

University of Porto, Portugal & CMUP

In this paper, I describe and analyse a student teacher's evolving teaching modes throughout her year-long practicum, and within a modified teacher development experiment research design. I also discuss some factors that may influence the student teacher's anticipated developmental trajectory along three teaching modes.

Keywords: student teaching, classroom interaction, teacher development experiment, teaching modes.

THE TEACHING MODES AND THE CONCEPTUAL FRAMEWORK

It is widely accepted that the quality of teacher-student classroom communication plays an important role in students' learning. In this regard, teachers' questioning, listening, and responding approaches may be seen as underpinning the core of classroom communication. In fact, these three facets of teachers' practices have been suggested to characterize their pedagogical approaches and to reflect their beliefs about mathematics and its teaching and learning. Additionally, teachers' analyses and reflections about how they question, listen, and respond to their students have been shown to foster teachers' increasing awareness of their own beliefs and practices, thus helping them in improving their own teaching (e.g., Coles, 2001; Nicol, 1999).

Research has suggested that the student teaching experience of teacher education programs does not have a significant impact on aligning student teachers' beliefs and classroom practices with current recommendations for school mathematics; furthermore, student teaching has often failed to foster prospective teachers' reflective thinking and awareness of their own practices. These are cumbersome results for mathematics teacher educators, pushing for further inquiry. Based on existing research and on theoretical developments in the field of mathematics education, I built a conceptual framework (CF) that was used to conduct a study, whose major goal was to trace and understand how the teaching modes of a group of Portuguese secondary mathematics student teachers evolved over the course of their year-long student teaching practicum (Tomás Ferreira, 2005). Following a teacher development experiment research methodology (Simon, 2000), the study was designed to provoke teacher development and to describe and interpret that development. Yet, the CF itself was investigated for its adequacy for analyzing and interpreting classroom teaching and for informing the data collection and analysis procedures.

The teaching modes are comprised of teachers' inter-related classroom questioning, listening, and responding approaches. As described in an earlier paper (Tomás

Ferreira, 2007), the CF encompasses several strands, each one of them drawn from frameworks that emerged from or were used in prior research in the field: (1) teachers' *teaching modes*, by extending Davis's (1997) framework of listening modes to include Ainley's (1988) categories of teachers' questions, as well as teachers' different forms of responding to students (e.g., Nicol, 1999); (2) teachers' dominant patterns of classroom interaction (e.g., Bauersfeld, 1992; Cobb, Wood, Yackel, & McNeal, 1992; Voigt, 1985, 1995; Wood, 1998); (3) teachers' key beliefs about mathematics and its teaching and learning (e.g., Ernest, 1989); and (4) teachers' levels of reflective thinking (e.g., van Manen, 1977; Schön, 1983). Next, I briefly explain my understanding of these constructs.

Acknowledging the lack of consensus about the notion of reflection, my understanding of teachers' reflective thinking is teachers'

intentional engagement in thinking about their classroom practices with two main goals: (a) becoming aware of their actions in the classroom and of their key beliefs about mathematics ... against the perspectives on mathematics teaching and learning envisioned by current school mathematics reform movements; and (b) using those insights to improve their teaching ... and ... students' learning (Tomás Ferreira, 2005, p. 34).

The construct of teachers' beliefs does not gather consensus either amongst the research community in mathematics education. However, teachers' beliefs about mathematics and its teaching and learning shape their classroom practices (Thompson, 1992). Ernest's (1989) model of teachers' views of mathematics as a whole, their orientations towards mathematics learning, and their models of mathematics teaching resonates with van Manen's (1977) model of teachers' reflective thinking. The patterns of classroom interaction emerge "from the permanent interaction between teacher and students, as well as among students themselves" (Bauersfeld, 1992, p. 21). Research has identified several patterns of classroom interaction; in this research, I considered six of them. Though recognizing their differences, I grouped the patterns of classroom interaction that are typically centred on the teacher and called them *traditional patterns*: the IRE pattern (e.g., Cobb et al., 1992), the funnel pattern (e.g., Voigt, 1985, Wood, 1998), the elicitation pattern (Voigt, 1985), and the direct mathematization pattern (Voigt, 1995); the patterns of classroom interaction typically centred on the students' mathematical activity were grouped into *inquiry patterns*: the focusing and the discussion patterns (e.g., Voigt, 1995; Wood, 1998). To construct each strand of the CF, I chose existing frameworks in the literature that were fairly accessible to student teachers to work with. The use of a CF was an attempt to reduce and simplify the complexity of the classroom phenomena while emphasizing some specific aspects, which were at the core of the study.

The three teaching modes – evaluative, interpretive, and generative – were not considered in isolation but sharing qualitative characteristics amongst each other. Figures 1, 2, and 3 depict the anticipated relationships amongst all four strands of the

CF for each of the teaching modes. It is important to notice that the thicker the linking lines in the figures, the stronger the relationships amongst the constructs were likely to be. No *exact* correspondences were expected to exist. Despite being instrumental in the course of this research, the conceptual framework was a focus of inquiry for its adequacy for analysing and interpreting classroom teaching, as well as for its appropriateness for guiding the whole research design (Tomás Ferreira, 2005).

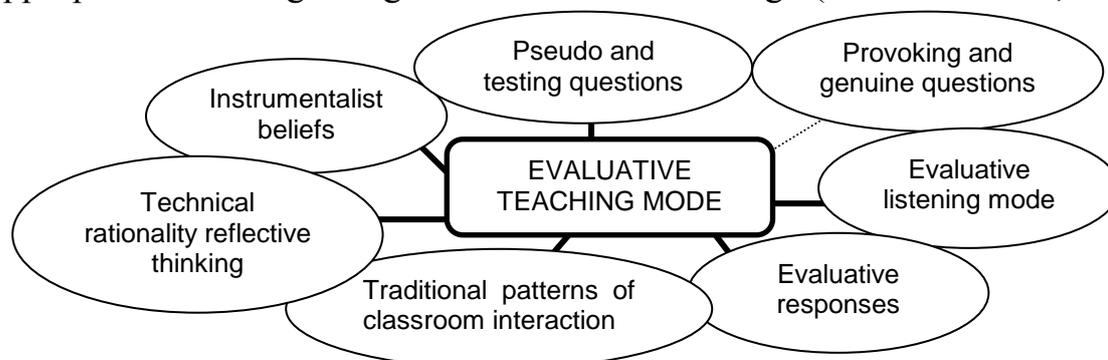

Figure 1. Evaluative teaching mode.

Some of the most distinctive characteristics of an *evaluative teaching mode* are asking students many pseudo and testing questions (Ainley, 1988) – to establish an acceptable behaviour and to find whether students answer correctly, – listening to them in an evaluative mode (Davis, 1997) – that is, looking for the *correct answers* they have in mind, – and responding to students to evaluate their answers since having students producing right answers is more valued than understanding students' underlying reasoning. Someone teaching predominantly in an evaluative teaching mode tends to closely follow lesson plans, not allowing for the *emergent* during the lessons. Communication is seen as a matter of speaking; yet, students' contributions to the classroom discourse are largely ignored. Traditional patterns of classroom interaction are the norm, such as the IRE pattern (Cobb et al., 1992) or the funnel pattern (Voigt, 1985; Wood, 1998); thus, the teacher owns the locus of authority. Typically, evaluative teachers hold instrumentalist beliefs about mathematics and its teaching and learning, seeing themselves as instructors (Ernest, 1989), and their reflective practices are very superficial, hardly ever allowing themselves to question their actions in the classroom – van Manen's (1977) technical rationality level.

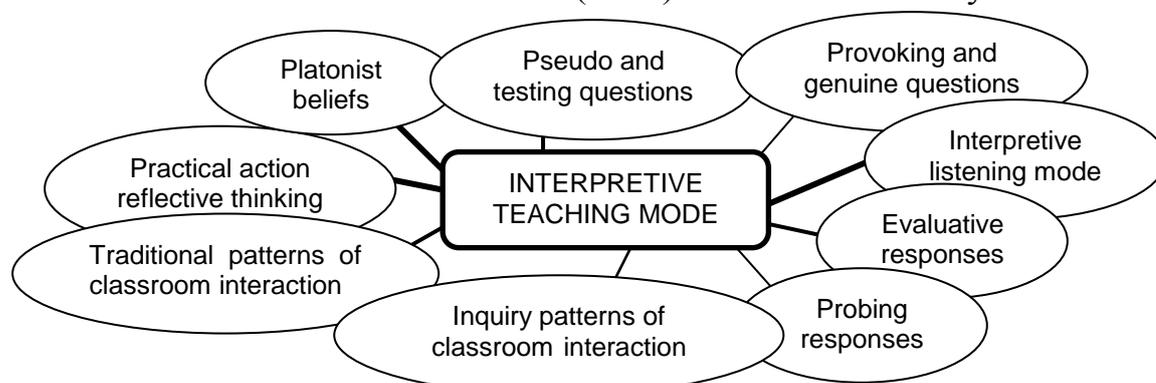

Figure 2. Interpretive teaching mode.

Teachers teaching in an *interpretive mode* tend to ask fewer testing questions than in an evaluative mode. In addition, they begin asking more genuine and provoking questions (Ainley, 1988), that is, questions that seek information and questions aimed at stimulating students' thinking and sense making. The interpretive listening mode (Davis, 1997) is now predominant, as teachers increase the opportunities for classroom interaction and discussion; yet, their responses to students are still evaluative in nature. Teaching is still much *textbook-driven*, though teachers tend to enrich classroom tasks by diversifying its nature. The “students' contributions to the discourse still do not have a significant impact on lesson unfolding, since despite some room for inquiry patterns of interaction, the traditional ones are clearly predominant” (Tomás Ferreira, 2007, p. 8). However, the locus of authority is mainly allocated to the teacher, whose Platonist typical beliefs about mathematics and its teaching and learning are related to his/her perception of self as an explainer (Ernest, 1989). Teachers teaching in an interpretive mode tend to focus their reflections on assessing the appropriateness of their teaching strategies in order to guide future practices, thus relying on van Manen's (1977) practical action level of reflective thinking. Hence, teachers predominantly reflect *on* action, in Schön's (1983) terms.

Within a *generative teaching mode*, to communicate is to participate, interpret, and negotiate meanings, involving all classroom members alike. Genuine and provoking questions (Ainley, 1988) are predominant, though there is room for other types of questions. Teachers teaching in a generative mode tend to listen to students in a hermeneutic listening mode (Davis, 1997), that is, accessing and assessing students' thinking in order to inform teaching. They tend to respond to students by stimulating discussions, probing answers, etc. Teaching is now a matter of responding in a flexible manner to constantly changing circumstances. Thus, the inquiry patterns of classroom interaction are predominant (though there is also room for other patterns), and the locus of authority is equally shared amongst all classroom members.

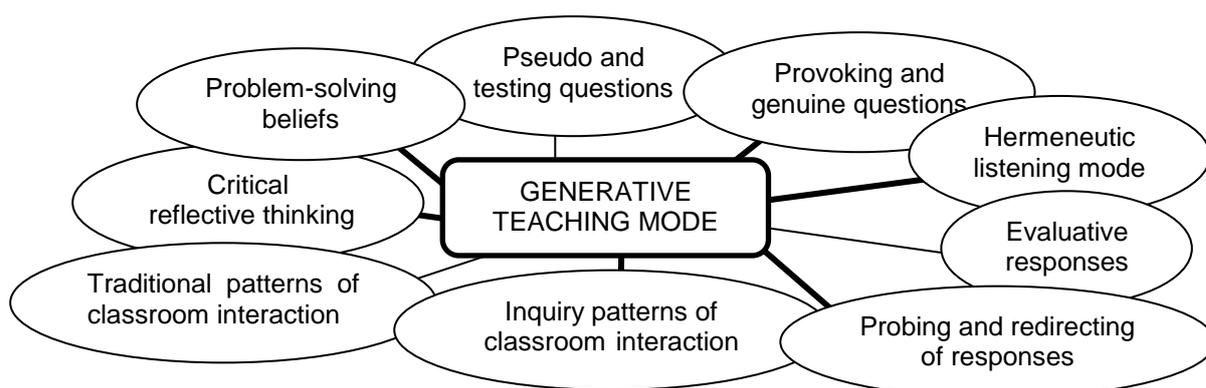

Figure 3. Generative teaching mode.

Generative teaching implies teachers' “revising of their own mathematical knowledge while exploring and constructing mathematical ideas with their students ... [and] questioning of their own practices and beliefs” (Tomás Ferreira, 2007, p. 9), perceiving themselves as facilitators of student learning. These teachers tend to hold

a problem-solving perspective on mathematics and its teaching and learning (Ernest, 1989), and to reflect at van Manen's (1977) critical level as they problematize the whole teaching in context, looking for reasons and consequences of their actions in the classroom. Hence, teachers often reflect both *in* and *on* action (Schön, 1983).

RESEARCH DESIGN

The research reported here is part of a larger study (Tomás Ferreira, 2005) which followed an overall teacher development experiment (TDE) research design (Simon, 2000), involving a teacher-educator/researcher, myself, four Portuguese student teachers, their students, and their cooperating teacher. A TDE “can allow researchers to generate increasingly powerful schemes for thinking about the development of teachers in the context of teacher education opportunities” (Simon, 2000, p. 338). The teacher-educator/researcher “teaches courses for teachers, endeavours to understand the teachers’ perspectives, identifies goals for teachers’ learning, and plans course activities to promote learning in the direction of those goals” (Simon, Tzur, Heinz, Kinzel, & Smith, 2000, p. 581). The TDE design has two different components: a *whole-class teaching experiment* in the context of teacher education courses, and a *case study* approach of individual teachers in their own classrooms.

The teacher-educator/researcher engages in several interaction-reflection cycles (Simon, 2000). The *interaction phases* aim at promoting professional development based on the teacher-educator/researcher’s “ideas of the current state ... [of the participant teachers’ practices, and on the researcher’s] current hypotheses about how development might proceed” (Simon & Tzur, 1999, p. 253). Relying on existing literature and personal experiences, and drawing on the CF presented, the participant student teachers were expected to begin their practicum enacting an evaluative teaching mode. The CF provided the hypothetical developmental trajectory I envisioned for the participants, guiding my interactions with them, as a teacher-educator, under the scope of the teaching experiment component of the whole research design. Thus, the interaction phases with the student teachers were aimed at stimulating their awareness and understanding of their own development, mainly in terms of their teaching modes and, specifically, concerning their questioning, listening, and responding approaches in the classroom.

The *reflection phases* (Simon, 2000) aim at the teacher-educator/researcher’s analysis of the interactions with the participant teachers in which they engage in the context of the teaching experiment component of the overall research design. Again, using the CF, my reflections were focused on the participants’ current teaching modes, as well as on the remaining three strands. Although the developmental trajectory envisioned for the participants had specific goals, the reflection phases of the interaction-reflection cycles ensured that other emergent issues would be addressed.

The context of this research was the student teaching phase of the mathematics teacher education program offered by a large public university, in a large urban area in northern Portugal. I worked with four student teachers, placed in the same school, interacting with them once or twice every week, for about six months, divided into four interaction-reflection cycles. I focused my attention on how the individual student teachers evolved in their teaching modes, and replaced the case study component of the TDE for the generation of *accounts of practice* (Simon & Tzur, 1999). Teachers' accounts of practice are characterized by the explanation of the teachers' perspectives from the researchers' perspectives, having two main goals: to describe teachers' current classroom practices, and to promote and sustain the development of those practices. In this research, the CF provided "the basis for considering current and potential development" (Simon & Tzur, 1999, p. 255) since it guided my interactions with the participants, focused my reflections about their development, and structured the generation of accounts of practice of the participant student teachers.

Each participant student teacher taught a 7th grade and an 11th grade class, sharing each class with another student teacher of the group. The sharing of classes was an innovative aspect of the placement school due to a sudden decrease in the pupil population, thus in the number of classes. The pairing of the student teachers was made by their cooperating teacher ensuring as much variability as possible, and it

... was not meant to stimulate team teaching in any aspect. Each pair of student teachers shared a class in terms that one of them was *the* teacher in charge of the class, while the other served as a secondary teacher in the classroom, as a supportive peer, not intervening in the lesson except for monitoring student behaviour ... (Tomás Ferreira, 2005, p. 137)

For each one of the four interaction-reflection cycles, data were collected through field notes of classroom observations, audiotape-recorded lessons and semi-structured interviews of distinct types (all transcribed and translated into English), and several documents such as lesson plans and written essays. The analysis was guided by the CF and had two approaches: (1) ongoing analysis occurred during and between the interaction-reflection cycles, providing foundation for planned and unplanned interactions, and allowing the modification of the participants' models of professional growth; and (2) retrospective analysis occurred after all data were collected, allowing the re-examination and reinterpretation of situations. The sharing of classrooms became a significant aspect in the generation of the accounts of practice. Next, I summarize Diana's case in terms of her evolving teaching modes, leaving the other dimensions of the CF and the analysis of the other participants to another paper.

THE CASE OF DIANA

Diana always expressed her dislike for expository teaching, direct instruction. Her enthusiasm and commitment to the various activities proposed in the scope of the

Working Group 17

teaching experiment component of the research design were probably two factors that pushed her to try to move beyond teaching in an evaluative mode from the beginning. She wanted to “give meaning to mathematics and to learning ... and to try to change the students’ heads ... It’s a huge challenge but I want to try” (October, 2002). However, over time, she experienced many tensions in her teaching modes. Diana shared a 7th grade class with Abel and an 11th grade class with Júlia. Table 1 summarizes Diana’s teaching modes throughout all four cycles of the study.

Table 1. Diana’s evolving teaching modes.

	First cycle	Second cycle	Third cycle	Fourth cycle
Teaching mode	Mostly an evaluative mode, though sometimes enacting an interpretive mode.	Mostly an evaluative mode when irritated with Abel’s role as secondary teacher or 7 th graders’ unproductive noise. Otherwise, tensions to enact an interpretive mode.	Evaluative mode with a few instances of an interpretive one when feeling more comfortable with the math and 11 th grade students collaborated in the lessons.	Evaluative mode with a few instances of an interpretive one when the students collaborated in the lessons.

Starting from the second cycle of the TDE, it became clear she was struggling to cope with Abel’s inappropriate behaviour as a secondary teacher in their shared 7th grade class. This was the most determinant factor for Diana’s tensions and difficulties in enacting in her classroom what she believed teaching should be. Abel frequently distracted the students with questions, comments, or repetitions of what Diana was explaining to the whole class. His quick movements around the classroom added a distracting factor, and his chatting with the students contributed to the widespread (unproductive) noisiness, which significantly irritated Diana:

... compare the role of Júlia in her 7th grade classroom with Abel’s ... I think he destabilizes because he gives too much confidence to the students! What am I going to do?! That is why I start getting enervated ... The students make much noise because of him and ... I start losing control ... It seems like he likes to have students almost kissing his feet ... But, I do not need that they ... venerate me. (March, 2002)

Despite her efforts to make him realize how he should act as a secondary teacher, Abel never questioned the effects of his actions on his partners’ teaching, seeming to always wanting to maintain his status as a *head* teacher. When his behaviour was not a problem, Diana did manage to engage her 7th graders in lively and fruitful discussions, using students’ input to construct mathematical meaning, stimulating students to explain their thinking to each other, and so on, thus enacting many instances of an interpretive teaching mode; otherwise, her teaching mode was mainly an evaluative one. Diana became increasingly aware of the conflicts between her actual classroom practices and what she would have liked to do with her students:

Working Group 17

... it is very difficult for me to listen to the students in a lesson where there is noise... in a normal lesson, I am aware that ... I listen to the students much better. And ... perhaps I pose more questions when I am calmer ... I hate when there is that noise. It is a complete frustration to me ... I cannot pose questions or listen to them. I start getting irritated and I don't do anything of that! (November, 2002)

Realizing she was able to move beyond an interpretive teaching mode only seldom was a source of great frustration.

Diana fought three different kinds of battles when teaching 11th grade. On one hand, she felt much pressure from the school mathematics department to cover the curriculum and maintain a certain instructional pace gauging it in accordance with other classrooms. Diana's 11th graders showed many learning difficulties, needing more time to work on the mathematics ideas being taught than other students from other classes. The pressure to move on caused Diana frustration and a sense of helplessness. On the other hand, Diana struggled to motivate her students to engage in mathematical tasks and to share their ideas and solutions with each other. Yet, the students were always very passive and apathetic, making no efforts to surpass their difficulties. Their attitudes contrasted greatly with the dynamic and inquiry environment that Diana strove so hard to establish in that classroom:

They forget everything! Then they do nothing on their own ... They just copy things from the board! That is why these lessons are very frustrating ... Would it make a whole lot of a difference if I would go to the board and solve everything? And tell them 'You do this in this way'? ... That would be expository teaching! [sighing deeply] (January, 2003).

On the rare occasions the students were more involved in the lesson, Diana was indeed able to enact an interpretive teaching mode.

Another factor that forced Diana to enacting an evaluative teaching mode emerged during the third cycle of the study. Her insecurity regarding the topic she was teaching led her to no longer attempt to *spice up* her lessons or promote a classroom environment that contributed to her students' active participation in their own learning. Not being comfortable with her visualization skills, Diana closed the possibilities for dialogue, using rhetoric questions to structure her speech and prevent *threatening* situations, and increasing her instructional pace. Realizing the effects of her lack of sound mathematical knowledge in her teaching created another source of frustration:

I am a bit afraid of this material ... teaching something I cannot visualize very well ... I am afraid of getting mixed up ... I will continue doing more expository teaching because I do not feel at ease asking questions and all of that ... I don't know! (January, 2003)

In sum, the tensions in Diana's teaching modes throughout her entire student teaching experience were never resolved. She did not win her battle to teach in ways that resonated with her problem-solving oriented beliefs (Ernest, 1989), fighting against very different factors: if Abel's inadequate behaviour as a secondary teacher

in their shared 7th grade classroom was the determinant factor for her lack of success in teaching in an increasingly generative mode, distinct factors accounted for a great sense of frustration and helplessness when teaching 11th grade: external pressures to cover the curriculum, passive and unmotivated students, and, above all, lack of a sound mathematical knowledge to give her the sense of security she needed to teach how she wanted to teach. Nevertheless, when conditions were favourable, Diana temporarily resolved the conflicts between her espoused and enacted beliefs, evidencing clear instances of an interpretive teaching. Yet, she did not give up on pursuing her goal, postponing her attempts to enact a generative mode for further.

FINAL REMARKS

The CF worked as a fundamental tool for conducting the teaching experiment component of the research design, especially for selecting readings for discussion and reflection. It was also instrumental for interpreting and analyzing the participants' progression regarding all its four strands, and for generating the accounts of practice. However, while the anticipated relationships between teachers' teaching modes and dominant patterns of classroom interaction, and between teachers' key beliefs and levels of reflective thinking were somewhat *confirmed*, there were inconsistencies between those two groups of teaching aspects. In addition, the CF did not show itself useful as a reflective tool for the participants themselves. More research is needed to, for example, explore and assess the influence of factors such as sharing classrooms with peers on one's own teaching modes, and to investigate the usefulness and appropriateness of the CF as a support construct to frame other professional development endeavours, in various contexts.

PRESERVICE ELEMENTARY TEACHERS' GEOMETRY CONTENT KNOWLEDGE IN METHODS COURSE

Fatma Aslan-Tutak

Bogazici University

The goal of this presentation is to discuss using mixed methods to study preservice teachers' (PST) geometry content knowledge. Effective geometry instruction practices in methods courses were investigated by qualitative methods to develop a protocol to enhance geometry learning of PST, then the effect of the protocol was studied by quantitative methods. The individual interviews (n=3), classroom observations and artifacts from the methods courses data yield to narrative analysis results and thematic analysis results. The following quasi-experimental (n=102) investigation to study intervention protocol which is developed from the qualitative investigation results, showed a significant change in treatment group participants' geometry content knowledge and a significant main effect of knowledge but no significant interaction between geometry content knowledge and grouping.

Keywords: teacher knowledge, geometry content knowledge, mathematical knowledge for teaching, mixed methods

INTRODUCTION

Teachers bear an important role in reform movements. "The desired learning environments can result only from knowledgeable teachers" (Putnam, et al., 1990, p. 225). Teachers' knowledge should be addressed in PST education and in professional development for in-service teachers. This study reports a two-phase research study which integrated qualitative and quantitative research methods to study elementary first PSTs' geometry learning and then their geometry content knowledge. The first phase of the study was the qualitative investigation to understand elementary school PSTs' *geometry learning* and the effective geometry learning experiences for PST. Integration of results from the study of the qualitative investigation and theoretical knowledge from the literature, the researcher *developed* a protocol for a mathematics methods course. The protocol used as the intervention for the quasi-experimental quantitative phase with purpose of improving the *geometry content knowledge* for teaching of PST.

REVIEW OF LITERATURE

The most commonly accepted definition of teacher knowledge was given by Shulman (1986, 1987), who developed a cognitive model of teacher knowledge, which consists three types of teacher knowledge; content knowledge (CK), pedagogical content knowledge (PCK) and curriculum knowledge. CK refers to knowledge base of the content one is teaching, such as mathematics. PCK "... goes beyond knowledge of subject matter per se to the dimensions of subject matter

knowledge for teaching...” (p. 9). PCK is the type of knowledge that distinguishes the work of a teacher from the work of a scientist. The third knowledge, curriculum knowledge addresses effective use of curriculum materials and being familiar with other subjects that students study.

Among these knowledge types, content knowledge stands out as a point of focus for teacher education. Brown and Borko (1992) asserted that PSTs’ limited mathematical content knowledge is an obstacle for their training on pedagogical knowledge. In the mathematics education field, *mathematical knowledge for teaching* (MKT) was developed as following the Shulman’s model for teacher knowledge (Ball et al., 2008). MKT model addresses how a teacher uses mathematics for teaching (Ball, 2000). According to MKT model, there are six domains of teacher’s content knowledge which can be categorized under Shulman’s different types of knowledge (Ball, Thames & Phelps, 2008). There are three domains under subject matter knowledge: *common content knowledge* (CCK, mathematics knowledge not unique to teaching), *specialized content knowledge* (SCK, mathematics knowledge unique to teaching), and *horizon content knowledge* (knowledge of mathematics throughout the curriculum). Also, there are three domains under pedagogical content knowledge: *knowledge of content and students* (KCS, interaction of knowledge of mathematics and students’ mathematical conceptions), *knowledge of content and teaching* (KCT, interaction of knowledge of mathematics and teaching methods), and *knowledge of content and curriculum* (interaction of knowledge of mathematics and mathematics curriculum).

Many leading mathematics education researchers, Ball (2000), Rowland, Huckstep and Thwaites (2005), Usiskin (2001) discussed role of addressing content preparation of teachers in the context of teaching. There are two practices stands out in the literature to address teachers’ knowledge which are using video discussion groups (Sherin & Han, 2004) and using students’ work to analyze (Kazemi & Franke, 2004). The synthesis of the literature on these two practices shows that the practice of video discussion groups allows for deeper discussion on PCK while absence of classroom environment in students’ work allows for deeper discussion on CK by teachers (Lampert & Ball, 1998; Sherin & Han, 2004). Using students’ work to analyze what students know and what they are learning to facilitate teacher learning results in teachers’ deeper subject matter knowledge (Kazemi & Franke, 2004). Therefore, using students work in a methods course could also improve PSTs’ mathematics knowledge for teaching especially when they have no classroom connection during the methods course.

Content knowledge of teachers is important for every subject including geometry. The limited number of research projects focused on knowledge of geometry for teaching concludes that beginning teachers are not equipped with necessary CK and PCK for geometry, and it is important to address this issue in teacher education (Jones, 2000; Swafford, Jones, & Thornton, 1997). In a study of middle and

secondary school teachers' geometry content knowledge, Fostering Geometric Thinking (FGT), content activities and analysis of student work were used with in-service teachers (Driscoll, Egan, Dimatteo & Nikula, 2009). FGT study showed significant difference between control group teachers who did not receive any professional development and treatment group teachers who received 20-week long intervention. The intervention was designed to provide geometry content experiences for teachers and analysis of student work from teachers own classroom in order to address geometry content knowledge in the context of teaching.

Therefore, this study strives to investigate the following research questions in elementary school mathematics methods course from the constructivist perspective to inform PSTs' geometry preparation. The first two questions were investigated through qualitative methods in order to pursue deeper understanding of PSTs' own perception on their geometry learning and effective practices to promote their learning.

1. What is elementary school preservice teachers' understanding of geometry for elementary school?
2. What are the perceptions of elementary school preservice teachers on effective instructional strategies to promote their learning of geometry content knowledge in mathematics methods courses?

Integration of the results from the above research questions and literature on teachers' mathematics and geometry preparation led the below research questions to be investigated by quantitative methods to study PSTs' geometry content knowledge. For example the topic of geometry to focus, quadrilaterals were chosen according to the results from the qualitative investigation and suggestions from the literature.

3. Does use of geometry activities focused on quadrilaterals with analysis of student work influence elementary school preservice teachers' geometry content knowledge for teaching as measured by CKM-T?
4. Is there a difference in geometry content knowledge for teaching as measured by CKM-T between preservice teachers who are in a traditional mathematics methods course and preservice teachers who are in experimental mathematics methods course?

SETTINGS

This study took place in elementary mathematics methods course in a large south eastern public university in the U.S. This course plays an important role in PSTs' education because it is the only mathematics methods course for elementary school PSTs. Usually, there are three sections of the course for the spring semester whereas there are four sections for the fall semester. The qualitative investigation took place during the spring semester and the following quantitative investigation was conducted during the fall semester.

QUALITATIVE INVESTIGATION DATA SOURCE

The goal of the qualitative investigation was to understand PSTs' geometry learning and effective instructional practices to promote their learning. The results of this study informed teacher education practice to develop geometry practices for methods course to be used in the second phase (quantitative investigation). One student from each of the three sections of the elementary mathematics methods, Christiana, Emma and Liz (pseudonyms) participated in this investigation. The data collection included observations of geometry instruction in each section, and the collection of materials for the geometry instructions. Field notes were taken during the observations. The primary data source was individual interviews. The interview protocol was designed for semi-structured and open-ended narrative interviews. The narrative interviews are tailored to intrigue story telling from participants through open-ended questions or probes (Reissman, 1993).

QUALITATIVE INVESTIGATION DATA ANALYSIS

Individuals may use narratives for meaning making or for sharing their experiences (Reissman, 1993). Furthermore, teachers may prefer to discuss their learning and their knowledge through stories (Cortazzi, 1993). According to Labov (1972) a narrative has a structure and a sequence. If a narrative is fully formed, it has six components; *abstract, orientation, complicating action, resolution, evaluation, and coda*. The structure of the narratives gives insights about how the participants perceive their experiences. In addition to structural analysis of narratives, thematic analysis (Coffey & Atkinson, 1996) was used and the whole interviews were coded. Literature supports using other analysis methods in addition to narrative analysis in order to deepen the analysis of the rich data similar to the data of this study (Lloyd, 2005; Reissman, 1993).

QUALITATIVE INVESTIGATION FINDINGS

There were two main kinds of stories with sub headings emerged from participants' narratives: *stories as a learner* and *stories as a beginning teacher*. The thematic analysis yielded three themes from PSTs' geometry learning: *history of learning geometry, perceptions about geometry, and effective geometry instruction approaches*.

Narrative Analysis Findings

(a) *Stories as a learner*. Even though all three participants took one of the required mathematics courses, only Liz had taken the content course before the methods course. All three participants told stories from the mathematics courses they took and they expressed that those courses were as a review of high school mathematics rather than rigorous study of mathematics topics for elementary school. The stories of Liz from the content course reflect her concerns of limited mathematics (especially in geometry) learning and the lack of the connection to her teaching career.

(b) *Stories as a beginning teacher.* The beginning teacher aspect, being able to relate college education into teaching, was briefly expressed in the narratives from mathematics courses. For example, even though Liz's priority in that the content course was to learn mathematics as a student, she had thoughts about ways to transfer the presented knowledge into her teaching. Most of the stories of all three participants as a beginning teacher took place in methods course. Only one participant (Liz) was satisfied from her learning in the methods course. The other two participants expressed their frustration as the lack of the mathematical discussions and connection between content and the teaching methods (Emma) and the misguided flow of the course by moving to the more difficult topics before discussing easier topics (Christiana).

Thematic Analysis Findings

(a) *History of geometry learning.* Participants' background in geometry played an important role in their learning in college courses especially the methods course. All of them stressed the emphasis on algebraic topics in K-12 education with limited opportunities to learn geometry. Furthermore, they all perceive geometry as being different than mathematics because they have the perception of mathematics as algebraic topics.

(b) *Perceptions about geometry.* All the participants recognized the importance of visualization in geometry. Participants think geometry as a study of shapes and measurement features related to the shapes (such as area). Other important topics of geometry such as transformation were not mentioned by any of the participant. Even for the two dimensional shapes they expressed their limited knowledge in quadrilaterals. They classified topics of three dimensional shapes as difficult. Their limited experiences with geometry resulted in distorted perception of geometry.

(c) *Effective instructional approaches.* The mostly emphasized instruction approach was addressing geometry topics for elementary school in addition to the studying pedagogical aspects of those topics. Even tough, participants perceived college mathematics courses as reviews before the methods course, because those reviews did not provide desired understanding of in-depth geometry for elementary school, they were expecting content preparation from methods course too. Some instructional practices were highlighted from the data. Those practices were considered while developing the protocol.

QUALITATIVE INVESTIGATION DISCUSSION

All three of the participants stressed the importance of providing discussion on content before pedagogy. The content as noted by participants is not college level geometry, but geometry that they would be teaching. Especially Emma emphasized content preparation because in spite of the effective pedagogical preparation she could not relate to the ideas. This emphasis on learning geometry for teaching is parallel with MKT model (Ball et al., 2008) in terms of knowing mathematics in the

context of teaching. The second aspect was to progress from easy to more difficult topics. Because of participants' limited knowledge of geometry, they needed to study geometry from basic topics (e.g. 2-D shapes). Furthermore, they especially stressed that they could not learn classification of quadrilaterals in spite of studying that topic in college level courses.

DEVELOPMENT OF GEOMETRY PROTOCOL

The researcher developed a series of geometry activities to use in methods course for two weeks. The length of the protocol was limited because there were only two weeks for geometry topics. The topic of the activities was the classification of quadrilaterals as informed by the qualitative investigation. The first week of activities focused on content aspect of the topic whereas the second week focused on analyzing students' work in order to address geometry topics in the context of teaching. There were three groups of activities: sorting shapes, attributes of shapes, and classification of polygons. In addition to individual characteristics of the activities, the combination of them provided coherence. Participants worked individually, in pairs and small groups. The participants experienced geometry topics with visual representations. Also, the activities progressed through van Hiele geometric thinking levels. Therefore, the activities reflected suggestions from both literature and qualitative results. Kazemi and Franke (2004) suggested that the student work to be used to improve teachers' content knowledge should be challenging. In other words, the student work should show wrong student answers and misconceptions in order to intrigue teachers' discussions on mathematics topics. With this purpose, the researcher collected student work from local elementary schools with mathematically struggling students. The participants were given a protocol to study student work. The protocol was developed by suggestions from several resources (E. Kazemi, personal communication, August 17, 2008; NCTM, 2006). First in pairs, the participants discussed what the student did, what the student knew (and misconceptions), what they would ask the student in order to learn more about the student's knowledge of geometry. Then, in small groups (two pairs), participants discussed what they would do to teach these concepts to the student and how they would address the student misconceptions.

QUANTITATIVE INVESTIGATION DATA COLLECTION AND ANALYSIS

There were three instructors for four sections of the methods course for the fall semester. There were one hundred and seven students enrolled and 102 of them volunteered to participate in the study. All the participants were female. Two of the sections were assigned to be the treatment and other two to be the control groups.

All the instructors were teaching geometry for two weeks during the last third of the semester. The intervention took 90 minutes (half of one class meeting) of each geometry week. The remaining half of the time of class meetings were used to discuss other geometry topics.

The instrument to measure PSTs' geometry content knowledge, Content Knowledge for Teaching Mathematics Measures (CKT-M Measures)¹ was developed as continuum of research on mathematics knowledge for teaching (MKT) which provides the theoretical framework for this study. The instrument aims to measure elementary school PSTs' mathematics knowledge in the context of teaching. For this current study, only the geometry section of the instrument was used. Two parallel forms of the geometry section of the test were administered as pre and post test.

