THE CHALLENGES OF TEACHING STATISTICS IN SECONDARY VOCATIONAL EDUCATION

Arthur Bakker, Monica Wijers and Sanne Akkerman

Freudenthal Institute for Science and Mathematics Education

Utrecht University, the Netherlands

The challenges of teaching statistics in vocational education, an underresearched area, are likely to be different than in general education due to the focus on a particular occupation. The current paper addresses the question what these challenges are. Through interviews with teachers, apprentices and supervisors as well as analysis of the curriculum and classroom instruction, we identified such challenges. These include the difficulty to engage students and prepare them for diverse workplaces with different levels of mediation by technology. Moreover, competence-based projects, common in vocational education, require artful coordination of theoretical and practical knowledge, and the design of representations that assist future employees to draw appropriate conclusions.

CONNECTING SCHOOL AND WORK

One of the key challenges in statistics and mathematics education is to engage students by giving them a sense of purpose and utility of the concepts and techniques they learn (Ainley et al., 2006). One way, both in general education (Dierdorp et al., 2011) and vocational education, is to seek inspiration for designing engaging statistics education in professional practices and thus make a connection between disciplinary content and future work. After all, as Lave (1988, p. xiii) noted: “It seems impossible to analyze education – in schooling, craft apprenticeship, or any other form – without considering its relations with the world for which it ostensibly prepares people.” In vocational education, this relation between education and occupation is apparent and the vocational area is indeed an interesting but underresearched area of study: It is where teachers and students face the challenge of connecting abstract disciplinary knowledge to its usefulness in occupations. We therefore expect that research in general education can learn from research in the vocational and workplace domain.

However, we should also note that the differences between school and work statistics are big (cf. Noss et al., 1999) because school and work practices entail very different aims, tools, communities, rules and divisions of labour. For example, school statistics is mostly general but workplace statistics is typically context-specific and mediated by technology – which is the reason that Hoyles et al. (2010) highlight the need for Techno-mathematical Literacies (which include statistical literacy). The term Techno-mathematical Literacies (TmL) refers to the technology-mediated nature of mathematics at work and the need for communicating quantitative information.

To gain more insight into these challenges we draw on a 3.5-year research project on TmL in Dutch senior secondary vocational education (MBO), which prepares for intermediate-level occupations. This project came to focus on laboratory work. Common in industry, but also in health services and safety institutes, laboratories are statistically rich and subject to rapid changes in work organisation, hence interesting places to study the challenges that vocational teachers face when preparing their students.

In this paper ask: *What are the challenges of teaching statistics in vocational laboratory education?* Articulating these can provide a basis for improving the teaching and learning of statistics in vocational and presumably other settings. The challenge of preparing students for the technology-mediated use of statistics, for example, is a general one – just like the challenge of engaging academically less able students. We do not confine our analysis to challenges that teachers experience themselves but also include those that we inferred from discrepancies between school and workplace approaches to using statistics.

DUTCH SENIOR SECONDARY VOCATIONAL EDUCATION (MBO)

To sketch the setting of our research we first provide information on the MBO school system. About 40% of Dutch senior secondary students (aged 16-17) attend general education or pre-university tracks; the remaining 60% enrol in senior secondary vocational education (MBO). Levels 3 and 4 of MBO are just above basic school qualifications but much below Bachelor level (see also Bakker et al., in press). MBO used to have attainment targets for each MBO occupation (including hair dresser, baker, electrician, lab technician). For mathematics and statistics in many technical programmes this was a list of about fifty topics. Attainment targets that were less relevant for the occupation were ignored by mathematics teachers and general subjects were generally considered separate from the occupation. Over the past ten years vocational education has become more and more competence-based (Van den Berg & De Bruijn, 2009). There are now qualification files for 237 occupations which are formulated in terms of what starting employees should be able to do. The effect has been that subject knowledge such as mathematics is taught and assessed less than about ten years ago. In the file for lab technicians, for example, references to the statistical knowledge required are scarce and broadly phrased (e.g., “basic knowledge of mathematics”; “care for quality”).

THEORETICAL BACKGROUND

Hardly any statistics education research has been carried out in vocational education. Therefore hardly anything is known about the challenges of teaching this subject. Given the fact that vocational education forms a link between general education and workplaces, it is likely that we can yet draw on workplace research in this area. We can also learn from international trends of competence-based education.

Working Group 5

The workplace research most relevant to our research is that by Hoyles et al. (2010). Key trends in workplaces such as automation and computerisation of work processes are likely to lead to particular challenges. Hoyles et al. (2010) analysed these trends and the effects on what employees need to know about mathematics and, notably, statistics. Bakker et al. (2009) described a way to draw on employees' rich context knowledge but often poor knowledge of statistics by designing alternative representations of statistics that do not draw on inaccessible symbolic language. Key artefacts (boundary objects) in work processes were reconfigured in software (technology-enhanced boundary objects) so as to allow manipulation and easy interpretation. Teaching required hybrid expertise of statistics and work processes, hence our collaboration with workplace trainers.

The main reasons for introducing competence-based education in our country were first to prepare students better for specific vocations and second to take into the changing population of students (Van den Berg & De Bruijn, 2009) – those who find general knowledge hard to learn and consider themselves doers rather than thinkers, of with language or personal problems. Like in many vocational systems in the world, projects and simulations are often used to stay close to particular work tasks. The underlying reason for such pedagogic measures is the general acknowledgement of the situatedness of cognition and problematic transfer of general knowledge to everyday situations (e.g., Lave, 1988).

METHODS

To identify the challenges we analysed interviews with fourteen teachers (18:05 hours in total) at four different vocational laboratory schools (MBO) – three schools were relatively close to the university and one teacher in the fourth school was interested in the theme of our project and provided us with access to its teachers, students and supervisors. As a background to understanding the challenges mentioned by teachers we also studied their course materials and observed several lessons to get a sense of how course materials were used. We further conducted interviews with eight supervisors of apprentices in a variety of labs (in total 10:40 hrs), one school and two workplace managers (2:20 hrs), nine apprentices in the workplace (4:20 hrs), 27 apprentices at release days at school (5:40 hrs). With the help of three teachers we analysed 35 final apprenticeship reports to see what statistical technique apprentices used and how well they did so. In addition, we undertook four workplace tours in different labs (2:10 hrs), spent a day of observation and interviewing in one lab, and collected several prototypical artefacts that represented how statistical knowledge was mediated (e.g., Standard Operating Procedures including calculations, graphs, data etc.). This background information helped us derive challenges that teachers did not explicitly mention.

The interviews were transcribed verbatim and coded for challenges experienced by teachers. These were categorised into seven different but related challenges

summarised in the next section. We used the remaining data sources to offer explanations and further background to these challenges.

CHALLENGES

1. To cope with limited resources

All teachers complained that their hours for disciplines such as statistics had diminished due to longer apprenticeships (work placement) and the introduction of competence-based education – trends that several teachers considered to be a matter of economising on costs. In practice this meant more time on projects and learning on demand, and less on general subjects such as languages and mathematics. There is generally very little time for teaching statistics, for example one hour per week for the first two years. Yet the topics encountered in labs are numerous (Bakker et al., 2010). Moreover, both teachers and students noted that students had often forgotten many topics by the time they became apprenticed. A related challenge therefore is to keep their knowledge fresh and available over the course of the years even if not required in a particular company.

2. To engage students in learning statistics

All teachers and supervisors considered it important for students to understand the how and why of statistical techniques, but they also characterised their students as “doers, not thinkers”. They found it challenging to engage them in disciplinary knowledge that is not immediately linked to what students see as their purpose: becoming a lab technician. We have interviewed students who were able to attend general education but had deliberately chosen the vocational route because they thought this was better preparation for becoming a lab technician or because they preferred doing something practical. However, most vocational students have failed in general education for whatever reason. We return to this point in the last section.

3. To make statistics visible to managers and colleagues

Teachers had a hard time to convince their managers and some of their colleagues that students needed some disciplinary knowledge such as statistics in order to develop the competences formulated in the qualification files. In most cases, the number of teaching hours for subjects such as mathematics, statistics and the languages decreased considerably. The time available for teaching is often dedicated to projects that simulate some work task typically found in the workplace. Managers and even colleagues of the mathematics or science who taught statistics often thought that disciplinary content could be taught “just in time”, just before it was needed in a project. We probably do not have to convince the reader that teaching hypothesis testing (t- and F-test are common in lab work) has to be carefully prepared, especially to vocational students, who typically have not succeeded academically in general education. These observations illustrate that teachers found

it hard to make statistics visible to their managers and colleagues. From the literature we can derive an explanation.

It is well known from the research on workplace mathematics (of which a large part actually is statistical in nature) that employees tend to say they do not do any mathematics, even if mathematics educators observe them using it (Noss et al., 1999). We have also experienced this: One supervising lab technician claimed his work only involved “pluses and minuses”, but when he showed us around we saw technicians modelling chemical reaction processes, using extrapolation, slope and other mathematical concepts. When confronted with this observation, he responded this was chemistry rather than mathematics. We refer to this phenomenon as the Janus head (two-faced) nature of workplace mathematics and statistics: Where employees see working with numbers as part of their discipline (in this case chemistry), we as mathematics educators see mathematics being part of their work. It is only if we look for the use of statistics in workplaces and deliberately try to improve production processes that it becomes more visible (Bakker et al., 2006). This trend is corroborated by the omnipresence of black boxes in which most of the mathematical models and statistical techniques used at work are crystallised (Williams & Wake, 2007).

The drive to make the work error-free, one manager commented, has led to a situation where the younger generation often no longer knows what happens behind the screens. The paradoxical situation is that this hardly ever leads to problems – those have been ruled out by the system – but we did hear concerns about this situation; many lab technicians found it important for apprentices to understand the why and how of what they were doing and we have evidence from observations in one lab that blindly following procedures can lead to waste of materials and time. The tension observed can be seen as a result of the black box phenomenon that Latour (1999, p. 304) described:

... scientific and technical work is made invisible by its own success. When a machine runs efficiently, when a matter of fact is settled, one need focus only on its inputs and outputs and not on its internal complexity. Thus, paradoxically, the more science and technology succeed, the more opaque and obscure they become.

The Janus head black-boxed nature of statistical knowledge required might explain why the qualification files pay so little attention to it and why teachers found it so hard to convince their managers of its importance.

4. To prepare students for the technology-mediated nature of work

Teachers often ask the question what they should teach their students and how. What do students need to understand about more complex statistics if it is carried out by a computer system? The fact that t-tests are used in many labs does not necessarily mean that an MBO lab technician should understand the formula or be able to perform one by hand, or even with a software package.

Working Group 5

One of the teachers' key challenges that we think are relevant to education more generally is thus how to prepare students for the technology-mediated nature of statistics usage at work. One question here is whether students should learn the background of, say, statistical process control, before they use pre-fabricated SPC charts or whether they should learn SPC in relation to spreadsheets straightaway. The common assumption among teachers seemed to be that theoretical introduction with the conventional representations is the basis for practical usage. Previous research in a car factory has shown that this assumption is problematic (Bakker et al., 2009) and our observations in laboratory education corroborate this. For most students the step from symbolic representation, whether SD, t-test or correlation, to what can be inferred from them in practical terms is simply too big to teach in limited instruction time available for each topic.

Labs vary in terms of automation and computational tools, which means that schools have to prepare students for both manual and automated computation. Computations are not always taken away from employees. In some labs (about 14%, see Bakker et al., 2010), all calculations were automated in Excel sheets or dedicated computer software (such as LIMS: Laboratory Information Management System). In most others, a mix of computational tools (calculator, Excel, software) was used. The general image from the interviews was that calculations had become easier over the years because of software and automated machines, but what lab technicians need to know has not become less, only different; for example fluency in Excel has become more important. With computations outsourced to software, it becomes important to know something about the software and what it is doing. In one lesson we indeed observed how a teacher clarified to students the difference between computing something in Excel by column or by row – something relevant to statistics education we rarely find in a textbook.

5. To prepare for a diversity of workplaces

Teachers are well aware that their students may choose to work in very different labs. Should all students then learn what is required in the most advanced labs? Where chemical and clinical-chemical (medical) work involves correlation, regression and validation, the biological work often has a more qualitative nature (recognizing types of crystals etc.). Microbiological work does require good understanding of powers and logarithms, because amounts of bacteria are reported in powers of ten. Interestingly, common measures of centre easily turn out problematic when working with powers of ten. One supervisor preferred medians and geometrical means over arithmetic means but did not expect MBO level technicians to understand these alternatives.

6. To keep up with innovations at work

Laboratories change rapidly due to technological innovations. For example, students learn to calibrate machines in the old-fashioned way, but modern companies have big

Working Group 5

analysers that can be calibrated with a press on a button. The statistical background of calibration – measurements modelled by regression lines and correlation coefficients – has been completely blackboxed in such cases. Employees state they only judge the correlation coefficient to see if the measurements have been precise and accurate enough (e.g., 0.999964 was considered very good).

The aforementioned rapid developments at work raise the challenge for teachers to stay up to date. This is not easy once a teacher is ‘caught’ in a teaching job. Those who have a background as lab technicians themselves typically stay in touch with old colleagues and friends on these developments. However, those with a background in mathematics or science teaching find it harder to develop a good image of trends at work and their implications for curriculum change.

7. To develop their own statistical expertise

Most teachers we interviewed did not feel expert enough to assist students with the statistics required in their projects. Adding specialist teachers to the team was no option because there was a tendency to keep the number of teachers for each student as small as possible to make supervision easier for everybody. Workplace supervisors differed considerably in terms of statistical expertise and could not always help students either. Finally we were struck by the fact how vocation-specific statistics could be: The type of statistics taught by mathematics teachers was often considered too general to be useful for lab technicians, who thought in terms of method validation, reproducibility and stability, rather than correlation and variation coefficients.

TO CONCLUDE: MEETING SOME OF THE CHALLENGES

In answer to our question what are the challenges of teaching statistics in vocational laboratory education, we identified seven challenges illustrated above. Some challenges are the consequence of competence-based education (1, 3, 7), one of the student population (2), and some of the changing nature of work (5, 6), in particular the technology-mediated nature of statistics in workplace (4). Many of the challenges are related. For example, the technology-mediated nature of using statistics at work not only raises the question of how to prepare students for it, but also contributes to the invisibility of this disciplinary knowledge at work and hence at competence-based education.

One challenge we see, but teachers did not address explicitly, is how they can help their students to develop the number sense required (Bakker et al., 2010). From the interviews with supervisors we assume this requires the integration of disciplinary knowledge typically developed at school and practical knowledge developed through experience at work. For example, whether a measurement value is judged correctly also depends on experience with the range in which that value typically falls. Judgement of correctness presumably draws on multiple resources including

disciplinary and more workplace experiential knowledge. To conclude we mention how some of the challenges are or could be dealt with in practice or in research.

Teacher apprenticeships to stay up to date

One important way in which teachers can stay up to date with recent developments at work is by means of teacher apprenticeships. Teachers, in particular those with a disciplinary background in mathematics or science, get the opportunity to work in a company for a few days to see how what they teach informs apprentices' work. One teacher of statistics we interviewed was very enthusiastic about this opportunity. In his case, he felt reassured that the topics he taught, such as statistical process control, were indeed used in ways that he propagated in his lessons. However, the general picture from the limited research on teacher apprenticeships (de Schutter, 2009) is that organising them and convincing teachers to take part is not easy. Moreover, not every workplace is suitable as a learning site for teachers.

Diversity of labs

The way in which lab schools address the diversity challenge is to start with a general programme for statistics and tie the statistical aspects of lab work to the variants chosen. The biggest school we investigated had six different variants from which students could choose in their last two years. However, small schools did not have the resources to offer more than two variants (e.g., chemical and medical).

Diversity is not always problematic, because students are also diverse. They have different interests and qualities, and look for laboratories in which they can flourish. Likewise, companies select students that seem to fit in their type of labs. Some are good at routine work, other function better in non-routine work.

Workplaces also demonstrate a high degree of adaptivity which is possible due to the diversity of employees and tasks in a lab. If tasks turn out too difficult or important for apprentices or beginning lab technicians, they are carried out by higher-level or more experienced lab technicians. Thus workplace systems are serving as an ecology adapting to particular gaps or weaknesses in apprentices' knowledge. Such adaptivity and division of labour also has another side: We were told about lab technicians with an affinity for statistics who were given the opportunity to develop their statistical knowledge and become the team's statistics expert.

Finding alternative representations

One of the main challenges in our view is how to deal with the discrepancy between how statistical measures and techniques are typically represented at school on the one hand, and how they are used in practice on the other. In course materials standard deviation and the t-test are typically represented in a symbolic language with Σ -signs – a language that is inaccessible to most vocational students. Our impression from observations and previous research (Bakker et al., 2009) is that many teachers and trainers think the essence of, say, a t-test is captured by its

Working Group 5

formula, just like the mean by its calculation, and that they see little opportunity to represent such concepts alternatively, or to emphasize their meaning in usage. However, what intermediate-level employees need to know about such techniques is what their purpose and utility (Ainley et al., 2006) are and how they should be interpreted when produced by a computer system, and some conditions of usage. To us it seems sufficient for student lab technicians who do not plan to attend higher professional education to know that a t-test is useful for comparing means of data sets (e.g., to check if a new instrument is as accurate as the standard), and what it means that there is a significant difference. The little time attributed to teaching the t-test (typically one lesson) is perhaps better spent on such insights, including how to perform a t-test in Excel, than on explaining and applying the formula.

The problem of representation of such statistical concepts and tests was dealt with by Bakker et al. (2009) in the context of process improvement in a car factory. To avoid the symbolic language about process capability indices, they designed relatively simple, visual computer tools with which employees could get a sense of what these indices conveyed, and how their indices could be manipulated by changing mean, control limits or specification limits. These tools proved to facilitate communication between employees with diverse educational background. We therefore expect that it is in principle possible to convey the practical usage and implications of many statistical concepts and techniques in the context of work without anxiety-evoking formulae. We see ample reason to continue this line of research, especially in vocational settings where we can observe the connections between school and work practices and test out ways to engage students in seeing statistics as useful for a clear purpose: work.

ACKNOWLEDGEMENTS

CHILDREN'S EMERGENT INFERENTIAL REASONING ABOUT SAMPLES IN AN INQUIRY-BASED ENVIRONMENT

Dani Ben-Zvi¹, Katie Makar², Arthur Bakker³, & Keren Aridor¹

¹University of Haifa, ²The University of Queensland, ³Utrecht University

Research on informal statistical inference has so far attended little to sampling. This paper analyzes children's reasoning about sampling when making informal statistical inferences in an inquiry-based environment. Using data from a design experiment in Israeli Grade 5 (age 11) classrooms, we focus on the emergent reasoning of two boys working with TinkerPlots on investigations with growing sample size. They turn out to have useful ideas about whether inferences can be made from samples of different sizes. Initially, they oscillate between deterministic and relativistic conclusions, but they come to reason in more sophisticated ways with increasing awareness of what is at stake when making inferences from samples.

INFORMAL STATISTICAL INFERENCE

One of key things that statistics allows us to do is to draw inferences from samples. Doing so with formal techniques such as estimation, confidence intervals or hypothesis testing goes well beyond what most students will have the opportunity to learn, yet it seems important to give them a sense of the power of statistics by making such inferences informally (Garfield & Ben-Zvi, 2008). For these reasons, statistics educators have studied *informal statistical inference*, characterized as a generalized conclusion expressed with uncertainty and evidenced by, yet extending beyond, available data (Makar & Rubin, 2009). Two special issues have already been dedicated to this theme (Makar & Ben-Zvi, in press; Pratt & Ainley, 2008).

In earlier work we addressed the question of how informal inferential reasoning, the reasoning processes leading to informal statistical inference, can be nurtured and supported (Makar, Bakker, & Ben-Zvi, in press). Supporting elements include statistical concepts and tools, knowledge of the problem context, inquiry drivers such as doubt, explanation, and resolution of cognitive conflicts. We proposed that an inquiry-based learning environment with suitable tasks and tools as well as teacher scaffolds is especially suitable to support students' informal inferential reasoning.

SAMPLES AND SAMPLING

The concept of sample is a central concept in statistics yet it has received limited attention in the research literature compared to other concepts such as average, variation, and inference. Concepts and issues surrounding sampling are complex and require coordinating several ideas at once. Researchers note that students and teachers often conflate samples with their population when working with data (Lavigne & Lajoie, 2007; Pfannkuch, 2008; Pratt, Johnston-Wilder, Ainley, & Mason, 2008). Others caution that students may hold extreme beliefs about

Working Group 5

relationships between samples and their population: Those focusing on sampling representativeness might believe that a sample provides complete information about a population, while students focusing on sampling variability might believe that a sample provides no information (Rubin, Bruce, & Tenney, 1990). Watson and Moritz (2000) found that children in their study (Grade 3, age 8-9) had fairly primitive notions of samples and were typically comfortable making claims from small samples with little concern about bias, while the older children (Grade 9, age 14-15) generally attended to both sample size and representativeness in making claims, recognizing potential problems of bias and variability of small samples. Students between these ages (Grade 6, age 11-12) held a diversity of beliefs about sample size and sampling, suggesting they are at a critical age in their development of concepts of sampling.

Recent interest has arisen about the potential of informal statistical inference as an organising principle in learning statistics. Several aspects of informal statistical inference have been addressed in the literature, but the role of sampling has received surprisingly little attention given its centrality in inference. Several researchers (e.g., Arnold & Pfannkuch, 2010; Konold & Kazak, 2008) have used hands-on activities, visualisations, and simulations in helping students coordinate the complex issues of sampling in inferential reasoning. In this paper we focus on the question: *How does children's reasoning about sampling emerge when making informal statistical inferences in an inquiry-based environment?* We use 2010 data from Ben-Zvi's Connections Project (Ben-Zvi, Gil, & Apel, 2005) to respond to this question by examining the work of two boys (aged 11) participating in a teaching experiment as they grapple with drawing inferences from samples of increasing sizes.

GROWING SAMPLES

A key idea behind the design is that of growing samples—an instructional idea mentioned by Konold and Pollatsek (2002), worked out by Bakker (2004) and elaborated by Ben-Zvi (2006). Starting with small data sets (e.g., $n=8$), students are expected to experience the limitations of what they can infer from them about the whole class. They are next asked to draw conclusions from the whole class and speculate on what can be inferred about the whole grade in the school. Bakker (2004) found that such an approach is helpful in supporting coherent reasoning with key statistical concepts such as data, distribution, variability, tendency, and sampling. What-if questions proved particularly stimulating.

METHOD

We address the research question by drawing on findings from a design study (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) carried out in three Grade 5 classrooms in Israel. This study is part of the Connections Project—a longitudinal development

and research project (2005-2010) aiming to develop an inquiry-based environment for learning statistics in grades 4-6 using *TinkerPlots* (Konold & Miller, 2005).

The setting and participants

The learning sequence was built around five cycles of extended data investigations (2-3 lessons of 90 minutes each) of a student-administered survey across several grades in their school. The survey gathered student information about dimensions of body parts, free time activities, pets ownership, etc. (33 variables, $n=270$), creating a rich and interesting database for investigation. In each cycle, students posed a research question, organized their sample data using *TinkerPlots*, and made sense of it to draw informal inferences.

In line with the literature on growing samples, the design of activities evolved around the idea of starting from a sample of size 8, moving to about 30 (a whole class), then 90 (a grade level), and finally 270 cases (entire cohort) (see Figure 2 in Ben-Zvi, 2006). Starting with a small sample size was a pedagogical design decision to draw students' attention to the limitations of small samples, gradually developing their reasoning about samples, confidence level in their inferences, and "what-if" questions about larger sample sizes (e.g., "If you had a sample size of X, would the inference you just made still hold?").

Students worked in pairs through a scaffolded, open-ended inquiry of the data, with some pairs presenting their investigations in front of the class for further discussion. Independent investigations were videotaped using Camtasia to capture both their computer screen and faces. In this paper we focus on one pair of academically successful and articulate boys—Liron and Shay—in their first two investigations.

The episodes

In the first episode—their first independent investigation with *TinkerPlots*—the pair studied issues about free time (e.g., what students do in their free time, preferred communication method). They were given a sample of 8 students from their class (including themselves) with eleven variables to analyze and make inferences beyond the data at hand and a handout with instructions and questions about sampling issues (e.g., "Would the conclusions you have reached apply also to half of the class? Please explain."). In the second episode, the sample was increased to 29 (whole class) and they were asked to see if their conclusions still held for the larger sample.

Data analysis

Videos were observed, transcribed, translated from Hebrew to English and annotated for further analysis of the development of their reasoning about samples in relation to inferences. Interpretations were discussed until consensus was reached. Differences between Hebrew and English connotations of words (inference, conclusion, sample) were discussed extensively. Episodes were selected to illustrate the boys' developing reasoning about samples when making informal inferences.

RESULTS

First investigation, n=8

After orienting to *TinkerPlots*, Shay and Liron organized the small data set with the software. In their first graph, the eight data points spread across six categories of students' free time activities, with most categories having only one point (Figure 1).

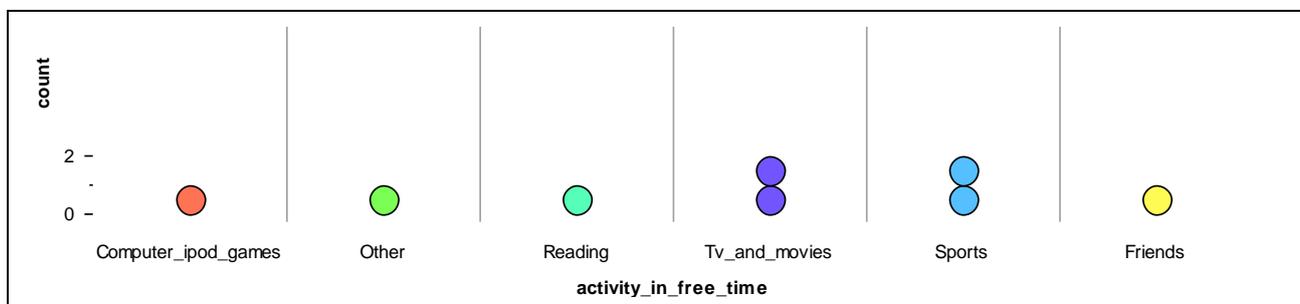

Figure 1: Liron and Shay's initial graph of 8 data points spread across 6 categories

They expressed initial dissatisfaction with working from such a small set of data: “We only have 8 kids, we don't have enough data!... We don't have enough to know things properly!” (Shay, lines 9-12) and found it frustrating to draw conclusions. With only eight data points, they considered them not to be “real data”:

- 25 Shay: So let's see. Still, we don't have enough data that we can see because we have only 8 kids and it kind of spreads out. So we'll try to see something else, and then we will see if we have enough real data.
- 26 Liron: Pets is very easy. Let's check this first [scanning the pets data].
- 27 Shay: Well OK, we see it's [also] too spread out, and since we have only 8 kids, we don't have much to see. So let's try to see, err, what shall we try to see, Liron?

In looking for other variables to investigate, the boys seemed to search for an apparent pattern. With most variables having low frequencies in each category (due to the small sample), they characterized the data as too “spread out” to draw conclusions. This implies that their reluctance to draw conclusions involved both sample size and its relation to frequencies (in this case, large spread and a “flat distribution”, cf. Ben-Zvi et al., 2005) and suggests a need to acknowledge students' statistical conceptions more broadly (e.g., variability and distribution) when focusing on sampling. When exploring the number of after-school activities per week (Figure 2), the boys finally felt able to draw a conclusion from numerical data. These data were not spread out like in the variable *activity in free time*:

- 39 Liron: 3 is the biggest. It is the most common.
- 40 Shay: According to what we see, the ‘most mode one’ is 3. What we see is that it can also be said that the average here is 3. The average is 3.
- 45 Shay: ... Ok, wait, we have found something very interesting – we have the average number of children [activities] in a week is three. Let's save it.

Working Group 5

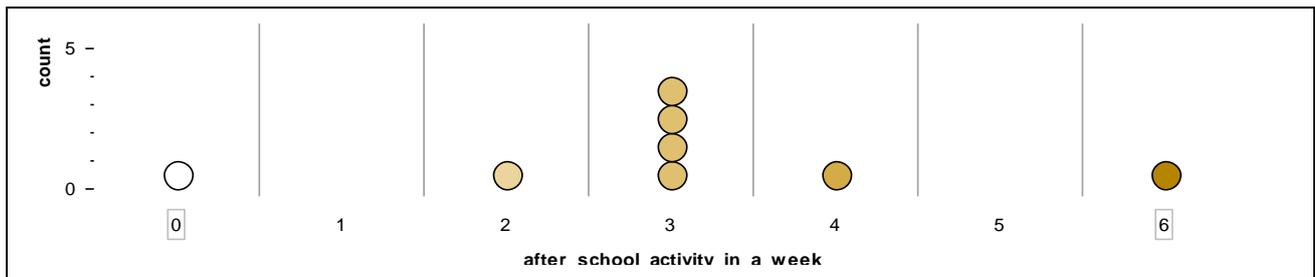

Figure 2: Liron and Shay's distribution with higher frequency in one value

As they searched for interesting and sensible stories in their data, they reviewed several additional variables (e.g., methods of communication with friends). However, after having done these analyses, Shay dismissed them almost immediately:

- 56 Shay: So usually you use the telephone at home, some use the cell phone and chats on the internet. [But] as we said before, we don't have enough kids in order to have something, a proper result as needed.

Shay realized again that the small sample size was a flaw in the validity of the inference. The conflict of making valid conclusions from a small sample arose several times during the investigation. At other times, they set the issue aside and made fairly strong claims (e.g., "Boys like computers more than girls."). This oscillation between stating there is nothing to say and stating claims deterministically continued throughout this first investigation. We should cautiously note, however, that it is not clear whether Shay had changed his mind or went through the analysis with the impression that the results would be improper results. To overcome this concern, Liron proposed to collect more data.

One aim of the growing samples activities is to develop, as well as gain insight into, students' inferential reasoning about the relationship between conclusions drawn with a small sample and their inferences to larger samples (e.g., limitations of small samples, confidence about their inferences). When asked whether their claims applied more generally to the class, their initial response was quite confident that they would be. When pressed, however, their responses were qualified. "According to *these data for now*, only based on these, boys like computers more than girls and girls like to spend time with their friends more than boys" (line 198). Shortly thereafter, their responses changed again:

- 207 Int.: And what if I ask you about the whole class? What do you think your inferences look like?
- 208 Shay: It could be completely different!
- 210 Int.: ... What do you mean by "completely different"? Could it be, say, that girls like computers more than boys?
- 211 Shay: It will not be *that* different.
- 213 Int.: ... Won't it surprise you? If you see for example that the girls in the whole class, there will be more girls that like computers than boys?
- 214 Shay: Yes, it will surprise me, but there is a chance it will happen.

Working Group 5

- 215 Int.: Why will it surprise you?
- 216 Shay: Because I know from personal experience that boys like computers more than girls, but there is a chance that my personal experience is wrong! There is a chance.

Although Shay thought the results in the entire class might be completely different than the sample results, his answer in line 211 is more nuanced. This remark may suggest that Shay anticipates that the results in the sample compared to the entire class could be similar and he sees a small chance that the results will be completely opposite. This is the first time the role of chance is mentioned in the discussion, not in explicit relation to the sample size but rather to the boy's personal knowledge of the context. In the end of this discussion, the interviewer explored the limits of what the boys were willing to conclude from different sample sizes:

- 243 Int: Can you say based on the conclusion from these data that they are true for a larger group of kids?
- 244 Liron: No. Every child has a different opinion.
- 245 Int: Shay, what do you think?
- 246 Shay: I agree. Each child has their own characteristics.
- 247 Int: How many kids in your class?
- 248 Liron: 29.
- 249 Int.: What if we ask 15 kids? Do you think then we could conclude something?
- 250 Liron: Yes.

We saw this same reasoning about the ability to infer from half of the population in discussions among other students as well. Even at the end of this activity, the boys still oscillated between not being able to say anything ("Every child has a different opinion") and being able to infer something regarding bigger samples. Their confidence in drawing conclusions oscillated during their investigation. They repeatedly asked for more data, offering even to go to the class and collect it themselves; at the same time, they often made claims based on a frequency of one (e.g., girls like to talk to friends more than boys). When probed, they were able to qualify the claims, but were uncertain whether their claims would hold more broadly.

Second investigation, n=29

In the second investigation, students were given data for their entire class (29 students) as well as five additional variables (e.g., various body measurements, additional pet ownership data). Shay and Liron's immediate reaction was one of excitement "Wow! ... It's so much fun now!" (Lines 255-257). Before investigating the data, Liron anticipated that the conclusions would be different from those they made for the sample of eight. This suggests one way that the growing samples sequence stimulated students to think about sample-population relationships:

Working Group 5

- 258 Int.: Do you think they will be similar or different for the entire class and why?
- 259 Liron: Different.
- 260 Shay: Not just different. We should say in what [way] they will be different.
- 261 Liron: Eight kids can't represent an entire class!

When the boys were given the data for the entire class, they compared their new findings (sample size 29) with those from the previous investigation (sample size 8).

- 265 Shay: I knew! Girls love to be with friends more than boys. Boys like computers more than girls. Here, here, my hypotheses are materializing!
- 266 Liron: Because?
- 267 Shay: Look, it's really beautiful. We really have conclusions!

Although the boys easily recognized the similarities, they didn't understand why.

- 289 Liron: Most of our hypotheses were confirmed. ...
- 292 Shay: ... But I don't understand. It is the same data. It is unfair. I don't get it.
- 293 Liron: Neither do I, but what do you know?
- 294 Shay: I was sure it would be entirely different data.
- 295 Liron: So was I, but here it is. You can see it.

The boys expressed surprise by the unexpected similarity then questioned its validity. Their language became more subtle, focusing on the uncertainty.

- 307 Shay: But you know it happened by chance.
- 308 Liron: It happened by chance. They didn't do it on purpose.

And later:

- 316 Shay: This quite surprised me, and I thought that if I take more kids, it will change, but who knows, apparently it is the same thing.
- 317 Liron: It must have been a coincidence.
- 318 Shay: Maybe, not for sure.

When asked for an explanation, Liron said he had no idea and Shay repeated that it happened by chance. Later, following the design idea of growing samples, they were asked again whether they expected the result to be similar for the entire 5th grade.

- 423 Shay: Now I think that if you take like, what happen is that it was [first only] 8. Now we took the entire class, it was exactly the same properties. So I think now that if you take the entire 5th grade, it will also be the same conclusions.
- 424 Int.: Why? Try to explain once more why? You just said something and I am not sure I got you.
- 425 Shay: Because from the conclusions here, we saw that once we expanded it, there were the same conclusions. Now what do I infer from this?

Working Group 5

426 Int.: What?

427 Shay: That it is really true. That it will keep being true, also.

When probed, the boys informally quantified their level of confidence about the conclusions, both now and from the original sample of eight, but cautioned that the results would not necessarily extend to other ages in the school.

441 Int.: In the same age, if we take a scale from 1 to 10, ... how much are you certain from 1 to 10 that the results will remain the same?

442 Shay: 7.

443 Liron: I am also 7. ...

447 Int.: How sure were you from [the sample of] 8 about the entire class? ...

448 Shay: About 2. Maybe 3.

DISCUSSION

The brief excerpts from Liron and Shay's investigations give us some insight into initial ways that children can reason about samples in an inquiry classroom designed to provoke their informal statistical inferences. The analysis of Liron and Shay's inferential reasoning about sampling issues shows a development from fairly extreme and seemingly contradictory views of what can be concluded from a small sample to more nuanced statements about the strength of their later claims and emerging quantification of confidence in making inferences. In the first investigation, the boys repeatedly expressed their lack of confidence in conclusions drawn from only eight data points while concurrently making fairly strong claims (e.g., boys like computers more than girls do) based on frequencies of only one or two data points. As they progressed, they qualified their claims as only holding for their limited data and were rightly conflicted about whether the sample would provide any information about a larger population. In the second investigation, the larger data set confirmed many of their previous conclusions, which surprised them. This confluence appeared to provoke them to question the way the data were gathered.

In addition to working with concepts of samples and informal statistical inference, strong links to other statistical key concepts arose during the investigation, such as average (average of 3 activities per week), spread and distribution, likelihood, randomness, and graph interpretation. The excerpts further underline Bakker and Derry's (in press) discussion of the importance of a holistic approach to concept development as these concepts were not encountered in isolation, but emerged collectively as relevant tools by provoking their reasoning in the context of inquiry. The opportunity to probe the students' reasoning was helpful to explore the scope, flexibility and robustness of students' concepts in action. This aligns with inferentialist approaches to have students reason within the context of complex problems and through that process find the scope and limit of their conceptions in the act of reasoning with them.

Working Group 5

We end with a few questions for future research:

1. How can ideas about sampling in relation to informal statistical inference be further developed in the next grade?
2. What was the role of the activities design and the inquiry-based environment in the development of students' reasoning about samples and sampling? And in particular how can the instructional idea of growing samples can be further improved and used?
3. How can new tools (e.g., *TinkerPlots2*, see Konold et al., in press) probe students' inferential reasoning?

ACKNOWLEDGEMENTS

We gratefully acknowledge Hana Manor who interviewed the two boys, and Einat Gil who supervised the activities design. The Freudenthal Institute funded part of Dani Ben-Zvi and Katie Makar's visit to Utrecht where the videos were analyzed.

INVESTIGATING RELATIVE LIKELIHOOD COMPARISONS OF MULTINOMIAL, CONTEXTUAL SEQUENCES

Egan J Chernoff

University of Saskatchewan

By focusing on a particular alteration of the relative likelihood task, this study contributes to research on teachers' knowledge of probability. The novel task presented prospective teachers with multinomial, contextualized sequences (possible answer keys to a 10 question multiple-choice quiz) and asked them to identify which sequence was least likely. Results demonstrate that the sample to population ratio and reflection of randomness determinants of representativeness (featured in research on binomial, platonic sequences) are present in the current situation as well. Results further suggest that the context in which tasks are presented significantly influences probability judgments. Consideration of context also provides a news lens and, concurrently, potential obstacles for analysing certain results.

In the first *Handbook of Research on Mathematics Teaching and Learning*, Shaughnessy's seminal (1992) review of "research in learning and teaching stochastics" (p. 466) concluded with "a wish list" (p. 488) for future research. Included in the list, a call for investigation into teachers' conceptions of probability. Fifteen years later, in the *Second Handbook of Research on Mathematics Teaching and Learning*, Jones, Langrall, and Mooney (2007), who were given the "main task of reviewing and analyzing research in probability education during the period since Shaughnessy's (1992) review" (p. 910), included "Stohl's (2005) review[, which] concluded that there had been limited response to Shaughnessy's call for research on teachers' knowledge and beliefs about probability" (p. 945), in their research synthesis.

Given the dearth of research documented above, the purpose of this article, in general, is to contribute to research investigating teachers' conceptions of probability. In specific, the purpose of this article is to present results demonstrating that Kahneman & Tversky's (1972) representativeness determinants (described in detail below) extend to multinomial sequences (i.e., sequences derived from a multinomial experiment) and contextual sequences. In order to examine the relationship between representativeness and multinomial and contextualized sequences, prospective mathematics teachers are asked to compare the relative likelihood of two answer keys for a 10 question multiple choice (i.e., A, B, C, or D) math quiz.

THEORETICAL CONSIDERATIONS

Kahneman and Tversky (1972), in examining how "people replace the laws of chance by heuristics" (p. 430), produced an initial investigation into what they called

the representativeness heuristic. According to their findings, an individual who follows the representativeness heuristic “evaluates the probability of an uncertain event, or a sample, by the degree to which it is: (i) similar in essential properties to its parent population; and (ii) reflects the salient features of the process by which it is generated” (p. 431). Kahneman and Tversky theorized that events are considered more probable when appearing more representative and, similarly, events are considered less probable when appearing less representative. In order to test their theory, the authors focused on some now well-known probability comparisons.

Kahneman and Tversky (1972) presented individuals with birth sequences that were considered equally likely, but were hypothesized by the authors to not be “equally representative” (p. 432). Of the three sequences presented (GBGBBG, BGBBBB and BBBGGG), the sequence BGBBBB was considered less likely than GBGBBG because BGBBBB does not reflect the ratio of boys to girls found in the parent population. Further, BBBGGG was deemed less likely than GBGBBG because BBBGGG did not reflect the random nature associated with the birthing of boys and girls in a family. While the findings supported the authors’ initial hypotheses (more representative sequences would be judged more likely) they also declared that similarity of a sample to the parent population is a necessary, but not sufficient, determinant of representativeness. As such, they further investigated the reflection of randomness determinant.

In an investigation into the appearance of randomness, Kahneman and Tversky (1972) declared that “two general properties, irregularity and local representativeness, seem to capture the intuitive notion of randomness” (p. 433). To explicate their point, the authors showed how alternating sequences, e.g., a perfect alteration of heads and tails, was too regular and thus would not correspond to the result of a random process. Local representativeness, on the other hand, is the belief that “the essential characteristics of the parent population are represented not only globally in the entire sample, but also locally in each of its parts” (p. 434). For example, individuals, when examining a short sequence of coin tosses, would expect (1) the ratio of heads to tails to be close to one, and (2) short runs, which would correspond to frequent alterations, because, as the authors indicated, “People view chance as unpredictable but essentially fair” (p. 434).

TASK DESIGN AND RATIONALE

Although not the first individuals to conduct an experiment comparing the relative likelihood of sequences of outcomes, researchers of, and literature in, probability education consider – by acclamation – the early seventies research of Tversky and Kahneman (e.g., Kahneman & Tversky, 1972; Tversky & Kahneman, 1974) as *the* canonical research into comparing the relative likelihood of sequences of outcomes.

Task developments

Kahneman and Tversky's (1972) investigation into the relative likelihood of sequences of outcomes (detailed above) was, actually, two tasks: A task was first presented that would address the sample to population ratio determinant of representativeness (i.e., are there more families with a birth order sequence of BGBBBB or GBGBBG?) and, second, a related task was presented to address the reflection of randomness determinant (i.e., are there more families with a birth order sequence of GBGBBG or BBBGGG?). These two tasks would undergo a number of changes, as they became a fixture in the field of mathematics education.

Shaughnessy's (1977) research introduced two new, important developments to the tasks. First, in comparing the chances of occurrence of different sequences, his version of the task gave students the option of choosing "(c) about the same chance" (p. 309) as one of the response items. Second, Shaughnessy asked participants to "give a reason for your answer" (p. 309). Despite these two new developments, one thing remained the same: the task remained as two tasks.

Konold, Pollatsek, Well, Lohmeier, and Lipson's (1993) version(s) of the relative likelihood task unified, for the first time, into one task, both the sample to population ratio determinant and the reflection of randomness determinant.

Which of the following is the most likely result of five flips of a fair coin?
 a) HHHTT b) THHTH c) THTTT d) HTHTH e) All four sequences are equally likely

Figure 1. Konold et al.'s (1993, p. 395) iteration of the relative likelihood task

As seen in Figure 1 above, three of the options presented have a ratio of 3 heads to 2 tails, while option c) has a ratio of 4 heads to 1 tail, which is consistent with earlier tasks investigating sample to population determinants. The options containing 3 heads and 2 tails present a variety of symmetrical, switch, and run considerations, which is also consistent with earlier tasks examining the reflection of randomness determinant. Further, Konold et al.'s (1993) iteration of the task adopts Shaughnessy's (1977) developments, which not only provides the equally likely option, but also "also asked subjects to provide a written justification for their answer" (p. 396). Despite Chernoff's (2009) alteration, which maintains the same ratio of heads to tails in all sequences, all other versions of the relative likelihood task found in mathematics education (e.g., Hirsch & O'Donnell, 2001; Rubel, 2007) adopt a similar framework to Konold et al.'s (1993) version of the task.

Task consistencies

Despite developments and new versions of the task, two things have remained the same. First, the use of sequences of outcomes derived from a binomial experiment (hereafter referred to as binomial sequences) and, second, the use of what I will define below as, *platonic sequences*).

Working Group 5

The majority of research on the relative likelihood of sequences of outcomes (e.g., Chernoff, 2009; Cox & Mouw, 1992; Hirsch & O'Donnell, 2001; Kahneman & Tversky, 1972; Konold et al., 1993; Rubel, 2007; Shaughnessy, 1977, 1981), thus far, utilizes, exclusively, binomial sequences. Although certain research does investigate sequences where the probability of success does not equal failure (e.g., Konold et al., 1993), multinomial experiments, such as the rolling a six-sided die, are reduced to binomial experiments, by, for example, painting the sides of the die two colors.

To help frame this discussion, I will distinguish between two types of sequences, which I have denoted as *platonic* and *contextualized*. *Platonic sequences*, which currently dominate research literature, are characterized by their *idealism*. For example, a sequence of coin flips derived from an ideal experiment (where an infinitely thin coin, which has the same probability of success as failure, is tossed repeatedly in perfect, independent, identical trials) would represent a platonic sequence. On the other hand, *contextualized sequences*, which are less represented in the current research literature, are characterized by their *pragmatism*. For example: the sequence derived from the severed left and right feet, which were washing up on the shores of British Columbia, Canada in late 2007 and early 2008 (e.g., LLLLLR); the sequence of six numbers obtained when buying a (North American) lottery ticket (e.g., 4, 8, 15, 16, 23, 42); the answer key to a true or false quiz (e.g., TFTTF); the answer key to a multiple choice mathematics quiz or test (e.g., ACCBDCAADB); and others, would represent contextualized sequences.

As I claim above, platonic sequences currently dominate the research literature; however, this *platonicity*, which Taleb (2007) defines as the “tendency to mistake the map for the territory” (p. xxv), of the sequences, which are devoid of context, occurred over time. For example, in the ‘beginning’, Tversky and Kahneman (1972) incorporated a frequentist or experimental perspective with their sequence of six children, when declaring, in their task, that “72 families” (p. 34) were surveyed. As the task migrated from psychology to mathematic education, platonicity began to occur. Shaughnessy’s (1977) research witnesses the first explicit move towards ideal sequences. In his version of the task, Shaughnessy declares, up front, that “the probability of having a baby boy is about $1/2$ ” (p. 309) and, in the second half of his task states, “(same assumptions as [task 1])” (p. 309). However, the assumptions explicitly stated in Shaughnessy’s version became implicit in subsequent versions of the task. By the beginning of the 1990’s the platonification of the experiment and the sequences, in essence the entire task, was complete. For example, the research of Chernoff (2009), Cox & Mouw (1992), Hirsch & O’Donnell (2001), Konold et al. (1993), and Rubel (2007) all utilize the following phrase: *A fair coin is tossed x times*; which, in these cases, is intended to mean (from a rationalist perspective) that an infinitely thin coin, which has the same probability of success as failure, is tossed repeatedly in perfect, independent, identical trials to produce the sequences of coin

flips. In other words, the map is mistaken for the territory. Despite the platonification of the task, pragmatic responses are a mainstay in individuals' responses and are part of the motivation for the new version of the task.

THE ANSWER KEY TASK

Given the domination of binomial and platonic sequences found in the literature, the new task contributes to existing research by utilizing multinomial, contextualized sequences. The new version of a probability comparison task, as seen in Figure 1, asked individuals to compare the relative likelihood of two different answer keys to a 10 question multiple choice quiz and to explain or justify their answer.

Which of the following, answer key 1 or answer key 2, is *least likely* to be the answer key for a 10 question multiple choice math quiz? Explain your answer
Answer key 1: A C C B D C A A D B **Answer key 2:** C C C B B B B B B B

Figure 1. Answer key version of the comparative likelihood task

PARTICIPANTS AND RESULTS

Data for this study was gathered by asking participants, 59 prospective teachers, to respond, in writing (with no time limitations), to the task presented in Figure 1. Results show that the majority (48 / 59) of the participants in the study (81%) chose answer key 2 (hereafter referred to as AK2 and, similarly, answer key 1 as AK1) as least likely to be the answer key for a 10 question multiple-choice quiz. More specifically, 23 participants (74%) in Class A and 25 participants (89%) in Class B chose AK2 to be least likely. Given similar themes in the identified response justifications, the impending analysis of results does not distinguish between the two classes.

ANALYSIS OF RESULTS

In this section, exemplary response justifications from the 48 individuals who chose AK2 as least likely to be the answer key for a 10 question multiple choice quiz are analyzed. Responses justifications are organized into two main sections: (1) multinomial considerations and (2) contextual considerations.

Multinomial considerations

As noted, Kahneman and Tversky (1972) declared two determinants of representativeness as sample to parent population and reflection of randomness. As such, the analysis of responses for determinants of representativeness extending to multinomial sequences is similarly broken into (1) sample to parent population and (2) reflection of randomness sections.

Working Group 5

Sample to population. The response justifications for 9 particular individuals demonstrate that representativeness – more specifically “the features that determine the similarity of a sample to its parent population” (Kahneman & Tversky, 1972, p. 33) – extend from binomial to multinomial sequences of outcomes. While all 9 individuals declared the proportion of multiple choice answers presented in AK2 (i.e., 3 C’s and 7 B’s) does not reflect the proportion of multiple choice answers for the population, different individuals presented the notion in different ways, as seen in the responses of Adam and Ben.

Adam: AK2 because there is too little variety of answers.

Ben: AK2 is least likely because it has only C’s and B’s!

While implicitly stated in certain responses, Frank is explicit in his use of percentages and expected frequencies when declaring that the sample population should have an equal distribution of available answers.

Frank: There are 4 possible letters, so each should show up around 25% of the time. This is true of AK1 (A:30% B:20% C:30% D:20%). So AK2 (C:30% B:70%) is least likely.

Ike’s response epitomizes the similarity of sample to population determinant of representativeness extended to multinomial sequences.

Ike: AK2 upon first impression because it doesn’t appear to be random, since each question has 1 in 4 chances of either being A, B, C, or D. The likelihood/probability of that occurring is low.

For Ike, AK2 is less likely than AK1 because AK2, by not having an even distribution of answers A, B, C, and D, “doesn’t appear random.” In other words, AK2, with only B’s and C’s, is not representative of the sample to parent population and is influencing Ike’s (and Adam, Ben, and Frank’s) appearance of randomness, which, in turn, is influencing his probabilistic judgment, because, according to Kahneman and Tversky’s (1972) (confirmed) hypothesis, less representative sequences are deemed less likely.

Reflection of randomness. As with the sample to parent population determinant, it will be shown that the reflection of randomness determinant, more specifically local representativeness, extends from binomial to multinomial sequences of outcomes. Kahneman and Tversky’s (1972) notion of local representativeness (which states “a representative sample is one in which the essential characteristics of the parent population are represented globally in the entire sample, but also locally in each of its parts” (p. 36)) influences the relative likelihood of the answer keys for two participants, whose answers are featured in the responses below.

Jen: AK2 [...] because the probability of sequential answers being identical is low.

Working Group 5

Kate: AK2 is the least likely because there would not be so many “B” answers in a row.

For Jen, the chances of “sequential answers being identical” (i.e., 3 C’s and then 7 B’s) is not representative for part of the answer key and, thus, not likely to be the answer key. Similarly for Kate, “the so many ‘B’ answers in a row” is not locally representative and, thus, she concludes AK2 is least likely to be the answer key. Although stated differently by Jen and Kate, for both, the long run of 7 B’s found in the latter section of AK2 is not locally representative. That is, the essential characteristics of the parent population are not found in the BBBB BBB section of the answer key. As such, the entire sequence, which, for them, does not appear random, is not representative of a 10 question multiple-choice answer key. Given the answer key is not (locally) representative, AK2 is considered less likely to be the answer key.

Contextual considerations

According to Kahneman and Tversky (1972), “As is true of the similarity of sample to population, the specific features that determine apparent randomness *differ depending on context*” (p. 35, my italics). Taking into account certain contextual considerations associated with the answer key task, however, demonstrates that an innate answer key structure (not only the determinants of representativeness) can account for probability comparison responses. To get a sense of the innate structure of answer keys, a variety of perspectives – including: answer key, personal experience, teacher, student, and combined or multiple perspectives – will be presented with the main goal of presenting the subject under investigation, that is, innate answer key structure, in a greater context.

Answer key perspective. The responses from six individuals took the answer key into consideration in their response justifications and, in doing so, they provided insight into the properties associated with an innate structure of answer keys. For example Mary (like Jen and Kate above) references the length of runs for answers C and B, which are found in AK2. However (unlike Jen and Kate), the respondent qualifies that long runs are not a feature found with answer keys.

Mary: answer keys usually do not have a constant answer for consecutive questions in a row. They are usually mixed up upon each other and will occasionally be in a row.

Similarly, the justification of Quinn, like that of Adam and others above, makes reference to the lack of variety of answers found in AK2. However, unlike Adam and others above, Quinn also qualifies that the lack of variety is not a feature found in answer keys.

Quinn: #2 because it seems there’s only two possible answers for this quiz – not multiple choice.

Working Group 5

For all six respondents, the long run of B's and the lack of variety amongst the available answers found in AK2 are reasons why AK2 is deemed less likely. However, the features they mention are inherent, for these individuals, to an innate structure associated with the answer key and answer keys in general.

Personal experience. Instead of qualifying responses with references to the structure of answer keys, six individuals made reference certain properties associated with their personal experiences with answer keys. For example, the reference to a lack of variety of answers, seen below in the response Tara, and the reference to the long run of the one answer, see below in the response of Uma, exemplify responses seen from other individuals who also referred to their personal experience with answer keys.

Tara: From my experience with multiple-choice exams, the answers never line up one after the other, like in AK2. The multiple choice exams I studied for such as math, have always looked more like AK1, where there is a variety of answers such as ACCBD instead of CCCBBB.

Uma: there are too many answers that are the same ex)ccbb. This (as a student) always made me confused. If the answers are all in a line like that, it makes the student feel like they did something wrong.

However, for Tara and Uma, as was the case with those individuals who referenced answer key perspective, the features they describe, i.e., long runs and a lack of variety are inherent, for these individuals, to their personal experiences with answer keys and answer key structure.

Teacher perspective. Certain individuals, three in total, projected themselves into a teacher's perspective for their response justifications. Wendy's response provides insight into how she perceives teachers' use of and experience with answer keys.

Wendy: Normally teachers or instructors who set up answer keys tend to highlight a number of letters and use variation. A teacher would very rarely chose B to represent an answer 7 times in a row, as they usually seem to make random answer keys according to correct letters.

In her response, Wendy references both a lack of variation (i.e., sample to parent population) and the answer B appearing 7 times in a row (i.e., local representativeness) as reasons for AK2 being least likely. She notes that there would not be a of consecutive answers because this is not something that instructors who set up answer keys would do because teachers would make more "random" answer keys. Seen again, the respondent references a lack of variety and a long run of one answer as features in AK2; however, the justifications for these individuals are based on how they inherently perceive a teacher would set up the answer key.

Student perspective. A focus on the presence of a pattern was apparent in the responses justifications of 6 individuals who projected themselves into a student's perspective. Similar to previous perspectives analyzed, their responses provide

Working Group 5

insight into how they perceive students' use of and experience with patterns and answer keys. For example, and as seen in the response justification below, the presence of a pattern for AK2 and the absence of a pattern for AK1 led to the declaration that AK2 is less likely than AK1.

Doug: I think AK2 is least likely to be the answer key because there is only 2 lines going straight down. AK1 has a zig-zag and it just seems better to have the answers all over rather than a boring pattern. Everyone knows the answers don't follow a pattern, if they did, everyone would get the answers right.

Doug's response deviates from previous perspectives because it does not, at least explicitly, reference the small variety of available answers presented and the long run of B's. Instead, the respondent qualifies that patterns are a feature not inherent to multiple-choice exams because students will be able to pick up any pattern that exists. Therefore, multiple choice quizzes containing a pattern are less likely than quizzes containing a pattern, because of students' acute ability to pick up on the pattern and, thus, the integrity of the test is compromised. However, Doug's response does not deviate from previous perspectives because it, too, is based on how the respondent inherently perceives a student would interact with an answer key.

Multiple Perspectives. The response justifications from 13 individuals, who also chose AK2 as least likely, combined many of the perspectives detailed above. For example, the following response combines all previously detailed perspectives.

Mike: AK2 is least likely. Answer keys go something like a rhyming scheme: ABBACC etc. A "teacher" would never give so many consecutive correct answers under the same letter. It would both corrupt the integrity of the test and play mind games with the student.

Mike's response, like those of the other 12 individuals, references the long string of one answer in a row and, further, with his notion of a "rhyming scheme," references a pattern or lack thereof inherent to answer keys. However, Mike justifies his stance according to interplay of: personal experience, the teacher's perspective, student perspective, and the answer key. His response exemplifies an answer-key ethos and, for Mike, is the basis for why he considers AK2 as least likely to be the answer key.

DISCUSSION AND CONCLUSION

Theoretically speaking, the answer keys presented to participants are equally likely to occur. In fact, each of the 1 048 576 possible answer keys are equally likely to occur. Despite this fact, the majority, over 80%, of participants in this study indicated that AK2 was least likely to be the answer key for a 10 question multiple-choice exam.

On the one hand, for individuals who referenced the multinomial nature of the sequences they were presented, the little variety of answers (i.e., no use of A and D) and the long run of answer B justified their responses of AK2 being least likely. As

such, it appears that certain representativeness determinants (specifically and respectively: sample to parent population and the local representativeness component of reflection of randomness) extend to multinomial sequences.

On the other hand, for individuals who referenced the contextual aspects of the sequences they were presented, the little variety of answers, the long run of B responses, and the presence of a pattern in AK2 and lack of a pattern in AK1 were all used as justifications for why AK2 was deemed less likely. As such, it *may* also be argued that the representativeness determinants (i.e., sample to parent population and both components – local representativeness and irregularity – of perceived randomness) extend to contextual sequences. However, the innate structure of answer keys, also revealed in the analysis of results, provides a new way to account for these response justifications and, simultaneously, provides a potential obstacle for research(ers).

According to the representativeness heuristic, people expect sequences of outcomes to accurately reflect the parent population, to have frequent switches and short runs and irregularity. However, as shown in the analysis of results, specifically for answer keys, people already expect a variety of answers coupled with frequent switches and short runs and irregularity, as they feel these features are inherent to answer keys. As such, it becomes difficult to declare whether, for certain contextual sequences, like in the answer key task, participants are employing representativeness determinants or, in this instance, the representativeness lens is rendered moot due to contextual considerations. To better understand whether the representativeness heuristic influences innate answer key structure or whether answer key structure influences the representativeness heuristic, further research in this area will need to be conducted.

PROSPECTIVE TEACHERS' COMMON AND SPECIALIZED KNOWLEDGE IN A PROBABILITY TASK

J. Miguel Contreras¹, Carmen Batanero¹, Carmen Díaz², and José A. Fernandes³

¹University of Granada, Spain; ²University of Huelva, Spain,

³University of Minho, Portugal

The aim of this research was to assess the common and specialized knowledge of elementary probability in a sample of 183 prospective primary school teachers in Spain, using an open-ended task. Common knowledge of probability was assessed in the first part of the task, where teachers had to compute simple, compound and conditional probability from data presented in a two-way table. The specialized knowledge of probability was assessed in the second part of the task, where teachers were asked to identify and classify the mathematical content in the problem proposed. Results suggest participants' poor common and specialized knowledge of elementary probability in this task and point to the need of reinforcing the preparation of prospective teachers to teach probability.

INTRODUCTION

The reasons for including probability in schools have been repeatedly highlighted over the past years (e.g., Gal, 2005; Jones, 2005): usefulness of probability for daily life, its instrumental role in other disciplines, the need for a basic stochastic knowledge in many professions, and the important role of probability reasoning in decision making. Consequently, probability has recently been included in the primary school curriculum in many countries, where changes do not just concern the age of learning or the amount of material, but also the approach to teaching (Franklin et al., 2005). The success of these curricula will depend on the extent to which we can convince teachers that probability is an important topic for their students, as well as on the correct preparation of these teachers. Unfortunately, several authors (e.g., Franklin & Mewborn, 2006; Chick & Pierce, 2008) agree that many of the current programmes still do not train teachers adequately for their task to teach statistics and probability. The above reasons suggest to us the need to reinforce the specific and didactic preparation of primary school statistics teachers, and also the relevance of assessing the teachers' difficulties and errors in learning the topic.

Components in Teachers' Knowledge

An increasing number of authors have analysed the nature of knowledge needed by teachers to achieve truly effective teaching outcomes. Shulman (1987) described "pedagogical content knowledge" (PCK) as "that special amalgam of content and pedagogy that is uniquely the province of teachers, their own special form of professional understanding" (p. 6). Ball and her colleagues (Ball, Lubienski, & Mewborn, 2001; Hill, Ball, & Schilling, 2008) developed the notion of

“mathematical knowledge for teaching” (MKT) in which they distinguished six main categories (see Ball et al., 2001 for a comprehensive description). Our research was intended to assess two of these components in prospective primary school teachers in relation to elementary probability. More specifically we were interested in the following components of teachers’ knowledge:

- *Common content knowledge* (CCK) or the mathematical knowledge teachers are responsible for developing in their students; that is, the mathematical knowledge that is typically known by competent adults (Hill et al., 2004). In this research we assess common knowledge of elementary probability with a task where teachers are asked to compute single, compound and conditional probability from a two-way table.
- *Specialized content knowledge* (SCK). In addition to common knowledge, teachers need to know the content they teach in ways that differ from what is typically taught and learned in mathematics courses. SCK is the mathematical knowledge that is used in teaching, but not directly taught to students (Hill et al., 2004). We include here the ability to recognise what probabilistic concepts or properties can be addressed in the teaching tasks and resources (that was considered by Chick & Pierce, 2008 as a part of PCK). To assess this knowledge, in this research participants are asked to identify and classify the mathematical content they used to solve the first part of the task.

Below we first summarise related previous research and then describe the method and results in this study.

PREVIOUS RESEARCH

Two-Way Tables and Conditional Probability

A two-way or contingency table serves to present in a summarised way the frequency distribution in a population or sample that was classified according to two statistical variables (an example is included in the task presented in Figure 1). Research on contingency tables, started with the pioneer study by Inhelder and Piaget (1955), and focused on students’ strategies and conceptions when assessing association between the variables in rows and columns from the data presented in a two-way table (e.g., Batanero, Estepa, Godino, & Green, 1996). More recently research has focussed on students’ performance when computing probabilities with data presented in a two-way tables (see Huerta, 2009, for an analysis of the structure of these problems).

Also relevant for this study is research related to conditional probability, such as that by Falk’s (1986) who remarked that many students do not adequately discriminate between the two different conditional probability, that is, $P(A/B)$ and $P(B/A)$. Falk termed this confusion as *fallacy of transposed conditional*. Einhorn and Hogarth (1986) observed that some students confused joint and conditional probability because they misinterpreted the conjunction “and”.

Teachers' Probabilistic Knowledge

The scarce research related to primary school teachers' understanding of probability indicates this understanding is weak. For example, Begg and Edward (1999) found that only about two-thirds of the in-service and pre-service primary school teachers in their sample understood equally likely events and very few understood the concept of independence. Batanero, Cañizares, and Godino's (2005) found three widespread probabilistic misconceptions in a sample of 132 pre-service teachers related to representativeness (Tversky & Kahneman, 1982), equiprobability (Lecoutre, 1992) and the outcome approach (Konold, 1991). Fernandes and Barros (2005) study with 37 pre-service teachers in Portugal suggested the teachers' difficulties to formulate events and to understand compound and certain events. In addition, these teachers frequently used additive reasoning to compare probabilities.

In relation to knowledge needed to teach probability, Stohl (2005) suggested that few teachers have prior experience with conducting probability experiments or simulations and many of them may have difficulty implementing an experimental approach to teaching probability. In Lee and Hollebrands's (2008) research, although the participant teachers engaged students in investigations based on probability experiments, their approaches to using empirical estimates of probability did not foster a frequentist conception of probability. Teachers almost exclusively chose small samples sizes and rarely pooled class data or used representations supportive of examining distributions and variability across collections of samples so they failed to address the heart of the issue.

Estrada and Díaz (2006) asked 65 prospective primary school teachers, who had followed a 60 hours long course in statistics education at the University of Lleida, in Spain, to compute simple, compound and conditional probability from data presented in a two-way table and analysed the solutions provided by these teachers. The authors found a large proportion of participants who were unable to provide any solution to the problems. There were a variety of errors, including confusion between compound and conditional probability, confusion between an event and its complementary, confusion between probabilities with possible cases (absolute frequencies), and assuming independence in the data. The aim of the present paper is to expand the research by Estrada and Díaz (2006) with a bigger sample of prospective teachers, who had not followed a specific course in statistics education. In addition, the second part of the task is intended to assess the SCK of probability that was not taken into account in Estrada and Díaz's research.

METHOD

The sample in the study consisted of 183 prospective teachers at the Faculty of Education, University of Granada, Spain. The task analysed in this paper was answered individually by each participant as a part of the final assessment in a course of Mathematics Education. In this course (60 teaching hours), the prospective

Working Group 5

teachers are introduced to the primary school mathematics curriculum, didactic resources, children's difficulties, and technological tools for teaching elementary mathematics. Most sessions are devoted to practical work, in which participants performed didactic analyses (including identification of mathematical content) of curricular guidelines, school textbooks, assessment items and children responses to these items, and teaching episodes. Several sessions of the course are devoted to probability and statistics education. The previous year all these prospective teachers took a Mathematics course (90 teaching hours) with about 10 hours of in-classroom work and 40 additional hours of extra-classroom work devoted to statistics and probability (data, distribution, graphs, averages, variation, randomness and probability, including some exercises of compound and conditional probability).

The task given to participants is presented in Figure 1 and is similar to another task used by Estrada and Díaz (2006), although the statement was simplified, in order to avoid the use of negative statements in the wording of the item and the use of inequalities in the definition of the events in the sample space. The three questions in the first part of the task, were aimed to assess the prospective teachers' CCK in relation to elementary probability. More specifically we were interested in the prospective teachers' ability to read the table and identify the data needed to compute a simple probability (question a), a compound probability (question b) and a conditional probability (question c). The second part was aimed to assess the participants' SCK knowledge of probability; more specifically we were interested in their ability to identify the mathematical problems, concepts, properties, language, procedures and language implicit or used to solve the task.

A survey in a small school provided the following results:

	Boys	Girls	Total
Liking tennis	400	200	600
Disliking tennis	50	50	100
Total	450	250	700

Part 1. Providing that we select one of the school students at random:

- What is the probability that the student likes tennis?
- What is the probability that the student is a girl and likes tennis?
- The student selected is a girl. What is the probability that she does like tennis?

Part 2. Identify the mathematical content you used to solve the above tasks (specify the types of problems; concepts, procedures; properties, mathematical language and mathematical arguments you used to solve the task).

Figure 1. Task given to participants in the study

RESULTS

Common mathematical knowledge

The written reports produced by the participants in the study were analysed and the answers to each question were categorized, taking into account the correctness of the response, as well as the type of errors, in case of incorrect response, as follows:

Basically correct answers: We group in this category answers that showed students correctly read the two-way table, identified the probability required and provided a correct solution to the problem. We also include here responses that provided a correct numerical result, with incorrect symbolization of probabilities, such as for example: “*The probability of liking tennis is $P(600/700)$* ” (Student 70). The percentage of basically correct responses is low, except for the first question (65,6%), in agreement with what was reported by Estrada and Díaz in their sample.

Confusing probabilities: Some participants confused simple, compound and/or conditional probabilities. The most frequent confusion (13,7%) was between conditional and compound probability: “*Probability of liking tennis assuming the student is a girl is $200/700$* ” (Student 73). This is an error described by Einhorn and Hogarth (1986) in university students and also found in 17% of prospective teachers in Estrada and Díaz’s research. A few participants confused $P(A/B)$ and $P(B/A)$, an error that was described by Falk (1986): “*There is 33% probability that a girl likes tennis*” (Student 71). In the following example, instead of computing a simple probability, the student computed two conditional probabilities; we observe the student’s inability to read the data in the two-way table as he did not reach the “reading between data” level (Curcio, 1989): “*Probability of liking tennis is: $4/6=66,6\%$ for boys and $2/6=33,3\%$ for girls*” (Student 36). Other students confused simple probability with the probability of an elementary event: “*Probability of liking tennis if you select a student at random is $1/700$, since there are 700 students*” (Student 82). The percentage of pre-service teachers confusing different probabilities was slightly lower than that reported by Estrada and Díaz, possibly because the task was simplified.