Participants completed the CKT-M Measures geometry test one week before their geometry instruction. For next two weeks they received the geometry instruction and the following week they completed the post-test. Both pre and post tests were administered at the beginning of the class. In order to address the last two research questions, geometry knowledge growth of treatment group and detection of any difference of knowledge growth between treatment and control groups, two different analysis methods, repeated measures ANOVA and mixed ANOVA, were used, respectively.

QUANTITATIVE INVESTIGATION RESULTS

In order to study the first research question, geometry knowledge growth of treatment group, repeated measures ANOVA was used. Results showed a significant change in participants' geometry content knowledge, $F(1, 49) = 16.08, p < .001, R^2 = .25, \eta^2 = .25$. This indicates statistically significant positive change in treatment group participants' geometry content knowledge. A mixed ANOVA method of analysis was conducted to study whether there was difference of knowledge growth between treatment and control groups. Results indicated a significant main effect of time $F(1, 91) = 28.38, p < .001$ but there was no significant interaction between time and grouping (treatment/control), $F(1, 91) = .21, p = .646$. The results showed that geometry knowledge of participants was increased significantly, however the grouping did not have any effect on participants' knowledge growth. It can be concluded that even though treatment group participants' geometry content knowledge growth was significant, the difference between treatment group and control group participants' growth in geometry content knowledge was not significant.

QUANTITATIVE INVESTIGATION DISCUSSION

The analysis of growth in treatment group can be interpreted as that use of the protocol developed from the previous studies resulted in significant increase in PSTs' geometry content knowledge. However, the control group results showed increase in PSTs who received regular instruction too. Even though treatment group participants' increase was more than the increase of control group participants, the difference was not statistically significant. However, it should be noted that the regular instruction for the control group also addressed the geometry topics from the perspective of learning mathematics in the context of teaching. During the geometry

instruction of the control group, the researcher observed the control group instruction. For further research, the control group instruction designed not to address geometry in the context of teaching may provide further information on affect of using the protocol with PSTs. Furthermore, using student work with PSTs to promote their content knowledge might not be as effective as using them with in-service teachers (e.g. Driscoll et al., 2009). In the case of in-service teachers, participants first experience teaching the materials and then analyze student work. On the other hand, in the case of PSTs, participants only experience the materials without teaching them. Therefore, this study might start the discussions on the role of actual teaching of the materials before analyzing student work.

CONCLUSIONS

Therefore, this study provides further understanding on teacher' geometry content knowledge. It informs mathematics teacher education in three important points. For the qualitative investigation, PSTs reported that they have limited geometry knowledge as previous research studies have showed (Jones, 2000; Swafford et al., 1997). Since PSTs perception of geometry for elementary school is limited to the 2-D shapes, it may be suggested to conduct further studies on geometry content knowledge of PSTs for other geometry topics too. Lastly, use of student work in PST education may not lead to similar results as using with in-service teachers.

HOW TO PROMOTE SUSTAINABLE PROFESSIONAL DEVELOPMENT?

Stefan Zehetmeier & Konrad Krainer

University of Klagenfurt, Austrian Centre for Instructional and School Development

ABSTRACT. *The paper deals with the sustainable effectiveness of professional development programmes. This article links theoretical considerations with research findings a case study about a secondary mathematics teacher, who took part in the Austrian nationwide teacher professional development programme IMST² in 2002. The case study's results provide information regarding the teachers' professional growth and the sustainable effects of the professional development programme. The paper also discusses implications for the design of teacher professional development programmes.*

Keywords: Sustainability, professional development, effectiveness, case study, long-term impact of innovations.

INTRODUCTION

Evaluations of long-term impact of innovations or programmes are well established in disciplines like health promotion, social medicine, or management research (e.g., Lawrence, Winn, & Jennings, 2001; Pluye, Potvin, & Denis, 2004; Scheirer, 2005). Goals and sustainable outcomes of teacher professional development programmes are of great interest, in particular for both the participating teachers and the facilitators. Despite its central importance, research on this issue is generally lacking within the educational disciplines (Datnow, 2006; Rogers, 2003).

LITERATURE REVIEW AND THEORETICAL FRAMEWORK

In most papers that put an emphasis on the impact of teachers' professional development programmes, *teachers' learning* is the main focus (see e.g., Guskey, 2000; Lipowsky, 2004, 2010; Sowder, 2007; Zehetmeier, 2008). The major indicators for describing teachers' learning are their knowledge, beliefs, and practice. However, the situation is rather complex since each of these notions can be defined in different ways:⁹¹

Teachers' knowledge, for example, can be differentiated into content knowledge, pedagogical knowledge, and pedagogical content knowledge (Shulman, 1987); but it can also be regarded as knowledge about learning and teaching processes, assessment, evaluation methods, and classroom management (Ingvarson, Meiers, & Beavis, 2005); other foci are expressed by the notions of attention-based knowledge (Ainley & Luntley, 2005) or knowledge of mathematics for teaching (Ball, 1990).

⁹¹ See more detailed in Krainer and Zehetmeier (2008).

Similarly, *teachers' beliefs* can include different aspects of beliefs about mathematics as a subject, and its teaching and learning (Leder, Pehkonen, & Törner, 2002). It includes also the participating teachers' perceived professional growth and their satisfaction (Lipowsky, 2004, 2010), their perceived efficacy (Ingvarson et al., 2005), and the teachers' opinions and values (Bromme, 1997). At the *teachers' practice* level, the focus is on various kinds of classroom activities and structures, teaching and learning strategies, methods, or contents (see e.g., Ingvarson et al., 2005).

Zehetmeier (2008) points out that the complexity of possible impact is not fully covered by this taxonomy. For example, results of an impact analysis (Zehetmeier, 2010b) in the context of an Austrian professional development project (see e.g., BMUKK, 2010; Krainer, 2008; Pegg & Krainer, 2008) show that the project made impact also on students' beliefs or other – non participating – teachers' practice. So the taxonomy of levels of impact needs to be extended. Other aspects that also could be considered are the *learning of teacher educators* and of *other relevant environments* of professional development programmes, like participating teachers' colleagues, their principals, their school, etc.

A model that comprises this rather wide range of possible levels of impact is the IPD-model (Impact of Professional Development model; Zehetmeier, 2008, 2009, 2010b, see Figure 1):

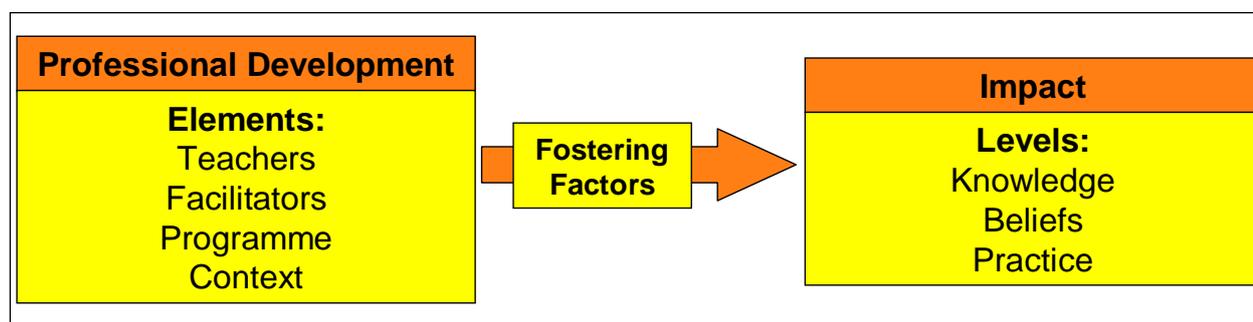

Figure 1: The IPD-model

This model uses the categories knowledge, beliefs, and practice to analyse the impact not only on the teachers' level but also on other in-school levels like pupils, colleagues, principals, or parents. Moreover, this model considers beyond-school levels to analyse the impact of professional development projects: e.g., other schools, media, policy, or scholarship (see Zehetmeier, 2010b). Besides this extended taxonomy of possible levels of impact, the IPD-model also includes an overview concerning factors fostering the impact of professional development projects (see e.g., Zehetmeier, 2010a). Moreover, the IPD-model opens the scope for various types of impact (e.g., short-term or long-term; planned or unintended) on different levels (e.g., new knowledge, changed beliefs, or new teaching practices).

BACKGROUND: THE AUSTRIAN IMST² PROJECT

The initial impulse for the IMST² project (Innovations in Mathematics, Science and Technology Teaching) in Austria came from the 1995 TIMSS achievement study. In particular, the results of the Austrian high school students (grades 9 to 12 or 13) in the TIMSS advanced mathematics and physics achievement test, shocked the public. The responsible federal ministry launched the IMST research project (1998-1999) in order to analyse the situation.

The research identified a complex picture of diverse problematic influences on the status and quality of mathematics and science teaching. Mathematics education and related research was seen as poorly anchored at Austrian teacher education institutions. Subject experts dominate university teacher education, other teacher education institutions show a lack of research in mathematics education; the collaboration with educational sciences and schools is – with exception of a few cases – underdeveloped. A competence centre like those established in many other countries was not existent. Also, the overall structure (including two institutions for the education of prospective teachers that are mostly unconnected, a variety of different kinds of schools with corresponding administrative bodies in the ministry and in the institutions for the education of practising teachers, etc.) showed a picture of a “fragmentary educational system” of lone fighters with a high level of (individual) autonomy and action, however, there was little evidence of reflection and networking. The situation in science education was even worse.

The analyses mentioned above led to the four year project IMST² (2000-2004). The project focused solely on the upper secondary school level and involved the subjects, biology, chemistry, mathematics and physics. The two major tasks of IMST² were (a) the initiation, promotion, dissemination, networking and analysis of innovations in schools (and to some extent also in teacher education at university); and (b) recommendations for a support system for the quality development of mathematics, science and technology teaching.

In order to take systemic steps to overcome the “fragmentary educational system”, the approach of a “learning system” (Krainer, 2005) was taken. It adopted enhanced reflection and networking as the basic intervention strategy to initiate and promote innovations at schools.

Besides stressing the dimensions of reflection and networking, “innovation” and “work with teams” were two additional features. Innovations were not regarded as singular events that replace an ineffective practice but as continuous processes leading to a natural further development of practice. Teachers and schools defined their own starting point for innovations and were individually supported by researchers and expert teachers. The IMST² intervention built on teachers’ strengths and aimed at making their work visible (e.g., by publishing teachers’ reports on the website). Thus teachers and schools retained ownership of their innovations. Another

important feature of IMST² was the emphasis on supporting teams of teachers from a school.

Teachers' participation in IMST² was voluntary and gave them and their schools a choice among several priority programmes (e.g., "basic education" or "teaching and learning processes") according to major challenges concerning mathematics and science teaching. In general, teachers in these priority programmes were supported by mathematics and science educators and experienced teachers. The priority programmes can be regarded as small professional communities that not only supported each participant to proceed with his or her own project but also generated a deeper understanding of the critical reflection of one's own teaching, of formulating research questions, of looking for evidence based on viable data, and on methods that help to gather that data.

METHOD

In 2005, eleven case studies (Stake, 1995; Yin, 2003) were generated to describe and explain specific aspects regarding the impact of the IMST² project (Benke, Erlacher, & Zehetmeier, 2006). In 2010, all these case studies were revisited to analyse the project's impact five years later (Zehetmeier, in preparation). For this purpose, semi-structured interviews were again conducted with the teachers who formerly took part in the IMST² project; interviews were also conducted with the teachers' respective colleagues, schools' principals, and former project facilitators.

The data gathered in 2010 was analysed according the IPD-model (Zehetmeier, 2008, see above) and contrasted with the 2005 case studies' results. This comparison allows a thorough discussion of the following questions: Which of the 2005 impact was still effective in 2010? Which were the respective fostering factors? Which impact did disappear within the last five years? Which were the factors hindering the sustainability of impact?

In this paper, exemplary results from one of these studies (the case of Barbara⁹²) are provided to discuss the question about effective ways of promoting sustainable mathematics teachers' professional development. Thus, this study provides insight going beyond the evaluation of short-term effects of a particular professional development programme. In fact, the study analyses and discusses various levels of impact and their respective fostering factors that occur more than eight years after the programme's termination. The objective of this research is not to evaluate the respective professional development programme (which was not explicitly designed to have sustainable impact, but to support teachers for the time they are participating). Rather, the case study aims to analyse, why some impact is sustainable, while other effects disappear after the programme's termination. In other

⁹² The teacher's name is a pseudonym.

words, the particular professional development programme is rather the case study's frame, not its focus.

We decided to use a case study approach for this research, because they are particularly suited for analysing the impact of innovations: "The usual survey research methods are less appropriate for the investigation of innovation consequences. [...] Case study approaches are more appropriate" (Rogers, 1995, p. 409). Similarly, Hancock and Algozzine (2006) state: "Through case studies, researchers hope to gain in-depth understanding of situations and meaning for those involved" (p. 11). The case study presented here is *historic* (Merriam, 2001), *intrinsic* (Stake, 1995) and *explaining* (Yin, 2003), since it analyses the teacher's developments over time, focuses on the particular teacher's case, and quests for her professional developments' fostering conditions.

The case study includes data from varying sources and dates to gain validity by "convergence of evidence" (Yin, 2003, p. 100): Collection of data was done during 2002 and 2006 and contained both documents (teacher's annual written project reports), archival records (first author's artefacts), and open-ended and structured interviews (with teacher, project facilitator, colleagues, and principal).

Creswell (2007) has identified eight verification procedures for qualitative studies and recommends that qualitative researchers engage in at least two in any given study. Four of these verification procedures were present in this study: *prolonged engagement*, *triangulation*, *negative case analysis*, and *rich description*: The contact with the teachers has spanned more than one year in the contexts of teaching and coursework, and the time span under research lasted for more than eight years (*prolonged engagement*). Our data came from a variety of sources (*triangulation* by convergence of evidence, see above). We refined our results with regards to disconfirming evidence until we eliminated any disagreements among the findings (*negative case analysis*). Finally, the case study provides detailed information on all persons and activities relevant for this research (*rich description*).

The data were analysed by qualitative content analysis (Mayring, 2000) in order to identify common topics, to elaborate emerging categories, and to gain deeper insight into teacher's professional growth over time.

RESULTS

The case study's results point to different levels of impact of the IMST² project (e.g., teachers' knowledge, beliefs, or teaching practices), that endured over time, even after the project's termination. In the next sections, the 2005 case study's results are contrasted with the recent 2010 data. This allows discussing the question, which of the 2005 impact was still there in 2010. For the sake of reducing complexity, these results are presented according Zehetmeier's (2008) levels of impact (see also Figure 1, above).

Barbara's knowledge

Barbara took part in the IMST² priority programme “teaching and learning processes” during the school-year 2001-02. Barbara integrated open learning environments into her mathematics classes. The 2005 case study showed various results concerning long-term effects, for example regarding Barbara's *knowledge*: She learned that open learning environments had positive effects on pupils' content knowledge, as well as on their self confidence. In particular, there were positive changes regarding low-performing pupils' self esteem, as well as concerning the further development of high-performing pupils' competences. Moreover, Barbara's pupils stated to have more fun and less anxiety in her mathematics lessons. This impact was sustainable: Barbara still used this knowledge in 2005 and 2010. Her expertise and her knowledge regarding open learning environments enabled her to create and implement innovative teaching methods. For example, since Barbara knows about the importance of time resources for these open settings, she is very conscious of providing enough resources in each implementation phase. The school's principal stated: “This had very positive effects on the didactics of our mathematics lessons. In particular, the open learning settings represent sustained impact” (Principal, 2005, interview).

Another impact was Barbara's *new knowledge* regarding the activities of teachers from other schools. During her participation in IMST², she had the opportunity to network with and to learn from colleagues teaching at other schools. The teachers met in seminars, workshops, and conferences organised by the IMST² project. Moreover, all teachers wrote project reports which were distributed mutually. “This was a very useful source of ideas. I got motivation and suggestions to try similar things in my classroom” (Barbara, 2010, interview). Similarly, the principal valued these project reports as „a basis for good ideas and comparisons” (Principal, 2005, interview). This impact was not sustainable. After the projects' termination, there was no opportunity to exchange (as easy) with colleagues from other schools, nor were there any written project reports.

Barbara's beliefs

On the level of Barbara's *beliefs*, she developed a reflective stance towards the content and the method of her teaching; she stated: “Now I see the value of letting the pupils work self-dependently and I am aware of the importance to reserve extra time for this” (Barbara, Interview, 2005). This stance was mirrored by her belief about the value of feedback: Topics like classroom atmosphere and teaching quality were discussed with her pupils on a regular basis: “Now I see the value of discussing questions of good mathematics teaching together with the pupils” (Barbara, 2005, interview). This impact was sustainable: In 2005, as well in 2010, Barbara was convinced of the importance of critically evaluating one's own teaching. “It is important to reflect on good and problematic aspects of my work” (Barbara, 2005, interview).

Barbara's practice

Also on the level of her *practice*, the project caused some impact: Barbara actively facilitated her pupils' cooperation and communication, because: "The pupils learn much more when they work in groups autonomously and when they experience that they can solve the tasks for themselves" (Barbara, 2005, interview). This impact was sustainable: Even after the projects' termination, Barbara provided time for her pupils' open learning: "This remained: I facilitate their individual work and provide time for this. (...) I have the courage to do so" (Barbara, 2010, interview).

Another impact regarding Barbara's *practice* was the use of evaluation methods. For example, she used questionnaires in order to learn about her pupils' perspectives and used tape recordings in order to gain new insight into her pupils' competences or difficulties. This impact peaked off. Barbara still used questionnaires after the end of her participation in IMST², but not as often as during the project phase. Tape recordings were no longer used: "During IMST², there were smaller classes with fewer pupils, so I could manage the recordings. Now, in classes with over 30 pupils, this is not possible any more" (Barbara, 2010, interview).

Barbara's colleagues' practice

Going beyond Barbara's individual level, there were also effects on the level of her *colleagues' practice*. For example, a system of mutual exchange and teaching observations between Barbara and her colleagues was established within the school. "Even after two years, this system of mutual classroom visitations is still in progress – without being imposed by the principal or school administration, just because we all know its value" (Barbara's colleague, Interview, 2005). In 2010, this system of mutual feedback is persisting. However, the number of participating teachers peaked off, because "now, this immediate need is no longer given. The most important and interesting things are already said" (Barbara's colleague, 2010, interview). In particular, the school's novice teachers gladly make use of this opportunity to learn from their experienced colleagues. Similarly, Barbara stated: "This peaked off. The colleagues can do it, if they want. But this opportunity is no longer used as often as in the first years after the project's termination" (Barbara, 2010, interview).

DISCUSSION

Even though Barbara's project was not explicitly designed to have sustainable impact, the case studies' findings show that more often than not the effects could be sustained over eight years. Some other levels of impact disappeared as the professional development project was over. One explanation for this finding is that some of the respective fostering factors are tightly bound to the existence of the professional development project, while others are not.

Another highly important question, that should be considered in the conception of professional development projects, is: Which of the influencing factors can actually

be controlled or affected by the professional development project? (And which cannot?) Maybe the most important factors lie beyond the project's realm. In this case, it could also be reasonable to look out for alternative and supplementary factors that can be provided and influenced by the project itself.

To sum up: Professional development projects with the objective to cause sustainable impact should be designed by carefully considering the following questions

- Which factors are dependent from the project itself?
- Which factors are located beyond the project's realms?

For professional development projects to be sustainable, it is crucial to carefully consider the fostering and hindering factors. This implies to know these factors and to be sensible for them. Considering and facilitating these factors when designing and implementing professional development projects is one important step on the journey to effective in-service teacher professional development. The next step should be to enhance further research and evaluation to get new results regarding the relevance of these factors. These findings should be again integrated into the conception of future projects. In sum, this can lead to a virtuous circle towards the goal of effectively promoting sustainable mathematics teachers' professional development.

CONCEPTS FROM MATHEMATICS EDUCATION RESEARCH AS A TRIGGER FOR MATHEMATICS TEACHERS' REFLECTIONS

Mario Sánchez

National Polytechnic Institute, Mexico

This article reports part of a research project that attempts to identify the elements of an online course that promote the emergence of teachers' reflections. A definition of reflection that is helpful to identify instances of reflections that appear spontaneously in an online course is used in the study. Elements of the documental approach (Gueudet & Trouche, 2009) are applied to try to establish connections between components of the design of an online course and the emergence of teachers' reflections. The main finding presented is that concepts from mathematics education research can help teachers to see their own teaching practice from a different perspective and thus stimulate reflexions in them.

Keywords: Reflection, online mathematics teacher education, research literature as a tool for teacher development.

INTRODUCTION

This paper reports part of a research project focused on identifying some of the elements in the design of an online course that promote the emergence of reflections in in-service mathematics teachers (see Sánchez, 2010a). In particular, this article addresses the following research question:

Which non-human elements of an online course promote the emergence of mathematics teachers' reflections?

The previous research question is located at the intersection of two sub-areas of research within the field of mathematics teacher education research, namely, *reflective thinking* and *online mathematics teacher education*. Its scientific relevance lies in trying to identify components of an online course that have the potential to encourage the emergence of teachers' reflections, which in turn are considered as an important element for the development of mathematics teachers (see for example Ticha & Hospesova, 2006).

This research was developed in an online mathematics teacher education program, aimed at in-service mathematics teachers working at different educational levels, and coming from all over Latin America¹.

CONCEPTUAL FRAMEWORK

In this section I clarify the key terms that are involved in the research question, but I also refer to the theoretical constructs that I used to address such question.

What is an online course?

An online course is a course that is based on the use of the Internet. This means that the content and the activities of the course are delivered via the Internet. The participants in this type of course do not meet physically to interact and discuss. All the interaction and communication within the course are carried out by using the Internet and related communication tools such as email, discussion forums, audio and video conferencing.

Human and non-human elements

Another key term is *non-human elements of an online course*. I perceive the structure and content of an online course as an amalgam of human elements and non-human elements. I use the term human elements to refer to the people who participate in an online course. In the context of this study, the human elements are the mathematics teachers and the teacher educators who are participating in an online course. When I use the term non-human elements I refer to the resources that a participant in an online course interact with, but which are intentionally provided by the teacher educator. These are resources that are part of the design of an online course. The resources can be of different nature: software, video, activities, articles, audio files, web pages. The two main characteristics of the non-human elements of an online course are: (1) they are elements that are intentionally provided by the course designer. The designer has control over them in the sense that he/she decides when and how they will appear within the course; and (2) they are elements that serve to represent and communicate mathematical and/or didactical ideas that are considered relevant to mathematics teachers' development.

I find relevant to differentiate between human elements and non-human elements of an online course, because the latter are more likely to be controlled by the designer of an online course. That is, although it could be possible to identify some of the human elements in an online course that favour the emergence of reflections (for example, attitudes or types of human interactions), such elements cannot be easily controlled and regulated within an online course.

Reflection

A central theoretical construct used in this study is reflection. I think of *reflection* as a mental process by which our actions, beliefs, knowledge or feelings are consciously considered and examined. To reflect involves more than just recalling or considering something consciously. A process of reflection provides enlightenment about the actions or ideas that are being considered. A process of reflection involves a kind of "Aha! moment" in which something is discovered or revealed.

Comparing my definition of the concept of reflection

A fundamental similarity between my definition of the concept of reflection and other definitions that can be found in the specialized literature is that reflection is

interpreted as a mental process in which *something* is considered or examined in a conscious way. I wrote “something” using italics because many researchers in mathematics teacher education usually interpret such “something” as the act of teaching. In other words, researchers in mathematics teacher education lay particular emphasis on the kind of reflections that are anchored in teaching practice. The widespread use of video recordings in reflection research, through which teachers are asked to analyse classroom episodes, can be considered as an evidence of the emphasis on reflection on teaching practice (see for example Stockero, 2008). The extensive use of theoretical concepts such as reflection-for action, reflection-in-action and reflection-on-action is another kind of evidence of this emphasis on teaching practice (see for example Scherer & Steinbring, 2007). However, in my interpretation of the concept of reflection not only the teaching practice can be the focus of a reflection. You can also reflect on your mathematical knowledge, on the role and application of mathematics in non-mathematical contexts or even on your own feelings and values.

An important difference between my definition of the concept of reflection and other definitions that can be found in the literature is that, in my definition, emphasis is placed on the stage of discovery or revelation (the “Aha! moment”) that a reflection can produce. I decided to include the Aha! moment in the definition of reflection on methodological grounds. This point is discussed in the methodology section of the article.

Documentational approach

In order to answer the research question it was necessary to investigate the possible connections between the components of an online course and the emergence of mathematics teachers’ reflections. I used the documentational approach (Gueudet & Trouche, 2009) to investigate such connections. This theoretical approach is adequate to address the research question because it helps to study the “effects” that the different resources that a teacher interact with (books, webpages, notes, discussions with colleagues, etc.), produce in his/her practice and schemas. Thus, I used the documentational approach to try to identify the non-human elements of an online course that produced teachers’ reflections. The concepts of *instrumentation process* and *documentational orchestration* were particularly useful for the study.

In the documentational approach it is claimed that the professional development of mathematics teachers can be tracked by focusing our attention on the activities that mathematics teachers develop outside the classroom, but that influence their work within the classroom. The focus is particularly centred on *teachers’ documentation work*. That is, the interaction between the teachers and a set of elements that allows them to shape and define their work in the classroom. Expressions of such interaction are for example: to extract examples and exercises from a textbook in order to include them in their lesson plans; to analyse their students’ mathematical productions; to listen to the suggestions, ideas and experiences from colleagues; to

review the contents of a website that contains educational materials; to study a curriculum reform to be applied in their own school, etc. The set of elements with which a teacher interacts during her documentation work is called *resources*.

In the documentational approach it is argued that, when an interaction between a teacher and a set of resources takes place, a *documentational genesis* (DG) may appear. The concept of DG can be interpreted as an analogy of the concept of instrumental genesis (Trouche 2005) applied to the field of mathematics teacher education. Like the instrumental genesis, the DG is a two-way process in which the teacher appropriates and/or modify the set of resources with which she interacts (this part of the process is called *instrumentalization*), but the set of resources also shapes and influences teacher's activity and way of thinking (this part of the process is called *instrumentation*). The latter concept was used to try to establish links between the non-human elements of an online course and the emergence of reflections.

Finally, a *documentational orchestration* (DO) can be defined as the selection and arrangement of resources that a teacher educator (or a group of teacher educators) carry out with the intention of facilitating teachers' documentation work. Such documentation work is aimed at contributing to the development of teachers' professional knowledge.

METHODOLOGY

In order to answer the research question, I designed an online course which had the scientific aim of promoting the emergence of teachers' reflections, and thus help me to study the influence of the non-human elements of the course on the emergence of such reflections. Three methodological challenges were identified at this stage: (1) to determine what non-human elements were likely to stimulate teachers' reflections (in order to include them as part of the course design); (2) if reflection is an entity that is not directly observable, how to detect a reflection in an online setting?; and (3) how to establish connections between the non-human elements of a course and the emergence of reflections?

To address the above-mentioned points (1) and (2), I conducted a literature review on the concept of reflection in mathematics teacher education research (see Sánchez, to appear). In this review I analysed, among other things, (a) what kind of methodological tools are used to detect a reflection, and (b) what type of elements or conditions have been identified as promoters of teachers' reflections. The information obtained in (a) and (b) was used as inspiration to devise a strategy to promote and identify teachers' reflections in an online setting. To try to establish the connections mentioned in point (3), I applied the concepts of documentational orchestration and instrumentation process. Next I illustrate these points.

Stimulating reflections in an online setting

Several elements were identified in the literature review as promoters of reflections, but only three of them were considered in the design of the course because of their applicability in an online setting. Here I refer to the act of writing, the availability of time, and the reading of mathematics education publications.

Several researchers claim that the *act of writing* is a vehicle for reflection. For example Ponte & Santos (2005) assert: “[W]riting is a powerful way of reflecting, helping teachers to clarify ideas, to look at them from different angles, to come back and revise; the steadiness of the written word also seems to provide more depth to the ideas” (p. 123). I also found that *the relevance of time* in the emergency and the depth of a reflection has been highlighted by several researchers: For instance Sowder (2007) underlines: “[T]ime is needed for developing the ability and habit of reflection. Reflection rarely occurs when time is not a resource available to teachers” (p. 198). These two elements, the act of writing and the availability of time, were considered in the design of the course through the inclusion of asynchronous discussion forums. In this kind of forum people interact through the exchange of written messages. Here the feedback or responses to your written messages and comments are not received immediately. You can post a question in a discussion forum and get an answer some hours or even days later. The asynchronous interactions usually last several days, allowing the participants to have more time to formulate their opinions and to consider the comments and opinions expressed by the other participants. The comments and discussions expressed in the asynchronous discussion forums were the main empirical evidence used in this investigation

Researchers like Shari L. Stockero suggest that the *reading of mathematics education publications* is another activity that improves the level of reflection: “Course readings, for example, exposed the PTs [prospective teachers] to alternative ideas that allowed them to begin to think about learning mathematics in ways other than how they had learned as students. Without these readings to draw upon, the PTs may not have had the tools necessary to reflect at higher levels” (Stockero, 2008, p. 391). Thus, I decided that the structure of the online course should include some sort of writing produced within the community of mathematics education research.

Detecting reflections in an online setting

In the literature review that I conducted it was found that sometimes researchers explicitly ask teachers to produce reflections. This is usually done through the application of questionnaires or through some sort of written assignment. Let me present the following quotation as an illustration of this practice:

“[T]he PTs [prospective teachers] were required to write a paper in which they reflected on their experience by analyzing how they as the teacher helped or hindered the development of students’ mathematical understanding of the problem” (Stockero, 2008, p. 378).

I think that this way of identifying reflections is somewhat artificial. I was interested in identifying reflections that could appear more spontaneously. This was one of the reasons why I decided to include the “Aha! moment” as part of my definition of reflection. My intention was to use the “Aha! moment” as an indicator that the teacher had experienced a reflection. Another reason for using the “Aha! moment” was to avoid confusing instances of reflection with instances of remembering or recalling. The “Aha! moment” indicated to me that the teacher had done more than just remembering. It indicated me that the teacher had discovered or learned something based on the explicit consideration of his/her actions or values.

Establishing connections between non-human elements and reflections

To try to detect the possible connections between the emergence of reflections and the non-human elements of the online course that I designed, I did the following: Firstly, I ordered the set of non-human elements (which in terms of the theory can be called “resources”) of the course into stages. Each stage had a particular purpose and comprised a particular subset of resources. I explicitly defined the resources that each stage should contain, and the function and location of the stages within the course. I have called this sort of arrangement *documentational orchestration* (see Sánchez, 2010b).

When the course was being implemented, the concept of reflection was applied to identify teachers’ reflections within the asynchronous discussion forums. It was necessary to read and reread several times each utterance within a forum in order to become familiar with its contents. While I was trying to get familiar with the contents of a specific discussion, I also focused on locating the moments of an interaction that could be labelled as reflections, according to my own definition of the concept.

After having these two sets (the set of ordered resources and the set of teachers’ reflections), I focused on observing the instrumentation and instrumentalization processes that appeared between these two sets (Gueudet & Trouche, 2009). That is, it was studied how teachers used the resources (instrumentalization processes), but the kinds of effects that the resources produced on teachers (instrumentation processes) were also observed. When the effect produced by an instrumentation process was a reflection, then the development of such process was analysed “backwards” in order to identify the particular resource that produced it.

DATA ANALYSIS

The course that was designed for this study was an in-service course on the use of technology in mathematics teaching. The didactical aim of the course was to make teachers aware of the potential changes that may occur in the mathematics classroom when the use of CAS technology is introduced.

During the course, teachers were solving different mathematical tasks (algebraic factorisations, for example), and comparing techniques based on the use of CAS and techniques based on the use of paper-and-pencil. Then they discussed their experiences obtained through these comparisons in asynchronous discussion forums.

Due to space limitations, it is not possible to describe each of the stages that constituted the course. I will only refer to the latter stage of the course in which the teachers read and discussed the paper by Lagrange (2005). The aim of this stage of the course was to make teachers to compare the experiences that they obtained when using CAS and paper-and-pencil techniques during the course, with the ideas and concepts included in the article.

Two of the main theoretical concepts included in Lagrange (2005) are the pragmatic and the epistemic value of a technique that is based on the use of technology. The *pragmatic value* of a technique refers to the efficiency and economy (of time, of effort) with which a technique helps to solve a mathematical task. For example, the pragmatic value of any CAS software may be related to the speed and efficiency with which the software performs algebraic factorisations. The *epistemic value* of a technique refers to its potential to serve as a means to understand the mathematical objects involved in the application of the technique. For instance, the epistemic value of CAS-based techniques may be related to the fact that such techniques allow a more experimental approach to elemental algebra, where students can explore several particular cases of the factorisation of an algebraic expression ($x^n - 1$, for example) and produce conjectures about the general factorisation of the expression.

After analysing the teachers' asynchronous discussions produced during the initial stages of the course, it became clear that many of them only acknowledged the pragmatic value of CAS techniques. In other words, teachers perceived CAS software as a tool that facilitates the execution and verification of algorithms, but not as a tool that can serve as a means for mathematical inquiry and the construction of mathematical knowledge. See for instance the following comment expressed by a teacher called Francisco³:

I agree with Rosa on the usefulness of the calculator in the sense that it saves a lot of work [...] In general, when there is a discussion on this topic I always conclude that it is important for students to first learn the methods by hand, let us say pencil and paper. [...]

However, eight days later, and after reading Lagrange's paper, this same teacher expressed the following reflection in an asynchronous forum:

Until I read Lagrange's article I only applied it [the technology], using the terminology of the article, in a pragmatic way. I even felt that without a prior knowledge the use of tools such as CAS and/or calculators did not help to generate learning, i.e., I did support the use of these tools but apparently only attaching value to their pragmatic aspect. In integral calculus I encouraged the use of these tools in all the required calculations up to derivation. In differential equations I incentivise its application in the calculation of

integrals and so on. So I was very surprised that the article emphasises the epistemic aspect of these applications. Partly he was right, because the epistemic application apparently requires planning and construction of new specific activities that do not arise naturally from the teaching with paper and pencil. I would like to conclude this contribution leaving the reflection and concern of how a methodology for applying the epistemic value should be.

RESULTS AND FINAL DISCUSSION

My interpretation of the reflection mentioned in the last section is that such reflection was triggered by the interaction between Francisco and the contents of the article Lagrange (2005). The theoretical concepts contained in Lagrange's paper were the only non-human resource identified in the study as trigger for mathematics teachers' reflections. Thus, a possible answer to the research question posed at the beginning of this paper is that theoretical concepts from mathematics education research can promote the emergence of mathematics teachers' reflections.

I try to be cautious and say that it is a "possible" answer because I did not obtain more empirical evidence to confirm that the theoretical concepts contained in mathematics education articles are non-human elements that promote the emergence of reflections. The lack of more instances of reflections to support this conclusion can be caused by the definition of reflection applied in the study. Such definition is restrictive in the sense that requires the appearance of an Aha! moment. The definition for example is not appropriate for detecting reflections that are internally experienced by the individual, but which are not expressed externally by an Aha! moment.

I however claim that the answer to the research question is likely to be a result with some degree of generality. I claim this because there are other studies where it is also argued that the study of concepts and theories from mathematics education research promotes critical reflection on our own beliefs and practices as mathematics educators (see for example Even, 1999 and Tsamir, 2008). If one accepts that the theoretical concepts from mathematics education research have the potential to encourage the emergence of teachers' reflections, then a question naturally arises: what kind of theoretical concepts must be used for this purpose? Tsamir (2008) raises similar questions, without providing a specific answer. Of course these questions deserve further investigation, however, it is possible to formulate a hypothesis: I believe that the type of theoretical concepts that can help teachers to reflect on their own practice and values, must be concepts that seem applicable to them. In other words, teachers need to find some relationship or application between such concepts and their own teaching practice. Thus, it is likely that theoretical concepts with little or no relation to teachers' practice will not serve for this purpose.

TEACHER COMPETENCES PREREQUISITE TO NATURAL DIFFERENTIATION

Marie Tichá, Alena Hošpesová

*Institute of Mathematics of the Academy of Sciences of the Czech Republic,
University of South Bohemia České Budějovice*

The paper describes our work with pre-service primary school teachers focusing on development of their ability to cope with heterogeneity in mathematics classroom. In our experiment students were introduced to three substantial learning environments: Way, Room, Mosaics. The students' task was to (a) pose problems supporting natural differentiation and (b) identify the substantial mathematical ideas inherent in these environments. Similarly, we worked with a group of teacher educators and researchers, in which case we focused primarily on development of properties of the concept of natural differentiation.