Confusing events: A few prospective teachers identified the probability but confused an event and its complement, an error described by Estrada and Díaz (2006); “*Probability of liking tennis is $\frac{50}{250} = 20\%$* ” (Student 102), which again suggest the pre-service teachers’ inability to read the two-way table. Additionally some prospective teachers confused other different mathematical objects; such as probability and frequency (or number of favourable cases) and for this reason obtained a probability higher than 1.

Confusing formulas: A small number of pre-service teachers identified correctly the probability to be computed and used correct symbols, but did not remember the formula, so that the final result was wrong. *Other errors* consisted in computing

means of frequencies, or assuming independence in the data and applying directly the product's rule for independent events when computing compound probabilities.

Table 1. Frequency (and percentage) of responses to the three questions

Teacher's answer	P(A)	P(A∩B)	P(A/B)
Basically correct	120 (65,6)	75 (41,0)	80 (43,7)
Confuse probabilities	8 (4,4)	46 (25,1)	30 (16,4)
Confuse other objects	9 (4,9)	10 (5,5)	5 (2,7)
Confuse formulas	3 (1,6)	2 (1,1)	2 (1,1)
Confuse events	0 (0,0)	7 (3,8)	8 (4,4)
Other errors	1 (0,5)	4 (2,2)	11 (6,0)
Do not provide an answer	42 (23,0)	39 (21,3)	47 (25,7)
Total	183 (100)	183 (100)	183 (100)

The students' responses are presented in Table 1, where we use the following abbreviations: A ="the student likes tennis"; B ="the student is a girl". Although the majority of participants correctly computed simple probability, less than 45% of responses when computing compound and conditional probabilities were correct. Also, similarly to Estrada and Díaz's research, an important percent of participants in our study did not provide any solution. There were a variety of errors reported in previous research, in particular confusion between different probabilities, and at the same time we found other mistakes which have not been described in the literature, such as confusing a simple probability with the probability of an elementary event.

Specialized knowledge of content

In the second part of the task, we asked the participants to identify the probability content needed to solve the task. We included the following categories of objects:

- *Problems*: We expected the students to identify the three different specific problems in the task: A simple probability problem in part (a), a compound probability problem in part (b), and a conditional probability problem in part (c).
- *Language*: Verbal, numerical and tabular mathematical language appears in the task statement; depending on the solution, some students would also use symbolic and graphical language.
- *Concepts*: Implicit in the task we can identify the concepts of random experiment (selecting a school student at random); simple and compound events; sample spaces, favourable and unfavourable cases for each question; simple, compound and conditional probability, fraction, ratio and proportion, frequency and percentage, integer numbers, operations with integer numbers (division).

Working Group 5

- *Properties* (or relationships between concepts). Some properties implicit in this task are: The probability axioms; the relation between the probability for an event and that of its contrary; the fact that sample space is restricted in computing conditional probability; equivalence of two fractions when dividing the two terms of the fraction by the same number; the Laplace rule; the relation between the total sample size and the totals in rows or in columns; the relation between double, marginal and conditional frequencies.
- *Procedures* (or algorithms). Possible procedures that can be used in solving these tasks include doing numerical operations, such as division or addition, operating or simplifying fractions, reading a table; transforming a probability in percentage; applying the formulas for computing simple, compound and conditional probability, and computing percentages or proportions.
- *Arguments*. The main correct type of argument used to solve the task is *deductive* argument, which was identified by many students.

Many students were able to identify and correctly classify some of the above mathematical objects in the problem; although, in general, the number of objects identified was quite small, and an important proportion of students were unable to give examples in some categories. Other examples provided by the students were considered incorrect, due to some of the following reasons:

- Some responses were too imprecise, for example, answering that a mathematical problem was “*replying the questions that appear after the data table*” (Student 95) or that “*there are three different mathematical problems in the task*” (Student 125); these responses do not specify the type of problems (simple, conditional or compound probability problem).
- Some students confused the different types of mathematical objects; for example, some of them considered the procedures “*interpreting the table*” or “*performing a division*” to be concepts. Other students confused procedures with their solution or confused phenomenological elements with mathematical objects. For example, some students suggested “*girls*” or “*liking tennis*” instead of “*event*” as examples of mathematical concepts.
- Other students included in their responses some mathematical objects that were not needed to solve the task, such as, for example, “*median, mode, standard deviation*”.

The number of correct and incorrect examples of mathematical objects provided by each participant in each category varied, ranging from not being able to identify a mathematical object in a given category to including several examples (in table 2 we present the mean and standard deviation). Results suggest that identifying the mathematical objects implicit in the task was not easy for the participants in the sample. On average, only half the students correctly identified a mathematical

Working Group 5

problem (even when three different problems were proposed in the task) and only a third identified correctly a property or the use of deductive argument. The easiest elements for the prospective teachers were concepts (2-3 concepts correctly identified per participant), procedures and language (1-2 correctly identified). Anyway, although some prospective teachers suggested incorrect mathematical objects in all the categories, the average number of correct responses was higher than the number of incorrect responses in all the categories and the differences were statistically significant, except for properties and arguments that were hardest to be identified in the task by participants.

Table 2. Mean and standard deviation for the number of correct and incorrect mathematical objects identified in the task

Objects	Correct		Incorrect		p-value in the t-test of differences
	Mean	Std. Dev.	Mean	Std. Dev.	
Problems	0,54	0,70	0,17	0,47	0,004*
Language	1,37	1,91	0,57	1,23	0,007*
Concepts	2,22	2,01	0,87	1,58	0,002*
Procedures	1,40	1,71	0,38	0,89	0,003*
Properties	0,32	0,77	0,26	0,62	0,076 N.S.
Arguments	0,37	0,62	0,26	0,62	0,066 N.S.

* Differences statistically significant at 0,05.

IMPLICATIONS FOR TRAINING THE TEACHERS

Our results suggest that computing simple, compound and conditional probabilities from a two-way table was not easy for participants in the sample who showed a weak common knowledge of probability to solve this task. Many teachers were unable to provide an answer to the problems, in agreement with Estrada and Díaz' (2006) research, or made errors reported in previous research, particularly by Einhorn and Hogarth (1986) and Falk (1986). We agree with Falk that the everyday language we use to state a conditional probability problem lacks precision and is therefore ambiguous. However, a future teacher should master both the concept and the language used in teaching, particularly the language which today is part of statistical literacy, which is important for their students, and which they should transmit them.

Participants also had difficulty in identifying and classifying mathematical objects in this task coinciding with Chick and Peirce's (2008) results, which suggest that the specialised knowledge of elementary probability was also poor. These results are cause for concern, since prospective teachers in our sample are likely to fail in future teaching of probability in some professional activities, such as "figuring out what

students know; choosing and managing representations of mathematical ideas; selecting and modifying textbooks; deciding among alternative courses of action” (Ball, Lubienski, & Mewborn, 2001, p. 453). These activities involve mathematical reasoning and thinking, which were weak for these teachers when dealing with probability. To conclude these results suggest the need to reform and improve the probability education these future teachers are receiving during their training in the schools of education.

INVESTIGATING SECONDARY TEACHERS' STATISTICAL UNDERSTANDINGS

Helen M. Doerr & Bridgette Jacob

Syracuse University

Most secondary teachers are familiar with the procedures of basic descriptive statistics, but they have not necessarily been prepared to interpret graphical representations of data or to reason about sampling distributions. In this exploratory research study in the United States, we investigate the understandings of eleven teachers who participated in a semester-long course, using Fathom, to develop their understanding of these concepts. We present the analysis of a pre- and post-test of content knowledge, the teachers' performance on two tasks, and their use of Fathom as a tool to simulate and represent sampling distributions.

INTRODUCTION

Over the last twenty years, researchers have made substantial progress in understanding students' conceptions of probability and statistics. Over this same time frame, there have been calls for a greater emphasis in schools on the inclusion of statistics topics throughout the curriculum (NCTM, 2000; Pfannkuch & Begg, 2004). However, a vision of improved teaching and learning of school statistics relies heavily on the knowledge and skills of teachers to enact instruction that engages students in developing statistical reasoning. Unfortunately, considerably less progress has been made in understanding teachers' statistical reasoning. As Shaughnessy pointed out in his recent review of the research on statistics learning and reasoning, "More research is needed on teachers' conceptions of statistics. Teachers have the same difficulties with statistical concepts as the students they teach." (2007, p. 1000). The broad goal of the research reported in this paper is to contribute to the research base on teachers' understandings of statistics, with an eye towards characterizing the knowledge that teachers bring to tasks involving graphical representations of data distributions, including sampling distributions. These understandings are key to developing a robust understanding of statistical inference, a topic that is taught at the upper secondary level in the United States. In particular, we are interested in two questions: (1) how do secondary teachers interpret graphical representations of data and (2) how do secondary teachers reason about sampling distributions?

BACKGROUND

The statistics background for most secondary mathematics teachers in the United States is very limited (Shaughnessy, 2007). Some pre-service teachers will have had limited formal coursework in statistics, and often their experience of this coursework is somewhat removed from the statistical content that they will need to teach in the

Working Group 5

secondary school. Such formal coursework in statistics would rarely address the specialized kinds of statistical knowledge that is needed for teaching that is different from just more statistical content, such as the potential misunderstandings that arise from students in the classroom (c.f., Shaughnessy & Chance, 2005). While many secondary teachers will be fluent with the procedures of descriptive statistics such as those in the study by Makar and Confrey (2004), teachers are likely to struggle with using graphical interpretations to data distributions. These researchers found that teachers were able to develop a robust understanding of distribution when working with data in a meaningful context, namely, interpreting test results for students, but the teachers encountered difficulty in distinguishing between the variability in a data set from that of a related sampling distribution. In their study with secondary teachers using *Tinkerplots*, Rubin and colleagues (Rubin et al., 2005) found that the shape of the distribution influenced the strategies that teachers used when comparing two distributions and that the teachers were more confident in their conclusions about symmetric distributions than about skewed distributions. As Pfannkuch (2006) points out, reasoning about data sets from their graphical representations is a complex task, requiring one “to attend to a multiplicity of elements within and between box plots, and to make judgements.” (p. 29). For the teacher, the complexity of this task is further layered with the necessity of generating the kinds of talk that will communicate the concepts represented in box plots in ways that will build towards informal inference.

While the most widely available technological tool for data analysis in the secondary classroom in the United States is the graphing calculator, this tool is more limited in its capabilities for learning data analysis than currently available software. Software designed for the learning of statistics (such as *Tinkerplots* or *Fathom*) provides the learner with opportunities to flexibly explore the data. The “landscape-type” design (Bakker, 2002) of *Fathom*, in contrast to “route-type” software tools, does not assume a particular learning trajectory for the teachers, but provides many routes for exploration. In her study of secondary teachers' comparing distributions, Madden (2008) argues that route-type tools can scaffold teachers' learning of both statistical content and new technology environments by moving from physical experiment to route-type tools to landscape-type tools. In addition, landscape tools have the potential to support an “expressive” approach to data modeling (Doerr & Pratt, 2008) that would allow teachers to create meaningful representations and interpretations of data and sampling distributions. In this study, we assume the reciprocal relationship between representations and models described by Rubin et al. (2005): “Not only does the model of data a person currently holds influence the representation she chooses to use, but the representation in turn influences the model of data she is developing.” In this sense, the simulation and representational capabilities of *Fathom* can reveal the person's current way of thinking and support the development of that thinking.

DESIGN AND METHODOLOGY

This exploratory study was designed to gain insight into secondary teachers' knowledge about the graphical representation of data and sampling distributions. To this end, authors designed and taught a one-semester course that would engage teachers with a range of tasks involving the investigation and exploration of statistical concepts using the software package *Fathom* (Finzer, 2001). The statistical content of the course consisted of investigations into variation and distribution, sampling distributions, confidence intervals, and inferential statistics. In addition, the course included various readings and discussions about (a) the nature of statistical reasoning and how it compares to other forms of mathematical reasoning and about (b) secondary students' learning and statistical reasoning.

The choice of *Fathom* was intended to support the teachers' learning by providing an interface that would allow them to flexibly explore multiple graphical representations (e.g. shifting between box plots, dot plots and histograms) while being able to easily compare data sets and to make changes to the data so as to explore conjectures. *Fathom* also provided the simulation tools necessary to create sampling distributions and representations of the population, the sample, and the sampling distribution. We saw this as critical to developing the teachers' knowledge of sampling.

There were 11 subjects who participated in this study. Eight of the participants were pre-service teachers, two were in-service teachers, and one was a doctoral student in mathematics education. Eight of the participants were female and three were male. All participants had completed the equivalent of an undergraduate major in mathematics, with all but one having had at least one course in statistics. All participants completed a 20 item pre- and post-test of their statistical knowledge in six categories: graphical representations, sampling variation, inference, data collection and design, bivariate data and probability. These items were drawn from the Comprehensive Assessment of Outcomes in a First Statistics course (CAOS, <https://app.gen.umn.edu/artist/caos.html>). These items have been used with college students, and this study extends those results to this group of teachers.

All participants completed two paper-and-pencil tasks prior to specific instruction that (a) required them to compare the standard deviation of two distributions, based on their graphs (delMas & Liu, 2005), and (b) to analyze the relationship between a population and a sampling distribution (Chance, delMas, & Garfield, 2004). As we anticipated, the teachers had many of the same difficulties as college students did with these tasks. Because of the difficulties, we designed a third task (described in more detail below) using *Fathom* that engaged the participants in investigating confidence intervals and how the number of samples and the size of samples affect the sampling distribution. The multiple display windows and the animation features in *Fathom* provided an opportunity for participants to build displays that showed the population, a particular sample, and the sampling distribution as it was being built.

RESULTS

In this section, we first report on the results of the pre- and post-test. We then present the findings on two tasks on graphical interpretations. This is followed by a brief analysis of one participant's use of *Fathom* to represent her understanding of sampling distributions.

Post-Test Results

The post-test results suggest that there was an overall improvement in the teachers' understanding of the statistical concepts, as measured by the 20 items on the test, and this gain was significant ($p < 0.05$), as shown in Table 1, $n = 11$. The only sub-area of the test where there was a significant difference from the pre-test to the post-test was in the area of graphical representations with six items. This result likely reflects the emphasis given to graphical representations and the extensive use of *Fathom* within the course.

	pre-test mean (SD)	post-test mean (SD)	p-value
Overall $n=11$	11.09 (4.23)	12.54 (3.96)	0.027
graphical representation $n=11$	4.09 (1.45)	5.00 (1.79)	0.033

Table 1: Pre-post test results for overall concepts and graphical representations.

The first item among the six graphical representation items addressed the ability to describe and interpret a distribution displayed in a histogram. There was no change in this item from the pre- to the post-test, with 82% correct. The persistent error was misinterpreting the magnitude of the standard deviation of a near normal distribution as too small. Performance on the second item increased from 64% correct to 73% correct; the most common error was tending to select a normal distribution that did not make sense in the context of the problem. Items three and four addressed the ability to interpret the median and the quartiles in a box plot; these two items went from 73% to 91% correct and 55% to 82% correct. The error made on item four was incorrectly reasoning that the boxplot with a longer upper whisker would have a higher percentage of data above the median. On item five, which tested the understanding that a distribution with the median larger than the mean is likely skewed to the left, the correct response rate went from 64% to 82%. All participant errors on item five (both pre- and post-test) were incorrectly selecting a somewhat symmetric, mound-shaped graph. On item six, which addressed the ability to estimate standard deviations for different histograms, there was a change from 73% to 91% correct. Taken together, these results seem to suggest a tendency for some teachers to have more difficulty interpreting skewed distributions than symmetric distributions and a tendency to incorrectly choose a normal distribution.

Graphical Interpretations of Standard Deviation

Early in the course, we gave the participants the task from delMas and Liu (2005) on interpreting standard deviations graphically to the participants. Three of these items (#4, 8, and 10) are shown in Figure 1. The mean and the standard deviation are displayed for the graph on the left, but only the mean is displayed for the graph on the right. The participants were asked to determine whether the standard deviation for the graph on the right was greater than, less than, or equal to the standard deviation for the graph on the left. As delMas and Liu point out, test item 4 “was specifically designed to see if students understood that given the same frequencies and range, a distribution with a stronger skew tended to have a larger standard deviation” (2005, p. 63). According to delMas and Liu, test items 8 and 10 were “designed to challenge the belief that a perfectly symmetric and bell-shaped distribution will always have a smaller standard deviation. Students were expected to find these items more difficult than the others.” (2005, p.63). Unlike the students in delMas and Liu’s study, the participants in our study had more difficulty with item 10 than item 8.

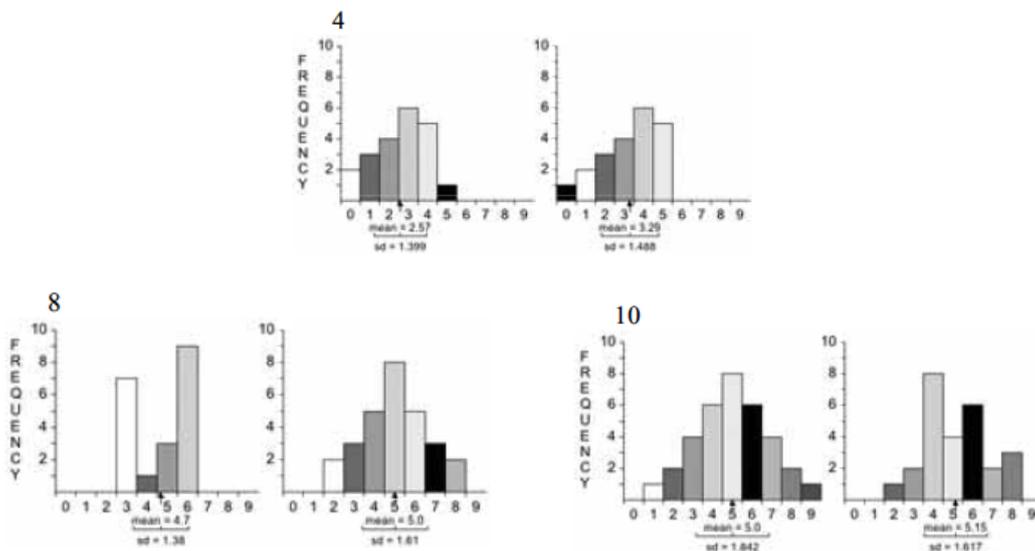

Figure 1: Comparing standard deviations graphically.

Of the ten participants who completed this task, four incorrectly answered that the standard deviations of the two distributions shown in item #4 were equal. This suggests that these participants are not attending to how skew affects the standard deviation. For item 8, four of our participants incorrectly concluded that the graph on the right had a smaller standard deviation, despite the fact that the graph on the left has a smaller range and represents a smaller number of values. This suggests that these participants might have reasoned that the symmetry of the bell-shaped curve with a large portion of the density centered about the mean would result in a smaller standard deviation.

Working Group 5

For item 10, the graph on the right appears to have less density around the mean, but at the same time, it has a smaller range and represents a smaller number of values. As delMas and Liu point out, a reasonable response to both items 8 and 10 could be that the standard deviations needed to be calculated in order to determine how they differ. In their study, many of the students used calculations to come to a correct answer. Those who did not calculate came to the same incorrect conclusion as nearly all of the participants in this study. Only one of the ten participants answered this item correctly. Seven concluded that the distribution on the right had the greater standard deviation. One of the remaining two students concluded that the standard deviations were equal and the other answered with a question mark. These results suggest that these participants might be assuming that a symmetric normal distribution minimizes the standard deviation. The results also point to the difficulties in determining the standard deviation from a graph when having to interpret combined effects of density about the mean, range, and frequency.

Graphical Interpretations of Population Distributions and Samples

We asked our participants to compare the shape and the variability of a sampling distribution to a population, based on a task described in Chance, delMas and Garfield (2004). Prior to specific instruction, we asked our participants which of the graphs in A through E represented a distribution of sample means for 500 samples of size 4 and of size 16, based on the population distribution shown in the upper left in Figure 2. We asked them to state whether these sampling distributions would have less, more or the same variability as the population and as each other. The results of this task are shown in Table 2 and Table 3.

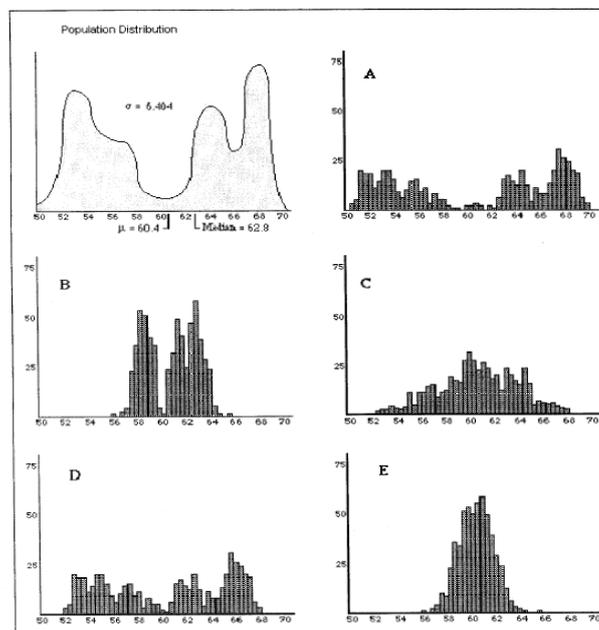

Figure 2: Population distribution from Chance, delMas, & Garfield (2004), p. 321

Working Group 5

Only 4 of the 11 participants chose the correct response (*C*) when asked for the distribution of sample means for 500 samples of size 4. When asked for the distribution of sample means for 500 samples of size 16, only 5 of the 11 participants chose the correct response (*E*). For both items, the majority of participants chose distributions that indicate a belief that the sampling distribution should look like the population. This is a common misconception held by students (Chance, delMas & Garfield, 2004). The choice of response *B* for the second item would indicate that some participants believed that the sampling distribution continued to look like the population as the sample size increased, but with reduced the variability.

responses	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>
sample means of size 4	2	0	4	5	0
sample means of size 16	2	4	0	0	5

Table 2: Possible distributions of sample means drawn from a population

As shown in Table 3, most participants (7 out of 11 and 10 out of 11) correctly compared the variability of the samples of size 16 to both the population variability and the variability of the samples of size 4. However, when comparing the variability of samples of size 4 to the variability of the population, 5 of the participants incorrectly expected the samples of size 4 to have *more* variability. This misconception is particularly interesting given that nearly all of the participants correctly compared the variability of a sample of size 4 to a sample of size 16. We speculate that these participants might be confusing the variability of a single sample with the variability of the sampling distributions. This needs further investigation.

responses	<i>less</i>	<i>same</i>	<i>more</i>
samples of size 4 compared to population	6	0	5
samples of size 16 compared to population	7	3	1
samples of size 16 compared to samples of size 4	10	0	1

Table 3: Comparing the variability of the sample distributions

Representing the sampling distribution using *Fathom*

Given the difficulties that a number of participants had with the previous task, we designed a task using *Fathom* to help participants better understand the three levels of abstraction that are present in a sampling simulation: (1) the population; (2) a particular sample from the population; and (3) the collection of measures that result from repeated sampling. This task consisted of two parts: the first part of the task asked the participants to set up a simulation in *Fathom* and investigate how the

Working Group 5

sampling distribution of a summary statistic compared to the population distribution and how changing the number of samples and the sample size affects the sampling distribution. The participants successfully completed this first part of the task using a collection of 100 random rectangles (Key Curriculum Press, 2002, p. 127).

The second part of the task asked the participants to create a display that could be used to help students understand the difference between the population distribution, the sample, and the sampling distribution. This creation of a display that could be understandable to a learner was a substantial shift in the nature of the task that the participants were engaged in. Rather than convincing themselves about the relationships involved, the participants now shifted their attention to create a representation that could be used to illuminate the relationships among the population, a sample and the sampling distribution of a particular statistic. The work of one pre-service teacher is shown in Figures 3 and 4 and is representative of the kind of displays most participants created.

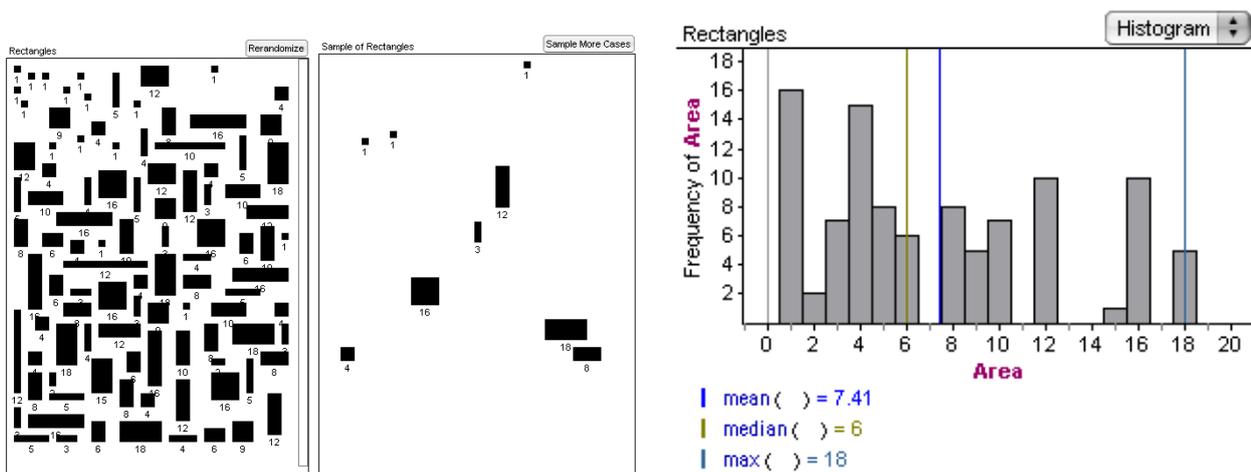

Figure 3: Juxtaposing the population, the sample and the population distribution

This pre-service teacher displayed the entire population of 100 rectangles, next to a randomly chosen sample of 10 rectangles along with a histogram showing the distribution of the areas along with the summary statistics for the entire population (as shown in Figure 3). The next section of her display (shown in Figure 4) juxtaposed a table that summarized the dimensions of each of the ten rectangles in the randomly drawn sample and the distribution of the areas for that sample. Just below this, she positioned a table (lower left in Figure 4) that showed the mean, median and maximum area for each sample of 10 rectangles up to 101 such samples. Next to the table is the graph of the distribution of the sample means. The pre-service teacher created this display with the animation feature of *Fathom* turned on so that she could see the sample distribution changing with each sample of 10 rectangles, while the sampling distribution was slowly being built and taking on the shape of a normal distribution. All participants introduced dynamic elements of animation into their displays, which are not fully captured by static snapshots.

Working Group 5

This display suggests that this pre-service teacher was separating the three levels (or tiers as Madden (2008) refers to them) of abstraction that one needs to understand in order to grasp the concept of the sampling distribution. By using the simulation capabilities of *Fathom*, along with its flexibility in selecting representations, this pre-service teacher has clarified the distinction between the population, the sample, and the collection of sample means. The animation feature seemed to make visible how the sampling distribution is built over time as samples are collected. This particular display has the potential to help the pre-service teachers avoid confusing the population distribution with the sampling distribution as seen in the second task reported above. On a related item on the pre- and post-test, that asked participants to select an appropriate sampling distribution for a particular population and sample size, we found that the response rate went from 45% to 64% correct.

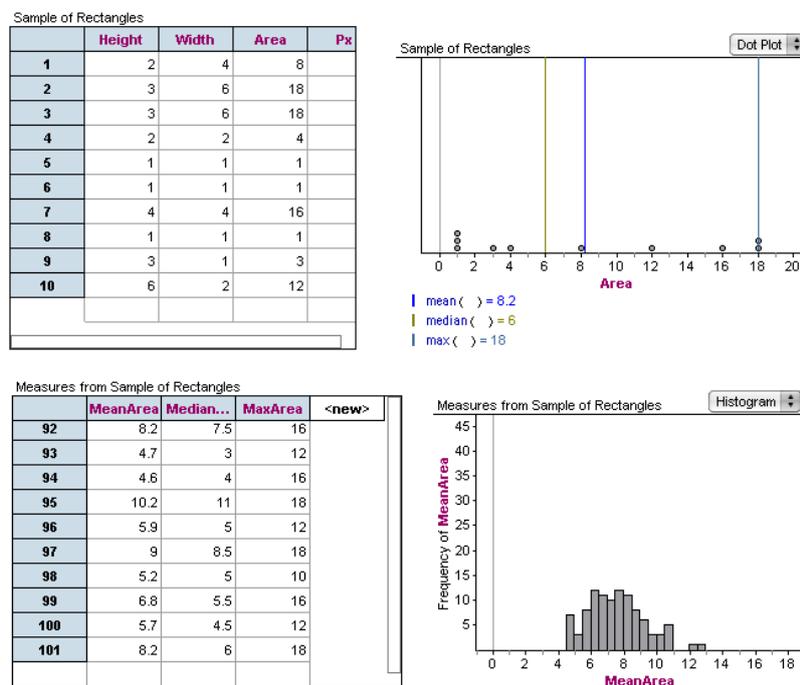

Figure 4: A snapshot of a dynamic display building the sampling distribution

DISCUSSION AND CONCLUSIONS

The results of this study provide some evidence that, as Shaughnessy (2007) argued, teachers have some of the same difficulties with statistics as do students. We note that a limitation of this study is the small number of participants and that while there was a statistically significant gain on the post-test, this gain was small and largely in the area of graphical representations. Consistent with the findings of Makar and Confrey (2004) and Rubin et al. (2005), we found that some teachers had difficulty interpreting skewed distributions and tended to inappropriately choose symmetric normal distributions. This was evidenced when having to interpret how the combined changes in density about the mean, range and frequency affected the standard deviation. It is likely that these secondary teachers' prior learning of statistics

focused largely on the computational algorithm for standard deviation. Extending the results of Chance et al (2004), we found some teachers, like students, had a tendency to see the sampling distribution as having the same shape as the population distribution. Most teachers correctly reasoned about the variability of the distribution of larger samples, but incorrectly expected greater variability in the sampling distribution of smaller samples when compared to the distribution of the population. We found nearly all participants were able to create animated displays with *Fathom* that brought clarity to the three levels of abstraction that are present in any sampling distribution. This suggests that a land-scape tool such as *Fathom* has the potential to make visible teachers' models of statistical concepts.

MENTAL MODELS OF BASIC STATISTICAL CONCEPTS

Andreas Eichler, Markus Vogel

University of Education Freiburg, University of Education Heidelberg

This report focuses on a research programme that aims to identify the ability to cope with basic statistical concepts of young students (primary school and secondary school) without schooling in statistics, and to identify the students' mental models when acting within simple statistical situations. Firstly, the basic elements of the theoretical framework of the research programme will be outlined. Afterwards the method and exemplary results of a pilot study will be discussed. Finally, these results will be evaluated with regard to follow-up studies.

Keywords: mental models, basic statistical concepts, statistical knowledge

INTRODUCTION

About 60 years ago, Piaget and Inhelder (1951) published their seminal work referring to the development of thinking with probabilities. Nowadays, a huge amount of subsequent research exists that, on the one side, replicates the well known levels of the student's development of probabilistic thinking but, on the other hand, modifies, enhances or contradicts the findings of Piaget and Inhelder (Jones et al., 2007). Overall, however, we have a substantial knowledge about the development of the (naïve) probabilistic thinking of young students which is a basis to decide on the time to introduce probabilistic concepts in schools (Fischbein, 1975).

In recent years statistics instead of probability seem to become both the essential part of the stochastics curriculum in many countries, and a crucial part of the research into stochastics education (Shaughnessy, 2007). The majority of the existing research approaches in this field are intervention studies, trying to investigate how instruction promotes the students' statistical thinking (Ben-Zvi & Garfield, 2004; Shaughnessy, 2007). In addition, researchers developed theoretical frameworks towards statistical acting (e.g. Wild & Pfannkuch, 1999). However, in contrast to the research on students' probabilistic thinking, Mokros & Russel (1995) suggested 15 years ago that we knew little about students' development of a statistical thinking without statistical schooling and the situation has not improved today. Nonetheless, empirical knowledge about students' naïve knowledge of basic statistical concepts and statistical situations is important in order to adequately design a statistics curriculum, and to avoid students' misunderstandings referring to statistical concepts or statistical methods (Fischbein, 1975). For this reason in this paper we will discuss the first phase of a research programme that has the main aim:

- to identify the naïve knowledge represented by mental models of young students (aged 9 to 18) regarding basic statistical concepts and situations, and
- to investigate the development of this knowledge depending on age.

Working Group 5

To discuss our research approach, firstly, we will clarify basic elements of our theoretical framework. Afterwards, we will discuss the method and provide some examples of the main results of a pilot study of our ongoing research. The pilot study itself consists of the following aims:

- to prove several tasks with regard to their adequateness for investigating students' naïve knowledge towards different statistical concepts and situations,
- to get information about whether students actually show different mental models by working with different statistical tasks, and
- to explore whether it is possible to identify differences in the students' ability to cope with basic statistical concepts and situations depending on age.

THEORETICAL FRAMEWORK

The theoretical framework involves two components. The first part deals with the identification of possible subjects and competencies that may represent students' basic statistical knowledge. The second part involves the discussion of students' development of thinking concerning statistical concepts.

Statistical Reasoning and Prior Statistical Knowledge

Wild and Pfannkuch (1999) suggested five aspects to be the main thinking processes in acting statistically. They considered them as being independent from the expertise of the actor. These five processes are

- the recognition of the need for data,
- transnumeration,
- the consideration of variation,
- reasoning with statistical models, and
- integrating the statistical and contextual information, knowledge, conceptions.

Except for the second type of reasoning, these components are not necessarily based on the students' prior statistical knowledge gained through schooling. Thus, it should be possible to identify them as parts of young students' naïve knowledge concerning statistical concepts.

While the five aspects of the statistical thinking represent an individual's statistical acting beyond specific statistical topics, several topics were declared to be central referring to statistical knowledge, i.e. sampling, central measurement and variation, distribution, graphical representation of data, or regression and correlation (e.g. Curcio, 1989; Mokros & Russel, 1995, Bakker 2007).

Students Development Concerning Statistical Thinking

A main assumption for this research is that students' competencies in basic statistical concepts develop with age. Unlike Piaget and Neo-Piagetians like Case (1992) we

Working Group 5

assume that this development cannot be described adequately by a staircase model. We follow Siegler (1996) who postulated the development of children's thinking had to be considered as "overlapping waves". The fundamental idea of his approach is making allowance for the observable variability of children's thinking. This variability depends on different factors, like specific circumstances, requirements and available knowledge, which influence a child's concrete actions within different situations. Based on several empirical studies Siegler provided evidence for high inter-individual as well as intra-individual variability when using complex strategies for solving problems (e.g. Siegler, 1995; Schauble, 1990).

The theory of mental models (Johnson-Laird, 1983) incorporates the situation's impact on cognitive processes, too. This theory suggests that, when interacting with (statistical) demands of a specific situation, the learner builds a mental model in order to simulate relevant aspects of the situation to be cognitively mastered (cf. Seel, 2001). Mental models are of dynamic nature: They are not to be seen as being fixed structures of memory; mental models are constructed according to a task and its requirements within a situation representing the structure or the function of the modelled object (Schnotz & Bannert, 1999). Thus, mental models concern the situation and they also facilitate to differentiate the students' cognitive development (or maturation) in using basic statistical concepts. Furthermore, tasks concerning statistical thinking and statistical knowledge contain information a student could proceed and internalize in a mental model being specific with regard to his or hers individual abilities, pre-knowledge and apperception of the task's representation. According to the information process model of Schnotz & Bannert (1999), the elements of a mental model may be changed, enriched or modified during the persistent mutual processes of internalizing and externalizing, when a student is working on a statistical task but they do not disappear at all. Thus, information about statistical mental models, and hence statistical thinking and statistical knowledge, could be made available by analyzing the tasks (content, representation), the learners specific situation (experience and pre-knowledge with regard to statistical content, statistical methods and statistical context) and the learners outcomes (written or spoken responses) after working on the tasks.

Not the statistical mental models themselves are claimed to be captured, but the researchers' reconstruction of these models based on learning outcomes. It is obvious that different students will show different grades of performance. A categorization system describing different performances that is often used in statistics education is based on the SOLO model of Biggs and Collis (1982). In the adaptation of Watson and Moritz (2003), this model has four levels or rather modes, i.e.

- the prestructural mode: students solve a task using irrelevant information,
- the unistructural mode: students solve a task using an isolated information,
- the multistructural mode: students solve a task using a set of information,

Working Group 5

- the relational mode: students solve a task using a set of information and considering an interconnected knowledge of context and statistical concepts.

Although alternative models exist to describe students' performances in acting with specific statistical tasks (e.g. Watson et al., 2003), in the pilot study we used the model outlined above only, but consistently, since the scope of statistical tasks in the pilot study encompassed different basic statistical concepts.

In summary, using this theoretical framework the underlying aim of the pilot study was to get information about students' ability to cope with basic statistical concepts within different situational requirements. A further aim was to see if and how it could be done to reconstruct students' potential mental models when working on different statistical situations.

METHOD

To investigate different aspects of students' naïve knowledge concerning basic statistical concepts and situations we have designed tasks referring to

- central measurement,
- variability of statistical data,
- proportional reasoning involving the students consideration of variability,
- interrelation of bivariate data, and
- simple random experiments.

The design of the tasks was based on the research literature as mentioned above. Some of these tasks were adopted without changes, some other tasks were modified, and some new tasks were developed. Every task contains a decision-making process in a statistical situation and an open-ended item in which the student had to justify the decision. The particular aim of the pilot study was to investigate whether the students of different age were able to work with these tasks and whether these tasks could be useful to identify students' mental models when acting with different statistical situations.

Figure 1 shows two of the tasks. The first task, called the *frog-task*, deals with the students' mental models referring to proportional reasoning and variability of statistical data. The second task, called *the die-task*, deals with the students' mental models referring to a simple random experiment (Figure 1).

Both items have adequate normative solutions. For instance, estimating 100 frogs in field 3 after 100 jumps or choosing the ordinary die in the second task are inadequate solutions. Our main focus in analysing students' solutions, however, was to code students' different performances in justifying their solution according to the four-level-model of Watson and Moritz (2003). In this study we coded no solution with 0, a solution that matches the prestructural mode with 1, a solution that matches the

Working Group 5

unistructural mode with 2, a solution that matches the multistructural mode with 3, and, finally, a solution that matches the relational mode with 4. We also tried to identify different mental models that were, potentially, the basis of the students' justifications of their solutions.

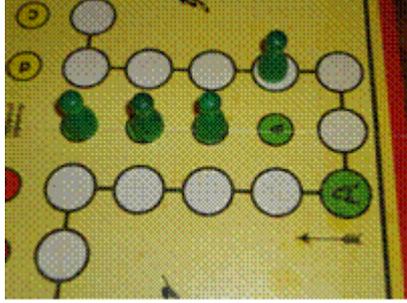

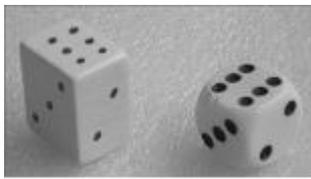

<div style="text-align: center; margin-bottom: 5px;"> field 1 field 2 field 3 field 4 </div>  <p>Andrea lets the frog jump ten times from the starting line. The frog ends in field 1 once, in field 2 twice, in field 3 seven times, and never in field 4.</p> <p>Make an estimation:</p> <p>How often will the frog get to field 3 after 100 jumps? Justify your answer.</p> <p>How often will the frog get to in field 3 after 1000 jumps? Justify your answer.</p> <p>How often will the frog get to field 4 after 1000 jumps? Justify your answer.</p>	 <p>You will win a game if one die shows 3 the first time you throw.</p>  <p>Which of the two dice would you choose to win this game?</p> <p>Why have you chosen this die!</p>
--	---

Figure 1: The frog-task (left side) and the die-task (right side)

To identify possible differences in the performances of the students' solutions depending on both the students' age and the students' specific situation (experience and pre-knowledge with regard to statistical content, statistical methods and statistical context; see above), we selected samples of students in different grades. The samples answering the two tasks we discussed above are shown in Table 1.

die-task		frog-task	
Grade [age]	Sample size	Grade [age]	Sample size
2 [7-8]	19	4 [9-10]	21
4 [9-10]	25	10 [15-16]	45
8 [13-14]	65	12 [17-18]	23
11 [16-17]	17		
n = 126		n = 89	

Table 1: Sample sizes in the pilot study

All primary students and most of the students in higher grades had never learned about statistics in school before taking the test. There were only a few students who had gained mostly little statistical experience along their schooling.

As we proceed, we begin with the discussion of students' solutions of the die-task. Afterwards, we will discuss the results in a broader sense including open questions that have arisen from the results of our first research step, and including possible next research steps.

SOME RESULTS OF THE DIE-TASK

The die-task provides the following question (see Figure 1): "Why have you chosen this die?"

A grade 4 student who chose the ordinary die justified his solution as follows: "Because, it will spin better". This student provided an inadequate solution on the one side and, on the other side, referred to a physical feature of the die, which is irrelevant in the statistical situation of choosing one of the two dice. For this reason, we coded his solution with 1 (representing the prestructural mode).

Another grade 4 student justified his selection of the cubic-die as follows: "Because the side is bigger. Thus, you get the three faster." The student referred to a single physical feature of the die which is relevant for an adequate choice of one of the two dice. The student was not able, however, to describe the relationship between the different sizes of the sides of the cuboid-die, and, respectively, the different sizes of the side showing the 4 on both dice. For this reason, we coded this justification with 2 (unistructural mode).

A third student (grade 8) justified his selection of the cuboid-die as follows: "Because the first die has sides of the same size, which is not the case for the second one". This student compared the two dice according to a relevant physical feature, and, thus, used a set of relevant information in the statistical situation. For this reason, we coded this justification with 3 (multistructural mode).

Finally, one student (grade 8) justified her selection of the cuboid-die as follows: "The sides showing the 3 and the 4 are bigger than the others. For this reason, the chance of getting a 3 is about $\frac{2}{8}$ (two eighth), thus $\frac{1}{4}$ (one fourth). This chance is bigger than $\frac{1}{6}$ (one sixth) in the other die." This student considered a lot of relevant information. She compared the symmetrical areas of the cuboid-die showing the 3 and the 4 and estimated a probability by comparing all the areas of the die. She also showed knowledge about the probability of the ordinary die and was able to compare these probabilities. Thus, we coded this justification with 4 (relational mode).

In Table 2 the absolute numbers of students' justifications in the whole sample ($n=126$) that were coded from 0 to 4 is shown. The justifications are divided into those that are given concerning the cuboid-die (r: right) and the ordinary die (w: wrong).

Three results of the descriptive analysis can be pointed out:

- The students' ability to select adequately the cuboid-die seems to increase by age.

Working Group 5

- The students' performance in formulating a justification for their choice of one of the two dice seems to increase by age, as well.

If the students choose the inadequate die, they show a low performance in justifying their choice.

Code	Grade 2 n = 19		Grade 4 n = 25		Grade 8 n = 65		Grade 11 n = 17	
	r	w	r	w	r	w	r	w
0	0	0	0	0	0	0	0	0
1	5	14	4	12	8	8	1	1
2	0	0	6	0	44	0	12	2
3	0	0	2	1	4	0	1	0
4	0	0	0	0	1	0	0	0
Sum	5	14	12	13	57	8	14	3

Table 2: Absolute numbers of codes concerning the students' justifications

SOME RESULTS OF THE FROG-TASK

The coding of the students' justifications in the frog-task was based on considerations similar to the die-task. Although we coded the justifications to the four answers of the frog-task as a whole, we illustrate the codes from 1 to 4 by presenting only justifications to the last question ("How often will the frog get to field 4 in 1000 jumps?"):

- 1: "250 times. The chance that the frog will get to each of the four fields is 25%."
- 2: "0 times. 1000 is a hundred times larger than 10 and, thus, we have to multiply 0 (number of frogs having reached field 4 by jumping 10 times) by 100."
- 3: "8 times. Because getting to field 4 seems to be more difficult."
- 4: "0-10 times. The more often the frog will jump, the bigger is the chance that the frog will get to field 4."

The justification of the first student (grade 10) describes an equal-probability model, which is an inadequate model in the statistical situation of the frog-task (which would imply a distribution of jumps according to the normal distribution). The justification of the second student (grade 12) describes a fixed proportional model without consideration of variation. In contrast, the third student (grade 4) seems to grasp the idea of variation implicitly and in an unsophisticated way. Finally, the fourth student (grade 12) showed a more sophisticated understanding of variation and of the relationship between variation and the number of jumps. Table 3 shows the absolute numbers of students' justifications in the whole sample (n = 89) that were coded from 0 to 4.

Regarding the results of the descriptive analysis, it is important to state that:

Working Group 5

- the performance of the students' justifications seems to increase with the student's age. However the increase is low in comparison to the die-task and, for instance, one student of grade 4 (see above) showed a higher performance as a student of grade 10 and even a student of grade 12;

the performance of the students' justifications is higher compared to the justifications referring to the die-task.

Code	Grade 4, n = 21	Grade 10, n = 45	Grade 12, n = 23
0	0	1	0
1	7	5	3
2	10	19	11
3	4	17	6
4	0	3	3

Table 3: Absolute numbers of codes concerning the students' justifications

DISCUSSION

The results of the first step of our on-going research have to be interpreted carefully. These results, though, should facilitate the finding of appropriate questions and the phrasing of adequate hypotheses referring to students' ability to cope with basic statistical concepts. Taking into account these constraints the following aspects seem, nevertheless, to be worthwhile being considered in follow-up studies.

Firstly, the results concerning the two tasks as well as for other tasks gave evidence that students' ability to cope with basic statistical concepts and to justify decisions in different statistical situations are dependent on age (see the results in both tasks). This hypothesis will be investigated in a follow-up study involving randomised samples of students of different grades. Although there seems to be a correlation between the students' performance concerning different tasks, students of the same age also justify their acting in a statistical situation in considerably different ways (see for example the two students of grade 12 concerning the frog-task). Further, there is some evidence that, partially, students formulate different justifications in tasks that are structurally equivalent. Both results meet the Siegler's theory of "overlapping waves" in children's thinking (Siegler, 1995).

There is some evidence that students use different mental models coping with statistical situations. Although it is, theoretically, not possible to identify the mental model a student actually uses, research results seem to reveal some indication of equivalent inter-individual mental models. For instance, some of the students neglected in both tasks the randomness of the data's genesis or, respectively, the randomness of future data (e.g., the student we coded with 0 in the die-task). Another pattern concerns the omnipresence of the fair chance: Neglecting the information given in the frog-task, these students estimate future events consistently based on the model of an equal-probability (see the student, we coded with 0 in the frog-task).

Working Group 5

According to the theory of mental models, we found great differences in the students' ability to cope with statistical situations depending on the representation of the task. For instance, students' seemed to use significantly different mental models when the die-task was represented by two real dice, the picture of the dice (c.f. the die-task discussed above), or the description of the two dice. We also hypothesise that different representations of other statistical situations will have a great impact on the students' ability to cope with these statistical situations. For instance, the frog-task using the picture of the statistical situation shown in Figure 1 could be compared to the same task involving a picture of a real experiment or more abstract graphical representations of the situation, e.g. a dot plot.

Two important questions were not investigated in our pilot study: Do we measure the students' ability to cope with statistical situations or do we only measure the students' ability to communicate their ideas? Do the differences in communicating decisions and their justifications in a statistical situation contrast with a student's acting in the same situation? The outward appearance of the written justifications of students of different age varies considerably (c.f. Figure 2 to 5). At the current stage of our research programme, however, we postulate that a student's ability to cope with statistical situations is similar to the student's ability to verbalise his decisions and his decisions' justifications in a statistical situation.

Two follow-up-studies are being undertaken currently on the dependence of students' ability to cope with basic statistical concepts from age and on the students' different mental models by coping with statistical situations that will be—in the first step— structured using the SOLO taxonomy but will be described by a more differentiated systems inductive developed categories. From both studies which will include quantitative and qualitative parts we expect to get a better understanding of students' (naïve) knowledge concerning statistical concepts and students' (naïve) statistical thinking.

INSTRUCTIONAL REPRESENTATIONS IN THE TEACHING OF STATISTICAL GRAPHS

M^a Teresa González Astudillo

Jesús Enrique Pinto Sosa

University of Salamanca

Autonomous University of Yucatan

Abstract: This work is focused on the knowledge that two teachers of Statistics have about instructional representations and strategies in the teaching of statistical graphs. The instructional representations they use for teaching are definitions and explanations, questions, examples and exercises, and instructions; all of them centered on explanations, the use of examples and prototypic exercises, and the construction of graphs. Occasionally, the manipulation of data and graphs is used to explore the meaning of previous concepts and explore the characteristics and elements of the graph.

Key Words: pedagogical content knowledge, instructional representation, statistical graphs, teaching statistics

INTRODUCTION

Pedagogical content knowledge (PCK) emerges from Lee Shulman's theoretical framework entitled "*the knowledge base for teaching*". This knowledge base consists of seven categories, three of which are content related: (a) content knowledge (CK), (b) pedagogical content knowledge (PCK), and (c) curriculum knowledge. The other four categories refer to general pedagogy, learners and their characteristics, educational contexts, and educational purposes (Shulman, 1987).

Within the category of PCK, Shulman (1986) included three closely connected key elements or domains of knowledge: the subject matter knowledge for teaching, the knowledge of instructional representations and strategies, and the understanding of specific learning difficulties and students' conceptions (Pinto & Gonzalez, 2006).

The purpose of this research is to explore the PCK of two teachers who teach Statistics focusing on the topic of statistical graphs in schools of Psychology and Education. In this paper we present exclusively what corresponds to one of the three elements of PCK, i.e. the knowledge of instructional representations.

Instructional representations

Instructional representations are "ways of talking, showing, enacting, or otherwise representing ideas so that the unknowing can come to know, those without understanding can comprehend and discern, and the unskilled can become adept" (Shulman, 1987, p.7). Therefore, the teacher must bear in mind both to the possible

meanings within the subject, and the comprehension that his or her students are able to reach.

McDiarmid, Ball & Anderson (1989) apply the term *instructional representation* to “a wide range of models that may convey something about the subject matter to the learner: activities, questions, examples, and analogies, for instance”. The sources from which instructional representations derive are two; those originated from the teacher himself and those originated from outside. The forms of instruction in the first group are: worksheets, activities, explanations, questions and answers that teachers provide their students with. The second group of representations derives from the curricular materials (textbooks, guidelines for the teacher, equipment, software, films and videos), courses or workshops for teachers and experiences shared by colleagues in the school context.

Regarding the type of representation there are different forms. Shulman (1986) mentions some: *analogies, illustrations, examples, explanations and demonstrations*. Llinares, Sanchez & Garcia (1994) suggest additionally *drawings* and the *graphical representations* found in books or those provided by the teacher on the board. Even and Tirosh (1995) present *questions, activities and discussions* linked with the mathematical content as examples of representations. McDiarmid, Ball & Anderson (1989) also talk about *verbal expositions, diagrams, simulations, dramatizations, and content analysis*; verbal, symbolic, graphic or concrete representations stand out as inherent to mathematical content. Furthermore, Putnam & Borko (2000) discuss *models and metaphors*.

Shulman (1986) states that a teacher should select and use a wide repertoire of representations, according to the specific content in question, which highlights the importance of the teacher’s knowledge of instructional representations linked to the topics being taught and the way the teacher uses them (Llinares, Sanchez & Garcia, 1994).

Statistical graph

We will focus specifically on knowledge of the instructional representations of a specific topic: statistical graphs. A statistical graph is a “construct which was developed in specific cultural contexts to mediate interpretation of data... an activity which is related to a complex range of elements and processes” (Monteiro & Ainley, 2006, p.1) and it is considered a reasoning tool to learn something new about the context it represents, gain new information or learn from the data (Pfannkuch, 2006). For this reason, teachers should develop PCK that will help them design activities to increase the conceptual understanding of statistical graphs in their students, based on the relationships between the main components of the graph and the necessary process for its interpretation (Friel, Curcio & Bright, 2001).

Each instructional representation for teaching and learning statistical graphs favours certain conceptions that are transmitted to the students. For example, Meletiou &

Working Group 5

Stylianou (2003) considers that when students *use technology* this enables them to engage in interpretation and translation of graphically represented information. Thompson (1994) proposes a strategy to *incorporate significant data* from the student, Curcio (1989) sequence a set of *activities* to develop graphical understanding, and Peden (2001) shows an *activity* from four data sets to capture and select, analyze and interpret the best graph. Moreover Cazorla & Santana (2006) show examples of *problem situations* of interest either for quantitative or for qualitative analysis to understand the characteristics of graphs. Moore (2000) suggests using *appropriate software* to make graphs, *group problem solving* and *discussion, written and oral presentations* and *projects*.

However, several studies in statistics education (Burgess, 2002; Monteiro & Ainley, 2006) have concluded that the difficulties for the teaching and learning statistical graphs as well as a limited repertoire of instructional representation, clearly exemplify the training that statistics teachers have.

THE RESEARCH

This research focuses on the representation of statistical data, specifically graphical representation, which is one of the first topics in any introductory course in statistics at any school level, as well as the point of departure for the statistical analysis process in a group of data and a basic element in statistical thinking (Pfannkuch & Rubick, 2002).

Considering this view, the critical issues that we wanted to establish were: How does a teacher plan his/her classes? What kind of knowledge does he/she have about the instructional representations of the content that is being taught? What kind of activities does he/she use in teaching? How does he/she use them? We did not attempt to characterize or typify teacher's knowledge, but to understand and go deeper into his/her knowledge, to know how it is used to teach statistical content in his/her classes.

In order to achieve this, two cases were selected (Alicia and Luis) on the basis of the following criteria: knowledge about the topic of statistical graphs (SG), different initial training (a mathematician and a psychologist), a teacher who taught Statistics in a school of Psychology and the other in a school of Education, different teaching experience in Statistics, willingness and motivation to collaborate and share their thoughts and knowledge, as well as a positive attitude towards learning. Both teachers teach at a public university located in Mérida, México.

The following instruments were used for data collection: the syllabus of each Statistics course (Sy), a contextual and biographical interview (I1), a didactics questionnaire with four hypothetical teaching-learning situations about SG (Q1 to Q4), each of them with different items (1a,1b..), an in-depth interview about their answers to the questionnaire (I2), and the materials used for the teaching of SG which included class notes (Not), exercises (Exe), Exams (Exa), course programs

(Pro), textbooks (Txt), student notebooks (Sno), presentations (Pre) and web pages (Web).

RESULTS

From the answers to the questionnaire and the interviews and from the materials used in their classroom we have classified the instructional representations used by Luis and Alicia to teach SG in their classroom in five types: definitions and explanations, questions, examples and exercises, instructions and data and graphical manipulation. Alicia uses the first four, and although Luis uses other types of instructional representations (project based learning and case study) in his classroom, the only ones linked to SG are questions and data and graphical manipulation. These instructional representations are discussed by Shulman (1986) (*explanations and examples*), Even & Tirosh (1995) and Peden (2001) (*questions, activities*), Curcio (1989) (*activities*) and Meletiou & Stylianou (2003) (*using technology*).

We will describe the characteristics of each of them as follows using only certain excerpts regarding each of the teachers as illustrations considering that they repeated the same ideas though out the documents we have analyzed.

Definitions and explanations

Definitions are a description of topics that appear at two points of the explanations: *as a closure of an inductive process* after an explanation as a synthesis or conclusion, or *to begin a new topic*. For instance, to start to work with the histogram, Alicia presents its definition showing some of its characteristics, indicating the kind of variable associated to the graph, and then provides an example with the criteria for its construction specifying the sequence of steps that the students should follow.

Graph

Bar Graphs allows a simple visualization of the distribution of qualitative data for absolute frequencies and relative ones. On the horizontal axis the categories are represented and on the vertical axis, in a continuous line, the values from zero to the maximum reached by the frequencies.

The frequencies are shown by the height of the bars, and all of them have the same width.

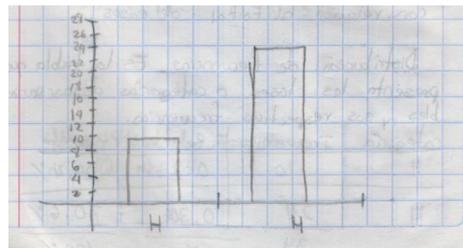

Figure 1. Translation of a definition used by Alicia (Sno.01)

Definitions come, generally, from textbooks (Txt) or course notes (Not) that Alicia uses in her classrooms and she dictates them to the students or writes them up on the board for them to copy. These definitions are supplemented with explanations where every characteristic of the graphic is commented, clarified, described and supported, for example indicating what kind of a variable each graph is useful for.

Questions

Questions are instructional representations posed to the students in order to help them reflect on the characteristics of SG. They vary according to the context in which they are asked: those related to the teacher's knowledge of the teaching of SG or those generated from the hypothetical situations that were proposed in the questionnaire.

In the *first context* Alicia and Luis used questions as a resource to develop statistical reasoning, to find out if the concept was understood, to reinforce acquired knowledge or to identify mistakes.

- 38 Alicia: In this sense they are quite familiar with their grades average. It is appropriate to ask them: "Well, when you get your grade average, what meaning does it have? Why do you only manage to get a particular grade? Let's say that while you were taking a subject, how did you get the final score?" and then they start saying: "well, [because] there were some partial exams, they were graded this way and then we get that er... final grade," and "why do they only consider that grade?" (I2)
- 06 Luis: Well what graph do you think is better? "I am going to do a pie chart", Ok what are the advantages that this has compared to this other one?...(I2)
- 87 Alicia: Then, when I see that something is... like they are just writing it or they are copying it from somewhere, then I start asking them, I tell them: "Well er... why did you write this? What are you going to answer?". I start asking questions and that's the way I can see more or less who are the ones who have some difficulty and what is happening (I2)

In the *second context*, questions are posed with a clear intention to make the students realize, in an inductive way, what the characteristics of each graph are and the nature of the data represented or to develop a critical sense to help them learn.

- Alicia: What is the meaning in the graph of each one of the axis? (Q3b.1)
- 02 Luis: What does the stem in a stem-and-leaf plot represent? (I2)
- Alicia: First I would ask them: "What is the variable to be studied?" (Q4a.1)
- 09 Luis: Is it a continuous variable or not? (I2)
- Alicia: Is it clear for the reader what the cars positions represent? (Q4a.5)
- Luis: What are the parts of the graph whose relationships are incorrect? (Q4bii.3)
- Alicia: What could be included in the graph to make it is easier for any reader to understand? (Q3b.2)

The questions associated to each context differ from those of the others. In the first one we find questions more related to reinforcing knowledge and to clarifying the students' doubts, while in the second one, they are centered mainly on the exploration of the structural components of the graph.

Exercises and examples

Examples are learning activities that have a direct relationship with the knowledge and understanding of the concepts or topics of the program and are generally provided immediately after a definition or explanation of the topic. *Exercises*, however, are learning activities whose main objectives are to develop practice, and to confirm that the concepts have been understood. Despite this difference, Alicia mentioned both terms repeatedly and indistinctly so they are included within the same category.

This instructional strategy was used to *assess the students' knowledge* of graphs construction or to enable the student to *discriminate between one graph and another*:

82 Alicia: (she is thinking) They did some exercises in class where they had to do, from their frequency distribution, then some graphs, we handled histograms, mm... some pictograms. Then I asked them for exercises in which I gave them some data and they had to do their distributions and their graphs. (I1)

39 Alicia: ...In the exercises where they are figuring out their distribution of frequencies, I ask them to make a graph... I tell them to make all the graphs without paying attention to which one is the best or which one would be more suitable for that type of information. (I2)

These are activities in which, starting from a data set, the student must organize them, prepare a frequency table and, finally, build up one or more selected graphs (Figure 2). All the exercises come from textbooks.

2.4. In example 1.6, the situation proposed is that of a teacher who applied a mathematics diagnostic test to his students. Suppose that the 53 results obtained by the teacher were:

STUDY ACTIVITY

4	1	5	6	4	2	4	3	5	2	4
8	6	6	0	6	10	6	8	7	7	5
6	9	6	7	3	7	7	7	10	5	8
4	9	11	6	9	6	8	9	6	10	
7	5	3	7	8	5	1	5	4	11	

Organize this data in a frequency distribution table and build up the corresponding bar graphs, frequencies and relative frequencies.

Figure 2. Representative example of the type of exercises (Exe.20)

In relation to the context of the exercises, most cases provide a set of data from an educational context: psychological or intelligence test scores, students' height measurements, exams, means of school transportation, preference for a school subject, and values from a students' opinion poll. However, exercises far removed from the educational context were also found: bulbs, salaries, stocks and shares sold, enterprises, currencies, daily consumption of water and measurements of earthquakes. Regarding this, Alicia stated that "it is difficult to find examples related to the area of education" (I1) although she recognized the need to find appropriate examples for these students.

Working Group 5

In another set of exercises, in addition to drawing the corresponding graph, the student is asked to *calculate and/or interpret some statistical value* (e.g. mean, median, and mode).

- 40 Alicia: I only worked with the histogram as the exercise I showed you, where I give the histogram and from there they have to give a distribution, for example, of frequencies and obtain their central or dispersion measurements starting from that graph. (I2)

Only 3 out of the 22 exercises that were analyzed asked for computing certain statistical values, and all of them were notes in Alicia's own handwriting, that is, she added these tasks to the exercises. In another 3 exercises, the idea was to *explore the graph(s)* and to answer certain questions related to their interpretation.

Instructions

Instructions are indications, activities, signals or orders given to help students understand different aspects of GR. Apart from exercises which are done on paper; instructions are in general oral, sometimes supported by some concrete object.

- Alicia: I would also ask them, based only on their diagrams (without looking at their data), to tell me how many people took exactly 23 minutes to get to school... (Q1a.2)

- Alicia: and that if these were not that clear to them, what they could include in the graph so that it would be more comprehensible for any reader (Q3b.2)

These instructions are often supported by questions.

Data and graphical manipulation

Data and graphical manipulation is a modification of data and graphs, with the help of different resources such as technology, with some particular aim. Specifically, to teach SG is a way to explore what happens along the axes of the graph, as well as the similarities and differences between graphs, for example with the stem and leaf and the histogram:

- 01 Luis: For example, when we have worked with graphs, I ask them to manipulate the graph itself in their minds. For example, in this class, I generally do that in the computer lab because we can handle the graphs with the projector and things, for example, suddenly, "What would happen if you turn the axis and change the graph?" because in the case of the stem and leaf graph... " in other words, if we turn it and leave it ... or turn the graph of the histogram, what happens? in other words, what similarities do you find between the two? Yes? And at that moment to start to see what particular elements are found in both of them. (I2)

Luis makes reference to the manipulation of data to generate the graph, or to the rotation of the axes or the graph itself. This strategy is not a systematic or habitual activity in his classrooms, but circumstantial, depending on what occurs during the lesson and it is aimed at the analysis of the graph during SPSS practice.

DISCUSSION

We have identified and characterized the instructional representations used by Alicia and Luis to teach SG, their types, purposes, points at which they are used and the role of teachers and students. Four of them are oral: definitions and explanations; questions; instructions and data and graph manipulation; and one of them is a concrete representation: examples and exercises (McDiarmid, Ball & Anderson, 1989). The teacher is the source of the questions, instructions, and data and graphics manipulation; while definitions, examples and exercises are taken from textbooks.

The instructional representations used by Alicia are teacher-centered whereas the ones used by Luis are thought to actively engage the students. Both of them resort to representations that allow interaction with the students like questions and data and graphical manipulation. Nevertheless, they are not previously planned activities but they arise from the dynamics of the classroom and the students' needs. These activities are only directed to reading data and reading between the data because they only aim to uncover the characteristics of the graphs and the relationship with the context.

Instructional representations used for teaching do not adequately nourish the development of statistical literacy in students and support materials reflect a passive approach to the teaching of graphing, and are quite different from: the recommendations of Meletiou & Stylianou (2003) to improve the comprehension of graphs; the developmental process of the cognitive levels of graph comprehension through interactive activities in the real contexts discussed by Curcio (1989); the information about general graph techniques and broad bibliography about graphs proposed by Pittenger (1995); the inclusion of updated texts with recent novelties regarding the way to approach the study of SG from Moore (2000) and Salkind (2000), and the practical applications presented in the *Teaching Statistics*, to mention just a few examples.

The results obtained suggest the need to better understand the role and effect of teachers' practices on students' learning statistics, such as the instructional representations. It is important to know and understand the nature and origins of instructional representations with the aim of designing training programs to help teachers to develop strategies to correct inappropriate beliefs and conceptions and to identify their prior knowledge on SG. These instructional representations can be a useful referent to train other teachers. Also, curriculum developers should consider teachers' limited knowledge and experience of data handling, and adopt an active graphing perspective that emphasizes the learners' role as interpreters and users of graphs in different moments and opportunities as analytical tools in solving problems in real contexts.

ASSESSING DIFFICULTIES OF CONDITIONAL PROBABILITY PROBLEMS¹

M. Pedro Huerta, Fernando Cerdán, M^a Ángeles Lonjedo, Patricia Edo

Universitat de València (Spain)

In this paper we define some difficulties of conditional probability problems and their measurements. We also show some results about the measurements of those difficulties in relation to the structure of problems, the contexts in which they are formulated and the sample of students that solved them. Finally, we also comment on the possible influences of these factors on the difficulties of problems.

INTRODUCTION

Some research reports inform us of the difficulties and the low success rate students have in solving tasks or problems involving Bayes' rule, or in general in solving conditional probability problems (Diaz & De la Fuente, 2007). These difficulties, it is said, depend on multiple factors. One of them is the cognitive complexity of the concept. Sometime this complexity is related to data format and the presentation of the data in problems (Estrada & Diaz, 2006; Huerta & Lonjedo, 2006; Lonjedo & Huerta, 2007), the context in which problems are put forward (Ojeda, 1996; Carles & Huerta, 2007) and the particular language with which conditionality and events are expressed (Maury, 1984). However, in general, these studies do not pay attention to the mathematical structure of problems and the context in which problems are put forward, at least not in a systematic way, factors that could be the reason why these problems are so difficult for students. Therefore, in the main, these factors are not taken into account in research results. Nevertheless, for us, they are influential factors on the students' success and on their difficulties in solving problems.

Due to their structure, we already know that we can consider a particular world of problems that is generated by means of a limited set of events and probabilities and the relationships between them (Huerta, 2009). Concretely, with two basic events, 16 probabilities and 18 ternary relationships² between these probabilities it is possible to generate this world of problems, which we call the *world of the ternary problems of conditional probability* (Cerdán & Huerta, 2007; Huerta, 2009). Many school problems belong to this world, as do a considerable number of tasks used in research, and they can be seen as instances of more general realistic situations (Carles & Huerta, 2007). For this reason their study, we think, is relevant.

Two particular pieces of research will be briefly examined in this paper. Apart from problems and the students' sample, both pieces of work share the same objectives and research methodology. Thus, we will firstly show the shared objectives and methodology and, in continuation, the results we have obtained up to now. Because the research is still not finished and due to the limitation number of pages available

for this report, only the global results of the research is shown along with a few comments on them.

OBJECTIVES

Our general objectives in this report are as follows:

1. To identify difficulties of conditional probability problems.
2. To introduce a measure of these difficulties and to carry out these measurements.
3. To consider to what extent the structure and context variables, considered as independent variables, are influential factors on the difficulty of the problems.

BACKGROUND: ELEMENTS OF THE FRAMEWORK

Several years ago, we began the study of the conditional probability problems in a systematic and methodical way (Lonjedo & Huerta, 2007; Huerta & Lonjedo, 2006; Cerdán & Huerta, 2007; Carles & Huerta, 2007; Lonjedo, 2007; Huerta, 2009; Edo, 2010). In these works the main object of research is the problems themselves. We identified a particular family of problems that we call *ternary problems of conditional probability*³, and with the help of a tool we call *trinomial graph* we carried out analytical readings of the problems (Huerta, 2009). An analytical reading of a problem is one that only pays attention to known and unknown data and their relationships but ignoring other elements of the problem that we know are also important. The analytical readings of problems on a trinomial graph allow researchers and teachers to determine the complexity of problems by means of their minimal graph, that is to say, the graph containing the minimum number of required relationships between known and unknown data that solves the problem. At the same time, we use the graph in order to identify problems in which the analytical reading is either arithmetical or algebraical⁴.