Keywords: mathematics education, teacher training, subject knowledge, natural differentiation

INTRODUCTION

It has been stressed in a variety of contexts that mathematics forms an integral part of many different spheres of life. That is why the importance of mathematics education and of achievement of functional mathematical literacy is growing. This makes considerable demands on teachers' knowledge of the subject and on their pedagogical skills and techniques, i.e. on their professional competences. There is no doubt that teachers must be helped on their way to enrich, develop and refine their professional competences. Therefore over the last years, we have searched for ways of facilitating the enhancement of teachers' professionalism (Tichá & Hošpesová, 2006).

Our research clearly shows that the quality of education greatly depends on the subject didactic competence of the teacher, i.e. on knowledge both of the content and its didactic treatment and on the application of this knowledge in school practice (Tichá & Hošpesová, 2010). This paper discusses a different area of our recent research, namely some of the aspects of coping with heterogeneity of pupils. It is another competence that teachers must master in order to create favourable conditions for the development of their pupils' educational potential.

THEORETICAL BACKGROUND

Natural differences between children; the need of individualization and differentiation

It is a generally accepted fact that there are differences in how children learn that they need different lengths of time to master the same subject matter under the same

conditions with peers and with the same teacher (e.g. Jonassen & Grabowski, 1993). That is why an increasing number of educators and teachers try to apply the principles of individualization in teaching. Individualization is closely connected to differentiation. Educators looked for and proposed various methods of external and inner differentiation which would respect the differences between pupils and their individualities, and whose objective is optimum pupils' development (Skalková, 1999).

Natural differentiation is one of the forms of inner differentiation. The roots of our interest in this issue go down to the solving of the just finished Comenius project "Motivation via Natural Differentiation in Mathematics" (NaDiMa). We found important sources of motivation in the works of Wittmann (1995), Scherer and Krauthausen (2010). They use such an approach to the issue of heterogeneity in teaching in which differentiation is not perceived as an obstruction but as something natural and in some aspects also beneficial and challenging.

"Usually, measures on differentiating are pre-determined by the teacher. In contrast, when using natural differentiation the topic as such enables the children to choose their own level to work on. The same learning offer for all children is one constituent characteristic of natural differentiation (the teacher being responsible for the subject-related framing). Further constituents are a holistic content-related learning offer with a sufficient level of complexity (i. e. complex tasks, e. g. in the form of a research or exploration assignment; see below), the free choice of solution strategies and manipulatives and, where applicable, free choice of the tasks as well as the form of presentation (oral or written) within the framework of social conventions (Wittmann/Müller 2004, p.15)." (Krauthausen, Scherer, 2010, authors' translation).

In addition to allowing children to work at their own level, such problems also facilitate social aspects of learning. In this approach, during the concluding discussion pupils present their solving procedures and their result and justify them. The possibility to solve the same problem on different levels is beneficial for the weaker and slower as well as for the highly talented pupils. The pupils on lower level acquire new knowledge in the final discussion and move to a more advanced level, the talented pupils are generally led to look for and apply new approaches.

Substantial learning environments

If we want to enable and support natural differentiation, we must try to foster such a learning environment in which there are inherent tasks and problems that all pupils will be able to handle, albeit on various levels. Wittmann puts emphasis on the creation of *substantial learning environment* (SLE). SLE is

„a teaching/learning unit with the following properties: (1) It represents central objectives, contents and principles of teaching mathematics at a certain level. (2) It is related to significant mathematical contents, processes and procedures beyond this level, and is a rich source of mathematical activities. (3) It is flexible and can be adapted to the

special conditions of a classroom. (4) It integrates mathematical, psychological and pedagogical aspects of teaching mathematics, and so it forms a rich field for empirical research.” (Wittmann, 1995, 365/366)

The characteristics quoted above make considerable demands on teachers who try to create such environments and teach in them. Wittmann points out that the search for, conception and creation of SLE is one of the fields where researchers’ and teachers’ objectives interlink, where not only theory and practice, but also mathematics and didactics of mathematics mingle and which is open to natural long-term, systematic cooperation of researchers and teachers.

It is not uninteresting to recall at this point that Vyšín (the prominent Czech mathematics teacher educator) already emphasized in the beginning of the 1970s’ the need for simultaneous theoretical and practical conduct of research in the didactics of mathematics. He regarded systematic cooperation with teachers and preparation of materials for development and refinement of teachers’ work to be crucial. Similarly Bell, claimed already in the middle of the 1980s’ that “The developing theory of mathematical learning and teaching must be a refinement, an extension and a deepening of practitioner knowledge, not a separate growth” (Bell., 1984, p. 109, quoted from Wittmann, 2001). There are a number of developing trends in the various forms of cooperation between researchers and teachers, e.g. action research (Benke, Hošpesová, & Tichá, 2008). For that matter the authors of this paper have been developing similar ideas for a long time.^[1]

STUDY WITH TEACHERS AND TEACHER EDUCATORS

Starting points, aims, objectives

Most existing works on natural differentiation deals with algebra or arithmetic. That is why we tried to construct geometrical SLEs and asked whether and to what extent it is possible to use them for natural differentiation. We chose three environments, which we entitled *Way*, *Room*, and *Mosaics*. The SLEs were originally created for primary school pupils and were experimentally tested at this level (Hošpesová, Matějů, & Fantová, 2010; Tichá, 2010).

Later we used the same environments in in-service and pre-service teacher training with the aim of training both pre- and in-service teachers for work in SLE and for natural differentiation. We introduced them to the SLEs and asked them to analyze pupils’ productions and to create problems.

In a subsequent stage we also had the opportunity to study the reactions of teacher educators to these environments. We primarily focused on two areas of questions (i) which mathematical topics may be developed in the given SLE, which mathematical topics may be pursued in them, (ii) which substantial mathematical and pedagogical knowledge is prerequisite, what knowledge the teacher needs for efficient use of the environment. First and foremost it was mathematical content, potential for natural differentiation and posing a wide variety of problems that were discussed.

Description of the created SLEs and our experience from teaching primary school pupils

The environment *Way* works with an idealized street plan (see an example in Fig. 1). In the introductory lessons pupils became familiar with the map; with the structure of a description of a way; with interpretation of instructions; with criteria that a description should meet. After that we focused on three types of problems: (a) drawing a verbally described way in the map, (b) verbal description of a mapped way, (c) pupils' individual choice of a way and its description.

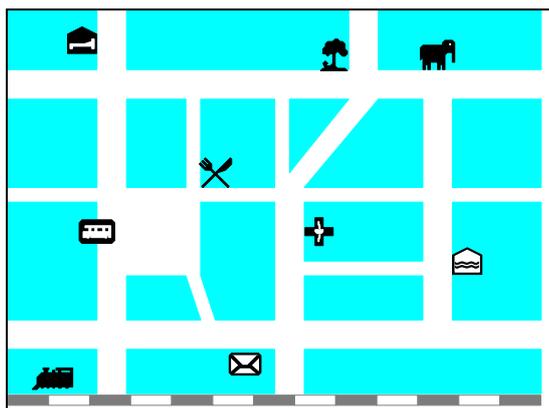

Fig. 1 Street plan

In the background of the choice of this context was our belief that development of the ability to move and orientate oneself in space contributes to development of mathematical literacy in various areas (for example construction of geometrical conceptions, modeling of real situations and use of appropriate language, introduction to various concepts and procedures and to an algorithmic approach).

The second environment was named *Room*. Two basic activities were used in this environment: (a) modeling of 3D space and objects in 2D and (b) placing objects in space. Pupils were given a room plan and models of furniture. They were asked to furnish the room. It was up to them how many people would inhabit the room, whether they would use all items of furniture and so on. The environment opens space especially to development of modeling, estimating, of work with scales, of the concepts of congruent shapes (symmetry, translation, rotation) and of filling up the space. The pupils' work displayed a considerable number of differences. The source of these differences often was on the social level; the differences were most often connected with different real-life experience with this activity. What was positive was the pupils' effort to find a fair layout of furniture in the room when the room was furnished for more than one person. There were differences in the ability to estimate the size of the items of furniture (estimations and measuring), the ideas of the size of the (needed) free space. There were also differences in the number of items of furniture used, the number of inhabitants etc.

In the third environment *Mosaics* we worked with different sets of geometrical shapes (see an example in Fig. 2). The goal of the designed tasks was to make pupils identify geometric figures and their properties by assembling shapes from elements of the mosaic. In a

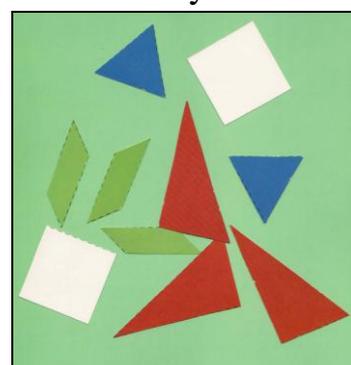

Fig. 2 Mosaic

sequence of tasks, pupils successively assembled (a) the figures given in the model, (b) their own pictures, (c) all possible figures, (d) figures from 2, 3, 4, n elements of the mosaic, (e) a given figure (square, triangle etc.) from 2, 3, 4, n elements of the mosaic and (f) created their own mosaic.

Use of SLEs in seminars for pre-service teachers; a new perspective

Pre-service teachers for primary school level were asked to assess all the above mentioned environments. The students' task was to explore their potential for natural differentiation and to pose questions and problems. Our former research clearly shows that problem posing is of a strong stimulating and motivational value both for pupils and for students (Tichá, 2009). That is why we decided to use a new point of view and in the following phase of our research we focused on differentiation while posing problems in a given context (a street map). We present here what our students proposed.

In the environment *Way* the students tried to pose problems enabling natural differentiation connected to the environment of the street plan. The most common problems were the following two types:

Describe the way.

Follow the shortest way to get from the hotel to the restaurant. From the restaurant, go to the bus stop and take a bus to go to the swimming pool. On the way, make a stop at the post office. Once you have reached the swimming pool, go to the zoo and from the zoo back to the hotel. How will you go? Draw it in the plan.

Where will you arrive?

We go to the right from the bus stop. On the first crossing we turn left and go straight on. On the next crossing we continue walking straight on. Then we turn left. Where do we arrive?

Very rarely we came across problems with hints of combinatorics:

Go from A to B. You can take whatever way you want. Or: Go from A to B passing C, D and E in any order.

There were differences in the posed problems, for example in the number of places that were to be passed on the way; in the number of changes of direction; in the use of "diagonal" connecting lanes (see Fig. 1) etc.

We have ascertained again that if results of pre-service teachers and pupils are compared, they turn out to be of a similar nature.

Finally we asked the students in the concluding discussion to state the mathematical concepts and methods that can be developed in the particular environment. The students suggested: orientation in space (right, left), estimation of distances (what is closer/farther), reading of a map (the meaning of symbols). They did not realize other possibilities which this SLE offers.

In SLE *Mosaics* students suggested that natural differentiation could be supported by different difficulty of the models (of some elements of the mosaic lined out in the model, only the outlines of the assembled figure given) and assembly of shapes of various difficulty. They also proposed that pupils record their results in various ways: copy the figures on blank sheets of paper, draw the figures into various grids (making it easier for them to construct the shapes). We regard this as a very becoming possibility for natural differentiation, because in geometry, construction of the solution is a substantial part of the solving process. Traditionally, geometrical problems are constructed with a pencil and ruler. Our problems were designed for primary school pupils and thus we expected that the results could be drawn and “exact drawing” is difficult for the pupils.

As far as mathematical content in this environment is concerned, students expected pupils to enrich their ideas of geometrical figures in plane (2D). They also believed that the SLE would on an intuitive level develop pre-concepts of the concept of isometry (the figures if placed in a certain way overlap), of angle and symmetry. Differentiated records of the solution require from the pupils the ability to draw a figure with certain properties, e.g. the length of sides in a particular ratio, with particular interior angles.

Both SLEs however also confirmed our initial opinion that pre-service teachers are not very “fond” of geometry, they have very little idea of how to teach it at primary school level^[2]. In consequence they highly appreciated the opportunity to work in SLE.

Seminar with teacher educators and researchers; new stimuli

The described environments were also used for work with a group of researchers and teacher-educators within the frame of a working seminar on CME 2010 conference (Hošpesová, Roubíček, & Tichá, 2010). Our work with this group helped us considerably in our effort to deepen the theoretical background of the concepts of SLE and natural differentiation. All the participants welcomed the focus on geometry and emphasized the wide range of stimuli stemming from geometrical environments and the potential for their use in the system of propaedeutics. The discussion concentrated on the mathematical core and didactical possibilities as well as pre-service teacher training for primary school level. The participants emphasised the question: What knowledge do we develop? They asked for an example of the task which cannot be taken as SLE.

The conclusion of the discussion was that all the environments provide a wide range of opportunities for natural differentiation. The proposals of the participants included structured requests for: related mathematical knowledge, activities, and tasks.

The environment *Way* was seen as suitable for: (a) orientation in space and plane, (b) utilization of pictures as universal language, (c) development of coding and decoding (requiring from the pupils to erase unnecessary words, substitute words by signs in

the description of the way), (d) development of algorithmic approach, optimization of the procedure, (e) adding/completing estimation and comparing distances (lengths), (f) challenging pupils to create their own ratio scale/measurement.

The environment *Room* was regarded as suitable for development of intuitive ideas, pre-concepts: (a) projection in two dimensions and in three-dimensional space and transition between the two, (b) covering the plane, (c) orientation in space, (d) measuring and using the scale, (e) solids, shapes, ..., (f) transformations – isometry, symmetry, congruency, similarity, (g) mathematical ideas, meaning, (h) language (describe your room, the room you have designed, create a room according to a description), (i) sense of representation (design furniture and cut it out from a piece of paper).

In their comments the participants also paid attention to the relation to reality and proposed questions such as: Why do we furnish a room? What kind of a room? Why are wardrobes cuboids? How high should wardrobes be? What happens if our room is not a cuboid? Why do you use double beds in a bedroom? What would be the price of having the room redecorated? [How does the position of objects in a room influence the social dimension of that room?](#)

The environment *Mosaics* in their opinion provides the opportunity:

- To assemble and identify geometric figures (e.g. they posed the following problem with triangles whose one side is red and the other white: create various shapes combining two triangles – see examples in Fig. 3 – and questions: propose criteria for classification of the created shapes, why are some of them monochromatic and others dichromatic?)

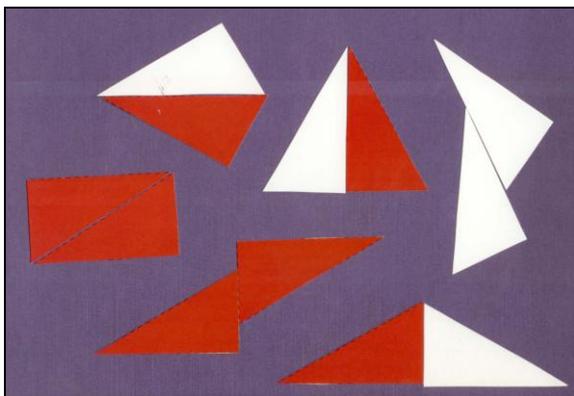

Fig. 3 Shapes from triangles

Fig. 4 Material for tessellations

- To seek similarities and differences in geometric figures; on intuitive level to identify their properties such as length of their side, size of the interior angles
- To enrich notions of polygonal shapes
- To develop intuitive notions of congruence
- To gain experience with homothetic transformations on visual level
- To introduce pupils to measuring area – problem: cover the rectangle using geometrical figures; what figures did you use?

- To use this knowledge in modelling of practical situations

The participants also suggested other environments and activities: tessellations (proposed shapes designed by participants in fig. 4), constructions in Cabri.

CONCLUDING REMARKS

As stated above, this paper presents information of ongoing research, on its background and its preliminary results. We are convinced that creation of SLE pertaining to the subject matter taught should be at the centre of attention of didactics of mathematics. It is not only research but also teacher training that should be related to it. The first experience of work targeted on this issue show that it is a long-term, systematic research focusing both on theoretical and experimental solution of the promising issues of teaching goals, contents and methods and pupils' learning of mathematics.

Work with pre-service teachers confirmed our belief that teacher training must involve activities of this type as students often fail to “see mathematics in the world that surrounds them”. It is even in-service teachers with long teaching experience who lack this ability. They often fail to realize that what they deal with is an open problem, open situation – they cannot make any use of it for they are not able to see, understand, and grasp mathematics inherent in it. It is becoming more and more apparent that it is mathematics that is the leading agent. It confirms again that the teacher must master mathematics – mere teaching experience, however long it may be, not anchored in knowledge of mathematics is not sufficient.

In our work with pre-service teachers we observed that the nature of the posed problems gradually changed: from simple problems with easy solutions of “textbook” nature, commonplace (both with respect to the context and to the topics) and often badly worded problems, to challenging uncommon problems with diversiform assignments (graphs, tables, diagrams, ...), representations (iconic, symbolic) facilitating various solving procedures and approaches, asking for justification, leading to further meditation (open problems). Referential contexts were enriched.

It is gratifying that the atmosphere in mathematics lessons changed: teacher students became more active, everybody participated in the lesson as their abilities were respected, not only their attitude but also their beliefs and self-confidence improved. Again joint reflection proved to be of utmost benefit as it shows that students penetrate mathematical concepts, procedures and structures in greater depth.

Working with teacher educators we realized their orientation towards mathematics and their ability to grasp the depth of the content. At the same time they discussed the pedagogical aspects in relation to the mathematical classroom and teacher training. We saw that realization of benefit of natural differentiation requires the change of approaches to coping with heterogeneity in mathematics classroom.

NOTES

1. Similar ideas are in the background of our studies of the process of grasping a situation (Koman & Tichá, 1998). By grasping a situation we understand the thinking process which blends activities focusing especially on formulation of questions and problems springing from the situation, solution of the posed problems and interpretation of the results. To be able to grasp a situation with comprehension, it is necessary not only be able to construct a mathematical model, but also to communicate and reason. The social aspect is of great importance here. We want to make pupils and pre-service teachers see mathematics in the world that surrounds us, in different “mathematical” and “non-mathematical” situations. Our exploration of grasping became the starting point of our research of development and use of the ability to pose problems. We perceive it not only as a goal, but also the means of mathematics education and also as a diagnostic and motivational tool (Tichá, Hošpesová, 2010).

2. In the Czech Republic, geometry is a component of primary school curricula. The Framework Education Programme for Basic Education (2007) demands that: “In the thematic area of two- and three-dimensional Geometry, pupils identify and draw geometric figures and model practical situations, seek similarities and differences in common figures, study an object’s position on a plane (or in space), learn to compare, estimate and measure length, angle, circumference and area (surface area and volume), and to improve their graphic skills.”

DIFFERENCES IN THE PROPOSITIONAL KNOWLEDGE AND THE KNOWLEDGE IN PRACTICE OF BEGINNING PRIMARY SCHOOL TEACHERS

Fay Turner

University of Cambridge

In this paper I draw on a four year study into the development of mathematics teaching of beginning primary school teachers. I focus on the finding that in the early stages of teaching, it appeared to be difficult for the teachers to apply 'propositional' pedagogical content knowledge (PCK) that had been 'taught' in the university, even though they were able to demonstrate this PCK in discussion. As the teachers became more experienced, their supported reflection on practice seemed to enable them to draw on, and activate, their propositional knowledge. This perhaps suggests that mathematics educators should not 'despair' that their students do not appear to apply the content of their mathematics methods courses when they begin teaching. Rather, they should encourage beginning teachers to reflect on their practice with a focus on mathematical content knowledge.

Key words: elementary teachers, content knowledge , professional development

INTRODUCTION

From the start of their careers, beginning primary school teachers have a bank of knowledge about mathematics teaching on which they can draw in their practice. This knowledge originates variously from their own experience as a pupil, from their observations of mathematics teaching and from the mathematics methods courses they undertook as part of their teacher education. However, the knowledge of beginning teachers might be considered to be qualitatively different to that of experienced teachers because it is not 'embedded in practice'. There a number of theoretical perspectives which help us to understand the qualitative difference between the knowledge of beginning teachers and knowledge which is embedded in practice.

Shulman (1986) proposed three *forms* of knowledge: *propositional knowledge*, or academic knowledge; case study knowledge, i.e. knowing what worked from observation or from past experience and *strategic knowledge*, i.e. the ability to make appropriate strategic decisions while in the act of teaching by drawing on relevant propositional and case study knowledge. The knowledge of beginning teachers might be categorised as propositional knowledge, gained from their teacher education courses, and also case study knowledge gained from reflections on their own teaching and the teaching of others as a student teacher. Strategic knowledge can only be developed through the act of teaching and beginning teachers will therefore have little access to this.

Other mathematics educators have argued for a kind of *active* knowledge that can only develop in practice. Mason and Spence (1999) distinguished between *knowing-about* and *knowing-to*. They drew on the seminal work of Ryle (1949) in which he distinguished between *knowing that* (factual knowledge), *knowing how* (knowledge of how to perform acts), and *knowing why* (having stories to account for actions). Mason and Spence suggested that these three ways of knowing may all be considered as *knowing about*, but that knowing about a subject does not guarantee being able to apply this knowledge in practice. They proposed *knowing-to* as a fourth way of knowing that is active rather than static. They suggested that *knowing to* might arrive ‘suddenly like a bolt of lightning’ (p. 146), which resonates with the model of teacher knowledge suggested by Hegarty (2000). In this model the teacher is seen as having a number of incomplete sets of relevant insights, elements of which come together in instances of teaching to form a new insight specific to that situation. According to Hegarty’s model, teacher knowledge is firmly situated within the act of teaching, and can only be developed in practice.

These ideas are consistent with a social theory perspective of knowledge and knowledge development. Lave and Wenger (1991) suggested that knowledge does not exist in the consciousness of individuals but rather in their participation in social practices. Rather than bringing knowledge to situations and applying it, knowledge is constructed in social practice, and can therefore only be identified or developed in context (Greeno, 1998; Putman and Borko, 2000). Hodgen (2003) found mathematical content knowledge to be *situated* in the professional context of practitioners. Experienced practitioners in his study demonstrated more sophisticated knowledge of mathematics in the context of their practice than they were able to do in an interview. These practitioners appeared to *know to* when involved in professional action and when surrounded by the artefacts of their practice. This was in contrast to the findings of the study reported here where the mathematical content knowledge of the beginning teachers did not initially appear to be supported in the same way by the contexts of their teaching. In this paper I explore why this might be, and suggest how working with the Knowledge Quartet (KQ) framework (Rowland, Huckstep and Thwaites, 2005) appeared to accelerate the teachers’ ability to turn their *propositional knowledge* into *strategic knowledge*.

The KQ framework was developed from observation of mathematics teaching and the categorisation of situations in which mathematical content knowledge was revealed. The original 18 ‘situations’ or codes were later classified into four ‘superordinate’ categories based on associations between them. These categories make up the four dimensions of the Knowledge Quartet; *foundation*, *transformation*, *connection* and *contingency*. The *foundation* dimension encompasses situations in which *subject matter knowledge* (SMK) (Shulman, 1987) including *common content knowledge* (CCK) and *specialised content knowledge* (SCK) (Ball, Thames and Phelps, 2008), become apparent. It also encompasses situations in which

propositional *pedagogical content knowledge* (PCK) (Shulman, 1987) becomes apparent. The prefix ‘propositional’ suggests that this knowledge is in the form of *knowing-about* (Mason and Spence, 1999) and is knowledge which may be gained ‘in the institution’, from personal research or experience.

The three remaining dimensions categorise types of situations in which teachers’ ‘propositional knowledge’ is activated to make it accessible to learners in the process of teaching. Knowledge relating to these three dimensions may be conceptualized in terms of Mason and Spence’s (1999) notion of *knowing-to*. The *Transformation* dimension encompasses situations in which the *active* forms of PCK are revealed through demonstrations, representations and examples used by teachers. The *Connection* dimension encompasses situations in which a teacher’s knowledge of connections in mathematics is made visible in their teaching and involves drawing on their SMK. *Connection* also encompasses situations in which knowledge of how to sequence mathematics teaching and make connections for learners becomes visible and relates to PCK. Finally, the *Contingency* dimension relates to situations in which teachers respond to the unplanned-for and the unexpected in their teaching, when they are seen to draw on combinations of knowledge from the categories defined by Shulman (1986) and Ball Thames and Phelps (2008).

THE STUDY

The KQ framework was used in this study to facilitate reflection both as a means to, and as a measure of, professional development. I wanted to investigate how effective the KQ would be as a tool for supporting beginning teachers in reflection on practice that would facilitate developments in their mathematical content knowledge. This paper focuses on whether the KQ supported the ability to activate in practice aspects of mathematical content knowledge learned in the institution. The study was conducted in four phases, each lasting one year, and the data collection methods were developed to suit the objectives for each phase. These included observations and videotaping of teaching, post-lesson interviews, group and individual interviews and participants’ written reflective accounts. The KQ was used by me to analyse observed teaching and was used as a framework for discussion with participants about their teaching. The participants used the KQ to structure their written reflective accounts of their teaching. The study began with twelve student teachers from the 2004-5 cohort of primary (5-11 years) postgraduate pre-service teacher education course at the University of Cambridge. The numbers reduced, as anticipated, to 4 in the fourth and last phase of the study. Case studies were completed for three of the four teachers who participated throughout all four years of the study. Two of the teachers worked with Reception classes (4-5 year olds) and it was decided to complete a full case study for just one of these. The three case study participants were given the pseudonyms Amy, Kate and Jess. Amy was an early years trainee (3-7 years) and her highest formal mathematics qualification was a grade B at

GCSE⁹³. Kate was a general primary trainee (5-11 years) and her highest formal mathematics qualification was an A* at GCSE. Jess was a general primary trainee and had gained a B in her mathematics GCSE.

FINDINGS IN RELATION TO ACTIVATION OF PROPOSITIONAL KNOWLEDGE

Amy's lesson that I observed during her final student teaching placement contained two instances in which it appeared that she did not draw on her propositional knowledge. This was a lesson on counting with a Reception class (4-5 years) and during the introduction part of the lesson Amy wanted to assess whether the children could match spoken and written numerals. She asked the children to write various numbers on their individual white boards. One example was '19' and several children wrote '1P', at least one wrote '99' and many wrote '91'. Amy then asked two children to demonstrate how to write '19' on the class white board. One of the children wrote '1P' and Amy spent some time demonstrating how to write '9' correctly. She focused on the reversal of the nine but did not address the problem of incorrect digit order that was apparent for several children. During the post-lesson interview I observed that I had seen several children write '91' and asked Amy if she knew why this might be:

Because you say nine first, then you say the teen that's why often they write the nine first they often want to write nine first then write it from right to left instead of left to right. (Amy, Phase One, Post-lesson reflective interview)

Amy knew about the problems children encounter in writing teen numbers (Wigley, 1997; Anghileri, 2007), but did not apply this knowledge in her practice.

Later in the lesson, the children worked at a number of tasks, some of which involved counting objects. I asked Amy why she had chosen these activities and she explained that she had selected sets of interesting objects in order that the children might practice their counting. I then asked what she thought the children needed to know in order to be able to count these objects:

It's number names and order ... it's not anything to do with cardinality or anything yet, it's just the rote and the reciting numbers ... (Amy, Phase One, Post-lesson reflective interview)

I suggested that some of the activities were practising other pre-requisites of counting (Gelman and Gallistel, 1978), and asked Amy if she remembered what these were:

One to one correspondence ... moving an object, that's in one to one really, so if you've got a random pile of objects you might want to move them out of that into a line or a

⁹³ National examinations taken at 15 years

Working Group 17

group ... and remembering the final count is the total. (Amy, Phase One, Post-lesson reflective interview)

Amy also knew that “remembering the final count is the total” was called ‘cardinality’. Amy was able to explain this aspect of her PCK even though she said she had not drawn on these ideas when planning her teaching.

I observed Amy teaching another lesson on counting during the second term of her first year of teaching. This lesson suggested that Amy had become more likely to apply the propositional PCK in her teaching that she had demonstrated in our earlier discussion. In the introduction to this lesson the children guessed how many unseen objects they thought were in various boxes, and then counted them. When the children were counting the objects, Amy praised them for, and drew attention to, the strategies they used, i.e. putting the objects in line, pointing to each in turn with their fingers, saying the numbers in order, and saying that the last number was the answer to ‘how many’. At the end of the introductory part of the lesson, Amy reinforced what had been good about their counting, saying “We said the numbers in the right order, we touched each thing once, and the last number we said was how many there are.” Amy made several comments in her reflective account of this lesson that suggested she had drawn on her propositional PCK when planning and teaching the lesson:

When I was planning this lesson I drew on my knowledge of the pre-requisites for counting: knowing the number names in order, one to one correspondence, the cardinal principle, being able to count objects that cannot be moved/touched and counting objects that cannot be seen e.g. sounds or beats. These developmental stages formed the progression and structure to the lesson. (Amy, Phase Two, Reflective account of observed lesson)

The principles of counting that Amy referred to and made explicit in her teaching had been taught during her teacher education course. She had not made explicit use of this knowledge in the lesson observed in her training year however her knowledge became more explicit in the lesson observed the following year. It seems likely that Amy’s supported reflection on her teaching led her to make greater use of her knowledge of the pre-requisites for counting in the later lesson:

I could have stressed moving the objects rather than putting them in a line ...when they were counting sounds it would have been helpful to match each sound to a held up finger ...When I asked are there more frogs or more snakes I could have asked a child to come up and show these on the number line ... (Amy, Phase Two, Reflective account of observed lesson)

Amy’s reflection on her practice appeared to draw on her propositional knowledge of the principles of counting and enabled her to make informed suggestions for improvements.

Kate also appeared to have early difficulties in drawing on the propositional knowledge that had been taught in her teacher education course. In a lesson with a Year 1 class (5-6 years), observed during her final student teaching placement, Kate used a representation of a witch's cauldron to record doubling. The number to be doubled was written as an addition sentence in the cauldron, e.g. $3 + 3$, and the answer in a bubble above the cauldron. After demonstrating doubling the numbers 1-9, Kate moved on to doubling two digit numbers. Her method for recording these involved writing the doubled number of tens and of units in separate bubbles, e.g. double 13 was recorded as 2 tens in one bubble and 6 units in another. This method of recording would seem to reflect *column value* rather than *quantity value* (Thompson, 2003). When discussing this in the post-lesson reflective interview, Kate recognised that her recording of this procedure might have been problematic:

Maybe it wasn't the most helpful thing to do at all because the easy way to do it is to think about it as a column method and if you are not doing it that way then it is probably quite hard. (Kate, Phase One, Post-lesson reflective interview)

In discussion, Kate demonstrated that she knew that by recording the tens as single units she had obscured the value of the tens number and suggested a column method for addition. She recognised that this was not the most appropriate calculation method for these problems. Propositional knowledge concerning the advantages of using quantity value over column value and mental over written methods for addition was available to her in discussion but had not been drawn on during the lesson.

On a number of occasions during the lesson, Kate used a number line to help children complete addition calculations such as ' $8 + 3$ ' by beginning at one of the numbers and then counting on the second number, e.g. starting at 8 on the number line, counting on 3 and giving the answer as the number at which she had arrived. This pre-supposed that children had reached the 'count on' stage in addition (Carpenter and Moser, 1984). However, observation of the children's independent use of the number line suggested that some were still at the 'count all' stage. I asked Kate if she remembered the stages children go through in learning addition:

At first not knowing that you can just start at numbers, that you have to count the one, two, three ... so you have to count three to get up to three before you can carry on. (Kate, Phase One, Post-lesson reflective interview)

Although she knew that some children would not be able to understand the addition strategy of starting with one number and then counting on the second number, Kate had not drawn on this knowledge in her teaching. Like Amy, Kate demonstrated that when probed, she could refer to PCK that was not apparent in her teaching. In phase two of the study I observed a lesson in which Kate modelled a number of methods for solving addition problems, involving both 'count all' and 'count on' strategies. Kate demonstrated that she was now drawing on her propositional knowledge of the stages in which children learn addition by counting, and applying this to her

teaching. Kate's reflection on her phase one lesson appeared to have enabled her to draw on and activate her propositional knowledge in the later lesson.

In a lesson observed during her third year of teaching, Kate demonstrated that she had become adept at drawing on her propositional knowledge in the act of teaching. The lesson had been planned by another teacher. This teacher had prepared a power point presentation to demonstrate addition strategies for two-digit numbers. Kate had only briefly looked at this before starting the lesson. When a slide was displayed showing $23 + 12$ as $(20 + 10) + (3 + 2)$, Kate 'deviated from the agenda'⁹⁴ and made a new slide showing $23 + 12$ as $23 + 10 + 2$. In the post lesson reflective interview, I asked Kate why she had changed her demonstration in this way. Kate explained that for two-digit addition, she normally used the strategy of keeping one number whole and partitioning the second number as children found this easier. When she realised that the slide was introducing a different addition strategy, she had changed it to represent the method her class were used to. Although she did not use the terms 1010 and N10 (Beishuizen, 2001) which had been referred to in her mathematics methods course, Kate demonstrated that she was aware of these two different methods of addition, and was able to make decisions about the appropriateness of their use in the act of teaching.

There was evidence from my study that both Amy and Kate appeared more able to draw on their propositional knowledge as they gained experience of, and reflected on, teaching. I observed instances at the beginning of their teaching in which they did not draw on knowledge taught during their teacher education course although they did refer to this knowledge in post-lesson interviews. In later lessons, there was evidence that they were drawing on the same propositional knowledge and activating it in their teaching. The findings were slightly different for the third case study participant, Jess. I observed an instance in Jess' early teaching in which she did not seem to draw on propositional knowledge taught in her teacher education course. However, unlike Amy and Kate, Jess was not able to recall this propositional knowledge during discussion. There was evidence however that she was able to develop this knowledge and to draw on it as she reflected on her teaching experience.

The observation happened in the second term of Jess' first year of teaching. This was a lesson involving the relationship between multiplication and division and Jess wrote ' 3×4 ', ' $12 \div 3$ ' and ' $12 \div 4$ ' on the class white board. She represented the relationship between these operations by drawing four circles, each containing three dots. For $12 \div 3$, this reflected a 'quotition' structure of the division problem and for $12 \div 4$ a 'partition' structure. Teachers commonly refer to these two structures as 'grouping' and 'sharing' respectively. Jess consistently used the term 'share' when

⁹⁴ Deviate from the agenda (DA) is a code of the Knowledge Quartet framework from the Contingency dimension

talking about this division calculation. During the post-lesson interview, I probed Jess' understanding of the two structures of division, and she admitted to being unsure of the distinction:

Explaining dividing in terms of grouping and sharing still gets me mixed up. It is something I need to work on myself. The aim was to explain in terms of grouping. In future I am going to sort this out before the lesson so my physical representations don't get mixed up. (Jess, term two first year of teaching, reflective account)

Helping student teachers understand the two structures of division was a key objective of one of the sessions in Jess' mathematics methods course. At this stage, Jess appeared unable to draw on the knowledge taught in this session. However, a year later there was evidence that Jess was more secure in her knowledge of the two structures and was able to draw on this in her teaching. During a lesson on division, Jess told the children that they would be focusing on the word 'share' and using sharing to answer some division problems. She displayed an interactive whiteboard screen showing the problem '16 divided by 2 equals []' also written as ' $16 \div 2 = []$ ' and 16 small circles which she referred to as buttons.