Because of the structure of data, ternary problems of conditional probability have been classified into four families and twenty sub-families (Lonjedo, 2007). The L-family of problems is characterized because every problem belonging to it has either 0 or 1 or 2 or 3 known conditional probabilities as a maximum. We call this Level of problems (Huerta, 2009). Related to each L-family, the C_iT_j -subfamily of problems is characterized by having 0, 1 or 2 known absolute (marginal) probabilities (the characteristic C_i of a problem) and one unknown probability, which is asked for in problem (the type T of the problem: Type T_1 if a conditional probability is asked for, T_2 if a marginal and Type T_3 if an intersection probability). Therefore, analytically speaking, for each family and sub-family, there is at our disposal a problem representing each one of the classes of problems. All these previous theoretical studies about problems permit us to construct questionnaires of problems to be administered (look at the examples in the annex).

All the above-mentioned are elements of the framework in which we place our research on conditional probability problem solving. This framework is still in progress but some of its components can be studied in Huerta (2009).

METHODOLOGY FOR ASSESSING DIFFICULTIES OF PROBLEMS

Bearing in mind all the above considerations, in order to construct questionnaires for assessing difficulties of problems we first must to decide on what independent variables they might depend. Thus, as task variables (Kulm, 1979) they are, and in order to investigate difficulties depending on structure and context variables, we fixed data format in every problem we put forward. All data referring to probabilities, either known or unknown was expressed in a percentage format, in the case of conditional probability. The reason for taking this decision can be found in various studies (e.g. Watson & Kelly, 2007; Lonjedo & Huerta, 2007). There is a general agreement that students think better using conditional frequencies than with conditional probabilities (see for example, Jones, Langrall & Mooney, 2007).

Thus, for each problem in the questionnaires, we define the following independent variables:

- *Structure variable*, given by the L-family and the C, T sub-family.
- *Context variable*, taking the following values: *Stat-Social*, *Stat-Health* and *Diag-Health*. (See the examples in the annex)

Depending on these two variables, we analyse students' resolutions paying attention to two main dependent variables: process and product variables. Difficulties of problems will be measured throughout the product variable, which takes the following values:

- *Tackled*. Number of students who tackle a problem. We say that a student tackles a problem if we can recognize that student undertakes the problem in some way.
- *Answer*. Number of students that answer the question posed in the problem. The answer to the question may be anything that students declare is the answer to the question posed.
- *Number*. Number of students that respond to the question of the problem by means of a correct number (a percentage in this case).
- *Description*. Number of students that attach an expression to the numerical answer, describing what this number is measuring. For a given number, the attached expression may be correct or incorrect whether the number is correct or not.

By means of these variables we define the following difficulties of problems:

- *Appreciated difficulty (ADP)* of a problem. This tries to measure students' difficulties before the process of solving the problem starts. Therefore, we are

supposing that students, after reading the problem, decide whether to tackle the problem or not. If they do not, we suppose it is because he/she appreciates that the problem is too difficult to be solved.

- *Problem's difficulty (PD)*. This difficulty will inform us to what extent it is difficult to give an answer to the question in problem.
- *Problem solution difficult (PSD)*. In relation to the previous difficulty, this one indicates to us how difficult is to give a correct answer to the problem.
- *Difficulty of Correct Description of the solution of the problem (CorrectDescD)*. In this case, we will obtain information about students' difficulties in giving a correct description of the event which is measured by the given number as a solution.

Differences between difficulties may be also appreciated through their measures and the way we measure them. Indeed, each one of these difficulties is measured in percentages, as a result of applying the following formulae:

$$ADP = 100 - \left(\frac{\text{tackled}}{\text{number of students}} \right) \times 100$$

$$PD = 100 - \left(\frac{\text{answer}}{\text{tackled}} \right) \times 100 \quad PSD = 100 - \left(\frac{\text{number}}{\text{tackled}} \right) \times 100$$

$$DescD = 100 - \left(\frac{\text{Description}}{\text{answers}} \right) \times 100 \quad CorrectDescD = 100 - \left(\frac{\text{CorrectDesc}}{\text{Description}} \right) \times 100$$

These difficulties are ranked in an $[0, 100]$ -interval. If a difficulty is measured by one 0, then this means that the problem does not pose that particular difficulty for any student whereas, on the opposite side of the interval, a difficulty which is measured by one 100 is present in the problem for all students.

RESULTS FROM TWO INDEPENDENT, BUT RELATED, RESEARCHES

1. Research on difficulties of problems from L_0 -family in students 15-16 aged without previous instruction on conditional probability.

The L_0 -family of problems can be divided into three sub-families (Huerta, 2009; Edo, 2010): C_0T_1 , C_1T_1 and C_2T_1 . There are 6 *basic-options* of problems representing to this family: one from C_0T_1 ; two from C_1T_1 ; and finally three from C_2T_1 . Accordingly, we constructed one basic questionnaire containing 6 problems. Owing to the fact we finally consider three contexts, in order to explore difficulties of problems depending on contexts, we prepared a total of 18 problems (one of them is given in the annex). All those problems were distributed into 6 questionnaires each containing 3 + 3 problems structurally isomorphic in pairs, but put forward in different contexts. For each questionnaire, and from students' resolution of problems, the possible influence of the context in the difficulties of problems becomes observable for researchers.

Working Group 5

Furthermore, at the same time, the influence of the structure of problems on these difficulties is also observable.

Questionnaires were administered to 165 students aged 15-16 years. Students solved problems during their mathematics class. They received no teaching on conditional probability.

The 990 students' resolutions provided the following global results (Table 1):

L ₀ -Problems' resolutions	Tackled	Answer	Number	Descriptions	Correct Desc
990	712	585	214	320	139
Difficulties (%)	ADP (28.1)	PD (17.8)	PSD (69.9)	DescD (45.3)	CorrectDescD (56.6)

Table 1: Global results en frequencies and difficulties of problems from L₀-family, in percentages.

If we take into account contexts and structures, the following tables (Tables 2 & 3) show us to what extent these are influential factors:

Structure/ Difficulty	ADP	PD	PSD	CorrectDes D
C ₀ T ₁	8.5	13. 5	59.5	69
C ₁ T ₁	27.2	17. 8	64.9	49.6
C ₂ T ₁	41.9	21. 4	65.5	51.4

Table 2: Difficulties of problems from L₀-family, depending on their structure (%)

Context/difficult y	ADP	PD	PSD	CorrectDes D
Stat-Social	20.9	13. 4	50	41.2
Stat-Health	23	18. 1	75	75.7
Diag-Health	40.3	23. 3	62.9	55.1

Table 3: Difficulties of problems from L₀-family, depending on contexts (%)

A deeper analysis of data suggests that the structure variable is an influential factor on the ADP and PD but not on the PSD. At the same time, the context variable is also an influential factor but not in the same manner as the structure variable does. Indeed, the Diag-Health context is more influential on every difficulty than the Stat-Social context, but the Stat-Health is the most influential context on PSD.

2. Research on difficulties of ternary problems (problems belonging to all families) in student teachers of high school mathematics.

In this research we studied the difficulties of ternary problems in a sample of 54 students doing a Professional Master in Secondary Mathematics Teaching at the Universitat of València (Spain). Not all of them were Mathematics graduates, as there were also graduates in Economics, Engineering and Architecture. However all of them had taken courses in probability during their regular studies.

In order to construct a questionnaire for assessing difficulties of problems, and given that we did not have prior experience on problem resolutions in students belonging to this sample, many previous decisions had to be taken into account. Only the experience with L_0 -problems could help us in doing this. In addition to this, previous to deciding what problems were going to be included in the questionnaire, we carried out a theoretical study of problems at every level, in order to determine *basic-options* of problems representing all families and sub-families, as had been done for the L_0 -family. Based on this study, among others, the following decisions were taken:

- The questionnaire consists of 7 ternary problems distributed as follows: One problem from L_0 -family, two problems from L_1 -family, three problems from L_2 -family, and one problem from L_3 -family. Among them, two problems have algebraical readings (one from L_2 -family and one from L_3 -family) and five arithmetical readings (some examples are given in the annex).
- In every problem, the data format is percentages.
- *Stat-social*, *Stat-Health* and *Diag-Health/man* are the contexts in which problems are put forward. Differences between Diagnostic Test in Health or Manufacture must be found in the elements of the context: people or manufactured pieces that are tested.
- If a problem has a complex analytical reading, either arithmetical or algebraical, we decided to avoid extra difficulties by contextualizing the problem in a context that we know is not very influential in the difficulties (see the above study results). This is the case, for example, in the problem that belongs to the L_3 -family. We already know that all problems from this family have an algebraical reading. On the other hand, from the previous research, we also know that Stat-social is a less influential context on the difficulties than the other two we considered. Therefore, we decided to formulate the problem from L_3 -family in a

Working Group 5

Stat-social context. Conversely, the problem from L₀-family is formulated in the most influential context, the Stat-Health context.

The 378 students' resolutions produced the following global results (Table 4):

Resolutions	Tackled	Answer	Number	Descriptions	Correct Desc
378	369	269	109	183	138
Difficulties (%)	ADP (2.4)	PD (27.1)	PSD (70.5)	DescD (32)	CorrectDescD (24.6)

Table 4: Global results en frequencies and global difficulties of problems in %

In a similar way, as was done in the above example, the following table (Table 5) provides us with information concerning the difficulties of the problems depending on the family to which they belong:

Level	ADP	PD	PSD	DescD	CorrectDesD
L ₀	1.8	16.7	68.5	28.9	28.1
L ₁	1	26.2	68.2	29.1	25
L ₂	4.3	28.4	69.8	38.7	27.9
L ₃	0	37	79.6	20.6	11.1

Table 5: Difficulties of problems depending the family they belong to, in (%)

These results suggest that the structure of problems belong to L₃-family is a more influential factor on PD and PSD than the other structures of problems. Perhaps, this influence is due to the fact that problems belong to L₃-family have algebraical readings.

And, finally, the following table (Table 6) shows the difficulties of problems depending, this time, on the contexts in which the problem was presented:

Context	ADP	PD	PSD	DescD	CorrectDesD
Stat-Social	1.8	35.2	71.7	28.1	14.9
Stat-Health	4.6	31.1	74.6	33.8	27.7
Diag-Health/Man.	1	11.2	64.5	34.7	33.9

Table 6: Difficulties of problems depending on contexts, in (%).

As in the above study, for this sample of students, the Stat-Health context is the most influential context on the PSD, but not in a meaningful way. The students, however, do not appreciate difficulties in problems because almost all students tackled the problems (ADP<5%).

DISCUSSION AND CONCLUSIONS

From a global point of view, we can conclude that ternary problems of conditional probability are difficult for students. Finding a correct answer to a problem, which is basically finding a conditional probability when three known data are given in a context, is a difficult task for every student, whether they are from secondary school or graduated ($PSD \geq 70\%$ for both samples of students). But, in general, at the beginning of the process, it seems that these difficulties are not especially appreciated by students (ADP between 28%, in the first study, and 2.4% in the second one) when they tackle the problems and try to give an answer to the question posed in them (PD between 17.8% and 27.1%). However, the answers given are usually incorrect in a very high percentage of cases (PSD of 69.9% in the first study, 70.5% in second one). Among those students who give an answer, some of them do not describe the number, given as the answer, by means of an expression representing the event and the number is its measure (45.5% in first, 32% in second). That is to say, for these percentages of students, the answer is simply a number, neglecting what this number is measuring and why. Among the students that describe the number with an expression, there is a percentage of students that do it incorrectly (56.6% in the first one, 24.6% in the second one). In some of these incorrect expressions it is usual to recognize one of the most common misconception in conditional probability: the conditional probability by intersection probability (Lonjedo & Huerta, 2007; Lonjedo, 2007), even if the given number is a correct number and the students are either at secondary school or graduated.

Structures and contexts appear as influential factors on the difficulty of problems, as we have shown above. Thus, for example, in the second study, we can see how the difficulty of giving an answer to problems increases as the number of known conditional probabilities in text of problems also becomes greater. However, when an answer is given, the difficulty of giving the correct answer is not as sensitive to this factor, except in the L_3 -problem. It seems that there are other structure-based factors that are influential on this difficulty. Indeed, every problem from L_3 -family has an algebraical reading.

Finally it is reasonable to think that contexts are an influential factor on the difficulties of problems. But difficulties are not sensitive to these influences in the same measure. Thus, while the Diag-Health context is an influential factor on the appreciated difficulty of the problem for secondary school students, this is not the case for future teachers. This could mean that the context is not a well-known context for the former but that it is for the latter. On the contrary, if we pay attention to the problem solution difficulty, it is common to both samples that the Stat-Health context is the most influential. Considered in an isolated way or in combination with structure, difficulties are very sensitive to it. This context is characterized because it belongs to a more general situation called *Les situations causalistes* (Henry, 2005), that particularly in the Health context is very influential: every time someone treats

Working Group 5

himself/herself with a medicine, then he/she is cured of the illness, but if this is not so then he/she does not. Obviously, there are no conditional probabilities involved.

Although the results we just show in this report are global and their analysis is not yet finished, some suggestions can be made for the future, both for researchers in probabilistic education and for mathematics teachers. Researchers could take into account that tasks used to investigate students' behaviour have different difficulties depending on the structure of their data and the context chosen for putting forward the task. It is a hypothesis to suppose that varying structure and context in tasks imply that students' behaviour may also be different in each case, or not. This hypothesis might be contrasted.

On the other hand, teachers should be aware that there are families of conditional probability problems that contain problems with different difficulty degrees, again depending on structures of data and context. Perhaps a teaching model could be considered which was based on solving problems belonging to these families, organized sequentially, and exploring through them as contexts as possible. This could potentially be a good way to improve students' competence in solving conditional probability problems.

NOTES

[1] EDU/2008-03140/EDU Project, funded by Ministerio de Ciencia e Innovación, España.

[2] These are examples of them: $p(A) + p(\bar{A}) = 1$; $p(A | B) \times p(B) = p(A \cap B)$. They may be either additive or multiplicative.

[3] *Ternary problems of conditional probability* are defined as problems that fulfil the following conditions: (1) One conditional probability is involved, either as known data or as unknown data or both; (2) Three probabilities are known; (3) All probabilities, both known and unknown are connected by ternary relationships.

[4] If a problem has an algebraical reading then it means that, in order to solve it, an extra-data will be required (an unknown). If it has an arithmetical reading, then it does not.

Annex: Example of problems used in the researches

Problem in Level L₀, L₀C₀T₁-subfamily. Stat-social context. 15-16 years old students. The 4th grade class is made up of 30 students between boys and girls. Among the students, there are 7 boys who wear glasses, 10 girls who do not use them, and 8

Working Group 5

boys who do not wear them. Among boys in the class, what percentage wears glasses?

Problem in Level L_1 , $L_1C_1T_1$ -subfamily. Diag-Health context. Graduated students.

A population at risk for tuberculosis is subject to the tuberculin test. Different studies show that 57% of the population suffers from tuberculosis, and among those with tuberculosis 59.6% give positive in test. In addition, it is known that 13% did not have tuberculosis but is positive in the test. Among those who are positive in the test, what percentage is suffering from tuberculosis?

Problem in Level L_2 , $L_2C_1T_1$ -subfamily. Stat-Health context. Graduated students.

A population suffers from eye infection. Of these, 42% are treated with a new antibiotic. The results show that, of those treated with the antibiotic, 83.3% were cured, and people who have not cured 14.9% were treated with the antibiotic. Among those who have been cured, what percentage has not been treated with the new antibiotic?

Problem in Level L_3 , $L_3C_0T_2$ -subfamily. Stat-social context. Graduated students.

Of the girls in a high school, 37.5% wear glasses. Of the boys, 28.6% wear glasses. Of those who do not wear glasses, 50% were boys. Among high school students, what percentage are girls?

USING A RASCH PARTIAL CREDIT MODEL TO ANALYZE THE RESPONSES OF BRAZILIAN UNDERGRADUATE STUDENTS TO A STATISTICS QUESTIONNAIRE

Verônica Y. Kataoka¹, Claudia Borim da Silva², Claudette Vendramini³, Irene Cazorla⁴

¹University Bandeirante of São Paulo, ²University São Judas Tadeu, ³University São Francisco, ⁴State University of Santa Cruz

The aim of this study was to analyze the degree of difficulty of questions included in a statistical literacy questionnaire answered by 1343 Brazilian undergraduate students who were studying a statistics course for the first time. The responses to the questionnaire, which was made up of multiple-choice items, were classified according to the structure of the observed learning outcome (SOLO) taxonomy, and the results were analyzed using item response theory. Questions that involved the calculation of measures of central tendency with an outlier and variability associated with reading a graph presented the highest degree of difficulty, implying that these areas are not explored in basic education. Considering the importance of measures of central tendency and spread for statistical literacy, it is important to continue promoting the improvement of statistics education in Brazilian schools.

Keywords: SOLO taxonomy; item response theory; statistics questionnaire

INTRODUCTION

In Brazil, at the end of the 1990s, following the publication of the National Curricular Parameters (Parâmetros Curriculares Nacionais – PCN), basic statistical concepts were formally incorporated into the mathematics curriculum in primary and middle schools (Brazil, 1997, 1998) and in high schools (Brazil, 2002, 2006). With regard to teaching statistics, these curricular guidelines are in line with Watson's (2003) suggestion that, in order to attain statistical literacy in adults, it is important that students, whilst still in school, are exposed to statistical and probabilistic concepts. Wallman (1993, p. 1) was one of the first authors to define statistical literacy as:

[...] the competence to understand and to critically assess statistical results that permeate our daily lives, together with the capacity to recognize the contribution that statistical thought can provide to public, private, professional, and personal decisions.

This idea of statistical competence forms the cognitive component of Gal's (2002) definition of statistical literacy. This author supplements his definition with the component of disposition, which relates to the competence of individuals to discuss or communicate their reactions to statistical information, such as their understanding of the meaning of information, their opinions on the implications of such information or their considerations in relation to the acceptance of the conclusions provided (Gal, 2002, pp. 2-3).

Working Group 5

According to Gal (2002), the cognitive elements of statistical literacy are: (a) mathematical knowledge; (b) contextual knowledge; (c) literacy skills (i.e., being able to understand written or oral text and tabular or graphic displays); and (d) the competence of developing critical questions. The author suggests five areas of basic statistical knowledge that together make up statistical literacy: (a) knowing why data are needed and how data can be produced; (b) familiarity with basic terms and ideas related to descriptive statistics; (c) familiarity with graphic and tabular displays and their interpretation; (d) understanding the basic concepts of probability; and (e) knowing how statistical conclusions or inferences are reached.

Considering the literacy model suggested by Gal (2002) and keeping in mind the Brazilian context, which, for over 10 years, has included curricular guidelines for teaching statistics in basic education (consequently, the Brazilian students who entered university after 2008 should have finished their basic education with a minimum level of statistical literacy), this research aims to answer the following questions: do university students learn about these five topics and therefore attain a basic knowledge of statistics during their school education? Which topics are easier or harder for students? The answers to these questions may guide pedagogical initiatives that will contribute to the improvement of the teaching and learning of statistics in Brazilian schools.

In order to answer the questions above, the objective of this study was to use item response theory (IRT) to analyze the degree of difficulty of questions answered by undergraduate students who were studying statistics for the first time. The questions covered the statistical content included in the PCN and were fully in line with the components of Gal's (2002) model.

METHOD

This study was conducted with 1343 undergraduate students from five Brazilian universities in three different states. The following instruments were applied in the first semester of 2009: a statistical questionnaire and a profile questionnaire which included questions relating to the students' socio-educational characteristics, knowledge and utilization of statistics in their daily lives, both personal and professional. The data were collected during the first two weeks of the semester with the objective of minimizing the influence of formal learning on the results of both questionnaires.

The age of the participants ranged from 17 to 58 ($M = 22.3$, $SD = 5.3$), and 52.0% were male. In terms of specialty, 35.4% were studying an exact area of science, 14.5% were studying biology/health and 49.7% were studying human sciences (0.4% did not answer). The students were distributed across two private universities in São Paulo (40.6% and 24.3%), a state university in São Paulo (7.2%), a private university in Rio Grande do Sul (4.2%) and a federal university in Pernambuco (23.6%).

Working Group 5

Of the students involved in this survey, 41.7% and 31.0% considered statistics to be very important for their personal capabilities or as a basic requirement for other undergraduate courses respectively. Only 21.0% of the students could not imagine other areas for which statistics would be important. In addition, 35.7% of students considered statistics to be moderately relevant to their daily lives.

Statistical questionnaire

The statistics questionnaire included seven multiple-choice questions involving the following content: measures of central tendency and spread; probability; reading and interpreting two-way tables and confidence intervals. All of this content, except confidence intervals, is included in the Brazilian curricular guidelines for schools. Despite the fact that confidence intervals are not a part of the Brazilian school curriculum, one question was included in order to assess whether or not this concept, which appears frequently in the media, should be part of students' extra-curricular knowledge.

The first question (Q.1), covering measures of central tendency, was adapted from the work of Watson and Callingham (2003) and Garfield (2003), and required the students to choose the most accurate measure to represent the weight of the an object measured by nine students using the same instrument. The sample contained an outlier. The expected response was that the outlier should be removed and the mean of the other remaining values should be calculated. There were three questions relating to probability. The second question (Q.2) was taken from the work of Watson and Callingham (2003) and Garfield (2003) and required the interpretation of a simple probability (a bottle of medicine has the following notice: "For application to areas of skin, there is a 15% chance of developing a rash."). The third question (Q.3) was suggested by Garfield (2003), and asked studentes to analyse the accuracy of a weather forecast (the meteorologist identified in his reports the days on which there was a 70% probability of rain). The expected response was the selection of an option that included the value of 70% in the interval.

Statistics from the State Highway Dept. are presented in the table below, providing information about the number of accidents (fatal or otherwise) with victims, and the condition of the driver (sober or drunk):

Driver/ victim	Non-fatal	Fatal
Sober	1228	275
Drunk	239	86

Would you say that the condition of the driver (sober or drunk) affects the occurrence of fatalities? What is this probability? (a) Sober, $P(\text{sober}|\text{fatal}) = 275/361$ (b) Drunk – $P(\text{drunk}|\text{fatal}) = 86/361$ (c) Sober – $P(\text{fatal}|\text{sober}) = 275/1503$ (d) Drunk – $P(\text{drunk}|\text{fatal}) = 86/325$ (e) None of the above

Figure 1: Fifth question from the statistics questionnaire

Working Group 5

The fifth question (Q.5) required the interpretation of conditional probability in a problem suggested by Kataoka et al. (2008) (Figure 1). For this question, we expected the students to answer that the condition is the driver being drunk, and to calculate $P(\text{fatal}|\text{drunk}) = 86/325$.

A research agency held a survey in order to assess voters' intentions in one State Government election. A total of 6000 voters in 26 cities were randomly selected. Based on this research, in which 41% of voters in the poll said that they intended to vote for candidate A, 23% for candidate B, 21% candidate C, and 15% for one of the remaining candidates, and considering that the margin of error was 2% with a 99% degree of confidence, is it possible to predict who will dispute the run-off election with candidate A? Choose one answer:

- (a) Yes, candidate B (b) Yes, candidate C (c) No, it could be candidate B or C
(d) No, more information is required (e) None of the above

Figure 2: Excerpt from fourth question from the statistics questionnaire

The fourth question (Q.4), which was developed by the authors of the present work, covered the confidence interval for proportion, and required the student to analyze the results of an electoral poll regarding the state government (Figure 2). For this question, we expected that the students would add the margin of error to the percentage of votes for candidates B and C, and that a technical tie occurs between the two candidates, and it did not allow the students to choose between them.

The principal of School X was interested in assessing students' reading skills. Therefore, he asked for the number of books read by the girls and boys at the school during the first semester. The results are presented in the bar chart below. Based on the graph, the principal concluded that (choose one answer only): (a) The variability of the number of books read by boys is higher, because they read between two and eight each; (b) The variability of the number of books read by girls is higher, because there are many girls who read six to eight books; (c) The variability of the number of books read by girls is higher, because on average they read more books; (d) The variability of the number of books read by girls and boys is almost equal; and (e) None of the above.

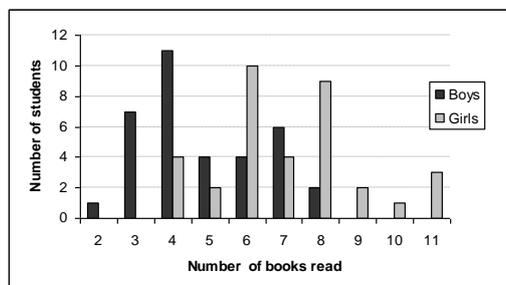

Figure 3: Excerpt from sixth question from the statistics questionnaire

Working Group 5

Questions six and seven were developed by the authors and were related to the concept of variation in the context of a group comparison. This concept is considered by Wild and Pfannkuch (1999) to be a central element of statistical thinking. In both questions, data about the groups were presented graphically, with one question about variability and another about standard deviation. In question six (Q.6), a double bar chart was presented in order to allow the students to compare variability between the groups (Figure 3).

Data analysis

The responses of the students were classified using content analysis (Bardin, 1995) and reclassified based on hierarchical levels of the structure of the observed learning outcome (SOLO) taxonomy devised by Biggs and Collis (1991) (Table 1).

Q.	Description of categories
1	0. Blank response or use of an inadequate method 1. Calculates the mean with all of the values or notices the outlier 2. Uses a method in which the result is a good representation of the data e.g. mode, median etc. 3. Removes the outlier (15.3) and calculates the mean
2	0. Blank or incorrect response 1. Answers considering only informal interpretation (small or good chance) 2. Answers considering only one numerical interpretation of 15% (approximately 15 in 100) or a numerical and informal interpretation
3	0. Intervals that do not contain 70% 1. Notices that for all of the days, the forecast was 70% and, of these, 95% and 100% of these days had 70%. 2. Interval that contains 70%
4	0. Blank response or incorrect interpretation 1. Chooses one of the probable candidates 2. Notes that the margin of error does not allow selection between candidates B and C
5	0. Blank reply or calculates simple probability 1. Calculates the conditional probability, but uses the incorrect sample space 2. Calculates the correct conditional probability
6	0. Blank reply or reads the graph with only one measure of central tendency 1. Reads the total range only 2. Correct comparison, taking into consideration variation (total range and density frequency)
7	0. Blank reply, or reads the graph with one measure of central tendency only 1. Reads the total range only 2. Correct comparison, taking into consideration variation (total range and density frequency)

Table 1: Description of the categories of each question according to the SOLO taxonomy

Working Group 5

According to Biggs and Collis (1991), the SOLO taxonomy consists of: the prestructural level (code 0), in which the student makes basic mistakes and provides insufficient answers; the unistructural level (code 1), in which the student presents several conclusions that could be correct, but which are not mutually consistent and focus on only one relevant aspect of the problem; and the multistructural level (code 2), in which the student notices more than one relevant aspect, but does not integrate them, meaning that their answers may be inconsistent. The relational level (code 3) was not used in the analysis, with the exception of the question about the measure of central tendency, in which one of the options required the student to suggest a method with which to define a measure that would represent the set of weight measures that included an outlier (Table 1). In this level (code 3), the student presents a conclusion that could potentially relate to all of the relevant aspects, showing an overall degree of consistency.

Each response category for each question was denominated as an item and is represented by the number of the question followed by the category value; for example, the notation 2.1 means question 2 and the response which was classified as category 1. After classifying the responses, the items included in the instrument were analyzed based on a Rasch partial credit model (Rasch, 1980; Masters, 1982), which is an extension of the Rasch model for dichotomous items. This model is suitable for the analysis of responses obtained from two or more ordinal categories (polytomic items), such as the categorization of responses based on the SOLO taxonomy. The quality of the items was analyzed using the difficulty/adjustment measure of the model (*infit* and *outfit*) and the correlation between the question and the Rasch measure.

RESULTS AND DISCUSSION

In the profile questionnaire, the students were asked if they had already studied statistics and probability in basic education; 30.5% of them said yes, 38.3% said that they had studied these two subjects but that they did not remember the content and 31.2% said that they had never studied statistics or probability. In another question, when asked which terms they knew and were able to recall, the most familiar terms were: percentage; mean; probability; frequency and sample (Figure 4).

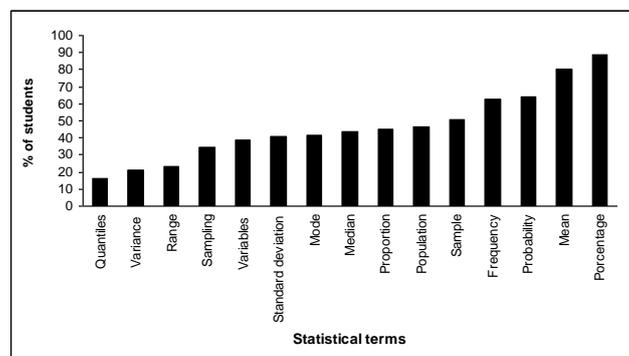

Figure 4: Percentage of statistical terms that students knew and could interpret

Working Group 5

These responses relate to the students' educational backgrounds at school, as the questionnaire was conducted during first two weeks of the semester. As previously stated, of the content covered in the statistics questionnaire, the students were not expected to be (formally) aware of confidence intervals.

The IRT results indicate a good fit to the Rasch model, because the infit/outfit rates of questions were within acceptable limits (between 0.5 and 1.5) and the correlation was higher than 0.2 (from 0.39 to 0.52). The difficulty of the questions ranged from -0.93 (Q.4) to 0.65 (Q.7). The skill level of the 1343 students involved in the present survey varied from -2.74 to 2.90 ($M = 0.14$; $DP = 0.78$), indicating that the difficulty level of the questionnaire ($M = 0.00$; $DP = 0.62$) was slightly below the skill level of the participants.

The two questions with a greater level of difficulty were related to variation: Q.6 (with a difficulty index of 0.58) and Q.7 (with a difficulty index of 0.65), despite the fact that 21.4% and 41.1% of the students confirmed that they knew and were able to interpret the terms "variance" and "standard deviation" respectively (Figure 4). In this case, what probably happened is that students know how to compute a standard deviation, but the interpretation of a standard deviation associated with reading a graph is not taught in basic education. Silva and Coutinho (2008), in their study, noted that even though many mathematics teachers reported having an understanding of standard deviation, the majority only presented a informal level of variation reasoning, and this affected the correct interpretation of this measure.

	Item	Logit	% response		Item	Logit	% response
Increasing difficulty ↓	1.0	-1.14	7	Increasing difficulty ↑	1.3	1.52	4
	2.0	-0.89	16		5.2	0.71	27
	4.0	-0.88	13		6.2	0.71	25
	3.0	-0.61	27		7.2	0.69	20
	5.0	-0.32	45		3.2	0.49	47
	7.0	-0.24	45		4.2	0.44	61
	6.0	-0.22	49		2.2	0.38	67
	4.1	-0.22	26		1.2	0.31	37
	2.1	-0.05	17		7.1	0.20	35
	1.1	0.02	52		5.1	0.19	28
6.1	0.14	26	3.1	0.15	26		

Table 2: Order of item difficulty (according to logit) and % of response for each item in the questions

According to the analysis of item difficulty (Table 2), we noted that, among the categories with a SOLO unistructural level, item 4.1 (question 4, category 1) presented the least difficulty (without considering the answers in the prestructural level – code 0), despite the fact that the response was associated only with reading a percentage value in a simple table, without considering the margin of error presented in the question (Table 1). In addition, 61% of the responses (item 4.2) were classified

Working Group 5

at the highest level expected for this question. This result makes sense, as 88.5% of the students stated that they knew about and were able to interpret the term "percentage" (Figure 4).

The most difficult item (logit 1.52) with the lowest percentage of answers (4.0%) was the first question in category 3 (item 1.3), even though 80.6% of the students stated that they knew and were able to interpret the term "mean" (Figure 4). A probable explanation is that measures of central tendency are taught in basic education without the presence of outliers, which requires an extended grasp of the subject by the student. This difficulty was also identified by Garfield (2003) and Watson and Callingham (2003).

With regard to the three questions about probability (Q.2, Q.3 and Q.5), the students had difficulty with the items corresponding to categories 1 and 2, varying from -0.05 to 0.71. The highest proportion of answers in category 2 was 67.0% for the second question (Table 2). The results of Q.2 were as expected, as 64.1% of the students said that they knew about and were able to interpret the term "probability", but not conditional probability, which was the concept which was required in order to discern the correct reply to the fifth question (Figure 4). Students' difficulty with questions involving the concept of conditional probability has already been identified by several researchers, such as Estrada and Díaz (2006), Díaz and de la Fuente (2007) and Díaz (2010).

FINAL CONSIDERATIONS

The IRT analysis helped to improve the interpretation of these results, taking into account that this method not only considers the students' total score, but also the questionnaire response vectors that can vary for the same total score. In addition, it is important to consider that in accordance with IRT, the items' level of difficulty and the skill level of the students were measured on the same scale, thus allowing a more detailed analysis of the results.

In a global analysis, the results seem to indicate that Brazilian students enter university with a basic knowledge of statistics and probability. However, the questions that involved the calculation of measures of central tendency with an outlier and variability associated with reading a graph had apparently not been explored in basic education, and for this reason they presented the highest degree of difficulty. According to this point of view, it is probable that the principles of statistical literacy have not yet been fully incorporated into the teaching and learning of statistics at this educational level. The results of the present survey are an indication that a change is needed in Brazilian schools in order to put into practice the PCN recommendations as well as the statistical literacy model suggested by Gal (2002).

The next phase of the present research will be to investigate the results of a post-questionnaire that was applied to the same students after their experience with the

statistics course at undergraduate level, thus checking whether or not these difficulties persist after a formal university education in statistics.

ATTITUDES OF TEACHERS TOWARDS STATISTICS: A PRELIMINARY STUDY WITH PORTUGUESE TEACHERS

José Alexandre Martins¹, Maria Manuel Nascimento² and Assumpta Estrada³

Instituto Politécnico da Guarda (IPG) and UDI-IPG, Portugal¹, Universidade de Trás-os-Montes e Alto Douro (UTAD) and CM-UTAD, Portugal², Universitat de Lleida, Spain³

In this paper, we will discuss teachers' attitudes towards statistics, as we believe that these attitudes have a key role in the teaching and learning process. We will examine the attitude concept, review the literature regarding scales for the measurement of attitudes towards mathematics and statistics, and present and analyse some of the results of a questionnaire/scale applied to a sample of Portuguese teachers.

INTRODUCTION

This work is part of a preliminary study of the attitudes of teachers from the second (ages 10 and 11) and third (ages 12 to 14) cycles of basic education in Portugal towards statistics. It could be argued that without the full commitment of teachers to the teaching and learning process, it would be very difficult to implement any significant changes in the ways in which statistics is taught. Nóvoa (1992, 30) stated that “the schools can not change without the participation of the teachers”. In addition, Gal and Ginsburg (1994, 1) wrote:

While statistics educators have focused on improving the cognitive side of instruction, i.e., the skills and knowledge that students are expected to develop, little regard has been given to non-cognitive issues such as students' feelings, attitudes, beliefs, interests, expectations, and motivations. (...) We believe that further attention to such factors is warranted, as they may contribute to students' difficulties in learning basic concepts in statistics and probability.

Therefore, it is necessary for this approach to include aspects such as attitudes, beliefs, interests, expectations and motivations which are associated with statistics, because teachers must go beyond the transmission of knowledge, positive attitudes, both in terms of the discipline and of its contents, and in relation to students, schools and education in general.

In this work, we will provide a brief summary of the current understanding of attitudes towards statistics and the Scale of Attitudes Towards Statistics (Escala de Actitudes hacia la Estadística de Estrada EAEE) (Estrada, 2002). We will also begin to analyse the results of a survey of in-service Portuguese teachers in the second and third cycles of basic education. The main purpose of this survey is to analyse Portuguese teachers' attitudes towards statistics.

ATTITUDES TOWARDS STATISTICS

Theoretical and empirical issues related to attitudes have received a great deal of attention over recent years, and different perspectives regarding what attitudes are have emerged. In conceptualising the affective domain in relation to mathematics education, McLeod (1992) distinguished between emotions, attitudes and beliefs and conceptualised attitudes as learned predispositions to respond positively or negatively to given objects, situations, concepts or people. As such, according to Aiken (1980, p. 2), the attitudes comprise three dimensions: cognitive (beliefs, knowledge), affective (emotional, motivational), and performance (behaviour, active tendencies). More recently, Phillip (2007) described attitudes as ways of acting, feeling or thinking, which (in this case) indicate the disposition or opinions of a person with regard to statistics.

Attitudes are intense feelings which are relatively stable, and which result from positive or negative experiences encountered whilst learning a subject (in this case statistics) over a period of time. Students may have these experiences of statistics at school, or as part of an informal extra-curricular learning process. In other cases, students transfer their negative feelings towards mathematics onto statistics (Gal & Ginsburg, 1994).

Within the field of statistics education, the level of interest in the beliefs, attitudes, and expectations that students bring to the classroom is increasing, as “such factors can impede learning of statistics, or hinder the extent to which students will develop useful statistical intuitions and apply what they have learned outside the classroom” (Gal & Ginsburg, 1994, p.1). These authors have suggested that statistics teachers should not focus solely on the transmission of knowledge and skills, because if students encounter difficulties whilst learning about statistics, this experience might impede their desire to receive further instruction. They may also fail to appreciate the potential usefulness of statistics in their professional and personal lives. These theories are particularly relevant in terms of the training which teachers receive.

In the last two decades, a large number of tools with which to measure attitudes and anxiety levels relating to statistics have been developed (Gal & Ginsburg, 1994; Carmona, 2004). Three of the most widely used instruments with which to measure attitudes towards statistics are Wise’s (1985) Attitudes Towards Statistics Scale (ATS), Roberts and Saxe’s (1982) Statistics Attitude Survey (SAS) and Schau, Stevens, Dauphine and del Vecchio’s (1995) Survey of Attitudes Towards Statistics (SATS).

These scales have been validated using samples of students at college or university, but not among teachers or future teachers. For this purpose, Estrada (2002) proposed and developed a Scale of Attitudes Towards Statistics (EAEE), which was applied to prospective and in-service teachers.

Working Group 5

The EAEE is a combination of three scales: the SAS (Roberts & Bilderback, 1980) and the ATS (Wise, 1985), which are the most commonly used in an international context, and the Spanish scale proposed by Auzmendi (1992).

Based on these three scales, a list of 36 items was developed, consisting of both positive (affirmative) and negative items in order to avoid the problem of acquiescence (Morales, 1988), and including various pedagogical and anthropological components, as described by Estrada (2002) and Estrada et al. (2004). These items were submitted to a panel of expert judges, and, following their evaluation, a final scale consisting of 25 items (14 affirmative and 11 negative) was proposed. The distribution of items according to the various components is provided in Table 1.

Teaching component	Anthropological component		
	Social	Educational	Instrumental
Affective	1, 11, 25	7, 12, 23	10, 13, 16, 20
Cognitive	2, 19, 21	4, 6, 17	3, 24
Behavioural	9, 18	8, 15, 22	5, 14

Table 1: Components of attitudes as assessed in the EAEE

In this study, attitudes were measured using a 25-item Likert scale. The independent variables we considered were: gender, group (prospective vs. in-service teachers), the number of previous courses taken in statistics, specialty (the subject in which the prospective teachers were specialising or the subject which the teachers taught) and the number of years of teaching experience in mathematics (for in-service teachers).

METHOD, RESULTS AND DISCUSSION

In this study, we analysed the results of a survey of 71 teachers in the second and third cycles of basic education in Portugal. The survey was distributed in the teachers' annual meeting (ProfMat 2008, 2-4 September) and in some of those cycles schools in Seia, S. Romão, Oliveira do Hospital and Lisbon. This allowed us to obtain a sample of the 212 teachers who were involved in these teaching cycles in Portugal at the time. The EAEE (Estrada, 2002) was translated and adapted to the Portuguese language by the authors, and two items were added. These two new items were related to the use of technology in statistics classes. In Table 1, these items were included in the section in which the behavioural components of teaching overlap with educational and anthropological components (items 26: "In statistics classes, I need to use the computer and the Internet in order to perform the tasks that I have set", and 27: "I do not need to use a calculator in order to perform the tasks that I set in statistics classes"). All of the items comprised statements, to which the

Working Group 5

respondents marked their level of agreement or disagreement on a five-point Likert type scale (from 1: strongly disagree, through 3: neither agree nor disagree, to 5: strongly agree). Of the 27 items, 15 were positively worded (for instance, question 26) and 12 were negatively worded (for instance, question 27). For the 12 negatively worded items, the scale was reversed when the responses were analysed (from 1: strongly agree, through 3: neither agree nor disagree to 5: strongly disagree), meaning that the teachers' attitudes towards statistics could be measured in terms of the total score for all of their answers. The minimum score was 27, and the maximum was 135, with a mid-point of 81. In the data analysis, statistical software and a spreadsheet were used.

Of the 71 respondents, 61 (86%) were women. With regard to the teachers' years of experience, we found a mean of approximately 15 years, with a standard deviation (SD) of 7.8 years. The distribution is shown in Figure 1 (left), in which we can see the number of new teachers and those with far more experience.

The cycles in which the teachers were working are also shown in Figure 1 (right). Of the 71 respondents, only 51 indicated the subject in which they had graduated (we think that the 20 missing answers may have been a result of the presentation of the question). Of these respondents, around 78% were mathematics graduates (in teaching or other areas) and around 6% were economics graduates. These 51 respondents had graduated from a total of 13 different subject areas.

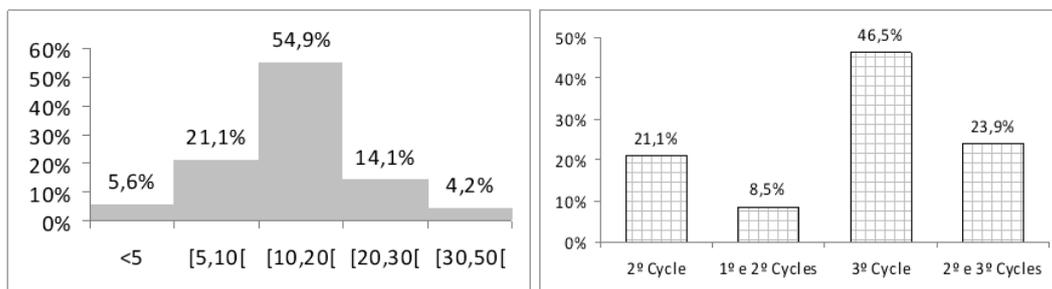

Figure 1: Years of experience of teaching (left) and teaching cycles (right)

Table 2 provides an analysis of each item. The mean value and SD were computed for a positive scale, meaning that all of the scores are comparable. The nearer to five they are, the stronger the indication of a positive attitude towards statistics. In contrast, if the scores are closer to one, this indicates a negative attitude towards statistics.

	Item	Mean	SD
1	Some statistical information transmitted in television programmes bothers me	2.7	1.2
2	Statistics helps me to understand today's world	4.2	0.9
3	Through statistics, one can manipulate reality	1.6	0.7

Working Group 5

4	Statistics is fundamental to the basic training of future citizens	4.3	0.6
5	I solve day-to-day problems using statistics	3.6	0.7
6	We should not teach statistics in schools	4.9	0.3
7	I have fun in classes in which I teach statistics	3.8	0.7
8	I find that statistical problems are easy	3.8	0.9
9	I do not understand the statistical information that appears in the media	4.1	1.0
10	I like statistics, because it helps me to fully understand the complexity of certain issues	3.7	0.9
11	I feel intimidated by statistical data	4.4	0.8
12	I find the world of statistics interesting	4.0	0.7
13	I like serious work which involves statistical analysis	3.9	0.8
14	I do not use statistics outside of school	3.4	1.0
15	When I attended statistics classes, I did not fully understand what was said	3.7	1.1
16	I am passionate about statistics because it helps me to view problems objectively	3.3	0.8
17	Statistics is easy	3.5	1.0
18	I find it easier to understand the results of elections when they are shown using graphics	3.7	1.0
19	Statistics are only good for people in scientific areas	4.7	0.5
20	I like to solve problems using statistics	3.8	0.7
21	Statistics is worthless	4.8	0.7
22	If I could eliminate part of the syllabus, it would be statistics	4.6	0.9
23	I usually explain statistics problems to my colleagues if they do not understand	2.7	0.9
24	Statistics helps people to make better decisions	3.8	0.7
25	When I read, I avoid statistical information	4.4	0.6
26	In statistics classes, I need to use the computer and the Internet in order to perform the tasks that I have set	3.2	1.1
27	I do not need to use a calculator in order to perform the tasks that I set in statistics classes	3.7	1.1

Working Group 5

Table 2: Mean and SD for each item

The items with the highest mean scores (> 4.5) were 6, 19, 21 and 22 (all of them are negatively worded, we note again). In addition to indicating positive attitudes towards statistics, these results reinforce our idea that these mathematics teachers seem to be aware of the importance of statistics as a part of the mathematics curriculum, as well as its importance for citizens in the modern world.

The items with the lower mean scores (< 3) were 1, 3 (both of them are negatively worded, we note again) and 23. The result for item 23 seems to indicate a lack of collaboration between colleagues. With regard to items 3 and 1, we suspect that the respondents “wrongly” understood the meaning of the statements.

It is important to note that the two items which were related to the use of technology in statistics classes (26 and 27, this last one is negatively worded) had mean scores of 3.24 and 3.68 and SD values of 1.08 and 1.09 respectively. These results may indicate that there is still room for improvement, as teachers do not make use of technology in their classrooms.

Figure 2 indicates the frequencies of the total scores. From the graph, we can see that most of the respondents had a mean total score which was higher than 81 (the level of indifference). The modal score is 104, and the mean is 102.58, with a SD of 8.38 and a slight negative skewness (-0.53).

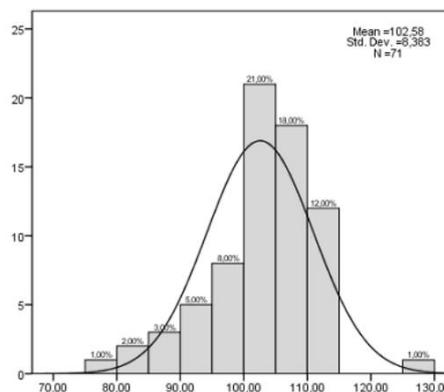

Figure 2: The frequencies of the total scores

Teaching component	Anthropological component			Total
	Social	Educational	Instrumental	
Affective	3.83	3.67	3.70	3.67
Cognitive	4.55	3.99	2.73	3.99
Behavioural	3.94	3.77	3.48	3.77
Total	4.13	3.80	3.40	3.80

Table 3: Mean scores according to the components of attitudes

Working Group 5

Table 3 presents the respondents' mean scores according to the components of attitudes. According to a briefly analysis of these scores, none of the components – teaching or anthropological – presented high mean scores (> 4.5) or low mean scores (< 3). Nevertheless, a high mean score arises when the cognitive component of teaching is combined with the social anthropological component, and a low mean score can be obtained by crossing the cognitive component of teaching with the instrumental anthropological component.

We also studied the reliability of this survey; we obtained a Cronbach's alpha of 0.749 as a coefficient of internal consistency, and, taking into account the small number of respondents for this preliminary study, we believe this to be a reasonable value. Furthermore, in order to test the effect of each item on the internal consistency of the scale, we ran 27 more tests, using only 26 items at a time. For these 27 tests, the values for Cronbach's alpha varied from 0.725 to 0.768.

We analysed the influence of gender on attitudes towards statistics, and we did not find any statistically significant differences ($F(1, 69) = 1.582$, p -value: 0.213). However, we found that the mean total score for women, which was 103.8 (SD 1.09), was higher than the mean total score for men, which was 99.5 (SD 2.31). This result is in accordance with the results of Estrada et al. (2004).

With regard to the effect of their years of experience on teachers' attitudes towards statistics, despite a generally positive attitude, no statistically significant differences were found ($F(4, 66) = 0.367$, p -value: 0.831). Nevertheless, we found that the mean total score was higher and the SD was lower if the respondents had been teaching mathematics for fewer years, and vice versa. This result may be related to specific training in statistical and pedagogical approaches and teaching methods which the teachers received during their initial training.

Regarding the influence of the cycles of education on the teachers' attitudes towards statistics, we noticed that the mean total score was relatively high, but with no statistically significant differences ($F(3, 67) = 0.963$, p -value: 0.415). Slightly higher scores were observed in the case of teachers who taught in the second and third cycles and the first and second cycles (the smaller group of respondents), who also had the highest SD values. Nevertheless, the question of whether or not a more positive attitude towards statistics may be associated with the cycles of basic education needs further research.

Regarding the different areas of training and their relationship with attitudes towards statistics, no statistically significant differences were found ($F(1, 49) = 0.021$, p -value: 0.885). However, we noted that the respondents with basic training in mathematics had slightly lower mean scores (102.55 and SD 1.36), while those with training in other areas had a mean score of 103, but a greater SD (3.28). This result is interesting and somewhat unexpected; suggesting once again that further analysis in this area is required.

PRELIMINARY CONCLUSIONS

The sample size and the characteristics of this survey mean that our results cannot be generalised. We must state that the purpose of this study was not to make any generalisations, but to test the validity of the items and the performance of the scale used in the similar study carried out by Estrada et al. (2004).

Distributing this survey through the ProfMat 2008 organising committee did not prove to be a good option, since there the teachers had several other requests (workshops, conferences, team groups, and so on) which may explain the low response rate and possibly even some of the “wrong” answers.

For this preliminary study, Cronbach’s alpha (the coefficient of internal consistency) was 0.749. In our view, this value is reasonable, given that the sample size was very small. For the purposes of the survey, this initial study suggests that teachers’ attitudes towards statistics are generally positive, with a mean total score of 102.58 (and SD 8.38), which is well above the mid-point (81), which would indicate their indifference. These results are in line with the results of Estrada et al. (2004). We did not find statistically significant differences in the respondents’ attitudes towards statistics in terms of some of the variables studied, but we should emphasise the following points: women had a slightly higher mean total score than men; the mean total scores were slightly lower in the groups of teachers with fewer years of teaching experience; the mean total scores were lower for the teachers who taught in only one of the cycles of basic education, and teachers with training in mathematics also had a higher mean total score than teachers with other forms of training. The mean scores of the two additional items were only slightly above three (indicating indifference), which leads us to infer that (in terms of these respondents at least) the use of technology in statistics classes needs further study.

These results must be read with great caution and with full knowledge of the (very) small size of the studied sample. Nevertheless, this preliminary study has provided us with some directions for further research and action; for instance, in terms of rewriting some of the items and the need to validate this Portuguese translation of the EAEE (Estrada, 2002).

Having followed on from the study by Estrada et al. (2004), we have not addressed all of the issues which were raised during the survey, but we intend to do so in further analysis. In order to continue this study of attitudes towards statistics, we feel the need to collect more answers using this survey in order to validate the scale when studying teachers in the second and third cycles of Portuguese basic education, and in order to improve the graphical presentation of the first section: the questions regarding sample characteristics of teachers. We also intend to conduct further statistical analysis, including multivariate analysis.

DEVELOPING AN ONLINE COMMUNITY OF TEACHING PRACTITIONERS: A CASE STUDY

Maria Meletiou-Mavrotheris, Efi Papparistodemou

European University Cyprus, Frederick University Cyprus

The article presents an overview of the main experiences gained from a case study which investigated the forms of collaboration and shared knowledge building undertaken by a multinational group of teachers participating in online professional development. This study took place during the pilot delivery of Early Statistics, an online professional development course in statistics education targeting European elementary and middle school mathematics teachers. A central conviction underlying the course design is that learning is a social act best supported through collaborative activities, and thus learning as part of a community of practitioners can provide a useful model for online teacher professional development.

INTRODUCTION

Numerous initiatives in online teacher training serving large numbers of educators are underway (e.g. Garfield & Everson, 2009; Cady & Rearden, 2009). Several of these programs exploit the richness of interactions fostered by the Web to build and study network-based services with the aim of fostering online communities of teaching practitioners. Communities of practice is a construct grounded in an anthropological perspective that examines how adults learn through social practices (Gray, 2004). A community of practice consists of a group of individuals with a shared domain of expertise, who engage in a process of collective learning about practices that matter to them (Wenger, 1998). A promise of new web-based technologies is that they can enable geographically dispersed teachers to engage in online communities, in which they can exchange ideas with other teachers and garner support as they try new strategies in their classrooms (Cochran-Smith & Lytle, 1999).

This chapter focuses on the question how the information and communication tools made available by modern internet technologies could be effectively utilized in order to build and study network-based services with the aim of fostering online communities that promote statistics teachers' learning and development. It first provides an overview of the existing literature on online communities of practice. It then reports on some of the experiences from an exploratory study designed to investigate the forms of collaboration and shared knowledge building undertaken by a multinational group of teachers participating in online professional development in statistics education. The main insights gained from the study regarding enabling and constraining factors to the successful implementation of an online community of practice are discussed. Based on the analysis of these data, some recommendations for mathematics educators involved in pre-service and/or in-service teacher training

who wish to incorporate online communities of practice in their work are provided.

BACKGROUND

Online communities of practice are constantly evolving into many forms and styles as they embrace new and evolving technologies. While, however, they proliferate in cyberspace, little is still known about best practices for their effective design, as empirical research on this topic is still at an initial stage. Conducted studies indicate that online communities of practice are, indeed, a promising model for both pre-service and in-service teacher training (Cady & Rearden, 2009; Dalgarno & Colgan, 2007). They have a great potential to support teacher professional development through placing educators at the center of their learning (Kayler & Weller, 2007), thus promoting their independence and self-directed learning. Online communities of practice facilitate not only communication, but also the collaborative finding, shaping, and sharing of knowledge among teachers.

Despite the potential of online communities of practice, several studies have found their introduction in educational contexts to be less successful than anticipated (e.g. Kennard, 2007). These studies highlight several difficulties in building and maintaining online communities involving shared professional learning. A study by ten Cate (2007), for example, has identified the following obstacles to participation in an online community of practice: limited time, limited access, limited opportunities to meet face-to-face, and language barriers. Language barriers are a particularly serious challenge for international communities of practice, where members come from different countries and time zones, and communicate with other teachers in a foreign language (Trayner, Smith, & Bettoni, 2007).

Timely postings by group members are considered to be a necessary component in building a functional community of practice (Kayler & Weller, 2007). However, studies of participation demographics in online communities and social networks have found that between 46 percent and 82 percent of users are invisible observers who rarely or never participate (Preece, 2000). There is strong research evidence indicating that many distance learners join discussion forums, read messages, but do not contribute to discussions (Simpson, 2002).

The design of cognitive tools to promote learner participation in online communities of practice involves many inter-related considerations (e.g. moderator involvement, reliability and stability of the technology, etc.), most of which are not yet well understood (Stahl, 2006). More research is still needed to shed light into how to best support the development of healthy and sustaining online communities of teaching practitioners. Below some experiences related to educating statistics teachers at a distance are analyzed.

METHODOLOGY

Context and Participants

The research comes from *EarlyStatistics*, a 3-year project (2005-2008) funded by the European Union under the Socrates-Comenius Action, which exploited the affordances offered by distance learning technologies to help improve the quality of statistics instruction offered in European schools. The project consortium, comprised of five universities in four countries (Cyprus, Spain, Greece, Norway), developed and pilot tested an intercultural online professional development course in statistics education. The course aims at helping European teachers improve their pedagogical and content knowledge of statistics through exposure to innovative web-based educational tools and resources, and cross-cultural exchange of experiences and ideas. A central conviction underlying the course design is that learning as part of an international community of practice can provide a useful model for teacher professional development (Wenger, 1998).

A case study design with mixed methods was employed in the study. The case studied consisted of the group of fourteen in-service teachers that participated in the pilot delivery of *EarlyStatistics*, which took place during the final year of the project (in spring 2008) in three of the partner countries – Cyprus, Spain and Greece. Participants voluntarily enrolled in the course. They did not gain any extrinsic rewards such as compensation, or academic credit incentives. A prerequisite for participation in the course was proficiency in English, since English was the language of instruction and of online communication.

Nine of the course participants were female and five male. Seven were aged between 31-40, while three were younger (21-30 years old) and four older (41-50 years old). The majority of the participants had been teaching for more than ten years. Since they originated from three different European countries, teachers were geographically, culturally, and linguistically heterogeneous. They came from different educational systems, and had varied educational backgrounds. They were either elementary or secondary school teachers (9 elementary school teachers, 5 secondary school level teachers), and differed considerably in their mathematical and statistical knowledge, and in their confidence and experience in teaching statistics. There was also variety in teachers' experience and comfort with internet technologies, and in their previous experience in taking online courses.

The *EarlyStatistics* course lasted 13 weeks, and was made up of six Modules. In Modules 1-3 (Weeks 1-6), the focus was on enriching the participants' statistical content and pedagogical knowledge by exposing them to similar kinds of learning situations, technologies, and curricula to those they should employ in their own classrooms. To help teachers go beyond procedural memorization and acquire a well-organized body of knowledge, the course emphasized and revisited a set of central statistical ideas. Through participation in authentic educational activities

Working Group 5

such as projects, experiments, computer explorations with data, group work and discussions, participating teachers learned where the “big ideas” of statistics apply and how, and developed a variety of methodologies and resources for their effective instruction. In Modules 4-6, the focus shifted to classroom implementation issues. Teachers customized and expanded upon provided materials (Module 4; Weeks 7-9), and applied them in their own classrooms with the support of the design team (Module 5; Weeks 10-11). They wrote up their experiences, including a critical analysis of their work and that resulting from their pupils. Once the teaching experiment was completed, they reported on their experiences to the other teachers, and also provided video-taped teaching episodes and samples of their students’ work, for group reflection and evaluation (Module 6; Weeks 12-13).

The course was delivered through a blended learning approach. There were a few face-to-face meetings with local teachers, but the biggest part of the course was delivered online, by utilizing the project information base for teaching, support and coordination purposes. To offer teachers flexibility and to accommodate different time zones, the largest portion of the course was conducted asynchronously through online discussion and e-mail groups. There was also some synchronous communication through use of technologies such as chat rooms, audio/video streaming, and videoconferencing.

Each module involved a range of activities, readings, and contributions to discussion forums, as well as completion of group and/or individual assignments. Both the dialogue and the assignments were structured so as to explicitly make ties among theory and practice. Reflective questions created situations for the participating teachers to critically examine the subject matter through additional personal research or reading of the course material, thus giving them the opportunity to make new connections between theory and their personal and professional experiences.

Concurring with Roseth, Garfield, and Ben-Zvi (2008), *EarlyStatistics* was built on the premise that statistics instruction ought to resemble statistical practice, which is an inherently cooperative enterprise. A number of strategies were employed by the project consortium to promote online dialogue and transnational collaboration among participating teachers, and to ensure that all teachers actively contribute to course activities and discussions, including the following: (i) Monitored discussion forums allowed teachers to discuss content and help each other; (ii) Discussion questions were assigned bi-weekly. These were conceptual questions keyed to a major theme, and addressing content as well as pedagogical concerns; (iii) Participation in discussion forums and other collaborative activities was a compulsory element of the course; (iv) Participants were assigned to small groups, and each group was facilitated by a tutor. Groups received periodic milestone group assignments which they jointly completed using social software tools such as wikis.

Members of the *EarlyStatistics* consortium with expertise in statistics education facilitated the course. Since the course was designed to be a community-based

learning experience, their role was to guide discussions, encourage full, thoughtful involvement of all participants, and provide feedback. Facilitators helped to deepen the learning experience for course participants by encouraging productive interaction and critical reflection on workplace practices.

Instruments, Data Collection and Analysis Procedures:

Documenting online interactions is a multifaceted phenomenon that requires complementary methods of data collection and analysis in order to understand how learning is accomplished through interaction, how learners engage in knowledge building, and how designed media support this accomplishment. Consequently, to increase understanding of the research setting, the current study employed a variety of both qualitative and quantitative data collection techniques, including: (i) The contents of the online discussion boards in which teachers participated during the course; (ii) Group assignments completed by teachers throughout the course; (iii) Quantitative statistics automatically collected by the system (e.g. number of teachers participating in a discussion forum, or successfully completing group assignments, number of postings by each participant, etc.); (iv) An open-ended web-based survey administered at the course completion, aimed at determining teachers' perceptions, opinions, feelings and motives regarding their participation in collaborative course activities and the impact these might have had on their professional development; and (v) Semi-structured interviews of a selected group of teachers that surveyed their views on the effectiveness of the online communication during the course.

RESULTS

The overall feedback from the target user groups from all partner countries participating in the *EarlyStatistics* course pilot delivery, as well as from external experts regarding the course content, services, and didactical approaches was generally very positive. Key conclusions from the analysis of the user feedback were that *EarlyStatistics* was quite successful in helping teachers to improve their pedagogical and content knowledge of statistics by offering interactive, technology-rich instructional materials and services that enhance the teaching and learning process, and by providing course participants the opportunity to collaborate with other teachers and begin the construction of a community of practice. Moreover, data obtained from the teaching experimentations in the course participants' classrooms suggest positive gains in student learning outcomes and attitudes towards statistics (for more details see Chadjipadelis & Andreadis, 2008).

In the survey administered at the completion of the pilot course delivery and the follow-up interviews, teachers were asked to indicate “*what they liked the most about the EarlyStatistics course*”. The promotion of communication and collaboration among teachers was an aspect of the *EarlyStatistics* course that was considered by all course participants to be an important strength of the program: “I

Working Group 5

liked the interaction with the other teachers. It is useful to share your ideas and problems with other teachers from different educational levels”; “It was very useful to be able to communicate with teachers of different levels and perspectives. This direct communication with everyone has helped to continue the hard work of self-learning”.

In particular, teachers praised the fact that *EarlyStatistics* had allowed them, through computer-mediated communication, to share content, ideas, and instructional strategies with teachers from different countries and educational systems:

The international cooperation among teachers having the same agony on how to teach their students better statistics; the fact that I also learned a lot of things about statistical syllabus, pedagogical aspects, and how education is implemented in other countries.

Distance training has helped me to understand that the problems that I have when teaching statistics are also common in other European Countries.

It is good to ‘hear’ colleagues from other countries that face similar problems like you and sometimes, because of a different view on a point, suggest ideas you didn’t think of.

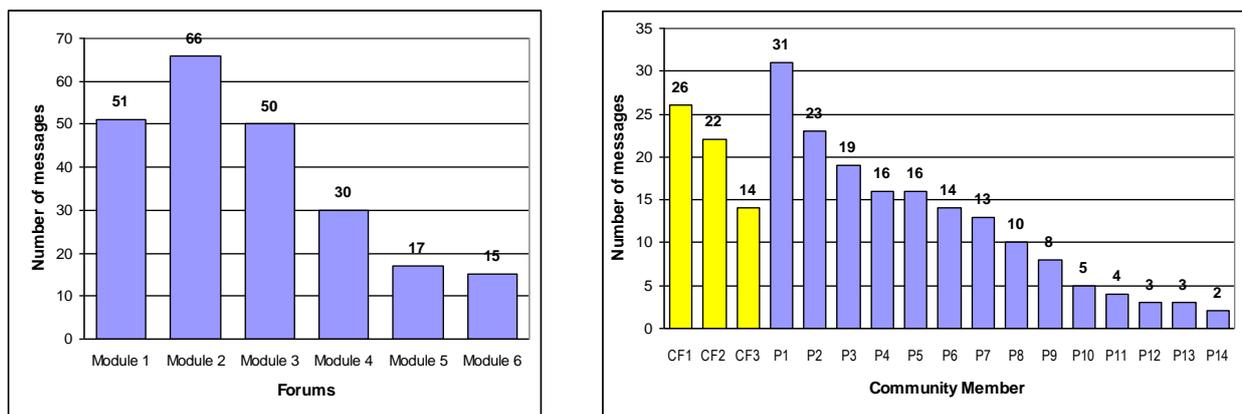

Figure 1: Distribution of messages in the *EarlyStatistics* Discussion Forums per Module (Figure 1-left), and community member (Figure 1-right)

Recently, *EarlyStatistics* won, ex-aequo with *Maths4Stats* (a joint project coordinated by Statistics South Africa), the 2009 Best Cooperative Project Award in Statistical Literacy. This award is given every two years by the International Association of Statistics Education (IASE) “*in recognition of outstanding, innovative, and influential statistical literacy projects that affect a broad segment of the general public*”.

Despite the overall success of the *EarlyStatistics* project and the very positive feedback from the groups of teachers participating in the pilot delivery and from external experts in statistics education, a number of shortcomings have also been identified. The biggest difficulty experienced by the consortium was its limited success in establishing a functional online community of practice, which was a main objective of the project. Despite the fact that the course team employed several

Working Group 5

strategies to promote teacher dialogue and collaboration, and that the course facilitators tried their best to ensure that all teachers actively contributed to discussion forums, there was often a lower than anticipated learner-to-learner interaction.

Figure 1-left shows the distribution of messages in *EarlyStatistics* per forum. We can see that while at the beginning of the course there was big enthusiasm and very high participation in the discussion forums, interaction dropped off over time. In contrast to the vibrant interaction and rich dialog characterizing the earlier part of the course, often what happened towards the end of the course was that only 3-4 teachers would actively participate in the discussion forums, while the rest would make minimal or no contributions.

Figure 1-right shows the distribution of messages written in the forums per community member (P1-P14 stand for the course participants, and CF1-CF3 for the course facilitators). As we can see, there was a huge variation in the degree of participation among community members. There were a few teachers whose level of engagement was very high. At the same time, several other teachers participated only sporadically in the forums and, as a result, wrote a very small number of messages. These teachers exhibited a silent manner of participation. Checking their records of participation, we discovered that despite them not being active in the discussion forums, they continued to join the forums and read the messages posted by other members. Based on the analysis of the data collected during the study, we have identified a number of factors that adversely affected online participation of course participants:

Course Workload: A reason that might have contributed to our limited success in building an online community of practice is the pilot course workload, which proved to be overwhelming. When asked, in the end-of course survey and in the follow-up interviews, to indicate “what they liked the least about the *EarlyStatistics* course”, most participants mentioned the course workload which made it very difficult for them to keep up with the course requirements due to their overburdened schedules: *“The papers we had to read in the first modules were too many and our time to work on them limited, because of our jobs”*; *“There was too much studying involved.”*

Duration of Discussion Forums: The short duration of the discussion periods was another aspect of the course criticized by participants. Several participants noted that the study pace had been too high for them, and that the time allocated to each discussion forum (two weeks in average) was not adequate: *“The course had too many assignments on the theoretical part, and there was not enough time for working on them and posting on the forums.”*

Lack of physical proximity: During the pilot delivery there were a few face-to-face meetings with local teachers, but not with the group as a whole. Course

Working Group 5

participants got the chance to virtually meet teachers from the other countries through video-conferencing, this however cannot be as effective as face-to-face interaction. Moreover, planning of videoconferencing and other activities that required synchronous communication (e.g. chat sessions) proved very difficult to schedule, as it was almost impossible for all of the teachers to be available at the same time. As a result, teachers built strong local groups but had more limited than desired interaction with teachers from other countries.

Language barriers: Researchers that have studied the dynamics of international online communities of practice (e.g. Trayner, Smith, & Bettoni, 2007) have found communication among people who speak different first languages to be a very serious challenge for such communities. In this study, language of communication also proved to be an obstacle to participation for some of the course participants. While most of the teachers did not seem to have any problems reading and writing in English, for a few of them language was a barrier that prevented them from fully participating in online discussions: *“It was a bit difficult and time consuming for us to read bibliography in English and to post our thoughts in the forum.”* Teachers with language difficulties did not post as often as their peers who had better English writing skills, and their contributions tended to be shorter.

Limited experience of course facilitators in online instruction: The important role of facilitators and moderators is a main theme emerging from research studies examining online communities of practice. In *EarlyStatistics*, the limited experience of the course facilitators in distance learning was a drawback of the pilot course. The team members that facilitated *EarlyStatistics* are very experienced statistics educators who have been involved for several years in teacher training. Nonetheless, this was the first time they were offering professional development online. Consortium partners with extensive previous expertise in distance education acted as mentors and provided hands-on training on a number of topics relating to distance learning. This undoubtedly helped course facilitators to improve their instructional skills in distance education. However, they still faced some difficulties in running the pilot course, and particularly in leading the discussion forums. While in guiding discussions, they tried to encourage full, thoughtful involvement of all participants, and to provide constructive feedback, they did not always manage to achieve productive interaction and critical reflection of the participants.