Jess demonstrated a procedure for solving this problem involving 'sharing' the sixteen 'buttons' one at a time into two groups and counting how many in each group. A similar 'sharing' procedure was demonstrated for $20 \div 2$, $20 \div 5$ and $24 \div 4$. All the models used in this lesson reflected Jess' intended focus on the partition (sharing) structure of division. During the group interview Jess explained how she had become clearer about the structures of division:

In the [previous] division lesson you saw I got my sharing and my grouping mixed up ... now I have got like this clear idea so when I was planning I did think about 'is this sharing, is this grouping' and did actually draw a diagram out to make sure I had my ideas clear. (Jess, first term second year of teaching, group interview)

It seems that when she began teaching, Jess did not have sufficiently secure knowledge about the two structures of division to support her teaching. However, reflection on her teaching supported by the KQ framework appeared to enable her to develop this propositional knowledge and to activate it in her teaching

If you make a mistake in a lesson, like I got sharing and grouping wrong, every time I do division now I get my book out and go 'that's sharing, that's grouping' and draw some pictures so I know I have got it clear in my head before I start. (Jess, Phase Three, term three, Group interview)

DISCUSSION

There were instances in the early teaching of all three teachers that suggested they did not draw on PCK that had been taught during their mathematics methods courses. There was evidence, particularly in the cases of Amy and Kate, that some of the ideas that they had been taught appeared to be held as propositional knowledge but

that they were unable to draw on this and activate it in their teaching. Amy was able to state the principles for counting, but did not use them explicitly in her planning and teaching. Kate recognised the advantages of using quantity value rather than column value when recording calculations, but did not take account of this in her teaching. She also failed to recognise the need of some children to use ‘count all’ strategies when doing addition. However, Amy and Kate were both able to answer questions about these aspects of PCK during post-lesson reflective interviews. This would seem to be inconsistent with the notion of knowledge as being *situated*, which suggests that teachers should exhibit greater knowledge in their professional context than they could demonstrate through questioning (Hodgen, 2003). However, the professionals in Hodgen’s study were experienced ‘experts’, whereas Kate and Amy were both at the very beginning of their careers. It may be that some experience is necessary before beginning teachers are able to draw on *situated* knowledge. In her second year of teaching, Kate was able to draw on her knowledge of the 1010 and N10 strategies for addition when using a power point presentation prepared by another teacher. Two years of experience enabled her to bring together the knowledge *situated* in the context of her teaching and the propositional knowledge taught in the university.

There was evidence that all three teachers drew on propositional knowledge in their later teaching that they had not seemed able to draw on in earlier lessons. Amy explicitly referred to the principles for counting, Kate used both ‘count-on’ and count-all’ strategies and Jess clearly focused on the ‘partition’ structure in her lesson on division. The beginning teachers in this study appeared to become more able to draw on their propositional knowledge as they had more experience of teaching and as they reflected on that experience. Reflection on their practice close to the teaching context, in terms of both time and physical proximity, seemed to enable the teachers to draw on knowledge that had been inaccessible to them when planning and when teaching. Propositional knowledge appeared to become more likely to become activated in future lessons following such reflection. My study suggested that reflection, supported by the KQ framework to focus on the mathematical content of teaching, helped the teachers to draw on their propositional knowledge and to activate it in their teaching. This suggests that in order to help student teachers apply mathematical pedagogical content knowledge taught during their teacher education courses we should perhaps take a longer view and support beginning teachers in consistently reflecting on their practice in a way that focuses on the mathematical content.

DIDACTICAL ENVIRONMENTS “STEPPING” AND “STAIRCASE”

Nad'a Stehlíková, Milan Hejný, Darina Jirotková

Charles University in Prague, Faculty of Education

A scheme-oriented teaching strategy based on developing mental schemas (Hejný et al., 2007) has been systematically studied at the Faculty of Education. Its main tools are didactical environments (substantial learning environments, see Wittmann, 2001). The focus of the poster are two arithmetic environments that we use for learning operations with natural numbers, negative numbers and as a preparatory vehicle for equations. (The whole poster is available from the first author.)

Keywords: substantial learning environments, natural numbers, integers, operations

The learning environments “Stepping” and “Staircase” were developed in the Czech context by M. Hejný to support teaching at the elementary school: handling integers and understanding simple equations and their systems. The poster presents a brief description of the recent implementation of this environment in Grade 6 with students who had not met any stepping in their elementary grades (see Stehlíková, 2010).

In the “Stepping” environment, students **took steps** according to instructions in the school corridor with square tiles on the floor (see fig.). E.g., Adam and Boris were standing next to each other

Working Group 2

on the blue tiles facing forward. Adam got an instruction “Two steps forward, then three steps backward, begin now!” and carried it out. The teacher asked the class: “What is the instruction for Boris so that he stands next to Adam?” The class: “One step backward.” (A step backward was done without turning.)

Note: In “Stepping”, numbers are used as *operators*. If we take steps on numbered stairs, we work with two types of numbers: *addresses of stairs* and *operators of the position change*. This environment is called “Staircase”.

To record the instructions, the pupils spontaneously used arrows or plus/minus signs. The teacher negotiated with them that they would use the **arrow notation**: an arrow to the right meant one step forward and an arrow to the left, one step backward:

$|\rightarrow\rightarrow|\rightarrow\rightarrow\rightarrow|$ or $|\rightarrow\rightarrow\rightarrow\rightarrow|\leftarrow\leftarrow|$.

Next, a new instruction was introduced – ‘**turn about**’, which meant that a pupil turned 180° to the opposite direction. It always came in pairs (so that the pupil faced the original direction). The pupils took actual steps and solved tasks which should start their journey towards understanding the effect of the minus sign before a parenthesis; i.e., subtracting a negative number is the same as adding a positive one.

A new abbreviation was used: $|\check{C}V|\rightarrow|\check{C}V| = \leftarrow$, $\rightarrow\rightarrow\rightarrow|\check{C}V|\leftarrow|\check{C}V| = \rightarrow\rightarrow\rightarrow\rightarrow$, etc. ($\check{C}V$ as ‘turn about’ in Czech.) When taking steps, the pupils experienced that “turning about changes the direction of the arrow”.

Later, the pupils were to **transcribe the arrow tasks in numbers** and the question was what to do with $\check{C}V$. The pupils felt the need to separate a part of the calculation so it was natural to introduce a convention: the first $\check{C}V$ is written as the minus sign and left parenthesis and the second $\check{C}V$ is written as the right parenthesis.

Instead of continuing with actual stepping, each pupil was given a **stepping slip** (see fig.) and a little figure with a marked nose (so that it was clear where it faced). The pupils put the figure on the blue tile, facing to the right, and then moved it as if they took steps. An important rule was that the figure had to begin and end with its face in the ‘forward’ direction (facing to the right).

With the tasks, the pupils were to get experience with operations with integers and to realise the meaning of minus before a parenthesis. E.g., $-(-1) = 1$, $-(1) = -1$, $3 - (-1) = 4$, $-3 + 1 = -2$, $-1 + 3 = 2$, $-1 - 3 = -4$, $-(-1 - 3) = 4$, $-(1 + 3) = -4$, etc. Differences in the pupils’ performances were seen. Some quickly spotted rules. Some began to calculate without the use of the figure. The aim was to let everyone use the slip as long as they wanted. After writing numbers 0, 1, 2, 3, ... -1, -2, -3, ... on their slips they created a model of a number line. Negative numbers explicitly acquired double meaning: *procedural* (movements backwards) and *conceptual* (an address).

CONCLUSIONS

We have observed that Stepping-Staircase environments: 1) reinforce the idea of addition and subtraction as a movement on a number line and that is why it preceded the use of the stepping strip; 2) help pupils to grasp the meaning of calculating with negative numbers by means of the arrows notation; 3) illuminate the difference between subtraction and negative numbers; 4) help pupils to understand the rule of ‘minus before a parenthesis’; 5) serve as a model which bridges the gap between the informal and formal understanding of operating with integers.

UNDERSTANDING THE INFINITE SETS OF NUMBERS

Cristian Voica

University of Bucharest, Romania

Florence Mihaela Singer

University of Ploiești, Romania

INTRODUCTION

We present an overview of a long term research program focused on students' understanding of the concept of infinity. Many questions connected to the idea of infinity could be addressed to school learning. Among these: Does an intuition of infinity really exist in children? Does the school build an understanding of infinity? How is this understanding reflected on problem solving along the schooling period? What capacities do trigger one's choice of a strategy in solving problems that deal with infinite sets? We answered these questions in a series of papers, some already published and others in progress. The poster was a summary of this research, organized around the themes listed below.

PERCEPTIONS IN UNDERSTANDING INFINITY

When discussing infinity, children seem to highlight three categories of primary perceptions: processual, topological, and spiritual (Singer&Voica, 2003, 2007). Around 11–13 years old, processual and topological perceptions interfere each other, while before and after this age they seem to coexist and collaborate, one or the other being specifically activated by the nature of different tasks.

REASONING ABOUT THE INFINITY OF THE SETS OF NUMBERS

School mathematics is dealing with infinite sets of numbers: these are, actually, the only infinite objects that we “know” so far. Based on a processual perception, children see the set of natural numbers as being infinite, and endow \mathbf{Q} with a discrete structure by making transfers from \mathbf{N} to \mathbf{Q} . In addition, children are able to make a transfer of reasoning from \mathbf{N} to \mathbf{Q} (Singer&Voica, 2008). Contrary to other studies, we found that, for many children in the lower secondary school, the concept of infinity of \mathbf{N} is strong enough to permit reasoning. For example, some students found it necessary to apply negation for arguing that a given set is finite.

STRUCTURES ACTIVATED IN THE PROBLEM SOLVING PROCESS

When reasoning about infinite sets, children seem to activate four categories of conceptual structures (Singer&Voica, 2010): geometric (*g*-structures), arithmetic (*a*-structures), fractal-type (*f*-structures), and density-type (*d*-structures). Students select different problem-solving strategies depending on the structure they recognize within the problem domain. They naturally search for structures in challenging learning contexts.

FURTHER RESEARCH: RELATION MISCONCEPTIONS - STRUCTURES

Students activate various misconceptions when comparing infinite sets of numbers (e.g. Tsamir, 1999). Our research leads to the conclusion that the emergence of a certain structure is responsible for the misconceptions the students show when dealing with infinite sets. An overview of the relations between the categories presented above is given in Figure 1.

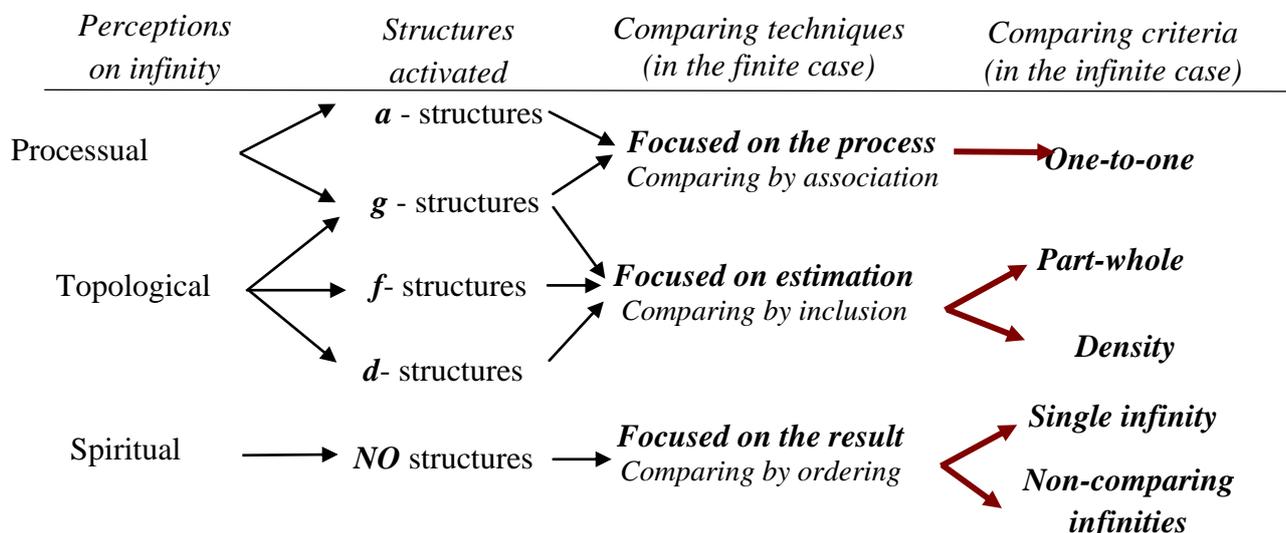

Fig. 1: Connections between perceptions, structures and comparing strategies

BRIEF DESCRIPTION OF THE CONTENT OF THE POSTER

The poster contained the scheme presented in Figure 1, brief explanations, and some excerpts from relevant comments and drawings of the interviewed students. The pdf version of the poster is available under <http://gta.math.unibuc.ro/pages/cristi.html>.

EXPLORING PATTERNS IN ALGEBRAIC THINKING

António Borralho, Elsa Barbosa

Education and Psychology Research Centre, University of Évora, Portugal

Nowadays algebraic thinking has become central to the mathematics curriculum. The development of algebraic thinking is seen as essential to the mastery of algebra. The transition between numbers and a higher level of abstraction is not trivial and in moving from arithmetic to algebra students experience genuine difficulties (Barbosa and Borralho, 2009 and Sinistsky, Ilany and Guberman, 2009). Teachers should diversify strategies, allowing their students to develop algebraic reasoning and symbol sense (Arcavi, 2006). Considering the classroom environment, the present study aims to understand the use of patterns in a context of research tasks as a way to improve the progress of algebraic thinking. We started out with two main research questions focused on: (1) algebraic reasoning and (2) mathematical communication.

Keywords: mathematics education, investigations tasks, patterns, mathematic reasoning, Algebra, algebraic thinking.

INTRODUCTION

The transition between numbers and a higher level of abstraction seems to be one of the thorniest stages in the mathematics teaching-learning process. Therefore, it is essential to choose adequate strategies that allow students to broaden and deepen their understanding of the algebraic language.

Algebraic equations may have multiple solutions, giving students the opportunity to explore different solution paths. This view acknowledges the crucial role played by teachers, in what concerns encouraging and exploring varied solutions; that is, helping students to improve algebraic thinking.

Orton and Orton (1999) claim that patterns are a possible way to approach algebra and, consequently, develop algebraic thinking. According to Bishop (1997), when a student identifies the relationship between quantities and patterns he/she acquires important mathematical knowledge, for example, the concept of function. This means he/she is learning to investigate and communicate algebraically. Solving research tasks related to patterns emphasizes, on the one hand, investigation, conjecture and proof. On the other hand, and no less important, these tasks need to be interesting and challenging to students (Vale and Pimentel, 2005). Finally, they need to promote the communication of mathematical ideas (Barbosa, 2007). In short, they need to promote a patterning approach to algebra furthers mathematical skills as it interconnects itself with exploration and investigation tasks.

METHODS

A qualitative and interpretive method was chosen, where a class was considered the unit of analysis in what concerns research tasks involving patterns. The study was carried out in an eighth-grade class (13-14 years old) and between two of its students, considering definite criteria, and aimed a descriptive and analytical outcome. The methodological option in conducting this research led to a qualitative and analytical study case.

CONCLUSIONS

Our study confirms Orton and Orton's results (1999) that the study of algebra may be initiated through inquiry and generalization of patterns. We found that exploring patterns in a context of investigative tasks enables the development of algebraic thinking and that such tasks are interesting and challenging to students. However, at the same time, teaching practices must be changed, leaving behind a "traditional" teaching that promotes routine and an "isolated" learning experience of contents, and move to teaching practices that give rise to meaningful and contextualized learning.

PROSPECTIVE TEACHERS DOING MODELING ACTIVITIES AND INTERPREATING STUDENTS WORK

Neusa Branco

Escola Superior de Educação do Instituto Politécnico de Santarém, Portugal
Unidade de Investigação do Instituto de Educação, Universidade de Lisboa

The poster presents strategies of prospective elementary school teachers in modeling situations and the contribution of the exploratory approach of their course of algebra and functions to their understanding of how to promote its teaching before the use of formal notation.

Keywords: Prospective elementary school teacher, algebraic thinking, modelling.

The poster presents the understanding of prospective teachers about modeling situations and the contribution of the exploratory approach of their course of algebra and functions to the understanding of how to promote its teaching to elementary school children. Moreover, this approach intends to promote discussions with prospective teachers about the development of algebraic thinking in their future students and about some misunderstanding and errors starting by students.

MODELLING AS A STRAND OF ALGEBRAIC THINKING

In Portugal algebra is taught throughout all grades. Thus, recent programs for elementary school try to articulate the algebra in all mathematical topics and to adapt the strands of algebra to each grade. Kaput (2008) presents two central aspects of algebra: (A) symbolic generalization of regularities, and (B) syntactically guided reasoning and actions on generalizations expressed in convectional symbol systems. These aspects are integrated into three strands: (1) the study of structures and systems abstracts, (2) the study of functions, relationships and covariation, and (3) application of a cluster of modeling languages. In elementary school, before the introduction of algebraic notation, students must be able to generalize situations using natural language and drawings in informal strategies. Students may guess and check solutions informed by the identification of linear relations and use their own notations (Sutherland, 2004). The focus of this poster is the third strand of algebra in two dimensions, the prospective elementary school teachers' understanding of algebraic activities and the expanding of these activities to elementary school students.

THE STUDY

The research follows a qualitative approach, using case studies. The participants are a class of 20 prospective teachers that attended the algebra and functions course in the third year of a teacher education program. This course was taught by the researcher. The main instruments of data collection are two mathematical tasks where two quantities are unknown (Task A – carried out before the course and Task B – carried out after the course), participant observation and documents produced by

Working Group 3

participants. Exploratory tasks proposed in the course contribute to develop participants' algebraic thinking and their knowledge about learning and teaching algebra in elementary school. One of the tasks proposes the analysis of strategies used by Grade 6 students to solve the chicken's problem and the reflection about the teaching approach (Reeves, 2000). Collecting and analyzing of data run, in part, in parallel (Merriam, 1988). The analysis of data takes into account the strategies used by the participants and discusses the contribution of the exploratory approach to the understanding of how to promote the learning of algebra.

RESULTS

In task A, five prospective teachers gave the right solution but only four participants justified their solution with one guessing the values based on the difference of prices and three solving the system of equations. In task B, 15 participants present a correct solution and all explained their strategies, using pictorial representations, natural language or symbols: Twelve participants established their own strategies based on relationships and three solved the system of equations (not exactly the same three from task A). In the classes, the prospective teachers recognised the importance of discussion with students about different strategies to solve a problem with one or more unknown quantities and the initial uses of algebraic symbols:

The fact that the teacher valorised the reasoning more than the results also contributed to the development of algebraic thinking. (Student 1)

Some children used the letters and then explained their reasoning to colleagues and why they used them. From here the teacher can encourage the use of the letters, what begins to happen in a natural way. (Student 2)

CONCLUSION

The study analyzed the participants' answers in modeling situations, before and after the course. After the study, a greater number of students present a solution based on the identifications of relations. The study shows the perspective of the prospective teachers about the exploration of modeling activities with their students, emphasizing the relevance of reflecting about pedagogical aspects, namely the work that can be used in the classroom to promote algebraic thinking.

DIFFERENTIATED LEARNING ROUTES FOR SCHOOL ALGEBRA USING ONLINE DATABASE SYSTEMS

Julia PILET

*Paris-Diderot Paris 7 University, France
Laboratoire de Didactique André Revuz (L.D.A.R.)*

This poster presents the main lines of my current PhD work. It aims to design computer resources to help mathematics teachers to differentiate students' learning in school algebra in France in the final stage of compulsory education (15-16 years) and to study students' algebra activity.

Keywords: School algebra differentiated learning routes, online database system, cognitive assessment

CONTEXT AND AIMS

While algebra constitutes an essential element of the curriculum in order to have access to higher education, it has the reputation of being a difficult, disheartening subject, which poses many challenges for students (Kieran, 2007). Many teachers also have difficulties taking into account their students' cognitive diversity in algebra. Taking this into consideration, the *PépiMeP* project¹, of which my PhD is a part, consists of implementing computer resources in the *LaboMeP* online database system to help teachers to differentiate students' learning in elementary algebra and to study mathematics teachers' practice and students' algebraic activity. *LaboMeP* is an online database of exercises developed by one of *PépiMeP*'s partners: *Sésamath*², a French mathematics teachers association, which has had a central place in French online database systems for ten years. In the project, the *Pépité* software, a starting point of my research, based on a multidimensional analysis of algebraic skills (Grugeon, 1997), is integrated in *LaboMeP* and produces an automatic cognitive assessment of students' algebraic skills (Delozanne & al., 2008). My research consists of modelling differentiated learning routes for school algebra adapted to the cognitive assessment produced by *Pépité*, implementing them into *LaboMeP* and evaluating them as regards to students' algebraic activity. My research questions are: How to model differentiated learning routes? Which series of tasks to conceive in order to improve students' relationship with school algebra? How to conceive these tasks to integrate them into *LaboMeP*? Which feedbacks and tools to conceive in order to support students' activity? What are the effects of learning routes on students' activity?

FROM THE MODELLING OF DIFFERENTIATED LEARNING ROUTES ...

The model of learning routes is based on a cognitive approach with Kieran's model for conceptualizing algebraic activity (Kieran, 2007), an epistemological approach and an anthropological approach (Chevallard, 1992) in order to construct the model. A differentiated learning route is defined by types of tasks and didactical variables

Working Group 3

(expression complexity and task formulation) adapted to students' cognitive assessment established by *Pépité* and in order to develop transformational, generational and global/meta-level activities. Exercises are selected from *LaboMeP* or conceived with feedbacks and tools within the context of *PépiMeP* in order to enrich *LaboMeP* with new exercises. An example of learning routes is developed in the poster presented at CERME 7.

... TO THE EVALUATION OF STUDENTS' ALGEBRAIC ACTIVITY

Evaluation is linked to the use of technology because learning routes will be integrated and evaluated from the *LaboMeP* database. The following questions are considered: Are learning routes pertinent from a cognitive and epistemological point of view? How do students appropriate learning routes on the *LaboMeP* database? What are their effects on students' activity? Methodology combines qualitative and quantitative studies: a large-scale one with an ICT monitoring in *LaboMeP*, and some case studies with observations and interviews in classroom.

NOTES

1. The three partners are: Laboratoire de didactique André Revuz (Paris 7 University), Laboratoire d'Informatique de Paris 6 (Paris 6 University) and the Sésamath association. Ile de France region supports the project. TEACHING AND LEARNING OF PARAMETERS IN FUNCTION FAMILIES ^[1]

Magda Nunes Pereira^a and Manuel Joaquim Saraiva^b

^aGroup of Schools Almeida, School EB 2,3/S of Vilar Formoso, Portugal

^bUniversity of Beira Interior and UIDEF, Portugal

Abstract: *In the study that supports this paper was created a model for teaching the concept of parameter in functions, which intended to answer to the students' difficulties in this mathematical subject. It results from the reflection on the semiotic representations and transformations associated with the development of algebraic thinking in the resolution of investigative and exploratory tasks. In this model were defined three main levels – First: Operational level of reference; Second: Operational informal level; and Third: Structural level. These three levels interact dynamically in semiotic-cognitive processes in the learning of the parameter concept in a functional relationship, and in a hierarchical way (from the first to the third).*

Keywords: *Function Families; Parameters; Semiotic Representations*

THE PROBLEM OF THE STUDY

How do students represent, transform and convert the parameters in a functional relationship in achieving the structural level of knowledge?

THE MODEL

In a functional relationship, that involves parameters, our model considers three levels of understanding:

First Level (Operational level of reference) – The student recognizes the correlation between dependent and independent variables, identifies and implements numerical parameters; the student uses informal representations (schemas, tables, graphs and statements in natural language) in his reasoning.

Second Level (Informal operational level) – The student recognizes the change of the variables (independent and dependent) and of the parameter; the student uses yet the informal representations (schemas, tables, graphs and statements in natural language) in his reasoning.

Third Level (Structural level) – The student turns and connects the representations that he used in the previous level; the student uses formal representations (symbolic, graphical, schematic, and statements in natural language) in his reasoning.

THE RELEVANCE OF THIS MODEL TO THE LEARNING OF PARAMETER CONCEPT

In function families, a parameter is a generalized number that, when concretized, identifies functions of that family. For this understanding is necessary abstraction, but the progressive formalization of the concept causes difficulties for students. With the use of this model is intended to promote the learning of parameter concept by its three different levels – from the elementary to the structural one.

NOTE

LEARNING RISK IN SOCIO-SCIENTIFIC CONTEXT

Hasan Akyuzlu

Institute of Education, University of London

This poster gives you a glimpse at research on how students make sense of the concept of risk and how they create their own models when a technology-enhanced approach is taken.

Keywords: probability, impact, risk.

WHAT IS RISK?

Risk is an important socio-scientific concept in everyday life. There is a large body of literature on risk, covering a range of disciplines from mathematics to psychology. Each of these perspectives can contribute to a better understanding of how risk is constructed, perceived and managed by experts and the general public. However, neither mathematics nor psychology can explain risk by themselves; a combination of both sciences is needed, with risk at the socio-scientific intersection of the two. Adams (1996) proposed that risk is the product of the probability and utility of some future event. However, there is no agreed definition of risk in the literature; therefore this issue yields different epistemologies of risk. Sometimes, risk can be considered as possible harm, which is an issue relating to impact. Sometimes, it can be presented as a probabilistic idea, which is the quantification of likelihood. In some cases, risk can be presented as the coordination of likelihood and impact. This coordination makes risk a complex issue because, in situations which are not well defined, most people do not know how to coordinate likelihood and impact. In this theoretical account, we set out these issues in order to motivate the need for design research to explore students' thinking about risk.

Methods:

We aim to design computer-based modelling tools which provide students with the opportunity to explore the context, to build their own model and to express their own understanding in that context. To do that, we have decided to use Deborah's Dilemma, which has been designed for teachers to explore and interrogate their knowledge of risk. We have conducted interviews with a pair of students (aged 17-18) and asked questions to trigger the discussion, to expose the idea behind their decision. In this sense, the students' activity provides us a window on their thinking about risk (Noss & Hoyles, 1996).

Findings and Conclusion:

Pratt et al. (in press) found that teachers drew on personal experiences and values of their risk-based decision-making in a personal dilemma. The mapping tool was designed at the end of their study but it has not been systematically tested. I used

Working Group 5

mapping tool in order to facilitate students' risk-based decision-making. In contrast to teachers, students in this study talked in a superficial way about their personal experiences and emphasising her condition in a social aspect.

Student: My mum was in pain and she had the operation, then she got rid of the pain. I knew Deborah is in pain and she has to get rid of it. So, she should have the operation... "Not having the operation" affects her relationship and her job. .. She will not be happy if she cannot do sports as she might likes.

Subsequently, the same study and methodology was tested with 15 years old students and they referred to impact separately from likelihood even though their discussions were more thoughtful and rational than 17-18 years old students.

FUTURE ELEMENTARY AND KINDERGARTEN TEACHERS’ KNOWLEDGE OF STATISTICS AND OF ITS DIDACTICS

Raquel Santos

Escola Superior de Educação de Santarém, Portugal

This poster addresses prospective teachers and infant educators’ knowledge of statistics and of its didactics. The poster presents the results of a pilot test made with a questionnaire given to two classes of students. Some results of the questionnaire are presented and some conclusions are made regarding the improvement of their training.

Keywords: statistical knowledge, professional development

INTRODUCTION

Most teachers do not feel able to teach statistics at the early years of schooling. Given their weaknesses in this field, they avoid teaching it or teach it in a superficial way. Nonetheless, in Portugal, the new mathematics curriculum indicates that statistics should be taught since the first years of school so that students can deal critically with the information around them. Therefore, there is a need to improve the professional development to prepare teachers to work accordingly to the curriculum. It is with this idea in mind that I propose to diagnose the prospective teachers’ knowledge of statistics and of its didactics at the School of Education of Santarém.

The poster includes part of this investigation, since it regards only the results of a pilot test made with a questionnaire. 26 students in their 3rd and last year of the teachers’ program answered the questionnaire. The questionnaire, composed by 14 questions, included both questions concerning statistical knowledge and concerning their knowledge of didactics of statistics, covering primarily the topics: organization of data, statistical measures and statistical investigations. A quantitative analysis of the answers to the questionnaire is presented and some conclusions are elaborated.

THEORETICAL FRAMEWORK

Prospective teachers usually have weak or no training in statistics (Batanero et al., 2004), as well as in statistical pedagogy (Froelich et al., 2008). However, as Shulman (1986) underlines, to teach, it is essential to master the subject and the way of teaching it. In his perspective, the knowledge needed to teach a certain subject – “pedagogical content knowledge” (PCK)– includes not only knowledge of the subject, but also examples, applications, models and representations, connections between topics, etc.. This particular poster uses the Curcio’s (1987) components of graphic comprehension (reading the data, reading between the data and reading beyond the data), Mokros and Russel’s (1995) conceptions of average (as mode, as

algorithm, as reasonable, as midpoint and as balance), as well as Monteiro's (2009) different properties of average.

FINDINGS

A student answered, in average, to 70% of the questionnaire and left the other 30% blank. This can be related to the fact that it was the final of the year when they answered it or may be consequence of their statistical knowledge. Regarding the organization of different types of data, these students revealed more difficulty with the organization of quantitative continuous data. An interesting fact is that 7 students, when asked to make generalizations based on a graphic representation, used data from their own experience. Concerning the statistical investigation implementation in class, the majority of the students who answered this question stated a theme (recycling) and a survey or questions to be answered, which is probably related to their own experience in class as learners. Only one student was able to briefly discuss the class implementation of the statistical investigation. All the others connected the task to doing the investigation itself.

CONCLUSION AND FURTHER RESEARCH

The most interesting conclusion of this pilot test was that students are stuck to their own experience as learners when thinking about teaching. They are not able to go further on the planning of a lesson, stating only tasks that they did during their training. This may be an indication that students need more diverse experiences as learners, where afterwards they discuss its usefulness for students and its implementation in a classroom. The actual poster presented at CERME7 may be obtained from the author by emailing her at raquelfms@gmail.com.

COMPARING ATTITUDES TOWARDS MATHEMATICS AND STATISTICS OF K-10 STUDENTS: PRELIMINARY RESULTS

Assumpta Estrada and Ana Serradó

Universitat de Lleida, Spain, aestrada@matematica.udl.cat

La Salle-Buen Consejo, Spain, ana.serrado.bayes@gmail.com

Attitudes towards mathematics and statistics of 48 grade-10 Spanish students are analysed. The descriptive analysis of students' response to ATMI and SATS as well as a qualitative analysis of students' justifications for their scores are used to comparing the value component of attitudes towards mathematics and statistics.

Keywords: statistics, attitudes, secondary compulsory education

INTRODUCTION

Attitudes are a key factor in improving the learning process (Estrada, 2009). They are manners of acting, feeling or thinking that show a person's disposition or opinion, and may involve negative or positive feelings, which result from positive or negative experiences over time in learning a topic (Phillips, 2007). A hypothesis suggested by Gal and Ginsburg (1994) is that students may transfer their feelings towards mathematics into statistics. In this paper we present results from an exploratory study that is oriented to provide empirical results that support this conjecture.

METHOD

The ATMI (Attitudes Towards Mathematics Inventory) by Tapia & March (2004), and the Survey of Attitudes Towards Statistics (SATS) by Schau, Stevens, Dauphinee & Del Vecchio (1995) were given to the same sample students. The subjects were 48 undergraduate students, with an average age of 15 years and 60.4 % of girls in the sample. We carried out a descriptive analysis of scores in questionnaires as well as a content analysis of the students' written justifications for their scores in each item. We also compare our results with previous research (Carmona, 2004; Estrada & cols, 2005, 2009 and Tapia, 2004).

RESULTS

The results of the descriptive analysis of the ATMI suggest a slightly positive attitude in mathematics, since the mean score is over 3 (neutral point) in all the items. An exception is item 33 (average score only 2.79). *I plan to take as much mathematics as I can during my education* that corresponds to the factor "motivation". As regards attitudes towards statistics (SATS), three items (22, 13, 26) resulted in scores lower than 3. In general, ATMI scores were higher than SATS scores, and the factor "value" had higher scores in both scales. The content analysis of written justifications suggested that: (a) Mathematics was seen as important and

useful in personal and professional life by these students; and (b) Statistics was not considered to be so important in the personal and professional life for these students. Moreover, the importance given to statistics by these students depends of the type of work and they were not aware of the full range of application of statistics.

CONCLUSIONS

Attitudes towards statistics and towards mathematics were moderate or positive in both groups, but attitudes towards mathematics were better, in general. Contrary to the suggestion by Gal & Ginsburg (1994), this result suggests that not all the students transfer their feelings towards mathematics into statistics. Students have different view of the usefulness, relevance and value of statistics and mathematics in personal and professional life. All these results should be interpreted carefully, given the sample size, but they provide an interesting starting point to future research.

TEACHING DIFFERENTIAL EQUATIONS WITH MODELLING

Guerrero-Ortiz, C.

Camacho-Machín, M.

Cinvestav- IPN, México

University of La Laguna, Spain

Some results obtained from the implementation of a teaching experiment are presented in this paper. Particular attention has been paid in the modelling process of a problem leading to an Ordinary Differential Equation (ODE). The research is framed within the methodology of Design Research and the problem used in the teaching experiment was designed taking into account certain elements of modelling.

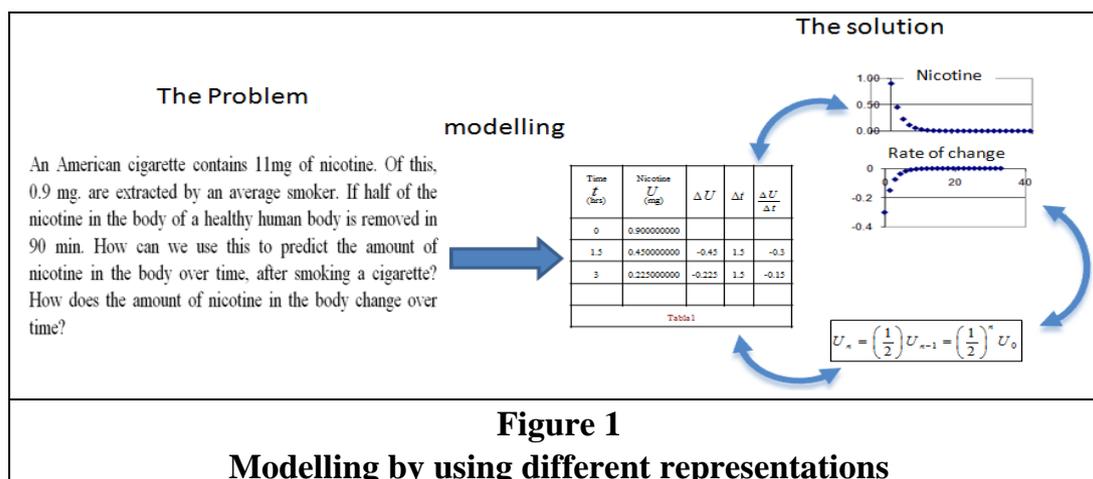

Introduction and Conceptual Framework

The activity presented in this paper is part of a teaching sequence that has been developed with the aim of introducing the concept of Differential Equation. Our main purpose is to provide students with tools to interpret an ODE and its solutions when they model a phenomenon. The results shown here are part of the first cycle of investigation in accordance with the Design Research Methodology (Brown, 1992; Drijvers, 2003). Several representations of the solution appear in the modelling process, therefore, the focus is to show how one can promote the conversion between different representations of the solutions (Duval, 1988) and what the students' interpretations are regarding the rate of change by using different representations. As Doerr & Tripp (1999) said, modelling activities stimulate students to show different solution strategies as a result of the mental activities generated. Thus, they provoke the development of their conceptual comprehension by trying to represent their ideas.

Methodology

As part of Design Research, there are two key aspects: the cyclic character of design research and the central position of the design of instructional activities. This research methodology consists of three phases: preliminary design, teaching experiments and retrospective analysis. Here we present the results of the first cycle of investigation. The instruction took place with activities involving mathematical skills and processes related to Problem Solving (Barrera & Santos, 2002).

The teaching activity was carried out with a group of seven engineering students, who chose to participate voluntarily in the experiment. One of the primary goals of the teaching was to begin modelling simple phenomenon by ODE such as $\frac{dU(t)}{dt} = kU(t)$, the activity in figure 1 was designed in this way. The following three representations are present in the process of modelling: numerical, graphical and algebraic. The students can obtain the algebraic representation of problem by looking for patterns of behavior and the visual representation can help them to elaborate conjectures about behavior of the substance in the body.

Results and Comments

Among other results, we can observe, by implementing the teaching sequence, some of the student's knowledge of concepts such as: rate of change, continuity, and some representations of the derivative. A part of these results show that students think in terms of amounts when they interpret a rate of change, this difficulty is verified in the different representations of rate of change. However, later activities showed that the students built the instantaneous rate of change more easily. We support the idea that building the concept of the ODE through modelling can help students to develop interpreting skills between the real context and the mathematical context and establish relationships between different mathematical concepts. The change from the discrete function to the continuous function is not trivial. It is important to work on the connections between average rate of change and instantaneous rate of change. It is necessary to introduce activities that promote reflection on these topics in the future design of teaching sequences.