Insights gained from the *EarlyStatistics* pilot delivery have informed the revision of the course to better support online community building. The heavy course workload was corrected in the revised version of the course, and the length of time allocated to each discussion forum was increased from two to three weeks, in order to allow teachers more time for reflection and for online communication. Similarly, the technical difficulties experienced in the pilot delivery have been resolved. Additionally, the lack of a face-to-face meeting with participants from other countries experienced by the teachers participating in the pilot delivery, will not be

Working Group 5

an issue in future offerings of the *EarlyStatistics* course, which will have a blended-learning format. At the beginning of the course, teachers from all over Europe will gather together to attend a one-week intensive seminar (they can finance their expenses by applying for a grant under the Lifelong Learning/Comenius In-Service Training Program). During this meeting, they will get familiarized with the course and its objectives, and with the facilities offered by the course e-Learning system. More importantly, they will get the chance to meet and interact with one another, and with the course facilitators. We believe that this initial in-person meeting will reinforce teacher online engagement by helping mitigate the problem of trust and social presence online (Ardichvili, Page, & Wentling, 2003). Finally, the limited experience of the *EarlyStatistics* course facilitators in online instruction will not be such a big issue in future offerings of the course. Undoubtedly, however, the valuable experiences they gained from this pilot delivery will allow them to employ much more effective moderating strategies in future offerings of the course.

DISCUSSION

A common thread emerging from educational research is the direct relationship between improving the quality of teaching and improving students' learning. Thus, the provision of high-quality, ongoing professional development for teachers has become a paramount issue in school reform efforts. The need for the training of large numbers of teachers makes distance learning an attractive option. The traditional approach is to provide teacher training through a well-designed course package. The *EarlyStatistics* project has adopted a different approach, guided by contemporary visions of web-based instruction which support "learning" and "community" rather than "instructional" models of professional development.

Unlike traditional, individualistic approaches to teacher professional development, properly designed online communities of practice can foster a culture of sharing and sustained support for teachers. By allowing geographically dispersed teachers to interact, communities of practice can enable them to connect and learn from each other in ways not possible in more traditional, face-to-face professional development programs. However, despite the potential of online communities of practice, the existing research literature indicates that their introduction in educational contexts is often less successful than anticipated. Findings from the current study concur with the research literature, indicating that successful building of an online community of practice, particularly in a cross-national context, is very challenging.

While online teacher professional development courses share many features with face-to-face programs, the experience gained from the *EarlyStatistics* program, suggest that they also present some unique challenges. Teachers participating in such a course are likely to be characterized by diversity in a number of parameters (pedagogical and content knowledge of statistics and mathematics, educational level and grade they teach, cultural and/or professional backgrounds, comfort with

Working Group 5

technology and with distance learning, etc.). Several pedagogical and technical issues should be taken into account in the design of an online professional development course, in order to provide an effective environment that motivates teachers and supports the development of a functional online community of practice:

- Access to multiple distance collaboration tools that promote interaction with peers and with course facilitators;
- Careful scheduling of course activities to offer teachers flexibility, and to accommodate different time zones;
- Adoption, whenever possible, of a blended learning approach, to allow teachers to personally meet and interact with each other.
- Setting of realistic work expectations so as not to overburden teachers;
- Provision of adequate time for teachers to formulate and articulate contributions to online discussions;
- Prompt and effective moderation of online interactions by course facilitators;
- Support, in the case of international online communities, of members experiencing difficulties in oral and/or written communication in English.

Research in the area of online communities of practice is still at an embryonic stage. More research is needed to advance our understanding of how to best take advantage of computer-mediated communication tools to support the development of effective virtual communities that can act as vehicles for teacher learning and growth. Despite the tentative and non-generalizable nature of the current case study's findings, it does contribute some useful insights into the factors that may facilitate or impede the successful implementation of an online community of teaching practitioners, suggesting possible methods for improving their implementation in distance education. These insights have helped to further enhance the quality and effectiveness of the EarlyStatistics course, and sketch a road map for our future research work and for other similar online community building endeavors.

RISK TAKING AND PROBABILISTIC THINKING IN PRESCHOOLERS

Zoi Nikiforidou, Jenny Pange

University of Ioannina

Decision making under uncertainty involves the underlying concepts of risk and probabilities. By getting involved in risk taking experiences preschoolers develop stochastic thinking and skills that allow making risky or riskless choices depending on the outcome and related information. In the current study, children (N= 80), at the age of 4-6 participated in the 'Cups' task (Levin et al, 2003) through concrete manipulatives versus pc. Findings allow implications for the design of the probabilistic tasks in relation to the cognitive capacities of young children.

INTRODUCTION

Risk challenges and undergoes most human activities and decisions. Through risky contexts children and adults understand and confront the dangers and uncertainties of life at a personal and more general level (Slovic, 1999). There is no one definition of risk thus, according to Harding (1998) risk refers to “*a combination of probability or frequency of occurrence, of a defined hazard and the magnitude of the consequences of the occurrence*” (p.167). The terminology and methods used for dealing with risk and uncertainty vary a lot and make it difficult to communicate across the various areas of applications and disciplines (Aven, 2009).

Methodologically, risk-taking has been analysed not only through actual rates (i.e., with the use of interviews or questionnaires) but also through more artificial, laboratory based risk-taking tasks. The major goal in this later approach has been to provide analogues to the risks children and adolescents actually engage in, while controlling extraneous variables and assessing the effects of key variables (Boyer, 2006). One such key variable is the estimation and apprehension of probabilities and the likelihood of events.

Recent studies support that preschoolers may exploit and develop probabilistic thinking, as for instance they have been found to possess characteristics of probabilistic thinking (Jones et al, 1997; Nikiforidou & Pange 2010) and make use of probabilistic evidence in order to produce causal relations (Kushnir & Gopnik, 2005). The development of such skills in the preschool context, under appropriate pedagogical practices, is a matter in progress (Pange & Talbot, 2003) and strongly complements the field of decision making under risk and uncertainty by implying what is called ‘*risk literacy*’ (Gigerenzer et al, 2007).

Research in the area of risky decision making by young children usually consists of an adaptation of tasks that aim at older ages and have already been tested on adolescents and adults. The ‘Cups-task’ developed by Levin et al, (2003) is one example, among others, that supports that risk is age-related and that children get

affected by the loss or gain domain and the expected value (Schottmann, 2001; Levin et al, 2007). Among these lines, young children tend to select more risky choices in order to avoid losses than to achieve gains. This constitutes the preference shift as proposed by the Prospect Theory (Kahneman and Tversky, 1979) and analysed mainly with older participants. The aim of the current study is to examine whether preschoolers may or may not participate in a risky decision-taking task (similar to the ‘Cups-task’) by assessing the likelihood of an event in terms of immediate gain and loss. Can they estimate the probability of winning and losing under risky and riskless options? Will they show differences in the gain and loss domains?

MATERIALS AND METHODS

The study took place in two Greek kindergartens, during 2010. Children ($N = 80$), aged 4-6, participated in mixed age-groups consisted of five members. The between-subject study was realised after parents gave their written consent and as soon as teachers expressed their willingness to collaborate.

The material used in the experiment included six small round metallic boxes and 12 cards of 4.5 x 5.5 cm each: six depicted happy faces and six sad faces. Children would record by themselves the outcome of their choice in specially designed sheets. There were two domains; the domain of gain and the domain of loss. In the gain domain children would win the equivalent number of stamps. On the contrary, in the loss domain they would cross out respective happy faces from a given bank of faces.

The experiment took place within the participants’ schools, thus in a separate room from their classroom in order to avoid disturbance. At a first point, children were seated around a table and were presented with the stimulus. After counting the boxes, the researcher would divide them in two sections composed by 3. Each section would be placed on each side of the table (right and left) by producing the risky and the riskless sides, depending on the number of cards that would be placed under each box. Therefore, children would observe the researcher separate the boxes in triads and place cards underneath them. In the riskless side, there would be one card per each box and in the risky side randomly 1 box would get 3 cards while the remaining two boxes would get no card at all (Table 1).

Material	Design of gain domain		Design of loss domain	
	risky	riskless	risky	riskless
concrete manipulative (metallic boxes and cards)				

Table 1: Design of the risk-taking task

Working Group 5

As the researcher explained orally the whole procedure in both domains, children would follow the shuffling of the boxes per each side; the risky boxes within them and the riskless accordingly within them. Then, each child was asked to select one box and this implied a two-level decision.

Firstly, children were expected to choose between the risky and riskless option and afterwards they were expected to point at a particular box in order to find out whether and what they had won or lost. In the gain domain if children selected from the risky side they were prone to win 3 stamps by 33% chance, otherwise they would come up with none by 66%. If they chose a box from the riskless side they would gain one stamp for sure. In the loss domain, depending on their choice, children would either erase for sure one happy face from their bank of faces if they went for the riskless option or if they went for the risky option they would either erase all 3 happy faces by 33% or none by 66%.

As soon as one domain ended children went on with the other domain. The domains were counterbalanced and every time instructions were provided orally. Each trial was repeated 3 times and participants marked down their gains or losses. Children with more stamps or less crossed out faces were considered to be the winners, thus there was no final prize.

RESULTS

Children preferred the risky option compared to the non-risky option by 74.3% in the gain domain and by 91.3% in the loss domain. By conducting a χ^2 chi-test it can be seen that in both domains there are statistically significant differences in children's responses as, in the gain domain, $\chi^2(1) = 54.5$, $p < 0.00$ and in the loss domain, $\chi^2(1) = 157.9$, $p < 0.000$.

In the following table (Table 2) the frequencies are reported per domain and trial.

Responses				
		trial 1	trial 2	trial 3
Gain	Risky	57	54	60
	riskless	19	23	17
Loss	Risky	70	70	71
	riskless	7	7	6

Table 2: Overall responses.

A binomial test revealed that there is a significant preference for the risky option in every trial of both domains: $z_{1g} = 4.07$, $p < 0.05$, $z_{2g} = 3.887$, $p < 0.05$, $z_{3g} = 4.21$, $p < 0.05$, $z_{1l} = 4.67$, $p < 0.05$, $z_{2l} = 4.67$, $p < 0.05$, $z_{3l} = 4.7$, $p < 0.05$.

Working Group 5

The trend of selecting the riskless option instead of the risky was more evident in the gain domain. In the loss domain children were more likely to go for the risky boxes. In the gain domain the odds ratio in selecting the riskless/risky option in the 1st trial was 4.16, in the 2nd trial 7.3 and in the 3rd trial 7.4. In the loss domain, in the 1st trial children were more likely to select the riskless response by 1.77, in the 2nd by 2.16 and in the 3rd by 2.22.

DISCUSSION

Children participated actively in this child-oriented risk-taking task. They were excited with this game and expressed patterns in their choices that comply with the preference shift phenomenon (Kahneman and Tversky, 1979). Under this perspective, choices involving gains are risk averse and choices involving losses are risk seeking. One of the basic features of decision under risk and uncertainty is that losses loom larger than gains. Risk seeking is prevalent when people must choose between a sure loss and a substantial probability of a larger loss and alternatively, people often prefer a small probability of winning a large prize over the expected value of that prospect.

Young children at the age of 4-6 would select the risky option so as to avoid losing happy faces rather than maximizing their stamps. The preference shift phenomenon related to this age group is in compliance with Levin's et al (2003) and Levin's et al (2007) studies. If children had no indications of probabilistic thinking then they wouldn't show such patterns of choice; they would either be risk-seeking in all trials or risk-averting. On the contrary, children seemed to estimate and try to avoid in the loss domain not only the -1 but also the -3, whereas in the gain condition they would be satisfied with a +1. Findings in this direction support that children possess a limited understanding of probabilistic notions (Nikiforidou & Pange, 2010).

Risk-taking tasks addressing to young children have been developed during the last years, usually as an adjustment of tasks designed for older participants. Within the laboratory-based tasks external variables are expected to be controlled and participants are encouraged to express their risky or riskless choices. Thus, the act of choosing, for instance one box, based on prior information is different from the reasoning and inferring that accompany this choice. In this direction further research should take in consideration children's justifications and explanations concerning these choices not only in experimental tasks but also in tasks that relate to real life situations and children's interests.

To sum up, matters of design and ways of measuring young children's decisions under risk and uncertainty are a field of great interest that has emerged during the last years. By taking into account that risk-taking is very complicated and multidimensional, research investigates aspects of children's cognitive and probabilistic thinking. How can children at the age of 4-6 get engaged at a first point and learn at a more long-termed level to manipulate decisions under risk that entail

probabilistic concepts? How can concrete stimuli provide incentives that allow young children to express stochastic ideas and take risky decisions and finally, how can they be perceived in a useful manner for individuals' personal and social life within the framework of 'risk literacy'?

INFLUENTIAL ASPECTS IN MIDDLE SCHOOL STUDENTS' UNDERSTANDING OF STATISTICS VARIATION¹

Antonio Orta, Ernesto Sánchez

Department of Maths Education, Cinvestav. México

This study explores the way in which certain statistics notions influence the understanding of variation among junior high students. A teaching experiment with 50 13-year-old students was undertaken, in which the concept of statistical variation was studied in the context of temperature measurements. After the teaching, a problem of comparing wait-time for a movie of different cinema chains was administered to the students. Some of them learnt to identify which set of data have more variation by reading their frequency distributions; others also did it by calculating and comparing the ranges. However, students are unable to respond to a question related to choosing a cinema chain to go by considering the uncertainty that should have been seen through variation. This observation brings a reflection on the understanding of the relationship between variation and uncertainty.

INTRODUCTION

It is acknowledged among the statisticians and statistics educators that variation is the core of statistics. Moore (1990) emphasized the omnipresence of variation and the importance of modelling and measure variation in statistics; Wild and Pfannkuch (1999) proposed the perception of variation as one fundamental kind of statistical thinking and Watson, Kelly, Callingham, and Shaughnessy (2003: 1) pointed out that “statistics requires variation for its existence”.

Variation is a very complex concept, complex in such way that understanding it requires connecting it with many other notions. For example, Watson, Callingham and Kelly (2007) suggest that understanding variation involves perceiving uncertainty, anticipated change, unanticipated change and outliers. Konold and Pollatsek (2002) emphasized the importance of jointly considering variability (noise) and centre (signal), because both ideas are needed to find meaning when analyzing data. Garfield and Ben-Zvi (2008: 203) remarked that “understanding the ideas of spread or variability of data is a key component of understanding the concept of distribution, and is essential for making statistical inferences”. Wild (2006: 11) suggested that the notion of distribution “underlies virtually all statistical ways of reasoning about variation”.

The absence of the notion of variation in the curricula in mandatory education and the lack of research on students' understanding of it, in contrast to its importance in statistics, was pointed out by Shaughnessy (1997). Since then, an increasing number of studies on students' understanding of variation have been published. Recent research results indicate the possibility of developing intuitive notions of variation from earlier grades. In the present study the way in which the notions of mean, range

and uncertainty influence middle school students' understanding of variation is explored.

CONCEPTUAL FRAMEWORK

The notion of *understanding* used in this paper is described by Hiebert and Carpenter (1992: 67); they point out that a concept “is understood if its mental representation is part of a network of representations. The degree of understanding is determined by the number and strength of the connections”. This means that a certain degree of understanding of a mathematics or statistical concept involves recognizing at least some of its relevant relationships with other concepts and procedures.

Variation of data is connected with many concepts, but in comparing tasks three basic connections are the mean, the range and the graph of data. Two other concepts considered in this study are the mean deviation as a more precise measure of variation and the notion of uncertainty as a bridge to interpret variation in some contexts. All these concepts are related each other and they have connections with other more elemental notions.

Variation in data can be seen through the frequency distribution of the data. Line and bar graphs, and histograms are some of the ways of representing the frequency distribution of data. Since these representations are spread across the curriculum of middle school it becomes important to investigate how students learn variation through them.

As Konold and Pollatsek (2004) suggested it is convenient to consider signal (in our case, mean) connected with noise (variation) to have a concise but meaningful description of data. Since in calculating the mean deviation the mean itself is necessary as a reference point and, in comparing sets of data, it is convenient to consider their means, the knowledge of mean cannot be disregarded in achieving an understanding of variation in data.

Although range is the most elemental measure of variation and it is easily understood by students, range is insufficient to describe variation. Standard deviation is the most convenient measure, but this is a very difficult notion. An alternative could be the mean deviation since it can be more comprehensible to middle school students.

Watson et al. (2007) point out the relation between variation and uncertainty. In this sense, it is convenient to consider the idea of Tal (2001) about that variation can be information or uncertainty; it is information when it can be explained and uncertainty when it cannot. In contexts where variation is uncertainty, perceiving it as risk could lead to making good decisions. Kahneman and Tversky (2000) point out that people are risk-averse; this means they tend to choose situations where the risk is minimal. The problem however is whether students see properly uncertainty and risk in the situations where variation is uncertainty.

METODOLOGY

Participants. The participants in this study were 50 students, one teacher and the authors of this paper. The students were distributed in two groups of the eighth grade (13 years old) from a public middle school in Mexico City. The teacher has 10 years experience and he recently received a master degree in a professional development program in maths education.

Instruments. In this study, three different instruments were designed and implemented in order to obtain data: a diagnostic test, a set of worksheets filled by the students during a teaching sequence and a post-test. This last one contained three tasks, one of which is about comparison of the waiting time in theatres of different chain cinemas (adapted from Shaughnessy, et al 2004); it is presented in Figure 1 below. Only the responses to this task are analyzed in this paper.

A recent trend in movie theatres is to show commercials along with previews before the movie begins. The *wait-time* for a movie is the difference between the advertised start time (like in the paper) and the actual start time for the movie. A class of 10 students investigated the wait-times at three popular movie theatre chains in Mexico: *Cinemex*, *Cinépolis* and *Multicinemas*. Each student attended three movies, a different movie in each theatre. The class's results are shown in the charts below. (Times were rounded to the nearest half-minute.)

Cinemex	Cinépolis	Multicinemas
12.0	15.0	15.5
21.0	15.5	17.0
15.0	16.0	18.0
15.0	16.0	16.5
13.0	16.5	16.0
16.0	16.5	16.5
16.0	18.0	16.5
16.0	16.0	15.0
20.0	15.5	15.0
18.0	17.0	16.0

- In the attached sheet, make the graph corresponding to each chart.
- Calculate the average waiting time for each movie chain and draw a line along the mean in the graph that you made.

[Incises c-h are presented below]

Figure 1. Task on comparing wait-times in movie chains

Procedures. A teaching experiment of eight sessions, of 100 minutes each, was designed with the purpose of providing conditions for the learning of the variance notions. The students were instructed in the handling and organization of data through the eight sessions, in each they filled out a worksheet. In sessions 1 to 7 the body temperature context was used. In session 1, the students responded a questionnaire about body temperature. Every student measured his or her

Working Group 5

temperature with a mercury thermometer. Data were gathered in a list. The mode and mean were calculated. In session 2, students made graphics freely with data gathered in the previous session. In session 3, students were taught about the correct way to make frequency graphs; they were also given a squared sheet with axes on it for the purpose of more accurate graphics. Students were asked to locate the mean in the graph. In session 4, data belonging to the other group were considered. Students were taught how to calculate the range and how to associate it with the variability. They discussed the accuracy of measurement in each of the groups and their relation with the range. In session 5, new data were gathered, but this time, it was done with digital thermometers. The new data obtained were processed in the same way as previously. Students were asked to compare the data groups in terms of their accuracy and variability; to do this they used the range. In session 6, the concept of mean deviation was introduced as a more accurate measure of variance. The students calculated the mean deviation from the data obtained in previous sessions. In session 7, the accuracy of the temperature measurements obtained with the mercury thermometer were discussed and analyzed compared to those obtained with the digital one; to do this they used the range and the mean deviation of their data. Finally, in session 8, some problems with new data given were solved where range and mean deviation had to be calculated to obtain the solutions.

Analysis procedure. After the teaching, the post-test was administered to the students. The responses to the task on waiting time were analyzed by ranking them in different categories inspired by the SOLO model of Biggs and Collis (1991). These authors define a PUMR learning cycle as follows.

Prestructural, The task is engaged, but the learner is distracted or misled by an irrelevant aspect [to the task] [...]. *Unistructural*, The learner focuses on the relevant domain and picks up one aspect to work with. *Multistructural*, the learner picks up more and more relevant or correct features, but does not integrate them. *Relational*, The learner now integrates the parts with each other, so that the whole has a coherent structure and meaning (p. 65).

For the sake of analysis, the post-test activity was divided in four sub-tasks: Graph construction, mean and variation, reading variation in the graph, and interpretation of variation. The responses of the first three tasks were analyzed by defining levels analogous to PUMR levels.

RESULTS

Instructions observations

The students showed familiarization with the context of body temperature. They knew that temperature varies from person to person and that such variation is low, just around 36.5°C. Data were obtained and organized without difficulty and its mean and median were calculated.

However, students had some difficulties representing data in frequency graphics. Even when they chose the X axis to represent the temperature values, most of them

Working Group 5

neither grouped data nor organized them according to the magnitude of values but rather by the order in which they were obtained. Some others grouped and arranged data in order, but did not place them according to their relative magnitude. In order to overcome these difficulties, a session to instruct students in constructing frequency graphs was implemented. With the support of the teacher's instructions, students had no difficulties in constructing the graphs of the data obtained in the previous sessions.

It must be highlighted that, when requiring one value of the temperature of the group to inform another person (the principal, for instance) about the measures taken, students agreed on proposing the mean. Some of them say mean because they see in this a precise value resulting from operating the data, and others for considering it a representative value.

When students were asked to compare the accuracy of measurements in the two groups of data, many of them proposed using the mean and/or the graph or comparing against clinical data; only three students mentioned the range as a measure for accuracy in data. When they were asked to compare the variability of the groups of data, they identified variability in the graphs, especially focused on outliers, and spontaneously looked for causes of variation: illness of some students, errors in the measurement process, and the quality of thermometers. After that, students were formally instructed in calculating the range and mean deviation of data and in using them to measure variation.

The instructions sessions provided the students with knowledge and language that permitted undertaking observations about their thinking about statistical notions related to variability. Although the performance in group tasks seemed high, many difficulties persisted in the individual performance on post-test tasks.

Graph construction

One way to perceive variation in data is by looking at its frequency graph. To define the PUMR levels the following aspects were considered relevant to complete the task:

1. Select the X axis to distribute data on it in an ordered way
2. Calculate the frequencies of each value and represent them in Y-axis of the graph
3. Respect distances between values, this mean considering the X-axis as a numerical straight line and not only a place to put labels.

In the *prestructural level* none of these aspects were considered. In the *unistructural level* the responses are focused only on one of these aspects. In the *multistructural level* the responses are focused on two aspects (mostly 1 and 2), but failed in the third. Finally, in the *relational level* responses focused on the three aspects mentioned. The distribution of the responses is show in the table1.

Working Group 5

SOLO Categories	Pre-structural	Uni-structural	Multi-structural	Relational	No answer
Number of students	30	5	7	3	5

Table 1

Mean and variation

Based on the graphs they made, the students had to answer the following questions.

- c. Is there any difference in the average waiting time in the three movie chains? Explain your answer.
- d. How can you know and determine the variation in the waiting time from the three movie chains?
- e. Which of the three movie chains has more variation?

The responses to these questions are jointly considered in order to catch the students' understanding about mean and variance. First, they had to verify that the waiting-time mean is the same in the three Cinemas; second, they should know that can use the range or the mean deviation to determine the variation and, finally, they should apply this criterion to say that Cinemex has more variation than the others.

In an analogous way to PUMR levels, the responses can be classified in different levels taking into account some statistical clue aspects, namely the mean, the range or the mean deviation, as well as the identification of the cinema with greater variation.

In *level 0* (analogous to prestructural), the responses are not based on any statistical clue aspects nor indicate the cinema with greater variation; for example, the answers of Anahí to the three questions are as follows, respectively.

- Anahí:
- c) Both are too different from the last one.
 - d) By going to the movies just like the other teenagers but to three movie theatres.
 - e) There is more variation in the third one than in the second one.

In a *level 1*, the responses show evidence that only one of these clue aspects was considered, without indentifying the cinema with greater variation; for example, the answers of Alejandro are the following.

- Alejandro:
- c) No.
 - d) By getting the average or range.
 - e) Any of them.

In *level 2*, the responses show evidence that the mean and the range or mean deviation from the data were considered. Sometimes the chain with greatest variation is identified, however they present some error or inconsistency, as in this example.

Working Group 5

- Mónica:
- c) No because the average of the three movies is the same.
 - d) By adding the minutes and dividing them by the number of data.
 - e) At Cinemex because the range is bigger.

In a *level 3*, the responses show evidence that the mean, the range or media deviation from the data were considered and that the chain with greatest variation is identified.

- Miguel:
- c) No
 - d) Range.
 - e) In the first one, Cinemex.

The frequencies resulting from classifying the responses are shown in Table 2

Categories	Level 0	Level 1	Level 2	Level 3	No answer
Number of students	19	17	3	3	8

Table 2. Analysis of the answers on questions of points f, g and h

In some responses can be seen that there is confusion between the notions of mean and variation. For example, a student says that the variation can be determined “by getting the average or the range”, and another says that “by adding up the minutes and dividing them by the number of data”. Even when the students are acquiring and incorporating terms such as “mean” and “variation” or synonyms of these, they have not yet acquired their corresponding meanings.

Reading variation in the graph

In a second part of the same task, the students were given the corresponding well made graphs of data (Figure 2) and they were told the mean and median of each movie theatre data set. The idea was to give the opportunity to answer the questions about variation avoiding mistakes made when making the graph or calculating the mean.

[A graph of data is presented]
f. Which of the three movie theatre chains has more variation in waiting time? Why?
g. In which of the movie theatre chains is there more variation, Cinépolis or Multicinemas? Explain.
h. If the three theatres are equidistant from your home, which one would you choose to watch a movie?

Figure 2: Graphs given to students

To answer question f, the variation can be seen at first sight and argued by comparing the ranges. To answer question g, it is necessary to calculate the mean deviation and therefore use the mean.

Working Group 5

To analyze the responses to questions f and g, only the justifications or explanations are considered. Again, the responses can be classified at different levels taking into account the presence of some correct aspects in their justifications.

At *level 0*, students focus on idiosyncratic aspects or on their experiences without using statistics arguments:

Josue: f) At Cinemex because it takes more time to go in.

g) Cinépolis, because there are more people waiting all that time for the movie to start.

At *level 1*, the arguments focused on visual perceptions in the graph

Itzel: f) At Cinemex because of data are more dispersed

g) Cinépolis and Multicinema because of data are equally dispersed.

At *level 2*, responses are supported by considering the range

Garay: f) At Cinemex because its range is that from 12 to 21 and at Cinepolis and Multicinemas it is 18.

g) Cinepolis, because at Cinepolis the 16.5 is 2 and at Multicinemas it is 3.

At *level 3*, responses are supported by considering the range or mean deviation in incise a) and mean deviation in b). None of responses fell in this category.

The frequencies of responses in each level are presented in Table 2.

Categories	Level 0	Level 1	Level 2	Level 3	No answer
Number of students	22	14	7	0	7

Table 3. Frequencies of responses in each level

Interpreting variation in the context of the task

Question h takes us to considering how the problem of variation in the context of cinema-chains should be interpreted, how the question should be answered taken into account the data given? In a previous analysis students were expected to relate variation to uncertainty. This may require that students make a ‘mental experiment’, imagining the consequences of variation in waiting time in different cinemas when they go there: the greater the variation in the waiting time, the greater the uncertainty about when the movie will start. If someone likes watching previews or waiting for the movie, it does not help choose the cinema with most variation because the movie may start too early. However there was no response where students related variation to uncertainty.

In fact most justifications were in terms of the personal experiences of the respondents, for example, seven students gave reasons similar to that given by Juan: “Cinemex, because it is very near to my home”. The students that attained higher levels in other questions did not discern that the best theatre to go to is Multicinemas

Working Group 5

(or Cinépolis) because it has less variation and therefore less uncertainty. These are some of the answers:

Miguel: h) Cinépolis. Because I like how they have the things and I do not mind how many previews they show.

Estefany: h) Cinépolis because the waiting time is less there and it is more famous.

In a later analysis it was discovered that the context is not the best to promote interpreting variation as uncertainty. The justifications of a selection of a theatre in terms of personal experiences are reasonable although participants didn't draw conclusions from the data. The reason is that in this case uncertainty does not bring adverse or grave consequences since most people do not mind to wait for long or short time in a cinema.

DISCUSSION AND CONCLUSIONS

It is important that, during the process of understanding the notion of variation, students be able to make and read graphs as well as to calculate and interpret the mean of data. Acquiring these competences implies different levels of complexity. Most students that show a good level of competence when making graphs and who are able to compare sets of data based on the mean can identify which cinema chain has the greatest variation.

This study shows that it may be convenient to teach the graphing of distributions and central tendency measures (in particular the mean) by presenting them through problem-situations in which variation is also part of the problem. The meanings of those notions are mutually binding and the understanding of each of them is stronger when they are conceived as part of a concept web rather than as isolated notions. However, it must be expected that the understanding of each of these notions goes through different levels so that they progressively join into more complex concept webs.

It is particularly convenient to rethink the role of uncertainty within this concept web. The intuition of "avoiding uncertainty as much as possible" can indeed be applied to many situations in which data variance can be understood in terms of uncertainty. This can help when making decisions or when making informal inferences.

It becomes frustrating to observe that students were not able to infer that it is more convenient to go to the movie theatre which has less variability in its wait-time. One of the students, whose answers are classified in the higher levels, chooses the movie theatre with less variability but her reason is that less variability means "less wait-time". This is one way mean may be confused with variation. Even when this confusion was also present among other students, this particular case is interesting because she gave good responses in the other questions. This leads to the question of what was missing in order to achieve better understanding of variation. Our answer

Working Group 5

is that she was unable to associate variation with uncertainty. This difficulty may not be surprising because the teaching episodes did not help students to see that relationship since, in the context of body temperature, variation is interpreted as information, not as uncertainty. Also, in the problem of wait-time in cinemas waiting for long or short time is not really important for people. The authors are trying to investigate the same research question using another problem or context where variation brings more serious or grave consequences.

CARRYING OUT, MODELLING AND SIMULATING RANDOM EXPERIMENTS IN THE CLASSROOM.

Michel HENRY* & Bernard PARZYSZ**

Today, the teaching of randomness in schools makes frequent use of technology – for example, random experiments that are simulated by the use of a random generator. In fact, what is actually being simulated is a probabilistic model of the experiment. This is a problem when one must teach probability through both a classical and frequentist approach, as is the case in French high schools. We propose a solution for overcoming this issue and approaching the concept of a probabilistic model by on the one hand preserving the ‘isomorphism’ between the protocol put into play in the ‘concrete’ experiment and the simulation process, and, on the other hand, by making the experimental hypotheses explicit and taking an interest in the analogies between the tables produced by the software when simulating different experiments (which means that they implicitly refer to the same model). More generally, making use of computers is of didactical interest because they can help students to grasp and better understand the modelling process in random experiments.

Keywords: random experiments, simulation, spreadsheet, model, modelling process.

INTRODUCTION

Today, many countries include statistics and probability in their math curriculum at the high school level. This change is obviously linked – at least in part – to the increasing amount of statistical data published in the media. But it is also linked to the evolving development of technology, especially with regard to software that can process vast numerical data. Teaching probability at the high school level is indeed a delicate issue, since students are confronted with many difficulties – difficulties that often compound one another. These include: the introduction of a new concept – one of its meanings being related to a specific idea of limit (stabilized frequency); language of sets; logic of events; and, above all, modelling processes.

At any rate, the didactic answer to such a challenge cannot be to overlook this process. It is, rather, to have students become familiar with and experiment with – as soon as possible – real-life random situations, as is now the case in many countries at the junior high – and even elementary – school levels. It is also necessary to give students the linguistic tools associated with the description of such situations.

Additionally, various instruments (calculators, computers) and forms of software (spreadsheets) have become important tools in the domain of probability study [Batanero *et al.* 2005]. They include a ‘random’ generator to simulate random

* Université de Franche-Comté.

** Université d’Orléans & LDAR (université Paris-Diderot).

Working Group 5

experiments – which is much quicker than performing the actual experiment. For this reason, it is necessary that research in didactical engineering at the high school level should emphasize the study and proposition of various situations that can easily be simulated and are, of course, efficient from an educational point of view [Pratt 2005].

In France – and in many other countries – probability curriculum develop an approach of the concept of probability through relative frequency, in which the probability of an event linked with a random experiment can be estimated by a large number of iterations of that experiment. This is opposed to calculating it from symmetry considerations, using the classical formula (which cannot always be done):

$$\frac{\text{number of favourable issues}}{\text{total number of issues}}$$

Even if the genuine experiment can be repeated, this is difficult and time-consuming. Therefore, genuine experiments are often replaced by simulations using a spreadsheet. But this is not as simple for students as it is for us ([Pichard 1998], [Girard 2005]) and frequently, students do not acknowledge the similarities between several experiments that look different but implicitly refer to the same theoretical model (of which they have no idea at that time). In this presentation, we want to address these questions and propose some solutions that make use of spreadsheets.

A RANDOM EXPERIMENT

In order to simulate a random phenomenon with a spreadsheet, one must decide how to use the random generator in accordance with the phenomenon. To illustrate this, we shall use a famous historical example: a game called ‘heads or tails’ (*croix ou pile* in French), which was widely played in France in the 18th century and which comprises two players and the use of one coin. The first player tosses the coin: if he gets “heads,” he wins; if he gets “tails,” he tosses the coin again. This time, if he gets “heads,” he wins, and if he gets “tails,” the other player wins.

About that game, the French mathematician Jean le Rond d’Alembert (1717-1783) [D’Alembert 1754] wrote in the great Encyclopedia that two solutions could be given to determine each player’s chances. First solution: there are four combinations – heads/heads, heads/tails, tails/heads and tails/tails. Since the first player wins in three of these four combinations, his odds are three times better than the second player’s. But d’Alembert suggests that one can reduce the number of total combinations to three, “*since when heads has come at first, the game is over and the second tossing is of no use.*” These combinations are: heads, tails/heads and tails/tails. In this case, the first player’s odds are only two times better than the second player’s.

D’Alembert’s text has been discussed in several high school classrooms. However, it causes great confusion, and students are generally split into three groups of differing opinions [Parzysz 2007]. To get over this puzzling situation, students quickly think of playing a certain number of games, and, by doing so – by chance – they soon

become convinced that the first player has more chances to win than the second player. But what are the correct odds? Three against one or two against one? To be ‘almost’ sure, a great number of games must be played. In some cases, because not enough games are played (around 1,000 are necessary), students find a frequency of about 0.7 and cannot choose between $\frac{2}{3}$ and $\frac{3}{4}$. This is typically the problem posed by a frequentist evaluation of probability: even if it allows for the dismissal of some solutions, it does not necessarily ascertain that one of them is correct.

EXPERIMENT, SIMULATION, MODEL

Since playing a number of ‘real’ games is time-consuming – and, moreover, is not always practical – another option is to simulate the game. But, for many students, even replacing a dice by another one is dubious, so replacing a genuine experiment by a ‘fake’ one (a simulation) – particularly with a spreadsheet – poses similar difficulties. In these conditions, can a simulation really replace the experiment to get an answer of probabilistic nature?

Let us now see what French 10th grade textbooks say about what it means to “simulate” a random experiment. You can sort the ideas into four primary points where the fourth corresponds to our point of view [Parzysz 2008]:

- First idea: a simulation is a *substitute* of the experiment
- Second idea: there must be an *analogy* between the experiment and its simulation
- Third idea: a simulation is more *economic* than the experiment
- Fourth idea: a simulation is a *model* of the experiment

These ideas can be synthesized by saying that simulation consists of replacing a given random experiment by another one, which is easier and/or faster to put into play – provided it can be ascertained that the simulation statistically reflects the characteristics of the genuine experiment. In fact, its appropriateness is ensured by the probabilistic model which underlies the simulation. On the whole, the process is as follows: being given an experimental protocol and the possible tools, one suggests a model for the experiment and implements a simulation of this model. Afterwards, the experimental data will be confronted with the simulation and the model is then either accepted or rejected (fig. 1).

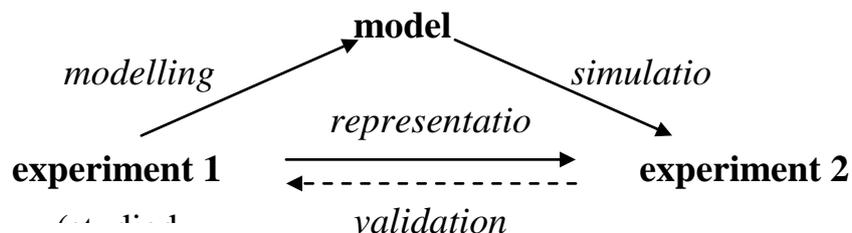

Figure 1

Working Group 5

This may be a real problem for younger students who do not know what a probabilistic model is. For them, in those cases, the above ternary diagram becomes binary (the ‘model’ vertex disappears). In our example, the class could be split into two groups: in one group, students will carry out the genuine random experiment (exp 1), while in the other group, students will simulate it with a spreadsheet (exp 2).

Then, a comparison between the two experiments may be carried out, leading to reflection that aims to make explicit some hypotheses and the ways in which they correspond to features of the simulation.

For instance, let us consider the elementary example of tossing a coin, for which we want to study the distribution of heads and tails in a designated number of tosses. We can make the following hypotheses:

- (H1) There can only be two results: ‘heads’ or ‘tails’ (according to the visible side of the coin).
- (H2) If the coin falls on its edge, the try is nullified.
- (H3) The coin is well-balanced (*i.e.* heads and tails have the same chance of occurring).
- (H4) The coin is tossed so that the result cannot be foreseen.

This set of hypotheses obviously constitutes a simplified abstraction of reality [Henry 1999], in which some aspects of the experiment are neglected (*e.g.* H2: coin falling on edge) or assumed (*e.g.* H3: well balanced coin) and some details of an experimental protocol are made explicit (H1, H4).

Now the hypotheses must be transformed into issues of the random generator. This will be attained by defining a transformation and associating an issue, H (heads) or T (tails), to any number x ($0 \leq x < 1$) produced by the random generator, such as:

- (H1) + (H2) \rightarrow the issue H is associated with a value $x < .5$, and the issue T with $x \geq .5$;
- (H3) and (H4) correspond to the randomness of the sequence of numbers.

To make this last point clear, let us recall that a so-called ‘random’ generator is in fact a deterministic generator, since the numbers produced are successive terms of a recurrent sequence given under the form of decimal fractions with a fixed number of digits [Parzysz 2005]. Nevertheless, we may assume that the generator has been tested by the manufacturer and can consider it a fair simulator of a random sequence.

SIMULATION PROCEDURES AND MODELLING

When simulating a random experiment with a spreadsheet, it frequently happens that several possibilities can be considered *a priori*. To illustrate this, let us go back to our example: the ‘heads or tails’ game described above, in which we shall suppose that the coin is well balanced. Two procedures (at least) are possible:

Procedure 1.

Produce a random variable (alea1) with two equally distributed issues H and T:

- if H happens you win;
- if T happens, produce a random variable in the same conditions as above (alea2), then: if H happens, you win;
- if T happens you lose.

This procedure leads to table 1, in which H is associated with a random number smaller than .5.

<i>Game</i>	<i>Alea 1</i>	<i>Result</i>	<i>Alea 2</i>	<i>?</i>
1	.732	again	.813	lost
2	.307			won
3	.042			won
4	.967	again	.274	won
5	.766	again	.819	lost

Table 1

Procedure 2.

Produce two independent random variables (alea1 and alea2) with two equally distributed values H and T:

- if both show T you lose;
- otherwise you win.

This procedure leads to table 2, in which H is associated with a random number smaller than .5.

<i>Game</i>	<i>Alea 1</i>	<i>Alea 2</i>	<i>?</i>
1	.732	.813	lost
2	.307	.785	won
3	.042	.654	won
4	.967	.274	won
5	.766	.819	lost

Table 2

The second simulation is easier to carry out than the first, which contains two interwoven aleas, but it introduces a second tossing that does not always occur in the real game. Although very useful, this virtual toss may cause some students to only reluctantly accept the second procedure as a simulation of the real experiment. The same opposition was expressed by the French mathematician Roberval (1602-1675), as Pascal mentioned in his famous exchange of letters with Fermat in 1654 about the now-famous ‘share-out problem’ [Parzysz 2009]. Therefore, it proves necessary to make students understand that this kind of change does not modify the results (as Fermat himself did).

But this difficulty can be overcome. Let us consider the two above tables (intentionally, the same numerical data appears in both tables). We can observe that in table 1, the “Result” column can be removed without any consequence and that in table 2, suppressing some numbers (namely .978 and .724) has no effect on the outcome of the game, since the player has already won.

Working Group 5

After these changes are made, the two tables become identical, showing that the two implemented procedures (hence the two associated experiments) yield the same results and that one can replace *procedure 1* by *procedure 2* without any disruption to the data.

More generally, comparing several experiments through their simulations by looking both at the associated procedures (in order to make the underlying hypotheses explicit) and at their implementations on a spreadsheet makes it possible to convince students that some simulations (and their corresponding experiments) may be 'equivalent' in spite of any apparent differences. When carried out, they behave similarly from a probabilistic point of view. This is because they correspond to the same 'experience scheme,' which can be considered a first step toward the notion of a probabilistic model to be built later on (fig. 2).

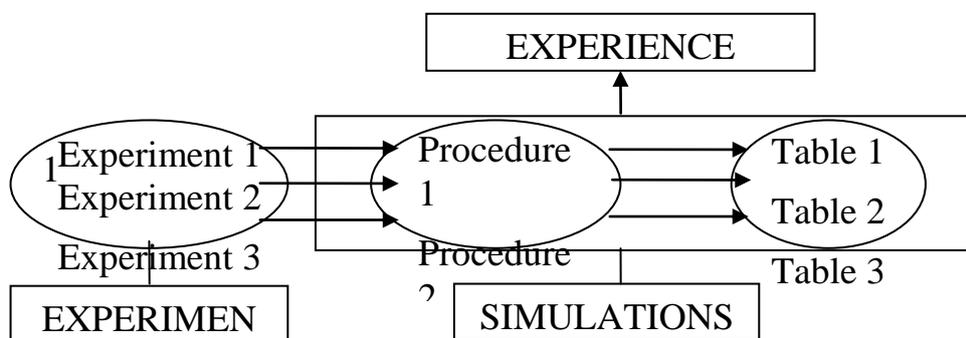

Figure 2

Thus, through the idea of experience scheme, such examples of simulations lead students to a first idea about probabilistic models and the modelling process [Garfield 2008]:

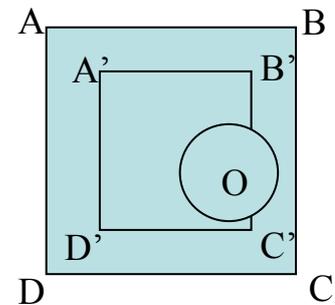

- describe and analyze the random experiment at stake
- work out an experimental protocol, i.e. the set of features defining the experiment from a probabilistic point of view: list of observable issues, characteristics of the events that will be considered (corresponding to each issue), actions to perform in order to ascertain that the *same* experiment is repeated
- make work hypotheses explicit in order to be able to control the relevance of the model in construction
- interpret the characteristics of the real experiment in terms of model hypotheses (especially the probabilities representing randomness)
- translate these hypotheses into computer instructions, in order to solve problems that seem, at first sight, inaccessible via mere calculation
- theoretically exploit the model to draw properties accounting for phenomena which can be observed in reality
- interpret the results of the simulation by comparing them to the initial model hypotheses

SIMULATION AS A TOOL FOR SOLVING PROBLEMS

With the d'Alembert's problem, we can verify that the result of a simulation is in accordance with the probability calculated a priori in the model – assuming the same probability to all ordered pairs of possible issues. This reinforces student confidence in simulation (but, in fact, this confirms that the computer and software makers satisfied the schedule of conditions with regard to the random generator). Nevertheless, the didactical interest of simulation must not be neglected, since it allows for finding solutions to problems that are too difficult or even impossible to solve by hand [Biehler 1991].

Let us now consider the following example inspired by the 'free tile' game (*franc-carreau*, in French). This game was very popular in France during the 18th century, and the probability problem associated with it was first analyzed by the mathematician and naturalist Buffon (1707-1788) [Buffon 1733]. In this game, a coin is thrown on a floor covered with square tiles and players bet on its final position: will it stop on a single tile ('free tile') or land on a line adjoining two tiles?

Let us consider the tile where the centre O of the coin is fallen. With the hypothesis (implicit for Buffon) that all locations of the tiling had the same chance to be reached, the answer to this – now classical – problem can easily be found by comparing the areas of the two squares $ABCD$ and $A'B'C'D'$ to obtain this geometrical probability : $A'B'^2 / AB^2$.

In a simulation of this problem, with $AB = 1$ and the radius of the coin equal to $\frac{1}{4}$ ($A'B' = \frac{1}{2}$ and the probability of 'free tile' is .25), we obtained for several series of 10,000 successive throws relative frequencies equal to .2564; .2515; .2445; .2497...

On the one hand, the simulations will give similar results from a probabilistic point of view. On the other hand, a simple calculation will show that the ratio of the 'good' area ('free tile') to the total area is quite close to the values obtained by simulations. Thus, students can interpret these values as approximate measures of the probability of 'free tile' and, convinced by quality of this simulation, gain confidence in this tool.

In 1733, Buffon also studied the case of a small stick thrown on a parquet floor (this is the well-known 'Buffon's needle problem' [Klain 1997], [Aigner 2006] or [Henry 2003]). These historical examples lead us to a more difficult problem than the free tile game, which can be solved by a simple simulation on a spreadsheet. Let us now assume that a rod – and not a coin – is thrown on a square-tiled floor. The probability of 'free tile' cannot be calculated so easily. However, made confident by the good result given by the computer simulation in the case of the coin, we infer that it will be the same for the rod, *i.e.* that the stabilized frequency will be close to the probability which could – perhaps – be calculated by hand (such a calculation

implies advanced mathematical knowledge). Thus, our problem is as follows: throwing a rod on a floor covered with square tiles, what is the probability of it landing on a ‘free tile’

Let us represent the rod by a segment [AB] (fig. 3), the length of which is a , and consider the tile on which the end A fell. This tile is represented by the unit square in a cartesian coordinate system.

Let x and y be the random coordinates of A ($0 \leq x < 1$, $0 \leq y \leq 1$) and t the random angle between the x -axis and vector AB ($0 \leq t \leq 2\pi$). The rod makes ‘free tile’ when these two conditions are satisfied:

$$0 \leq x + a \cos t < 1 \text{ and } 0 \leq y + a \sin t < 1$$

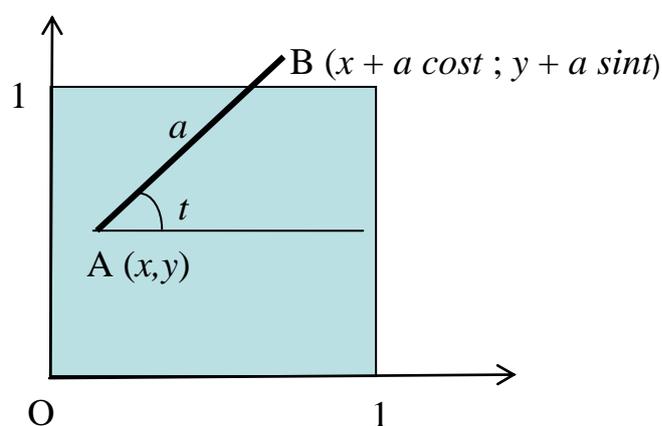

Figure 3

The volume in x, y, t delimited inside the cartesian product $[0,1] \times [0,1] \times [0,2\pi]$ by these conditions is not easy to calculate, but the simulation of the experiment is within reach of a senior high school student with the model hypothesis of the uniform distribution of (x, y, t) in the above product. Here is a possible carry-out of this simulation with a spreadsheet.

Length of AB	(cell) A1	.44	Comment	Example
$x(A)$	B1	=ALEA()	Alea 1	.306
$y(A)$	C1	=ALEA()	Alea 2	.477
angle t	D1	=2*PI()*ALEA()	Alea 3	5.786
$x(B)$	E1	=B1+A1*COS(D1)		.692
$y(B)$	F1	=C1+A1*SIN(D1)		.267
Free tile = 1	G1	= IF((E1>0)*AND(E1<1)*AND(F1>0)*AND(F1<1);1;0)		1

For instance, by implementing this simulation, we had got the following results for a rod of length $a = .44$

Frequency of free tiles in 250 tries	Frequency of free tiles in 1000 tries	Frequency of free tiles in 5000 tries	Frequency of free tiles in 10,000 tries	Confidence interval at 5% risk for 10,000 tries	
.496	.496	.493	.499	.489	.509

Thus, we have here a tool for solving problems that plays the exact same role as graphic calculators, which can draw curves to represent functions – for finding the approximate graphical solution of a system of equations, for instance.

DIDACTICAL SIGNIFICANCE OF SIMULATION

Despite the obvious utility of simulation, our interest is fundamentally didactic. First, computers are capable of working on vast statistical series, which gives meaning to statistical summaries (parameters, graphs) and demonstrates their relevance. They also provide a dynamic presentation of how the notions of relative frequency and probability work and interact – notions that are encountered in France in the 9th grade, either theoretically, in an equiprobabilistic context, or through practical experiments with numbers large enough to foster an understanding of the law of large numbers in actuality.

Of course, the computer does not make use of the notion of probability when it performs a simulation: it just exhibits the effects of the equirepartition principle on the random numbers that it generates, (a principle which is part of its specifications.) But even so, the use of computer simulations in the classroom – as a pseudo-random generator – fosters a better understanding of the notions of relative frequency, sample fluctuation, variability of empirical parameters and, finally, probability.

Making the most of the power and speed of computers to generate pseudo-random numbers and introduce them in relevant formulas – which realizes a simulation of the model of a studied experiment – introduces students to a great richness of new virtual random experiments. This is not the only interest of computers, however, for the didactical significance of simulation is fundamentally to lead students to grasp the modelling process as described above. From a didactical point of view, we stress the importance of posing problems in terms of modelling, which implies that one must make the model hypotheses explicit and choose them in relation to the studied problem [Henry 2001]. This allows students to avoid paradoxes and overcome obstacles linked with their own preconceptions, since probability is a domain in which intuition is often misleading. Identifying such insufficient or erroneous conceptions among students, investigating their origins, spotting and analyzing such difficulties (which are cultural as well as epistemological and didactical) and designing didactical situations in order to overcome them – these are all necessary tasks for future research in math education.

To conclude, we quote a paper presented in CERME 6 [Papaieronymou 2009], which reports these recommendations of four U.S. professional organizations that place considerable emphasis on experimental vs. theoretical probability and simulations:

“Secondary mathematics teachers need to be able to plan and conduct experiments and simulations, distinguish between experimental and theoretical probability, determine experimental probabilities, use experimental and theoretical probabilities to formulate and solve probability problems, and use simulations to estimate the solution to problems of

chance. Secondary mathematics teachers should be able to provide a model which gives a theoretical probability that can be compared to experimental results, which in turn is essential when studying the concept of relative frequency. In order to help students develop an understanding of probability as a long-run relative frequency, secondary mathematics teachers need to understand the law of large numbers and be able to illustrate it using simulations”.

RISK-BASED DECISION-MAKING BY MATHEMATICS AND SCIENCE TEACHERS

Dave Pratt, Ralph Levinson, Phillip Kent & Cristina Yogui

Institute of Education, University of London

In modern society, the notion of risk is drawn upon to convey much human decision-making. In fact, risk is variously depicted and the psychological literature is divided in how people make sense of risky situations. At a time when curricula, especially in the UK, are recognising the need for students to be sensitised to risk-based decision-making, we have been studying how mathematics and science teachers make sense of risk, focussing on activity around a specific personal dilemma. We analyse this data through the lens of the priority heuristic. We identify possible limitations in the priority heuristic. We conclude that these teachers needed greater support for coordinating the dimensions of risk and offer one software response.

RISK

In this paper, we consider how a mathematics and science teacher engage in risk-based decision-making with a view to evaluating whether recent psychological research adequately describes that process and what additional resources might be offered to support such decision-making.

In modern society risk permeates decision-making at both personal and policy levels, a fact now being recognised in curricula. The exponential increase in talk around risk has not ironically resulted in its clear definition and the epistemological basis for risk continues to be a subject of debate (Adams, 1995; Stirling, 1999).

In the media, risk is typically portrayed as identical to likelihood, a problem when hazards with differing severity are compared. In such circumstances, both likelihood and impact need to be addressed simultaneously in some sort of trade-off. Indeed, standard decision-making theory formulates risk as the product of the probability (as a measure of likelihood) and disutility (as a measure of loss) and proposes that decisions should aim to minimise the total calculated risk. However, the psychological literature has demonstrated that individuals often do not make risk-based decisions by minimising total risk as in standard theory.

HEURISTICS FOR MAKING JUDGEMENTS ABOUT RISK

Risk-based decision-making is especially complex and so people draw on intuitive heuristics. It has been demonstrated that such heuristics are vulnerable to bias (see, for example, descriptions of the availability and representativeness heuristics in Kahneman et al., 1982). Recent research (Brandstätter et al, 2006) has focussed on trying to specify what people attend to and the information-search procedures used when making risk-based decisions. According to Brandstätter et al, in the case of losses, the decision-making process is described by the *priority heuristic* as follows:

Working Group 5

First, compare the minimum losses of the alternative decisions. If the difference between the two minima is at least 10% of the maximum loss, choose the decision associated with the lesser of the two minimum losses. Otherwise, compare the probabilities of the minimum losses of the alternative decisions. If the two probabilities differ by more than 0.1, choose the decision associated with the higher probability of loss. Otherwise, compare the maximum losses of the alternative decisions and choose the decision associated with the lower maximum loss. (*Our paraphrasing of the heuristic.*)

It is claimed that, under certain conditions, the priority heuristic predicts the decision most people will make *and* the decision-making process that they will undertake. In the literature, this heuristic has been demonstrated by reference to situations in which people are making decisions about different gambling situations with clearly specified profits (or losses) and probabilities.

In this paper, we use the priority heuristic to analyse the teachers' decision-making. We have two main research questions in conducting this exercise. First, we ask whether the priority heuristic is an adequate model in a complex situation where the losses and likelihoods are not clearly specified and may even not be easily quantifiable. We hope through asking this question that we might gain some insights into the scope of the priority heuristic. Second, we ask whether, through such an analysis, what sort of resources might support teachers (and perhaps others) in deploying more sophisticated strategies.

METHOD

Through an iterative design process, we developed a computer-based scenario, Deborah's Dilemma (DD), in which mathematics and science teachers were required to respond to the fictitious Deborah's difficulty in deciding whether to have an operation that could cure a painful spinal condition. The operation might result in a number of complications described through various, and at time conflicting, sources of information. Should Deborah choose not to have the operation, she would need to manage her pain level through changing her daily routines of work, domestic and leisure activity.

Information about Deborah's condition was set out within the software in a deliberately personal way, to offer different perspectives with varying levels of authority. Two software tools accompanied the information about the condition. First, a probability simulator allowed the teachers to model the possible complications to gain a sense of how often the operation might be successful, and how often complications of varying degrees of severity might occur. Second, a 'Painometer' offered a quantified experience of Deborah's pain in relation to a "tolerable" level, as the pain was influenced by the activities in which Deborah engaged. The teachers modelled which activities Deborah would undertake to infer the effect of these on Deborah's pain level.

Working Group 5

Three pairs of teachers (one science and one mathematics from the same school in each pair) worked through DD to arrive at a specific response. A researcher sat with each group but only intervened to demonstrate relevant aspects of the software, to address any technical points and to ask questions for clarification. Video screen capture software recorded the teachers' dialogues and on-screen actions. The session lasted approximately 2 hours. Data for the analysis consists of an audio transcript and a video record of their interactions with the software for each pair of teachers.

We present below the findings through the case of Peter (science) and Emma (mathematics). Analysis of the data from the other teachers' is ongoing.

PETER (P) AND EMMA (E) ENGAGE WITH DEBORAH'S DILEMMA

We present the activity by P and E in two stages. The first stage represents the process by which P and E came to a decision based on their interpretation of the information given in DD. Later, we present their ongoing activity after an intervention from the researcher (the first-named author).

Stage 1: Before the researcher's intervention

P and E read the introductory information about DD and formed an initial reaction:

P: If I was Deborah I think I'd have the operation.

E: I agree – so we'll go for operation first.

They then began to look more closely at the information available about the operation and expressed some concern about the reliability of the data, especially in relation to Deborah's personal research:

P: Now her own research. Reliability, source.

E: Yes, that is questionable – one list from any old website you don't know, could be one person.

As they read the information, they discussed the chance of the operation being successful as well as the possible severity of the complications and their likelihoods.

P: Right that's saying 95% of the time it works, but if it doesn't you have to have the operation again.

E: 1 in 1000 of nerve root or spinal cord damage. 5[referring to the fifth listed complication] is temporary and happens 1% of the time...

P: Number 4 sounds scary [referring to nerve root/spinal cord damage]... it might mean a bit of tingling, pins and needles, which is a different level from being in a wheelchair. But you don't know, and of course they can't tell you because, when you're in the operating theatre, different things happen to what was expected.

P and E discussed which complications should be included in their model:

E: Shall we put the other one – the 1 in 500, what was that? [checks web page] damage to trachea/oesophagus - only possibly permanent, but if you can't eat that is significant I would say – it would worry me! [laughs]

Working Group 5

P: That sounds really horrible. Should happen less than 1 in 500 cases. Let's add that one *[returning to the software tool]*... call it 'trachea damage'.

35 minutes into the investigation, P and E ran their model, starting with one case, then extending it to 10, 100 and 10010 trials.

E: That's not bad, 17 [failures] out of 10,010. I'd take those odds.

P and E continued to modify and run their model, adding complications related to anaesthetic and infection from a superbug.

E: 9010 successful. And anaesthetic is 1, which doesn't necessarily mean dying *[laughter]*. And 33 superbugged – slightly horrible, but they should have gone to a better hospital. So that was the biggest. Nerve damage was pretty low *[referring to the number of cases of nerve damage out of 1000, which was 8]*. The no eating no drinking thing, 17.

P: But you don't know how severe that is; it could be anything from a sore throat up to no eating.

E: Only one had a problem with the general anaesthetic.

P: I think that probably means death, or severe brain damage, something pretty awful.

E: And superbug can be awful. But again, out of 990, which have failed, only 49 people, which is 50 in 1000, which is tiny.

P: And the rest just had the pain they had before.

E: If you had the operation without success, you had the uncomfortable experience, but you haven't lost much else apart from time. At least you haven't gone backwards. I think she should have it.

E confirms in line 0 their original intuition (line 0) that Deborah should have the operation. At this point (49 minutes into the investigation), the researcher proposed that they began to consider Deborah's lifestyle through the second software tool. They discussed which activities to include and what levels to set the amount of activity and consequent pain incurred.

E: I don't believe her, that she does that much sport. She didn't seem that upset about not being able to do sport.

P: It did impact on her life though.

E: Shall we leave it as, a fair bit?

P: May not be higher than that, just 'more pain'.

After 56 minutes, P and E ran their model of Deborah's lifestyle.

E: Look! *[Laughter]* She's always above the tolerance, apart from once in a blue moon.

P: Yes... oh look though, it's painful to look at isn't it?

P: If it was like that you would stop doing your sport.

The researcher proposed that they experiment with different settings.

P: OK, take her sport, like I can't do all these things.

E: But even if she does, she's still above it *[Sport slider is moved to zero]* – she can do lots and lots of work and no sport and she is OK *[pain level always under the tolerance level]*

Working Group 5

P: Yes, though she's always up to tolerance level.

E: If I increase this [*gradually increasing the Sport slider*], watch for the first point...

P: There!

E: See, that is not much sport she is allowed to do.

P: You'd want the operation immediately.

Having added the sorting activity, P and E felt even more confident that Deborah should have the operation. They continued by adding further activities to model Deborah's lifestyle, and remained convinced that having the operation was the better option.

P: As soon as you look at this one it would make children think she should have the operation, with the impact on your life.

E: We were undecided until we started looking at the pain.

P: Yes, because then you are thinking about what it does to your life. Every day it always hurts, and when she does sport, it always hurts when she shops. The risky bits of the surgery might not happen to her, but she knows every day 'when I go shopping it's going to hurt me'. With the surgery lot of things are short-term, even if you got worse for a while then you know the end point is going to be better than you were in the first place.

E: When we were looking at the surgery, successful outcome, we did not really, it wasn't conclusive until we looked at the pain threshold.

P & E often thought about the problem through the eyes of their students in school (see line 0). Lines 0 and 0 give some indication of what influences P and E in coming to this conclusion as does E's later comment (line 0):

E: Yeah, you forget about all the numbers and think, "Bloody hell!"

Stage 2: After the researcher's intervention

After 85 minutes of the investigation, the researcher wished to probe P & E's basis for their position – wondering to what extent was it sensitive to the parameters in the problem. He asked P and E consider how far the probabilities would need to change for them to reverse their decision that Deborah should have the operation. As a result, P and E reviewed the complications and, after running the model 1000 times, found complications on 50 occasions i.e. a worse position than prior to the operation on 1 in 200 occasions.

E: 1 in 200, that's actually not - it's not as successful as we thought! [*laughter*] Are you mortified now? 1 in 200, that's still pretty good though, I think. You're not convinced are you?

P: I don't think they'd be keen on surgery – that's it's not working?

Noting that P & E were now aggregating the complications as 'being in a worse situation', the researcher pressed by asking what they would think if all 50 occasions involved death or impairment.

E: I'm slightly – if I was Deborah, and there was me dying, that would be better than being still alive with something horrible – do you know what I mean, it sounds stupid, but if I'm dead I don't care, but if I'm alive and feeling pain, obviously it

Working Group 5

depends - another thing is what her family situation was, if she's got young children, with a 1 in 200 chance, you'd rather be there for your kids, whereas being by yourself, you know you might have a slightly... I think I probably wouldn't, I dunno, I'm a bit of a...

P: Because the pain she has doesn't stop her leading a normal life.

E: She leads a restricted life, but she's not bedridden or anything.

After 100 minutes, P and E reviewed their position.

E: Oh, but she's still got to live with that pain every day, I'd still go for... I don't know if I'd change my mind...

P: She's got a 1 in 200 chance of being worse off.

E: But she's in pain for most of her life.

P: That is partly under her control; she could stop sport for example.

E: Yeah, I think I'm changing my mind, but she couldn't stop her work; she could stop driving, but she wouldn't be able to carry things. Oh, we should just have stopped when we were happy! *[laughter]*

P: She could change her job. Probably she's been through some of those thoughts already. She didn't go straight to the doctor. She's lived with it quite a long time.

E: You'd try to make adjustments, you wouldn't be considering the operation if you hadn't thought about adjustments.

The intervention apparently led to P and E being less confident about what decision Deborah should make. They finally wrote:

...she can to a certain degree control the pain by not doing certain activities like sport but this lowers her quality of life. If she has the operation, there is a 1 in 200 chance of her having horrible complications plus there are other alternatives with the exercises and the neck brace. Her personal home life would also be a significant factor, depending on children etc or if she is a carer...

DISCUSSION

Brandstätter et al (2006) claim that the priority heuristic not only predicts the decision but also describes the decision-making process. We examine both of these claims.

The priority heuristic as a predictor of Peter and Emma's decision

Table 1 shows the possible outcomes and their likelihoods as entered by P and E into their model of the decision to have the operation.

<i>Outcome</i>	<i>Likelihood as entered</i>	<i>Likelihood as n in 10000</i>
Operation successful	450 in 500	9000
Nerve damage	1 in 1000	10
Trachea/oesophagus soreness	1 in 500	20

Working Group 5

General anaesthetic	1 in 1000	10
Superbug infection	1 in 400	25

Table 1: Complications in P & E's model for the decision to have the operation

In modelling Deborah's lifestyle, P and E entered sport, work and shopping as three activities that impacted on her pain level. They formed the view that, with these activities in place, Deborah would suffer almost constant above-threshold pain.

Following the priority heuristic, as set out in the subsection on *Heuristics for making judgements about risk*, the minimum losses that could be incurred are zero for a successful operation and constant above-threshold pain if no operation. The lower loss is zero and so priority heuristic predicts an initial decision that Deborah should have the operation. However, that is only the final decision if the minimum losses differ by at least 10% of the maximum loss, death or paralysis. It is unclear whether the difference between zero loss and constant above-threshold pain is more than 10% of the loss incurred by death or paralysis. If not, then the priority heuristic may predict a different decision, based on the probabilities of the minimum losses, 0.9 (for the successful operation) and 1, or perhaps slightly below 1, for the constant ongoing pain. The difference between these two probabilities is less than 0.1 and so the priority heuristic refers next to the maximum loss. This is presumably death or paralysis and so the prediction is a decision not to have the operation.

In conclusion, the priority heuristic makes the correct prediction for Stage 1 provided constant above-threshold pain is regarded as an order of magnitude below the loss associated with death or paralysis, which is perhaps reasonable, though not entirely clear, given E's view in line 0. Insofar as P and E were, after the intervention, wavering towards a decision not to have the operation, it is unclear why the intervention might have changed any of the considerations above, other than possibly by placing 'unnatural' emphasis on the complications associated with the operation.

The priority heuristic as a description of the decision-making process

One criticism might be that P and E took an early view that Deborah should have the operation (lines 0-0), arguably signalling an end to the search for a decision, and yet continued beyond the apparent stopping condition, in contradiction of the priority heuristic's description of the process. We think this criticism would be unfair. The priority heuristic assumes that all information is available at the point of decision; it is certainly the case that, in taking their early view, P and E had not yet assimilated all of the information, so we take continued activity as part of the process of reaching a point where a decision might be made that could follow the priority heuristic (activity such as making sense of the likelihoods and judging to the severity of the complications in lines 0-0, and such as deciding which activities in Deborah's life were significant and how they should be measured in lines 0-0).

Working Group 5

The heuristic indicates that the decision-making process will place first priority on perceived losses. Certainly there is substantial focus on the harms that might result from complications arising out of the operation (lines 0-0; 0-0) and in Deborah's lifestyle (lines 0-0). However, there is also considerable discussion about likelihoods and these often take place alongside discussion of losses. More pertinently, P and E make specific reference to losses when describing how they were making their decision. Thus, in line 0, E explicitly articulates how her focus is on the possible zero loss outcome of having the operation and uses that fact to argue for Deborah having the operation. Similarly in lines 0-0, both P and E clarify that the operation became increasingly the better option when they considered the constant pain of not having the operation, presumably in comparison to the possible zero loss when having the operation. Perhaps line 0 captures the sentiment when E refers to forgetting about the numbers (by which we think she means the probabilities).

These articulations strengthen the notion that in the end, after assimilating all of the information through reading, discussion and modelling, P and E did in Stage 1 seek to minimise the minimum loss, in accordance with the priority heuristic.

After the intervention, P and E were encouraged to consider that extreme complications were rather likely. According to the priority heuristic, the decision should remain the same since the minimum losses were not affected by this re-evaluation. So, why might P and E show signs of changing their mind? Our interpretation is that the intervention, by focussing on likelihoods, artificially pushed P and E into the later steps of the priority heuristic, resulting in the consideration of maximum losses and a decision not to have the operation.

Limitations of the priority heuristic

Broadly speaking, we think the priority heuristic provides a good prediction of both the decision and the decision-making undertaken by P and E. In conducting this analysis, we have become aware of some interesting limitations. The findings reported in the Brandstätter et al study were based on responses to situations that were already quantified both in terms of loss (or gain) and likelihood. Rarely in real-world problems is it possible to quantify very precisely, if at all, either likelihoods or losses. This raises a question about how individuals cope with such uncertainty. Perhaps the priority heuristic is still relevant when there are clear and distinct differences, such as between the zero and constant above-threshold losses. But when the teachers were artificially pushed beyond that step in the heuristic, they found decision-making much more difficult. Perhaps their hesitancy was partly because the differences were far less self-evident, such as the differences in the probabilities of the two minimum losses. We wonder what the teachers would have done if the dilemma had involved two decisions with similar unquantified minimum losses.

The uncertainty in real world decision-making is further accentuated in practice by concerns about the source of data. P and E regularly referred to these concerns (such

as in lines 0 and 0). In such circumstances, people are likely to go with the judgement of what they see as the highest authority.

It is also important to recognise that the judgements of loss (and to a lesser extent perhaps likelihood) are essentially subjective and so differences in decision across individuals do not necessarily reflect a failure in the priority heuristic but might instead represent differences in individuals' judgements. This is highlighted by E in line 0, when she acknowledges that death might under certain circumstances be preferable to constant pain, and, in line 0 and in the final report, where she refers to the relevance of Deborah's family situation to making such judgements.

CONCLUSION

The above analysis demonstrates that the two teachers placed highest priority on losses (rather than probabilities) and that they decided according to the lesser of the minimum losses that would be incurred by the two possible decisions. It is also evident that their use of the priority heuristic is not robust. A simple intervention seemed to push them to focus on elements of the heuristic that would normally not have been triggered. Such a lack of robustness is not surprising when the teachers were dealing with a complex scenario with many aspects unquantified and in mutual conflict. Nevertheless, we believe that this uncertainty reflects common scenarios for personal decision-making. Perhaps this is indicated by Cokely and Kelly (2009), when they claim from their experimental evidence that more precise process modelling of risk choices with the priority heuristic would require at least one parameter that creates variation in the search and stopping rules.

We have presented the activity of one pair of teachers in detail. Analysis of the remaining data is continuing. This further analysis might reveal differences across different subject disciplines but any such findings would need to be treated with caution. Already, we see in our analysis reasons to be sceptical about the easy transfer of psychological research findings from straightforward situations to complex scenarios. These initial conjectures will be tested in the ongoing analysis.

Furthermore, the software is a response to another distinction between educational and some psychological research. As educators (rather than psychologists), we need to ask what does this mean for schools, and in particular for mathematics and science classrooms. The above activity demonstrates the complexity of risk-based decision-making, especially in rich scenarios such as DD. The evidence that people avoid trade-offs and apply heuristics such as the priority heuristic is compelling. As educators, should we be satisfied with increasing our understanding of how such decisions are made or should we take this evidence as a pedagogic challenge to find ways to support thinking that engages more explicitly with trade-offs by facilitating the co-ordination of the various dimensions of risk? Perhaps inspired by the progress made in statistics education in supporting students' meanings for randomness and inference (for example: Pratt, 2002; Konold, 2007; Ben-Zvi, 2004), we are aiming to

respond by designing new tools, with the explicit aim of supporting coordination of risk. We imagine tools that can list and order hazards by size of risk, that consolidate harm, likelihood as well as ethical and moral dimensions.

In the latest design of DD, we have incorporated a concept-mapping tool, which was not available at the time of the above activity. The teachers would be encouraged to keep an ongoing map by connecting boxes containing information they have entered about possible hazards. Later, the teachers could press a 'Show Risk' button and the hazard boxes would change colour. Boxes towards the left of the screen would become darker while those to right would become lighter on a continuous scale. The teachers would be told that the darker the hazard, the greater its risk. Inevitably, the teachers would now judge that some of the boxes were in the wrong position on the screen. They would be able to drag the boxes to what they would judge to be the correct relative position according to their estimation of the risks. We conjecture that such tools might provide an educational intervention that would enable teachers, and later non-teachers such as students, to coordinate the dimensions of risk into a single construct with the promise that they might, under certain circumstances, use thinking about trade-offs rather than strategies, such as the priority heuristic.

INDIVIDUAL PATHWAYS IN THE DEVELOPMENT OF STUDENTS' CONCEPTIONS OF PATTERNS OF CHANCE

Susanne Prediger & Susanne Schnell

Technical University of Dortmund, Germany

An essential property for distinguishing random from haphazard events is the existence of patterns in the long term. Its inclusion into the individual repertoire of conceptions counts as a prerequisite to developing adequate conceptions of chance and probability. This paper exemplifies results from a teaching experiment designed to investigate 11 to 13 year-old students' individual pathways of constructing, enriching and refining their conceptions of patterns of chance

Students' individual conceptions of chance and probability have often been investigated empirically. The construction of conceptions that match the underlying stochastic theory (shortly called *intended* or *mathematically-appropriate* conceptions) seems to be a major challenge for stochastic education (e.g. Shaughnessy, 1992) and is deeply influenced by students' initial everyday conceptions (Fishbein, 1975; Konold, 1989). While early conceptualisations of these initial conceptions labelled them as misconceptions (e.g. overview in Shaughnessy, 1992), stochastic education researchers with a constructivist background have taken them seriously as starting points for individual learning processes (e.g. Konold, 1989; Pratt & Noss, 2002) and studied their development. In this tradition, this paper aims at contributing to a deeper understanding of students' individual *pathways of constructing, enriching and refining their conceptions of patterns of chance* as observed in design experiments.¹⁶

THEORETICAL BACKGROUND

Context-differentiated activation of constructs as an aim for processes of horizontal conceptual change

The relevance of individual initial (mis-)conceptions for the construction of conceptions has been explained in constructivist terms: individual, active constructions of mental structures always build upon the existing prior mental structures by accommodation to experiences with new phenomena, while the initial structures serve as “both a filter and a catalyst to the acquisition of new ideas” (Confrey, 1990, p. 21). According to the conceptual change approach (Posner et al., 1982; first applied to probability by Konold, 1989), learning thus has to be conceptualised as “re-learning, since prior conceptions and scientific conceptions are often opposed to each other in central aspects” (Duit & von Rhöneck, 1996, p. 158). For many years, conceptual change approaches have (implicitly or explicitly) guided

¹⁶ The design experiments are embedded in the long-term project KOSIMA that conducts design research for a complete middle school curriculum (cf. Hußmann, Leuders, Barzel, & Prediger, 2011).

the design of learning situations by providing means to overcome initial conceptions and develop them into intended mathematically appropriate conceptions. These means concern, for example, the relevance of concrete experiences, the confrontation of predictions with real outcomes and the generation of cognitive conflicts (see Posner et al., 1982). However, the far reaching aim of “overcoming” individual prior conceptions in mathematics classrooms that guided early views on conceptual change is not universally applicable. Empirical studies show that it is not always realisable, as individual conceptions often continue to exist next to the new conceptions and are activated situatively (cf. Tyson et al., 1997; for probability e.g. Shaughnessy, 1992; Konold, 1989). Rather than a substitution of initial conceptions, the more adequate aim is the *shift of contexts* in which initial and intended conceptions are to be activated. “Successful students learn to utilize different conceptions in appropriate contexts.” (Tyson et al., 1997, p. 402). Pratt & Noss (2002) emphasise changes in priority between initial and intended conceptions as one pathway of a conceptual change.

Prediger (2008) called this modified perspective on conceptual change with persisting co-existence of initial and intended conceptions a *horizontal view*; in contrast to the *vertical view* on conceptual change, which aims at overcoming initial conceptions. The horizontal view considers students’ initial conceptions as legitimate ideas that can persist if they are weaved into a new framework (similar to Abrahamson & Wilensky, 2007) and can be refined by knowledge of their context-specific scope of validity. Thus, the question guiding the design and analysis of a learning situation for facilitating *horizontal* conceptual change transforms into the following: *How can a learning situation support the extension of individual repertoires of conceptions (constructing and enriching), and how can learners be enabled to choose adequate conceptions in varying contexts (refining and generalising)?*

For terminological clarification, we mention that in line with the conceptual change approach, the notion ‘conception’ here refers to all subjective mental structures used by learners to explain their experiences. Conceptions may range on different epistemological levels of complexity from concepts, intuitive rules up to local theories that connect different concepts (Gropengießer, 2001, p.30ff.) and can vary in the degree to which they match the underlying mathematical theory. Although the conceptual change approach is suitable to describe the macro-structures in individual pathways of development of conceptions (see for example Prediger & Rolka, 2009), the fine-grained analysis of micro-structures in the processes of constructing, enriching and refining conceptions require a further operationalization on the micro-level (similarly in diSessa, 1993; Pratt & Noss, 2002). For this purpose, we adopted the notion ‘construct’ as the smallest empirically-identifiable unit of conceptions from Schwarz et al. (2009) and their methodology of reconstructing them by means of three observable *epistemic actions*: Conceptions are seen as webbings of

constructs. An epistemic action of *constructing* is defined as (re-)creating a new knowledge construct by *building with* existing ones. This is identified when a construct is first verbalised or shown by action in the analysed learning situation (although sometimes being constructed before the observed situation). Previous constructs can be *recognized* as relevant for a specific context and used for *building-with* actions in order to achieve a localized goal.

Due to our horizontal view, two major adaptations of the notions were necessary: 1. As we consider idiosyncratic conceptions to be legitimate building blocks, we extended the normatively-guided focus from mathematically (partially) correct constructs (Ron et al., 2010) to all individual constructs, being in line with mathematical conceptions or not. 2. Our descriptions of horizontal learning pathways are mainly focused on the epistemic actions of constructing and required the distinction of two special cases of constructing, namely enriching and refining. A construct is identified to be *enriched*, when a complementary construct is put into relation to it which means there are connections to other constructs identifiable. A construct is said to be *refined*, when it is enriched by conditions of applicability; in our study mostly as narrowing the range of applicable situations from a broad initial one. In other situations, initial constructs are *generalized* and transferred to new contexts (as reconstructed e.g. by Pratt & Noss, 2010, p. 94).

of patterns and deviations distinguishing long-term and short-term Conceptions contexts as precondition for context-adequate choices

The existence of patterns in long series of chance experiments can be identified as a crucial insight for developing adequate conceptions of chance and probability (Prediger, 2008). This focus is strengthened by Moore's definition of random as "phenomena having uncertain individual outcomes but a regular pattern of outcomes in many repetitions" (Moore, 1990, p. 97). This includes the important distinction between short-term and long-term contexts which is central since Konold (1989) described many people's "different understanding of the *goal* in reasoning under uncertainty" (p.61, emphasis added) as an important source of deviant conceptions. Whereas probabilistic conceptions only apply to long-term contexts, many people intend to predict single outcomes of chance experiments in a short-term perspective (Konold, 1989). Deviant conceptions — like betting on numbers that have a specific significance such as birthdays — can be experienced as unsuccessful in long-term contexts, but they prove just as (un)suitable — for single outcomes — as the intended probabilistic conceptions. Therefore, the well-known empirical law of large numbers is crucial for horizontal conceptual change since it explains why one can adopt probabilistic conceptions in a successful way (in long-term contexts), although randomness cannot be predicted for single outcomes (the short-term context). The empirical law of large numbers explains the *sense* and *preconditions*, but also the *limits* of probabilistic considerations and offers thus the conceptual base for a context-adequate choice of conceptions.

Borovcnik (2006) emphasised that the learning process while experimenting with dice etc. is hindered by the fact that chance, and therefore the produced data does not only have *patterns*, but also many *deviations*. That is why students have to include these experiences into their conceptions. Therefore, developing context-adequate probabilistic conceptions does not only include the important shift of attention from short-term contexts to long-term contexts (cf. Pratt & Johnston-Wilder, 2007), but also the construction of conditions *when* regularities are visible: whereas patterns are visible in sufficiently long series of outcomes, they can be disturbed by many outliers in short series, and single outcomes might not conform to an expected pattern at all (see Table 1). In this paper, we describe a case of successful development while constructing, enriching and refining constructs of patterns and their deviations in relation to the context.

DESIGN OF THE TEACHING EXPERIMENTS

The learning situation based on ‘Betting King’

To facilitate the differentiation between short-term and long-term contexts in the sense of a horizontal view of conceptual change, a learning situation for 11 to 13 year old students has been designed by Prediger & Hußmann (2012) to provide opportunities for experiences with the empirical law of large numbers. The core element of the learning situation is the board game “Betting King” (Fig. 1), which challenges students to bet on one of four coloured animals in a race. Betting activities refer to making predictions which animal will be the fastest and on which position each animal will end up. The four coloured animals are powered by throws of a coloured 20-sided die (red ant: 7, green frog: 5, yellow snail: 5, blue hedgehog: 3), so that the red ant is theoretically the fastest with a chance of $7/20$. Most children quickly notice the red ant to be a *good bet*. Soon, they activate a fruitful ordinal conception of chance, relating the expected order of animals to the number of coloured faces on the die. In this way, the students’ initial resources to link the empirical pattern to the colour distribution are taken into account. Beyond that, the learning situation aims to refine these initial conceptions into an understanding of when this pattern can be predicted more confidently according to the long-term or short-term context. For this purpose, the context attribute “total of throws” is materialised in the game by a STOP sign for the throw counter. By setting the STOP sign for each game, students can deliberately define the total of throws between 1 and 40 for the board game, and between 1 and 10000 throws for the computer simulation (Fig. 2). In order to lead students from

Fig.1 The Game ‘Betting King’

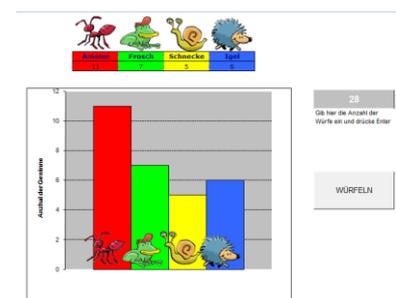

Fig. 2 Screen of corresponding computer simulation

Working Group 5

unsystematically playing the game into systematically investigating the situation, protocol sheets guide the collection of game result data for various predefined throw counts (1, 10, 100 and 1000, later 2000). For refining constructs by the conditions of their applicability, it is important to become aware of the role of the total number of throws.

	Short-Term Context: Single games with small total of throws	Long-Term Context 1: Series of games with small total of throws	Long-Term Context II: Series of games with large total of throws
Pattern	S-pattern non-existent	L1-pattern red ant mostly wins, frog & snail are in similar positions, hedgehog loses mostly	L2-pattern red ant always wins, frog & snail are second, hedgehog last
Quality of prediction	S-predictability difficult to bet, but red ant is still the best	L1-predictability red ant is a good bet, but not a secure bet	L2-predictability red ant is a good and secure bet
Relevance of disturbance	S-disturbance some single outcomes completely differ from any expected pattern	L1-deviation pattern difficult to see due to lot of disturbances	L2-deviation pattern strongly visible, still some disturbance
Explanation of appearing pattern	no adequate explanation for the outcome itself	e.g. L1-theoretical explanation L1-empirical explanation	e.g. L2-theoretical explanation L2-empirical explanation L2-law of large numbers

Table 1: Intended probabilistic constructs on patterns of chance in Betting King

From a probabilistic point of view, the distinction between different long-term contexts and a short-term context is crucial as was elaborated above. But whereas this distinction oriented our data-guided systematisation of intended constructs in Table 1, students first have to construct this distinction between contexts by themselves. In our learning situation, this construction of differences is facilitated by the following leading question: “Apparently, the red ant is a *good bet*. But when is this bet not only the best bet but also a *mostly secure bet*?” The question challenges students to enrich their conceptions by context-differentiated constructs of predictability which are linked to individual constructs of relevance of disturbance, but in many different ways, as we learned in the ongoing data analysis.

RESEARCH QUESTIONS AND DESIGN OF THE STUDY

Following the paradigm of design research (Gravemeijer & Cobb, 2006), the learning situation was tested and improved cyclically over three courses of evaluation in six classes (grade 5 and 6, students aged 11 to 13). The empirical analysis of classroom learning processes in Prediger & Rolka (2009) showed that most students could indeed find better and more secure betting strategies and learned to differentiate between long-term and short-term contexts. However, for gaining a deeper understanding on the detailed *processes* of the development of conceptions,

classroom data was too incomplete. For that reason, a further series of teaching experiments was conducted in a laboratory situation by the second author of this paper.

The teaching experiments (following Gravemeijer & Cobb, 2006) based on the presented learning situation were conducted in a series of game interviews with ten couples of students of grade 6 (age 11-13) in a German comprehensive secondary school. The semi-structured interviews of 4x 45-90 minutes were guided by an intervention manual that defined the role of the interview with the attitude of giving as little help as possible but also to provide guidance in situations that were crucial for the continuation of the interview sessions. Each session was videotaped and transcribed in detail for the analysis. The data corpus also included the record of the computer screen and written products. Though the underlying research interest of the ongoing analysis addresses a range of different questions concerning a more detailed description of the processes of conceptual change, this article focuses on the following questions:

26 How are students constructing, enriching and refining constructs for patterns, deviations of patterns and predictability in relation to short- and long-term contexts?

27 Which constructs do students use for explaining these patterns?

THE CASE OF RAMONA AND SARAH – FIRST RESULTS

The case of Ramona and Sarah exemplifies how relating and enriching different constructs can provide students with a tool to make sense of the different observations of patterns of chance in relation the specific short-term or long-term context. This case was chosen as the girls show a broad range of constructs and are highly able to verbalize their ideas. Due to limited space, comparisons with other couples are restricted to the concluding remarks.

Episode 1: Refining by differentiating the L1-context from S-context

When introduced to the learning environment, Ramona and Sarah are eager to find a strategy to win as often as possible. For this reason, they keep looking for patterns in single throws of the die or in results of games. Episode 1 below starts after 15 minutes of playing. All four games so far with totals of throws between 25 and 37 have been won by the red ant, with the first game tied with the green frog. Having the outcome of the fourth game on the board as documented in Fig. 1 (red ant on 11, frog on 7, snail on 5, blue hedgehog on 6), the students express their ideas on the found patterns.

422 Ramona (*points to red ant on the board*) This one is the fastest. Then, the hedgehog should come, then [green] frog, then [yellow] snail (*points to animals*)

423 Sarah Why?

Working Group 5

424 Ramona I don't know, because the- the ant has won almost every time so far.

As a first construct, Ramona describes in line 424 the pattern that the red ant wins more often (L1-pattern winning ant) and relates this to her empirical observation (L1- empirical explanation). She apparently refers to the series of four games by expressing “almost every time so far” in 424. In the (not printed) turns following the above episode, Sarah tries to find an explanation for the empirical pattern and comes up with the idea that not all faces of the die are equal, which prompts Ramona to count. After counting twice, they find the correct colour distribution of 7,5,5,3.

481 Interviewer Now you have counted [all colours on the die]. What does that mean?

482a Sarah That red, well, more- well, that red wins actually, because it has more and then you get it more often, when you throw the die. And then green and yellow, because they-

482b Sarah Well, you two- That is why they are again so- Green and yellow (*points on yellow snail and then blue hedgehog on the board*)

482c Sarah Eh, green and yellow (*points to yellow snail and then green frog, then to both simultaneously*) are sometimes far apart, but.

483 Ramona Blue has good chances, too, because-

484 Sarah Yes.

485 Ramona You also have- blue has sometimes a lot of luck and then it gets the three faces sometimes very often.

486 Sarah You see it here (*points on the board to snail and blue hedgehog*).

In 482a, Sarah enriches the pattern-construct that was so far only empirically explained with an additional theoretical explanation of the colour distribution (L1-theoretical explanation). While the observation and also the empirical explanation of the pattern of the red ant as best animal come from a *series* of games (with totals between 25 and 37, L1-context), she switches in 482b to the *single* result of the game that is still displayed in front of her (see Fig.1) and tries to transfer the L1-pattern to the single game. By pointing to the board, she is possibly trying to demonstrate the theoretically expected pattern, but her use of half sentences and her pointing to the wrong animals in 482b seem to indicate that she is experiencing a conflict between the deviant S-pattern and the expected L1-pattern. In this moment, the constructed L1-pattern is possibly already starting to get refined implicitly as Sarah experiences a problem in its scope of applicability for the single short game. In 482c, she corrects herself by pointing to green frog and yellow snail, but seems not to be describing a pattern anymore, as she uses the term “sometimes” (S-deviation). Sarah seemingly does not solve the problem between L1-pattern and the deviant S-pattern here, as she ends her sentence with a “but” in 482c, even though she is not interrupted.

Episode 2: Constructing luck as S-explanation for deviation

Ramona expresses in 483 to 485 a new construct that had not been mentioned before. She explains this situation that differs from the L1-pattern by the “luck” that the blue hedgehog must have had (S-explanation for the deviation). Keeping the term

“sometimes”, she is seemingly still speaking about single outcomes as opposed to a series. Sarah concurs with this explanation by demonstrating it on the board. Here, the girls seem to have found an explanation by excluding this and possibly other single outcomes from the scope of applicability of the L1-pattern and therefore making the difference between short-term and long-term context explicit. Still, the construct of luck is only brought up in relation with the notion of the distribution of colours.

Episode 3: Building with the luck-construct for S-explanation for deviation

Over the course of all interviews, they again build with this construct to explain single outcomes of games being not in accordance with the theoretically expected pattern. One example is Episode 3 (about 35 min. later). So far, Ramona and Sarah have filled in several protocol sheets while playing more than 25 further games with a total of throws between 1 and 20 and have written down their strategy for betting. The interviewer’s question leads Ramona to clarify the distinction between pattern and luck further:

- 1203 Interviewer Could you read out loud what you have written, Sarah?
 1204 Sarah Always stay on the ant-(...)
 1206 Sarah As it has the most faces on the die and therefore you roll it more often.
 1207 Interviewer Hm, you put that very well. What I don’t get completely yet: I bet on the hedgehog and won, for example. Or – well, not only ant has won-
 1208 Ramona That is just luck.
 1209 Interviewer It’s only luck?
 1210 Ramona It is not a strategy, it is truly luck.

Here, the previously constructed S-explanation for deviation is *recognized* as being usable in a situation, in which the interviewer seems to point to single games. By emphasising the difference between luck and strategy, Ramona *builds with* it by referring it to the unpredictability of the single (lucky) outcomes in single short games (S-Prediction) and the more predictable L1-pattern (L1-predictability). This contributes to refining the distinction of S- and L1-context.

Episode 4: Constructing the L1-L2-distinction

In the second interview, Ramona and Sarah start to focus on the long-term context L2 of games with high totals of throws, which is supported by using the computer simulation and protocol sheets that include total of throws up to 1000. Ramona and Sarah address the question, when the red ant is a good bet without an interviewer’s stimulus. Having filled in a protocol sheet and a series of 16 games with increasing totals of throws, they realize that their consequent bet on ant has won the first game, lost for the next four and won every game from the sixth one on (with totals of throws of 10, 100 and 1000):

- 975 Sarah (*points to sixth game on the protocol sheet; total of throws: 10*) From here on, you only always win with the ant.

Working Group 5

This utterance could be an indication that she is constructing a notion of the predictability of the pattern ant-winning in relation to the context (distinguishing L2-predictability from L1-predictability). Although not marking exactly those games with at least 100 throws, her formulation “from here on” clearly addresses a series of games and seems vaguely to refer to the larger total of throws as they increase in the bottom of the sheet. While filling in a summary sheet, the girls become aware of their results showing clear patterns: If the total of throws was one or ten, all animals won, while the red ant was the only winner in all games with throw totals of 100 and 1000. Asked to formulate their strategy now, the following dialogue begins:

1079 Sarah At 100 and 1000, the ant always wins. At 10 and 1, it's always different-

...

1085 Ramona [At 10 and 1], mostly winning are-

1086 Sarah (*points to upper part of protocol sheet*) snail, frog and sometimes ant, too.

1087 Ramona There, ant is not winning as often and here (*points to lower part of protocol sheet*) you can see it, only ant.

The girls refine their construct of L2-pattern by contrasting it to the L1-pattern. Both seem to accept that ant is the only one winning in long games which is in accordance with Sarah's statement in 975. Referring to the series of short games (i.e. the L1-context), Sarah revises her previous statement and remarks in 1079, that at a throw total of one or ten “it's always different”. It is possible that she emphasises the distinction between the L1 and L2 context and focuses the L1-deviation more than the L1-pattern itself. Furthermore, she might relate the absence of a pattern in L1 to the previous construct S-disturbance in the context of short games, which was then explained by the construct “luck”. Here, both girls do not mention luck as a possible explanation, but point out the shift of context as the explanation for the discrepancies in the observations of patterns (L1-explanation). When Ramona starts to mention winning animals in 1085, Sarah points out three of four animals, relativising the red ant by adding the adverb “sometimes”. In contrast to 1079, she is possibly now pointing out a L1-pattern, which is refined by Ramona in 1086. She emphasises the words “as often” and “always” and makes the distinction between her construct for L2-pattern (ant wins always) and L1-pattern (ant wins sometimes) very explicit. Furthermore, she hereby constructs the notion of both L1-deviation and L2-deviation.

CONCLUSION

Like the girls' pathway of developing conceptions, all ten interview-pairs create complex networks of constructs while trying to make sense of several, partially-conflicting experiences. In each case, a shift of focus between short-term and long-term context can be reconstructed. Beyond that, the individual pathways are highly individualised.

Working Group 5

Ramona and Sarah are able to enrich pattern constructs with explanations not only in a long-term perspective, but also refine these patterns regarding the absence of patterns in a series and single outliers in short-term contexts. Their individual constructs “luck” and “pattern” seem not only to be connected to each other, but also to the distribution of colours. The deviation of patterns is only mentioned in relation with “pattern” and while mentioning explicitly the total of throws as being low. Though the girls don’t compare this whole network of constructs and test its coherence, it seems from an outside point of view that by defining the scopes of applicability, their constructs are not contradictory, but in coexistence with each other. This gives evidence to the horizontal view on conceptual change and provides a short but deep insight into how the individual pathways of students can lead into conceptions consisting of networks of constructs, in which even rather idiosyncratic constructs such as luck have a scope of applicability that does not seem to obstruct the intended mathematical constructs. For some students, the negotiation of ranges of applicability of constructs is more complicated than for Ramona and Sarah. Further steps of data analysis include the identification of common conceptions for many participants and sharpen the description of the character of the network of constructs.

THE ROLE OF RELEVANT KNOWLEDGE AND COGNITIVE ABILITY IN GAMBLER FALLACY

Caterina Primi & Francesca Chiesi

Department of Psychology – University of Florence, Italy

A new model by Stanovich et al. (2008) specifies the ways in which knowledge and cognitive capacity might interact in shaping reasoning performance. This model proposes that normative performance relies on knowing relevant rules and procedures (called “mindware”), detecting the need to implement them, and holding of the necessary cognitive capacity to acquire/use them appropriately. The aim of the present study was to test these assumptions investigating gambler fallacy inside probabilistic reasoning. Participants were primary (N=251) and college students (N=151). Results provide support for the claim that mindware plays an important role in probabilistic reasoning, and there is an interplay with cognitive ability. Theoretical and educational implications of results are discussed.

INTRODUCTION

According to dual-process theories, mental functioning can be characterized by two different types of process which have different strengths and weaknesses (e.g., Brainerd & Reyna, 2001; Epstein, 1994; Evans 2006; Sloman, 1996; Stanovich, 1999). Type 1 processes¹⁷ are rapid and mandatory when the triggering stimuli are encountered, they do not require much cognitive effort, and they can operate in parallel. Type 1 processing is cognitively economical, its output is not consciously generated but seems to “pop” into consciousness (Sloman, 1996), and people “feel” intuitively that the responses are right (Epstein, 1994). Whereas Type 1 processing often leads to correct responses, in some cases they lead to systematic biases and errors. By contrast, Type 2 processes are relatively slow and computationally expensive, they are available for conscious awareness, serial, and often language based. Type 2 processes are also often associated with the use of normative rules and logical responding.

To exemplify the role of the two types of process in reasoning, imagine that in order to win a prize you have to pick a red marble from one of two urns (A and B). Urn A contains 20 red and 80 blue marbles, and Urn B contains 1 red and 9 blue marbles. When you respond to the task, you can compare the ratio of winning marbles in each urn (20% vs. 10%) which requires some time, mental effort and computations, or you can simply rely on the feeling/intuition that it is preferable to pick from the urn with more “favourable events”. In this example, both processes cue the normatively correct answer (that is, Urn A). On the other hand, it is possible to set up a task

¹⁷ Several terms have been used to refer to these two aspects of cognitive functioning (e.g. heuristic vs analytic, experiential vs rational), here we follow Evans (2006) in using the terms Type 1 and Type 2 processes.

where Type 1 and Type 2 reasoning cue different responses. For example, if you can choose between picking a marble from an urn containing 10 red and 90 blue marbles, or from an urn containing 2 red and 8 blue marbles, the feeling/intuition that it is preferable to pick from the urn with more “favourable events” results in a normatively incorrect choice.

When Type 1 and Type 2 processes do not produce the same output, Type 1 processes usually cue responses that are theoretically incorrect and, according to dual-process theorists one of the most critical functions of Type 2 processes in these cases is to interrupt and override Type 1 processing. However, this does not always happen. In the case of a conflict between intuitions and normative rules even educated adults will predominantly produce heuristic responses.

In a recent paper Stanovich, Toplak and West (2008) outlined how people can reach a correct solution when the task besides the normative solution elicits competing response options that are intuitively compelling. They stated that people have to possess the relevant rules, procedures, and strategies, they have to recognise the need to use them, and then they have to have the necessary cognitive capacity to inhibit competing responses. In their model of reasoning, Stanovich and colleagues (2008) referred to rules, procedures, and strategies derived from past learning experiences as “mindware” (Perkins, 1995). If the relevant mindware can be retrieved and used, alternative responses became available to engage in the override of the intuitive compelling answers.

Errors can arise when we have a *mindware gap*. Indeed, when relevant knowledge, procedures, and strategies are not available, i.e. they are not learned (or poorly compiled), we can not have an override since to override the intuitive response a different response is needed as a substitute. Instead, when the relevant knowledge, procedures, and strategies can be easily retrieved, and a normative solution becomes available, errors are termed *override failures*: different alternatives are produced and there is the attempt to take the intuitive response offline, but this attempt fails since beliefs, feelings and impressions seem to be right beside rule-based considerations. So we have an override failure when people hold the rule but they do not base their answer on it.

Finally, Stanovich and colleagues (2008) addressed the role of several factors that might affect reasoning and, among them, particular attention was paid to cognitive ability. Kahneman and Frederick (2002) pointed out that “intelligent people are more likely to possess the relevant logical rules and also to recognize the applicability of these rules in particular situations [...] that enable them to overcome erroneous intuitions when adequate information are available.” Thus, in both children and adults, reasoning errors are expected to be related to cognitive ability (Evans, Handley, Neilens, & Over, 2009; Kokis, MacPherson, Toplak, West & Stanovich, 2002; Morsanyi & Handley, 2008).

Working Group 5

Starting from these premises, the aim of the present study was to test the Stanovich and colleagues' model inside probabilistic reasoning investigating gambler fallacy (Kahneman, Slovic & Tversky, 1982). Indeed, the model of Stanovich and colleagues provides a theoretical framework for integrating the educational and dual-process approaches emphasizing the role of both relevant knowledge and cognitive capacity in the development of reasoning skills. As the rules of probabilistic reasoning are very hard to derive from personal experiences (e.g., Fischbein, 1987) – that is, the actual patterns of probabilistic outcomes are “messy” or even resemble more what could be predicted based on the fallacies of probabilistic reasoning than on the relevant normative rules (see Hahn & Warren, 2009) - normative probabilistic knowledge mostly stem from what learned at school.

In details, we aimed (a) to investigate when sound probabilistic reasoning could be prevented by the lack of relevant knowledge (that we call “mindware” following Stanovich et al.'s terminology) for dealing with probability comparing different educational levels, and (b) to take into account the role of individual differences in cognitive ability and the interactions between mindware and cognitive capacity.

Committing gambler fallacy, people tend to estimate the likelihood of an event by taking into account how well it represents its parent population, i.e. a sequence of the same outcome (given two possible options) must be followed by the other outcome in order to equilibrate the proportion. In this way they do not take into account base-rates along with the independence notion. In the present study gambler fallacy was investigated in primary students since these basics of probability are taught to the fourth and fifth graders following the Italian national curricular programs¹⁸. Then, we compared primary school students probabilistic reasoning to college students in order to better explore the role of mindware starting from the assumption that relevant knowledge should be consolidated through education as well as the ability to recognize the need to use it in specific situations. In sum, we included three groups: students before they were taught probability issues (third graders), students who had been taught probability issues (fifth graders) and college students who had encountered issues related to probability throughout primary to high school years.

We predicted that probabilistic reasoning performance strongly relied on relevant mindware. We expected that younger primary students should perform worse due to their *mindware gap*. This difference should be observed even when individual differences in cognitive ability are partialled out. We predicted that college students

¹⁸ Specifically, curricula include statistical surveys and their representations, some linguistic/conceptual issues related to possible, impossible, improbable events, and the development of judgment under uncertainty and estimation of odds through games of chance, inside the classical definition of probability (see <http://www.rhoda.it/programm.htm>). These issues were firstly included in the 1985 reform, and more recently the importance of teaching these topics was stressed in the revised government program (Moratti, 2004).

would generally perform better due to their more consolidated knowledge of the relevant rules of probability, and their higher cognitive ability. Whereas no difference should be observed among older primary students and college students once individual differences in cognitive ability are taken into account.

METHOD

Participants

The participants were 251 primary school students attending Grade 3 ($n= 133$, 68 males; mean age: 8.3 yrs) and Grade 5 ($n= 118$, 65 males; mean age: 10.5 yrs) and 151 college students (30 males; mean age: 20.3 yrs). The primary schools students were enrolled in Italian primary schools that serve families from lower middle to middle socioeconomic classes. Primary students were invited to participate. Their parents were given information about the study and their permission was requested. The college students were all students in Psychology degree program at the University of Florence (Italy). They were volunteers, and did not receive any reward for their participation in this study.

Measures and Procedure

Gambler Fallacy Task: A preliminary version of this task was used in a previous study run with children and college students (Chiesi & Primi, 2009). It consists in a marble bag game in which different base-rates in combination with two different sequences of outcomes were used. Using marbles - compared to the tossing of a regular coin traditionally employed to test gambler fallacy – the present task allows for testing this bias with both equally likely and not equally likely proportions. In detail, the task was composed of 3 different trials in which proportion of Blue (B) and Green (G) marbles varied (15B & 15G; 10B & 20G; 25B & 5G).

Before the actual task was presented, all children were shown a video in order to exemplify the concept of sampling with replacement. The bag shown in the video has a see-through part and instead of drawing a marble from the bag, the marble is pushed into the corner and then moved back inside the bag. Since the bag is closed it's a way to make clear that the number of the marbles stays always the same.

After the video, each participant received a sheet where it was written the following instruction: “15 blue and 15 green marbles have been put into a bag such as the one shown in the video and one ball has been pushed in the see-trough part” The first question was “It's more likely it is...”. The following instruction explained that: “The game was repeated with same bag and a sequence of 5 green marble was obtained”. The second question was: “The next one is more likely it is...”. The following instruction told that: “The game was repeated again with same bag and a sequence of 5 blue marble was obtained”. The third question was: “The next one is more likely it is...”. After this first trial, the other two trials with different marbles proportion were presented, and for each one the three questions were asked. In sum, each participant had to answer 9 questions, three for each trial.

Working Group 5

We formed two composite scores summing correct answers. One represents the necessary knowledge to tackle the task, i.e. how the probability of a single event changes referring to base-rates, and it was called Mindware score (range 0-3). The other, represents normative reasoning, i.e. higher the score, higher the respondent's ability to avoid gambler fallacy, and it was called Probabilistic Reasoning score (range 0-6).

After the Gambler Fallacy task, cognitive ability was measured using two short forms of the Raven's Matrices, one suitable for children, the other for adults.

Set I of the Advanced Progressive Matrices (APM-SET I): To measure children's cognitive abilities the APM-SET I (Raven, 1962) was administered as a short form of the Raven's Standard Progressive Matrices (Raven, 1941) as suggested by Nathaniel-James et al. (2004). The Set I of APM is composed by 12 matrices increasing in their difficulty level, and the items covered the range of difficulty of SPM (Raven, 1962). These items are composed of a series of perceptual analytic reasoning problems, each in the form of a matrix. The problems involve both horizontal and vertical transformation: figures may increase or decrease in size, and elements may be added or subtracted, flipped, rotated, or show other progressive changes in the pattern. In each case, the lower right corner of the matrix is missing and the participant's task is to determine which of eight possible alternatives fits into the missing space such that row and column rules are satisfied. Test adaptation to the Italian children population was done using IRT analysis procedure (Ciancaleoni, Primi & Chiesi, 2010).

Advanced Progressive Matrices Short Form (APM-SF, Arthur & Day, 1994): College students were administered the Advanced Progressive Matrices Short Form (Arthur & Day, 1994). The APM-SF is composed by 12 matrices derived from the APM. Matrices characteristic are described above. Test adaptation was done using IRT analysis procedure (Primi, Galli, Ciancaleoni, & Chiesi, 2010).

RESULTS

As expected, a differences between Grade 3 and Grade 5 was found in Mindware ($t(247) = -4.3, p < .001, d = -.55$) and Probabilistic Reasoning ($t(247) = -4.92, p < .001, d = -.62$). Older children performed better (Mindware: $M = 1.90; SD = .86$; Probabilistic Reasoning: $M = 2.83; SD = 1.52$) than younger children (Mindware: $M = 1.45; SD = .80$; Probabilistic Reasoning: $M = 2.07; SD = .84$).

In order to control the effect of cognitive ability, two ANCOVAs were run in which Raven Matrices score was used as a covariate, Grade as the independent factor, and Mindware and Probabilistic Reasoning score as the dependent variables. The results showed that once the significant effect of cognitive ability was partialled out ($F(1,246) = 15.16, p < .001, \eta_p^2 = .06$), the main effect of educational level on Mindware was still significant ($F(1,246) = 6.25, p < .01, \eta_p^2 = .03$). In the same way, once the significant effect of cognitive ability was partialled out ($F(1,246) = 31.24, p < .001,$

Working Group 5

$\eta_p^2=.13$), the main effect of educational level on Probabilistic reasoning remained significant ($F(1,246)=6.53, p<.01, \eta_p^2=.03$).

Starting from these results, we aimed to identify the relative weight of the two factors related to correct reasoning, that is cognitive ability and relevant knowledge. So, we conducted a hierarchical regression analysis - separately for third graders, fifth graders and college students - in which the criterion variable was the Probabilistic Reasoning, and predictors were Cognitive Ability, entered first into the analysis, and Mindware.

Third Grade				
Step		Multiple R	R^2 Change	F Change
1	COGNITIVE ABILITY	0.03	/	4.64*
2	MINDWARE	0.00	0.00	<i>ns</i>
Fifth Grade				
1	COGNITIVE ABILITY	0.19	/	26.24**
2	MINDWARE	0.30	0.11	18.27**
College				
1	COGNITIVE ABILITY	0.05	/	4.31*
2	MINDWARE	0.47	0.42	68.14*

* $p < .05$, ** $p < .01$

Table 1: Hierarchical regression for each student group with Cognitive Ability and Mindware entered as predictors of the Probabilistic Reasoning score.

Different patterns of results were observed for the three groups (Table 1). In third graders probabilistic reasoning was totally unrelated from mindware, and cognitive ability accounted for a little part of it (less than 5%). In fifth graders both cognitive ability and relevant mindware predicted probabilistic reasoning: cognitive ability accounted for 19% of the variance, and mindware accounted for an additional 11%. Finally, mindware explained in large part college students' reasoning accounting for the 42% of the variance.

Results show that both cognitive ability and relevant mindware would lead to increase students' reasoning performance and the relative weight of the two factors depend on educational level. Moreover, we can argue that students who correctly answered the first question not only hold the relevant mindware but the question makes them aware of the need to use it in answering the following questions. In other word, mindware was retrieved and made available to substitute the compelling intuitive response likely elicited by the sequence of five identical outcomes (i.e., all green/blue marbles).

In order to further ascertain the role of mindware on probabilistic reasoning, we compared who hold a well-learned rule and who lack or hold a poorly compiled rule. To do that, we created two groups (Hold vs Lack) using as a criterion the maximum

Working Group 5

Mindware score (that is, who always answer correctly, even when the correct answer was “blue and green are equally likely” and not a dichotomous choice between blue and green). In this way third graders were excluded from the analysis since only few students (as expected) were found to belong to Hold group. A 2X2 ANCOVA was run in which cognitive ability was used as a covariate, Educational Level (Fifth Grade vs College) and Mindware (Lack vs Hold) as independent variables, and Probabilistic reasoning as dependent variable. The results showed that once the significant effect of cognitive ability was partialled out ($F(1,199)=15.58, p<.001, \eta_p^2=.07$), the main effects of Educational Level ($F(1,199)=5.03, p<.05, \eta_p^2=.03$) and Mindware ($F(1,199)=113.07, p<.001, \eta_p^2=.36$) were significant, as well as the interaction between them ($F(1,199)=4.54, p<.05, \eta_p^2=.02$) (Figure 1). Looking at the effect sizes, we can observe that the stronger difference depends on mindware, i.e., in both groups students had a low performance when they lack, or lack to retrieve and apply, the relevant mindware.

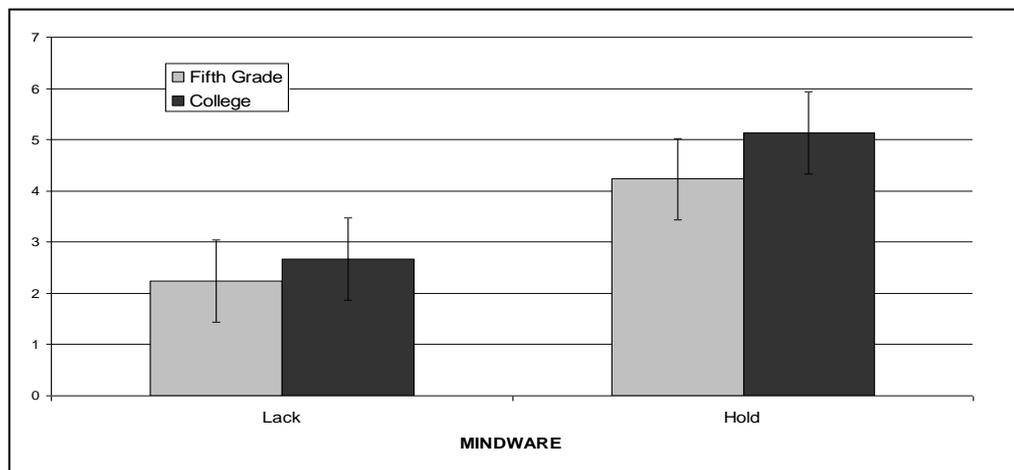

Figure 1: Means of Probabilistic Reasoning score in function of Mindware and Educational Level.

CONCLUSION

In this work we investigated the effects of relevant knowledge on primary and college students' probabilistic reasoning ability, and we examined the interactions between relevant knowledge and cognitive ability. According to Stanovich et al. (2008), the present study suggests that in solving gambler fallacy tasks the correct solution can be reached holding the relevant mindware and recognising the need to use it. Moreover, we found that individual differences in cognitive ability can be accounted for explaining sound reasoning in both primary and college students but, once the effect of cognitive ability has been taken into account, if the relevant knowledge is hold, retrieved and applied primary and college students perform equally well. In the same way, when they do not possess it or use it, their performance is equally bad.

Working Group 5

In sum, correct probabilistic reasoning relies strongly on knowledge about rules. Since these rules are very hard to derive from personal experiences, we may conclude that normative probabilistic reasoning mostly stem from what learned at school. In this way, it becomes relevant define methods to make students aware of the need for rules even when they “feel” that these rules do not work, that is when conclusions derived from the theory are counterintuitive.

This study offers some cues to cross the bridge from a psychological approach to an educational approach. Psychological theories on reasoning assert that people are prone to rely on intuitions and that in dealing with probability intuitions seem to be right beside rule-based consideration. Nonetheless, rules are needed to reason normatively and to avoid biases. Didactical interventions have to focus on solving this puzzle.

CONNECTING EXPERIMENTAL AND THEORETICAL PERSPECTIVES

Theodosia Prodromou

University of New England, Australia

This paper presents a case study of a group of pre-service teachers (age 21- 52) as they work in a domain of stochastic abstraction to reason about “experimental” and “theoretical” perspectives. I am particularly interested in investigating whether pre-service teachers could construct a bidirectional link between the data-centric and modelling perspectives on distribution, similar to the tentative model I introduced elsewhere for coordinating the two perspectives on distribution. In this study, we have seen echoes of these ideas in relation to experimental and theoretical probabilities. The results show students’ movement between probabilities at the micro level and the shape of histograms at the macro level.

INTRODUCTION

The concept of probability distribution lies at the heart of statistics at university level (Cohen & Chechile, 1997). Students at university level are expected to have a sophisticated understanding of theoretical statistical principles. This requires an appreciation of probability theory, an ability to describe the variation due to sampling and calculate and judge the variation pattern of a random variable and its respective probabilities.

Konold and Kazak (2008) claim that there are four fundamental ideas which are central to the domain of data and chance: model fit, distribution, signal-noise, and the Law of Large numbers. Model Fit involves the development of expectations about certain characteristics of the data with regard to the possible kind of a “model” that the data follows (Konold & Kazak, 2008). For instance, if we examine the outcomes of tossing a fair coin repeatedly, we expect to get about an equal number of sequences of heads and tails. When we look at the data, we evaluate our data with regards to our “model”. However, there are two approaches to model fit. Exploratory data analysis (EDA), introduced by Tukey (1972), is an approach that places emphasis on looking at data sets in order to form hypotheses worth testing, instead of putting forward hypotheses concerning the possible kind of probability model the data follows. EDA, therefore, allows the data to reveal an underlying structure and suggest admissible models that best fit. EDA seems to have two working principles: Firstly, to look at the data, valuing: i) graphical displays, ii) numerical summaries, and iii) the natural pattern-recognition capabilities that humans possess. Secondly, to look at the data with a fundamental respect for real data, and a profound distrust in modelling that is not related to real data, because there is always an element of uncertainty whether the data that is being generated from some assumed theoretical

distribution sufficiently imitates the fundamental features of the process that generated the data.

EDA approach is taking a data-centric perspective (Prodromou, 2008; Prodromou and Pratt, 2006) on distribution in the underlying sense that the primary focus of the principal techniques and principles used in EDA is on data from which a pattern or model may or may not be discerned. In the data-centric perspective on distribution, data will spread across a range of values. From this perspective, variation generates distribution since “without variation, there is no distribution” (Bakker and Gravemeijer, 2004, p. 149). This perspective is compared to that of the statistician, who accounts for unexplained variation as that part of a hypothetical model which is not apparently associated with a main effect. Here the emphasis is on mathematical models that are called theoretical distributions (e.g. Normal, Binomial), in which we attribute probabilities to a range of possible outcomes (discrete or continuous) in the sample space. Prodromou and Pratt (2006) and Prodromou (2007; 2008) refer to this approach as the modelling perspective on distribution. The modelling perspective on distribution pays attention to randomness and the shape of the probabilities that determine the outcomes. In this modelling approach the model gives rise to variation that is portrayed as a random movement away from the main effect. In the modelling perspective, data distributions are seen as variations from the ideal model, the variations being the result of noise randomly affecting the signal, as reflected in the model itself. Prodromou (2007; 2008) introduced the tentative model (Fig1) for the coordination of the data-centric and modelling perspectives on distribution.

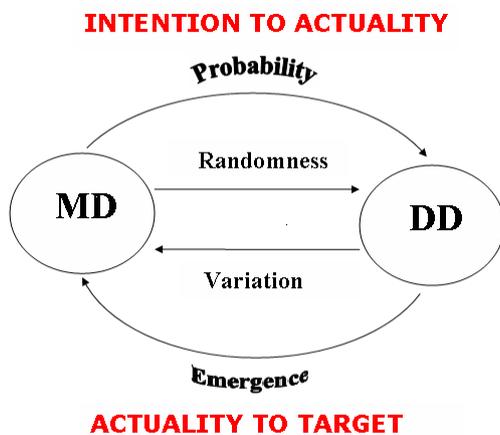

Fig1: A tentative model for the connection of the data-centric and modelling perspectives on distribution.

Prodromou (2008) first considered the connection from modelling distribution (MD) to data-centric distribution (DD), in the top half of Fig1. Her 15 year old students typically tended to gravitate towards simple causal explanations when they observed the modelling distribution which in some sense generates the data. They invented probability (Piaget and Inhelder, 1975) to operationalise randomness. She considered the connection for DD to MD in the bottom half of Fig1. Many of her students first

Working Group 5

recognised variation in data and made the connection from data-centric to modelling perspectives, the target interpretation. Her students had great difficulty however in operationalising variation to explain this connection, and turned to relatively vague references to emergence, as if emergence were a causal agent by which the data-centric distribution targets the modelling distribution.

Prodromou (2007; 2008) claimed that the target and intention models probably are not dissimilar from how experts appreciate the co-ordination of the two perspectives on distribution. She suggested that, experts add to this image a co-ordinated understanding of how the Law of Large Numbers which appears to be the principal aspect of synthesizing the two perspectives on distribution, relates the probabilistic and emergent mechanisms.

APPROACH OF THE STUDY

At an Australian regional university, one hundred pre-service teachers, who were destined to deliver the content of the K-6 Mathematics Syllabus (NSWBOS 2002) in the state of New South Wales, were attending an online unit called ‘Numeracy Enrichment for Primary Teachers’.

The main purpose of this course was to provide primary pre-service teachers, with access to studies in selected topics in mathematics that would enhance their enjoyment and knowledge of mathematics and help them to become more positive about their ability to understand some of the structures of mathematics, its applications and relationships. It is noteworthy to point out that this course was designed for pre-service teachers’ personal mathematical understanding, rather than about teaching mathematics. Many of the activities could, however, be used in the primary classroom.

The content of this unit of study was organized into eight topics. These topics address all the content strands [1] of the Australia mathematics curriculum: number, space, measurement, data and patterns and algebra.

This course was available online and located on the Blackboard Learning System. The online site of this unit included features such as a message board, a discussion forum, an online white board and a virtual classroom, and electronic downloads of teaching material. For each topic there was a discussion forum set up on UNEonline. The discussion was monitored regularly, and the unit co-ordinator contributed as well as students in the course. Pre-service teachers were expected to attempt all investigations and activities outlined in the Topic Notes for this unit and write up their solutions, explain, justify and reflect on their thinking processes throughout the unit in a journal or logbook format that would be compiled into a portfolio. This portfolio constituted the assessment for the unit and submitted into parts.

The eighth topic of this unit was about probability investigations, experiments with random number generators, simulations and mathematical models. The Game of

Working Group 5

Craps described below, was one of the computer-based simulations [2] that pre-service students used. It simulates a gambling game played by rolling two dice. Players take turns rolling two dice and make bets with chips on different areas on a craps table that displays the various different areas which pay out according to numbers rolled. The simulation displays the odds for each different bet when the cursor is hovered over the spot where the bet would be placed. The user of the Craps simulation could set the amount of his wager and clicks on the spot where he wants to place his bet. When the first roll total of both dice is seven (7) or eleven (11) is an instant win and the roll is called “natural”. This outcome pays \$1 for a \$1 bet. A first roll total of two (2), three (3) or twelve (12) which is called “craps” loses the bet. If a roll total of (4, 5, 6, 8, 9, 10) is rolled, that number becomes the “point” and the “point” must be rolled again before a seven (7) is rolled in order to win. There are different payoffs for each point. A point of four (4) or ten (10) will pay pre-service teachers 2:1 (\$2 for a \$1 bet); 5 or 9 pays 3:2; 6 or 8 pays 6:5. If a seven (7) is rolled before that next “point” the player loses the bet (Crapped out) and the two dice must be passed to the next player.

Pre-service were asked to create a strategy for playing the craps game. The assignment task encouraged pre-service teachers to look at this game and see what the chances of winning were by finding out how often a number came out when they added the faces of two dice. The problem involved rolling two dice 50, 1000 and 5000 times, adding the numbers together and recording the sum of the rolled dice outcomes on the respective positions from 1 to 12.

Pre-service students decided to create a spreadsheet that would simulate randomly rolling to dice and add their faces. After they simulated 50 rolls of two dice they drew a histogram for the sum of two dice (Fig2). Moreover, they drew histograms to show the sum of the rolled dice, 2-12 after 1000 rolls and 5000 rolls (Fig2).

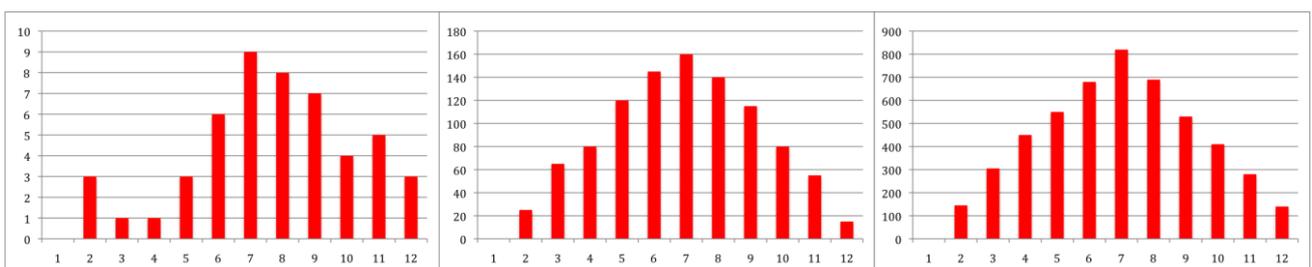

Fig2: Histograms for the sum of two dice after 50, 1000 and 5000 rolls.

Pre-service teachers were asked to observe the three graphs very carefully and : 1) describe the pattern they could see emerging, and discuss the occurrence of the outcomes from rolling two dice; 2) explain which numbers occurred more often and which occurred least often; 3) determine the percentage for each outcome when reading the ‘5000 rolls’ graph.

Working Group 5

The notes drew pre-service teachers' attention to the fact that not every probability was calculated using simulation and experimental probability. It therefore, introduced another type of probability called theoretical probability, that was a method which did not perform a single experiment, but instead used theory and reason to determine the chance of an event occurring.

Pre-service students were asked to 4) complete a chart by adding the different possibilities together when two dice are rolled and (5) complete a table for each sum of the two dice, the frequencies and % of occurrence. (6) The sixth task was to draw a histogram of the data and compare the histogram they constructed to the '5000 rolls' histogram. (7) They were also asked to compare the percentage of the occurrence of the theoretical probabilities to the experimental probabilities calculated earlier when pre-service teachers constructed the '5000 rolls' histogram and make connections to the Craps simulation. The questions required pre-service teachers to justify their answers based on their knowledge about empirical and theoretical distributions, experimental and theoretical probabilities.

The series of the seven tasks was selected because it was approachable, both through conducting physical trials and through theoretical analysis via the sample space. When pre-service teachers were asked to determine the optimal sample space for an event, they were restricted to contexts where the sample space was relatively small, such that pre-service students were capable of generating all possible cases, being the only source of probability.

One hundred pre-service teachers e-submitted their portfolio. To illustrate the ideas emerged from pre-service teacher' work, I present excerpts taken from the portfolios of ten pre-service teachers (PT 1, PT 2, PT 3, PT 4, PT 5, PT 6, PT 7, PT 8, PT 9, PT 10) who were ranging in age from 21 to 52 years old. The data included excerpts from pre-service teachers' explanation and justification of the assignment tasks and their reflections on mathematical processes. At the first stage, I wrote extensive field notes, during and immediately after reading each portfolio. Excerpts were coded and compared across portfolios to infer explanations for pre-service students' reflections. In this sense, the analysis was one of progressive focusing (Robson, 1993).

In this study, my overarching aim is to observe how pre-service students 1) justify their answers based on their knowledge about experimental and theoretical probabilities, and 2) whether they can construct a bidirectional link between the data-centric and modelling perspectives on distribution, similar to the tentative model for coordinating the two perspectives on distribution (Fig1).

RESULTS

Pre-service teachers were first challenged to describe the pattern they could see emerging from the three distributions for the sum of two dice after 50 rolls, 1000 rolls and 5000 rolls.

Working Group 5

- 1 PT 1: The frequency starts out low at the beginning of the graph, leading up to a peak in the middle and then descending back again towards the end of the graph, similar to a mountain. I have also noticed that certain numbers have partners on either side of the peak, however 7; the most frequent number has no partner. For example 8 and 6 are partners, as is 2 and 12. In that their frequencies are similar numbers.
- 2 PT 2: After rolling 2 dice 50 times, 7 is the most occurring number, followed by 8 and 9. Apart the clear 7 leader, the rest of the numbers are fairly scattered however, as the dice is rolled more times, 1000 and then 5000, the graph is peaking at 7, the leader and coming down evenly to 2 and 12.

PT 1 was inclined to resort to a causal explanation for the histogram by comparing its shape to a mountain and anthropomorphizing the occurrence of its underlying bars. PT 2, in his attempt to understand the emerging pattern, he assumed centralized control. In particular, he saw the histogram as a centralised system where a centralised controller – 7 the leader – impressively coordinated the pattern.

Pre-service teachers were also inclined to use geometrical shapes to describe the shapes of the histograms.

- 3 PT 3: The bar graph is triangular in shape with the outside bar being shortest and the inner ones becoming taller.
- 4 PT 4: The pattern is a pyramid, with the apex being number 7.
- 5 PT 5: I noticed the bell curve that is evident from the graphs.
- 6 Pt 6: A pattern is emerging whereby a bell curve is forming centred on the outcome of number 7.

Many pre-service teachers (PT 3) described the histogram as triangular in shape. PT 4 saw the histogram as a three-dimensional object. In contrast, PT 5 referred to the emerging pattern of a bell curve.

After comparing the histograms of 1000 and 5000 rolls, pre-service teachers noticed that the result of performing the same simulation a large number of times tended to provide more stable outcomes.

- 7 PT 2: As the dice is rolled more times, 1000 and then 5000, the graph, we see increasingly stable and symmetrical orderings of likeliness reaching a crescendo at 7 and falling away equally on either side.
- 8 PT 5: The more rolls that are undertaken, the more constant and smooth the results are becoming.
- 9 PT 8: ... the more rolls that are recorded, the more even the distribution becomes when 7 is rolled most frequently, then 6 and 8 then after that 5 and 9, ten 4 and 10 then 3 and 11, then 2 and 12 in even steps.

Pre-service teachers were challenged to work out the theoretical probabilities of each of the sums occurring, determine the percentage of the occurrence of each outcome (Table 1) and compare those percentages to the scores they calculated for the histogram 'Rolling two dice 5000 rolls' (Table 1).

Working Group 5

Outcome	% of occurrence	Frequency
2	1/36=2.78 %	1
3	2/36=5.56 %	2
4	3/36=8.33%	3
5	4/36=11.11%	4
6	5/36=13.89%	5
7	6/36=16.67%	6
8	5/36=13.89%	5
9	4/36=11.11%	4
10	3/36=8.33%	3
11	2/36=5.56%	2
12	1/36=2.78%	1

Outcome	% of occurrence
2	150/5000=3%
3	310/5000=6.2 %
4	425/5000=8.5%
5	560/5000=11%
6	675/5000=13.5%
7	830/5000=16.6%
8	690/5000=13.8%
9	520/5000=10.4%
10	410/5000=8.2%
11	290/5000=5.8%
12	140/5000=2.8%

Table 1: Theoretical probabilities (left hand side) and percentages of occurrence of roll total of two dice when ‘rolling two dice 5000 rolls’ (right hand side).

Pre-service teachers seemed to articulate a notion of signal with noise:

10 PT 7: The theoretical will always be the same and never fluctuate or change but experimental will deviate lightly above or below the theoretical probability.

11 PT 9: The more times a die is rolled... the histogram for the experimental probabilities will be above or below the histogram of the theoretical probability of an event occurring.

Pre-service teacher (PT 7) expressed noise as “above or below” the theoretical probability and saw the theoretical probability as a central value that might in a sense direct the outcome. PT 9, in turn, seemed to have a sense of there being a signal as the theoretical distribution and noise as a discrepancy between the data observed and the smooth bell curve.

When pre-service teachers referred to the tendency of individual values of experimental probability towards the expected values, they attributed this tendency to “chance”.

12 PT 10: It is evident that as the number of trials 1, wrote: “The percentage of occurrence I calculated using Theoretical probability is very close to the percentage of occurrence what we found using experimental probability, however the numbers are not exactly the same. For example for the outcome 7 in experimental probability I got 16.4% as the occurrence percentage, however in theoretical the answer is 16.6%. The numbers however are very close and I am sure that if further experiments were conducted, one such experiment would emerge in which the numbers would be exactly the same as the theoretical probability percentages, this is all up to chance.

As we have witnessed from the previous excerpt, pre-service teachers did not appear to perceive a continuum tendency of the data-centric distribution towards a target. The element of randomness appeared as a distractive factor for the successful coordination of the two perspectives on distribution. I wondered whether pre-service

Working Group 5

teachers might have developed an understanding (at the global level) of the distribution targeting the modelling perspective on distribution. When the question required them to compare the two perspectives on distribution, pre-service teachers appeared to make comparisons locally.

- 13 PT 6: It is evident that as the number of trials increases, the experimental probability approaches the theoretical probability.
- 14 PT 4: The experimental probability figures will, the more dice rolls that are completed, eventually get closer and closer to the theoretical probability figures...we used experimental probability to 'prove' theoretical probability.

There was, however, a reference (line 14) of using the experimental probability to prove theoretical probability. Some of pre-service teachers separated the theoretical and experimental probability.

- 15 PT 2: Theoretical probability is the knowledge that is calculated of what will happen under ideal conditions. Experimental is the action of going and doing a chance experiment and recording the results for analysis.

PT 2 appeared unable to suggest any connection for the co-ordination of the experimental and theoretical probabilities. Most of the pre-service teachers, however, preferred the security provided by the theoretical probability methods.

- 16 PT 5: While the experimental data, with a high number of trials, is quite successful at producing probability results, I believe that it is easier and more valuable and reliable to us the theoretical probability methods, as this ensures that every possible outcome paths is addressed.
- 17 PT 1: Experiments are not entirely necessary if you have theoretical probability, which also gives you an even more precise answer to the chance of something happening.
- 18 PT 7: This means that you can predict how many times a 4 will appear as a combination of rolling two standard die, without having to actually roll them. The answer you find in this theoretical probability will be the same if you actually perform the experiment physically. Thus, theoretical probabilities can provide us with the ability to predict the outcome of an experiment that may take a very long time to perform or one that it is difficult to perform due to reasons such availability of resources etc.

Pre-service teachers appeared to acknowledge that the theoretical probabilities have the power to predict the experimental probabilities (16, 17, 18). Although, those excerpts have provided an insight into the resemblance of the two perspectives on probability, a strong connection has not been suggested to be made from the modelling perspective on distribution towards the data-centric perspective on distribution, in which the modelling distribution in some sense generates the data.

Working Group 5

The role of large numbers (though probably finite numbers) in this process became very obvious.

DISCUSSION

Pre-service teachers resort to causal explanations to describe the shape of the emerging pattern (1). They gravitate towards adopting a centralised mindset to describe the organization of the histogram (2) by a centralised controller. It is interesting how pre-service teachers use terminology from geometry to describe the shape of the histogram as triangular or a three-dimensional object (3, 4). Pre-service teachers, who distinguish the theoretical from experimental probabilities, were not always able to coordinate those two different perspectives on probability. When they tried to make the connection from the experimental to theoretical probability there was an element of chance (or uncertainty) in the occurrence of the data, out of which the theoretical probability emerges (12). This element caused uncertainty for pre-service teachers, as the connection of data-centric to modelling perspective on distribution caused uncertainty for the 15 year old students in a previous study (Prodromou, 2008). In both cases there was variation omnipresence in the data out of which both entities emerge. The only difference is that the theoretical probability emerges at the local level and the distribution emerges through self organisation at the global level. In both cases students and pre-service teachers articulate their emerging sense of how both entities emerge, by using situated abstractions (Noss and Hoyles, 1996), informal heuristics that capture generally expressed in term of the structuring resources within the settings.

NOTES

1. The Australian *mathematics K-6 Syllabus* is organised into six strands — one process strand, Working Mathematically, and the five content strands, Number, Patterns, and Algebra, Data, Measurement, and Space and Geometry.
2. The game of Craps is available online from http://www.ildado.com/free_craps.html

IMPLEMENTING A MORE COHERENT STATISTICS CURRICULUM

Anneke Verschut and Arthur Bakker

Freudenthal Institute for Science and Mathematics Education, Utrecht University,
The Netherlands

Coherence is one of the objectives of a new statistics curriculum for grades 10-11 (age 15-17) in the Netherlands. Since coherence has different meanings for different curriculum representations, this paper evaluates to what extent the initial attempts to design and implement a coherent statistics curriculum were successful for different curriculum representations. Data were collected from curriculum developers (ideal curriculum), authors of teaching materials (written curriculum), teachers (perceived curriculum) and classrooms (operational curriculum). The results suggest that the implementation of a coherent curriculum in classrooms requires a clear statement of this objective in the ideal curriculum, worked out into guidelines for curriculum authors and concrete classroom activities.

Keywords: coherence, curriculum implementation, statistics education, teacher support.

INTRODUCTION

A new statistics curriculum for the high school level (grades 10-11, ages 15-17) is being developed in the Netherlands. The design and implementation process is part of a broader reform movement that should lead to more coherent science and mathematics curricula in general. In this paper we evaluate the initial attempts to implement the ideal of a more coherent statistics curriculum into the classroom.

What is new in this curriculum is that students learn the concepts of statistics through working with real data sets. The idea is that this helps them to see the relevance of the statistical concepts and techniques they learn. The reform follows similar movements in other countries (e.g., USA, Germany, and New Zealand) and is inspired by international research in the field of statistics education. Teaching students a list of statistical recipes is not enough to make them statistically literate. Students also need to see the coherence between the concepts they learn and the basic principles underlying data analysis (Moore, 1997; Tarr & Shaughnessy, 2007). In the new curriculum, to be implemented nationally in 2015, teachers are encouraged to let students work with real data sets and information technology. Furthermore, the curriculum has both a theoretical and a practical strand. In the practical strand students do research projects where they can apply to real-world problems the theoretical concepts they have learnt in the theoretical strand. The experts in statistics education whom we interviewed thought that these characteristics can indeed help to improve the coherence of the new curriculum (Verschut & Bakker, 2010).

However, it is a well-known problem that there is often a huge gap between the original ideas and intentions of a new curriculum and the curriculum actually enacted in classrooms (Begg, 2005; Van den Akker & Voogt, 1994). In this paper we describe the initial experiences with the development and implementation of the new curriculum, based on the experiences of a small group of schools that are piloting the exemplary teaching materials. The question we seek to answer is: *to what extent do curriculum developers, writers of teaching materials and teachers indeed succeed in making statistics education at the high school level more coherent?*

THEORETICAL BACKGROUND

When people in a reform process speak about a coherent curriculum, what do they actually mean? The first issue we have to deal with is that at least three representations of a curriculum are commonly distinguished: the intended, implemented and attained curriculum (Goodlad, 1979). In a more refined version of this typology the intended curriculum contains both the ideal curriculum (the vision or basic philosophy underlying a curriculum) and the written curriculum (intentions as specified in curriculum documents and/or teaching materials). The implemented curriculum includes both the perceived curriculum (interpretations of intended curriculum by users, particularly teachers) and the operational curriculum (teaching and learning activities actually enacted in classrooms). The attained curriculum is represented by students' learning experiences and learning results.

In this paper we focus on the intentions of policy-makers to have a coherent curriculum in 2015. However, their power is confined to the ideal curriculum. Many questions arise in such a situation: How has the policy-makers' ideal of a coherent curriculum been transformed into the written curriculum by the writers of the exemplary teaching materials? How did teachers perceive the new curriculum?

Curriculum materials play a role in encouraging or supporting new curriculum goals (Herbel-Eisenmann, 2007). So, those who develop curriculum materials need to carefully attend to their discursive choices so that they do not undermine their own intentions. Furthermore, additional support for teachers to make pedagogical choices in line with the new curriculum goals may be needed within the teaching materials (Herbel-Eisenmann, 2007). Teachers have a considerable impact on the transformation process from the written curriculum to the attained curriculum as they decide how to interpret the written curriculum (Stein et al., 2007). Teachers intend to match the written curriculum concerning the content, but their inclinations to match the innovative goals differ (Eichler, 2010). The differences result from teachers' different attitudes and beliefs towards statistics, their knowledge of statistics, and their professional identity (Eichler, 2010; März et al., 2010; Stein et al., 2007).

What people mean by coherence

Another issue that comes up when we talk about a coherent statistics curriculum is what stakeholders mean by coherence. In other words: what constitutes a coherent curriculum? From interviews with national and international experts (Verschut & Bakker, 2010), we inferred the purpose of a coherent curriculum basically is to provide students with coherent knowledge and that coherent statistical knowledge includes:

- conceptual understanding of statistical concepts and their connections
- knowing when, why and how to use what statistical concept or technique
- statistical reasoning, and
- transfer to subjects other than statistics.

Furthermore, we found that building curriculum materials around a central theme such as the key concepts of statistics was assumed to advance coherence of students' statistical knowledge. Another way is to use a concentric method around ever recurring topics, for instance by recognizing that there are two basic types of statistical questions: either you want to know whether a certain variable is correlated with another, or you are comparing two or more groups. Emphasizing the purpose of what is learnt, as happens in an inquiry-based or problem-based learning curriculum, could also improve coherence of students' knowledge. A further point that was mentioned is the importance of making the relation between chance and statistics more explicit; in the old curriculum these were two separate worlds. In other countries (e.g., United States) researchers have also observed this problem (cf. Konold & Kazak, 2008).