BELIEFS ON THE USEFULNESS OF MATHEMATICS AND MATHEMATICS SELF-BELIEFS AS IMPORTANT FACTORS FOR MATHEMATICS ATTITUDES

Peter Vankúš¹

Comenius University in Bratislava, Slovakia¹

The poster deals with the results of the questionnaire surveys of pupils' attitudes towards mathematics. The aim of the poster is to stress results which show the importance of specific attitudes in areas for the whole of pupils' mathematics education. The questionnaire used was a modified version of the Mathematics Related Beliefs Questionnaire and the research sample were students of the 5th and 9th school year in Slovakia. The results of the questionnaire were processed by the statistical software CHIC. The pupils' beliefs on the usefulness of mathematics and their mathematics self-beliefs were identified as important factors for their liking of mathematics and their mathematics achievements.

Keywords: affects towards mathematics, attitudes, MRBQ, questionnaire survey, improving of mathematics education

INTRODUCTION

The importance of pupils' attitudes towards mathematics is supported by the opinion, believed to be true in scientific and teacher communities, which states that pupils learn more effectively and they are more interested in the mathematics lesson and are performing better if they have positive attitudes towards mathematics (Ma & Kishor, 1997).

In our poster, we deal with the results of questionnaire surveys on pupils' attitudes towards mathematics performed in Slovakia. In our study, that was part of the comparative research study led by Jose Diego-Mantecon and Paul Andrews from the University of Cambridge, the modified Mathematics Related Beliefs Questionnaire (De Corte & Op't Eynde, 2002) was used. The questionnaire was designed to find out the compatibility of its use in various European states, specifically in England, Spain and Slovakia (Andrews et al., 2007; Andrews et al., 2008). The aim of this poster is to report on part of the results from the surveys carried out in 2007 on a sample of 204 Slovak pupils, 76 in the 5th year (9–11 years old) and 128 pupils in the 9th year of the primary school (14–16 years old) and in 2008 on a sample of 241 pupils in the 9th year. The outcomes were analyzed by the statistical software CHIC (Gras et al., 2008) and showed significant impacts of the beliefs on the usefulness of mathematics and mathematics self-beliefs on other components of pupils' mathematics education as liking of mathematics, mathematics achievements and active learning strategies.

These results are very informative for mathematics education. They show that we can positively influence process of mathematics education by the improving of two elements: pupils' mathematics self-beliefs and their beliefs on the usefulness of mathematics.

ON THE MEANING OF MULTIPLICATION FOR DIFFERENT SETS OF NUMBERS IN A CONTEXT OF VISUALISATION

Raquel BARRERA

Ph.D. candidate in Didactics of Mathematics

Laboratoire André Revuz – Université Denis Diderot – Paris 7

Abstract. *This work is a study of definitions, meanings and representations of multiplication for different sets of numbers from middle school to high school in France. Specifically, it concentrates on the integer, rational and complex number domains in order to determine the role that visual and geometric representations could play in the learning process of multiplication.*

Key-words. Multiplication, semiotics, geometric representations, transformation.

Description of the poster. Could a geometric treatment of multiplication highlight the link between different meanings of multiplication related to different number domains? This question serves as the title of the poster, followed by different geometric representations of multiplication in the integer, rational, and complex number domains. Meanings of multiplication, even those corresponding to magnitudes, can be visually linked to transformations in the plane (*i.e.*, factors as operators). Considering that geometric figures help students' reasoning by giving meaning to an assigned problem (Kuzniak, 2006) and by leading students to describe mathematical situations "in order to master mathematical concepts" (Duval, 2003), we reflect on a historical text. Descartes' product (1637) is one way teachers could introduce complex number multiplication: what will we find if we describe what goes on between the points, angles and line segments composing Descartes' geometric construction? Possible responses could include relations of proportionality between line segments, co-linearity of segments, as well as relations based on transformation in the plane such as homothety and rotation.

Summary of research and further questions to discuss. Several studies show that the learning of multiplication in the rational, integer and complex number domains implies a break with the first meaning of multiplication. This is because the product can no longer be seen as the result of repeated addition or as the area of a surface. What are the other meanings? How should we teach them and why? Are they important in the learning process of multiplication? Is there a "geometrical common thread" between the different meanings of multiplication?

The theoretical framework that has motivated our research on the meanings of multiplication in geometry is a cognitive approach to semiotic representations. Our assumptions, following Raymond Duval, are that "mathematical objects are never accessible by perception or by instruments. The only way to have access to them and deal with them is using signs and semiotic representations" (Duval, 2006, p. 107)

and also that “There is not mathematical thinking without using semiotic representations” (Duval, 2008, p. 1). Thus, we propose that (1) establishing a link between a numeric or algebraic register and a geometric register may aid comprehension of a complex notion such as multiplication; (2) understanding different meanings for multiplication may facilitate the emergence of various strategies for solving problems linked to this mathematical Notion; (3) more specifically, linking multiplication and geometry may give students a deeper comprehension of factors as operators.

Through this research, we seek to relate our interest in **the meanings of multiplication to the cognitive process linked to a change of semiotic representations** that these meanings make possible. A few research questions are: can meanings of multiplication allow us to move between one semiotic representation and another? Can we suggest didactical treatments for multiplication and its meanings linking algebra, arithmetic and geometry?

An epistemological and didactical analysis of multiplication in three number domains—integers, rational and complex numbers (Glaeser, 1981; Flament, 2003)—and an ecological study (Chevallard, 1985) of middle school and high school curricula in France are the starting point of our methodology. Is there a historical link between the meanings of multiplication and geometric representations? If not, do epistemological or didactical elements exist which propose this link? Can we suggest some didactical treatments for multiplication and its meanings linking algebra, arithmetic and geometry?

GESTURE AND VISUAL-SPATIAL THINKING

Conceição Costa

Escola Superior de Educação de Coimbra / UIED FCT UNL,

José Manuel Matos

Universidade Nova de Lisboa / UIED FCT UNL

This work attempts to grasp visual-spatial thinking in mathematics education. It analyses two classroom interaction episodes between two elementary students using a geometry software that stimulate the exploration of ideas of translation, reflection and rotation, through the motions slide, flip and turn. The excerpts are a follow-up of a study intended to create, explore and refine a theoretical model for visual-spatial thinking. This poster also presents part of conclusions of the research about the visual-spatial thinking, related to grasping “what is the role of the gesture for thinking?” and it intends to contribute to the reflection about the theme.

Key-words: Visual-spatial thinking, gestures and objectification.

The interest in gestures for mathematics education is growing. Differences in perspective about the role of the gestures in cognition have, to an important extent, to do with theoretical components about thinking (Radford (2009a)). Radford advocates that gestures are genuine constituents of thinking, and he presents a sensuous conception of thinking: "thinking cannot be reduced to impalpable mental ideas; it also made up of speech and our actual actions with objects and all types of signs. Thinking, hence, does not occur solely *in* the head, but *in* and *through* language, body and tools" (p.113). Within this perspective, gestures may be seen as part of the tactile mode that individuals use to conceptually grasp something; and thinking is considered a sensuous and sign-mediated reflective activity embodied in the corporality of actions, gestures and artifacts (Radford, 2009b).

Our interest is in gestures as they appear in mathematics learning settings that promote the acquisition of visual-spatial thinking and this poster presets a follow-up of a previous work (Costa, 2005) that intended to create, explore and refine a theoretical model for visual-spatial thinking and through it to understand the development thereof by the identification of the visual-spatial thinking modes and the thinking processes associated to them. The theoretical framework for visual-spatial thinking model took into account research in the areas of cognitive processes in mathematics education, embodiment in mathematics, a socio-cultural perspective on learning with emphasis on the social construction of knowledge and on semiotic mediation, theoretical perspectives on the teaching and learning of geometric concepts.

In this poster, we will use the lens of *theory of knowledge objectification* (TO) (Radford, 2008) and the perspective about gesture of Radford to interpret two

classroom excerpts. In the TO, learning is conceptualized as the active and creative acquisition (thematized as a problem of objectification) of historically constituted forms of thinking through means and processes; these means are called, *semiotic means of objectification*; and the processes are called, *processes of objectification*.

The methodology was qualitative integrating video registrations of individual answers and tasks performed in classroom activity. The analysis of those episodes centres on the gestures and words of the students that will be interpreted through the socio-cultural perspective of Radford, where mathematics learning involves the social and semiotically mediated process of objectification.

THE EVOLUTION OF SCHOOL MATHEMATICS DISCOURSE AS SEEN THROUGH THE LENS OF GCSE EXAMINATIONS

Candia Morgan* and Anna Sfard**

Institute of Education, University of London* and University of Haifa**

The ways in which mathematics is communicated to students shape the ways in which they may engage in mathematical activity. A particularly powerful influence on the forms of tasks offered to students is the high-stakes examination. In a new project, we propose to analyse changes in the discourse of English national examinations at the end of compulsory schooling through a period of curriculum change and to investigate how these changes affect students' mathematical activity.

Keywords: examinations; discourse analysis

Over the last decades there has been ongoing public and academic concern about the nature and standards of school mathematics. This concern has driven frequent revisions of curriculum and examinations, yet controversy continues and there are contradictory opinions about the effects of reforms. The overarching aim of our study is to investigate the evolution of school mathematics in England, as seen through the lens of examinations at 16+. Our main question asks: *What has changed since the introduction of the GCSE⁹⁵ examination in the mathematics that pupils are expected to learn and in the way they are expected to approach mathematics?* Rather than comparing syllabi or teaching methods, we seek to probe deeply into the nature of the mathematical activity expected of students. We do this by developing and applying a discourse analytic approach, drawing on Social Semiotics (Bezemer & Kress, 2009; Halliday, 1978; Hodge & Kress, 1988; Morgan, 2006) and Sfard's theory of mathematical thinking as communicating (Sfard, 2008). Studying discourse in this way, by focusing on the forms of language used in examination papers, allows a subtle characterisation of the ways they construct the nature of mathematics and of student mathematical activity. We argue that this type of analysis will provide insight into how changes in curriculum and assessment may affect students' mathematical learning.

There will be two principal parts to the study. First, discourse analytic methods will be applied to a sample of examination papers in mathematics for pupils aged 16+, taken from different points in time, including critical points in the development of mathematics examinations since the introduction of GCSE. This will allow us to:

⁹⁵ The GCSE examination is a national examination taken by almost all students at age 16+. It was introduced in 1988 at a time of major changes in the curriculum and has been revised several times since then.

Working Group 9

- develop a means of analysis of the discourse of mathematics examinations at 16+ that will allow a characterisation of the nature of mathematical activity required of students and that will be sensitive to changes over time;
- identify and characterise differences over time in the nature of mathematical activity required of students at 16+.

Second, a group of current school pupils will answer a sample of questions from these examination papers. Analysis of their responses and detailed follow-up interviews will allow us to:

- investigate how differences in the discourse of mathematics examination questions may affect the ways students approach the mathematics;
- contribute to a fuller understanding of how changes in curriculum and assessment have affected the nature of students' mathematical learning.

These two parts, when taken together, are expected to help us in addressing the question of in what ways GCSE examinations of different periods can count as mathematically comparable, that is, (a) whether they are “mathematically equivalent” in the eyes of expert mathematics educators (the first part of the study); (b) whether they lead to “equivalent” mathematical activity (the second part of the study). The study will thus:

- contribute to debates about changes in curriculum, pedagogy and assessment methods;
- provide knowledge and analytic tools to inform the design of mathematics examinations and curricular materials.

In presenting the poster we will provide a brief overview of the project, our initial schema for analysing the discourse of examination papers, and examples of analysis that illustrate the differences in the nature of mathematical activity constructed in examination questions from different periods.

SELF-REGULATION OF STUDENTS IN MATHEMATICS AND ORAL COMMUNICATION IN CLASSROOM

Sílvia Semana

Leonor Santos

PhD. Student of Institute of Education of University of Lisbon, AREA Project⁹⁶

Institute of Education of University of Lisbon, CIE, AREA Project

Through an interpretative case study, the poster focuses the teaching practices of a mathematics teacher, Joana, aimed at promoting students self-regulation, in a context of collaborative work between four teachers and one of the researchers. The results presented are based, mainly, on observation (with audio and video recorder) of two lessons of an 8th grade class of Joana. Special attention is given to oral communication in the classroom, as a central concern of Joana's reflection.

Keywords: *self-regulation, oral communication in classroom, teaching practices, reflection, collaborative work*

THEORETICAL FRAMEWORK

Research recognizes self-regulation as a process that can help improve students' learning and academic achievement (Boekaerts, Pintrich & Zeidner, 2000). It requires that students possess a concept of the standard level being aimed for, compare the current level of performance with that standard and engage in appropriate action which leads to the closure of the gap (Sadler, 1989). Oral communication in classroom could be an important element in the self-regulation, mainly if it is a thoughtful and informative communication that promotes reflection and argument, that is used to inform and adapt teaching practices and in which prevail discussion patterns (Voigt, 1995). Of course, this depends on how the teachers manage the discussions, question, listen and respond to their students. This requires the teachers to rethink what they do and how they do it, in other words, to reflect on their practice. But changes of practice are challenging. The collaborative work is a favourable setting for developing new forms of work in mathematics classroom (Sowder, 2007).

JOANA'S CASE

In order to promote self-regulation of students, two lessons of Joana were planned by the collaborative group of teachers, including the proposal of a task in small groups, oral presentations with discussion in all-class and request of a written self-assessment of each working group. In the first lesson, the dominant role of the teacher and the few interventions of the students in reaction to peers interventions were noticed by Joana. An overview of the lesson shows that the number of

⁹⁶ Project financed by FCT, n° PTDC/CED/64970/2006

Working Group 9

interventions of the teacher was about half of the total in group-class and that the voice of students tends to be “sandwiched” by Joana, that intervenes after each student. In the second lesson, Joana stress the need to students comment peers interventions and oral communication changed remarkably. The teacher passed much more unnoticed during oral presentations and the students asked questions to colleagues, commented and argued, communicating among themselves. Indeed, following this second episode we find 26 interventions by students, without any intervention by the teacher.

Eduardo: ... you are saying ... So, the number of the figure is one, isn't it? You have to do three times one plus one?

Duarte: No. You have to make the number of the figure, supposed that the figure is two (...) The number of the figure is two (...) three times, which are the points we add, and one more, which is the middle one.

Eduardo: Ah?

Filipe: Look, look ... Not counting this, two is what will be here [in the 2nd figure], three is what will be here [in the 3rd figure]...

Ana: Look. It's like this, I get it, we do the number of the figure, which is a ...

Eduardo: Yea...

CONCLUSIONS

The collaborative work provided opportunities for Joana to plan, discuss and reflect about her classroom practices, especially concerning oral communication and the promotion of self-regulation of students. A remarkable development is visible in oral communication in the classroom, from the first lesson to the second one. Joana seems to become aware of her role in oral communication in the classroom, being more concerned with giving space and encouraging the students to discuss, argue and counter-argue their ideas. The reflection by the teacher, in a context of collaborative work (Sowder, 2007) gains especial importance, by contributing to changes in the teaching practices, which are expected gradual and challenging.

TEACHERS' ENDORSED AND ENACTED NARRATIVES TO PROMOTE MATHEMATICAL COMMUNICATION

Marie Bergholm

Linköpings University/ Gävle University Sweden

Keywords: mathematical discourse, teacher interviews, commognitive framework

Ongoing study with the purpose of identifying teachers' strategies, tools and settings to give the students opportunities to participate in mathematical discourse. Several research methods are used to catch and compare the teachers' and students' discourse of mathematic. The study is guided by the commognitive framework and in this part teacher interviews are analyzed by a hermeneutic approach.

INTRODUCTION

The Swedish curriculum raises demands of individualization and an effect is that the students have been left to work individually at their own pace (Skolverket, 2009). When the mathematics communication decreases, the pupils cannot build up a useful language to master expressions and methods used in the textbook (Löwing, 2004). A conjecture is that teachers' awareness of the mathematical communication is fundamental for learning. The aim is to investigate the teachers' endorsed and enacted principles regarding mathematical communication and to identify teachers' discursive routines to encourage the participants' ability to take part in the classroom discourse.

THEORETICAL FRAMEWORK

This empirical study sets out from the commognitive theoretical framework (Sfard, 2008) rooted in the participationist assumption that the discourse in mathematics plays a central role for learning. Learning is here seen as an activity in which the students modify and extend their discursive repertoire. The discourse analyses will be guided by the commognitive framework and critical hermeneutics is used to interpret the teachers' narratives about the role of mathematical communication.

METHODS AND RESEARCH QUESTIONS

Several research methods are used to catch and compare the teachers' and students' discourse of mathematic; interviews, video recorded classroom observations and use of "smart pens". In this first part, with the purpose of investigating and identifying teachers' strategies, tools and settings to give the students opportunities to participate in mathematical discourse, 15 teachers in Upper Secondary School are interviewed in semi structured audio taped interviews. The transcribed interviews are analyzed according to a hermeneutic approach (Ödman, 2007). The research questions to deal with in the interviews of the teachers are: What narratives do teachers tell about the role of the discourse in learning mathematics and ways to foster the students'

mathematical conversation in different learning situations? What is the expected impact of the students' learning from the teachers' perspective?

RESULTS

The teachers emphasize that opportunities for students' learning in mathematics occur, when the students explain and discuss mathematics with others. Participating in the discourse the students can be aware of, and familiar with, the peers' strategies and methods to build up thinking structures in mathematics and identify their "error in thinking". The teachers stress that not only the students but also teachers themselves are learning in the classroom discourse. Their ability to understand the students' way of thinking increases and they can take more aspects of how students' struggle with mathematics into consideration in their planning. They put emphasis on the opportunities to observe the students when they are struggling with words and trying to enlarge the discourse in the current context. This enables them to help the students to modify and extend their use of words and fill the existing gaps in the used classroom language.

In order to promote the mathematical communication in the classroom, the most essential obstacle to clear away is the students' lack of self-confidence in the subject, to work against the feeling that it is possible to learn mathematics and defy negative attitudes from parents, teachers and society. Further to inspire the students' feeling that they have time to listen to each other, explain their thoughts with their own vocabulary and exchange ideas. The teachers have to work consciously to encourage the students to put their strategies and how they have figured things out into words. They underline the need to work towards a teaching learning agreement in the classroom where comprehensions is more important than getting a lot of exercises done. Most of the teachers try to avoid predetermined roles by randomly chosen working groups. To encourage the mathematical communication they prefer to arrange group discussions without right or wrong answers, and the students have to actively explore the explanations and interpretations from others and take sides for or against.

COMMUNICATION – A/THE KEY TO MATHEMATICS

Birgit Gustafsson

Department of Natural Sciences, Engineering and Mathematics,
Mid Sweden University

Abstract: This poster presents a part study of a larger project dealing with classroom communication and teacher-student interaction in mathematics education. The study focussed upon in the poster investigates communicative aspects and teachers' scaffolding strategies during lessons when algebraic concepts are being taught.

Keywords: Communication, teacher-student interaction, algebra

INTRODUCTION

The research project of which the presented study constitutes one part is dealing with teaching and learning mathematics in the latter part of compulsory education and the first year of upper secondary school. The focus of the project as such is upon classroom communication with respect to teacher-student interaction and the teachers' scaffolding strategies on the one hand and students' interpretation and understanding of the learning content on the other. The mathematical domain that is studied is algebra, and both mathematical concepts which are new to the students and concepts, which students are already familiar with, are of interest. It is frequently argued that algebra is an abstract and problematic area (e.g., Olteanu, 2007) which most students have not met in primary education in any formal sense, and which contains a body of new mathematical concepts. Shortcomings in the early teaching and learning of algebra and functions may, in turn, cause later problems in mathematics. There is a risk that difficulties occur if a large number of new concepts that the students have never met before are introduced within a short time and without ensuring an adequate understanding. The aim of the present study is to investigate the teacher-student interaction with focus on teachers' scaffolding strategies.

THEORITICAL FRAMEWORK

To answer the research questions the Theory of Didactical Situations (TDS) has been adopted as a theoretical framework (Brousseau, 1997). In this theory, the didactical situation is regarded as three-dimensional, and as a relation between the teacher, the pupils and the learning content. Leaning on TDS the analysis has taken its points of departure in: the didactical situation vs. the adidactical situation; the milieu created; the didactical contract

There is a *didactical situation* if the teacher has an active role. If the teacher plays a modest role, we have an *adidactic situation*. The *milieu* is constituted not only by the physical surrounding but also by the design of the lesson. The didactical contract – is

an interdependent obligation between teacher and students. It has characteristic rules that each one has to fulfill.

METHOD

In a first step, before their introductory lesson in algebra, semi structured interviews were carried out with each of the seven teachers participating in the project. These interviews focused on the learning content and the teachers' intentions with the lesson. Semi structured interviews were chosen because they allow both a certain flexibility and a relaxed conversation in which the teacher might relate to their experiences and understanding (Bryman, 2007). Next, the lesson in question was observed and both video and audio recorded in order to catch, as accurately as possible, the teacher-student interactions and scaffolding strategies used. Follow-up semi-structured interviews with the teacher were held after every classroom observation. Data have been collected through video-recorded observations of classroom situations as well as from interviews with the teachers in these situations. The analysis is inspired by the three dimensions suggested by Sensevy et al. (2005) and deals with (a) the teacher's organization of the milieu, (b) the teacher-student(s) interaction, and (c) the development of the knowledge.

RESULTS AND DISCUSSION

The analyzed lessons are mainly didactic situations as defined by Brousseau (1997) because the teachers control the learning situation most of the time. There is certainly a didactic contract between the teacher and her/his students. The milieu is organization with materials for learning and tasks to be solved – these tasks are mostly of the same kind as examples they have been shown, which is in line with the teachers' intentions that the students "need to practice". Different kinds of classroom interaction are analyzed. The teachers' introductions differed with respect to scaffolding strategies and ways of communicating with their students. However, all the teachers used everyday language to a great extent and tended to avoid the adequate mathematical concepts. When the students' worked individually with textbook tasks or with problem solving in groups, two teacher strategies were found, namely piloting the students past difficulties and more elaborate guiding.

FAMILY MATHEMATICS INVOLVEMENT: DRAWING FROM A SOCIOLOGICAL POINT OF VIEW

Javier Díez-Palomar, Sandra Torras-Ortin

EMiCS – Universitat Autònoma de Barcelona

This poster presents the research project FAMA (Family Math for Adult Learners) which aim is to built a European network of good practices and resources to promote the family Mathematics education in schools over Europe. Using interviews, questionnaires and focus groups whose applied to students, teachers and families, we collected data. Our findings show the importance of the family involved in children's education, and the influence of family members' past experiences and background in mathematics.

Keywords: Mathematics, family, involvement

FAMA (Family Math for Adult Learners)¹ is a research project funded by the European Commission (Grundtvig Program)². International studies provide a plethora of evidences showing that family involvement in Mathematics Education is a key element to improve children performances in this topic (PISA, TIMSS, PIRLS). Drawing on this fact, FAMA intends to contribute to the development of quality lifelong learning practices among adult learners (parents) in order to promote high performance, innovation and a European dimension in systems and practices in this field (specific priority). FAMA work is framed by a theoretical and methodological perspective based on a social justice approach (making special consideration for vulnerable groups, such immigrant, and working class families). This project contributes to encourage more experiences of family involvement in mathematics education grounded on scientific criteria and successful prior experiences.

This project proposes the following objectives:

- To contribute to the development of quality lifelong learning and to promote high performances.
- To help provide adults with pathways to improving their knowledge and competences.
- To improve the quality and to increase the volume of cooperation between organizations in adult education.

In this project we collected data using interviews, questionnaires and focus groups in the five countries involved in this research study. These instruments have been applied to students, teachers and families. To analyze the data we use discourse analysis techniques (Gee, 1999) and critical communicative methodology (Gómez González & Díez Palomar, 2009; Gómez, 2006). According to our findings, we claim that when families get involved in children's education they are able to overcome

Working Group 10

many of the barriers that make learning difficult for themselves as well as for their children. As result students improve their scores. In the same way, drawing on our data we have also observed that family members' past experiences and background also impact on their attitude towards mathematics, which mediates their involvement in their children's mathematics learning as well.

A lack of communication between families and teachers also arise from our findings.

ACKNOWLEDGEMENTS

We would like to thank the European Commission for the support given to the authors of this study titled FAMA: Family Math for Adult Learners (504135-LLP-1-2009-1-ES-GRUNDTIG-GMP). This publication [communication] reflects the views only of the author, and the Commission cannot be held responsible for any use, which may be made of the information contained therein.

NOTES

1. In this project six organizations are participating, which are linked in the field of education and formation: UAB and FACEPA (Spain), Kings' College of London (United Kingdom), University of Lisbon (Portugal), AFEC (France), GRIM (Italy). In addition, there are also three more participants that are involved in the proposal. This are: SVEB (Switzerland), VOX The University of Arizona (United States) and Monash University (Australia).

LEARNING MATHEMATICS

THOUGHTS AND INTERPRETATIONS OF STUDENTS WITH FOREIGN BACKGROUNDS

Petra Svensson

School of Education, Malmö University

In this study, which is in the first phase, students' foregrounds and rationales for learning mathematics will be examined with the aim of producing a qualitative picture of thoughts and interpretations of students with foreign backgrounds on their possibilities to learn mathematics in the Swedish socio-political context.

Keywords: Multicultural mathematics classrooms, students' foregrounds, rationales for learning.

BACKGROUND

My research interest originates from the complex of problems concerning the underachievement in school mathematics of students with foreign backgrounds; i.e. born abroad or born in Sweden with two parents born abroad (Siris databas 2009; SCB, 2002). In this text, I will use the term "student" instead of "students with foreign backgrounds". In Malmö, the third largest city of Sweden, the academic achievement in mathematics is very low in some multicultural areas; at some schools the majority of the students finish compulsory school without a grade in mathematics (Siris databas, 2009). Hence, too many students do not reach the *goals to be attained*, which according to the National curriculum are the minimum level that students should have when they leave compulsory school. But even more important, this is one of the reasons why too many students do not get access to equal social opportunities in life (Wigerfelt, 2009). In these multicultural areas, the classrooms are multicultural and the majority of the students come from Iraq, Yugoslavia, Bosnia-Herzegovina and Lebanon.

Mellin-Olsen, (1987) describes two major rationales that can be identified as drivers for school learning, the I-rationale (instrumental) and the S-rationale (social). Simplified the I-rationale means that students decide to learn to achieve good grades and pass exams and the S-rationale that students decide to learn the particular knowledge because it has an importance beyond passing the exams (Mellin-Olsen, 1987). These rationales combined with the notion of foreground will constitute the theoretical framework of this forthcoming study. The notion of foreground was first introduced by Skovsmose in 1994 but later developed;

The notion of *foreground* refers to a person's interpretation of his or her learning possibilities and 'life' opportunities, in relation to what the socio-political context seems to make acceptable for and available to the person. (Alrø, Skovsmose, Valero, 2009, p. 7)

PURPOSE AND RESEARCH QUESTIONS

The aim of my study is to learn more about students' thoughts and interpretations on their possibilities to learn – or not learn to mathematics – and what kind of rationales for learning they have, and to what extent the students' foregrounds have an impact on these rationales.

- How do students with foreign backgrounds experience their possibilities to learn mathematics and what are their reasons?
- To what extent do foregrounds of students with foreign backgrounds impact them when learning or not to learning mathematics?
- What do students with foreign backgrounds believe are their rationales for learning or not to learning mathematics?

EMPIRICAL STUDIES AND METHODOLOGY

The study is intended to be carried out through classroom observations and interviews with students from 8th or 9th grade. The purpose of the observations is to get a picture of the learning situation and to get to know the students and how they act during the lessons, and also to help me to decide which students to interview. Since I am interested in learning more about the immigrant students' own thoughts and interpretations about learning mathematics I will use narratives where the data will be constructed by the informants and the researcher together (Goodson, 2001). I will interview students from 8th or 9th grade because they are about to make a decision about their future since they are about to leave compulsory school. Only the student interviews will be used in the data analysis and it will be carried out by using discourse analysis techniques (Winther Jørgensen, 2000).

THE EMERGENCE OF CULTURAL MATHEMATICS: AN ETHNOMATHEMATICAL APPROACH IN THE CONTEXT OF CLASSROOM

Joana Latas *, Darlinda Moreira **

*EBI/JI de Aljezur **Universidade Aberta, UIDEF- U. Lisbon

This poster presents an ongoing research whose main objective is to understand the role of cultural mathematics in the development of transversal mathematical processes. Using an ethnomathematical approach based on the cultural profile of students in a 7th grade class who participated in the research, a curricular project was designed, which was implemented in the classroom in five phases. An initial data analysis shows that the students: i) appropriated culturally distinct practices through relationships established with their prior knowledge ii) gradually reveal greater predisposition to establish mathematical connections. Throughout the research students improved their capacity of mathematical communication.

Keywords: Cultural mathematics; mathematical connections; mathematical communication

The integration of cultural aspects in the mathematical curriculum contributes to the understanding of mathematics as part of everyday life, which, by its term, strengthens the possibility to establish meaningful connections between different contexts and, hence, is a factor of students' mathematical comprehension (Adam, Alangui & Barton, 2003 and Bishop, 2005; Boaler, 1993, Zaslavky, 2002). However, when children come to school they bring a set of cultural experiences with them that might not be valued in the academic context (Gerdes, 2007; Moreira, 2002). The review of the literature highlights that students' foreground and background are important issues that are related to students' predisposition and involvement in their learning process. Thus, not only it is necessary to understand and take into consideration students' different *backgrounds*, but also it is important to combine this information with what students long for their future - *foreground* - and how they deal with their expectations in their social context, (Alrø, Skovsmose & Valero, 2009; Skovsmose & Vithal, 1997). Teachers' pedagogical decisions should, therefore, take into account the understanding of the background and foreground.

Inspired by the theoretical model for the implementation of an ethnomathematical curriculum (Adams, 2004), grounded in an integrated vision between the concepts and cultural practices of students and the predominantly formal mathematics, a project was developed and implemented in five phases: 1) search for each student's background and foreground, their relationships with local meanings, 2) the emergence of practices and connections among different cultural practices, 3) search for mathematical cultural experience, 4) mathematical formalization, and 5) deepening of cultural knowledge based on mathematics.

The methodology was qualitative in nature, following the interpretative paradigm. Data was collected using participant observation, interviews and documentary analysis. Participants were students in a class of the 7th grade in a seashore zone in the south of Portugal. The teacher played simultaneously the role of investigator.

A first analysis suggests that the ethnomathematical approach to explore cultural mathematics in the context of the classroom promotes the establishment of mathematical connections with students' daily lives and previous knowledge, contributing to the appropriation and assignment of meaning to mathematical concepts. Throughout the presentation of students' tasks, the development of oral and written communication and of arguments that used mathematical concepts related to the cultural contexts was further evidenced.

PARENTAL INVOLVEMENT IN CHILDREN'S ACHIEVEMENT: AN EXPLORATORY STUDY WITH FRENCH 2ND GRADERS IN MATHEMATICS

Ana Lobo de Mesquita

Université d'Artois / Université Paris Diderot,

Laboratoire de Didactique André Revuz & IREM de Paris 7¹

Studies in literacy in mother tongue confirm the influence of the family behaviours in children's learning children in linguistic, cultural and urban backgrounds. With the idea of extending these studies, a group of teachers and researchers from two domains (mother tongue and mathematics) and from different countries, conducted studies about the influence of parental involvement in children achievement on these domains.

In our preliminary study, we analyse the case of parental involvement in pupils' achievement when mathematical activities are used. We focus on French 2nd graders (20 pupils from 7 to 8 years old), in a similar framework and setting than those used in literacy studies, issued from Villas-Boas (2001). We also use the notion of "communities of practice" developed by Wenger (1998). Our first results seem confirm the trend that parental involvement improves student achievement in mathematics².

Key words : Parental involvement, Achievement, Mathematics Education

Studies in literacy in mother tongue conducted in different contexts and countries have shown that the influence of the family behaviours appears to be strongly significant when those families help children to be aware of their cultural and linguistic backgrounds (Epstein, 1995; Henderson & Berla, 1994). Also, children's knowledge and achievement have been improved by the cooperation between generations (Villas-Boas, 2005).

In the study presented here, the notion of "communities of practice" - issued from a particular context (economics) - developed by Wenger (1998) and implemented in mathematics education by Díez-Palomar & Moratonas (2006), was used; two dimensions were specially important: the *mutual engagement* (of the child and the parent, engaged in their activities) and the *shared repertoire* (sharing texts, whose writing has a main role). (Note that the third dimension used by Wenger - the joint enterprise - was not considered here).

In our contribution we try to answer to the following questions: Is it possible to increase mathematics development by involving parents and children in activities about their common (urban, linguistic, mathematical) grounds? How do these activities influence pupils' achievement ?

Working Group 10

With this purpose, we have planned an on-going qualitative and quantitative study, where the activities proposed to 2nd graders (7 to 8 years old) involved also mathematical concepts.

In the exploratory study, we work with one class, divided into two groups, the experimental and the control groups. Pupils were proposed tasks where mathematics concepts were progressively used. We ask pupils to develop some activities, in partnership with a parent (mother, father, grandmother, brother, ...) and to write a small text about the realization of this activity. Texts were compiled in a booklet untitled « *When my mother [or else] was a little child* ».

A questionnaire of home environmental processes related to school achievement was proposed to the parents, adapted from Villas-Boas (2001) and Davies (1996), aiming to scale the importance of different activities of pupils at home.

In the poster presentation, focus was done: i) on the activities presented to pupils and parents during the exploratory study, ii) a qualitative analysis of the progresses of pupils observed by the teacher, iii) on “profiles” of home environment issued from answers of parents, iv) on a discussion about the study, with suggestions for future interventions.

The actual poster presented at CERME7 may be obtained from author by emailing to <mesquita@math.jussieu.fr>

STUDENTS' SELF-REGULATION, SELF-EFFICACY AND MATHEMATICAL COMPETENCE IN OECD'S PISA

David Pepper

King's College London

This paper is an iteration of a poster presented at CERME 2011. It describes the scope and methods of a planned international comparative study of the relationship between lower secondary students' self-regulation, self-efficacy and mathematical competence using the OECD's PISA survey and the ICCAMS study in England.

Key words: Mathematics, comparative, self-regulation, self-efficacy, competence.

SCOPE

This short paper is an iteration of a poster for CERME 2011 which presented the scope and methods of a proposed international comparative study. These have been revised as a result of feedback from CERME's Working Group 11- Comparative Studies in Mathematics Education and the author's subsequent reflections. The study's main research question is: to what extent is a relationship between lower secondary students' self-regulation, self-efficacy and mathematical competence generalisable across educational contexts and cultures in different countries?

Self-regulation is used with reference to students' monitoring, control or regulation of their cognition and behaviour (Pintrich, 1999). Self-efficacy is 'a judgment of one's capability to accomplish a certain level of performance' in a specific task (Bandura, 1986; Zimmerman, 2000). Self-efficacy is consistently highly correlated with academic performance, including mathematics (eg Pajares and Miller, 1994). Pintrich's (1999) general framework identified a strong and positive correlation between students' self-regulation, self-efficacy and academic performance. However, his call for future research to explore this beyond white, middle-class students in the USA requires attention. The study will therefore investigate the extent to which the correlation can be generalised across contexts and cultures in different countries.

The study will focus on students' monitoring of their own learning (as an aspect of self-regulation) and the calibration of their self-efficacy judgements to their attainment in mathematics. With reference to European and international policy discourses (Gordon, et al., 2009), it posits that this calibration should be viewed as an aspect of *mathematical competence*, enabling students' 'selection and use of the most appropriate solution strategy on a given mathematical item or problem, for a given individual, in a given sociocultural context' (Verschaffel, Luwel, Torbeyns, & Van Dooren, 2009, p. 343). Students' self-regulation and self-efficacy should therefore be predictive of their use of their solution strategies and their resultant solutions.

METHODS

The study will use multiple methods. Firstly, there will be a correlation analysis of self-regulation, self-efficacy and attainment using the influential OECD PISA (Programme for International Student Assessment) 2003 data set, which focussed on mathematical competencies in 41 countries with varied educational contexts and cultures. The analysis will include student background, school and country variables. It will also explore whether a multi-level model provides the best fit for the data. Secondly, interpretation of the data for selected countries will be supported by the development and validation of country profiles (Hodgen, Pepper, Sturman, & Ruddock, 2010) detailing socio-mathematical norms (Yackel & Cobb, 1996). Thirdly, students will be interviewed through the Increasing Students' Competence and Confidence in Algebra and Mathematical Structures (ICCAMS) study in England (Brown, Hodgen, Kuchemann, Coe, & Pepper, 2010). The interviews will explore students' use of solution strategies in the context of their self-regulation and self-efficacy. These interviews will also help to assess the validity of the associated PISA questionnaire items in some contexts in England, perhaps with wider implications.

CONTRASTING PROSPECTIVE TEACHER EDUCATION AND STUDENT TEACHING IN ENGLAND AND SLOVAKIA

Ján Šunderlík, Soňa Čeretková

Constantine the Philosopher University in Nitra, Slovakia

The poster presented a comparison of prospective teachers' preparation focused on student teaching in England and the Slovak Republic. Based on a small scale study, where we used observation of lesson structure and chosen lesson events, we try to understand some differences between English and Slovak approaches of prospective mathematics teachers' preparation.

Key words: Prospective teachers, lesson structure, comparative studies

FOCUS OF THE POSTER

Our poster presented some findings of a study in which we compared prospective mathematics teachers' preparation in England and Slovakia. To bring about a better understanding of mathematics teachers' preparation, we used a comparative approach based on the insight that "Being in an environment constantly, one usually takes things for granted and fails to see the characteristics of the environment as special or different from the others." (Runesson & Mok, 2004, p. 217)

THEORETICAL FRAMEWORK

Based on large scale comparative studies as PISA and TIMSS many countries try to implement reform mathematics instruction and reform curricula. But these reforms of learning and teaching mathematics depart significantly from the school mathematics tradition of countries as presented by Cobb, Wood, Yackel and McNeal (as cited in Lloyd, 2005, p. 441). One of the countries that have recently implemented a reform curriculum is Slovakia (since 2008). From many critical areas we decided to focus on student teaching. For the comparison we chose England, a country with different cultural traditions in mathematics education. Our main research question was: What kinds of differences in prospective teachers' learning can we identify during their student teaching?

METHODS AND DATA ANALYSIS

Our methodology is based on Clarke (2006). We used video based lesson observation, video simulated and narrative interviews with prospective teachers (Kaasila, 2007) teaching in the two specific cultural settings. All lessons and interviews were transcribed and coded. Based on the codes, we used cluster analysis by applying Ward's method to see the differences between observed lesson structures better. From all this information, we identified lesson events that were

critical for the prospective teacher and we considered them as an important part of prospective teacher learning.

FINDINGS AND DISCUSSION

According to the classroom observations and interviews, we identified several evidences of Anna's learning, a Slovak prospective teacher. There was a good cooperation with the associate tutor (AT), who used to give the prospective teacher direct advice and, based on this intervention, she kept improving her teaching. She was familiar with the style of teaching, because, as she said, "I taught the way I had been taught". On the other hand, Anna expressed beliefs about more progressive and problem based teaching, even though she kept using traditional ways. She tried some activating strategies but those were implemented within the same pedagogy and questioning as in a traditional setting. Ben is a prospective math teacher from England who prefers problem based and innovative teaching and learning. In contrast to Anna, he could teach and develop his teaching in a more innovative environment. He was able to use developed materials that helped him to focus more on his teaching strategies. Based on the course organisation, he was encouraged to reflect on his practice based and set up action points for his further development. The comparative analysis gives us a wider perspective for possible future development of prospective teachers and also helps us to see some advantages and difficulties of more "open" teaching and learning in a cultural environment that is not aligned with this approach.

DEVELOPING A MODERN MATHEMATICS PEDAGOGICAL CONTENT KNOWLEDGE: THE CASE OF TELESCOLA IN PORTUGAL IN THE MIDDLE 1960'

Mária Correia de Almeida and José Manuel Matos

UIED – FCT, New Lisbon University

Modern mathematics reform spread through many countries during the 1960s and 1970s producing changes in the representations of learning, of mathematical content, of the social roles of mathematics, and in classroom teaching practices. Telescola – a national network of schools complemented by classes on television – implemented a program with the “modern” vision of mathematics. This poster focuses on changes in pedagogical content knowledge to appropriate the new ideas.

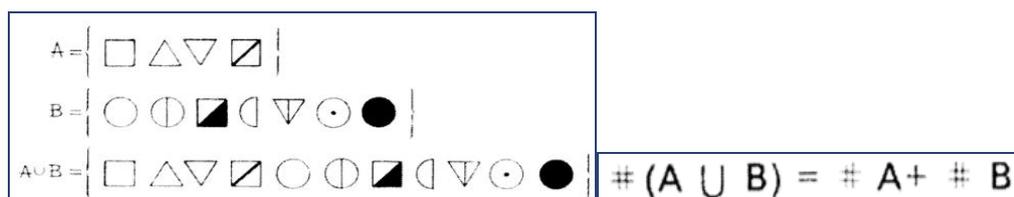

Keywords: Modern Mathematics, Pedagogical content knowledge, Telescola.

From 1965, a network of schools for 10 and 11 years-old supported by televised lessons was gradually put in place by the Portuguese Ministry of Education, in an effort to enlarge schooling after primary school, as it was demanded by economic development. Students that attended the Postos (the name of those schools) and finished a two-year course could enroll in the 7th grade of secondary schools. By 1968, this system that became known as Telescola covered the entire country, especially in remote areas. Modern Mathematics (MM) was gradually incorporated into these televised classes providing an experimental field for their later generalization to the entire population of 5th and 6th graders. Mathematics classes in Telescola were actually the first experience in the dissemination of the new ideas through an entire school sub-system in Portugal.

This study encompasses two dimensions aiming at understanding changes in pedagogical content knowledge (PCK) at this level: 1) a longitudinal study from 1965 to 1969 of the Mathematics “lessons” texts; 2) interviews with the teacher who prepared and enacted them on the screen, António Augusto Lopes (AAL). Qualitative procedures were performed (Bogdan and Biklen, 1994).

Shulman (1986) advanced thinking about teacher knowledge by introducing the idea of pedagogical content knowledge. This knowledge includes knowing what teaching approaches fit the content, and likewise, knowing how elements of the content can be arranged for better teaching. At the heart of PCK is the manner in which subject matter is transformed for teaching. This occurs when the teacher interprets the subject matter, finding different ways to represent it and make it accessible to learners. The gradual shaping (bricolage) of PCK was observed, so we could trace changes of school mathematics content put into practice and the difficulties that aroused for teaching. The distinctive characteristic of mathematical content is the adoption of set theory as an appropriate language to express mathematics.

Change: Now addition is the number of elements in the union of disjoint sets.

Now the teacher must draw the students' attention to the fact that addition may not be well defined. It depends upon the *universe*. In universe E , $E = \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$ addition is not defined for all pairs of elements of E ($3+4$ is defined, but $5+8$ is not). The possibility of addition was not in question at the primary school (its legitimacy was supported in the common sense of empirical, sensory experience).

The concept of *connected history* (Gruzinsky, 2003) developed by cultural historians, has been used to understand how communities elaborate their representations and practices in connection to other communities. The influence of one culture by another is seen as an act of hybridism (*métissage*) in which external appropriations are not seen as imitations from the original, but as producers of new originality. In this model, a key role is attributed to *mediators*, persons that travel among societies and cultures. The role of mediators was important in the expansion of the MM ideas in Portugal. A key mediator, AAL, author of the texts of the “lessons”, confirmed the influence of some authors and educators (Gattegno, Puig Adam, Servais) on the written materials he produced. The induction of change of classroom practices, due to external appropriation, is traceable in the perception that for students at this age it is important to see the real world applications of mathematic as well as to experience that mathematics embodied in objects that are real and accordingly in new materials used to support teaching. We could also trace the use of pedagogical materials, such as Geoboards and Cuisenaire Rods, on the written material produced for teaching.

A STUDY ON THE FUNDAMENTAL CONCEPT OF “MEASURE” AND ITS HISTORY

Ana Amaral^a; Alexandra Gomes^b; Elfrida Ralha^c;

^aESTM – IPEiria, CIEC/IE, anamaral@ipleiria.pt; ^bCIEC/IE, Universidade do Minho, magomes@ie.uminho.pt; ^cCMAT/Dep.to de Matemática e Aplicações, Universidade do Minho eralha@math.uminho.pt

This paper exhibits a small part of a PhD degree project on the theme: “The fundamental concept of Measure: epistemological and pedagogical aspects related with the first six years of schooling”.

It aims at presenting the analysis of the fundamental concept of measure at the so called elementary levels of schooling, in Portugal. We intend to: 1) distinguish elementary concepts and fundamental concepts; 2) explain why do we look at the mathematical concept of measurement as not only an elementary concept but, and above all, a fundamental concept in mathematics; 3) foresee implications of this distinction for teaching at the elementary level.

Keywords: concept of measure, teaching of mathematics, history of mathematics.

ELEMENTARY AND FUNDAMENTAL CONCEPTS

Concepts play a key role in the construction of mathematical knowledge with, certainly, different importance levels. At Elementary Mathematics’ schooling we are dealing with the so called elementary and fundamental concepts, deserving a special attention since their learning will influence the learning in higher levels.

In contrast to Ma (1999) (*Elementary Mathematics is fundamental mathematics*), we think that elementary and fundamental have different meanings, although a concept may be, at the same time, elementary and fundamental. On the one hand, a concept taught and learnt in elementary Mathematics created by Man to build a complex structure as a whole, or as a specific theme, is an elementary concept (Caraça, 2000). On the other hand, we say that a fundamental concept, emerges over time, its genesis is inherent to human activity and it is presented in many areas of mathematics as well as in several other areas of knowledge, both in the school context and in society, in general.

THE FOCUS OF THIS POSTER

Measure: Elementary and Fundamental concept

We consider the specific mathematical concept of *Measure*! Through its history we understand that this is a concept emerging over time, its genesis is inherent to human activity (Astronomy, Agriculture, Economy) and it presents itself in many areas of mathematics (Trigonometry; Arithmetic; Probability) as well as in several other areas of knowledge, both in the school context and in society in general (Nanotechnology;

Medical issues; Biology). Therefore it is considered a fundamental concept. It also is an elementary concept since it is taught and learnt at an elementary level.

Possible implications for the Teaching of Mathematics

We intend to answer the research question: *What is the approach of Measure in the Programs of Mathematics for Elementary Education, and in which way is History of Mathematics used to promote it as a fundamental concept?* To this end, we analyzed official portuguese mathematics programs (Mathematics Program for the 2nd Cycle of Basic Education, 1991; 1st Cycle Program for Mathematics, 1990 and the new Program of Mathematics for Basic Education, 2007), looking, in particular, at the role played by the history of *Measure*. Important works (Schubring (1998), Swetz (1995) and Siu (1996), among others) supported this analysis. We conclude that those programs present mainly the Geometric dimension of *Measure* and reduce the use of History of Mathematics related with this concept, to curiosities, examples, “historical aspects”. Seeing *Measure* as a seed of a future mathematical knowledge at a higher level, this approach may cause difficulties to the learning of mathematics. Namely, children may experience problems to integrate or to define units, develop misconceptions about measure/distance/length, fractions or when relating hours and angles in Trigonometry, misunderstanding measure statistics as measures, develop poor sense of money or work with temperature. This situation may aggravate if teachers aren’t aware of its importance to the development of mathematical knowledge and are unable to provide richer approaches.

Please recall that this is not a work developed directly with children, but meant to alert teachers, textbooks authors, programs and curriculum designers.

THE PROJECT OF MODERNIZATION OF THE MATHEMATICAL INITIATION IN PRIMARY SCHOOL AS CURRICULUM DEVELOPMENT (1965-1973)

Rui Candeias

UIED – Faculdade de Ciências e Tecnologia, UNL, Lisboa, Portugal

Escola Básica 1/JI Quinta de Santo António, Amora, Portugal

This poster refers to an ongoing research centered in a project of curriculum development in Mathematics, in Primary School (Project of Modernization of the Mathematical Initiation in Primary School, developed by the Educational Research Centre, of the Gulbenkian Foundation). This research intends to contribute to the knowledge of the evolution of mathematics teaching in primary schools, particularly the influence of “Modern Mathematics Movement” on curricular development and production of didactical material. This poster focuses on two aspects of the research: 1) a chronology of the project of Modernization of the Mathematical Initiation in Primary School; 2) a description of the documents produced for the 2nd grade according to the project’s scope, referring to mathematical subjects, the number of sessions dedicated to each subject, and a focus on the subject most worked (multiplication).

Keywords: elementary school, history of mathematics education, modern mathematics movement.

THE “MODERNS MATHEMATICS MOVEMENT” REFORM IN ELEMENTARY SCHOOLS

According to Moon (1986) Primary Schools only received the impact of Modern Mathematics Movement, from the mid 1960’s when several projects were developed. Some trends were detached in primary schools by introduction of Modern Mathematics Movement (Moon, 1986): (1) a structuralized trend, (2) an arithmetical trend, (3) an empirical trend.

In Portugal we can distinguish the work developed in some private schools and the work designed by the Gulbenkian Foundation (Candeias, 2008).

THE PROJECT OF MODERNIZATION OF MATHEMATICAL INITIATION IN PRIMARY SCHOOL - CHRONOLOGY

In the 1960’s the Educational Research Centre initiated a project to introduce the teachers in the Didactics of Modern Mathematics (Kindergarten and Primary School level). In October 1967, a seminar was attended by 37 teachers, twenty-five of them belonging to five Primary Pilot - Schools, that would lead mathematics teaching to

the experimental groups. The teachers discussed scientific texts, exercises and had contact with educational material that would be used in the experimental classes. In 1969 this project was extended to two official schools from the Lisbon area.

PRELIMINARY RESULTS

In this work we used two main sources: the bibliographic bulletin of the Gulbenkian Foundation (1965-1973) and the documents produced for the 2nd grade. From these sources it was made a qualitative analysis.

The project under study was an initiative of a private foundation, and in the beginning it was only implemented in private schools.

The mathematical themes and subjects for 2nd graders proposed in this project were similar to the Portuguese official programs at the time in study.

The most elaborated mathematical themes for 2nd graders were numbers and operations, especially the multiplication and division.

The approach to multiplication begins in the 2nd grade, and was based on the language of sets theory by means of “equipotent sets” which were used to introduce multiplication as repeated addition of equal terms. At this level, the multiplication was also addressed in rectangular arrangements, to introduce the commutative property of multiplication.

WHO CAN UNDERSTAND THE GIFTED STUDENTS? A LESSON PLAN BASED ON HISTORY TO ENHANCE THE GIFTED STUDENTS' LEARNING

Ersin İLHAN

Bayburt University

The need of gifted students of a deeper understanding of mathematics has lead to the “enrichment programs”. Al-Khwarizmi’s work is used to develop a lesson plan aiming to create the appropriate atmosphere to help gifted students in a modern classroom understand the mathematics created by a gifted mathematician in the past. The objectives and the associated lesson plan developed by the author are suitable for implementation in Science and Art Centers which the gifted students in Türkiye attend after school.

INTRODUCTION

The National Ministry of Education of the Turkish Republic (NME, 2005) formed the 8th grade mathematics syllabus having algebraic expressions, intended to show algebraic equalities using models. What is missing there or the part that needs the enrichment is the modelling concept, which could benefit from Al-Khwarizmi’s work on the solution of quadratics equations (Desay and Akin, 1994). For the gifted students, this part of syllabus can be implemented in two teaching hours, during the enrichment program they follow after school.

For the Lesson Plan format, I choose The Integration Education Model, developed by Clark (2008). Using this model, all parts (cognitive, intuitive, physical and affective) of the needs of learning is activated, especially for the gifted students. I choose Al-Khwarizmi’s work on the solution of quadratics equations. For the curriculum, I choose the 8th grade mathematics where the algebraic equations exist. I choose the historical packages, suitable for two or three hours of enrichment programs in the Science and Art Centers.

The aim of the Lesson Plan is to make students gain the ability of concrete and abstract thinking and their relationship after the objectives one and objective two are realized. For this reason, after the second objective, the third one is developed for the gifted students, who are studying the extended mathematics after school in Science and Art Centers belonging to the National Ministry of Education.

The Lesson Plan

Learning Subject: Algebra **Sub-Learning Subject:** Algebraic Expressions

Objectives:

1. To explain the differences between algebraic identities and equalities.
2. To explain identities via modelling (including equalities).

Working Group 12

3. To explain the solution of equations via models. (*This objective which does not exist in the National Curriculum is developed by the author to integrate the history of mathematics and use it in the enrichment programs for the gifted students.*)

Preparation before the class: To let the students form pairs and ask them to prepare their presentation by studying and working on Al-Khwarizmi's life including writing poems, theatre, songs, drawings, etc.

Procedure in the class:

1. To watch the documentary film about Al-Khwarizmi's life and works.
2. To teach in the light of objective 2 using modelling in the way described in the National Curriculum. To focus on the inductive thinking in the difference of squares (a^2-b^2) and deductive thinking in the squares of parenthesis $(a+b)^2$.
3. To let the pairs give their Al-Khwarizmi presentations, with focus on the works and life of the mathematician.
4. To let the pairs do worksheet 1 (to solve $x^2+10x=39$) for the objective 3 as a group.
5. To let the pairs continue their presentations with focus on sharing their feelings about the work of Al-Khwarizmi and his influence till today.
6. To let the pairs do worksheet 2 (to solve $x^2+5x=56$) for the objective 3 as a group.
7. To ask the pairs the question "Do you think the work of Al-Khwarizmi is important? Explain and discuss as a class".

REFLECTIONS

C. Tzanakis introduced a 2-D classification of the ICMI and Jankvist's *hows*; the lesson plan fits in the 2x2 cell; the cell history-as-a-tool (emphasis on inner-issues) & heritage ("learning mathematical topics" in the ICMI Study and Jankvist's "history based approaches"). Before CERME7 I implemented the lesson plan about history, but in the WG 12 sessions I realized that the above classification could help to further improve the teaching design and

TEACHER TRAINING AT PEDRO NUNES NORMAL SECONDARY SCHOOL (1956-1969)

José Manuel Matos

Teresa Maria Monteiro

Universidade Nova de Lisboa, Instituto Politécnico de Beja

This poster¹ presents a longitudinal analysis of the papers prepared by mathematics teachers trainees in the Pedro Nunes Normal Secondary school between 1957 and 1969. Three periods can be considered: 1957-1962, subjects related to Modern Mathematics in general are presented and the papers are focused in conceptual approaches of the new ideas; 1962-1965, although the subjects related to Modern Mathematics still show general approaches, the papers present specific pedagogical proposals; 1965-1969, the works mainly discuss the pedagogical experiences related to the introduction of the Modern Mathematics in the final years of secondary school.

Key-words: Mathematics education history, Mathematics teachers trainees, Portugal

The reform of Modern Mathematics in Portugal can be divided into three intertwined periods: the beginnings, from 1957 until 1963, in which the flow of new ideas can be detected; experimentation, from 1963 to 1968, during which the new ideas were implemented in classrooms; and dissemination, from 1968 onwards, that led to the gradual generalization of the reform to all students (Matos, 2009).

We have searched for articles printed in education publications authored by teachers of mathematics enrolled at a pedagogical training programme at Pedro Nunes Normal Secondary School (*Liceu*). The period of the study runs from 1957 (the restart of the teachers training program at the school) to 1969 (when changes were made to the teachers education programmes in Portugal). During this period, there were 36 mathematics trainees that published 12 papers, one in *Labor*, *Revista de Ensino Liceal* and the others in the *Palestra* (Matos & Monteiro, 2010).

New mathematical contents are mathematically studied in several papers. The axiomatic method-associated logic is probably the commonest mathematical topic. Although, in the analysed texts, logic is sometimes presented associated to axiomatics, it is usually linked to Set Theory. As an example, Fernanda Martins² describes it integrated in mathematical or symbolic logic. New contents mathematically studied include Modern Algebra, which itself includes the study of several structures with their corresponding composition laws, operations, unicity, neutral elements, inverse, commutativity, associativity and the distributive law. Fernanda Martins briefly discusses it, and Iolanda Lima³ describes several examples of this kind of structures associated to the concepts of group, field and isomorphism.

New approaches to geometry are also analysed. Maria Bento⁴, considers that “Geometry taught in the euclidian way is out of date” (p. 136), and shortly discusses two axiomatic alternatives, one proposed by Choquet, and another by Papy. In the same year, Lourdes

Ruiz⁵, based in the concept of “Geometry as a group of drawings’ properties that do not change under a given set of transformations” (p. 141), briefly presents transformations’ geometry (also designated by this author as dynamic geometry) and the associated hierarchy. Few works discuss in detail the methodologies. However, some trainees study the most appropriate pedagogical approaches. Discussing regular secondary school education, Iolanda Lima rejects a program “leading to individuals that are mechanized in dealing only with formulas and problems similar to the ones that are usually presented in examinations” (p. 61); Dulce Nogueira⁶ criticises Mathematics which is nothing more than a “mechanization and a theorem conglomerate” (p. 34). Several trainees declare to support an heuristic or active education, but only Iolanda Lima discusses in detail the meaning of the concept. Another two subjects, related with strategies to Mathematics classes, are discussed: workgroups and materials’ use. The constitution of these workgroups is proposed by some trainees. Dulce Nogueira discusses in detail their aims and working principles.

Many of these proposals were supported by valid studies at the time. There are many references to the books published by the CIEAEM: *L’enseignement mathématique* and *Le matériel pour l’enseignement des mathématiques*. Pedro Puig Adam is also referred, especially his book *La matemática y su enseñanza actual*.

From the school year 1964/65 the Pedagogical Lectures presented by the trainees discuss subjects concerning the practical aspects of the introduction of Modern Mathematics in high school. The aim was to stimulate reflections about the ongoing experiment in the last years of high school and how to expand it to the junior high school. Only two papers can be found in this period.

THE PEDAGOGICAL CONSEQUENCES OF A LAISSEZ FAIRE INDIVIDUALISTIC SOCIETY

Judy Sayers

The University of Northampton

This poster reports on some of the early findings from an analysis of several case studies examining how English Early Years' teachers conceptualise the whole class interactive phases of mathematics lessons. The poster reported on a comparative examination of the very different approaches adopted by two of the case teachers to the development of young children's (ages 5-7 years) conceptual and procedural knowledge. The findings highlight the ways in which a laissez-faire, individualistic culture (Hofstede, 1986) may fail to construct equal opportunities to young children's mathematical thinking, learning and experiences.

Key words: Pedagogical approaches, didactic foci, early years' mathematical thinking, measurable skills, early mathematical opportunities.

INTRODUCTION

The United Kingdom in general and England in particular has been described an individualist rather than a collectivist culture (Hofstede 1986). Recent government interventions (DfEE, 2003) have highlighted the extent to which individualism permeates education systemically in its encouragement of teachers to personalise the learning of their students. Moreover, teacher education in England has traditionally eschewed notions of a commonly understood and accepted pedagogy, resulting in Simon's (1981) well known and repeated plea; "why no pedagogy in England?" and Alexander's (2004) more recent "still no pedagogy?"

METHODOLOGY

A qualitative case study (Yin, 2009) approach was adopted to examine the practice of two teachers (Caz and Fiona). Initial and terminal interviews, videotaped lessons and stimulated recall interviews, and the method of constant comparison informed the analysis of the data.

FINDINGS

The findings highlight how these two teachers' different approaches, drew on their experience as both learners and teachers of mathematics. Their experientially formed beliefs about mathematics and its teaching, informed the opportunities they provided for their children to engage with and learn mathematics. Three categories emerged from the data which have emphasised both differences and similarities of these two teachers' practices. The first *Mathematical Focus*, relates to conceptual and

procedural mathematical knowledge emphasised by the teacher through reasoning, problem solving or other mathematical processes, prior knowledge, explicit connections or other mathematical emphasis the teacher makes. The second category is the *Pedagogical approaches* used by the teacher, such as questioning, discussion, explaining and models used. And finally the *Classroom norms* created by the teacher which create specific classroom cultures towards learning. This will include the regular and routine attention the teacher makes towards children's behaviour, attitudes and responses to questions e.g. putting up their hand. The espoused practice discussed by the teachers expressed identical key pedagogical concepts; however the enacted emphasis and explained rationale by the teachers are quite different.

DISCUSSION

The enacted practice and rationale provided by the teachers illustrate for Caz a deep understanding of mathematical structures which inform her practice in developing children's strategic competence, adaptive reasoning, productive disposition and procedural fluency (Kilpatrick et al., 2002). Whereas for Fiona, a deep focus on conceptual understanding through the development of a productive disposition and procedural fluency provide a very different experience and create very different classroom norms and approaches to mathematical learning.

The teachers work within an educational system that colludes and condones diversity in children's opportunities to engage with mathematics. We should then not be surprised that teachers do impose their own interpretation on the teaching and learning of mathematics. But can a society with a laissez-faire perspective on education ever offer consistent or equal opportunities?

ICT SUPPORTED LEARNING OF MATHEMATICS IN KINDERGARTEN

Martin Carlsen, Per Sigurd Hundeland and Ingvald Erfjord

University of Agder, Norway

Our project, ICT supported learning of mathematics in kindergarten⁹⁷, aims to develop and disseminate experience from implementation and use of ICT for pre-school children's learning of mathematics in kindergarten environment. We will present aim, focus, research questions and preliminary analysis.

Keywords: ICT, Kindergarten, Mathematics

AIM AND FOCUS

Recently, there has been an emphasis on implementation of mathematics in kindergartens and on use of ICT in kindergartens, in Norway explicitly outlined in the national curriculum for kindergarten from 2006. In a review of research literature on ICT use in pre-school settings, mathematics is not mentioned (Plowman & Stephen, 2004). We see this as indicating a need for paying attention to this field. Lately, in a review of studies focusing on young children of age 3 to 6 learning with digital media, Lieberman, Bates and So (2009) give a list of important lines of research in this area. There they point to research focusing on how digital media support children's early "learning of mathematical concepts" (p. 275) and how collaborative learning and ability to interact can be facilitated in what they denote as well-designed digital technology. In our project, a number of ICT applications developed for children will be adapted and implemented in the kindergarten environment. We want to give special attention to 3 to 5 years old children's learning of mathematics supported by ICT, and to the communication between children and the kindergarten teachers in their learning processes. Our research question is: In what ways can use of ICT tools give new learning opportunities for mathematics in kindergarten? In particular, we are interested in investigating: (a) the content of conversations between adults and children; (b) the nature of the mathematics at stake, and (c) children's mathematical learning outcome.

THEORETICAL PERSPECTIVE AND METHODOLOGY

In our study we take a sociocultural perspective on learning and development. Learning is viewed as a social and situated process where individuals, i.e. kindergarten teachers and children, appropriate concepts, tools, and actions through collaboration and communication (Rogoff, 1990).

⁹⁷ The project ICT mediated Learning of Mathematics in Kindergarten is funded by the LA2020 project at the University of Agder.

The methodology of this study is developmental research (Freudenthal, 1991). Researchers and kindergarten teachers collaborate in order to develop new forms of mathematical practice in kindergarten, i.e. we will establish a co-learning agreement (Wagner, 1997) with kindergarten teachers. Theoretically and methodologically the design of our project is a continuation of the TBM⁹⁸ project in Norway (Carlsen, Hundeland, & Erfjord, 2010). The participants are three kindergartens, six kindergarten teachers and children of age 3 to 5. Project activities are captured through use of video recordings, audio recordings and field notes.

PRELIMINARY ANALYSIS

We have analysed children's use of ICT applications designed for Norwegian children of age 3 to 5. It seems as if the applications do not challenge the children appropriately. We suggest that the children are not met in their zone of proximal development (Vygotsky, 1978). However, we have experienced that applications designed for children age 6 to 7 are more appropriate.

THE DESIGN AND IMPLEMENTATION OF MATHEMATICAL TASKS TO PROMOTE ADVANCED MATHEMATICAL THINKING

Sinéad Breen, Ann O'Shea

CASTeL, St Patrick's College, Drumcondra, Dublin

National University of Ireland Maynooth

This study concerns the design of mathematical tasks for first year large group mixed ability undergraduate classes. The tasks were designed by the two authors and assigned as homework in courses taught by them. The object was to foster deeper understanding through problems that facilitate engagement with concepts. We report on how the tasks were written and on preliminary student feedback.

Keywords: task design; conceptual understanding; thinking processes.

INTRODUCTION

Traditionally undergraduate mathematics courses have been defined in terms of mathematical content and the techniques students are expected to master or theorems they should be able to prove (Hillel, 2001). Although it is often assumed that students will develop an understanding of the higher level and often abstract mathematical concepts involved, such an understanding is seldom specifically fostered by the mathematical tasks and assessments students are required to complete (Pointon and Sangwin, 2004). Selden et al. (2000) found that more than half of their second year university calculus students could not solve any non-routine problems even though in a separate test they had demonstrated that they were familiar with the techniques required. They recommend that lecturers should 'scatter throughout a course a considerable number of problems for students to solve without first seeing very similar worked examples' (p.150).

TASK DESIGN

Homework tasks on first year Calculus topics were written by both authors drawing on the frameworks of Swan (2008), Schoenfeld (1992), and Pointon and Sangwin (2004). The tasks required students to generalise and specialise, generate examples, make conjectures, reason, make decisions, explore, make connections, and reflect. For example, students were given an incorrect statement and proof and asked to critique the reasoning used; they were asked to give examples of functions with certain properties; they were asked to use graphs to solve problems that they would normally solve algebraically. They were also asked to investigate the truth of statements, for example: 'Suppose $g(x)$ is an odd function, is $1/g(x)$ odd? Justify your answer' (Task 1); 'Does every rational function have a vertical asymptote? Explain' (Task 2). The authors recognised that no one task could foster all of the desired thinking skills, but aimed to achieve a balance over a suite of assignment problems.

IMPLEMENTATION AND FEEDBACK

During the Autumn 2010 semester, the homework tasks were assigned to large groups of undergraduate students at two institutions. Each assignment contained traditional tasks as well as the non-routine tasks designed (or selected from textbooks) using the frameworks mentioned above. At the end of the semester, student reaction to the tasks assigned was collected using questionnaires. In total 101 students gave feedback. In each institution, the questionnaire focused on pairs of tasks (one traditional and one non-routine) on the same mathematical topic. The majority of students reported that both task types contributed to their knowledge and understanding of the topic but felt that the non-routine tasks were more challenging or required more thinking or understanding than the procedural tasks. For example when discussing Task 1 and a related procedural task one student remarked:

There was more development into the knowledge of odd and even functions. The second task (*non-routine task*) was a lot more challenging.

For some students, Task 2 challenged their ideas about mathematics itself.

Problem 1 (*procedural task*) was mathematically based, and the other (*non-routine task*) was theory based.

CONCLUSION

The use of the task frameworks helped the authors expand their range of assignment problems and the new problem types challenged their students in meaningful ways. Link to poster: http://staff.spd.dcu.ie/breens/documents/BreenOSheaposter_A4.pdf/

CRITICAL MULTICULTURAL INSTRUCTION FOR UNDERGRADUATE MATHEMATICAL THINKING COURSES

Irene M. Duranczyk

University of Minnesota

***Abstract.** This poster reports the design and outcomes of a critical multicultural mathematics study on student performance and engagement in a required mathematics course for non-STEM (science, technology, engineering, or mathematics) majors.*

Key Words: postsecondary, math literacy, inclusion, multicultural

Students' sociocultural background and interests can enhance their understanding of academic mathematics, particularly statistics, if the instructor and the students are open to the idea and have beliefs/attitudes that allow the interplay of academic mathematics and the everyday mathematics used for negotiating information. We are bombarded daily with statistical information about our society and about us as members of multiple cultural identity groups. The Critical Multicultural framework interconnects these sources of information.

Critical multicultural instruction is an inclusive theoretical model, integrating multicultural education (Atweh, Forgasz, & Nebres, 2001; English, 2002; Joseph, 2000; Solomon, 2009), ethnomathematics (D'Ambrosio, 1985; Powell & Frankenstein, 1997), and universal instructional design (Higbee & Goff, 2008; Silver, Bourke, & Strehorn, 1998) for equity, access and success of tertiary learners.

A news story based on the writer/publisher's point of view, power, and privilege is often supported by numerical documentation. How does this information shape our ideas? How can this information be re-purposed to tell our story, a story that embraces diversity or be used to understand and address the dynamics of race, class, gender, sexual orientation, national identity, immigrant status, and other identity dimensions? What story would we tell given the same data and an empowering sociocultural lens? With statistical knowledge and skills; a critical lens (examining the hidden questions/assumptions) and purposive reflection, we can be empowered as individuals and members of society to reshape the story—and tell a powerful story of diversity and community strength.

CONTEXT OF THE STUDY

The qualitative data was collected from an undergraduate course that fulfills a mathematical thinking, liberal education graduation requirement for a student in a tier one, doctoral research university in the US. This preliminary qualitative study measures the impact of using the critical multicultural instruction model on students' performance and engagement.

POINTS OF EVIDENCE—ARTIFACTS AND OBSERVATION

Midterm grades, journal entries, analysis of evidence of mathematical thinking and

engagement within assignments and tests, within-semester and post-semester interviews, and comparisons between and among pre-enrollment characteristics were used to capture the model's impact.

PRELIMINARY OUTCOMES

The preliminary outcomes: (a) Students in Service Learning (Fall 2010, 10 out of 38 students) were more thorough in their discussion, analysis, and summary of the research project and statistical concepts; (b) Many students (Fall 2010, 15 out of 38) thought that the use of real data important to non-profit would be valuable but they did not have time to commit to a "real" study; (c) Most students expressed (Fall 2010, 30 out of 38) that they learned more about statistics by doing the project than by engagement in in-class discussions, in-class and homework assignments, or preparing and taking tests; (d) Overall, Students in the course identified more with a Deep Approach to Learning (intrinsic interest, commitment to work, relating ideas, understanding) over a Surface Approach (fear of failure, aim for qualification, minimizing scope of study, memorization).

PROBLEM-BASED LEARNING AS A METHODOLOGY OF STUDYING THE DIDACTIC KNOWLEDGE OF DERIVATIVES IN UNDERGRADUATE COURSES IN MATHEMATICS FOR ECONOMISTS

Moreno, M.M.; García, L., and Azcárate, C.

University of Lerida (Spain); University of Andes (Venezuela) and University Autónoma of Barcelona (Spain)

This poster reports a study focusing on the teaching of derivatives and their applications to an economic context at university level. It is an attempt to characterise the didactic content knowledge of teachers about the links between mathematical and economic concepts; and, about methodology of teaching and the use of problems for developing students' mathematical knowledge. We have organised four seminars, of two hours each, focused on the teaching of the derivative concept in an economic context.

MOTIVATION AND OBJECTIVES

Other studies suggest a lack of interest in teaching the derivative concept and its applications to economy. Teachers continue to be traditional in the sense that they seldom use derivatives to solve economic problems, and students use a large number of standardized procedures. There are no differences between the teaching of derivatives in chemistry, biology or economics. Our research aims: to characterise the didactic content knowledge of teachers about the teaching of derivatives and their links with economics; to evaluate the utility of seminars as a training tool for university mathematics teachers; and to evaluate a data collection instrument used to these purposes.

CONCEPTUAL FRAMEWORK AND DATA COLLECTING

We define didactic content knowledge as the specific knowledge required for an effective teaching based on the following four components: mathematical content knowledge, curriculum knowledge, teaching knowledge and learning knowledge (Kahan *et al*, 2003). Problem-based learning (PBL) is both a teaching method and an approach to the curriculum. PBL consists of carefully designed problems that challenge students to use problem solving techniques, self-directed learning strategies, team participation skills and disciplinary knowledge (Lee & Bae, 2008). The study was conducted with six teachers in a seminar consisting of four two-hour sessions. Data was collected through a questionnaire based on the seminar sessions and open, audio-recorded interviews. Thus, a teaching proposal was designed around four economic problems about derivatives and their economic meaning, the notion of domain of a function and extreme values, and the chain rule in an economic context.