Active learning and students' motivation are both recognized as promoters of coherent knowledge (Bransford et al., 2000; Kali et al., 2008). The experts we interviewed underlined this by mentioning motivating learning activities such as doing real-life research projects and working with real data, and active learning activities like discussion and reflection, when asked what teachers could do in the classroom to promote coherent knowledge (implemented curriculum). They also mentioned that the use of computer software for visualization of data could support development of conceptual understanding.

Thus, the characteristics of our new curriculum, working with real data sets and information technology, and the research projects in the practical strand, indeed have the potential to make statistics education more coherent. The question remains to what extent it works.

METHOD

In order to answer our research question we collected data from all people involved in the implementation of the new curriculum at different curriculum representations.

Working Group 5

We read the report of the committee that had the task to write down the basic philosophy of the new curriculum (SKACA, 2007), and interviewed all of its four members plus the person who initiated the curriculum reform together with one of the SKACA members, to better understand the *ideal* curriculum. For a better insight into the development process of the *written* curriculum, we attended the meetings of the authors of the exemplary teaching materials, made notes during these meetings and observed the evolution of the different versions of the instructional materials.

Fourteen teachers of five different schools have tried out three chapters of the exemplary teaching materials in their classrooms in the school year 2009/2010. The classrooms were all of grade 10 of the so-called general education track [1]. The teachers who implemented the materials did so because their schools had signed a contract with the Dutch reform committee for mathematics education (cTWO) to participate in the evaluation procedure of the new curriculum. Two of the teachers (of two different schools) had some knowledge of the ideas behind the new curriculum before they started piloting the materials, as they had been involved in a small try-out project of the initial ideas in the year before these pilots took place. They both initiated the participation of their schools in the evaluation procedure. The rest of the teachers were more or less charged by their schools to participate. We interviewed nine of the participating teachers (at least one per school) a few weeks after they started to work with the materials and attended at least one lesson per school. We also asked them to complete a short questionnaire on their educational and professional background, asking for information on years of experience in teaching mathematics, and statistics in particular, educational background, experience in doing statistical inquiries. This information is relevant since teachers' backgrounds have an influence on their attitudes and beliefs towards statistics education, and thus on their perceptions of a new curriculum (März et al., 2010).

In the interviews we sought a clarification of the *perceived* curriculum by questioning the teachers on their experiences with the former statistics curriculum, how they perceived the attempts to reform, and whether they were aware that coherence was one of the ideas behind the reform attempts. We further asked them what in their opinion coherence meant, and what type of teaching or learning activities they thought could help students to develop coherent knowledge. A first impression of what the operational curriculum would look like emerged by the answers to questions such as in what respect they thought they would teach differently in comparison to the former curriculum, and whether they felt capable of teaching in this new way. Furthermore we asked them what type of support they would need to implement this curriculum properly.

After each chapter all teachers were asked to send us evaluation materials such as teacher questionnaires, annotations with the materials, log-books and student questionnaires. We received materials from nine different teachers (at least one per school), whereas some of them stated that they had discussed their findings with

their colleagues (who did not send any materials) and that the materials reflected their shared views. At the end of the school year we had a group discussion with six of the teachers in order to evaluate their initial experiences of the past school year. This meeting, combined with the evaluation materials gave us a clearer picture of the preliminary *operational* curriculum.

All data collected were analysed according to a coding scheme based on the general evaluation criteria for a coherent curriculum that we developed in an earlier paper (Verschut & Bakker, 2010) and summarised in the previous section of this paper.

RESULTS

In order to answer our research question we first need a short description of the ideal curriculum.

Ideal curriculum

Although one of the objectives of the curriculum reform was that the learning strands should be coherent, which presumably helps students to develop more coherent knowledge, the SKACA committee did not explicitly mention the notion of coherence in their report. They did offer some ideas that could help to improve coherence of students' statistical knowledge, such as building the curriculum around the investigative cycle, developing concepts by making use of real world problems (problem-oriented approach), making the relationship between chance and data more explicit, and teaching probability as being at the service of statistics so as to avoid the common problem of probability and statistics being two separate areas in the mathematics curriculum.

From ideal to written curriculum

Based upon our notes on the meetings of the curriculum authors that we attended, it became clear that the writers of the exemplary teaching materials did not pay much attention to coherence of the materials. From the discussions about the new educational materials it transpired that the authors did not think it was necessary to clearly highlight the connecting thread in the materials for students or teachers, or to offer teachers additional material to explain the ideas behind the materials. An illustrative remark often made by one of the authors in this respect is: "We should not pamper the teachers too much." Furthermore, they did not explicitly try to incorporate teaching or learning activities that could advance coherent knowledge. Their main concern was to cover all of the attainment targets [2], which – admittedly – was already a puzzle in itself.

From written to perceived curriculum

The questionnaire on the educational and professional backgrounds of the participating teachers gave us a rather diverse picture: years of experience ranged from one to over thirty. Two of the teachers had an econometrist background rather than a mathematical one, and thus presumably had learned more about statistics than

Working Group 5

the other teachers. One of them even carried out statistical enquiries in the past for her profession. The other teachers had no specific interest in statistics or statistics education.

What came to the fore from the interviews with the teachers was that at the time they started working with the exemplary teaching materials most of them were not aware that coherence was one of the goals. When asked what they thought was important for this type of students, they mainly mentioned things that are related to what we can summarise as statistical literacy. For instance, they mentioned goals such as being critical readers of newspaper articles on statistical results, being able to critically evaluate the outcome of statistical reports written by other people, and understanding that statistical knowledge is useful in their daily life or other subjects at school.

When asked, they appeared to have an image of what constitutes coherent knowledge and how to improve it, but the notions they had were rather vague, and were not the same as the notions we mentioned in the theoretical background section. They mainly thought of a connecting thread or a clear structure in the materials, or they thought of coherence with other school subjects, such as geography or biology and applications of statistics outside the mathematics curriculum. When we explained the rationale behind a more coherent curriculum, they all considered it an objective worth striving for. However, teachers also complained that they did not know what the attainment targets were of the new curriculum, and thus could not see what the things they were teaching in this first chapter should lead to in the next chapters. This was also due to the fact that at the time they were working with Chapter 1 the rest of the chapters were still under development.

From perceived to operational curriculum

In the lessons we observed we saw hardly any classroom activities that were mentioned in the interviews or literature as stimulating coherent knowledge. An explanation of this disappointing result is that teachers had very little time to prepare their lesson series since the exemplary teaching materials were finished just before the lesson series started. We assume many of our observations could be different in a next year when teachers have worked with more chapters and have studied the attainment targets.

One of the teachers piloting the materials is a member of cTWO, and thus is more aware of the underlying ideas and intentions of the materials. In her lesson we could see some attempts to motivate students to seek for coherence in the things they have learnt. For example she told her students, while doing their exercises, to ask themselves the question “How can I make use of the knowledge I learn from doing this exercise, when I (in another context) am trying to find an answer on a research question?” We consider this an attempt to stimulate reflection on the applicability of acquired knowledge.

Working Group 5

Another positive example was a lesson we observed of a teacher with an econometrist background. She tried to give students a feeling for the role of statistics within the investigative cycle. For example, in one of her lessons she gave her students a group work assignment to invent a research question related to pocket-money and think about a possible research set-up that could lead to an answer to this research question. The results were discussed by the entire class. We think this activity stimulated coherent knowledge as it emphasized the central role of the investigative cycle in statistics, it motivated and activated students because of the real-life context and group work, and the class discussion at the end stimulated the students to reflect on the pros and cons of their research questions and methods.

Teachers' evaluations of the operational curriculum

From the evaluation materials collected during the rest of the school year and the evaluation meeting we had at the end of the school year, we learnt that teachers found the new teaching materials promising, but difficult to implement. They thought the new approach could lead to more coherent statistics education, as one of them stated:

Last year we basically taught them [the students] some tricks, now we also talk with them about statistics and they can get a clearer picture of what statistics is used for and how it works.

However, the first results were not promising, so the teachers felt they failed in utilizing the opportunities of the new curriculum. For instance, some teachers gave their students an assignment to do a small research project on their own or in groups of two or three students, but were disappointed by the results. Only a small proportion of the students showed that they got a grip on the aims and ways of thinking in statistics.

One of the reasons the teachers gave for the disappointing results was that the intentions of the authors of the exemplary teaching materials were not always clear. The teachers said they had difficulty in finding the connecting thread in the materials, how the different chapters were connected and what the entire curriculum was aiming at. They asked for more structure in the materials as a way to support teachers in implementing the curriculum.

The teachers recognized that they have a central role in advancing coherence of their students' knowledge because in their view this type of students has no natural inclination to seek for coherence in what they learn. The teachers understood that for instance having more classroom discussions or promoting reflection by asking a lot of questions could help their students to develop coherent knowledge. However, they did not have a lot of experience with this type of activities and were concerned that it would take up too much time of their lessons, since the entire mathematics curriculum is rather overloaded and statistics is part of the school exams, not of the national exams. Suggestions in the materials for classroom activities that stimulate

coherent knowledge and make efficient use of time would be highly appreciated: “When they think it is important, it should be in the materials!”

DISCUSSION

Our results indicate that the first year of piloting the new curriculum was not very successful. The original ideas and intentions of the *ideal* curriculum were not worked out neatly: what is meant by coherence within a statistics curriculum at different curriculum representations and how could it be promoted. This made the implementation process even more complex than could be expected on the basis of the literature (Begg, 2005; Van den Akker & Voogt, 1994).

It is hopeful that for the *perceived* curriculum we found that teachers indeed recognized the potential of the new teaching materials to provide students with a more coherent knowledge base of statistics: a better understanding of statistical reasoning processes, and a better understanding of when, why and how the statistical techniques they have learnt can be of use. However, the teachers felt they failed in transferring this rich knowledge to their students in the *operational* curriculum. This feeling was intensified by the disappointing results of a research project assignment.

The teachers complained that their failure was partially due to the *written* curriculum: The authors of the teaching materials had not highlighted the structure and connecting thread in the materials. Teachers asked for more guidance and support in implementing this curriculum, for instance by making the intentions of the authors of the materials more distinct, or by offering suggestions for classroom activities that stimulate coherent knowledge. Although the group of teachers piloting the materials consists of teachers of diverse educational and professional backgrounds, they were unanimous in their desire for more implementation support in the teaching materials. Our findings confirm the suggestions by Herbel-Eisenmann (2007) for more support for teachers within the teaching materials. An issue that remains for future research is to what extent differences appear in teachers' inclinations to match the innovative goal of this curriculum, i.e. coherent knowledge, following their different educational and professional backgrounds as has been reported by others (Eichler, 2010; März et al., 2010; Stein et al., 2007).

It is easy to ask for a coherent curriculum – this is done in policy documents worldwide. However, without specifying what coherence means in terms of connecting threads, recurring themes, a concentric approach, the repeated use of an investigative cycle or problem types (e.g., group comparison versus correlation questions), the concept remains empty to most curriculum authors, let alone teachers. Our impression is that more specific measures to promote coherent curriculum strands should be mentioned, trialled and investigated.

In the first place the objective should be clearly stated in the *ideal* curriculum, otherwise authors of teaching materials and teachers are not aware of the objective, but stating the objective of coherent statistical knowledge is not enough. The authors

Working Group 5

of teaching materials should include concrete measures and activities that can promote coherence of students' statistical knowledge in the *written* curriculum, and thus translate the broad concept of coherence, typical of policy documents into some concrete and easy to apply measures. One might think of indicating the connecting thread or structure in the materials, give suggestions for classroom activities such as discussion or reflection, and include exemplary items for assessment.

In the next stage of our research we will develop and evaluate concrete implementation support materials, such as suggestions for classroom activities that may contribute to coherent knowledge. The design of these implementation support materials will be based on teachers' initial experiences with the curriculum and literature on ways to promote coherent knowledge. Inspired by the notion of *educative curriculum materials* (Davis & Krajcik, 2005), and remarks made by the teachers of our research group, we argue these materials should be included in the teaching materials.

So far we only looked at the intended and implemented curriculum. In the next stage of our research we will also investigate students' results to see if the invented activities indeed lead to more coherent statistical knowledge. For that purpose we need to develop more insight into how coherent knowledge can be measured.

NOTES

1. In Dutch secondary education 60% of the students attend pre-vocational education, 20% are in the general educational track and 20% are in the pre-university track.
2. Attainment targets are the statutory objectives of a school subject as formulated by the Dutch government such as: the candidate can interpret statistical data that are represented and/or summarised in diverse ways, and critically appreciate their relevance.

INTRODUCTION TO THE PAPERS OF WG 6: APPLICATIONS AND MODELLING

Chair: Gabriele Kaiser

Team members: Susana Carreira, Thomas Lingefjård, Geoff Wake

The starting point of the working group was a panel discussion of the understanding of the nature of modelling and applications and its theoretical description. One central aspect, namely the distinction between applications and modelling, was intensively discussed by Blum, who referred to the ICMI Study on Applications and Modelling (Blum et al., 2007). He distinguished between modelling and applications as follows: modelling tends to focus on the direction “reality to mathematics” and emphasises the *processes* involved. When *modelling* we are standing outside mathematics looking into mathematics and asking, ‘where can I find some mathematics to help me with this problem?’ Applications tend to focus on the direction “mathematics to reality” and emphasises the *objects* involved. With *applications* we are standing inside mathematics looking out and looking for a particular piece of mathematical knowledge, we can use.

Furthermore, the differences and commonalities that exist between problem solving and modelling were intensively discussed by Doerr who described problem solving as inward looking, dealing with pre-mathematised word problems, in which the givens and goals are static and the goal is a particular solution. Modelling she described as outward looking with the phase of transition from real-world to mathematics as central and the givens and goals dynamic and with the goal being a tool that can be re-used. Both approaches share one important commonality, namely the fundamental question, whether modelling is for mathematics learning or mathematics learning is for modelling. She proposed an integrative view, in which the development of mathematical content and the development of modelling abilities are joint processes, in which the learning of mathematics happens in the context of modelling real world problems and modelling real world problems happens in the context of learning mathematics. An understanding of this joint development will be a key element in advancing a research agenda on modelling and problem solving.

Amongst other aspects the role of technology in applications and modelling was discussed intensively by Carreira. She argued that the inclusion of technology into modelling processes can allow the usage of more complex mathematics, especially the inclusion of simulation or experimentation, where investigation would be possible. Furthermore, the visualization of images and results would contribute to a better understanding of the real situation and of mathematical ideas.

The working group discussed various strands concerning modelling and applications: the majority of the papers dealt with results of empirical research, which displayed a large variety of themes. Several papers dealt with theoretical aspects such the

Working Group 6

distinction of hypotheses and assumptions within modelling processes by Grigoras or the usage of realistic Fermi problems from the perspective of the anthropological theory of didactics by Ärlebäck. Two reports were of psychologically oriented studies: the study on the connections between the mathematical thinking styles of teachers and their interventions by Borromeo Ferri and Blum and the analysis of the problems solving process by Johannes Gross. Frejd described a curricular oriented study of modelling in Swedish national course tests. A subject-bound study of the understanding of average rate of change was proposed by Doerr and O'Neil. Other papers dealt with theoretical aspects such as the role of the teacher's identity in a psychologically oriented study by Jensen and an interdisciplinary oriented study of modelling in an integrated mathematics and science curriculum by Wake. Teacher education was researched in a curricular oriented study of a teaching sequence for future mathematics teachers by Lingefjärd, the role of modelling as a big idea within the beliefs of future teachers was researched by Siller. The use of digital tools within modelling problems in German centralised examinations was discussed by Greefrath.

The sessions closed with reflections on the discussion in the light of the panel debate at the beginning and identified the following main research areas for the future:

- How to move forward in the scientific debate on applications and modelling?
- How to make progress concerning the inclusion of applications and modelling in curriculum and school practice?

These two areas give rise to questions that can be differentiated as follows:

- Where are research deficits? Can we identify them?
- What kind of empirical research is necessary? Large-scale studies versus case studies? Role of replication studies?
- What kinds of measures are necessary and can be constructed? Is the development of teaching units or learning materials sufficient? What is the role of comprehensive learning environments?
- What can we say about the role of culture in the teaching and learning of mathematical modelling? Is it culture-free or what do we need to consider as cultural effects in our debate?

ARE INTEGRATED THINKERS BETTER ABLE TO INTERVENE ADAPTIVELY? – A CASE STUDY IN A MATHEMATICAL MODELLING ENVIRONMENT

Rita Borromeo Ferri and Werner Blum

University of Hamburg and University of Kassel, Germany

A lot of empirical studies have shown that the learning and teaching of mathematics is highly complex and influenced by many factors. The teacher, in particular, can promote high-quality lessons with a substantial learning outcome. In previous studies, preferred mathematical thinking styles and preferred interventions of teachers were reconstructed as important factors when teaching modelling in the mathematics classroom. In the present empirical study, the main question was whether there is a connection between certain thinking styles and certain intervention types of teachers. In this paper, first results and hypotheses of this quantitative-qualitatively oriented study will be presented.

THEORETICAL BACKGROUND

First, we will briefly give a theoretical background regarding the two basic elements of our study, mathematical thinking styles and teacher interventions.

A mathematical thinking style is “*the way in which an individual prefers to present, to understand and to think through mathematical facts and connections by certain internal imaginations and/or externalized representations. Hence, a mathematical style is based on two components: 1) internal imaginations and externalized representations, 2) the wholist respectively the dissecting way of proceeding.*” (Borromeo Ferri 2003)

Within the theory of mathematical thinking styles the term “preference” is important, because a *style*, speaking in the sense of Sternberg (1997), refers to how someone likes to do something, whereas an ability refers to how well someone can do something. So styles are preferences in using abilities. Sternberg’s general theory of styles influenced also the construct of mathematical thinking styles. On the basis of empirical studies (see Borromeo Ferri 2003, 2004) three mathematical thinking styles could be reconstructed so far with students from grades nine and ten and with teachers of secondary schools:

- *Visual thinking style*: Visual thinkers show preferences for distinctive pictorial imaginations and representations as well as preferences for the understanding of mathematical facts and connections in a holistic way. The internal imaginations are mainly effected by strong associations with experienced situations.
- *Analytical thinking style*: Analytic thinkers show preferences for formal imaginations and representations. They are able to comprehend mathematical

Working Group 6

facts preferably through symbolic or verbal representations and prefer to proceed rather in a sequence of steps.

- *Integrated thinking style*: These persons combine visual and analytic ways of thinking and are able to switch flexibly between different representations or ways of proceeding.

In a further empirical study (see Borromeo Ferri 2010), one of the main questions was whether there is an influence of mathematical thinking styles particularly on the *modelling* behaviour of students and teachers. Summarising the results shortly only regarding the teachers' behaviour, it became clear that teachers who differ in their mathematical thinking styles have preferences for focusing on different parts of the modelling cycle while helping or discussing with students. More concretely: Analytic thinkers preferred the "mathematical part" of the modelling cycle and were more interested in formal solutions of modelling tasks, whereas the validation of the real results was not so important for them. Visual thinkers tended to think more in terms of the "real world" (the given situation in the task) and to enrich the reality with their own associations, whereas looking on formal solutions was not in their focus. Integrated thinkers found a balance between reality and mathematics for themselves and in their behaviour with their students. So mathematical thinking styles seem to have a substantial influence on the way teachers deal with modelling problems in the classroom.

Of particular interest is now whether and in which way certain types of teacher interventions are linked with certain mathematical thinking styles. In the following, we will refer to Leiß' (2007) theory of teacher interventions. Leiß characterises *teacher interventions* as all verbal, para-verbal and non-verbal interferences of a teacher in the solution process of students. *Adaptive* teacher interventions are characterised as supporting individual students in a minimal way, so that students can work as much on their own as possible (realising a balance between students' independence and teacher's guidance, in the spirit of Maria Montessori: "Help me to do it by myself").

Leiß (2007) carried out his empirical study for reconstructing teacher interventions within the DISUM project (see Blum/Leiß 2007b). He created, on the basis of existing theories of interventions (e.g. Zech 1996) and his own classification (Leiß/Wiegand 2005), a coding scheme for analysing his observations. He distinguished levels, activators and aims of interventions. These will be explained in the following tables into more detail, because we also used this coding scheme for our analyses.

Working Group 6

Levels of interventions	Aims of interventions
<i>with regard to the content</i> interventions of the teacher referring to the content, here: the modelling process and the corresponding mathematics	<i>diagnose</i> teacher asks students about the current state of their solution process
<i>strategic</i> interventions concerning the meta-level, that is general aspects of the modelling and problem solving process	<i>evaluation/feedback</i> teacher gives feedback to students' solution process without further information or correction
<i>affective</i> interventions trying to influence the mental state of students	<i>indirect advice</i> subtle hints of the teacher in order to help students to find the "best way of solving" according to the teacher's opinion
<i>organizational</i> interventions concerning the basic conditions of students' working including group interactions or presentations	<i>direct advice</i> teacher gives relevant explanations and information to students explicitly
	<i>conscious non-intervention</i> no intervention of the teacher although students may have problems

Table 1: Level and aims of interventions

Activators of intervention	
invasive	own initiative of the teacher to intervene in the solution process of the students
responsive	students ask the teacher explicitly for advice

Table 2: Activators of interventions

Main results of Leiß' study were, among others, that strategic interventions are included in the intervention-repertoire of the observed teachers only very marginally and that the teachers often choose indirect advice where students have to find only one step by themselves in order to come over the difficulty.

More sophisticated results were obtained in the so-called main study of the DISUM project (see Blum 2011). Altogether 25 grade 9 classes participated in this study with a pre-, post- and follow up test design and with ten lessons devoted to

modelling tasks. The research focus was the comparison between two teaching styles: a more teacher guided “directive” style and an “operative-strategic” style focussing more on students’ independent work in groups. The results showed a significantly higher progress of modelling competency of students taught in the “operative-strategic” style. The best results concerning progress in modelling competency could be reconstructed in those classes where the balance between students’ independence and teachers’ guidance was realised best, based on experts’ ratings. This corresponds to a constructivist view of learning where students have to build their knowledge and competencies as actively and independently as possible, supported by the teacher. More generally, the background model for our studies is a view on “*quality mathematics teaching*” characterised by a demanding orchestration of teaching the mathematical subject matter (by giving students vast opportunities to acquire mathematical competencies and making connections within and outside mathematics), by a permanent cognitive activation of the learners and by an effective and learner-oriented classroom management (see Blum/Leiß 2007b and Blum 2011).

RESEARCH QUESTION AND METHOD

The central question of our study was: *Do connections exist between teachers’ mathematical thinking styles and types of teacher interventions in mathematical modelling environments?*

In particular the results of the main study of the DISUM project, mentioned before, raised new questions. In fact, the “operative-strategic” style was more successful, but big differences among the teachers concerning the quality of teaching and the progress of their students could be observed, although all teachers got a special training for teaching the ten lessons modelling unit. So an open question is whether these differences can be explained more deeply with certain individual attributes of the teachers. The procedure of our study was as follows. Firstly, regarding data collection: we chose four of the 25 teachers of the main study of the DISUM project (for whom a particular lot of video material was available) for analysing the same two videotaped lessons with the tasks “Filling up I and II” (see Blum/Leiß 2007a). Additionally, we also conducted focussed interviews (Flick 1990) with all four teachers in order to reconstruct their mathematical thinking styles. The guideline for these teacher interviews was developed and used in the recent study Borromeo Ferri (2010). Examples of interview questions are: What does mathematics mean for you? Do you think that your attitude concerning mathematics changed through your teaching life? What is your preferred way of solving tasks (concretely: the “Filling up” task)? What is important for you when teaching mathematics?

The interviews were transcribed and analysed in combination with the actions of the teachers in the lessons for reconstructing their mathematical thinking styles. A basic instrument for the classification of the thinking styles was the coding scheme

developed by Borromeo Ferri (2003). In order to get more validity, two persons analysed the data independently, in the sense of so-called concurrent coding (Schmidt 1997, 559). With the same method, using the coding scheme of Leiß (2007), teacher interventions were reconstructed directly from the videos. For analysing the interventions, a structure was created so that interventions of the teachers could be better compared in several phases of the lessons. The following six phases were considered during the whole analysing process: 1. Introduction of the lesson (task “Filling up I”); 2. Group work; 3. Plenum (discussion about students’ results); 4. Improving students’ own results; 5. Plenum (reflections on the solution process); 6. Transfer to the second task “Filling up II”.

RESULTS

On the basis of the interviews and the videos, three of the teachers, Mr. H., Mr. B. and Mrs. R., could be reconstructed as analytic thinkers and one, Mr. S., as an integrated thinker. So a visual thinker was not in this (small) sample.

a) Quantitative analyses of teacher interventions (lessons “Filling up I and II”)

The duration of the six phases was different in the four classes. A deeper look at phases 2 and 3, which means the group work and the first plenum, offered interesting results how the teachers acted. In Mrs. R.’s and Mr. S.’ lessons the pupils worked in the sense of the ”operative-strategic” style independently in their groups. Mr. H. and Mr. B. were teaching in the “directive” style which is also their preferred way in everyday teaching: students sitting head-on, solving the tasks in the whole class. Mr. H. got the highest number of interventions namely in particular invasive, context-bound and directive interventions. During the plenum phase, only Mrs. R. and Mr. S. intervened. Because Mr. H. worked on the modelling problem with the whole class the students only got “one right result” that was not discussed further. Mr. S. asked every group of students to explain their results, which explains his high number of interventions. Mrs. R. also discussed the different results of the students.

In the following table 3, all interventions of all teachers during all phases are presented. Concerning the activators of the interventions, Mr. B. (152) has the the biggest number of invasive interventions, but also Mr. H. (115) and Mrs. R (107) intervened strongly invasively, in contrast to Mr. S. (87). Concerning the level of interventions, Mr. H. intervened 50% and Mr. S. 43% content-related, and Mr. B. even 65% Strategic interventions can be observed for Mr. S. twice as much as for the other teachers. Concerning affective and organisational interventions, Mrs. R. has the highest rate with 32% and 27%. Results of t-tests (confidence-interval 95%) showed that all these differences are significant.

Working Group 6

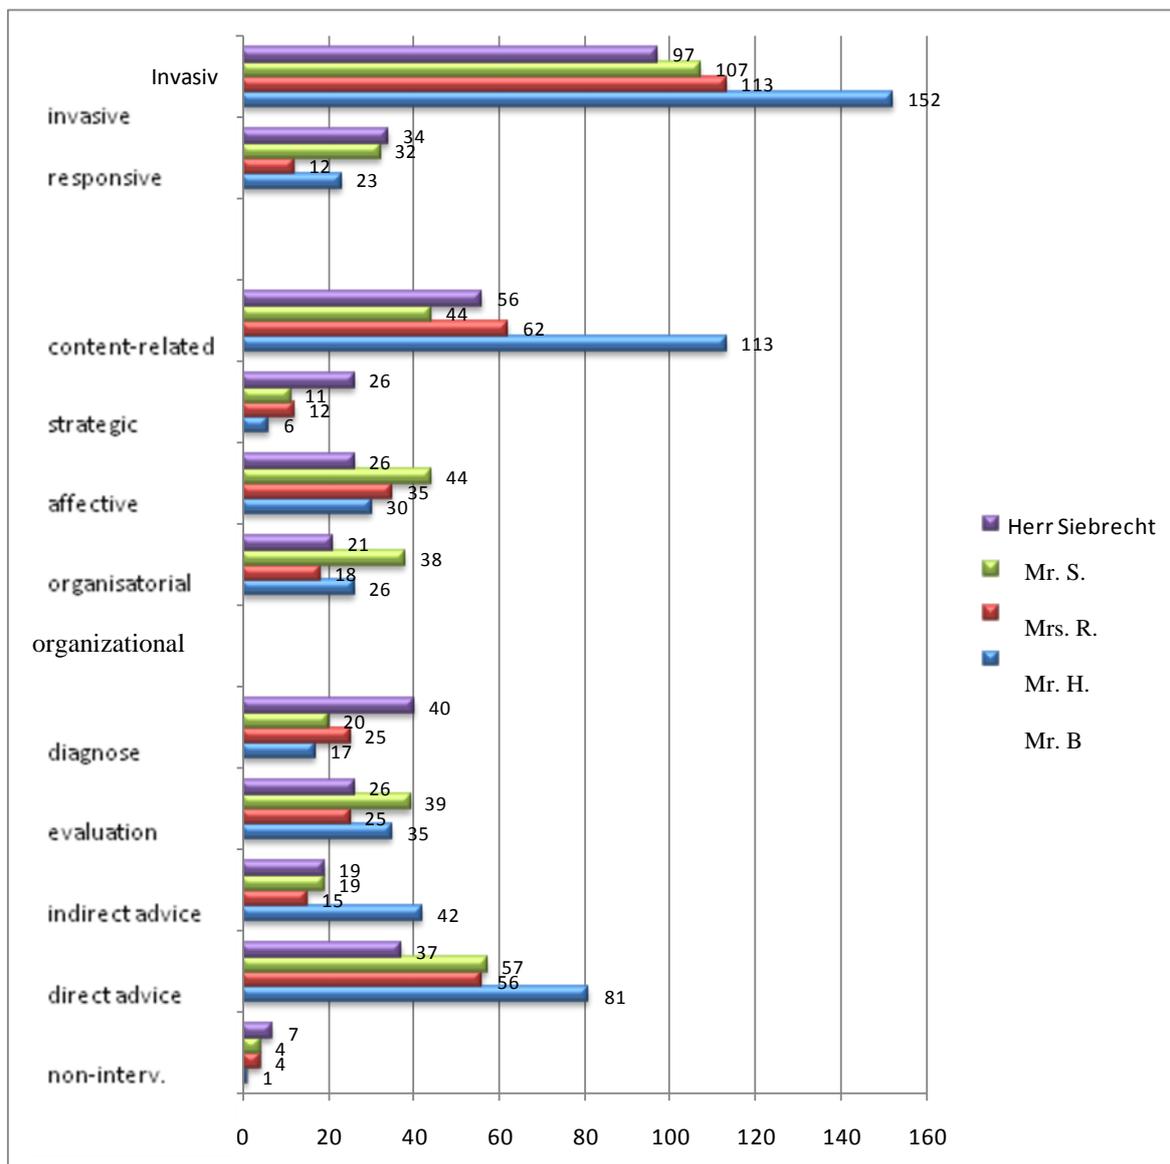

Table 3: Interventions in total

b) Qualitative analyses of teacher interventions (lessons “Filling up I and II”)

In the following, interventions and connections to mathematical thinking styles only of Mrs. R and Mr. S (both within the “operative-strategic” design) are reconstructed because of the restricted space. We do that firstly with the help of a table summarising the main characteristics of each teacher and secondly with a comparison of some concrete actions of the teachers. In the left column one can find the actions within the lessons and in the right column statements from the interview. We start with Mrs. R., reconstructed as an analytic thinker.

Working Group 6

<i>Interventions and actions (lesson)</i>	<i>Reflections about own teaching (interview)</i>
<ul style="list-style-type: none"> - lesson is structured - students can work independently in their groups - different interventions in the groups: less interventions in groups which work on the path preferred by Mrs. R., other groups are more or less guided during the solving process; altogether many affective and organizational interventions 	<ul style="list-style-type: none"> - she introduces new themes in maths by a concrete example and then mainly algorithms are important for her - she prefers a clear structure of lessons - she does not like some mathematical contents such as riddles - she personally likes to solve tasks formally

Table 4: Mrs. R. – some characteristics

Interpretation: Mrs. R. prefers and also shows well structured maths lessons. Analysing the two lessons as well as the other lessons in that teaching unit, it becomes clear that Mrs. R. intervenes regularly and consciously in the thinking and solving process of the students:

“I went from one group to the other and I always said think about it.”

Mrs. R. intends to have their students learn from mistakes:

“I always tell my students that it is not bad making mistakes, but learning from mistakes is good.”

However, this statement is in a certain contrast to her real actions in classroom. In all analysed lessons Mrs. R. was trying to prevent students from making mistakes and to guide them to her preferred solution. We interpret her well structured lessons in combination with her analytic thinking style as a kind of aplomb while teaching and a sign of her intention to avoid [ambiguity](#) regarding mathematical contents. She likes to have the control of as many aspects during lessons as possible, especially concerning the way of solving tasks:

“We have a certain ritual of solving tasks and I exercise this with my students.”

For Mrs. R. visualising is also relevant, but her preferred way of thinking becomes evident when she talks about solving a linear equations task:

“Personally I do not see the straight line, I see the actual data. Of course I know that behind is the system of equations.”

Altogether, according to our interpretation, Mrs. R. tries to compensate a certain one-sidedness, caused by her mathematical thinking style, by planning carefully each step during a lesson. She emphasised in the interview that acting this way is keeping her from ambiguity.

Working Group 6

Mr. S. was reconstructed as an integrated thinker

<i>Interventions and actions (lesson)</i>	<i>Reflections about own actions (interview)</i>
<ul style="list-style-type: none"> - lesson is structured - students can work independently in their groups - indirect interventions for getting partial solution of students without guiding them much - new ideas of students are picked up with extra information - helping the students to do things by themselves; he gives the same attention to all students and praises solutions not only when they are correct - aim of intervention is predominantly diagnosis or indirect, also often non-interventions 	<ul style="list-style-type: none"> - mathematics is for him “everything”, training thinking processes as well as applications - he likes diversity in teaching maths and developed special methods for several phases within a lesson - during university he had problems with the formal exactness of mathematics - he sees a balance for himself between formal and visual acting - he welcomes different solutions of students

Table 5: Mr S. – some characteristics

Interpretation: The main intentions and actions of Mr. S. can be summarised in one sentence: he tries to help the students to do it by themselves. For many students that is enough for being active during the whole lesson. Students are not afraid asking something. For him “the main principle is to inspire students for mathematics.” So that is why he created various methods. At the beginning of lessons he gives students sometimes a riddle or a logical story.

“Pupils should see that one can solve problems with the help of mathematics and that mathematics is training thinking processes.”

His own problem with the exactness of mathematics during his university studies has influenced his way of teaching and assessment at school. This becomes clear while analysing the two lessons:

“Students who understood the problem will not get a worse mark if they don’t do it totally formally correct.”

For Mr. S. it is important to support sustainable knowledge so he creates his lessons usually very open and uses several methods. He also welcomes individual solution processes of the students, for instance in the case of linear equations the whole spectrum from formal equations over tables to graphs. So we reconstructed in his lessons that Mr. S. is listening to students’ ideas and is doing some kind of

“juggling” with these ideas. He is encouraging every group to think in different directions and also to think about solutions of other groups.

c) Reconstructed connections

Connections between interventions and mathematical thinking styles were reconstructed on the basis of the cases shown here, both with respect to qualitative and quantitative aspects. The teachers’ mathematical thinking styles were clearly correlated with their actions in lessons. The integrated thinker, Mr. S., had a more flexible repertoire of intervening, including strategic interventions, he let students work much more independently and develop more individual solutions. The analytic thinkers tried a lot more to guide students according to the teachers’ preferred ways of solving the tasks.

Now what was the effect of these ways of teaching? Comparing the learning progress of the students (see the remark in section 1; for more details see Schukajlow et al., 2009), Mr. S.’s students learned significantly more during this ten lesson teaching unit (progress: half a SD) than the students of the other three teachers (progress: quarter of a SD), in particular concerning modelling.

So our central hypothesis on the basis of our case study is:

Integrated thinkers are better able to intervene flexibly and minimal-adaptively and thus get better results concerning students’ learning progress.

Of course, this result ought to be replicated with a bigger sample of teachers before implications for teacher education can be drawn.

An open question is how teachers’ mathematical thinking styles and interventions are connected with other factors such as their subject-related professional knowledge and competencies or their epistemological convictions and beliefs. Perhaps the guiding forces behind both thinking styles and interventions are the same. This should also be subject of further studies on teachers.

A MODELLING APPROACH TO DEVELOPING AN UNDERSTANDING OF AVERAGE RATE OF CHANGE

Helen M. Doerr and AnnMarie H. O'Neil

Syracuse University

Students' difficulties in reasoning about change are well documented in the research literature. In this paper, we describe a modelling approach to developing students' abilities to create and interpret models of phenomena where change is occurring and developing their concepts of rate of change. We describe the design of a model development sequence and its classroom implementation with 33 students just prior to beginning their university studies. The pre/post-test results show that the students made significant gains in their understanding of the concept of average rate of change. We present an analysis of the areas of greatest gains and of the difficulties some students encountered in their interpretations of changing phenomena.

Much research over the last twenty years has documented the difficulties that students encounter when creating and interpreting models of changing phenomena. Several studies have examined the role that students' concepts of function and rate of change play in students' abilities to represent and to reason about dynamic events (Carlson et al., 2002; Monk, 1992; Thompson, 1994). As Oerhtman, Carlson and Thompson (2008) argue, in order to reason dynamically, students must be able to simultaneously attend to both the changing values of the output of a function and the rate of that change as the input values vary over intervals in the domain. The complexity of such reasoning has proven difficult even for high achieving undergraduate students (Carlson, 1998). A related line of research (Confrey & Smith, 1994; Michelsen, 2006; Shternberg & Yerushalmy, 2003) has emphasized the role of context in the development of students' reasoning about changing phenomena. Michelsen (2006) argues that one source of difficulty for students in applying functions in context is that students fail to treat variables as related quantities that change and hence have difficulties in recognizing that functions are tools for describing, explaining and predicting the relationships among changing quantities.

The broad goal of our research is to understand the inter-related development of students' abilities to create and interpret models of phenomena where change is occurring and the development of students' concepts of rate of change. We also wish to move beyond descriptions of single model eliciting activities to characterize more fully the nature of model development sequences (Lesh et al., 2003; Doerr & English, 2003). In this paper, we describe a sequence of model development tasks that was designed to support the development of students' concept of rate of change by engaging them in creating and interpreting models of physical phenomena that change. In particular, we are interested in two research questions: (1) how did the sequence of modelling tasks support the development of students' concepts of rate of

change and (2) to what extent were students able to interpret rates of change in context?

THEORETICAL BACKGROUND

Modelling approaches to the teaching and learning of mathematics encompass a wide range of theoretical and pragmatic perspectives (Kaiser & Sriraman, 2006). As Kaiser and Sriraman point out, modelling research based in the “contextual modelling” perspective draws on the design of activities that motivate students to develop the mathematics needed to make sense of meaningful situations. Much work done within this perspective draws on model eliciting activities (MEAs) developed by Lesh and colleagues (Lesh et al., 2003). Model eliciting activities confront the student with the need to develop a model that can be used to describe, explain or predict the behavior of familiar or meaningful situations. Such MEAs encourage students to engage in a cyclic process where they express, test, and refine their own ways of thinking about meaningful situations.

However, a single MEA in isolation is seldom enough for a student to develop a generalized model that can be used and re-used in a range of contexts. To achieve this goal, we argue that students need multiple opportunities to explore the relevant mathematical constructs and to apply their model in new settings. Sequences of structurally related model exploration activities and model application activities are needed, accompanied by discussions and presentations that focus on the underlying structure of the model and on the strengths of various representations and ways of using them productively. Each stage of this sequence engages students in multiple cycles of descriptions, interpretations, conjectures and explanations that are iteratively refined while interacting with other students. Thus, in this study, we have designed an instructional sequence (described in more detail in the next section) that begins by engaging students with meaningful problem situations that elicit the development of significant mathematical constructs. Students then explore and apply those constructs in other situations leading to the development of a model that is usable in a range of contexts. This study was designed to examine students’ learning of the concept of average rate of change when engaged in a sequence of model development tasks.

DESIGN AND METHODOLOGY

The Model Development Sequence

Model development sequences are structurally related activities that encourage student exploration and are accompanied by teacher-led discussions, student presentations, and summaries so as to focus attention on the structural similarities among the tasks and on the use of representations across the activities. As in our prior work, we began this sequence with a model-eliciting activity, using a familiar and meaningful situation, in this case, motion along a straight line. Students were

asked to create graphs using a motion detector and their own bodily motion and to generate descriptions of that motion. The graphs included comparative situations of faster and slower constant speed, changing speed and changing direction, and graphs where the motion was not physically possible.

Following the model-eliciting activity, the students engaged in several model exploration activities. An important goal of these activities was to engage students in using everyday language to make sense of the average rate of change in two different contexts and to develop their understanding of the representational systems for describing change. These activities were designed to help students to think with the conceptual system (or model) and to think about the underlying structure and generalizability of the model. The first model exploration activity used SimCalc Mathworlds (Kaput & Roschelle, 1996). This activity reversed the representational space of the model-eliciting activity where bodily motion created a position graph and extended that space as the students made velocity graphs that generated the motion of a simulated character. From this motion, the students created position graphs, thus developing an understanding of how the position graph could be constructed by calculating the area between the velocity graph and the x -axis. In exploring this linked relationship between the velocity and position graphs, students began to reason about the position of characters solely from information about the velocity of the characters. For example, in one task, the students were given written descriptions of the motion of two characters and asked to create appropriate velocity graphs, such as that shown in Figure 1.

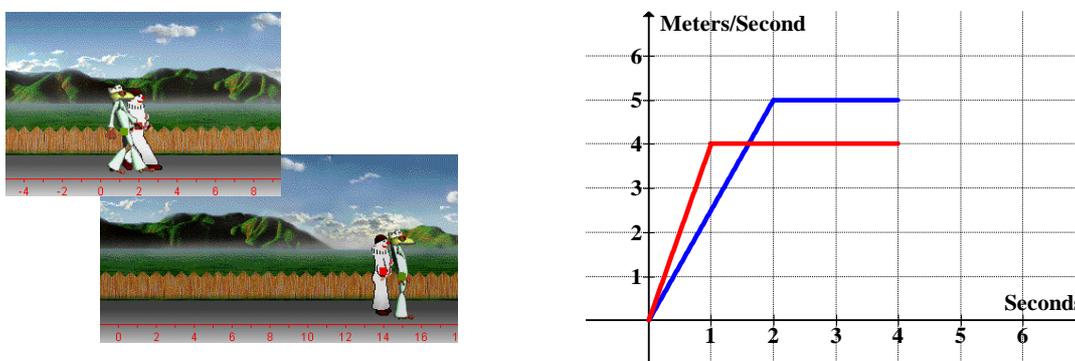

Figure 1. Interpreting position from a description of velocity.

The students were then asked to determine which character had walked farther and who was walking faster at various points in time. The students were asked to justify whether or not the two characters would ever be at the same position at the same time. This model exploration activity provided an opportunity for students to develop their abilities to interpret position information from a velocity graph and velocity information from a position graph.

The second model exploration activity used the “Gym” task from the interactive mathematics textbook by Yerushalmy (2005). This applet (<http://www.cet.ac.il/math/function/english/line/rate/rate10.htm>) was designed to help students understand

how the rate of change is expressed in table values, graphs, and equations. Using the context of training plans on a weight-lifting machine in a gym, the students explored the difference between constant and non-constant rates of change. Specifically, they investigated the graphical and numerical representations of weight training plans where the weight lifted increased or decreased at a constant rate, at an increasing rate or at a decreasing rate. The students were asked to explore the applet in order to make generalized observations about how setting the initial weight, the first change in weight and the change of the change affected the shape of the corresponding graph and the table of values.

The third component of the model development sequence consisted of two model-application activities that focused on applying their model to new problem situations. This was intended to lead to a generalized understanding of average rate of change. In the first task, students were asked to create a model of the intensity of light with respect to the distance from the light source, to analyze the average rates of change of the intensity at varying distances from the light source and to describe the change in the average rates of change as the distance from the light source increased. The second model application task investigated the rate at which a fully charged capacitor in a simple RC circuit discharged with respect to time. The students built the circuits, charged the capacitor, and then measured the voltage drop across the capacitor as it discharged. Students were given a set of resistors and capacitors and were asked to develop a model they could use to answer these three questions:

- (1) How does increasing the resistance affect the rate at which a capacitor discharges?
- (2) Compare the rates at which the capacitor is discharging at the beginning, middle and end of the total time interval. How does the average rate of change of the function change as time increases?
- (3) How does increasing the capacitance affect the rate at which a capacitor discharges?

Taken together, these two model-application tasks focused the students' attention simultaneously on the quantity that was measured and on how that quantity was changing with respect to some other quantity (i.e., distance or time). A coordinated understanding of these two measurements is at the crux of representing and reasoning about dynamic events (Oerhtman et al., 2008).

Rate of Change Concept Inventory

To measure students' understanding of average rate of change, we designed a "Rate of Change Concept Inventory" consisting of items in four categories: algebraic expressions (5 items), graphical interpretation (8 items), symbolic interpretation (3 items), and purely contextual (1 item). Fourteen of the items on this test were drawn from the research literature (described earlier) on students' conception of rate of change. Three items were developed to test the students' mastery of the algebraic

representations involved in expressing and computing average rates of change. The development of this concept inventory is part of our on-going work.

Setting, Participants, Data Collection and Analysis

This model development sequence formed the basis for a six-week course, taught by the second author, to students who were preparing to enter their university studies. There were 33 subjects from this course who volunteered to participate in the study. Eleven of the participants were female and 22 were male. All but one participant had completed four years of study of high school mathematics; 18 students had studied calculus in high school and 15 had not studied any calculus. The participants worked in groups of three or four to complete the model-eliciting tasks and model-application tasks. The model exploration tasks were done individually at a computer; however, the participants were encouraged to discuss their work with each other. Following each task in the sequence, there was a whole-class discussion which usually involved students in presenting the results of the work produced during the model-eliciting and model-application tasks. The class discussion following the model-exploration tasks focused on the structural features of the model and on the relationships among different representational systems. The students worked in pairs to complete final reports on their findings for each of the model-application tasks. All participants completed all of the tasks in the model development sequence described above. The written work from these collaborative tasks and from individual course examinations was collected and analyzed. All participants completed the 17 item pre- and post-test of “Rate of Change Concept Inventory.” The overall pre- and post-test scores and the four sub-scores were analyzed using t-tests.

RESULTS

Change in students’ understanding of average rate of change

The post-test results show that there was a significant improvement in the students’ understanding of the concept of average rate of change from an overall score of 52% correct to 75% correct, as measured by the 17 items on the test. There was a significant improvement in three of the sub-score areas: algebraic expressions, graphical interpretations, and symbolic interpretation. Table 1 displays the overall performance on the pre- and post- test and the performance on each of the sub-scores for $n = 33$ students.

While the overall scores improved by 23%, there were seven items on the concept inventory for which the improvement was greater than 30%. Two of these were algebraic expression items, four were graphical interpretation items, and one was a symbolic interpretation item. The two algebraic expression items asked the student to find the equation of the line joining two points and to calculate the average rate of change between two points on a parabola.

Working Group 6

	Pre-test mean (sd), percent correct	Post-test mean (sd), percent correct	p-value
Overall	8.87 (3.47), 52%	12.69 (2.81), 75%	<0.001
Algebraic	2.64 (1.27), 53%	3.70 (1.13), 74%	<0.001
Graphical	4.96 (1.82), 62%	6.78 (1.31), 85%	<0.001
Symbolic	0.94 (0.90), 31%	1.70 (1.02), 57%	<0.001
Contextual	0.33 (0.48), 33%	0.52 (0.51), 52%	n.s.

Table 1. Pre-test and post-test results for overall concepts and subscores.

There were substantial gains on two items that measured students' proficiency in being able to express algebraically two basic ideas about average rate of change. On the item that asked for the equation of a function with a constant rate of change $n=16$ (48%) students answered the item correctly on the pre-test and $n=26$ (79%) answered correctly on the post-test. Similarly, on the item that asked students to compute the average rate of change for a function with a non-constant rate of change the number correct went from $n=8$ (24%) on the pre-test to $n=22$ (67%) on the post-test.

The symbolic interpretation item required the student to interpret the meaning of the parameters in an exponential growth function: "The model that describes the number of bacteria in a culture after t days has just been updated from $P(t)=7(2)^t$ to $P(t)=7(3)^t$. What implications can you draw from this information?" There was a substantial gain on this question of 40 percentage points from the pre-test ($n=12$, 36%) to the post-test ($n=25$, 76%). This likely reflects the emphasis in the model development sequence on making meaningful interpretations of data and on giving descriptions of the average rate of change in various contexts, including the exponential change in the circuit task.

There were substantial gains on four items that measured students' proficiency at interpreting rate of change when given graphical information (see Table 2).

Graphical Items	Pre-Test		Post-Test		Δn	$\Delta\%$
	n	%	n	%		
Q4 C	19	58%	29	88%	10	30%
Q5 C and	22	67%	32	97%	10	30%
Q5 D	20	61%	30	91%	10	30%
Q8 A	18	55%	28	85%	10	30%
Q10	5	15%	19	58%	14	43%

Table 2. Improvement on graphical interpretation items

Working Group 6

Questions Q4 C, Q5 C and D, and Q8 all addressed interpreting information about velocity when given a position graph. Question Q10, on the other hand, involved interpreting position information when given a velocity (or speed) graph. This coordination of representational systems (shifting between the velocity or rate graph and its associated position graph) was the main focus in the model-exploration tasks described earlier. Due to space limitations, we will illustrate these results with Q5 C and D and Q10.

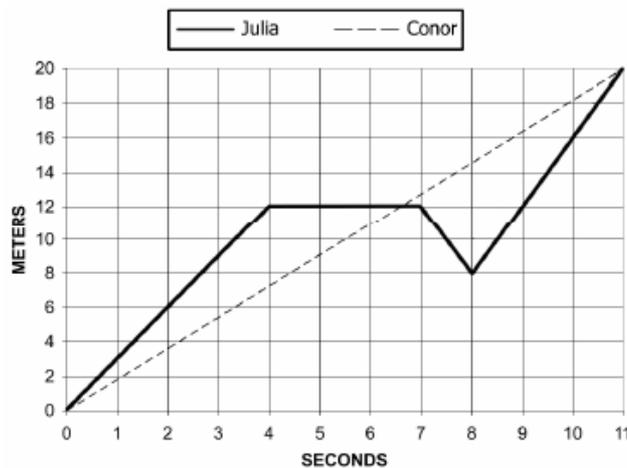

Figure 2. A graphical representation of a 20-meter race between two runners.

Item Q5 C and D asked for a description of the runner whose graph is shown by the solid line in Figure 2 over two time intervals: from 4 seconds to 7 seconds and from 7 seconds to 8 seconds. On the post-test, 97% and 91% of the participants were able to correctly describe the runner as standing still and as moving back towards the starting position. In other words, the participants were able to correctly reason about the velocity (or average rate of change) over an interval when given a position (or quantity) graph.

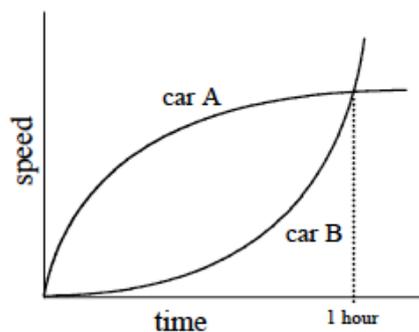

Figure 3. Interpreting the relative position of two cars given their speed.

Item Q10 represents an important reversal of the above problem and one that is a well-known source of difficulty for calculus students (Monk, 1992). This item requires an understanding of how to reason about position when given a velocity

graph. We found a 43% improvement in the number of students who were able to correctly interpret the relative position of two cars, starting from the same position and travelling in the same direction, when given the speed graph shown in Figure 3.

Interpreting rate of change in context

In this section we report on our analysis of the students' responses to a written examination item. The students were given a data set of the voltage drop across a capacitor for 50 seconds and asked to compute the average rate of change over three subintervals, from $t = 5$ to $t = 10$ seconds, $t = 20$ to $t = 25$ seconds and $t = 40$ to $t = 45$ seconds. After computing these average rates of change, the students were asked to "Write two or three sentences interpreting this data." Since this data is modelled by an exponential decay function, the voltage is decreasing over each sub-interval but the average rate of change is increasing across the sub-intervals. Describing such functions as decreasing at an increasing rate presents both conceptual and contextual challenges. The conceptual challenges reside, in part, in coordinating one's understanding of the change in function values with the rate of that change over various subintervals; the difficulty of the comparisons becomes more complex when the rates are negative but increasing. The contextual challenges arise from the difficulties in natural language in describing magnitude of the voltage drop, since this magnitude decreases, while the signed average rate increases as it becomes less negative. Everyday language for describing the change in rate appears in conflict with formal mathematical language for describing that change.

We categorized students' responses to this item into four levels. These levels and the number of student responses are shown in Table 3. Approximately 61% of the students correctly described both the behavior of the function and its average rate of change with half of those responses (10 out of 20) including a reference to the context.

Category	Number of Responses
(3) Correctly described both function and rate of change, referring to context	10
(2) Correctly described both function and rate of change, minimal or no reference to context	10
(1) Correctly described function, but not rate of change	1
(0) Incorrect description	12

Table 3. Interpretations of rate of change

An example of a response in category (3) is: "The average rate of change increases (gets less negative) as time progresses, meaning the voltage on the capacitor is decreasing at an increasing rate." An example of a response in category (2)

expressed that the function is decreasing, while “the average rate of change is going from a more negative number to a less negative number, meaning the average rate of change is increasing over time.” Although this response does not specifically refer to the context of the problem, namely the voltage drop across the capacitor, the student correctly distinguishes between the change in the function and the change in the average rate of change.

Of the 12 responses in category (0), six of those responses indicated that the student conflated the changes in the function with the changes in the average rate of change. An example of such a response is: “The average rate of change is decreasing at an increasing rate. This is because the numbers are getting closer to zero.” It is not the average rate of change that is decreasing, but rather the function values (or voltages) are decreasing. The values that the student correctly calculated for the average rate of change were negative and increasing since those numbers were “getting closer to zero.” This student is not using the values of the average rates of change to infer the characteristics of the function (decreasing at an increasing rate), but rather the student incorrectly concludes that it is the average rate of change itself that is decreasing at an increasing rate. This error points to the difficulty of simultaneously attending to changes in the function values and changes in the average rate of change.

DISCUSSION AND CONCLUSIONS

The results of this study provide some evidence that the model development sequence had a positive impact on the students’ understanding of average rate of change, as measured by the statistically significant overall gain on the “Rate of Change Concept Inventory.” The gains on the graphical items may be due to the model exploration tasks that focused on the coordination between representational systems. This coordination included shifting between position and velocity graphs, thus distinguishing between the function’s graph and the graph of its rate of change, and shifting between numerical and graphical data, thus linking the value of the average rate of change with the graph of the function. Overall, the majority of students were able to give meaningful interpretations of data and descriptions of change in contexts. At the end of the study, a small number of students still had difficulty in distinguishing between changes in the function values and changes in the average rate of change. The difficulty in expressing this distinction suggests the need for further research on the development of students’ language for describing changing phenomena.

AN INVESTIGATION OF MATHEMATICAL MODELLING IN THE SWEDISH NATIONAL COURSE TESTS IN MATHEMATICS

Peter Frejd

Department of Mathematics, Linköping University

Mathematical modelling is one competence assessed in the Swedish national course tests in mathematics (NCT) in upper secondary school. This paper presents, with empirical data from the NCT, a content analysis about what aspects of mathematical modelling are assessed and how it is assessed. The main conclusion is that only fragments (intra-mathematical aspects) of the modelling process are being assessed.

INTRODUCTION

Supported by curricula that stress the use of ‘real world problems’ in mathematics teaching, researchers in the field of mathematical modelling and applications in mathematics education have argued for more mathematical modelling activities into mathematics classrooms. However, the presence of modelling activities in day-to-day teaching is still limited at many places (Blum, Galbraith, Henn & Niss, 2007). The present situation in Sweden is quite similar, where the role of mathematical modelling in teaching and learning mathematics has been made more and more explicit in official curriculum guidelines for upper secondary school since 1965 (Ärlebäck, 2009). However, Frejd and Ärlebäck (in press) found that only 23% of the upper secondary students from a sample across Sweden (n=381) stated that they had used or heard about mathematical models or modelling in their education. In addition, the meaning of the notion mathematical modelling is only described in implicit terms in the curriculum, which opens up for various interpretations of the notion and how it should be implemented into school activities (Ärlebäck, 2009). A possible way to make modelling become a more wide spread activity in the classroom is to use more modelling activity in assessment tasks, according to Niss’ (1993) premise: “What is not assessed in education becomes invisible or unimportant” (p. 27). One activity assessing mathematical modelling for all students in Swedish upper secondary school is the national course tests in mathematics (NCT).

The aim of this paper is to investigate *what* is assessed in the national course tests about mathematical modelling and *how* is it assessed. It also investigates what interpretations of the notion of mathematical modelling have been done by its authors of the NCT and what reasons they provide for those interpretations.

THE ‘MODELLING CYCLE’

The notion of mathematical modelling is not unambiguously defined and is depending on the theoretical perspective adopted (Frejd, 2010). The theoretical

perspective used in this paper refers to a conception of mathematical modelling known as the ‘modelling cycle’. The ‘modelling cycle’ is a general mathematical modelling process (Kaiser, Blomhøj, & Sriraman, 2006) described in different ways depending on the research aim (Borromeo Ferri, 2006). One such cyclic process is described in terms of six phases and transitions between these, see for example Borromeo Ferri (2006). The starting point of the modelling process is called the *real situation (RS)*, which might be a description of the problem in everyday knowledge in the domain of an ‘extra-mathematical world’ or ‘real world’. A *mental representation (ME)* of the situation is made to understand the task. Then the information from the mental representation is idealized, filtered and simplified/structured to get a *real model (RM)*, which might be an external representation of the situation. This real model is then mathematized into a *mathematical model (MM)* in the domain of a ‘mathematical world’. Finally the modeller or the modellers work mathematically with the mathematical model to get solutions, *mathematical results (MR)*, which are interpreted in terms of *real results (RR)* and validated in the ‘extra-mathematical world’. The validation may show that the real result is not satisfactory and that other aspects have to be taken into consideration; the modeller or the modellers then have to do the process over again and make another lap in the cycle. In educational research literature one can find researchers both in favour of as well as critical to this cyclic perspective on modelling (cf. Jablonka & Gellert, 2007; Ärlebäck, 2009; Frejd, 2010). In this study the general modelling process was used, because the construction of national course tests in mathematics (NCT) is based on an interpretation of the curriculum guidelines by Palm, Bergqvist, Eriksson, Hellström and Häggström (2004), drawing such a view on modelling.

The modelling cycle and the National Course Tests (NCT)

Palm et al. (2004) have done an analysis and an interpretation of the present national curriculum guidelines, for upper secondary school in Sweden, as a basis for the construction of the NCT in mathematics courses B-D [1]. They state that “[...] this interpretation is one of many possible interpretations of the official curriculum guidelines” (Palm et al., 2004, p. 1, my translation). The result of their interpretation is described in terms of six mathematical competences (problem solving, algorithm, concept, modelling, reasoning, and communicating) similar to those adopted in PISA, TIMSS2003, NCTM (USA) and KOM (Denmark) (Palm et al., 2004). According to Palm et al. (2004) the modelling competence is needed to solve ‘real world’ problems. Some situations may be familiar to the students and the modelling process is then a routine procedure related to the algorithm competence. Other situations may be new to the students and demands a “*genuine modelling process*” (Palm et al., 2004, p. 18), related to the problem solving competence (no discussions are made if the modelling competence has connections to reasoning-, concept- or communication-competences). The *genuine modelling process* is defined as the entire process displayed in Figure 1. The process is cyclic and similar to the

‘modelling cyclic’ involving two domains as described in the previous section and is interpreted from the ‘goals to aim for’ in the curriculum.

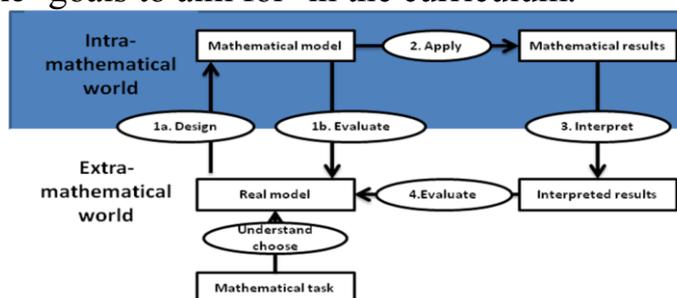

Figure 1. The structure of the modelling process from Palm et al. (2004, p.18, my translation).

The ‘goals to aim for’ in the curriculum declare that mathematics teaching should ensure the students to “develop their ability to design, fine-tune and use mathematical models, as well as critically assess the conditions, opportunities and limitations of different models” (Skolverket, 2000). How this statement has been turned into a cyclic process may not be obvious, but can be seen as one interpretation (cf. above). In relation to this interpretation, Palm et al. (2004) have identified five different types of modelling items that test; 1. The entire modelling process, 2. Parts (essential, 1a, 1b and 3; see Figure 1.), 3. Real life problems, 4. Open problems and 5. Items with too much or too little information.

The *genuine modelling process* is a holistic view about the modelling process. The competence to master this process similar to Blomhøj and Højgaard Jensen’s (2003) definition “[b]y mathematical modelling competence we mean being able to autonomously and insightfully carry through all aspects of a mathematical modelling process in a certain context” (p. 126). I have adopted Blomhøj and Højgaard Jensen’s definition, also used in Frejd and Ärlebäck (in press), and used it in the next section.

METHODOLOGY

To address the aim and based on the discussion in the previous section, the research questions are: Which transitions of the modelling process are presented and what are put aside in the national course tests? What types of problems are being used to assess modelling? How is it assessed in relation to the ‘official guidelines for assessment’ (a guideline for teachers on how to assess students’ solutions of items in the NCT)?

For examining course documents Robson (2002) suggests the method of content analysis. I have followed Robson’s guidelines for content analysis which are: start with the research question; decide on a sampling strategy; construct categories for the analysis which are to be mutually exclusive (categorized in one way), exhaustive (everything relevant should be categorized) and operational (explicit specifications); test the coding on samples of items and assess reliability.

The sample used is the last ten years of national tests in mathematics D (a total of 19 tests). It is the last mandatory course in upper secondary school (science programme) and it concludes “an in-depth knowledge of concepts and methods learned in earlier courses” (Skolverket, 2000); the main content is comprised by trigonometry, derivative and integrals, which may be used to assess mathematical modelling in the NCT. The strategy used in the analysis is to first identify items in the test that have an extra-mathematical context and then to scrutinize them.

The extra-mathematical domain is related to what is often called the ‘*real world*’ (Blum, Galbraith, Henn & Niss, 2007). To delimit the possibility to miss any modelling items with an extra-mathematical context an exclusion of texts related to pure mathematics has been done. Examples of excluded texts begin with “*Arrange the following numbers in increasing order*” and “*A triangle has the sides...*”, in contrast to “*water flows with a constant speed into an empty container*” and “*a tone sounds different if it is played on an organ or a violin*” (my translations).

In the definition adopted from Blomhøj and Højgaard Jensen (2003) the modelling competence is divided into sub-competencies (describing a more atomistic view of the process) to create exhaustive categories to answer the research questions. To capture significant aspects about the transitions in the modelling process, 11 *modelling categories* were developed. The categories or guiding questions used in the analysis, see the Appendix, were developed from: I) the curriculum guidelines (develop their ability to design, fine-tune etc.); II) Palm et al. (2004) (the five identified items, etc.); III) a research tool from Hains, Crouch and Davis (2000) designed to measure students’ ability in sub-competencies, IV) Other research literature discussing modelling competencies such as Mass (2006).

One reason for the choice of the material (I-IV) is that both the curriculum guidelines and the interpretation by Palm et al. (2004) are the base for the construction of modelling items in the NCT. Another reason is that the research tool (a multiple choice test) from Hains, Crouch and Davis (2000) has been used in several research studies (for details see Frejd and Ärlebäck, in press) and is measuring sub-competencies. The research literature focusing on modelling competencies was a help to strengthen and fortify the 11 modelling categories.

The process of linking together the material (I-IV) and to get as mutually exclusive categories as possible was done based on the transitions between the *phases* such as real model to mathematical model. To illustrate the construction process of the categories I will use an example, starting with the transition from the real situation to the real model. I identified aspects from: I) Skolverket (2000), the student should develop their ability to interpret a problem situation; II) Palm et al. (2004), open problem and understand the problem; III) Hains, Crouch and Davis (2000) the sub-competence *to make simplifying assumptions concerning the real world problem*; and IV) Maass (2006) a competence “to make assumptions for the problem and

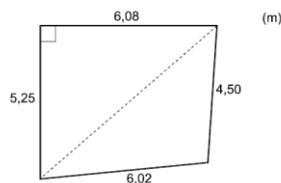

simplify the situation” (p. 116). These aspects turned into the modelling category/ guiding question nr 1 “Do students need to make simplifying assumptions about the problem situation in order to solve the problem?” To make the guiding questions more operational by the use of explicit specifications the example, *How long time does it take to evacuate your school?*, is discussed for each category (see Appendix).

To answer what types of problems being used the following questions were asked to each item: From where in the modelling process is the item originating, i.e. the starting point of investigation? What type of model do the students need to use? Is it a ‘realistic question’, i.e. is it stated in the text from where the data arise, such as real places (names of cities, countries etc), time (year, date) and is it possible to find similar data (e.g. on the web)?

To analyse the last research question, what do the ‘official guidelines for assessment’ outline (emphasize) in order to assess the item, have I developed *assessments categories*. These categories are based on frequently used words in the official guidelines for assessment and they are *motivation* (explanations, insight etc), *solution strategy* (general investigation, a general approved solution etc), *result* (correct answer, approved determination of something, approved solution with a specified answer etc), *to set up a mathematical expression* (to set up a equation, model etc) and *math language* (students use of math symbols, conventions etc).

I have analysed all 315 tasks (items) in the 19 national course tests (D-course) from the years 2000-2009. To illustrate the method for analysing I will present two examples (see Figure 2) from the test in spring 2005. First some information about the NCT (D-course) is provided. The NCT (D-course) is divided in two parts and the limitation of time is four hours. Part one is without access to calculators and part two with access to a calculator. Part two includes an item of *performance assessment* (i.e. an essay answer task that invites students to write a more extensive solution in some paragraphs).

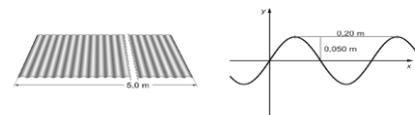

12. Daniel och Linda tittar på en lägenhet. Enligt uppgift är vardagsrummet $31,2 \text{ m}^2$. De vill kontrollera om detta stämmer och mäter väggarna och ritat en skiss över rummet. De vet att ett hörn i rummet är rätvinkligt. Så här ser deras skiss ut.

Vilken area har vardagsrummet enligt Daniels och Lindas skiss?

(2/2)

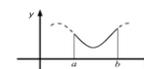

15. En korrigerad plåt tillverkas genom att en plan plåt veckas. Sedd från sidan har den korrigerande plåten på bilden formen av en sinuskurva med perioden $0,20 \text{ m}$ och amplituden $0,050 \text{ m}$.

- a) Bestäm en formel för "plåtkurvans" på formen $f(x) = A \sin kx$ (0/1)

Det finns en formel för beräkning av kurvylängd. Enligt denna gäller att längden s av en kurva $y = f(x)$ från $x = a$ till $x = b$ kan beräknas som:

$$s = \int_a^b \sqrt{1 + (f'(x))^2} dx$$

- b) Hur lång *plan* plåt ska man utgå ifrån för att den korrigerade plåtens längd ska bli $5,0 \text{ m}$? (0/3,00)

Figure 2. Two tasks (items) from the NCT (D-course) spring 2005 retrieved from: <http://www8.umu.se/edmeas/np/>.