SOME RESULTS AND CONCLUSIONS: EXAMPLE PROBLEM 3

Problem 3 is a classical economic situation about the production of a product (pencils) in which we propose four different questions. We analyse the first one which concerns the domain of a function in a mathematical context (\mathbb{R}^+) and in the economic context ($[0,2]$). Referring to the content knowledge (mathematics and economics) teachers express their opinion as follows:

- Ramón: We should separate both contexts but we do not do so.
- Manuel: This point of view is very interesting and it would help students to understand the differences between contexts and the concept itself.
- Alexis: To teach this way, teachers need to make many cognitive and methodological changes. Thus, we should make connections between both contexts and show the analogies that are there.

Referring to the teaching knowledge, Kenya considers that this approach implies anticipation to the students' questions and doubts, and a student-centred teaching. This change is necessary, according to most of the teachers, but it takes time, especially the first time the teacher prepares the lessons and the corresponding learning activities.

Teachers evaluated our seminars in a positive way and said the seminars helped them to think about different approaches depending on the context. They also felt more conscious of the difficulties of the planning and the importance of their role as tutors:

- Ramón: I liked the seminars as they were useful for working with and thinking about economic problems. I feel I lack knowledge and ideas for teaching this way.
- Kenya: I had never thought about economic problems this way. In my opinion, those were only examples and applications of the mathematical concept. I feel better sharing my ideas and doubts with my colleagues.
- Elio: After the seminars I am really worried about how to approach the derivative with our students. Changes are necessary but I am not prepared for them.

SOME MEANINGS OF THE DERIVATIVE OF A FUNCTION

Perdomo-Díaz^a, J., Camacho-Machín^a, M. and Santos-Trigo^b, M.

^aUniversidad de La Laguna (Spain) ; ^bCINVESTAV-IPN (Mexico)

The aim of this poster is to present the set of meanings that 15 first year university chemistry students associate with the concept of the derivative of a function. The research questions are as follows: Which meanings of the derivative of a function do students recognize and use? What kind of relationships do they establish between them? How do they use them in problem solving activities? The results obtained mark the starting point for the implementation of a teaching module designed to introduce Ordinary Differential Equations (ODE) using the link of this concept to the derivative of a function in a problem solving scenario.

Key words: derivative, ordinary differential equations

RESEARCH

A previous research project (Camacho-Machín *et al.*, submitted) showed there was some discontinuity in the learning of mathematics: several students do not relate the concepts of derivatives and ODE. This finding led to the design of a teaching sequence where the concept of ODE was introduced in a problem solving scenario, making the relationship between this concept and the derivative of a function explicit. As a prelude to the implementation of this teaching sequence we wanted to establish the set of meanings students associated with the concept of derivative, which is the aim of this poster⁹⁹. Results will be used in the future to analyse how students' understanding of the derivative evolves during the learning of ODE.

Conceptual framework

The following two main ideas shape the conceptual framework of this work: the importance of analyzing students' knowledge in order to explain how they solve problems (Schoenfeld, 1992) and that a mathematical concept is built by dealing with the different meanings associated with it that can be represented by different systems (Hiebert & Carpenter, 1992). In the case of derivatives, the concept can be thought of in different ways (Thurston, 1994) including the formal definition, an algebraic procedure, the slope of a line tangent to the graph, etc.

Methodology

This research was carried out with 15 university students in the first year of a degree course in chemistry (the whole population). They had just studied calculus with one

⁹⁹ Some other research results related with the concept of derivative are included in the poster. This work was partially supported by Grant no. EDU2008-05254 of the National Research Plan I+D+I of the Spanish Ministry of Science and Innovation.

and several variables. Last sessions corresponded to the introduction of ODE. In order to answer the research questions formulated here, we designed a questionnaire with 11 items (included in the poster) that could be solved in different ways. Students answered it individually, only using paper and pencil.

Analysis and results (Evidence of the results are included in the poster)

All the students used the derivative of a function as a mathematical procedure (although 5 of them showed some difficulties). Another six different uses associated with the concept of derivatives were detected in the students' answers: formal definition, description of critical points, slope, monotonicity, variation and rate. Even though most of these uses are closely related, they are considered individually because students did not show how to link them. For example, some students described the derivative of a function by analysing the monotonicity of that function but they did not obtain the slope of the line tangent to the graph of a function at one point. The classification of the students (table) shows the diversity that occurs in the construction of the network of meanings associated with the derivative of a function.

Students who relate the derivative (in addition to consider it as an algebraic procedure)		
at most to 2 meanings	to 3 different meanings	to 4 or 5 meanings
Sonia (none) Nieves (monotonicity) Silvia (slope, monotonicity) Juan (slope, rate) Ginés (formal definition, rate)	Virginia- Carmen (formal definition, slope, monotonicity) Alberto (slope, variation, monotonicity) Zoraida – Naomi (slope, monotonicity, rate)	Mar (formal definition, slope, monotonicity, rate) Manuel (slope, monotonicity, rate, variation) Milagros - Nicanor (formal definition, slope, monotonicity, rate, variation) Alexis (formal definition, slope, critic points, rate, variation)

This classification will be useful for a future analysis of the evolution of the students' understanding of the concept of derivatives during the learning of ODE in a problem solving scenario. The conference poster is available at: http://dl.dropbox.com/u/26255014/Poster_Perdomo-Camacho-Santos-CERME7.pdf

TRANSITION SECONDARY-TERTIARY LEVEL EDUCATION VIA MATH-BRIDGE

Julianna Zsidó, Viviane Durand-Guerrier

Université Montpellier II

Abstract. With the poster presenting the Math-Bridge project we would like to draw attention to this multilingual resource for online mathematics courses and training exercises that aims to help the transition for students between secondary school and higher education. This resource is developed in an ongoing European project. The poster presents briefly the specifics of the project and possible usage modalities.

Keywords: secondary-tertiary transition, bridging courses, e-learning, European project

THE AIM OF MATH-BRIDGE

The goal is to provide an e-learning tool that contains relevant mathematical content for typically first and second year university students in need for mathematical bridging courses. The common European problem of high drop-out rates among science and engineering students because of gaps in mathematical knowledge is tackled by this project. A large pool of common remedial courses and training exercises is created for use and reuse across European universities.

FUNCTIONALITY

Math-Bridge is based on an intelligent tutoring system called ActiveMath which adapts to the student users' field of study, competency level and progression profile. Moreover the multilingual and multicultural aspects (Melis et al. 2009) play an important role: the content is available in seven languages easing cross-cultural training and Europe-wide mobility.

Students can create their own personalized exercise books, exploratory books for new fields or even simulate tests from the pool of available learning objects and progress at their own speed. When doing exercises the system analyses errors in answers, gives feedback and adapts further reasoning guiding the student, instead of returning only “correct” or “wrong” feedback with the expected answer.

Tutors can create books for their classes containing learning material, exercises and tests. Student user statistics can be recorded in order to determine which content is more valuable.

Authoring of content is possible at any time, that is, adding learning material and exercises and translating into new languages. The pool of learning objects becomes richer and Math-Bridge evolves constantly.

MATH-BRIDGE SUPPORTS SECONDARY-TERTIARY TRANSITION

Since Math-Bridge provides remedial course material and training exercises, it includes secondary level learning material that proved to be partially acquired together with higher educational level material. Acquiring knowledge is guided by different learning models and the exercises can be repeated as many times as needed. Moreover the fact that it is an e-learning tool favours students' personal initiative and skills for self-organization typical for higher education level; see also (Mercat, 2009).

MATH-BRIDGE IN MONTPELLIER

A possibility for a (team of) teacher(s) at university is to elaborate a book with relevant training exercises for a given course; to use this book partly during their sessions and to invite students to go on working on the book as personal work. As a bridging course, it can be used by teacher teams encompassing both secondary and tertiary teachers, in order to smooth the transition.

In Montpellier, we are experimenting with these modalities at a rather limited scale in 2010-2011 in the first year Calculus course (and probably at a larger scale in 2011-2012) in order to investigate if the learning objectives are more likely to be reached by using Math-Bridge on the one hand, and the possibility of a smooth integration in the every-day work of students and teachers on the other.

It is possible for a student to switch between languages when learning or doing exercises, thus Math-Bridge claims to help to overcome linguistic difficulties, that arise when learning mathematics in a different language (Barton et al, 2005). Of course, further research in this matter needs to be developed. A first step has been made by an ongoing pre-experimentation with bilingual students.

The poster is available from the author at julianna.zsido@univ-montp2.fr.

CHASE FOR A BULLET – USE OF ICT FOR DEVELOPING STUDENTS' FUNCTIONAL THINKING

Antonín Jančařík¹⁾, Jarmila Novotná¹⁾, Alena Pelantová²⁾

¹⁾ Charles University in Prague, Faculty of Education, ²⁾ ZŠ Na Slovance, Prague

The poster presented an activity developed in the on-going Socrates Comenius project EdUmatics, European Development for the Use of Mathematics Technology in Classrooms (503254-LLP-1-2009-1-UK-COMENIUS-CMP). The project focuses on integration of technology into secondary school mathematics. Its main goal is the creation of a research based course for pre- and in-service teachers to use new technologies in math classrooms with the goal of maximising students' learning.

Keywords: Functional thinking, mathematical model, ICT, mathematical education

The outcome of the project will be teaching materials that illustrate the optimum use of ICT in mathematics teaching and learning. The activity presented in the poster, *Chase for a bullet*, has been designed for the module *Constructing functions and models*. It represents an example of a fruitful integration of ICT with paper-and-pencil activities. Two points A and B are given representing the current position of the Target (A) and the Bullet (B). A is moving on a trajectory at a given speed and B is trying to catch A. The main activity consists of choosing the trajectory of A and the following calculation of the approximation of the trajectory of B. The activity focuses on the potential of technology with respect to functions perceived as tools for modeling both the inner world of mathematics (internal modeling) and the outside world (external modeling). The proposed situation is based on the principles of the Theory of didactical situations (Brousseau, 1997). It possesses a high potential for dynamic access to families of functional objects depending on one or more parameters. It offers flexible access to a diversity of representations of functional objects and connections between them. The goal of *Chase for a bullet* is to enable students to learn indirectly about graphs of various functions, to make connections between parameters in formulas of functions and their properties. The situation is rich in the perspective of interdisciplinary relationships (physics, various environments for the same mathematical model). The foreseen age level is 14 years and up. The minimal mathematical knowledge is the Theorem of Pythagoras.

The design combines work without and with computers. ICT is mainly used for simulation of processes, as scaffolding for computations (e.g., solving quadratic equations), calculating new data using constructed formulas, verifying the correctness of the obtained results, and easy creation of examples and problems.

The added value of the use of computer technologies when solving bullet-target problems lies in the following two areas. Students learn how to model real situations with the help of a computer model. An analytic solution of the bullet-target problem is extremely difficult, even impossible. However a mathematical model constructed

by students for the solution of the problem enables a good enough approximation and offers a model solution applicable in other situations the student may come across in real life. In other words, the computer helps the student solve a problem that he/she would fail to solve without its support.

The benefit of the use of computer technology also lies in the fact that, after having developed a numerical model, the computer carries out the repetitive calculation of the position of the bullet using the formula that the student him/herself has developed within the frame of analysis. Thus the computer takes over the student's routine activity that he/she would be able to carry out on their own but due to time limitations only in a very limited number of problems. ICT allows modeling of the situation in real time and the student's attention shifts from routine calculations to analysis of the behavior of functions and to exploration of the dependence between the bullet and the target trajectory. Students may study the influence of the different parameters in an extent impossible without computer technology.

The poster presented the organization, course and analysis of the first pilot experiment of the situation in the Prague school Na Slovance (15-year old students). The following figures illustrate students' activities.

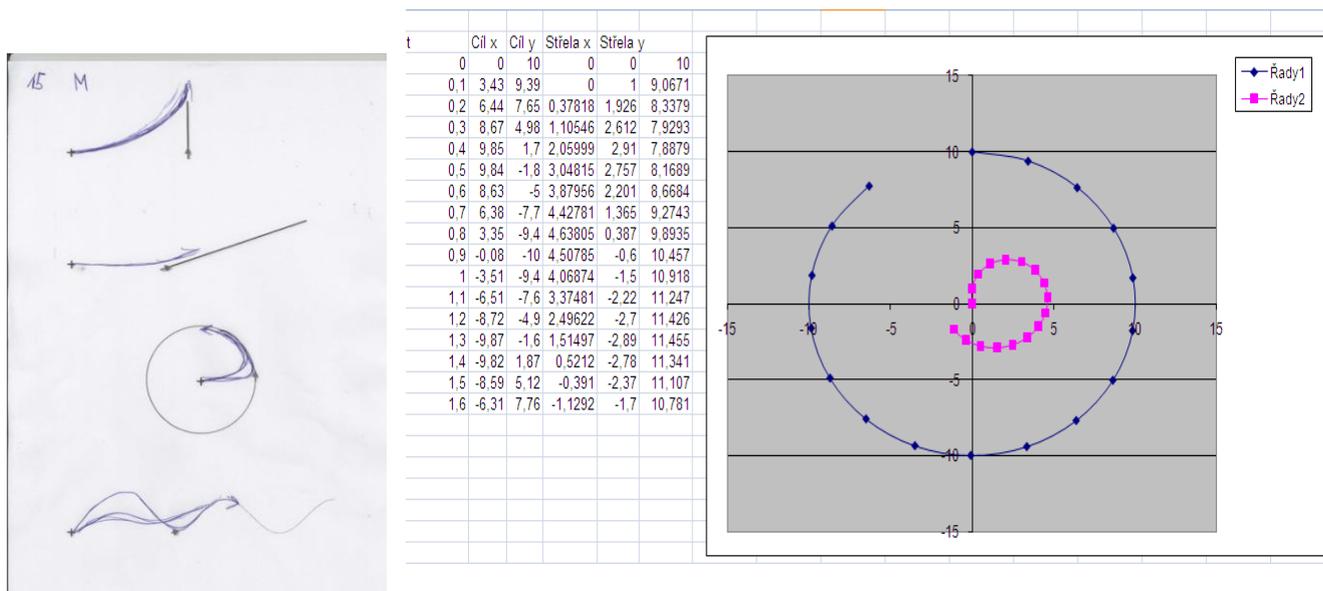

Figure 1: Estimated trajectories

Figure 2: Trajectory of the target: circumference (MS Excel)

THE CHALLENGE OF DEVELOPING A EUROPEAN COURSE FOR SUPPORTING TEACHERS' USE OF ICT

Michèle Artigue¹⁾, Claire Cazes¹⁾, Françoise Hérault²⁾, Gilles Marbeuf²⁾, Fabrice Vandebrouck¹⁾

¹⁾ LDAR, Université Paris Diderot – Paris 7, ²⁾ Lycée Jacques Prévert, Taverny

The poster concerns the on-going Socrates Comenius project EdUmatics (503254-LLP-1-2009-1-UK-COMENIUS-CMP), whose ambition is to develop a research based course which aims to educate in-service and pre-service teachers to use new technologies in their mathematics classroom to maximize students' learning. In the poster, we focus on issues raised by the development of one of the five modules for this course entitled "Constructing functions and models", and we take one family of situations used in this module: "The Sign Family" as an illustration [1] of the interaction between research and design.

Key words: teacher education, ICT, functions and modeling

The teams involved in EdUmatics have all a research and training experience in ICT but they live in different educational contexts, with different curricular organizations, teacher education systems, and they face different institutional constraints. Even if the use of ICT in mathematics education is promoted by every country involved, school equipment and educational policy regarding ICT is also variable. The research that these teams have developed also situates in different traditions, relies on different theoretical frameworks, and as evidenced for instance by the European project ReMath [2], such differences substantially impact the design and use of ICT. Building a European course for teachers supposes a good awareness of this diversity and its possible consequences, a reached agreement on some core points for teacher education in that area in terms both of content and form, and a conception of design allowing easy adaptation to a diversity of contexts. In the poster, we illustrate one particular facet of our work in progress on these challenging issues: how we approach the necessary design flexibility through the idea of family of situations.

The Sign family that we use as an illustration denotes a family of mathematical situations at the interface between geometry, magnitudes and the functional world which can be described in the following way: a initial geometrical form is given (square, rectangle, circle ... or even a 3D form); and a point variable in this form (along a side, a bisector, a diameter...) allows its division into different parts; from this division a sign is created whose area depends on the position of the variable point (see examples in figure 1). Several questions naturally emerge regarding the variation of this area or of the area of its different components, its minimum and maximum values...

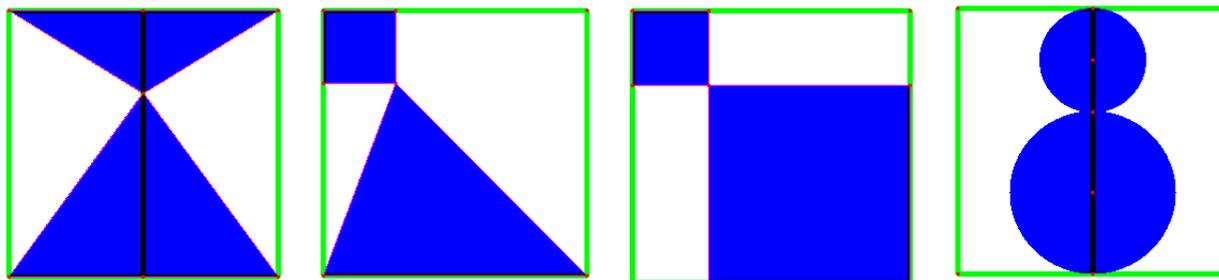

Figure 1: Some Sign examples

From this schema, according to the choices made in terms of *didactic variables* (Brousseau, 1997), one can generate a great diversity of didactic situations, varying the context of the task, the functional dependencies at stake, the autonomy given to students in the functional modeling, the technology used, and the didactic organization. The Sign family presents thus the adaptive character expected from the situations for this module. It also offers evident potential for addressing the issue of ICT affordances for the teaching and learning of functions: support to an inquiry based approach through the enrichment of the a-didactic *milieu*, support to the multimodal semiotic activity of students (Saenz-Ludlow & Presmeg, 2006).

In the poster, we will visually present how the research developed about the Sign family, combining an a priori analysis of the family of situations and analysis of screen captures and videos resulting from the experimentations carried out in the partner high schools, can be used in the design of the module for studying the affordances of ICT in the teaching and learning of functions, making teachers sensitive to instrumental issues (Guin, Ruthven & Trouche, 2004), discussing the specificities of the teacher's role in ICT sessions, and preparing the use of such situations in a diversity of educational contexts.

NOTES

1. Another example is provided in the poster proposed by our colleagues from Prague.
2. The European STREP ReMath has especially addressed the impact of theoretical diversity on the design and use of digital technologies. Its results are accessible on the project website: <http://remath.cti.gr>

REMEDIAL SCENARIOS FOR ONLINE AND BLENDED-LEARNING BRIDGING COURSES

Rolf Biehler*, Pascal R. Fischer**, Reinhard Hochmuth**, Thomas Wassong*

* University of Paderborn, ** University of Kassel

The European Project Math-Bridge¹ aims at providing technical and pedagogical support for mathematical bridging courses. Based on the ITS ActiveMath² Math-Bridge (MB) extends it to the project's special needs. MB provides amongst others pedagogical remedial scenarios which enable teachers and learners to use MB for different course scenarios. This poster will present these remedial scenarios.

Keywords: Bridging Courses, Remedial Scenarios, Self-Regulated Learning

THE LEARNING MATERIAL IN MATH-BRIDGE

Most of the project European partners already have experience with the development and implementation of math bridging courses and provide a big amount of learning material for reuse within MB. This material needs to be enriched by pedagogical and mathematic-structural metadata. Our pedagogical structure (Biehler *et al.*, 2009) bases on existing competency models like PISA (OECD, 2003) and the German Bildungsstandards (KMK, 2003) and defines four competency clusters on the 1st dimension: technical, math problem solving, modelling, and communication and reasoning. Our 2nd dimension contains three achievement levels: reproduction, connection, and reflection. Our math structure is defined in an ontology which bases on the taxonomy for Mathematical Sciences Education³.

THE USE OF LEARNING OBJECTS IN MATH-BRIDGE

In order to use the enriched content within the adaptive learning system, we extended the pedagogical scenarios of ActiveMath (Reiss *et al.*, 2005) to the purposes of math bridging courses. These scenarios aim at different learning goals (rehearse, workbook...) and select the most reasonable learning objects (LO) with regard to students' abilities and learning goals, bring them into a predefined order and hence give them an appropriate learning environment for their individual purposes.

An analysis of the learning material showed that some of the sequences of atomic LOs are not freely exchangeable and instead belong strictly together. These sequences should not be broken up since e.g. an "introduction" sometimes forms a holistic unit. Having the individual LOs and also keeping these units together, we introduced a new structure element called "complex learning objects" (CLOs). According to the learning material from the VEMA-project⁴ (Biehler *et al.*, in press), we identified the following types of CLO: Introduction, Info/Interpretation/Explanation (IIE), Application, Misconception, Practice, and Supplement (Biehler *et al.*, 2010).

FORMALIZED REMEDIAL SCENARIOS

For the remedial scenarios concerning the CLOs we developed a close order of units (overview, intro, info, IIE, application, typical mistakes, exercises, and supplement), where the learners can select relevant units for their learning process. To support the students in structuring their learning, MB provides scenarios with preselected units, e.g. Select Basic (overview, info, IIE, exercises) (Biehler *et al.*, 2010). Hence the students can create a book respecting their needs and pedagogical principles.

THE LEARNING ADVICE COMPONENT

Most of the first-year students are not trained in self-regulated learning especially in ITS. We thus designed a self-assessment component: After having chosen a specific domain the learners get an overview of the topics and the relevant definitions and theorems. Then they estimate their knowledge and assess themselves using a diagnostic test providing feedback on their performance and abilities. Finally they compare their own solution to a model one and the assessment results with their initial self-estimation. With this feedback, the learners are able to select content and learning scenarios adequately. Besides the learning advice component trains the student's ability of self-estimation and self-regulation (Biehler *et al.*, 2010).

I2GEO.NET – A PLATFORM FOR SHARING DYNAMIC GEOMETRY RESOURCES ALL OVER EUROPE

Jana Trgalova¹, Ulrich Kortenkamp², Ana Paula Jahn³, Paul Libbrecht⁴, Christian Mercat⁵, Tomas Recio⁶, Sophie Soury-Lavergne¹

¹INRP, Lyon, France - ²CERMAT, University of Education Karlsruhe, Germany - ³UNIFESP, São Paulo, Brasil - ⁴DFKI, Saarbrücken, Germany - ⁵University of Lyon, France - ⁶Universidad de Cantabria, Santander, Spain

The poster [1] presents the I2Geo platform developed within the Intergeo project [2] whose ambition was to develop a Pan-European math teacher community enabled to share resources and practices in using dynamic geometry (DG). We present the main tools and services i2geo offers to stimulate the use of DG in mathematics classes.

Keywords: Intergeo, I2Geo platform, dynamic geometry

Dynamic geometry systems (DGS) are well known computer tools to support math teaching and learning by means of personal explorations and experience. Despite their availability and recommendations in European countries curricula to use them, their integration in schools is still unsatisfactory (Hendriks *et al.*, 2008). The Intergeo project (Kortenkamp *et al.*, 2009) tackles main obstacles to DGS integration: (1) difficulties to find suitable resources due to the lack of metadata describing accurately their content, (2) impossibility to exploit with a given DGS resources created with another one, (3) lack of quality guarantee of available resources. We briefly expose solutions proposed to overcome these obstacles.

SHARING DG RESOURCES

An accurate resource content description is necessary for easy finding and sharing resources. The challenge in Intergeo consisted in defining metadata allowing a cross-curricular resource search regardless of language and cultural differences. This was achieved by defining a math topics and competencies ontology making it possible to find resources written in different languages. Sophisticated search tools (e.g., search associated to different national curricula key words) have also been developed.

INTEROPERABILITY OF DGS

One of the obstacles in the use of DG is the issue of user lock-in with respect to a particular software product. Learning new software is time consuming and usually unrealistic for teachers. The project defines a common interoperable file format to describe constructions created with a DGS in a way to enable content exchange between DGSs. The standards are supervised by Intergeo A.s.b.l. association.

QUALITY ASSESSMENT PROCESS

Quality assessment of DG resources (Trgalová *et al.*, 2009) aims at promoting access to best quality resources, as well as at ensuring their continuous improvement. The main tool supporting the assessment is a standardized questionnaire organized around nine dimensions of a resource related to its mathematical, didactical, pedagogical, technical and ergonomic aspects. Quantitative evaluation of a resource along these aspects in terms of a 4-level range of agreement can be complemented by qualitative comments, which are crucial for the resource improvement.

Figure 1: Main page of the platform

▶ ○○○○	I found easily the resource, the audience, competencies and themes are adequate
▶ ○○○○	The files are technically sound and easy to open
▶ ○○○○	The content is mathematically sound and usable in the classroom
▼ ○○○○	Translation of the mathematical activity into interactive geometry is coherent
○ ○ ○ ○	The math and the figures are related
○ ○ ○ ○	The figure is behaving consistently within the activity
○ ○ ○ ○	The figure shows no ill effect
○ ○ ○ ○	The numerical values (angles, lengths) are consistent
○ ○ ○ ○	Functionalities and specific behaviors like sliders, keyboard interaction or macros are well described
Comments:	
<input type="text"/>	
▶ ○○○○	In this resource, Interactive Geometry adds value to the learning experience
▶ ○○○○	This activity helps me teach mathematics
▶ ○○○○	I know how to set my class for this activity
▶ ○○○○	I found easily a way to use this activity in my curriculum progression
▶ ○○○○	The resource is user friendly and adaptable

Figure 2: I2Geo quality questionnaire

I2GEO PLATFORM IN A FEW NUMBERS

By April 2011, around 3500 resources are available on the platform and more than 700 evaluations have been performed to this day. The platform has more than 1000 registered members.

MOBILE TECHNOLOGY IN MATHEMATICS COURSES FOR TEACHER STUDENTS

Iveta Kohanová

Faculty of Mathematics, Physics and Informatics, Comenius University in Bratislava,
Slovakia

In August 2008, Faculty of Mathematics, Physics and Informatics at the Comenius University in Bratislava received an HP Technology for Teaching Higher Education grant to innovate and transform learning and teaching at the Faculty. The poster focuses on the usage of the above-mentioned HP mobile technology in preparing future mathematics teachers in courses of Mathematical Analysis, Didactics of Mathematics and Didactical seminar in school mathematics. It demonstrates how we prepare our future teachers to the integration of modern mobile technology in teaching mathematics at primary and secondary schools; how these teachers improve their mathematical knowledge, attitudes towards mathematics, connecting theoretical knowledge with practical one and increase their motivation.

Keywords: mathematics education, preparation of future teachers, technology in educational process

IMPACT ON STUDENTS' LEARNING

Achievement of project objectives are measured in form of group comparison (pilot course vs. control course - offered without the support of HP mobile technologies), tests, and interviews related to the change in motivation and attitudes towards mathematics.

Two Years Ago – A typically successful completion in a Mathematical Analysis (*Didactical seminar*) course was approximately 55% (44%).

One Year Ago – A typically successful completion in Mathematical Analysis (*Didactical seminar*) course was approximately 74% (58%).

Today – To the date, our successful completion rate is approximately 75% (63%).

IMPACT ON TEACHING

The teacher, as well as teacher students, work during the lessons with tablets. In this way, the students came from a passive role to the active role. They have all the materials in electronic form and therefore, they can edit them, share them, which leads to achieving better results.

During the course of the Didactics of Mathematics teacher students simulate the primary/secondary school classroom; one teacher student plays the role of the teacher, other teacher students represent pupils. By practicing of teaching and learning mathematics with the usage of the HP mobile technology, they prepare themselves for their future career and integration of technology into education.

TECHNOLOGY IMPLEMENTATION

Each teacher student works during the lesson with a tablet (Fig. 1); the tablet capability of on screen inking enables him/her to work directly with a given problem or a representation of a mathematical concept, to write, calculate and draw, to model and observe the behavior of functions, parameters, etc.

PEPIMEP PROJECT: ONLINE DATABASE SYSTEMS AND DIFFERENTIATED LEARNING ROUTES FOR SCHOOL ALGEBRA

Françoise Chenevotot, Brigitte Grugeon-Allys

Laboratoire de Didactique André Revuz L.D.A.R., Paris Diderot University, France

On this poster, we present PépiMep research project (running from 2010 to 2012). It articulates two research domains: educational research for school algebra (Kieran 2007) and Computer Learning Environments (C.L.E.). Our aim is to implement computer resources in online database systems to help teachers to differentiate students' learning in elementary algebra and to study the mathematic teachers practice and the algebra activity of students.

Keywords: online database system, cognitive assessment, teaching and learning of school algebra, differentiated learning routes.

FROM PÉPITE-LINGOT PROJECT TO PÉPIMEP PROJECT

Many teachers have difficulties taking into account their students' cognitive diversity. So maths teachers need computer resources to differentiate students' learning in elementary algebra. *Pépité-Lingot* project relies on a fifteen years collaboration between two partners: CLE researchers from LIP6 Paris and math education researchers from LDAR. *Pépité* software produces an automatic cognitive assessment for school algebra. This tool, based on a multidimensional analysis of algebraic skills (Grugeon 1997), generates automatic multi-criteria assessments of students' competence in school algebra (Delozanne and al. 2008). *PépiMEP* project is grounded on the collaboration of the two previous partners and a third one, Sésamath, a French maths teachers association which has had a central place in online database systems for ten years (Vanroyen 2008). The aim of *PépiMEP* project is to implement computer resources in the Sésamath online database *LaboMEP* to help teachers to differentiate students' learning in elementary algebra and to study the maths teachers' practises and the algebra activity of students.

AIMS

PépiMEP project will design and implement assessment and differentiation tools in the *LaboMEP* database. For researchers, the objective is to have large-scale data. For Sésamath association, the objective is to develop a new version of their database, which includes assessment and differentiation. We present our research questions. In educational research: Do mathematic teachers use learning situations and differentiated learning routes, structured by students' cognitive learning, to organize work in groups in their classroom? Are these differentiated learning routes adapted to usual evaluation and differentiation practices of teachers? What are their effects

on students' activity? In ICT research: Is automatic analysis of pupils' answers developed in prototypes (*Pépité*) rather robust to pass on the scale (*LaboMEP*)? By combining numerical and didactical analyses, is it possible to develop a dynamic assessment tool?

METHODS

Our method is based on both an analytical and a didactic engineering point of view. At the time of implementation in classrooms, we confront *a priori* analyses and models developed. Methodology is based on the combination of qualitative and quantitative studies: a large-scale study with an ICT monitoring in the *LaboMEP* database and some case studies with observations and interviews in classrooms (Abboud-Blanchard and al. 2007).

FIRST RESULTS

Experimentations with assessment tool and adapted learning routes just began in 10th grade classrooms. For example, before the use of the assessment tool, a teacher has constituted 4 groups for school algebra learning in his class of 35 pupils: the very good pupils, the very good pupils with few difficulties, the average pupils, bad pupils. The teacher needs help mostly for the average group. The diagnosis agreed with the teacher's groups with only few differences and helped the teacher by lightning some pupils' difficulties that need special training.

EXTENDING [1] THE MATHEMATICS TEXTBOOKS ANALYSIS: QUESTIONS OF LANGUAGE AND ICT

Carlos Alberto Batista Carvalho, José Manuel Leonardo de Freitas

Escola Secundária Lima de Freitas / UIED FCT UNL

This poster refers to an ongoing research, which deals with the integration of ICT in Portuguese mathematics textbooks. However it is relatively unknown how this integration has been made. The main goal of this study is to develop a comparative analysis of how the syllabus for Mathematics A and for Professionals Courses (CP) integrates the technologies and how these technologies are discussed in school textbooks, and to characterize the different kinds of language used. For this purpose an analytical tool is being developed and tested.

Keywords: ICT, Textbooks, language

In an attempt to characterize the language used in different types of textbooks and in the process of developing an analytical tool, crossed with an apparatus developed in a former work that analysed the levels of use of the graphing calculators in textbooks (Carvalho, 2006), we present here very briefly a part of literature review on the Theory of Social Activity (Dowling, 1998) directed to the analysis of textbooks.

A textbook should lead to the establishment of a pedagogical relationship between its authors and its content with its target audience to which it is intended. To be considered pedagogical, a text, according to Dowling (1998), must involve subjective relationship between two positions, on the one side, that dominates what should be taught, and on the other, someone with little or no knowledge about it.

A greater or lesser complexity of discourse adopted in school textbooks, called discursive saturation by Dowling (1998), is closely related to the pedagogical action being developed. The discursive saturation is directly related to metonymy and metaphor. When a math expression is looked at as a series of math symbols, ideally exemplified in a math equation or a demonstration, mathematics should be seen as a metonymy, presenting a high discursive saturation. If the school math often involves references to objects and not math relations, then they seem to have a metaphorical relationship, a low discursive saturation. According to Bernstein (1971, 2003), the discourse can be classified in two ways, one related to its specialization, the second related to the expression (language). For instance, a math expression has symbolic connotations in Portuguese, but the connotation with the non-mathematician is short. If the expression is translated into regular Portuguese, the content remains intact within the context of math, but the mode of expression is less specialized.

Dowling assigns three levels to the Theory of Social Activity: The Structural, the Textual and the Resources. The Structural – Activity level is further divided in other three levels: a) Practices – Domain, related to the forms of expression and content

relating to signifiers and signified, b) Practices – Discursive Saturation, related to the fact that the practices (DS+) present at the level of discourse, a highly complex organization and exhibit compared to a (DS-) practice a complete articulation, and c) Positions, related to the construction of hierarchical positions of transmission and acquisition. The textual level works on voices: who says what – the author, who hears – the reader, and messages, the content. The Resources level is essentially semiotic, assuming significant modes.

When testing the apparatus, we chose a topic: Properties of exponential functions, from the same textbooks authors, for two syllabuses: Mathematics A and Mathematics CP. Mathematics A is addressed to the students wishing to pursue studies, Mathematics CP is addressed to students who want to finish their studies. To the former, a more formal knowledge is needed, in the esoteric domain; to the later a more practical knowledge is expected, in the descriptive domain. However, in both textbooks, the presentation is equal, “copy and paste”. In the message, it is not possible to distinguish the intended audience. In both textbooks, the resource is iconic, no different strategies were used. A reference to the graphing calculator is made, in both textbooks, but nothing more than a reference. The pedagogic relationship, in the Mathematics CP is more of subject than dependent or even objectified, as it should be.

In conclusion, a student, who had problems with mathematics in a school route, will experience the same problems in the other route. The authors used the work of a manual for replicating the other, without regarding to whom it is addressed. The syllabus recommendations were not attended. Where we should find a practical approach, we find a formal approach. In the Mathematics CP textbooks where the references and examples with the use of ICT should prevail, the opposite is observed.

The actual poster presented at CERME7 may be obtained from the author by emailing them at almo_mou@hotmail.com

INTENSIVE USE OF ICT IN PRE-SERVICE PRIMARY TEACHERS' PROFESSIONAL TRAINING IN MATHEMATICS: IMPACT ON TEACHING PRACTICES.

Jean Baptiste Lagrange, Alexandre Becart

LDAR, Research Team in the Didactics of Mathematics, University Paris 7, France

Up to this year, the training of primary teachers took place in France during two years in a Teacher Training College (IUFM). The first year was mainly theoretical and aimed at completing students' disciplinary knowledge. The second year focused on the teaching profession in primary schools, alternating training and practice. Research has found that in spite of a significant social development of digital technologies, teachers' use of ICT is very limited, especially in their classroom practice. The specific ICT courses taught at the IUFM did not really change this situation. My hypothesis is that an intensive use of ICT in professional training in mathematics can be more effective.

CONTEXT AND PROBLEMATIC OF THIS RESEARCH

On the one hand, the current development of ICT, particularly in mathematical applications, allows considering new teaching practices in teacher training in mathematics. On the other hand, few or no in-service primary teachers introduce ICT in classroom practice in contrast with institutional guidelines and most of them use ICT poorly or not at all to prepare their class lessons and collaborate with colleagues. These first observations appear paradoxical in light of the availability of ICT in both private (Lagrange, Lecas, & Parzysz, 2005) and professional sphere. They appear also paradoxical with regard to the institutional demands. Primary teacher training considered in my thesis is multidisciplinary and punctuated by periods of practices with full responsibility of a class. For both these reasons a tension exists between the different training periods and the different requirements of disciplinary subjects. In my assumption, ICT, especially the communication via networks, can offer a way to manage this tension positively.