The item to the left in Figure 2 is about Daniel and Linda who want to evaluate if the size of a living room in a flat is correct. The outset for investigation may appear to be the *real situation*, but the focus is on *the real model* which is given (a sketch). It may

also look realistic with a reasonable size of a living room, but it is not described where it is and it is not described how the angle is measured. The modelling categories used are nr 4, 5, 8 and 9 (see Appendix), because the students are supposed to assign the diagonal as a variable, set up a trigonometry model, calculate a result and compare to $31,2 \text{ m}^2$. No assumptions, no clarifications etc. are needed (i.e. category 1 and 2). The guidelines for assessment and marking emphasize the assessment category result (calculations of diagonal +1point, calculation of any angle +1p, approved solution +1p, approved answer ($29,4 \text{ m}^2$) +1p marked [*result, result, solution strategy, result*]). The aim of the right item in Figure 2 is to decide a formula for a “platecurve” on $f(x)=Asinkx$ and to decide the length of a flat plate needed to create a 5 m long “platecurve”. The starting point of investigation is both the real model and the mathematical model. It seems not to be realistic: why do you want to have the shape of the curve in $Asinkx$? Why a curve in the first place? And in the second question a plater never makes a 5 m wide plate as it would be impossible to work with. The modelling categories used are nr 4, 6 and 8, because the students are expected to assign a variable in the integration (let x go from 0 to z), fine tune the model (search for A and k) and calculate a result (7,3 m). However, no formulations of any new models are needed, only to use the given ones. The mathematical models used here are the trigonometry model and the integration model (which includes differentiation). The guidelines for assessment emphasize to set up a math expression and to find a result. For assessing reliability of the coding and the additional questions, Holsti’s method (Holsti, 1969) was used for two independent coders, with a satisfactory result ($0.89 > 0.8$).

RESULTS

Extra-mathematical contexts were found in 55 items (four items in part one of the test and 51 items in part two including five performance assessments). The starting point of the modelling process in the scrutinized items was the mathematical model (in 54% of the items), the real model (29%), both the real model and the mathematical model (15%) and both the mathematical model and the mathematical result (2%). The frequency of investigated modelling categories from the content analysis and the frequency of number of modelling categories per item are displayed in Figure 3.

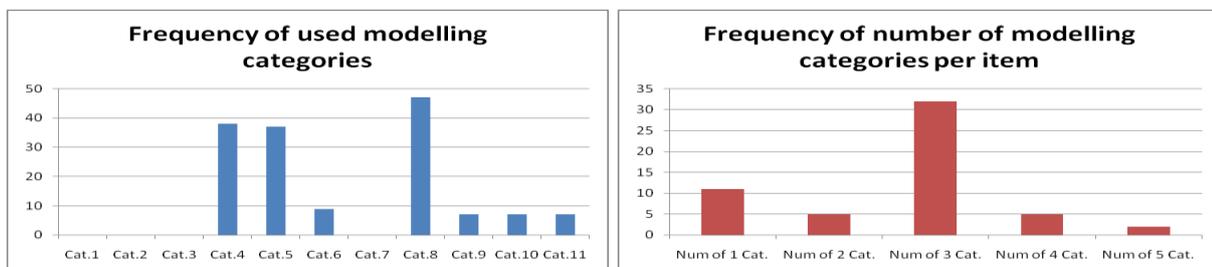

Figure 3. Frequency of used modelling categories and frequency of number of modelling categories per item

The left diagram in Figure 3 shows that the modelling categories 8 (calculate a result), 4 (assigning variables) and 5 (formulate a mathematical statement) are the most frequently appearing categories in the coding. Categories 6 (alter the mathematical model), 9 (relate the solution to the real world), 10 (interpret a given model) and 11 (critically assess the conditions) are together used in less than 20% of the items. Notable is that categories 1 (simplifying assumptions), 2 (clarify), 3 (simulations) and 7 (select) were not visible in the data. The right diagram in Figure 3 show that three modelling categories used per item are most common.

The results of the content analysis referring to the assessment guidelines are illustrated in Figure 4 below.

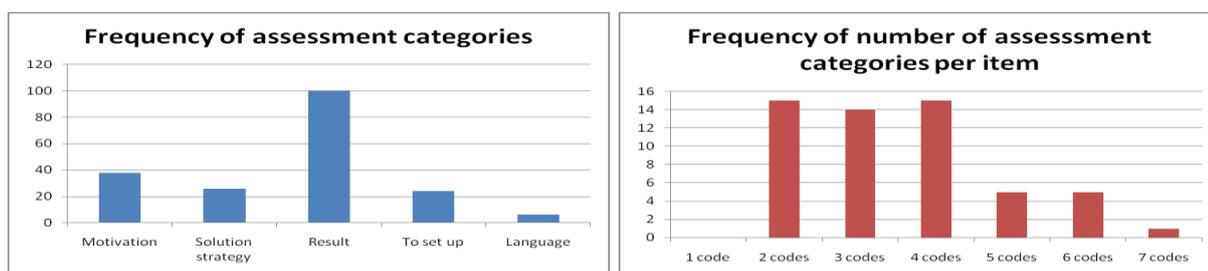

Figure 4. Frequency of assessment codes and Frequency of number of assessment codes per item.

The left diagram in Figure 4 shows that the *result* (correct answer, correct derived function etc.) is most frequently used in the assessment guidelines: more than every second assessment code is referring to the result (100 codes out of a total of 193). The right diagram in Figure 4 shows that two codes to four codes are the most frequently used number of codes to code an item in the assessment guidelines and five codes to seven codes are found in 20% of the items analysed.

The different types of models that the students were supposed to use were based on trigonometry (45%), integration (16%), polynomial functions (15%), exponential functions (11%), differential equations (7%), and a mix of these models (5% of the total number of items analysed). The items were realistic or close to realistic in 29% of the extra-mathematical items. The official assessment guidelines to the NCT also provide a list of items for every test referring to Skolverkets' (2000) statement that students should develop their ability to design, fine-tune and use mathematical models etc. The lists include in total 95 items (two tests did not have a list) but only 27 of those items had an extra-mathematical content according to my analysis.

CONCLUSION AND IMPLICATIONS

The designed research tool has been useful to pinpoint exactly what parts of the modelling process the NCT (D-course) focuses on and what has been left out. The primary aspects being assessed concerning the modelling process relate to the intra-mathematical world, such as to use an already existing model to calculate a result or assign variables to formulate a mathematical statement to calculate a result. Aspects

left out or occurring sparsely are related to extra-mathematical parts (the real situation and validation), such as to do simplifying assumptions about the problem, to clarify what facts are most important, critically assess conditions, and interpret the result and relate to the real situation.

From a holistic view of modelling the conclusion is that there have not been any modelling items in the NCT (D-course) during the last decade, because not all aspects of the modelling process were represented in a single item. The models that the students were supposed to use were oriented towards trigonometry (45% of the models), which is not odd as new content in the D-course is trigonometry. Most of the items were not based on realistic data (71% of the investigated items). However, in this study the result is based on a web search for possible comparative data.

The outcome that *result* (correct answer, correct derived function etc) is most frequently used in the guidelines for assessment is not surprising, because one of the goals of the NCT is reliable assessment, meaning that it should be equivalently assessed all over Sweden. According to Niss (1993), standardized schemes that are not time consuming are traditional requirements for treating large populations of students, and in this case the focus on *result* may be seen as a fast marking scheme (correct or incorrect).

One may question the impact of Palm's et al. (2004) interpretation of the curriculum on the construction of the NCT. Most of the listed modelling items in the assessment guidelines do not refer to extra-mathematical content and no items refer to the entire modelling process. Neither were open problems (open for different interpretations, assumptions and solutions) nor items with too much or too little information found. However, items questioning parts of the modelling process were found and maybe a further investigation of NCT from other mathematics courses will give another result.

In Frejd and Ärlebäck (in press) most of the students expressed that they had not worked with problems similar to Hains, Crouch and Davis (2000) problems before. This study can conclude that the students have not been assessed on such problems in the NCT (D-course) either. The discrepancies between the *sub-competencies* found in Frejd and Ärlebäck (in press) can therefore not be accounted for by the NCT. Many of the *sub-competencies* are invisible in the NCT such as categories 1 (simplifying assumptions), 2 (clarify), 3 (simulations) and 7 (select) and there is no difference in frequency between categories 4 (assigning variables is used in 69% of the items) and 5 (formulate a mathematical statement is used in 67% of the items).

Finally, some researchers argue that if only a limited set of aspects of mathematics is assessed it may create a disordered view of what mathematics really is (Niss, 1993). The result from this study that only fragments (intra-mathematical aspects) of the modelling process are assessed suggests further research. Questions investigating the issue may be: What conceptions do teachers in upper secondary school express about

Working Group 6

the notion of mathematical modelling? To what extent do they describe mathematical modelling activities as part of mathematics/ mathematics education?

APPENDIX

Guiding questions/ Modelling categories	How long time does it take to evacuate your school?
1. Do students need to make simplifying assumptions about the problem situation in order to solve the problem? [RS to RM]	Could be to do assumptions about number of students, locations of classrooms, number emergency exits, etc
2. Based on the real situation do students need to clarify what is to be accomplished by the mathematical model? (Is it unclear from the outset what kind of facts are most relevant to formulate a mathematical model and what relations are needed to formulate the mathematical model?) [RS to RM/MM]	Could be to clarify what of the following facts are important to include in the mathematical model: the width of emergency exits, number of students in a classroom or the velocity of some students walking in a line, etc? What are the relations between the facts?
3. Do students need to focus on exact arrangements that can provide a basis for the intended simulation? (Is the student supposed to do or evaluate some simulation method to investigate a problem?) [RM to MM]	How can we set up a simulation? Has a simulation of the problem been done, and if so could another method give a better result?
4. Are students expected to assign variables, parameters, or constants to solve the problem? [RM to MM]	Could be set x as length, v as angle, y' as velocity, n as number of students etc (But not just to use a given model for instance to set $t=0$ for evaluate reaction time)
5. Do students need to set up a mathematically formulated statement (a mathematical model) describing the problem addressed? [RM to MM]	Could be set up a new model or a function ($t= t_0+x y'+...$) and maybe included to integrate or differentiate some function. (But, not just to use a given model)
6. Do students need to adapt the mathematical model in order to improve (fine-tune) the result? [MM to RM]	A model is created (or given) for instance $t= t_0+x y'+..$ and t_0 is supposed to be decided to fit the given data.
7. Do students need to select one mathematical model out of several possibilities and motivate such a choice (the one that fits the data best)? [RM to MM]	Based on the assumptions made, several types of mathematical models are possible. (more than one model is given in the official guidelines for assessment)
8. Do students need to use the model to calculate a mathematical result? [MM to MR]	Example: Calculate the evacuation time for your school building? Could be $t=11,3$ min.
9. Do students need to interpret and relate the mathematical solution to the (real world) context? (Is it explicitly given in the item text a value/ a statement that is possible to compare to mathematical solution?) [MR to RM]	It could be stated in the text that during the last 10 years of emergency drills the average evacuation time is 13, 4 min.
10. Are students asked explicitly to explain the meaning of a given mathematical model or a mathematical result? [MM/ MR to RM]	It could be stated in the text that a model is found for evacuation time $t=...$ could you explain what it means?
11. Do students need to critically assess the conditions, opportunities and limitations of the mathematical model? [MM to RM]	The mathematical model might be valid only between 8 am to 2 pm during weekdays under certain conditions, factors not discussed might be panic etc.

MODELLING PROBLEMS AND DIGITAL TOOLS IN GERMAN CENTRALISED EXAMINATIONS

Gilbert Greefrath

University of Münster, Germany

In Germany many centralised mathematics examinations consist of modelling tasks or nearly realistic tasks. A further aspect is added by the usage of digital tools, e. g. a computer algebra system, in examinations. In this article we discuss the simultaneous use of realistic tasks and digital tools in examinations. Some criteria for good examination tasks with modelling problems and the use of technology are presented.

INTRODUCTION

The use of digital tools (i. e. spread sheet, dynamic geometry environments, function plotter and computer algebra systems) in centralised examinations influences many aspects of mathematics education. For example it was found that students working with a computer algebra system (CAS) tended to give shorter written solutions than non-CAS students (Ball 2003). Especially the use of digital tools in centralised mathematics examinations showed effects on the content of teaching, teaching methods, types of tasks and other questions concerning mathematics education. It becomes obvious that the question about suitable centralised examinations with digital media and tools does not only refer to examinations, but also to the teaching preceding the examinations.

Other competencies that are relevant in mathematical education are not automatically connected with the use of digital media and tools (s. e. g. Maaß 2006). Tasks relying on the use of digital tools do, however, require and promote certain process-related competencies such as problem solving, interpreting data or modelling. Moreover, it is possible to give the students CAS-tasks which require them to choose between several possible solution strategies by themselves.

The introduction of CAS into examinations has the potential to provide more solution strategies for the students. It allows the student to move on from an examination where the examiner controls the solution strategy to one in which the student controls the solution strategy (Brown 2003a). Thus there is a potential shift in tasks away from the ones in which only algorithms are trained to more realistic ones in which the students are required to do more modelling. So in addition to possible technical difficulties we have to consider possible blockages during transitions in the modelling process (s. e. g. Galbraith & Stillman 2006). In particular centralised examination questions containing modelling problems and digital tools require special attention. Based on the potential use of digital tools in the modelling cycle and the German situation in upper secondary school examinations we

formulate some criteria for good examination tasks with modelling problems and the use of technology.

MODELLING AND DIGITAL TOOLS

Realistic mathematical modelling problems (cf. for example Blum et al.) can be well-established in many classrooms, when we have adequate examination questions to not only test the modelling competencies but also the use of the necessary digital tools.

The solution of modelling problems using a digital tool requires that two important translation processes take place. Firstly, the real problem (cf. Blum & Leiß 2006) of the task has to be understood and translated into mathematical language. The digital tool, e. g. the computer algebra system calculator, though, cannot be used before the mathematical expressions have been translated into the language used by the digital tool. The computer results then have to be translated back into mathematical expressions. Finally the task can be solved by relating the mathematical results to the given real situation.

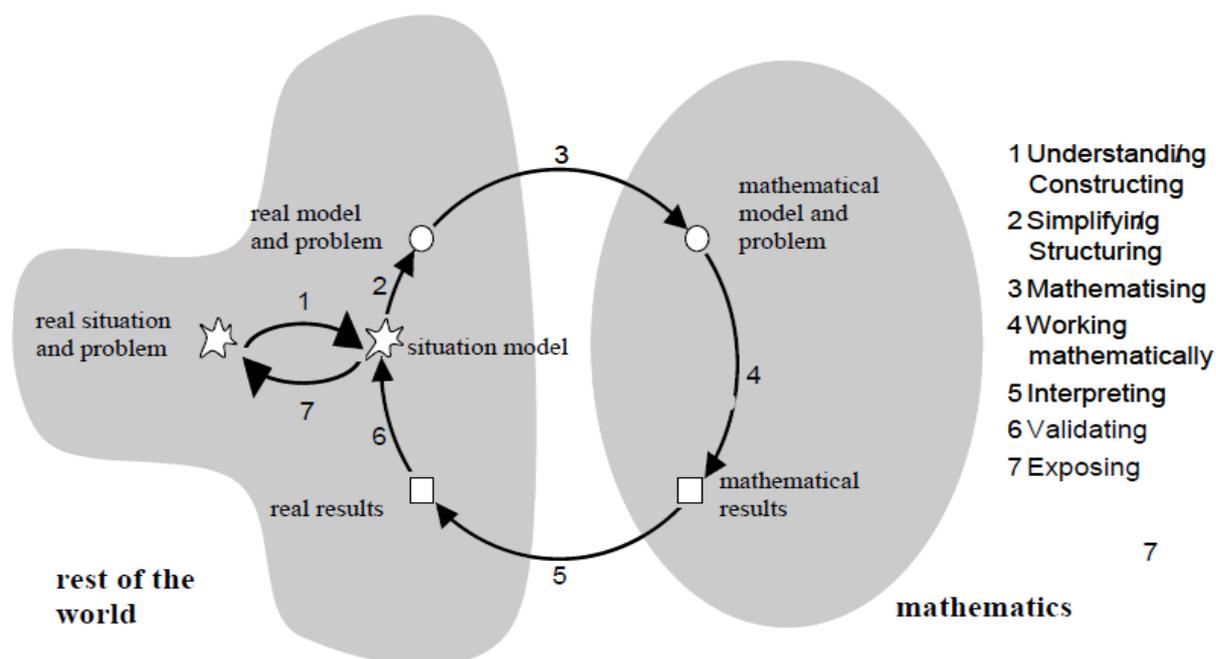

Figure 1. Modelling cycle (Blum & Leiß 2006)

As an illustration of the potential use of digital tools in the modelling process we integrate the use of digital tools as the technology world in a simplified modelling cycle. Compared with the modelling cycle of Blum & Leiß (figure 1), we use a less detailed characterisation of the rest of the world, because we focus on the other part of the cycle. The *situation* in our model (cf. figure 2) describes the *real situation* and the *real model* in Modelling cycle of Blum & Leiß. Here the *technology world* has been added to the mathematical world (mathematics) and real world (rest of the

world) in the common models of modelling (e.g. Blum & Leiß 2006, Galbraith & Stillman 2006).

The separation in three different worlds shown in figure 2 is artificial. For example the development of a mathematical model depends on the mathematical knowledge on the one hand and is on the other hand affected by the possibilities given in the technology world. Using technology provides additional possibilities to work with certain mathematical models, which would not be used and lead to a solution if technology was not available (Siller & Greefrath 2010, Geiger 2011).

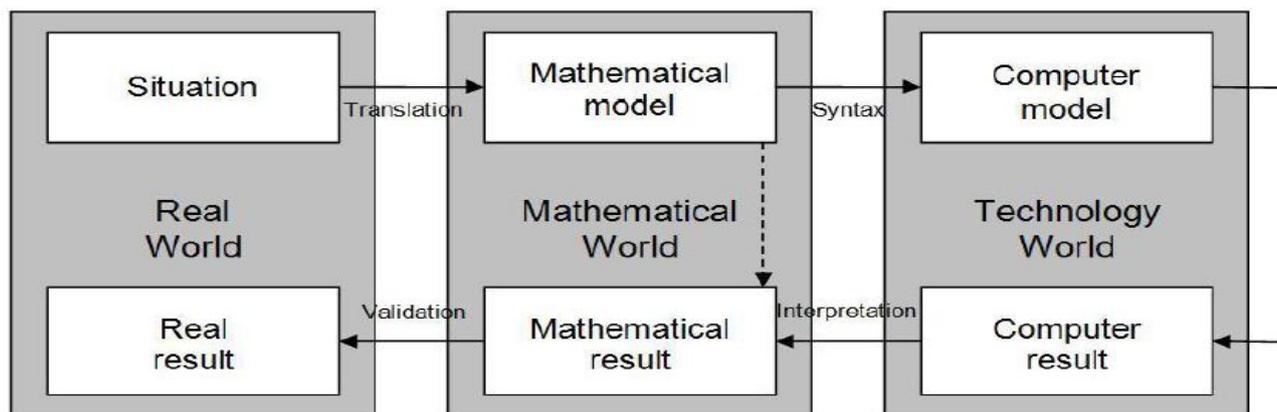

Figure 2. Modelling cycle concerning technology (Greefrath & Mühlenfeld 2007, cf. also Savelsbergh et al. 2008)

When creating examination questions many aspects should be considered. As a basic principle (following Winter), applications in education should only be used in sense-making real situations or if they bring advantages in understanding the problem (Henn 2007). But due to the complexity factor examination tasks containing a whole modelling process are not possible in most cases. Consequently we have to construct examination tasks with parts of the modelling cycle.

Examination questions can be categorized according to the potential use of digital tools when solving them. *Firstly*, the question can be deliberately structured such that digital tools cannot or may not be used to solve the problem. *Secondly*, questions are thinkable where digital tools can be used, but have no potential to contribute to the solution. *Thirdly*, there are questions where digital tools could contribute to the solution of the examination question but their use is not required and *fourthly* there are questions which cannot be solved without the use of digital tools (Brown 2003b).

Looking at the German situation mostly questions of the types two and three are used in examinations with digital tools (cf. Weigand & Bichler). In the following we illustrate the German situation of examination questions with modelling problems and use of digital tools. One aspect concerns problems resulting from the real situation described in the task; a second aspect concerns the use of digital media, i.e. the computer model (cf. figure 2).

THE GERMAN SITUATION

In Germany there are specific practical regulations for the usage of digital tools in upper secondary school examinations. Additionally, there are different regulations in all of the 16 federal states in Germany. Several federal states started with centralized examinations in the last years and permit the use of computer algebra systems. For example in the federal state of North Rhine-Westphalia (NRW) two calculator-specific versions of the mathematics examination have been employed since 2007. One group of examination questions is for standard or graphing calculators (non-CAS group) and another group for computer algebra systems (CAS-group). The mathematical content of the examination questions is (nearly) identical for both groups, but some interesting aspects are different. There are only minimal differences between these two groups of tasks, but a positive trend can be seen in the CAS-group (cf. Pallack 2008). Tasks with CAS are more open-structured. For example the described real model of a situation has no given equation of the function or no given coordinate system. Hence the tasks are a bit more realistic and the students have to take more steps (e.g. simplifying, mathematizing, cf. Figure 1) in the modelling cycle.

Another aspect when using technology in examinations is the diversity in the computer models (cf. figure 2) used. For example with a CAS-calculator we can determine a questioned polynomial of degree 3 with a linear equation system or a statistic regression. In addition the solution could be calculated numerically or algebraically. This is of course a good starting point for an interesting discussion in a mathematics lesson, but the evaluation in centralised examinations becomes more difficult. So the diversity of possible computer models complicates the marking in centralised examinations.

An analysis of current examinations in the NRW part of Germany shows that there are characteristic types of tasks depending on the treated mathematical domain (Greefrath, Siller & Weitendorf).

- In stochastics the tasks for examinations are application-oriented. The stochastic models used, for example, the binomial distribution, are well known. So the applications are not really modelling problems in the sense of ISTRON (Blum et al.), but standard tasks. The students in both groups (CAS and non-CAS) have nearly or even exactly the same examination questions, so the use of CAS does not change tests in stochastics. The main problem in stochastics is – apart from the CAS usage – the missing connection between reality and mathematical models. The fit of the stochastic model is one of the most important questions. But most of the final secondary-school examinations in Germany are lacking this part.
- Tasks in analytic geometry usually are unrealistic. A typical question, for example, is situated in the context of an excessive simplified tower. The question

is, if the temperature sensor in a special point is in the shadow of the tower or not. No one will think that this is a meaningful use of mathematics. There is no improvement imaginable due to the use of CAS. Examination tasks should show sense-making use of Mathematics. So tasks in this mathematical domain can only be improved by making them inner-mathematical with or without CAS. As a consequence, we have no modelling problems in this part of an examination, just a relevant use of Mathematics (in the sense of Winter, cf. Henn 2007, BE 2).

- The most common mathematical field for modelling problems in examinations is analysis. Here, tasks should include real-world problems. The changes due to the use of CAS show the right tendency, but actual tasks contain too many standard parts. For example in 2008 there was a problem on a model for concentration of a certain medicine in blood. The main part of the task was to calculate interesting points of the graph (e.g. maximum and inflexion point). The blood concentration context was not really necessary to solve the task. Considering all analysis tasks in the upper secondary school examinations for CAS in NRW the proportion of parts that really need a CAS (the forth role of digital tools in examination questions) and not only a graphing calculator is less than 5 per cent. Obviously there is high potential for improvements.

CRITERIA FOR EXAMINATION TASKS

On the Basis of the experiences in Germany some criteria for good examination tasks with modelling problems and use of technology can be pronounced. The first is the sense-making use of Mathematics. If necessary – like in analytic geometry – it is better to have relevant use of Mathematics rather than simple word problems with unrealistic contexts. The second is a good choice of interesting and relevant real world problems to treat an essential part of the modelling cycle in exams. The third is an essential use of CAS in tasks especially for CAS. That means the examination question for CAS should not be solvable without use of digital tools and the students have a real choice between different computer models (cf. the modelling cycle concerning technology above).

But not all parts of examinations need to require a digital tool. For the examination of mathematical competencies, which were acquired with digital tools, it is not necessarily needed, that the digital tools are present in the test situation (Greefrath, Leuders & Pallack, 2008).

CLOSING REMARKS

Centralised examinations with digital media and tools have to be prepared carefully. The use of digital tools can be discussed for e.g. from a socio-political or didactic point of view. Thus it is necessary to say why it is feasible to use digital media and tools in examinations, which can be done at different levels. On the other hand, the use of digital media and tools in class can be promoted by their use in examinations.

When we use digital tools in centralised examinations, certain mathematical operations that have so far been performed by the students themselves, such as differentiating or solving simple equations or systems of equations, will be performed by the digital tool. It is thus necessary to describe special competences for the use of digital tools (of CAS in particular) and to publish these descriptions before the examinations take place. It is necessary to develop clear guidelines for the use of calculators in examinations – in particular for the centralised ones. Especially, it has to be examined whether the examinations can be solved in a comparable way with all permitted digital tools, the comparability referring both to the time-frame and to the required competences.

Many examples show that technology can be helpful at any step of the modelling cycle (Greefrath, Siller & Weitendorf). Therefore the use of technology does not only create an important appendix to the modelling cycle (see Figure 2), but influences each part of the cycle (cf. Geiger 2011). So the technology world is relating to the real world and mathematical world. This multiple influence of technology in solving modelling problems can also be found and integrated in examination questions. The role of technology in modelling activities is as important in tests as in process-related educational situations.

³Department of Educational Psychology, University of Koblenz-Landau, Germany

The aim of this study was to analyze the structure of the problem solving process and the use of different external representations while working on complex story problems in primary school. 17 2nd grade students and ten 4th grade students participated in our study. Different influence factors on the process of solving a story problem were measured via questionnaires. In a maximum of 40 minutes, the students had to work on five complex story problems individually. They were allowed to use different auxiliary material. If the students couldn't continue on their own, they received help from the researcher. The students were videotaped individually and interviewed right after every story problem. The problem solving processes was analyzed according to a newly developed system of categories for this study. Our findings show that the ability groups and the grade levels differed in terms of representations they used, as well as in terms of the time they needed to solve the problems. Also, the total word problem score differed between grade levels as well as between ability groups.

Keywords: complex story problems, problem solving process, system of categories, external representations

THEORETICAL BACKGROUND

The term “complex story problems” specifies a group of problems, that are different from “regular story problems” (Rasch, 2001). Unlike regular story problems, these complex story problems are based on very complex mathematical structures, and cannot be solved by arithmetic operation models, with which students are usually familiar (Rasch, 2001). In order to solve these specific tasks, students have to restructure their prior knowledge (Winter, 1992). The positive effects of complex story problems on learning have already been shown by former research. For instance, Rasch (2001) reported that the use of these tasks can improve students' “problem solving competences” (Klieme, 2005) in primary school classes. Yet, there are very few studies on the use of complex story problems (Verschaffel, 2000). This group of tasks also plays a minor role in mathematical didactics. To convince didacts of the advantages of complex story problems and to get teachers to implement these tasks in their lessons, further research on the use of complex story problems in

primary schools is needed (Verschaffel, 2000). Our study makes a contribution to this goal.

The problem solving process can be observed from different perspectives. The field of mathematical didactics focuses on the modeling process (Verschaffel, 2000), while cognitive psychology has a special interest in the problem solving process (Franke, 2003). Every perspective has its pros and cons (Verschaffel, 2000). Moreover, solving story problems is a complex process. In order to be able to research this process, it is important to combine these different scientific perspectives (Franke, 2003). The presented study is working towards this aim.

The theoretical framework underlying our study is a combination of two models concerning the course of students' problem solving processes with regard to “story problems” (Verschaffel, 2000). The first model (Reusser, 1993) is called “Student-Problem-Solver” (SPS), which was developed for primary school. According to the SPS model, the story problem is recoded and gradually transformed by the student in stages (Textbase, Episodic Situation Model, Mathematical Problem Model and Numerical Equation) into a solution. The second model is the “cognitive-metacognitive model of mathematical problem solving” (Montague & Applegate, 1993). This model identifies seven cognitive processes (read, paraphrase, visualize, hypothesize, estimate, compute, check) as essential for effective and efficient problem solving. According to Montague and Applegate (1993), a student must be capable of selecting or developing the adequate cognitive processes with regard to the specific requirements and characteristics of the story problem. Both models focus on different aspects of the problem solving process on story problems and complement one another. By combining these two models we developed a new system of categories for analyzing the problem solving processes. This system (for details, see Groß, Hohn, Telli, Rasch & Schnotz, 2010) consists of 9 categories and 30 facets, which cover the whole problem solving process. The system can be used to analyze the problem solving processes and the use of different external representations while working on complex story problems in primary school mathematics.

The development of “problem solving competences” (Klieme, 2005) is an important aspect of the curriculum for mathematics (NCTM, 1989). The TIMSS-study indicated that German students show a great deficiency regarding mathematical problem solving competences (Baumert et al., 1997). Now, research is needed to find out where these deficits come from and what can be done to solve this matter. The present study is situated in the field of “problem solving” and makes a contribution to the goal mentioned above.

A representation is a mental or physical occasion, which stands for something else (Schnotz, Baadte, Müller & Rasch, 2010). Students were allowed to use different auxiliary material to solve the complex story problems (sheet of paper, colorful

pencils, 1-unit cubes, 10-unit rods). According to Schnotz et al. (2010) these materials are external representations. Representations are very important elements for the problem solving process in mathematical education (Goldin, 2007). The positive effects of representations on learning in the problem solving process in primary schools have already been shown in various studies (Stern, 2005). Yet, studies on the configuration of the problem solving process and the use of different external representations on complex story problems are scarce (Goldin, 2007). That is especially unfavorable, because the positive effects of complex story problems on learners' problem solving competences in primary school classes have already been shown in studies (e.g. Rasch, 2001). By closing this gap in research, an effort is made to help students in their struggles with problem solving in mathematics at school (Baumert et al., 1997). In this study we are trying to reach this goal.

RESEARCH QUESTIONS

The underlying study is supposed to analyze the structure of the problem solving processes of primary school students when working on complex story problems in general, as well as in terms of integrating external representations into the problem solving process. The aim of this study is to find out if there are specific differences in the research question 1), 2), 3) and 4) concerning the two grade levels and ability groups:

- 1) Which external representations are applied in the problem solving process regarding complex story problems?
- 2) What are the differences in the persistence and total word problem score when working on complex story problems?
- 3) How is the problem solving process organized concerning complex story problems?
- 4) Which stages of the problem solving process are connected to which external representations with regard to complex story problems?

METHODS

Participants

A total number of 27 students from a public primary school participated in our study, which was conducted in April 2010. 17 students were from 2nd grade; nine of them were girls, and eight of them were boys. The other ten students attended the 4th grade; six of them were girls, and four of them were boys.

Instruments and Procedures

Firstly, students provided information on gender and age. Secondly, the influence factor cognitive ability on the processes of solving a story problem (Renkl, A. & Stern, E., 1994) was explored via a well-established questionnaire. Verbal as well as

Working Group 6

visual spatial intelligence was measured with scales in this test (Kognitiver Fähigkeitstest [KFT], Heller & Geisler, 1983; Heller, Schön-Gaedike & Weinläder, 1976). Different test versions were applied with regard to the two different grade levels. Moreover, scales from the Project for the Analysis of Learning and Achievement in Mathematics (Projekt zur Analyse der Leistungsentwicklung in Mathematik [PALMA], Pekrun, Götz, Zirngibl, v. Hofe & Blum, 2002) were used to assess students' mathematical self-efficacy as well as their mathematical self-concept. Afterwards students were asked to solve five complex word problems that were selected from a book that contains complex story problems (Rasch, 2008). They had been used in former studies (e.g. Rasch, 2001) in math classes in primary school. The problems were different from each other regarding the mathematical areas they were based on and the subject areas they dealt with. In our study, students were successively given the following five complex story problems:

- 28 Two bandits discover a hidden treasure, 2 bags of gold coins. They count the coins. In one bag there are 34 coins, in the other there are 52 coins. They want to share the prey fairly. How many coins do they have to take out of the fuller bag and put into the other bag, until the coins are equally distributed between the bags?
- 29 The devil said to a poor man: "If you pass the bridge, I will double your money, but you have to drop 8 coins into the water when you come back." When the man returned for the third time, he didn't have any pennies. How much money did he have at the beginning?
- 30 A snail in a 20-meter deep well wants to go up to the meadow. She always crawls up 5 meters during day time and glides 2 meter down when she is asleep. On what day does she reach the top of the well?
- 31 Strebblinde, Quicki and Murks want to buy ice cream. Every child has got money for two scoops of ice cream. The iceman offers 3 flavors of ice cream: chocolate, vanilla and raspberry. What dish of ice cream could Quickie buy? Find all different possibilities!
- 32 Mummy, Daddy and Murks take a steamboat. For children it is only half price. Altogether they pay €30. How much does a ticket cost for an adult and how much does it cost for a child?

In a maximum of 40 minutes, the students could individually solve these five tasks. The problems were read out by the researcher and then given to each child in written form. The complex story problems were arranged randomly with regard to a Latin Square Design to avoid sequence). First, students had to try solving the problems on their own. They were given different [auxiliary material](#) they were allowed to use at all times. If the students couldn't continue on their own, they received help from the researcher who used standardized questions. If a child still was not able to solve a problem, the researcher turned to the next task. The students were videotaped

individually during the solution process and interviewed with a “structured task-based interview” (Goldin, 2007) right after every task about the heuristics they used to solve the story problem.

Analysis

The participants were divided into two groups, according to their results in a German standardized cognitive abilities test (KFT). Depending on these test results, there was a group of higher (HC) and a group of lower maths competence (LC) in both grade levels. The groups were put together through median split. In the 2nd grade there were nine students in the LC group: four of them were girls and five of them were boys. Eight Students in the 2nd grade were in the HC group: five of them were girls and three of them were boys. In 4th grade there were five students in both ability groups. In the LC group there were four girls and one boy. In the HC group there were two girls and three boys.

The videos were analyzed by two raters. An evaluation of the inter-rater reliability (Wirtz & Caspar, 2002) was scheduled and afterwards the training of independent raters was organized. The problem solving processes will be analysed according to a system of categories (Groß, Hohn, Telli, Rasch & Schnotz, 2010) which was newly developed for this study.

RESULTS

External representations which are applied in the problem solving process

The results of our descriptive analysis show that the ability groups of both grade levels differ in terms of the representations that were used to solve the story problems.

The results of the 2nd grade are listed in Table 1. At this grade level only members of the HC groups used “fingers” and “logical pictures” as kinds of representation.

In both ability groups, “spoken language” was the kind of representation that was used most. Members of the HC group used this kind of representation 7.70 times on average, the LC group 8.00 times. The external representation “realistic pictures” was not used in any of the ability groups of 2nd grade.

The results of the 4th grade are listed in Table 2. At this grade level members of the LC Group used all kinds of external representation. Meanwhile, “working materials” and “fingers” as kinds of representation were not used at all by members of the HC group. The kind of representation “number, arithmetic” was used the most in both ability groups. The HC group used this kind of representation 8.40 times, the LC group 7.80 times on average.

Looking at each grade level on its own, there was no big difference between the two ability groups: If a kind of representation was used, members of both ability groups used it similarly on average.

Working Group 6

	HC-group 2nd grade		LC-group 2nd grade	
	M	SD	M	SD
spoken language	7.70	4.79	8.00	4.93
numbers, arithmetic	4.50	0.71	3.00	.00
words, sentences	2.50	.71	4.50	.71
working materials	4.00	.00	2.67	1.53
fingers	3.00	.00		
logical pictures	5.00	.00		
realistical pictures				

Table 1: Average number of occasions individual representations are used (2nd grade)

	HC-group 4th grade		LC-group 4th grade	
	M	SD	M	SD
spoken language	6.80	5.07	4.60	3.44
numbers, arithmetic	8.40	4.83	7.80	5.63
words, sentences	2.80	1.79	5.20	2.59
working materials			3.33	1.52
fingers			1.00	.00
logical pictures	3.00	1.41	3.50	3.54
realistical pictures	1.00	.00	1.00	.00

Table 2: Average number of occasions individual representations are used (4th grade)

The comparison of the two grade levels (Table 3) showed that students of the 4th grade use the external representation “realistic pictures” in contrast to students of the 2nd grade. All the other kinds of representation occurred in both grade levels.

There is no big difference in the total number of uses of representation when comparing the two grade levels. Only “numbers, arithmetic” was used more often in fourth grade (8.10) than in second (3.60).

	2nd grade		4th grade	
	M	SD	M	SD
spoken language	7.80	4.69	5.70	4.24
numbers, arithmetic	3.60	.89	8.10	4.95
words, sentences	3.50	1.29	4.00	2.45
working materials	3.00	1.41	3.33	1.53
fingers	3.00	.00	1.00	.00
logical pictures	5.00	.00	3.25	2.22
realistical pictures			1.00	.00

Table 3: Average number occasions individual representations are used (2nd and 4th grade)

Working Group 6

Differences in the persistence and total word problem score

Table 4 shows the differences in the persistence which was measured in seconds via time sampling and the total word problem score. The total word problem score is the probability of students to solve a word problem correctly – it is the mathematical average of correct solutions for all word problems.

On average, members of the HC group (2nd grade) needed less time to solve the story problems. That was not the case for the 4th grade students. At this grade level, the members of the LC-group needed less time for working on the story problems.

On comparison of the two grade levels, it becomes obvious that students of the 2nd grade need more time to solve the story problems than students of the 4th grade. On average, 2nd graders needed 105.85, 4th graders 69.86 seconds.

At both grade levels, students of the HC group achieved a higher total word score than students of the LC group. HC students of the 2nd grade reached a score of .24, HC students of the 4th grade a score of .36. The 2nd grade LC students only reached a total word score of .03 and 4th graders only scored .16.

Comparing the two grade levels, it becomes obvious that students of the 4th grade achieve a higher total word score (.26) than students of the 2nd grade (.15).

	HC-group 2nd grade		LC-group 2nd grade		HC-group 4th grade		LC-group 4th grade		2nd grade		4th grade	
	M	SD	M	SD	M	SD	M	SD	M	SD	M	SD
persistence	102.38	59.36	110.80	93.86	71.08	28.29	68.64	18.09	105.85	72.83	69.86	22.42
total word problem score	.24	.27	.03	.08	.36	.26	.16	.17	.15	.24	.26	.23

Table 4: Average persistence and total word problem score (2nd and 4th grade)5

OUTLOOK

The design and development of the system of categories has been completed. Using this system, the remaining research questions will be answered. At the moment, the observers are analyzing the video material of our study using the system of categories. Further results of the analysis will be presented later on.

APPLICATION AND THE IDENTITY OF MATHEMATICS

Kasper Bjerling Søby Jensen, IMFUFA, Roskilde University, Denmark

In the paper a conceptual framework for discussing the identity of mathematics as a school subject is constructed with particular emphasize on application of mathematics. The framework is used to analyze the identity of mathematics, as it appears on two different kinds of domains: the political system and the teachers. At the end it is discussed whether this framework gives us new insights into mathematics teaching. It is concluded that the framework can articulates important aspects.

INTRODUCTION

This paper presents a theoretical element of a larger research project on the *identity of mathematics* as a subject in the Danish general upper secondary school (the Gymnasium). The term *identity* is borrowed from the subject specific regulations. Every subject of the Gymnasium has its own regulation, starting with a paragraph named “identity”. An analysis of those paragraphs shows that an identity of a subject seems to consist of three aspects: 1) A general description of the objects studied in the subject, 2) specific descriptions of methods, theories, contents, etc. in the subject and 3) external justifications of the existence of the subject as an independent entity.

Those three aspects are used to compare different subjects, by highlighting their principal differences. They are also used to declare how the political system officially wants the subject to be identified. For many of the subjects, such identification may be uncontroversial. But in the case of mathematics, this is not so. The identity of mathematics as a discipline and especially as a school subject is in general disputed.

I define an *identity of mathematics* as a holistic view of what kinds of tasks, contents, knowledge, actions, etc. that can be recognized as belonging to the field of mathematics. It is my claim that an identity of mathematics as a school subject can be described as a vector in (at least) three dimensions: 1) A view on the role of theory, 2) a view on the role of application and 3) a view on the role of meta-issues. In short they can be named the *in-*, *with-* and *about dimension* (with inspiration from Jankvist 2008). A dimension can be described in several ways. For this purpose, a set of levels ordered by inclusion will be convenient.

Identities of a school subject are not well described animals, living in a well defined territory. It is blurred creatures living on qualitatively different domains and in different states. The domains can be the political system, the individual teacher, a textbook, a student, etc. The different kinds of states found on a domain depend on the characteristics of this.

A math teacher is an example of a domain. Here we can find an identity of mathematics as a school subject in different states, e.g. *intended identity*, *practiced*

identity and *principal identity*. While the first two have to do with teaching, the last one is the persons more general identification of mathematics as a discipline and academic field.

My overall research question(s) is: »*Which identities dominate the mathematics subject in the Danish gymnasium today and what consequences does it have for the possibilities of making general changes in the identity?*«. By this I want to grab the struggle between identities focusing narrowly on mathematics as a theoretical field versus identities allowing mathematics to be a tool for application outside its own world.

To answer this question, I am investigating four categories of domains: 1) The political system, 2) the textbook systems, 3) the math teachers and 4) the academic environment around the subject of mathematics in the Gymnasium. In this paper I will present some of the theoretical considerations about the *with*-dimension. I will follow this up, by giving some examples on the analysis of two of those four mentioned domains, the political system and the math teachers.

I should underline here, that the discussion about the identity of mathematics as a subject in the Danish Gymnasium is relevant, because of a larger reform that was fully implemented in 2008. The reform has moved the subject of mathematics toward a stronger role for application. This can be seen in two ways:

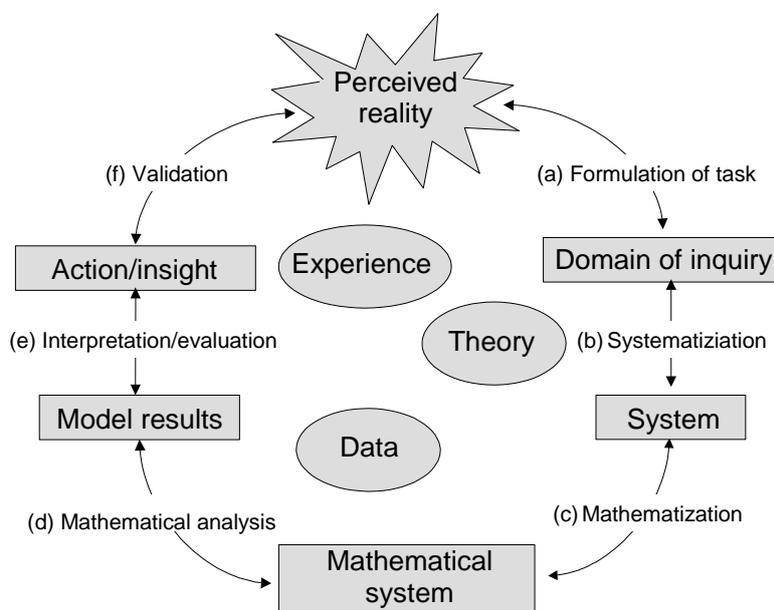

Firstly, the reform has emphasized cooperation between different subjects. This change forces mathematics to think in terms of application. This change has been discussed in several articles (e.g. K. B. Jensen (2010) and Andresen & Lindenskov (2008)). I will not go deeper into this in the paper. Secondly, there are a larger emphasize on modeling and application in the new regulations of mathematics as a single subject. It is this change that I will discuss here. What role does application and modeling play, when mathematics is on its own? This role has earlier in the pre-reform era been discussed in e.g. T. H. Jensen (2007).

THE ROLE OF APPLICATION

As claimed above, the view on the role of application is an independent dimension in an identity of mathematics. The simplest “value” for this dimension would be zero, corresponding to the view, that application of math shall not play any role at all. This is not the same as saying that mathematics can’t be applied, but that the applications belong elsewhere. This viewpoint can be found among the math teachers in the Danish Gymnasium (that typically holds a master degree in mathematics from a university), but in this very radical form, it will probably be rare.

So to describe the existing viewpoints as parts of identities, I have chosen to formulate a suitable number of inclusively ordered levels, i.e. that a lower level can be seen as contained in a higher level. In order to construct those levels, it will be necessary to choose a set of notions about application of mathematics.

Application is a matter of working with models in a more or less unfolded way. A model is an object, that can be described as a triple (S, M, R) , where S is a real-world situation, M a collection of mathematical objects and R a relation between S and M (Blum and Niss, 1991). Modelling is a process, in which a model is constructed. The modelling process can be described as six sub-processes, as in Blomhøj and Kjeldsen (2006). The sub-processes are shown in figure 1.

Figur 1: The modelling cycle consisting of six sub-processes

A good entrance to the discussion of the role of application is to talk about different kinds of tasks based on the application of mathematics. From the modelling-cycle, five kinds of such tasks can be defined:

- *Modelling task.* A task that can only be solved by going through sub-process (b), (c), (d) and (e), and eventually also (a) and (f).
- *Model task.* A task involving sub-process (c), (d) and (e).
- *Mathematization task.* A task involving sub-process (c) and eventually (d).
- *Interpretation task.* A task involving sub-process (e) and eventually (d).
- *Wrapped task.* A task that in any practical sense only involves sub-process (d).

I will then define roles of application on five inclusively ordered levels:

1. *Illustration.* The role of application is narrowly to illustrate the pure theory.
2. *Motivation.* The role of application is to motivate work with the pure theory.
3. *Service function.* Math has a service function in other subjects and areas.
4. *Personal tool.* Math is a tool, one carries around to use in the real world.

5. *Critical inquiry*. Math is a field for investigating a wide range of problems.

Level 1 and 2 will be found in identities that see mathematics as a field for only pure theoretical activities. Applications must serve theory. On the illustration level, it is not important that the application has anything to do with the real world, while on the motivation level the cases must have some sort of real world relevance. That gives the order of the two levels. On these two levels *wrapped tasks* are sufficient.

On level 3, mathematics is recognized as a field of theory that other subjects and fields may borrow with great advantage. For instance when biologists and physicists needs a differential equation to be set up, solved and interpreted, or a carpenter needs to calculate the dimensions of a roof. On this level mathematics should deal with real world problems, but not before they have a clear mathematical form. On this level *wrapped tasks* are found, but also *mathematization*, *interpretation* and *model tasks*.

On level 4, it is important to be able to solve real world problems, when you meet them. Math should be a tool that you carry with you to use on appropriate problems. An economist must know how to handle problems like »what is the actual taxation as a function of income tax and VAT«, and a physicist must know how to handle problems like »with what speed does a parachute land« and »how early does Venus rise«. Therefore those questions are relevant to ask in mathematics. *Wrapped tasks* play a minor role on this level and the *modeling task* are introduced.

On level 5, mathematics is recognized as a field where a lot of open questions can be examined critically. It can be tasks like »what is the best means of transport«, »how many bosses should a company hire«, »how many elevators are needed in a warehouse with many floors«, and »should we trust the polls«. On level 5 a major part of the tasks worked with should be of the *modeling* kind.

Those five levels will be a part of my framework to analyze what identities are dominating in the Danish Gymnasium. In the two following sections, I will give examples on the use on two different categories of domains.

THE POLITICAL SYSTEM

In the political system, the identity of mathematics as a subject in Danish Gymnasium lives primarily in different kinds of documents. Therefore document analysis is the most important method to uncover it. The political system is an aggregation of many peoples' individual viewpoints and interests, so it is not expected that a clear well defined identity is found.

The documents to analyze are first of all the *regulation*, especially its appendices on mathematics. Secondly it is the *guidelines* following the regulation. And then it is the annual written examinations. The written examination is taken by all students with mathematics on medium or high level. It consists of typically 16-17 tasks, which must be answered in 5 hours without communication with others.

Working Group 6

The regulation presents mathematics as a subject in three steps: 1) Identity and purpose, 2) Mathematical aims and 3) Core- and extension material. The purpose says:

One of the aims of the teaching is to give the pupils knowledge of some of the important parts of mathematics' interactions with culture, science and technology. In addition, the aim is to give the pupils an insight into how mathematics can contribute to understanding, formulating and solving problems within a number of different subjects, as well as an insight into mathematical reasoning... (EVA 2009, p. 59)

This text doesn't focus narrowly on mathematical theory. Actually one can barely say that it mentions that mathematics as a theoretical activity should play an independent role. So we must be above the illustration- and motivation level. The talk of interaction and solving problems in other subjects, points at a *service function-* or *personal tool* level. So let us look at just one of the following nine mathematical aims:

Pupils should be capable of using functions and their derivatives in setting up mathematical models based upon data or knowledge from other subject areas. They should also be able to have an opinion about the idealizations and range of such models, be able to analyze given mathematical models, and undertake simulations and extrapolations. (ibid)

This text presents theoretical elements as tools to apply in real world. So again we are above illustration and motivation, and the talk of pupils "being capable of" and "have an opinion about" draws towards the *personal tool*-level. But then the core material is presented. The core material is ten dots presenting the "syllabus". The content that every student are expected to learn. Here are three of the 10 dots:

- the definition and interpretation of the derivative, hereunder growth rate and differentials, the derivatives for elementary functions and the rules for the differentiation of $f + g$, $f - g$, $k \cdot f$, $f \cdot g$, $f \circ g$, proof of selected derivatives
- monotonic functions, maxima, minima and optimization along with the connections between these concepts and the derivative
- fundamental properties of mathematical models (EVA 2008, p. 60)

The first two dots present pure theoretical contents. Application and real world are not mentioned. The other seven dots are of the same character. And then the 10th last dot, talks about models. So in the core material, mathematics is presented as a large collection of theoretical concepts and rules, and models as a little additional aspect. From this perspective, applications are drawn towards something serving the theory. Finally, if we look at the Guidelines, they say:

To demonstrate knowledge about application of mathematics means, that you in a reflected way can present some content that you have worked with. In that do not lay the

Working Group 6

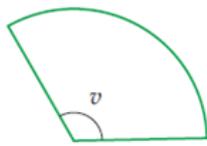

idea that students independently can take care of a mathematical problem and modeling of a material or problem, which has not been prepared. (UVM 2008, p.22., my translation)

In this text, the talking about unassisted applications is laid dead. Instead application is something taking place in continuation of work done by others. So this text places the role of application around the level of *motivation* or *service function*.

The four pieces of text draws together a blurred picture of the systems *declared identity*. The relation between theory and application is unclear. According to the general declarations of aims and purposes, application should be very central. But if one looks at the list of mandatory contents, it is the pure theory that is in focus. It is also unclear on what level applications are to be presented. But again, the general parts draw up, the concrete parts draw down.

It is therefore my claim that the regulation leaves the teacher with a broad range of choices of what identity he or she will practice in the daily teaching. Therefore it is very important to examine the identities held by the individual teachers. But the system has one important tool left: tasks for the written examination. Even though the rules are unclear, the teacher still has to take the written examination into account.

The written examination is a collection of typically 16-17 tasks, that every student must answer in 5 hours. The first five tasks must be answered and handed in, in the first hour, without any aid. The remaining tasks must be answered with the use of calculators, tables of formulas, computer programs and other means, not including communication with others. The tasks are very similar from year to year. They are therefore a clear message to teachers and students about what kind of task they should be training to answer. Out of the 11-12 tasks with aids, 5-6 are formulated in an applied way (i.e. by referring to some extra-mathematical context). It is my assumption, that these tasks are the strongest declaration from the system about, what role application should play. Here I will just give two examples of typically applied tasks from written examination on the highest level (UVM 2009, *my translation*):

Example A	Example B
<p>In a model, the weight of a certain fish as a function of the fish's age, is given by:</p> $w = 20 \cdot (1 - 0.89 \cdot e^{-0.17t})^3,$ <p>Where w is the weight (measured in kg), and t is the age (measured in years).</p> <ol style="list-style-type: none"> Use the model to decide the fish's weight, when it is 3 years. Determine the age of the fish, when the fish's weight is 13 kg. 	<p>In a garden a flower bed is landscaped with the shape of a circle sector (see the figure).</p> <p>It is informed, that the area of the flower bed as a function of the angle v (measured in radians) is:</p> $A(v) = \frac{200v}{(v+2)^2}$ <div style="display: flex; align-items: center;">  </div> <ol style="list-style-type: none"> Determine v, so the area of the flowerbed becomes as big as possible

Both of these tasks are of the *wrapped* kind. In both tasks are given an explicit expression and asked questions that it is very simple to unwrap as pure mathematical questions. Said in another way, it is possible to formulate both tasks as pure theoretical tasks. Therefore the term “wrapped”, because it is pure tasks wrapped in an extra-mathematical context.

Example A is a task of the kind *given $y = f(x)$, find $f(x_0)$ and x so that $f(x) = y_0$* . Example B is of the kind *given $y = f(x)$, find the x where $f(x)$ has its maximum at the interval $[a;b]$* . It is my claim, that those tasks focuses mathematics on the theoretical dimension, while it places what we could call the systems *practiced identity* on the lower levels of the application dimension. The tasks do illustrate and motivate theory through application, but they do not train how to apply math.

THE TEACHERS

In the case of a teacher, the identity lives as a collection of viewpoints, believes, habits, abilities, etc. inside the teachers mind. Therefore more sophisticated methods than document analysis are needed, to uncover it. In the singular case, the best method would probably be a combination of deep conversations and observation of teaching practice. But if we want an overview of the entire population of teachers, we need to do a survey on a well chosen sample.

Here the main problem is how to screen a person’s mind. If the person is asked directly about the identity, you will probably not get complete and accurate answers. Therefore it is necessary to ask questions where the answer builds more or less unconsciously on the teacher’s identity of mathematics. Examples of such a method are to present a number of different kinds of tasks to the teacher, and ask him or her to place it in relation to their ideas about the subject (e.g. central, supplementary or not belonging), and to show the teacher four proposals for the identity-paragraph in the regulation and ask which one the person would vote for in a referendum.

It is not the purpose of this paper to justify my methodology, present results or draw any conclusions. But I will exemplify the use of the identity concept on the domains of teachers, by referring to interviews made with four math teachers, as a pilot study before designing a survey.

The teachers were asked to comment on the task »How early does Venus rise? «. This task can be answered in many different ways. Venus is placed between the Earth and the Sun. Therefore it must rise relatively close to sunrise. One way to answer the question, is to estimate the greatest time difference between the rise of Venus and sunrise. By making a plane geometric model one can convince him- or herself, that this happens when the Sun-Venus line is perpendicular to the Earth-Venus line. In terms of Sun-Earth (r_E) and Sun-Venus (r_V) distances, this gives the following time difference (T):

Working Group 6

$$T = \frac{\arccos\left(\frac{r_V}{r_E}\right)}{2\pi} \cdot 24\text{h} \approx 3\text{h}.$$

The interviewed teachers were not presented for this or any other ideas to a solution. Two of the teachers refused the task, claiming that it does not belong to the field of mathematics. One of these two teachers explained this in the following way:

T1 [...] as the question stands, you can't calculate it unless you have some preknowledge, unless you have been taught astronomy. And of course there is some mathematics in it [...] It would be a good fourth question in a report, where a lot of other questions leads up to it.

According to this teacher, the question is first relevant, when another subject has been on work. Then there will be something to do for mathematics. This indicates a *service function*-level. The other refusing teacher says:

T4 It depends on where you see it from. And it requires different astronomy software at your disposal... I really don't think that has something to do with mathematics.

This teacher doesn't recognize the task as something where mathematics can play a role. This does as well indicate that we are not at the highest level of application. A teacher at the two highest levels would be expected to spontaneously being open towards investigating the possibilities of a question like this.

The two other teachers didn't refuse the task, but declared the task to be "supplementary", i.e. useful but not central.

T2 [...] the description of the celestial bodies is traditionally handled by physics. But fundamentally it is also a mathematical question and can be modeled with mathematics [...] so of course it can be supplementary, but as the task stands here... it demands to much additional knowledge.

Here the teacher does not refuse the task. Instead he talks about modeling. He is though critical to the missing informations. So to him, mathematics is not a field of *critical inquiry*, where open questions are examined. On the other hands, it is more a lack of information, than a lack of another discipline that bothers the teacher. This indicates a teacher on the *personal tool*-level.

So what I try to indicate here is that by asking those kinds of questions, it is possible to state a first impression of a teacher's position on the *with*-dimension of identity.

DISCUSSION

In this paper I have presented a conceptual framework of the identity of mathematics as a school subject. The part of the framework describing the application of mathematics was particularly developed. The framework has been used to discuss the identity of mathematics living on two different kinds of domains. The political

system and the teachers. Examples have been given on how to use the conceptual framework on those two domains.

Whether a conceptual framework is useable or not, must be decided in its ability to articulate relevant problems from reality. In this case it is the overall discussion on the conflict between a pure theoretical approach to mathematics versus an applied approach and the discussion between different approaches to application.

The identity concept adds a way of addressing the disputes on what should characterize the mathematics subject. The concept describes different holistic views on the subject. Differences in such views can be used to address special challenges, when the aims and contents of the subjects are changing. At the same time it can be used to give an overall quantitative description of “the state of the art”, though this is methodological complicated. So the conceptual framework presented, seems to be useful to the Danish context, but may very well be so for other countries as well.

STUDENTS CONSTRUCTING MODELING TASKS TO PEERS

Thomas Lingefjård

Department of Education, University of Gothenburg

In a mathematics education course at the University of Gothenburg, students were asked to develop modelling tasks or modelling situations to each others. There are many reasons for encouraging the development of peer tutoring among students. When explaining something for a class mate, students must clarify their own thinking in order to give an explanation and must be prepared to have misconceptions confronted and corrected through discussion and listening. In general students learn much more if engaged in the teaching of a course. But will the receiving students learn what was intended? In this paper I will discuss how this activity was carried out by two groups of students and what they thought they learned from it.

INTRODUCTION

To teach matters of learning and teaching principles to prospective teachers is a huge task. There is so much stuff and information to cover in order to prepare prospective mathematics teacher for the upper secondary school level and regularly rather few teaching hours in which we can teach it. In a mathematics education course for prospective mathematics teachers, we decided to try to combine several course objectives such as: Learning how to use a wide spectrum of technological resources, learning how to engage and challenge students' mathematical thinking, and learning how to create learning situations which are relevant for most students in upper secondary schools.

Technological resources

We wanted them to learn different aspects of GeoGebra since it is such an excellent tool when teaching and learning many different branches of mathematics. It is free, portable (runs on any machine who runs Java), and combines Algebra, Geometry and spreadsheet number theory. We also wanted them to learn how to use digital cameras and free software for splitting a film into images. All students had access to cameras and/or cellular telephones which they could film with. We also introduced them to the software VirtualDub, which enables you to split avi files into images. All films are made of many images, from 25 – 150 images per second. It is not surprising that there exist software that can separate the images from each other again.

Students

There were 24 students in this mathematics education course, they had all been studying mathematics at the university level for two semesters, and some of them (although not all) also had studied another teaching subject such as physics or chemistry. In our course, they have read and discussed article about theories on learning as well as papers on mathematical modelling (namely, Sfard, 1991;

Lingefjård, 2006). We decided to split them up in six groups with four students in every group. Some of the students were known to be good in mathematics, some of them already knew about GeoGebra, some of the students knew about software for editing and handling movies, and so forth. We tried hard to make the groups equally strong, with respect to these variables, as possible.

Three groups were chosen as teaching groups (presenting tasks) and three groups were chosen as students groups (receiving and solving tasks). One teacher group and one student group were paired.

Student activity

All three teaching groups developed interesting teaching materials. What I will present in this paper is just one task out of three and perhaps not the best or most accurate task. Nevertheless, it is an interesting activity in the sense that it combines most, if not all, of the course objectives mentioned above.

THEORETICAL FRAMEWORK

Studies on student learning (Ramsden and Entwistle, 1985; Johnson *et al.*, 1989, Johnson and Johnson, 1991, Ross and Cousins, 1993, Marton and Booth, 1997) suggest that students adopt at different times and in different circumstances, different approaches to learning. In groups of two or more individuals, students work together, share and clarify ideas. Through talking to each other about subject matter, students can discover what they know and what they do not understand and ‘make sense’ of what they are learning. Some studies show that peer or co-operative learning forces students to engage in higher order thinking, which includes application, analysis, synthesis and evaluation (Ellis and Whalen, 1990). Of course there is no certain way to declare that peer or co-operative learning is the best way to learn. It seems that the more we learn about different ways of learning, the more complex and vague the picture becomes.

The reader might find that it has been somewhat bewildering, our bringing together findings on qualitative differences in the way in which learning is experienced that originate from studies of learning in widely differing educational contexts, that if infants, preschool children, secondary school pupils, and university students, and moreover from such widely differing cultural contexts as Britain, Sweden, China, Uruguay. Our assumption is that a phenomenon, such as learning as experienced, can be described in the terms of the complex of differing dimensions of variation identified. (Marton & Booth, p. 54, 1997)

In order to learn something certain conditions must be met. Learning situations are always experienced within a framing of different circumstances, such as a context, a certain time, a place, and so forth – while a phenomenon is experienced as abstracted from or transcending such an anchorage. But learning is also closely connected to the possibility of variation.

Variation theory makes it possible to analyse teaching and learning in commensurable terms, which implies that ‘what the teacher intends the students to learn’, ‘what is made possible to learn in a lesson’ and ‘what the students learn’ are connected and described in a similar way. From a variation theory position, learning is defined as a change in the way something is experienced, seen, or understood. A fundamental assumption is that the learner, in one way or another, experiences what is learned. The educational system aims at developing the learners’ capability to handle various situations, to solve different problems, and to act effectively according to one’s purposes and the conditions of the situation. However, the possibility of acting on, or handling, a situation depends upon how we make sense of it. We act in accordance with how we perceive the situation. This is affected by our previous experiences, but the experiences we see as relevant are also affected by how we experience the situation. ‘We try to achieve our aims, not in relation to the situation in an objective sense but in relation to how we see it’ (Marton et al., 2004, p. 5).

When working with prospective teachers, it is of interest to regard what they see as possible to learn from a situation both in the sense of their own learning, but also in their role as future teachers. In variation theory, learning is seen as becoming able to discern critical features of an object of learning. The object of learning is the definition of a competence or understanding of something, for example a particular content taught in a mathematics lesson. The object of learning is consequently not the same as learning objectives in a course; it is not the subject or the content taught and learned but rather the capability connected to that particular knowledge.

Teacher group task

The students in this group went to a gym with a basketball hall and while one of them were practicing distance shots with a ball against the basket, the others in the group practiced to film the shots by different cameras and cellular telephones from several distances. When they were satisfied with the shooters performance and the content in the films, they went to a computer lab at the university and transferred all the films to a computer, watched all the short films and selected the best film in terms of quality. After that they downloaded the free software VirtualDub and used it to split the three second long film into frames. See figure 1 and figure 2 for two such frames. There are several more frames between these two.

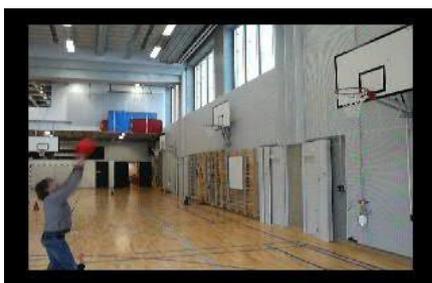

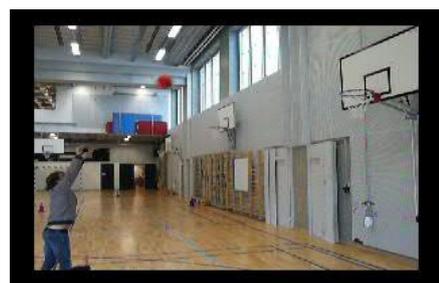

Figure 1&2: The start of a basket shot and the same basket shot a moment later

Working Group 6

Researcher: So why did you choose this specific activity? What do you see as the possible object of learning? What will your peers understand or learn from this activity?

Student 1: Our first objective of learning is of course that our peer students should learn more about mathematical modelling. But we also think that they will learn about specifics in the modelling process, specifics such as that every point in the graph has a certain value which defines the point's position in a Cartesian coordinate system. When you look at the different representations of the same object in GeoGebra, you understand more about that object.

Researcher: Please elaborate on that.

Student 1: I am referring to Sfard's theory on dual nature of mathematical conceptions. It must be better to see different representations and be able to vary between them in order to understand more about them...

Student 2: We also think that when you look at that ball's position, thereby sketching the trajectory of the ball, then you understand something about how the single images are part of a whole film. This is represented for thirteen positions of a ball. So you understand more about the connection between reality and the images and that connection is exactly the mathematical model.

It is obvious that the teaching group chiefly was focused on the mathematical modelling activity as their object of learning. For them this whole complex process with many different specifics became reification into the mathematical model. Besides being software for teaching geometry and algebra, GeoGebra also contains several other possibilities suited for teaching different branches of mathematics. One such possibility is to insert an image anywhere in the coordinate system and then use it as a background. Another one is to mark a point at that image and then select "copy the coordinates to the input line", e.g. $A = (-2.02, -0.56)$. From the input line, you can easily relabeling the coordinates to $A1 = (-2.02)$ $B1 = (-0.56)$ and thereby make them part of the spreadsheet. Once in the spreadsheet, the set of points can be used to create a List of points, which then becomes an object. In our example, the ball's centre act as the marking part in every picture and with every frame put in the same place, GeoGebra present us with a set of data points as in figure 3.

	A	B

Figure 3: The motion of the ball represented in two ways.

Student: And if you take any of the points (in GeoGebra) and drag it a little bit off, then you get another trajectory. See here, the fitted curve moves. So, by varying the position of just one single point, the mathematical model can indicate that the shooter made a goal or maybe missed to make a goal. It will teach you even more about mathematical modelling and how careful you must be when you measure data. (See figure 4).

$$f(x) = -0.31x^2 + 0.38x + 1.48$$

Correlation coefficient = 0.91

Figure 4: Observe that the trajectory of the fitted curve, the correlation coefficient and the formula for the polynomial will all change if one point is moved.

It seems as if the students hold an intuitive sense of the variation possibilities offered by the technology. It is important to acknowledge that variation can be represented in many different ways. In the student statement above, it is the concept of position which is varied in different representational forms. It is also notable that for the students in the teacher group the reality now was transferred into the film, with part of that reality expressed by the frames inside GeoGebra.

As indicated, the students in the corresponding student group were given 13 frames, illustrating the shot from the start and up to the peak of the balls trajectory towards the basket. They were asked to construct a mathematical model based on the balls position in the frames and then use the model to predict if the shot was a goal or not.

Student group solving

After some initial discussion about the procedures and command structure of VirtualDub and GeoGebra with regard to this specific problem, they started to insert the images into GeoGebra and once done with this and with creating the set of data points, they also started to analyse the situation:

Student 1: Now when we have all the points in the spreadsheet and have created the List of point, we can use the regression command `FitPoly[Lista1, 2]`. If we do that, with a polynomial of grade 2, we should get a curve fit that shows a hit or a fail. Do you follow?

Student 2: Yes, this is such an excellent way of introducing and using the concept of equations of second degree. This is actually the first time that I understand

Working Group 6

why we actually teach the students about them in the upper secondary school. Amazing!

Researcher: And what do you think that you are learning while you do this? What do you see as the object of learning?

Student 1: There are several things of course, I was not aware of the possibility to just go away and make a film and the split it into images and just say to the students: Analyse this situation. It is just so cool!

Researcher: So what did you learn?

Student 2: I also learned much more about second degree equations and I will definitely use part of this when I teach introduction to second degree functions next time, it is awesome.

What we see here is that the students group assume a different object of learning compared to the teacher group. The object of learning can obviously be seen from three different points of view: the “teacher’s”, the “student’s” and the researcher’s. The object of learning seen from the point of view of what the teacher or, in this case, the students who acted as teachers, is what is called the intended object of learning. Compare this to the “intended curriculum”. The intended object of learning was connected to mathematical modelling and the correlation between data points and regression curves.

Any teacher hopefully always has a particular goal and intention about what the students should learn, for instance that students are able to understand that a function must be continuous in order to have a derivative everywhere. On the other hand, what students (the learners) actually learn is the experienced (lived) object of learning and that can be observed during the learning situation by the students’ expressions, or after the lesson in an exam. Obviously, it is not necessary that the intended and the experienced (lived) object of learning coincide. In this activity, the students in the students group, experienced another object of learning, namely an example of how second degree equations can describe ball trajectory paths.

The object of learning seen and analysed from the researcher’s point of view, implying ‘what it is made possible to learn’, is the enacted object of learning. The enacted object of learning describes what features of the content are possible to experience during a “lesson”. The variation used to elicit the features, the values within a dimension of variation, is the range of change (Watson & Mason, 2006) and the way it is possible to discern the variation is through different patterns of variation.

For me, as a researcher, it was most obvious that the students now experienced a way of working with technology that can enable their own teaching in their future teacher professions. Some subset of their object of learning was of course related to mathematical modelling and the selection of suitable curves for the curve fitting

process. For me that was in the details, while the overall picture was about new challenging working methods and opportunities when technology is at hand. Altogether, these results created an opportunity for a challenging seminar with all the prospective teachers where we discussed what they had learned and what the intentions were. That was probably the most vivid discussion I had ever seen in a seminar.