THEORETICAL FRAMEWORK

The theoretical framework should apply to the specific training of primary teachers. Pre-service primary teachers' ages and background are very diverse. The training is accessible to any graduate. Brought together in a permanent training group, students make a community of learners in which diversity can become an advantage to their learning if they collaborate. Many researchers believe that ICT can promote and guide this collaboration, especially Internet-oriented tools (Beatty & Geiger, 2010). The work of a school teacher in mathematics is to construct workable classroom sessions. The choice of the trainer is to support this construction and to promote reflexivity, especially by collective discussions. ICT can help the mutualisation and

the collective discussion relatively to classroom sessions. The framework of communities of practice developed by Wenger (2006) seems particularly well suited to the study of learning through exchange and collaboration within a permanent group and induced by the structure of training to share practices. Jonassen (2000) revisited the activity theory, in order to build learning environments based on the analysis of systems of activities in the professional sphere, which is consistent with my goal of preparing students to work as members of communities of teachers. That is why I choose these two approaches: Wenger's communities of practice and the activity theory by Jonassen.

METHODOLOGY

As a trainer in mathematics, I taught courses for pre-service teachers and I choose to implement an intensive use of ICT. An agreement with the students allowed me to access to all digital exchanges in some groups. The experimental data collected during the courses was supplemented by questionnaires and group discussions with students in order to know more about their personal tools, skills, initial and final ICT use, how they work, their activities in training and how they use ICT in class.

FIRST RESULTS

An initial analysis of data collected reinforces my choice of a dual theoretical approach. Indeed, we can see that students built a community after arriving at the Teacher Training College. This community first exchanged about work placements and then integrated teaching. In addition, the mathematics session production work was built around a division of the task and the activity theory revisited by Jonassen corresponds to this work. Students' personal equipment available was sufficient to consider any use of ICT in training. However while a few students were very good at using ICT tools, uses by most of the students were limited to a few tools and their knowledge was generally poor. Scaffolding or additional training was therefore often necessary in order to generalize in-training ICT practice to the whole group. Regarding classroom uses, the results are contrasted.

THEORETICAL FRAMEWORK TO ANALYSE THE PROBLEM SOLVING PROCESS WHILE HANDLING COMPLEX MATHEMATICAL STORY PROBLEMS IN PRIMARY SCHOOL

**Johannes Groß¹, Katharina Hohn¹, Sibel Telli¹, Renate Rasch²,
Wolfgang Schnotz³**

¹DFG Graduate School “Teaching and Learning Processes”, University of Koblenz-Landau, Landau, Germany

²Institute of Mathematics, University of Koblenz-Landau, Landau, Germany

³Department of General and Educational Psychology, University of Koblenz-Landau, Landau, Germany

One of the goals of mathematical education is the development of problem solving competences. This development is fostered by working on complex story problems. There are different models describing the sequences of operations and actions during the solving process for regular story problems. Yet, these models cannot be used when dealing with complex story problems. The idea of a new model is described in this paper. Two existing models were combined and adapted in order to get one that is suitable for our purposes.

Keywords: problem solving, coordination, MLT-Model

THEORETICAL BACKGROUND

The term complex story problems specifies a group of tasks that is different from regular story problems (Rasch, 2001). Unlike regular story problems, these tasks are based on very challenging mathematical structures and cannot be solved by arithmetic operation models that students are usually familiar with (Rasch, 2001). The development of problem solving competences is an important element of the curriculum for mathematics. Concerning this aim, such competences can be built when working on story problems (Staub & Reusser, 1995). An according study shows the positive influence of complex story problems on the development of problem solving competences of primary school students (Rasch, 2001). Steps of the problem solving process of regular story problems are defined differently in various models. Unfortunately, these models do not fit the problem solving process of complex story problems (Ruwisch, 1999). Since there are no models that describe the process of problem solving with regard to this special group of story problems, we aimed to develop a suitable one for such problems.

The first model (Reusser, 1993) is called “Student-Problem-Solver” (SPS). According to the SPS model the student recodes and gradually transforms the story problem into the solution. The second model is the „cognitive-metacognitive model of mathematical problem solving” (Montague & Applegate, 1993). This model defines seven cognitive processes as essential for effective and efficient problem

solving. Both models focus on different aspects of the problem solving process of story problems and complement each other. Through the “coordination” (Prediger, Bikner-Ahsbahs & Arzarello, 2008) of these two models we developed a new model (Radford, 2008). Our MLT-Model (Groß, Hohn, Telli, Rasch & Schnotz, 2010) describes the sequence of the problem solving process of complex story problems. Based on this model, we also developed a system of categories that can be used to analyse the problem solving process and the use of different external representations while working on complex story problems in primary school mathematics.

THE COMPLEXITY OF ADVANCED MATHEMATICAL THINKING AT THE NON-UNIVERSITY LEVEL

Miguel Silva

Escola Secundária Jorge Peixinho - Montijo - FCT/UNL- (UIED)

António Domingos

Departamento de Matemática da FCT/UNL- (UIED)

This poster intends to be a presentation of the PHD research project by the first author. Understanding the reasons to the (un)success in mathematics, has attracted the interest of researchers worldwide. Starting with some theories of knowledge construction, it aims to understand the different interactions occurring in the classroom. In addition we expect to further study this complexity, by understanding the links between the representations of various concepts, and knowing what non-higher education students make of it. The technology emergence, in all its forms, in schools as catalyst for learning, may enhance the connections between various representations of a mathematical object as a relevant factor contributing to the clarification of learning issues.

Key-words: Advanced Mathematical Thinking, Mathematics Education, Significance, Connexions in curricula

In higher education, Domingos (2003) studied the understanding of mathematical concepts at the university. Internationally, several authors are references on this theme, namely Dubinsky(1991) work, on the APOS theory, inspired by Piaget. Equally important is the *proceptual* approach developed by Tall who bases his theory on three mathematical worlds of development of mathematical knowledge: conceptual-embodied world; *proceptual* symbolic-world, and formal-axiomatic world. (Tall, 2007). Dreyfus (1991), and his approach giving emphasis on representation and abstraction power, it will also be studied.

The main goal of this work is to understand how students acquire knowledge. Therefore, we want to: characterize the processes involved in understanding of mathematical concepts by students of the secondary school and characterize student actions in the appropriation process of mathematical concepts. Understand how they coordinate between different representations of the same mathematical object; understand how technology is able to influence the articulation and connection processes among the different concepts. The interrelation between the theories above is fundamental to understand the appropriation process of mathematical concepts. Dreyfus proposed the representation and abstraction as the main way to characterize this process. The *procept* notion and the *proceptual thinking* presented by Tall allow us to understand and explain the Dreyfus view. The Dubinsky approach became relevant in the way that allows us to describe more deeply the different steps of all

process and mainly the students' capacity of managing the encapsulation and de-encapsulation process. At this point the issues we bring to the investigation are: Does a better connection between different representations of a same object, makes a math student more skilled? Would these connection lines contribute significantly to an increased stage of abstraction leading students to a higher level of complexity? Is mathematics specific language used in the different representations of an object, too complex to promote peaceful interconnections among them? Would better links between different representations, allow a better understanding of upcoming knowledge? For studies of this nature makes more sense to use a qualitative interpretive methodology (Bogdan & Biklen, 1994). Field work consists on an 11th grade classroom observation on trigonometry topic. Later interviews will be conducted, and analyzed. Some documents analysis such as (notebooks, tests, worksheets) will be a complementary way of data collecting.

To analyze the data collected through the classroom observations and the teaching experiments based on proposed tasks, we intended to identify the representations that students have about the concepts studied and try to understand how the students abstract and reflect about them (Dreyfus position). To understand this process we use the notions of procedural and *proceptual lthinking* (Tall's theory) to categorize the student's answers to the proposed tasks, giving special attention to the *procept* notion. To analyze the transition from one to another kind of thinking we intended to take into account the interiorization of the student's actions on objects, the coordination and inversion of the processes developed and the encapsulation and de-encapsulation of these processes and objects are fundamental for our analyses of the mathematical objects studied (APOS)

NETWORKING THEORIES
THE ‘KOM PROJECT’ AND ‘ADDING IT UP’
THROUGH THE LENS OF A LEARNING SITUATION

Yvonne Liljekvistand Jorryt van Bommel

Karlstad University

Abstract: Mathematical skills and understanding have been described in different ways. Adding it Up and The Danish KOM project are two such frameworks and in this poster these are put side by side. Transcriptions of students working on a mathematical task were first categorized within each framework, where after comparing and contrasting revealed similarities and differences. We have classified these differences and similarities through four cases which are described in the poster.

Keywords: competencies, proficiencies, comparing and contrasting

INTRODUCTION

In spring 2009 the authors attended a PhD course where one aim of the course was to understand two different reports; the Danish KOM project (KOM abbreviation in Danish: Competencies and the Learning of Mathematics) (Niss, Højgaard Jensen, et al, 2002) and the American report Adding It Up: Helping children learn mathematics (Kilpatrick, Swafford, & Findell, 2001). Kilpatrick et al state that their descriptions give “a framework for discussing the knowledge, skills, abilities, and beliefs that constitute mathematical proficiency” (p. 116). Niss et al describe their work as “an overarching conceptual framework which captures the perspectives of mathematics teaching and learning at whichever educational level.” (Niss, 2003, p. 1).

USING NETWORKING STRATEGIES

Our interest lies in *understanding the frameworks*. Since both frameworks are in their own way describing cognitive and behavioural activities for learning of mathematics, a logical question for us was to see whether the frameworks were disjoint or overlapping, and in case they would have common characteristics, whether they were all inclusive, only partly joined or whether one is a subset of the other. In order to understand the core concepts in the frameworks we needed a tool, and an arena, to be able to better grasp some characteristics. Using networking strategies when applying these frameworks on transcriptions from a videotaped learning situation made it possible to answer our research question: Do the two frameworks represent a situation of parallel development of theory in mathematics education?

In order to understand the frameworks we worked with a comparing and contrasting procedure (Bikner-Ahsbahr & Prediger, 2010). Each relevant sentence expressed by

the students was analyzed to define competencies or proficiencies exposed within the sentence, and when possible the sentence was categorized in terms of proficiencies and/or in terms of competencies. The focus on our analysis was to find examples of all the core components of the frameworks. Once each proficiency and competence had been identified by a cluster of sentences, we could start looking for patterns and reveal similarity and diversity. Since the sentences could be categorized with components from both frameworks, or from one or the other, a contrasting procedure pulling out typical (co) variation was conducted.

FINDINGS AND IMPLICATIONS

The focus of the poster is the networking strategy method which is used to grasp core characteristics in two similar conceptual frameworks. When applying the two frameworks on the same data, patterns appeared that enlighten similarities and differences. Our results, presented through four cases, indicate that networking strategies can supply researchers (and teachers) with tools to understand the explanatory power of different conceptual frameworks. Hence the work to develop new theories by networking strategies goes side by side with the endeavor to more deeply understand existing frameworks.

Since we are participating in interdisciplinary projects where networking of theories is of importance the method using networking strategies to better understand (two) conceptual frameworks is useful in our further studies, even though we are at time not going to make a deeper study within these two frameworks.

A SUCCESSFUL COMBINATION OF COP AND CHAT TO UNDERSTAND PROSPECTIVE PRIMARY MATHEMATICS TEACHERS' LEARNING?

Kicki Skog

Department of Mathematics and Science Education, Stockholm University, Sweden

Can it be useful to combine two theoretical frameworks when attempting to understand what kind of challenges prospective teachers are facing and what makes sense in becoming a mathematics teacher? The poster suggests a combination of Lave and Wenger's theory of learning in Communities of Practice and Engeström's Cultural Historical Activity Theory. It also presents a discussion regarding commensurability within these frameworks, motives for using these theories in this study and what I find challenging.

Keywords: Communities of practice, CHAT, mathematics, prospective teachers

INTRODUCTION

There are times in our lives when learning is intensified: when situations shake our sense of familiarity, when we are challenged beyond our ability to respond, when we wish to engage in new practices and seek to join new communities. (Wenger, 1998, p. 8)

My primary aim for conducting this research is to understand what prospective primary mathematics teachers ascribe as meaningful and important in their process of learning to teach mathematics. From a first analysis issues regarding the role of mentors and peer-collaboration within the teacher education program are central, but also the individuals' background and school experiences. Thus I need to use theoretical frameworks that allow me to move from the present to history without changing research track. I believe this inside-view, i.e. social roles, agency etc., could be elaborated on as learning within different communities of practice, COP (Lave & Wenger, 1991; Wenger, 1998). When it comes to understanding how background, family and personal goals influence/affect the individual prospective teacher's learning, it could be fruitful to elaborate on these questions from a cultural and historical perspective. Therefore I consider using COP in combination¹⁰⁰ with Cultural Historical Activity Theory, CHAT (Engeström, 1999), as theoretical frameworks.

¹⁰⁰ For a further discussion on strategies and methods for connecting theoretical approaches, see Prediger et.al (2008)

THE POSTER

Three excerpts from early interviews with two prospective primary mathematics teachers were viewed on the poster. Both immigrated to Sweden as adults. The excerpts indicate that an analysis through modes of belonging (Wenger, 1998) – here with a focus on imagination – could facilitate understanding of prospective mathematics teachers' identity and identification in communities of practice. From a CHAT perspective there is a tension between what mathematics was for them in their country of birth, and what mathematics is in the Swedish teacher education programme. It affects the prospective teachers and makes an analysis from a cultural historical activity theoretical perspective possible.

CONCLUDING REMARKS

In this case, after having fruitful discussions with participants at the CERME 7 conference, I consider that the study can benefit from using both perspectives and create a broader picture of the process of becoming a mathematics teacher, but there are challenges to overcome. How, for example, do I distinguish between the different notions of community? Are the theories competing on the same level – and if they do: can that enrich the study? Can a combination of these two theoretical frameworks contribute with a deeper understanding of learning to teach mathematics as situated, but also as historically and culturally bound meaning?

CONNECTING THEORIES TO THINK OF PLANE GEOMETRY TEACHING FROM ELEMENTARY TO MIDDLE SCHOOL

Marie-Jeanne Perrin-Glorian

Laboratoire de Didactique André Revuz, Université d'Artois

Abstract: To think of continuity of geometry teaching along compulsory school, we coordinate the theory of didactical situations with a theoretical framework concerning elementary geometry obtained by integrating Euclid's geometry with semiotic theory of Duval (analysis of processing in the register of figures).

Keywords: geometry, figures, instruments, figure restoration, connecting theories

RESEARCH QUESTIONS AND NECESSITY TO CONNECT THEORIES

Motivation of the research: There is a discontinuity between geometry in primary school, drawing figures with usual geometrical instruments and further geometry with abstract objects and demonstration. In primary schools, teachers usually regard geometry teaching as not problematic but find no relation between geometry they studied in their secondary courses and the geometry they teach. The use of usual instruments for drawing geometrical figures is generally considered as a technical problem. Nevertheless, these instruments are strongly related to mathematical objects and properties of these objects; this relation is not obvious for pupils.

Our question: Is there a way to think of continuity in teaching geometry along compulsory school (from 6 to 15) and help teachers?

Necessity of connecting theories: To address our problem, mathematical theories and theories on learning are not sufficient. It is necessary to construct intermediary theories integrating both. The theory of didactical situations (Brousseau, 1997) is itself such an intermediary theory but, to take into account the specificity of elementary geometry teaching, we can say, using the definitions of Bikner-Ahsbaths et al. (2010), that we needed to coordinate it with a specific theoretical frame we constructed, itself integrating two other theories: the axiomatic geometry of Euclide as a theory of space and the semiotic theory of Duval (2006).

CONNECTED THEORIES AND THE WAY TO CONNECT THEM

First, our own theoretical frame about elementary geometry teaching leads to the following main hypotheses from an epistemological and cognitive point of view:

In relation with Duval's theory: There is a specific way to look at figures in geometry, different from the way to look at drawings in everyday life. The natural view of figures is to see a figure as composed of juxtaposed figural unities of dimension 2. However, to solve a geometrical problem as well as to construct figures with instruments, you have most of the time to see superposed figures composed of surfaces, lines, or points and relations between them and to articulate the register of

figures and the register of language. Many difficulties with geometry are rooted in problems to change the view on figures. An example is given in the poster.

In relation with Euclid's theory: The different axiomatic theories for geometry are not equivalent to define coherence between mathematical theory and a teaching progress compatible with students' development. By the important role given to the triangle, and its reference to magnitudes and ratios of magnitudes without numbers, the Euclidian axiomatic is adapted to help thinking of a progression from a view of figures as composed of two dimensional objects to a view in terms of relations between lines (straight lines and circles) and points.

We construct a progression, developing in primary school the identification of alignments, intersections... in 2D-figures, in relation with tracing with instruments and geometric objects and properties. Continuity in teaching geometry also demands extending the notion of instrument considering as well forms, templates, stencils, tracing paper, scissors and so on... as instruments. Some of these instruments are 2D-instrument, bearing 2D-information about the figure (e.g. templates) or not (e.g. tracing paper), some instruments are 1D-instruments, tracing lines (e.g. ruler), some are 1D or 2D-instruments according to how they are used (square, compass).

Coordination with TDS: This integrated theory of elementary geometry is then "coordinated" with the theory of didactical situations (TDS) seen as complementary. TDS is used to conceive a *milieu* (mainly figures and instruments) around production and reproduction of geometrical figures, possible modifications of this *milieu* and *situations* (rules to act on this *milieu*) helping students to progressively modify their view on figures and instruments and construct geometrical concepts. A situation, we called *figure restoration*, plays a particular role: a couple of figures is given such as one is the model, the other one is a "damaged" figure (partially deleted) that has to be restored and a "cost" is introduced for the use of instruments.

Examples and trends for discussion are proposed in the poster. The actual poster presented at CERME7 may be obtained from the author by emailing at glorian@math.jussieu.fr

DIDACTICAL ANALYSIS AND CITIZENSHIP WITH PROSPECTIVE MATHEMATICS TEACHERS

Yuly M. Vanegas M., Joaquin Giménez and Vicenç Font
Barcelona University

Our particular aim is to show some relationships between the development of didactical analysis and reflection about teaching of prospective mathematics teachers and developing citizenship, as a basic competence through the study of various professional math practices.

KEY WORDS: didactical analysis; mathematical practices; citizenship

A persistent problem in mathematics education research is how to justify and design training programs giving professional problems that arise and influence the nature and quality of professional practices. Such practices should enable the future teacher for knowing describing, explaining, evaluating and improving situated and contextualized teaching and learning (Llinares and Krainer, 2006; Font, Planas and Godino, 2010). In particular to know how to assess general competencies as “training for citizenship through mathematical practices”. We want to describe the path of a future math teacher, characterizing its evolution in relation to training analysis expertise, identifying how he evolve being aware of considering citizenship when using mathematical practices.

Citizenship is interpreted here by using 4 axes: political appropriation of knowledge, responsible participation, critical mathematical perspective, responsibility for practices (Vanegas y Giménez, 2010). To perform didactical analysis, the future teacher use tools of description and explanation which have been learned in different subjects of the master. Above all, by applying the notion of criteria of suitability proposed by onto-semiotic approach (Godino, Batanero & Font, 2007) in which it's considered at least six criteria for valuing didactical suitability: Epistemic suitability, Cognitive suitability, Interactive suitability, Media/resources suitability, Emotional suitability, Ecological suitability.

Methodologically, we discuss two types of didactical analysis practices about instruction processes in two different moments: (m1) analyze experienced teacher practices by using videoclips, (m2) implement a practice discussing with a tutor being a teacher in a regular class of 12-13 years old students, and (m3) analyze their own practice two weeks after. With regard to m2 and m3, we analyze: (1) immediate written reflection about their school practice conducted, in which it was asked to explain from planning to analysis about what happened. (2) Delayed reflected report by which it was to proposed a replanning of the former practice after a certain time (part of the Final Master work). In these two tasks, the future teacher reflects on the design and implementation of a knowledge-driven sequence of extent of areas with flat figures.

In m1, the future teacher recognize the value of the context to interplay citizenship discussion when analyzing a presented task about comparison of a density population problem. In m2, we found that organizes his proposal for students based on a realistic mathematics perspective. He introduces the understanding of the formulas of the areas, with puzzles and discoveries. Sequence ends with a proposal to measure the oil slick from the Mexico Gulf through the NASA pictures, "to analyze the magnitude of the tragedy (using future teacher words)". After the experience in a real classroom (in a third moment), he think about his mistakes, and discuss about a need for a collaborative debate with the students, because "it was a monologue".

We acknowledge a greater depth of analysis of the practice m2 y m3 in relation to practice m1, based on the use of structured tools during training process. With regard to the didactical analysis levels achieved, we identify adequate descriptions of suitability levels in the development of mathematical practice. He recognizes that there are different ways to introduce the notion of area and identifies a potential cognitive conflict in the passage to the limit when considering the irrational measurement. Awareness of the interactional valuing can be seen as identifying rules and active positioning of students. With regard to developing critical reflective citizenship, we conclude that the future teacher (1) considers that mathematics enable the creation of powerful tools for interpretation, characterization and solution of problems (in this case, environmental), recognizing the complexity of the situation raised not only by the diversity of concepts, processes and mathematical procedures involved, but, for the opportunity to reflect on the social impact of such situations (2) allowing its students to value the measure as a conceptual tool for interpreting a phenomenon and social impact analysis and (3) fostering a reflective analysis of students through problem solving and the use of ICT as a working methodology.

HOW TO TEACH MATHEMATICAL KNOWLEDGE FOR TEACHING

Jorryt van Bommel

Karlstad University

The paper presents the results of a learning study conducted at a teacher-training course in mathematics. The Object of Learning of the learning study was to develop Mathematical Knowledge for Teaching (MKT) for student teachers (ST). The data consists of three videotaped seminars and pre- and post tests (282) written by 47 ST. The data was analysed with help of variation theory and four critical features concerning MKT were found successively during the learning study cycle. Implementation of these critical features in the subsequent seminars increased ST results concerning their use of MKT.

Keywords: Mathematical Knowledge for Teaching, Learning Study, Teacher Education.

INTRODUCTION

Teachers in mathematics not only need a deep understanding of mathematics but also need knowledge on how to teach the mathematics (Ball & Bass, 2003; Grossman, 1990; Ma & Kessel, 2000). How to teach such MKT was the focus for the study described here. In what way would it be possible to work with MKT during a teacher-training course so that ST would consider aspects of MKT in their future teaching? Five aspects of MKT were chosen to work with: pupils' preconceptions, models for explanation, related (hands on) materials, suitable exercises and curricular knowledge.

FRAMEWORKS

Two frameworks were considered in this learning study. The conceptual framework *MKT* describing the kind of mathematical reasoning, insight, understanding and skill teaching mathematics demands (Ball, Hill, & Bass, 2005) was used as a background when planning the lessons and also to describe the data. Furthermore the theoretical framework *Variation Theory (VT)* was worked with in planning the seminars as well as analysing the data. VT sees upon learning as to be aware of the world in a new way. To learn about an object one has to identify its parts, see connections within the object and discern it from other items. Through a focus on an Object of Learning one can identify differences in learning and describe conditions necessary for learning to take place. (Marton & Booth, 1997)

ANALYSIS & RESULTS

The tests consisted of writing a lesson plan in which ST would reveal their use of the five aspects of MKT. VT was used to describe how the aspects were dealt with in relation to the way MKT was addressed during the seminar. What was made possible for ST to discern during the seminars and what did they actually discern? Four critical features were found and implemented in the subsequent seminars. There was a clear improvement in the way the 5 aspects of MKT were addressed by ST in the tests. The four critical features found were: 1) Curricular goals must be seen as something to choose from (not as a whole package to work with). 2) Contextual experiences have to be created and reflected upon from a teachers' perspective. 3) Components have to be described clearly in order to connect with other components. 4) The underlying mathematics should be understood when discussing an activity from a teachers' point of view.

ANALYSING EXAMS MATHEMATICAL QUESTIONS

Mário José Miranda Ceia

Escola Superior de Educação, Instituto Politécnico de Portalegre

The poster presents a model to analyse exams items. The model is inspired on the SOLO Taxonomy (Biggs & Collis, 1982), and in the cycles of learning they established. As in the SOLO taxonomy, three parameters were established to allow the items analysis: the capacity demanded to produced the answer (amount of knowledge required); the mental operations involved in the resolution (type of mental operation); and the type of answer required. The preliminary version of the model was designed to be used to any grade, and hypothetical answers were prepared to test the model. One example to exemplify the analysis made is provided.

STUDY OBJECTIVES

The present study pretends to develop a model that allows to establish different categories of exams questions complexity, and, in a second moment, to analyse exams quality.

THE MODEL (PRELIMINARY VERSION)

The model was design using three parameters: Capacity Demanded, the amount of concepts involved in the answer, how the concepts are related among them, and if they are provided or the student has to search them; Involved Operations, the type of reasoning used, inductive or deductive, and if it was an original one or similar to others studied before; and Answers Requested, answers are unique or there are more than one possible answers, if there are more than one possible answer, are they coherent, and consistency between the conditions provided and the answer requested.

Five categories were considered, using the same designations that Biggs and Collis used in their taxonomy: Pre-structural, Uni-structural, Multi-structural, Relational and Abstract.

METHODOLOGY

For the analysis of the examinations questions, it was considered hypothetical answers, produced by the authors according the level to which the examination was designed. With those optimal answers it was possible to realise the mathematical knowledge involved, the kind of reasoning, and possible coherence and consistency of the answers. To define the mathematical knowledge it was used the specific aims of the Curriculum of Mathematics for Basic Education (Ponte et al, 2007).

AN EXAMPLE OF ANALYSIS (QUESTION 3, 4TH GRADE EXAM, 2009)

Question: A group of 47 children, from a holiday camp, are going to climb. Children are going by car. Each car carries 6 children. How many cars are needed to carry the 47 children? Show how you reach the answer.

Hypothetical Solution: The correct answer is 8 cars. Dividing the amount of children, 47, by 6 (the number of children by car) we realise that 7 cars became full and remain 5 children, which make necessary another car.

To reach the solution it is possible to use: 1) Additive structure; 2) Multiplicative structure. In both cases to answer this question it is necessary to understand the meaning of the operation involved, and realise what the results mean for the proposed context.

Knowledge Involved: To answer the question it is necessary to use arithmetical knowledge from the 3rd and the 4th grades. It is necessary to use several pieces of knowledge to reach the solution, and in the end it is required to establish the connection between the mathematical solution and the real context of the question.

Operations: To answer the question it is necessary to use deductive reasoning similar to others experienced in class.

Answer: In both solutions the answer is closed and unique. However, it is necessary to solve the inconsistency between the arithmetical result and the real world.

Category: The question is considered a *relational*.

**THE PRACTICES OF PROSPECTIVE TEACHERS IN SOUTH
AFRICAN AND CANADIAN MATHEMATICAL LITERACY
TEACHER EDUCATION PROGRAMS:
WHAT WORKS AND WHAT DOES NOT?**

***Joany Fransman, **Joyce Mgombelo & *Marthie Van der Walt**

**North-West University & **Brock University*

Abstract

The implementation of Mathematical Literacy (ML) as subject in South African schools in 2006 necessitated the re-training of teachers to teach the new subject. The teacher education program for ML was implemented at the North-West University (NWU) in 2005. This program is therefore quite “young” hence the need for an investigation into other similar programs at universities in developed countries. The purpose of the poster was to report on a qualitative study that aimed at exploring the experiences of in- and pre-service teachers enrolled in ML teacher education programs at the NWU in South Africa (SA) and Brock University in Canada. Findings indicated that SA can indeed learn from Canada: Put more emphasis on the mathematics processes (MP) in the mathematics module in the program.

Keywords: Mathematical Literacy, mathematics processes, mathematics teacher education programs.

INTRODUCTION

The central question in our study was: In what ways can developers and practitioners of Mathematical Literacy (ML) in teacher education programs in South Africa (SA), learn from programs for similar courses in Canada? The implementation of ML as subject in the SA school curriculum in 2006 necessitated the re-training of suitable teachers. This raises an empirical question: How does ML teacher education programs in SA relate to a wider context of other ML teacher education programs from developed countries like Canada?

THEORETICAL FRAMEWORK

The definition of ML has been debated for decades, both nationally and internationally. A collage of the salient indicators from the various definitions of ML in extant literature (e.g. (Bowie & Frith, 2006) describe ML as the individual’s abilities and competencies to make sense of, communicate and engage meaningfully in mathematical situations that are encountered in his/her daily life. The approach that needs to be adopted in developing ML is to engage with contexts rather than applying Mathematics already learned to the context (Department of Education, 2003). For Bowie & Frith (2006) ML is about seeing every context through a quantitative lens.

Prospective teachers in an effective ML teacher education program should pay attention to the development of all the important skills and the Mathematics Processes which are problem solving, communication, connections, reasoning and representation (Brown & Schäfer, 2006).

RESEARCH METHODOLOGY

The study utilized a multiple case study approach due to its dual contexts (SA and Canada). Participants comprised of 61 out of 189 SA in-service teachers enrolled in the program and the 12 out of 30 Canadian pre-service teachers enrolled in the program. Data was collected from questionnaires, individual and focus group interviews, as well as lesson observation. The data was analysed using ATLAS.ti.5.0 – a computer-aided system used for the analysis of qualitative studies.

FINDINGS AND RECOMMENDATIONS

The study indicates that ML as concept is not yet fully comprehended by the SA participants. A thorough understanding of the concept of ML will enhance teaching methods as well as the understanding of the learner.

Analysis of data indicates that sufficient emphasis is placed on the Mathematics Processes in the Canadian program as these processes are explicitly stated in the curriculum documents. In SA, it seems that the Mathematics Processes are not explicitly implemented in ML classrooms as teachers seem not to be aware of them. The MP's have a large role to play in any ML curriculum and should be explicitly mentioned in the National Curriculum Statements in SA and not only be implied as is currently the case.

CONCLUSION

Developers of ML teacher education programs in SA can indeed learn from Canada by having a clear conceptualization of ML and placing more emphasis on the Mathematics Processes in the program. TEACHERS' USE OF GRAPHING CALCULATORS IN HIGH SCHOOL MATHEMATICS CLASSROOM - THE INFLUENCE OF TEACHERS' PROFESSIONAL KNOWLEDGE¹

Helena Rocha

Institute of Education, University of Lisbon, Portugal

ABSTRACT

The main focus of this poster is a new model of teacher's knowledge: Knowledge for Teaching Mathematics with Technology (KTMT). Central in this model is a set of inter-domains knowledge divided in two main areas: *Mathematics and technology*, and *Teaching & learning and technology*. This model is the basis for a study that intends to understand how teachers use graphing calculators in their practice and the influence of their professional knowledge on that use.

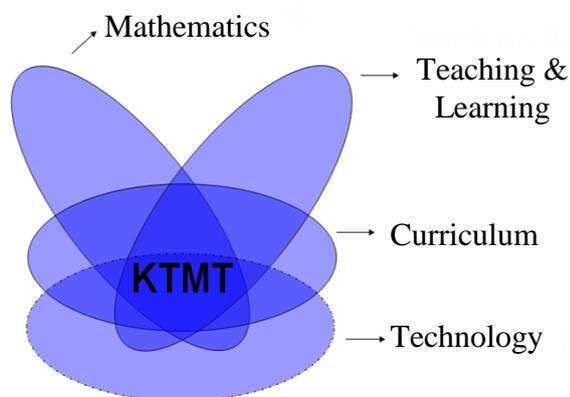

KEYWORDS: Knowledge for Teaching Mathematics with Technology (KTMT), professional knowledge, technology, graphing calculators

RESEARCH GOALS AND QUESTIONS

This is an ongoing study that intends to examine the nature and extend of teachers use of graphing calculators. Among other questions, it aims to answer the following question: What is the influence of the teacher's professional knowledge?

THEORETICAL FRAMEWORK

The evidence of how teachers' knowledge affects teachers' practice took to the development of frameworks such as *Didactical knowledge* (Ponte, 1999). Technology integration in schools raised new questions and prompted the need to a special focus on technology. *TPCK*, from Mishra & Koehler (2006), is one of the most

known characterizations that attends to technology issues, but problems still remain (Rocha, 2010). KTMT intends to articulate these two conceptualizations, overcoming the criticism and integrating important conclusions from technology research (Zbiek *et al.*, 2007). In KTMT, beyond the base knowledge domains (Mathematics, Teaching & learning, Curriculum, Technology), there are two important sets of inter-domains knowledge: *Mathematics and technology*, and *Teaching & learning and technology*. The first one involves knowledge of mathematical fidelity of the technology; knowledge of new emphasis on mathematical content; knowledge of new orders of mathematical content; and

representational fluency (i.e. knowledge of different representations and how to link them in meaningful ways). And the second one includes knowledge of effective ways of overcoming student difficulties in articulating technological and no technological information, promoting a critical attitude; knowledge of mathematical concordance; and knowledge of the diversity of classroom activities enhanced by technology, and of the new roles allowed. Curriculum is seen as a transversal domain that influences all the others. KTMT is then conceptualized as a unique body of knowledge constructed in an integrative way from the interaction of all the knowledges referred above.

METHODOLOGY

This study adopts a qualitative methodological approach, performing three teacher case studies. Data gathering includes class observation, interviews, and documental gathering. All interviews and classes observed are audio taped and transcribed. Data analysis consists of data interpretation, considering the problem studied, and the theoretical framework.

EXPECTED RESULTS

A better understanding of teacher's use of graphing calculator and how its effective integration can be achieved is the main outcome expected from this study.

DEEPER MATHEMATICAL UNDERSTANDING THROUGH TEACHER AND TEACHING ASSISTANT COLLABORATION

Paul Spencer, Julie-Ann Edwards

University of Southampton, School of Education, UK

This paper presents a summary of a poster presented at CERME7, the focus of which was to examine the way that teachers and teaching assistants (TAs) work together in mathematics classrooms in order to encourage mutual effective professional development. Within this paper the aims of the research project, the background to the research, the methodology employed and the significance of the research will be discussed.

Key Words: Teachers, teaching assistants, collaboration, professional development.

The main aim of this study is to determine which characteristics of ways of working promote opportunities for developing deep understanding of mathematics in order to develop and trial an intervention strategy which will encourage mutual professional development. The study is designed to work from existing practice to address issues relating to the professional development of both mathematics teachers and their teaching assistants.

The expected outcomes of the study are:

- a) A characterisation of the ways in which mathematics teachers and TAs currently work together in secondary classrooms in the UK (11-16 years);
- b) Identification of models of teachers' and TAs' experiences which lead to effective professional development;
- c) Intervention strategies which promote effective professional development opportunities.

The UK standards framework for teachers (Teacher Development Agency [TDA], 2007) places an increasing emphasis on the effective working relationships between teachers and TAs in the classroom. Although it is generally acknowledged that the presence of TAs in the classroom has a positive effect on pupils' achievement, there is little research evidence in the UK (other than Muijs, 2003) about how this is achieved. However, recent findings of the Deployment and Impact of Support Staff (DISS) project (Blatchford et al. 2009) suggest that teaching assistants may have a negative impact on the mathematical progress of pupils.

Research conducted by Ma (1999) found that Chinese teachers' deeper understanding of mathematics is linked to the time and support they are given to work collaboratively on the content of their lessons. The importance of this deeper understanding of mathematics has been recognised previously by Ball (1989) who

concludes that deep understanding of mathematics and its interrelation with pedagogical knowledge is crucial to effective teaching.

This research project combines the work of Ma (1999) and Ball (1989) by utilizing the teacher and teaching assistant partnership in order to mutually develop deeper mathematical understanding, whilst meeting some of the recent recommendations made in the DISS project, thus mirroring the successes in China, but using established patterns of working in the UK. The design of this study utilizes embedded case study research methods (Scholz & Tietje, 2002) to characterise mathematics teachers' and their TAs' informal experiences and ways of working together, and systematic case studies (Yin, 2003) of particular teachers and TAs. Grounded theory methods provide the means for developing the models of current working practice through analysis of qualitative data. An intervention strategy will be designed, based on these findings, and will be implemented through a trial that involves both teachers and TAs. The development of an intervention strategy which encourages professional development is planned to have an impact on school and government policy which will, in turn affect the way mathematics teachers and teaching assistants work together in secondary school classrooms. Successful implementation of an intervention strategy is intended to develop teachers and TAs' mutual deeper understanding of mathematics which should impact on pupil attainment in the subject.