DISCUSSION

It seems that this is an excellent example of how modern technology enables us to construct interesting mathematical problems directly from situations around us. It seems hard to imagine that this problem could have been constructed and presented by one group of prospective teachers to another group of prospective teachers without technology at hand.

Nevertheless, the experiment with students constructing problems for others enables someone to study the learning outcome and thereby observing the difference between the groups acknowledge of the object of learning and between my own expectations of the learning outcome.

The more complex a teaching and learning situation gets the harder it is to analyse the situation in stereotypes or easy commensurable terms. Whenever we try to teach something, we should be aware of the fact that students or humans never perceive reality, since here is no reality outside our notion.

We cannot separate our understanding of the *situation* or our understanding of the *phenomena* that lend sense to the situation. Not only is the situation understood in terms of the phenomena involved, but we are aware of the phenomena for the point of view in the particular situation. Furthermore, not only is our experience of the situation molded by the phenomena as we experience them, but our experience of the phenomena is modified, transformed, and developed through the situations we experience them in. (Marton & Booth, p. 83) (Italics in original)

MODELLING AS A BIG IDEA IN MATHEMATICS WITH SIGNIFICANCE FOR CLASSROOM INSTRUCTION – HOW DO PRE-SERVICE TEACHERS SEE IT?

Hans-Stefan Siller¹, Sebastian Kuntze², Stephen Lerman³, Christiane Vogl¹

¹University of Salzburg, Austria; ²Ludwigsburg University of Education, Germany;

³London South Bank University, U.K.

There is not only a consensus that modelling is a big idea for mathematics as a scientific discipline, but also that this big idea should have an impact on the mathematics classroom. Consequently, teachers should be aware of this big idea and know how modelling relates to a variety of curricular contents. However, empirical research into views of pre-service teachers related to big ideas in general and to modelling as a big idea in particular is scarce. Hence, this study concentrates on views of Austrian and German pre-service teachers about the significance of modelling as a big idea. For this purpose, we focus on the role of modelling as a big idea, and report about results concerning the pre-service teachers' perceptions.

INTRODUCTION

Modelling is considered as a big idea by the scientific communities in mathematics and mathematics education (cf. Blum et al., 2007; Lesh et al., 2007; Stillman et al. 2008) – it remains very important for mathematics and its development, and there is a consensus on its importance for mathematics instruction and mathematical literacy. In contrast, empirical findings have suggested that mathematics teachers might lack awareness of the significance of modelling in everyday instruction. However, there is still a need of broadening the empirical base in this field, and teachers' perceptions about the significance of modelling in comparison with other big ideas have hardly been the subject of research so far.

This paper responds to this need of research by investigating views of Austrian and German pre-service teachers about the significance of modelling. These views about modelling are also compared to views about other big ideas, and they are, moreover, examined with respect to specific content areas. The results indicate that modelling is perceived as a significant big idea among others. However, low evaluations by a subgroup of pre-service teachers suggest that the awareness of modelling as a mathematics-related big idea should be fostered. Intercultural differences could stem from differences in declarative and procedural professional knowledge about modelling.

In this paper, we will first give an introduction to the theoretical background of considering modelling as a big idea. After specifying the research questions, we will give information about sample and methods in a corresponding section. We will then present results and finally discuss them in a concluding section.

THEORETICAL BACKGROUND

The “idea” of big ideas

Learning opportunities can be particularly rich when they address mathematical concepts holistically (cf. e. g. English, 2003). In mathematical content knowledge, the importance of overarching concepts has been identified by Bruner (1960) and Schweiger (2010), in whose work the notion of “fundamental idea” is central. According to Schweiger (1992, p. 203), a fundamental idea is „a bundle of actions, strategies or techniques, [...] that

1. can be made visible in the historical development of mathematics, that
2. appear as sustainable for structuring curricular conceptions vertically, that
3. are appropriate as ideas for giving answers to the question, what mathematics is, and for speaking about mathematics, that therefore
4. can make mathematics instruction more flexible and at the time more transparent.

Furthermore, [...] an anchoring in everyday language and thinking, like a corresponding archetypical thought, expression or action [is] necessary.“

The idea behind the approach of putting such fundamental, overarching, or simply “big” ideas in the foreground of mathematics instruction is to facilitate building up links across contents, to foster the organisation of mathematical knowledge, to encourage reflection and to help learners to make sense of mathematics. Seen from a moderate constructivist perspective, these aspects can be used to describe what can be seen as a big idea. Such a characterisation affords integrating prior approaches to overarching concepts into a pragmatic understanding, and offering an openness towards the reflections about mathematics by teachers as it may take place in their professional development. Accordingly, by referring to the notion of big ideas in mathematics (s. also Kuntze et al., accepted), we think of ideas that should

- have a high potential of encouraging learning with understanding of conceptual knowledge (including orientation, linking and anchoring of knowledge)
- be relevant for building up meta-knowledge about mathematics as a science
- support abilities of communicating meaningfully about mathematics
- encourage reflection processes of teachers connected with designing rich and cognitively activating learning opportunities as well as with accompanying and supporting learning processes of students.

Hence we do not consider big ideas as belonging to a pre-defined catalogue, but we emphasise the potential of these ideas for making mathematics meaningful and rich for conceptual learning according to the aspects above. Examples of big ideas the project ABCmaths (www.abcmaths.net) focuses on are “using multiple

representations”, “dealing with infinity”, “doing-undoing/inverting”, or “generalising/specialising” (for more details, see ABCmaths team, in preparation). Of course, these ideas may overlap, but they have different emphasis.

Consequently, for profiting from rich learning opportunities, learners and also their teachers should be aware of big ideas linked to mathematics. We will exemplify this by focusing on the big idea of modelling.

Modelling as a big idea in mathematics

Indeed, “mathematical modelling” not only clearly satisfies well the meta-scientific, curricular, historical and learner-oriented criteria of Schweiger (1992), but also affords reflecting on mathematical concepts and their roles for solving real-world problems as well as creating rich learning opportunities. As Pollack (1979, p. 240) states, modelling “requires an understanding of the situation outside mathematics and of the process of mathematisation as well as of the mathematics itself”. And, conversely, the role of mathematics can be recognised particularly clearly when reflecting about modelling processes. The contribution of mathematical ideas and concepts (Lakoff et al., 2000) can be made transparent for learners through their use in modelling real-world problems. A prototypical example of the impact of modelling on mathematics with implications also for mathematics instruction can be seen in De Lange’s (1996) approach of using real world problems as an opportunity to develop mathematical concepts. Further, the approach of developing mathematical knowledge by using and refining models not only allows curricular conceptions but also helps to anchor modelling in everyday thinking (cf. Blum et al., 2007; Lesh et al., 2007; Stillman et al. 2008).

Implications for the classroom and desiderata for the professional knowledge of mathematics teachers

Although mathematical modelling has had a history as long as mathematics itself, the same cannot be said of the history of mathematical modelling in school curricula. A good deal about modelling as classroom teaching and learning strategy has been written e.g. by Swetz et al. (1991) or White (1994). Today the importance of mathematical modelling is acknowledged in current curricula and standards.

Consequently, modelling is given a key role in the assessment of mathematical competency. For instance, it is an important constituent in ‘Mathematical literacy’, which is defined by the OECD / PISA (2003, p. 24): “Mathematical literacy is an individual’s capacity to identify and understand the role that mathematics plays in the world, to make well-founded judgements and to use and engage with mathematics in ways that meet the needs of that individual’s life as a constructive, concerned and reflective citizen.” This definition highlights the relevance of modelling and underpins its role as a big idea. Consequently, competencies in modelling play an important role in national standards (cf. KMK, 2005; AECC, 2008), too.

Hence, developing modelling competencies is a fundamental goal for mathematics instruction as described by Klieme et al. (2001, p. 186): “In the centre of basic education the ability of mathematical modelling should be found.” In the classroom, students should be encouraged and supported to engage in meaningful modelling tasks and modelling activities (Blum, 1996; Maaß, 2004). As a precondition it is acknowledged that students learn mathematical modelling by (actively) participating in the experience of constructing a model and working to correct and improve their models. This requires teachers to allow students to formulate, test, discuss and adjust their thinking. The role of teachers is to provide opportunities for this learning to take place and to guide the students through a modelling process, while allowing them freedom within each stage.

As a prerequisite for teachers to design corresponding learning opportunities with rich modelling activities, teachers need to be aware of the idea of modelling and its relations to a variety of contents. Hence, teachers’ views about the significance of modelling appear as crucial for the development of mathematics instruction.

Teachers’ views about modelling

Studies into teachers’ views about modelling have to be seen as embedded in more general research focusing on professional knowledge and teachers’ beliefs or convictions (e.g. Shulman, 1986; Ball, Thames & Phelps, 2008). The corresponding theoretical background is developed in more detail in Kuntze (accepted). Leading to the research questions of this study about the significance of modelling as a big idea, we will, in the following, focus on specific findings. A recent study about teachers’ views about modelling has been realised in the framework of the LEMA project (Maaß et al., 2009). In this study, teachers demonstrated little knowledge about modelling, e.g. about the modelling cycle. Kuntze and Zöttl (2008) showed that pre-service teachers favoured tasks with low modelling relevance to tasks with higher modelling requirements. In a study by Kuntze (accepted) in-service teachers showed a tendency of similar patterns of answers in a task-specific survey centred on the idea of modelling. Again, the in-service teachers were not very confident with respect to their knowledge about the modelling cycle, which suggests a lack of professional knowledge related to modelling. We consequently expect that teachers might attribute not the highest significance to modelling, as a consequence of a non-optimal professional knowledge related to modelling. These findings correspond to evidence from other studies suggesting that modelling in classrooms has to compete for attention (cf. Kaiser-Meißner, 1985; Maaß, 2004). As there is probably a dilemma for many teachers between different instructional goals in concurrence with the aim of developing and fostering modelling competencies of the students, research should focus on the importance teachers associate with modelling in comparison with other important mathematics-related ideas like those presented in the previous section. As views about the significance of modelling as a big idea have hardly been subject to quantitative empirical research so far, this study on comparisons with the

significance attributed to other big ideas is exploratory. For linking the results with other findings in the ABCmaths project, we focus on the set of big ideas in the scope of ABCmaths.

RESEARCH QUESTIONS

Against this theoretical background, we focus on the following research questions:

- What views about the significance of modelling as a big idea in mathematics do pre-service teachers hold?
- How do these views compare to the significance attributed to other big ideas?
- In which content domains do pre-service teachers root the importance of modelling as a big idea?
- Are there differences between pre-service teacher groups of different school cultures?

SAMPLE AND METHODS

In order to find out about the research questions above, a test was administered to 117 German pre-service teachers (78 female, 35 male, 4 without data) and 42 Austrian pre-service teachers (27 female, 15 male) before the beginning of a university course, respectively. The German pre-service teachers had a mean age of 22.33 years ($SD = 3.56$ years) and had been studying on average for 2.19 semesters ($SD = 1.12$). 61 pre-service teachers were preparing for being teachers in primary schools, 35 in secondary schools for lower-attaining students, and 15 for working in schools for students with special needs. The 42 Austrian pre-service teachers had a mean age of 22.5 years ($SD = 3.34$ years) and had been studying on average for 4.93 semesters ($SD = 2.10$). All of them were preparing to be teachers in secondary schools. The choice of the sub-samples was not meant to be the base of a representative international comparison. However, comparing the answers in these sub-samples can give insights into how stable under a change of culture (internationally or related to school type) the considered teachers' views are.

The exploratory approach of this study and the research questions highlight the need of gaining an overview on the pre-service teachers' views. This suggests the use of quantitative methods based on a questionnaire survey. Accordingly, the pre-service teachers were asked to complete a questionnaire unit on their views about the significance of modelling and other big ideas. This questionnaire unit was part of a longer instrument, which was used in an analysis of needs study in the research project ABCmaths (www.abcmaths.net; cf. also Kuntze et al., accepted). The questionnaire unit contained a rating of the overall significance of modelling among other big ideas (see Fig. 1), and a rating of their importance for specific content areas, respectively. The pre-service teachers were asked to rate the significance of the big ideas with numbers between 0 (low significance) and 5 (high significance). Moreover, the questionnaire unit provided short explanations on the big ideas

appearing in the questionnaire in order to prevent the participants from misunderstandings. In the following analyses, pre-service teachers with complete data are considered.

RESULTS

In this section, we present results in the order of the research questions given above. As an exception, we will refer to the last research question about inter-cultural differences constantly while reporting the results, in order to support easy access to the data. The pre-service teachers held on average a positive view about the significance of modelling as a big idea in mathematics. The average values of the ratings are in the upper half of the scale, 3.46 (SD=1.28) for the German and 4.06 (SD=1.10) for the Austrian pre-service teachers. The difference is significant ($T=2.58$; $df=103$; $p<0.05$; $d=0.55$), indicating a possible inter-cultural effect.

Figure 1 shows the importance assigned to modelling compared to the average significance attributed to other big ideas. As can be seen, modelling was not the most important big idea in the eyes of pre-service teachers. For German participants, the importance given to modelling was significantly lower than the importance given to “argumentation/proof” ($T=2.08$; $df=70$; $p<0.05$; $d=0.33$), “multiple representations” ($T=4.38$; $df=70$; $p<0.001$; $d=0.59$) and higher than “infinity” ($T=2.94$; $df=70$; $p<0.01$; $d=0.49$) and “inverting” ($T=2.41$; $df=70$; $p<0.05$; $d=0.37$). For the Austrian pre-service teachers, no other big idea was rated significantly higher than modelling. However, the only big ideas to have been rated significantly lower than modelling were “infinity” ($T=4.54$; $df=33$; $p<0.001$; $d=1.03$) and “inverting” ($T=2.89$; $df=33$; $p<0.01$; $d=0.54$).

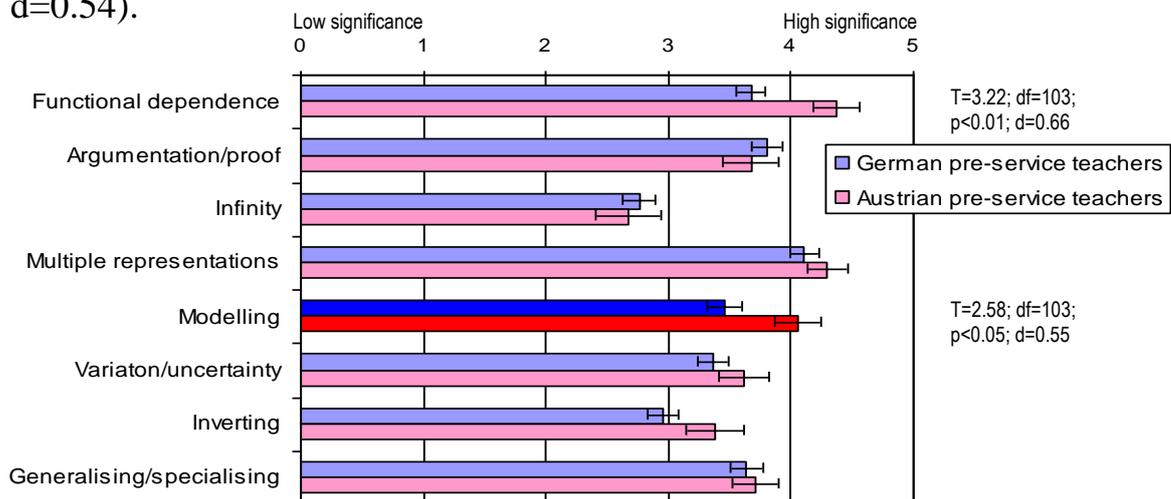

Figure 1: Ratings of the significance of big ideas: Means and standard errors

Beyond considering mean values, we focused on differences within the sub-samples by calculating (separate) cluster analyses on the base of the ratings of the big ideas (Ward method). The results are presented in Figure 2, showing a cluster with lower and one with higher ratings, splitting the sub-samples approximately by half. In the

case of the German pre-service teachers, these clusters show the largest difference in their views of modelling among all big ideas, whereas the ratings of modelling appear more homogeneous for the Austrian clusters.

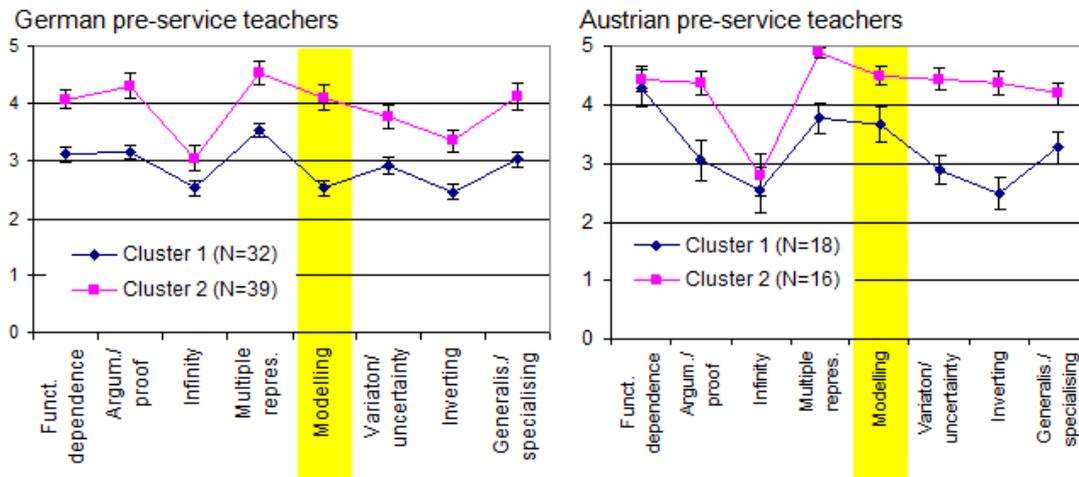

Figure 2: Ratings of subgroups of pre-service teachers based on a cluster analyses

Correlations between the ratings of the significance of big ideas can give further insight into how these were interrelated in the eyes of the pre-service teachers. In the German sub-sample, the significance of “modelling” correlates with the ratings of “functional dependence” ($r=0.45^{**}$, correlation significant with $p<0.01$), “multiple representations” ($r=0.75^{***}$, $p<0.001$), “inverting” ($r=0.42^*$, $p<0.05$), and “generalising/specialising” ($r=0.40^*$, $p<0.05$). In the Austrian sub-sample, the rating of “modelling” correlates with the perceived importance of “multiple representations” ($r=0.37^{***}$, $p<0.001$) and “variation/uncertainty” ($r=0.31^{**}$, $p<0.01$).

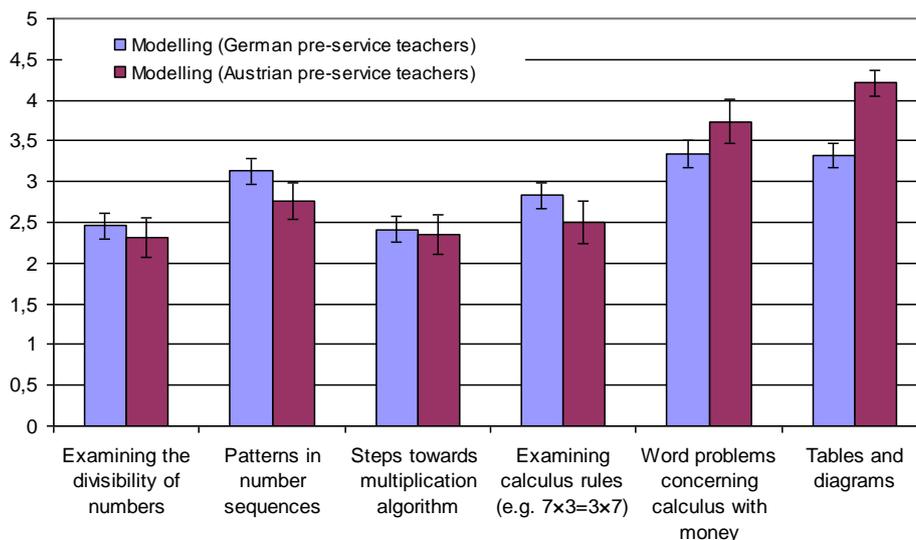

Figure 3: Significance of modelling related to content areas

In order to stay not only on the level of very general evaluations of the significance of modelling as a big idea, the third research question focused on making a link

between the pre-service teachers' general views and selected content areas. Figure 3 shows the average rating of the significance of modelling related to six content areas. The values concerning "patterns in number sequences", "word problems concerning calculus with money" and "tables and diagrams" were somewhat higher than the perceived significance related to the other content areas. With the exception of "tables and diagrams", there are no significant differences between the Austrian and German sub-samples.

DISCUSSION AND CONCLUSIONS

Views about the significance of modelling and other big ideas related to mathematics can be seen as an indicator of the awareness teachers have towards ideas linked to mathematics when defining learning goals and designing learning opportunities for their classrooms (cf. Shulman, 1986; Kuntze, accepted). Even if the results should be interpreted with care, given the exploratory approach of the study, modelling appears to have been perceived on average as a significant big idea. However, in the cluster analysis, it became apparent that a large portion of the pre-service teachers saw modelling as relatively insignificant compared to other big ideas. The Austrian pre-service teachers put more emphasis on this idea than did the pre-service teachers in the German sub-sample. This might be not, or not only, an effect of countries but it could also be an effect of the school types the teachers were preparing for and the corresponding cultures. Hence, school culture may play an important role for the professional development process of prospective teachers with respect to modelling. Against this background, the results do not contradict prior findings (e.g. Maaß & Gurlith, 2009; Kuntze, acc.), but they broaden the scope of possible explanations.

An interesting question related to these results is whether differences in professional knowledge may have caused the differences in the evaluations of "modelling" and "functional dependence". Possibly, prior professional learning of the Austrian teachers could have caused this effect. The more general question for further research would be whether and how views concerning the significance of big ideas can be developed and influenced by teacher education programs.

Even though there are some intercultural differences, it is interesting that some of the Austrian and German pre-service teachers' views were relatively similar, e.g. those related to the mathematical content areas. However, despite of these resemblances, teacher education should increase the awareness of modelling also related to a broad spectrum of other content areas, including areas that may be evaluated as less relevant in the first instance. This raises not only the question of further research about content domain-related views about the idea of modelling, but also to what extent such views may tend to evolve with increased instructional experience, in short terms: What are the views of in-service teachers related to the significance of modelling as a big idea? Moreover, the findings call for empirical research into the

role of the views examined in this study for the teachers' choice of learning opportunities in the classroom.

Considering the structure of professional teacher knowledge itself, research with the goal of identifying relationships with other aspects of professional knowledge could open up ways of effective mathematics teacher professionalisation. For the later research question, we expect results from ongoing studies and analyses in ABCmaths.

ACKNOWLEDGEMENTS

The project ABCmaths is funded with support from the European Commission (503215-LLP-1-2009-1-DE-COMENIUS-CMP). MODELLING IN AN INTEGRATED MATHEMATICS AND SCIENCE CURRICULUM: BRIDGING THE DIVIDE

Geoff Wake

University of Manchester

This paper explores the theoretical rationale behind a new approach to developing integrated mathematics and science curriculum experiences using the construct of bridging concepts. Such interdisciplinary approaches provide challenges for teachers and learners as they need to develop new practices in their classrooms and communicate across traditional subject boundaries whilst ensuring curriculum objectives in both subjects are met. Experiences from students across case study schools suggests that they need considerable time and space in which to develop conceptual understanding within and across mathematics and science and the vocabulary with which to communicate their thinking. The development to-date points to an important role for applications and modelling in mathematics in such cross-curriculum learning.

BACKGROUND:

The place of mathematical modelling in curricula of compulsory schooling is often contested and even with the pressure of international assessment such as PISA giving priority to applications of mathematics it may struggle to find a place (Ofsted, 2008). Equally scientific enquiry, as part of what might be considered a ‘reform’ agenda in science, that prioritises scientific method and consequently sees the need for enquiry as central, prioritises approaches that are not always prominent in day-to-day teaching (for example, Sadeh and Zion (2009), Wilson et al (2010)). The work described here relates to an EU (Comenius) funded project COMPASS (Common problem solving strategies as links between Mathematics and Science¹⁹) which seeks to tackle these issues promoting an integrated approach to the learning of mathematics and science by developing a range of classroom materials and professional development support for teachers. Fundamental to this project is the development of new approaches to teaching that motivate learning both within and across the disciplines. Pragmatically, given that there is no official demand for this (at least in England), this requires some understanding of how such innovation can be motivated in ways that ensure that current curriculum demands are being met.

Here, therefore, I present a theoretical rationale behind a new approach to interdisciplinary teaching and learning in mathematics. The outcomes of an initial adoption of materials based on this are reflected upon so as to inform a next iteration

¹⁹ Project: 503635-LLP-1-2009-1-DE-COMENIUS-CMP. This is funded under the Lifelong Learning Programme. For further details see <http://www.compass-project.eu/project.php>.

of their further development. I firstly explore how such aims might be achieved by considering, albeit briefly, the nature of the different domains of mathematics and science and exploring different ways that the demands of each, and indeed the demands of teachers and learners of each, might be met. I present a theoretical overview and a rationale of the design of interdisciplinary teaching and learning that, therefore, is also cognisant of these analyses of the subject domains of mathematics and science informed by an understanding of interdisciplinary learning approaches. Additionally, the resulting approach also has to meet the aims of the COMPASS project that seeks to see mathematical and scientific activity situated in contexts that are meaningful to critically informed European citizens of the future. The approach adopted is exemplified in this paper by outlining a set of materials that have gone through a first cycle of design and improvement in collaboration with mathematics and teachers working in a small group of schools in England. Finally, I draw on case study data and particularly focus group interviews with teachers to reflect further upon the design principles and implications for the integration of mathematics and science and the potential importance of applications and modelling in such curriculum design.

DEVELOPING A THEORY INFORMED DESIGN APPROACH

Nikitina (2006) identifies, on the basis of empirical classification, three basic approaches to the development of interdisciplinary approaches: contextualising, conceptualising and problem – centering. Her classification suggests that, in general, underlying differences and similarities in pedagogies and epistemologies in different disciplines are likely to result in one or other of these different approaches being adopted when school subjects are considered in common patterns of interdisciplinarity. For example, in the case of interdisciplinary approaches involving (1) disciplines in the humanities the common approach is often one of *contextualising*, that is one of developing tasks and materials that pay attention to issues of time, culture and personal experience. This contrasts with likely approaches to interdisciplinary work (2) in the scientific disciplines that is likely to focus on *concepts* that are central to constituent disciplines and work in quantifiable ways in making connections and (3) that takes a critical *problem-solving* approach to issues of social concern and which may require a more eclectic combination of knowledge and skills across disciplines. This would suggest that an interdisciplinary approach to study of mathematics and science is commonly one that focuses on concepts. It is perhaps not surprising that Nikitina's classification is reflected in other more philosophical analyses of mathematics and science knowledge domains that attempt to capture the essence of these in their enactment as school subjects. For example, Figure 1, adapted from the PISA overview of the mathematical literacy domain (OECD, 2003), draws attention to important components to take into account when considering this: concepts, competencies and contexts or situations in which these might be situated. These in turn inform formulation of tasks and ultimately learner

experience. The looping connections in the diagram suggest that there is no straight forward heuristic that can be adopted in developing tasks and approaches to lessons, but rather that the process is inevitably fuzzy as the different factors are brought to bear on classroom experiences.

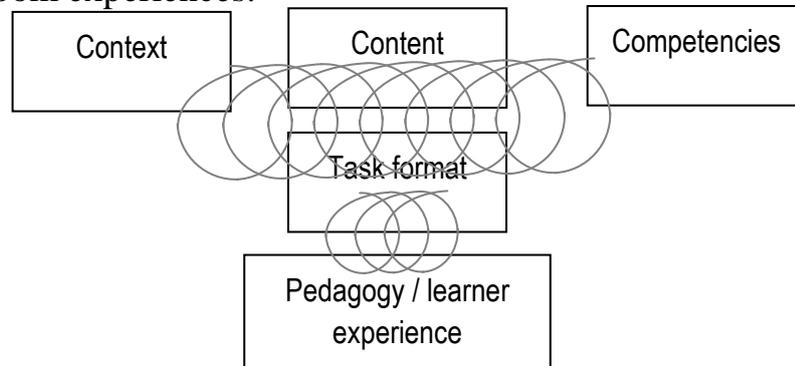

Figure 1. School mathematics domain (Wake, 2010) based on PISA analysis (OECD, 2003)

The influence of the OECD international comparative study (PISA) that has over recent years measured student performance at age 15 in mathematics, science and literacy has been important in informing curricula design across nations (Grek, 2009). This is the case in England where in 2007 (QCA, 2007) a new national curriculum for all subjects was introduced. In mathematics this gave greater prominence to competencies / process skills than had hitherto been the case reflecting the greater emphasis given to these by the PISA tests. The key processes of *representing*, *analysing* (using procedures and reasoning), *interpreting* and *evaluating* have been emphasised in relation to a problem solving cycle (see Figure 2) which is based on the modelling schema included in the OECD framework (OECD, 2003).

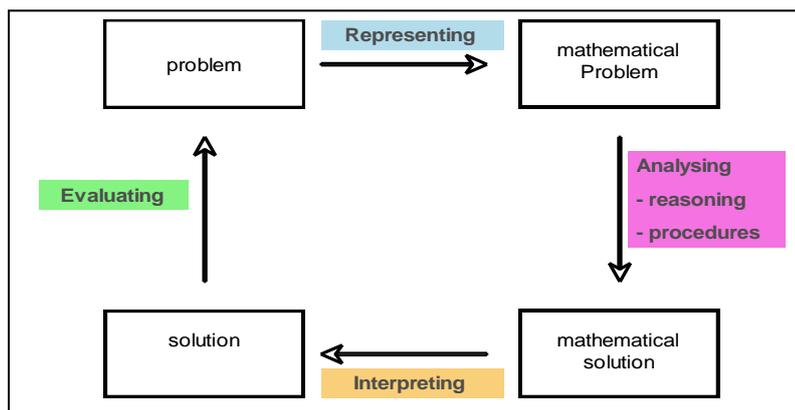

Figure 2. Problem solving / modelling cycle in the English mathematics curriculum

The problem solving cycle as represented in the curriculum is more general than in PISA as it is expected that students could be working in the world of mathematics itself rather than working towards solution of a problem in a non-mathematical reality (as in PISA). The corresponding framework for the scientific literacy domain

equally identifies the importance of the three components; (knowledge /) *concepts*, (processes /) *competencies* and (situations /) *contexts*. As in the case of mathematics, science in the school curriculum tends to focus on content and competencies at the expense of context with the emphasis on the former of these components. In science, discussion of concepts identifies thirteen major and diverse themes ranging from the property of matter to genetic control. Scientific processes are grouped under three main themes: (1) describing, explaining and predicting scientific phenomena, (2) understanding scientific investigation, (3) interpreting scientific evidence and conclusions (OECD, 2003, p137).

In summary, school mathematics and science practices may, therefore, be considered as being culturally and historically situated primarily in the *concept* component of the domain with recent curriculum formulations in England having the intention of shifting the focus to the *competency* component. This shift in focus of curriculum priority suggests a potential way forward in interdisciplinary curriculum design would be to focus on common mathematical and scientific competencies. However, there remains one component of the subject domain that as yet has not been discussed in relation to its potential to support interdisciplinarity: that of *contexts*. This is often neglected in both mathematics and science which, as school disciplines, may be seen as rather abstract areas of study with only hints of their applications and usefulness in contemporary contexts. There have been recent attempts in science to remedy this with courses such as 21st Century Science (Millar and Osborne, 1998) attempting to situate scientific understanding more realistically in the lives of the students who are expected to study this. It should be noted that such courses are not without their critics who see them as diluting true / ‘academic’ scientific knowledge and understanding. The role of *contexts* in the interdisciplinary approaches to be developed is considered important by the COMPASS project that seeks to provide teachers with rich, motivating materials that allow young people to explore meaningful problems in a European context. In other words an important aim of the project is to motivate students by posing problems that can immediately be seen to have importance to young people as citizens of Europe with a concern for their environment and the population that inhabits this.

Overall, then, in designing materials for classroom use in ways that bring together meaningful learning in both mathematics and science as separate disciplines, as well as in ways that makes powerful interconnections, it was the COMPASS group’s desire to pay due attention to each of the components (contexts, content and competencies) of the discipline domain without privileging any one at the expense of the other. In an attempt to do this whilst also addressing the pragmatic issue of providing neutral ground on which mathematics and science teachers might jointly work together we developed the construct of the “bridging concept”. This is an organising structure that draws on mathematical and scientific thinking in ways that provide a way of visualising and understanding how measurable and therefore

quantifiable phenomena (interact or) behave. Importantly, Nikitina's analysis suggests that this is likely to meet with least resistance from mathematics and science teachers who appear to be most comfortable with interdisciplinary approaches of a type that gives prominence to concepts. However, before going on to describe bridging concepts more generally, and exemplify in some detail one such concept, I wish to emphasise that the materials that we eventually produced pay due attention to the other important components of the discipline domains. The bridging concept, therefore, attempts to take a new epistemological approach to knowledge across science and mathematics by looking for ways in which understanding phenomena might be considered as being general and consequently having applications across many situations / contexts. For example, the need to understand how outcomes at the micro-level are scaled up and have implications at the macro-level appears important in many situations. Consider, for example, issues (1) of inoculation against disease: how does an individual's decision to be inoculated or not impact on the likely spread of disease at the level of the population? (2) of the impact of a switch to energy saving devices / equipment such as light bulbs: what are the implications for the individual and for society as a whole? To investigate these problems deriving from context driven issues clearly requires the use of both concepts and competencies from mathematics and science but it is the intention that at a meta-level students also have opportunities to consider how micro-level actions have implications and outcomes at a macro-level. It is the task formulation (Figure 1) that determines how concepts and competencies in mathematics and science will interact. At this stage we have not identified a substantive number of such bridging concepts but the examples and teacher and student reactions that I go on to discuss focus on a further bridging concept: that of *flow*. Again there are multiple needs to understand flow across the different sub-disciplines of science and indeed more widely in technology-based settings: flow is a central characteristic of contexts ranging from electric circuits to ecosystems, from the human heart to tidal estuaries, from solar emissions to traffic management. When linked with flow, the concept of equilibrium is a key to understanding stability in systems as varied as electricity supply, transport, geothermal activity and ecosystems. In summary, therefore, bridging concepts seek to value concepts from both the science and mathematics domain in making sense of phenomena and have general applicability at a meta-level. Importantly they provide a driver to facilitate cross-disciplinary thinking in ways that are deeper / richer than would otherwise be the case. The intention is that the bridging concept gives new insights to teachers and learners alike at how they can use mathematics and science to make sense of a range of issues of importance to European citizens of today and the implications of these for the future.

BRIDGING CONCEPT: FLOW

The materials developed and exemplified here focus on the bridging concept of flow and supported students towards a contextual problem based on flooding. "How can

further disastrous flooding and environmental damage be prevented? – a case study of Lynmouth in Devon, UK.” However, this task comes as the culmination of a substantial programme of lessons in both mathematics and science that focused on key underpinning conceptual understanding. The flow of liquid was central throughout this particular set of materials although at the beginning the need to understand flow as an important concept was motivated by video clips that allowed students to consider flow in the context of traffic and crowd movement. Here due to restrictions of space I will exemplify the teaching materials with reference to mathematics materials only, before returning to consider implementation issues that arise from case studies of classrooms in a number of schools.

The mathematics is organised around two web-based *research environments* or *applets*²⁰ which students are encouraged to use to explore in a systematic way how different parameters affect aspects of measuring / quantifying and controlling flow. These applets model, in an idealised way, situations that the students will need to understand when they come to consider flow in science (for example, how flow is affected by the permeability of materials) and eventually the flow of rainwater that may give rise to flooding. In working with the applets students are expected to *predict – test – explain*, that is, to pose a question and predict the outcome before they use the applet to test this, and then explain why their prediction was correct or not, following the problem solving cycle with questions posed and predictions of outcomes important in concept development.

The first applet “Roof” simulates rain falling on a roof and draining into a blocked gutter. This provides an opportunity for students to come to an understanding that water, being a liquid, can flow from one place to another, and that we can measure / calculate its volume when it collects in a container. This provides an idealised scaled down model of a hillside with rain draining into a river that students will need to consider at a later stage. The applet model assumes that all of the water on the roof drains into a gutter on each side of the roof (Figure 3), and that the gutters are blocked so that all of the water collects there and is distributed evenly throughout the gutter. The gutter is assumed to be horizontal and that the depth of water in all parts of the gutter is the same throughout. The *applet* allows students to vary the total amount of rainfall, the angle of slope of the roof and the width of the house with graphs showing how each of these affect the height of water in the gutter. Using a trace facility allows the user to see how each variable is affected as they alter, using the slider, any one of the parameters between its minimum and maximum values. Although it is possible for students to carry out calculations of area, volume and capacity it is also possible for them to pose questions such as, “What would happen if the width of the house was doubled, multiplied by three, halved and so on?”

²⁰ Currently available at: <http://130.88.43.249/compass/>

A second applet simulates water flowing into and out of different cuboid and trapezoidal containers. In these simulations it is assumed that flow rates are constant throughout and that the containers are horizontal so that depths of water are constant throughout the container at all times. Having selected either a rectangular or trapezoidal container of volume 10, 20 or 30 units, and selected flow rates for water entering and leaving the container, graphs, on one set of axes, can be selected to be plotted of (i) total water flow in, (ii) total water flow out, (iii) volume of water in the container and (iv) total volume of water overflow from the container against time. A separate additional graph of height of water in the container against time is plotted. Again students are expected to explore in a systematic way, and again “predicting – testing and explaining”, how the flow through a ‘container’ is affected by important parameters. This simulation can be used to model water flow through guttering from a roof or from a hilly landscape through a river or drainage channel.

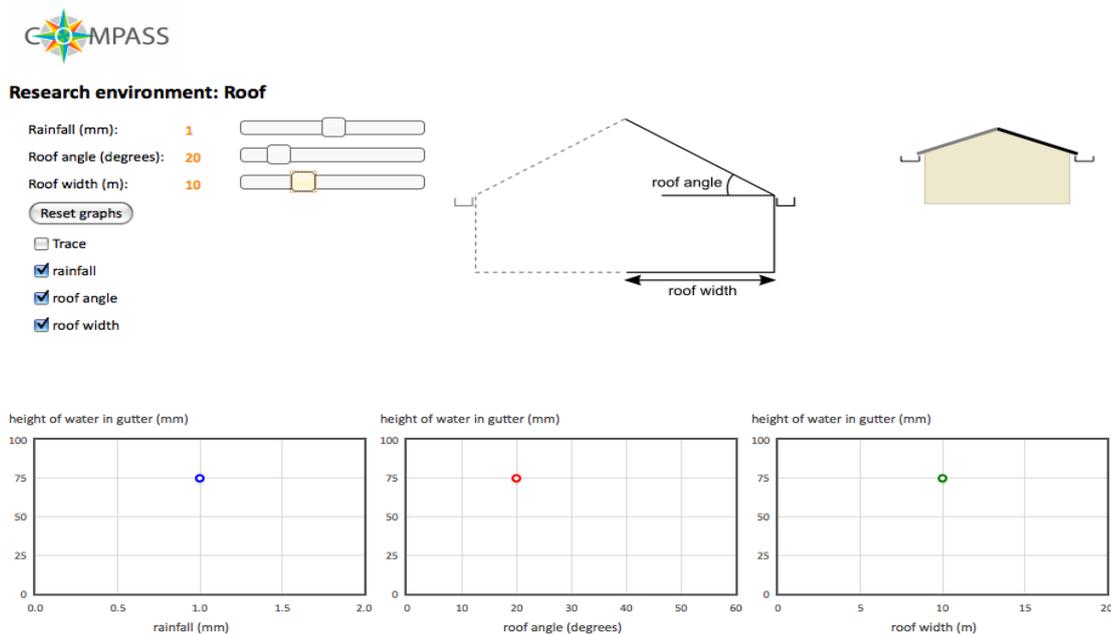

Figure 3. Applet used to investigate the collection of rainwater from a roof

As a final part of the sequence of activities students were asked to engage with a substantial problem that asked them to think about how flooding might be prevented in a valley leading to the sea: this scenario was based on an event in Lynmouth in Devon in 1952 where flash flooding caused substantial damage. Students were asked to use the results of some of the experiments they had carried out in maths and science to give the best possible advice to (a) farmers and others using and draining the land on the moors above Lynmouth; (b) bridge engineers planning to rebuild bridges in the valley; (c) engineers planning how the river should flow through the town; (d) people wanting to rebuild their houses and homes in Lynmouth. It was noticeable that much of the output of the students was descriptive rather than involving calculations. Some of this is shown in Figure 4.

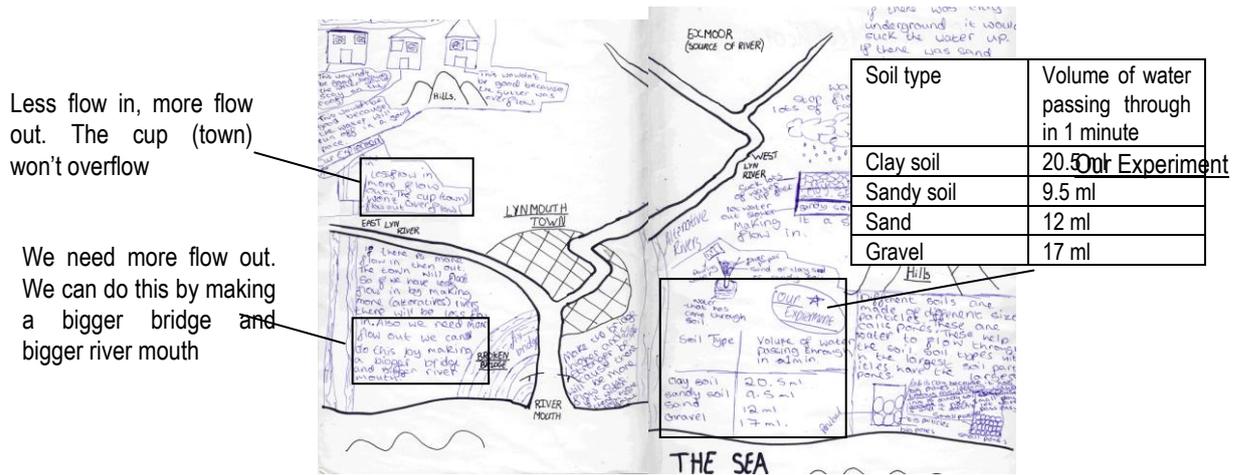

Figure 4. Student accounts in response to flooding problem

In England the approach and materials explained in this paper have been used in a first cycle of development by a mathematics and science teacher from each of eight different schools. The teachers’ work and accounts of their experiences²¹ with their students in using the materials has been facilitated by two days of professional development workshops generously funded by an IMPACT grant from the Science Learning Centre North West: additionally over a period of two weeks each school had the support of a newly qualified mathematics and science teacher. In general each of the schools worked with pupils in both mathematics and science using the materials. The following reflections on the outcomes of this implementation are informed by focus groups that were convened as part of the second of the workshops during which teachers were asked to reflect on nine key areas that explored the design approach and their implementation of this.

REFLECTIONS AND THE ROLE OF MODELLING

In considering the students’ work in mathematics many of the teachers drew attention to ideas of modelling although the applets effectively present them and their students with ready-made models that they were able to use to explore issues that would eventually relate to a more complex reality. This type of exploratory environment, therefore, might be classified as being of the perspective “Educational modelling type (b) conceptual modelling” in the classification system as proposed by Kaiser et al (2007). The applets allow quantifiable aspects of the situation to be varied and the effects of doing so to be explored systematically: however, other potential variables are fixed to ensure a relative simplicity of the model and consequently provide for a didactical focussing on key concepts and competencies. For example, in the use of both applets students were encouraged to “predict-test-explain” with teachers reporting that this enquiry based activity resulted in a much

²¹ These accounts can be accessed at: <http://www.education.manchester.ac.uk/research/centres/Ita/LTAResearch/compass/>

more dialogic classroom with students taking the lead in directing activity and working in collaborative groups. The conceptual understanding of issues relating to flow encapsulated in the applets appears to have been of fundamental importance to students learning to use these to inform their work in science and in tackling the substantial modelling task at the end of the sequence of lessons. Perhaps it is not surprising that students did not focus primarily on quantitative work when a more qualitative conceptual understanding had been sought by asking them to predict outcomes and graphical representations of these when working with the applets.

A crucial question for the design of the interdisciplinary approach I report here is the role that the bridging concept (in this case “flow”) played. In focus group interviews teachers reported that this was important (i) for themselves as teachers because it provided them with a new way of thinking / working together as a team developing a common frame of reference for participants, (ii) for students because it provided a new starting point and setting in which to work with familiar ideas to see things differently, (iii) in mathematics as it involved students in modelling and applications, and (iv) in science because it provided a common overview by which links and connections across the curriculum could be made. It appears, therefore, that the bridging concept provides a boundary object (see for example, Tuomi-Grohn and Engestrom, 2003) at the intersection of the usual formulations of the mathematics and science curricula. It seems that this allows students and teachers means by which they might develop a new epistemology that brings together knowledge and competencies in mathematics and science in ways that interplay with, and reinforce, each other. Our work with teachers and students in schools to date has highlighted that this requires that students have time and space in which they can explore key ideas (in this case related to flow) that allows them to develop conceptual understanding and gives them language and terminology by which they can start to communicate with each other about relatively complex ideas. The applets we developed in the case reported here (and which we have developed for other units of work) appear to provide a vehicle by which students might be able to develop this necessary understanding. However, we note that the understandings developed are indeed at a more conceptual level than merely being quantifiable / calculable. For example, students have considered what might occur if both flow-in and flow-out were doubled without worrying about specific rates of flow. We also note that the modelling work produced by students drew substantially on this conceptual understanding rather than leading naturally to an approach that resulted in careful calculation. We are led to conclude, at this stage, that in developing an interdisciplinary approach to mathematics and science the construct of ‘bridging concept’ is useful as it allows both teachers and students new approaches to developing knowledge that synthesises mathematics and science. In such approaches to learning we have found that students need support in understanding new concepts and language with which to discuss these. We have found purpose built applets that

students can use to explore how varying different parameters can affect a mathematical model of a situation particularly useful. These applets involve students in developing a range of modelling sub-competencies as well as engaging with important mathematical content, providing a playful environment in which a pre-constructed model can be used with purpose to explore potential outcomes relatively quickly. It is to be hoped that these new concept focused approaches in mathematics may ultimately have spin-off as and when students come to build their own, and quantifiable models of situations. In general, therefore, early indications are that bridging concepts have the potential to inform the design of materials that may support an interdisciplinary approach to the learning of mathematics and science content and competencies in meaningful contexts. For mathematics in particular they give a motivating purpose for more conceptual, dialogic classrooms with mathematical models central.

EXPLORING THE SOLVING PROCESS OF GROUPS SOLVING REALISTIC FERMI PROBLEM FROM THE PERSPECTIVE OF THE ANTHROPOLOGICAL THEORY OF DIDACTICS

Jonas Bergman Ärlebäck

Department of Mathematics, Linköping University, Sweden

Abstract: This paper reports on a first attempt to use the notions of 'Research and Study Course' (RSC) and 'praxeologies' within the Anthropological Theory of the Didactics (ATD) to analyse groups of students engaged in the mathematical activity of solving realistic Fermi problems. By considering so called realistic Fermi problem as a generating question in a RSC the groups' derived sub-questions are identified and the praxeologies developed to address these are discussed.

INTRODUCTION AND BACKGROUND

Working with mathematical models and modelling is a central part of the national intended written curriculum for the Swedish upper secondary mathematics education (Skolverket, 2000). Indeed, although without any definitions provided and only implicitly described, the notions of mathematical modelling and models have successively been explicitly more emphasised in the last two curricula reforms from 1994 and 2000 respectively (Ärlebäck, 2009a). Generally however, mathematics education research involving mathematical models and modelling at the Swedish upper secondary level is largely under-researched, and interest in research with this particular focus is just in its infancy. Nevertheless, one of the most palpable conclusions from this initial research is the big discrepancy found between the intended written curriculum and what the students actually attain (Ärlebäck, 2009b). For example, in a study of 381 third year upper secondary students 77 % stated that they never had encountered the notions during their upper secondary education (Frejd & Ärlebäck, accepted). Part of the problematique might be that teachers have difficulties in formulating and explaining their conceptions of these notions (Ärlebäck, 2010), or that mathematics teaching at this educational level in Sweden strongly is influenced by 'traditional' textbooks (Skolverket, 2003) with little or no discussions about models and modelling. However, it has been suggested and concluded that the introduction of, and students' initial conceptualisation of, mathematical modelling (interpreted in line with the written curriculum documents) at the upper secondary level adequately and efficiently can be done using so called *realistic Fermi problems* (Ärlebäck, 2009c; Ärlebäck & Bergsten, 2010). The aim of this paper is to continue, deepen and extend this line of investigation.

MATHEMATICAL MODELLING AND REALISTIC FERMI PROBLEMS

In the research literature in mathematics education there are many different perspectives on and ways to approach mathematical modelling (e.g. Blum, Galbraith,

Henn, & Niss, 2007; Lesh, Galbraith, Haines, & Hurford, 2010). Concepts and notations used are for instance those of *competencies* (Blomhøj & Højgaard Jensen, 2007; Maaß, 2006); *modelling skills* (Berry, 2002); and, *sub-processes* or *sub-activities* (Blomhøj & Højgaard Jensen, 2003). These all focus on the descriptions of, relations between and/or the transitions of phenomena in the real world and their mathematical representations. From a Swedish perspective, the intended written curriculum (e.g. Skolverket, 2000) permits a broad interpretation of the meaning and content of the notions of mathematical models and modelling (Ärlebäck, 2009b). One such interpretation with a real influence on the school practice has been presented by Palm et al. (2004), which is used for the construction of national test items focusing on mathematical modelling [1]. In principle, the interpretation by Palm et al. concord with the view on modelling illustrated in Figure 1.

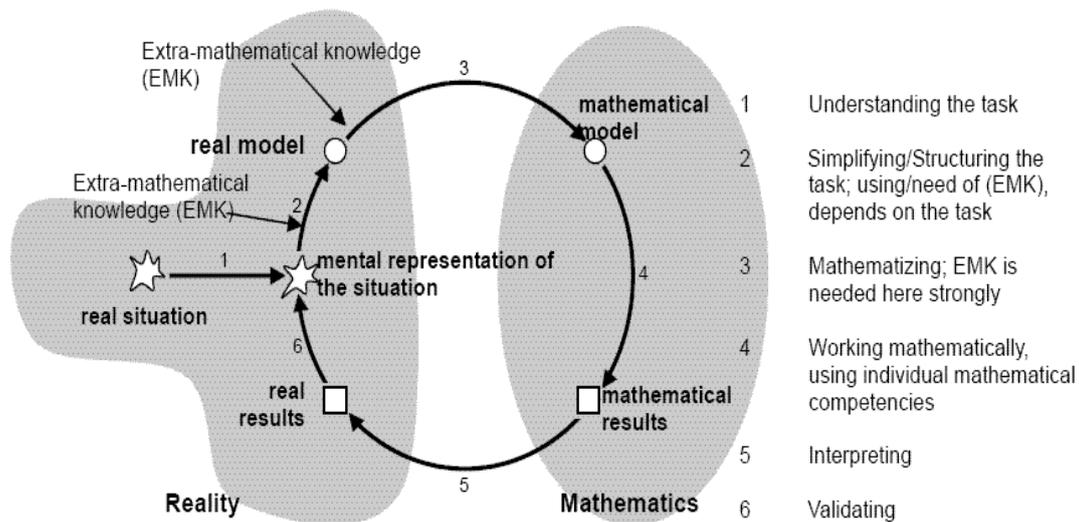

Figure 1: The modelling cycle as presented by Borromeo Ferri (2006, p. 92) after adaption from Blum and Leiß (2007)

Based on this view on modelling Ärlebäck (2009c) and Ärlebäck and Bergsten (2010) explored the idea that so called realistic Fermi problems are ‘modelling problems in miniature’, which potentially could be useful and time effective for introducing some of the typical features of mathematical modelling; see Ärlebäck (2009c) for details. Realistic Fermi problems are characterized by (1) their *accessibility*, meaning that they can be approached by all individual students or groups of students as well as be solved on both different educational levels and on different levels of complexity. Normally, any specific pre-mathematical knowledge is not required to provide an answer; (2) their clear real-world connection, to be *realistic*; (3) the need to *specify and structure the relevant information and relationships* to be able to tackle the problem. In other words for the problem formulation to be open in such a way that the problem solvers not immediately associated the problem with a know strategy or procedure on how to solve it, but

rather urge the problem solvers to invoke prior experiences, conceptions, constructs, strategies and other cognitive skills in approaching the problem; (4) the absence of numerical data, that is the *need to make reasonable estimates* of relevant quantities; and (5) their inner momentum to *promote discussion*, that as a group activity they invite to discussion on different matters such as what is relevant for the problem and how to estimate physical entities (e.g. respectively (3) and (4) above) [2].

The realistic Fermi problem the groups of students solved used in Ärlebäck (2009c) and Ärlebäck and Bergsten (2010) was *the Empire State Building problem*:

The Empire State Building problem (ESB-problem):

On the street level in Empire State Building there is an information desk. The two most frequently asked questions to the staff are:

- *How long does the tourist elevator take to the top floor observatory?*
- *If one instead decides to walk the stairs, how long does this take?*

Your task is to write short answers to these questions, including the assumptions on which you base your reasoning, to give to the staff at the information desk.

The data from three groups of students working on the ESB-problem using only paper and pencils for approximately 30 minutes was analysed using a developed analytical tool called *Modelling Activity Diagram (the MAD framework)*. This framework is inspired by Schoenfeld's 'graphs of problem solving' (Schoenfeld, 1985), the view adapted on mathematical modelling described above, and the five characteristic features of realistic Fermi problems. It pictures the different types of sub-activities the groups engage in during the problem solving process in terms of the categories *Reading*, *Making model*, *Estimating*, *Verifying*, *Calculating*, and *Writing* (see Figure 2 and Ärlebäck (2009c) for details). However, although this macroscopic schematic representation clearly shows that the sub-activities are dynamically and richly represented in the solving process of the Fermi problem (cf. Figure 2), it does not provide any detailed information about what kind of discussions, topics and questions the groups addressed and investigated. In order to get a more nuanced and circumstantial picture of the problem solving process involving realistic Fermi problems in these respects this paper aims to provide a more microscopic analysis focusing on what actually is discussed within the groups, especially in connection to mathematical topics and content. Hence, the research question studied in this paper can be states as follows: *What are the questions the students address during the problem solving process of the EBS-problem? What mathematics do the students use in the problem solving process and how is the use of this mathematics motivated and justified?*

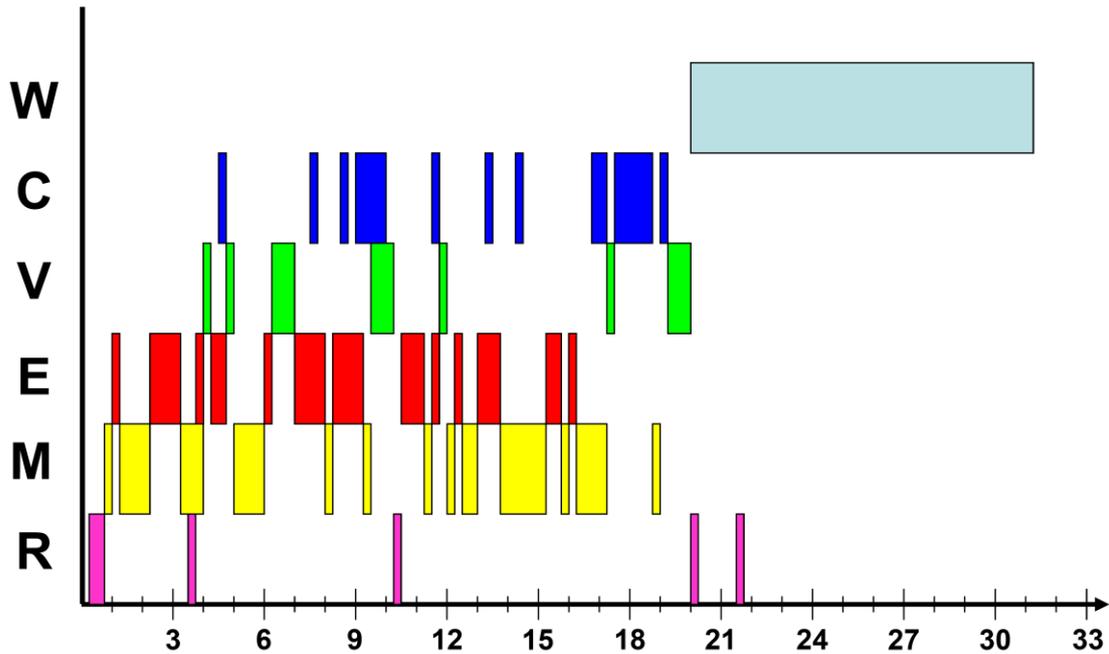

Figure 2: An example of a Modelling Activity Diagram of one of the groups solving the ESB-problem (Ärlebäck, 2009c, s. 346).

THERETICAL FRAMEWORK, METHODOLOGY AND METHOD

This paper uses the notions of *praxeologies* and *Research and Study Course* (RSC) from ATD. Within this framework *praxeologies* are used to describe any human activity in terms of two ‘blocks’: a *praxis* block (‘know-how’ or ‘practical-part’) containing both a designated type of *tasks* and the *techniques* used/needed to complete/perform these; and a *logos* block (‘know-why’ or ‘knowledge-part’) containing the *technologies* that explain, justify and describe the techniques as well as the formal justification of these technologies, the *theory*. As the name *praxeologies* suggests the *praxis*- and *logos* blocks are to be regarded as inseparable (Barbé, Bosch, Espinoza, & Gascón, 2005; Rodríguez, Bosch, & Gascón, 2008).

The notion of *Research and Study Course* (RSC) introduced by Chevallard (2004; 2006) is a general model that can be used for both designing and analyzing learning and study processes. A main emphasis of a RSC is on the *generating question*, Q_0 , which should be intriguing and of genuine interest to the students as well as ‘rich enough’ to encourage the students to derive, pursue and answer dynamically raised and related (sub-)questions, Q_i , in the quest of trying to arrive at an answer to the question Q_0 . In addressing these questions the students have to invoke, use and/or develop one or more *praxeologies*. The derived sequence of sub-questions Q_i and their respective answers R_i are often represented and illustrated in a ‘tree-diagram’ which illustrates the relationships between the different studied questions Q_i ; see Figure 3 for an example.

In terms of ATD the study reported on in Ärlebäck (2009c) and Ärlebäck and Bergsten (2010) can be conceptualised as an investigation of the *didactical praxeology* with the *task* to introduce mathematical modelling to students at the upper secondary level using the suggested *technique* presented by realistic Fermi problems. The issues addressed in these papers, as well as in this one, are concerning the (underdeveloped) *logos block* of this *praxeology*, especially the *technology* part. The ATD concepts of RSC and praxeologies provide theoretical constructs focusing both on what questions the students tackle when solving the ESB-problem as well as how and why. In the notion briefly introduced above the research question(s) studied in this paper can be reformulated as: *Given the ESB-problem as a generating question in a RSC, what sub-questions are addressed by the participating groups of students and what (mathematical) praxeologies are used and developed?* Due to space limitation the main emphasis in this paper will be on the first of these questions.

From an ATD perspective García et al. (2006) have presented a conceptualisation of mathematical modelling which basically equates all mathematical activity with mathematical modelling. In this paper however, the view of modelling is inherited from Ärlebäck (2009c) as briefly described and argued for in the previous paragraph.

To address the research question, widening and deepening the analysis of the groups of students solving realistic Fermi problems, the recorded video and transcribed data from one of the groups used in Ärlebäck (2009c) was revisited and re-analysed. The basic idea was to consider the students' work on the realistic Fermi problem in the context of a SRC as the generative question Q_0 and to see what (sub-)questions $Q_{i,j,\dots}$ this led the students to investigate, and in addition to link these questions the MAD representation of the problem solving process of the studied group. Note that in the ESB-problem the generating question, Q_0 , actually is two questions:

$Q_{0,1}$: *How long does the tourist elevator take to the top floor observatory?*

$Q_{0,2}$: *If one instead decides to walk the stairs, how long does this take?*

The approach taken was in line with Hansen and Winsløw (2010) who make use of the RSC as an analytic model. Focus of the analysis was on the group activity as whole and thus firstly on explicit questions uttered by the members of the group, and secondly on how these questions were addressed in terms the constituents of one or more praxeologies. Although there exist an a priori analysis in Ärlebäck (2009c) identifying some of the questions the problem solvers need to address in order to solve the problem, this paper only focus on the empirical questions actually addressed by one of the groups of students during their problem solving session.

RESULTS

The questions $Q_{i,j,\dots}$ the students derived from the generative questions and examined are presented below in the order in which they were raised and posed during the

problem solving session. The formulations below are in principle the students' own wording; some minor alterations have been made in order to make the actual question intelligible and more concise. Basically the questions $Q_{1...}$ are concerned with the ESB's physical appearance, $Q_{2...}$ address $Q_{0,1}$ (taking the elevator), and $Q_{2...}$ address $Q_{0,2}$ (taking the stairs):

Q_1 : How high is the Empire State building?

$Q_{1,1}$: How many floors are there in the Empire State Building?

$Q_{1,1,1}$: How high is a floor?

$Q_{1,2}$: How high can a general building be?

$Q_{1,3}$: How high was the World Trade Centre?

Q_2 : How fast is an elevator?

$Q_{2,1}$: What is the weight of the elevator?

$Q_{2,1,1}$: How much work is being done by the elevator?

$Q_{2,1,1,1}$: Given the work done by the elevator, can we then calculate its velocity?

$Q_{2,2}$: How long does it take to ride the elevator to Michael's apartment [a friend]?

$Q_{2,2,1}$: On what floor is Michael's apartment?

Q_3 : How tired does one get from walking the stairs?

$Q_{3,1}$: How longer does it take for one floor?

$Q_{3,2}$: How much longer does it take for each floor?

$Q_{3,2,1}$: How long does it take to walk up the first floor?

$Q_{3,2,1,1}$: How fast is normal walking pace?

$Q_{3,2,1,2}$: What is the inclination of the stairs?

$Q_{3,3}$: My [one of the students] mother lives on the fifth floor – I wonder how long it takes walking up the stairs to her place?

The relationships between these (sub-)questions are illustrated in Figure 3. Note that the dotted lines in the tree-diagram display the dependence of the answers R_1 , R_2 , and R_3 respectively with respect to previously answers to questions in the tree. However, due to space limitations, and the fact that the focus of this paper is on the derived questions, these details are omitted here to be discussed elsewhere.

All branches except $Q_{2,1,...}$ represent questions which answers contributed to the solving of the ESB-problem. The branch $Q_{2,1,...}$ is about the classical mechanics concept of work, which the students briefly discuss as one possible strategy to get an estimate for the velocity of the elevators in the ESB.

After having spent about 15 minutes on the problem the group starts working on details concerning their suggested model on how to take the physical exertion into consideration in the $Q_{0,2}$ question. They continue to do this in approximately 4 minutes, before the writing of the letter instructed in the problem formulation begins.

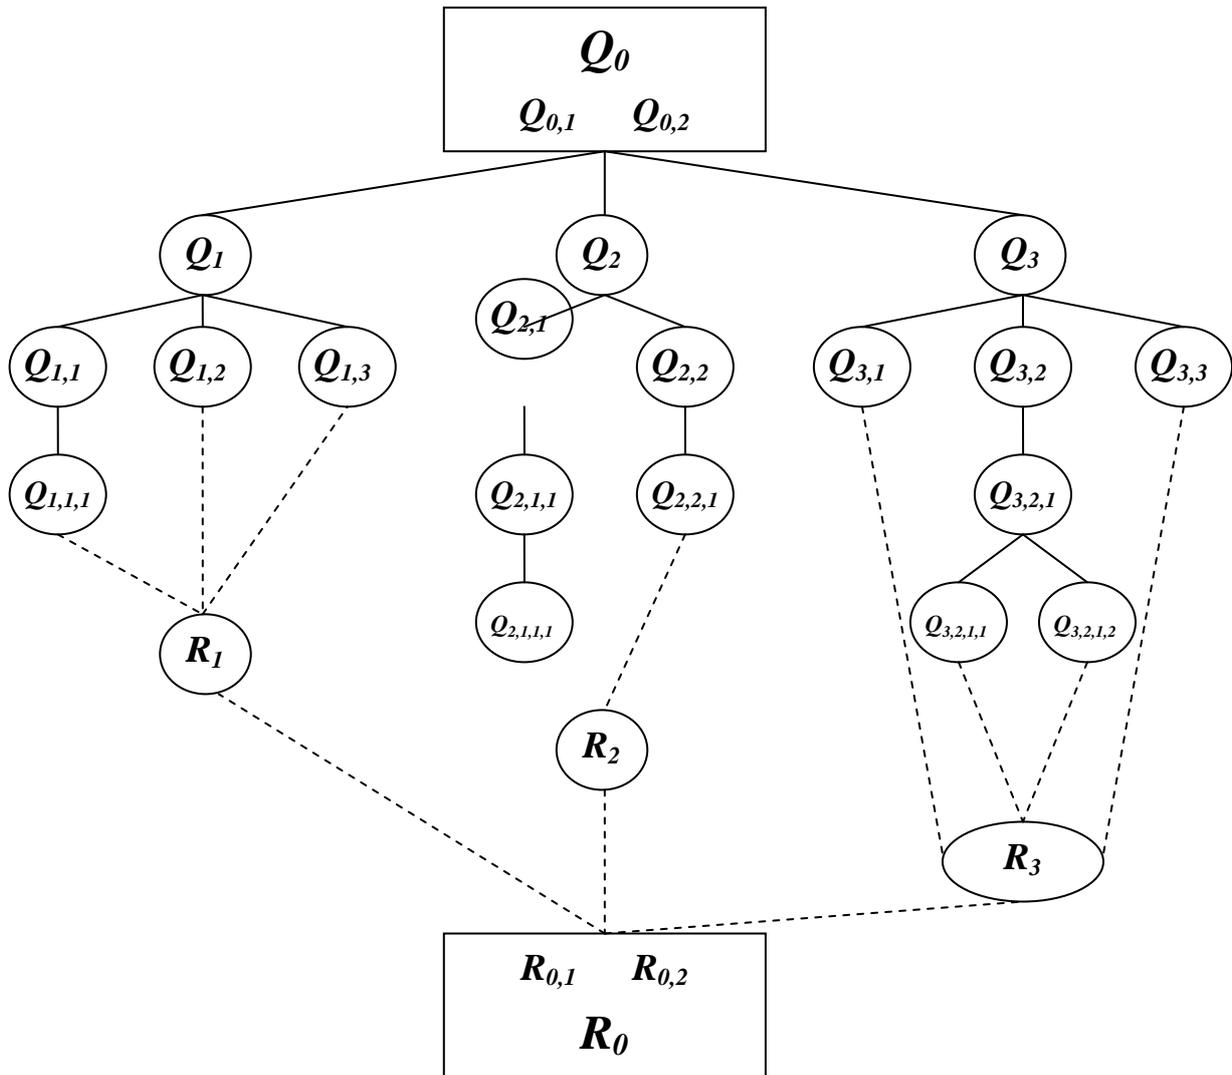

Figure 3: A tree-diagram illustrating the relationship between the questions addressed by the students solving the ESB-problem

Figure 4 illustrates the dynamic aspects of the addressed questions added to the MAD representation of the students' problem solving process. The first time a specific question is explicitly addressed it is preceded by an asterisk (*).

CONCLUSION AND DISCUSSION

One can notice that the actual modelling in terms of discussing, structuring and determining central variables and relationships important for solving the problem is something that is made implicitly and silently throughout the problem solving session. The praxeologies developed to address the questions (*tasks*) $Q_{0,1}$ and $Q_{0,2}$, in fact all three groups in Ärlabäck (2009c) used the mathematical model $t=s/v$ (t being the time, s the distance, and v the (average) velocity) as the basic *technique* to approach the questions. However, the decision to use this model was not explicitly uttered, or in any other way directly communicated, within the groups; it seems that all the participating students took it for granted that this was the model to use to

solve the problem. In other words, the logos of this praxeology is kept hidden. It is possible that this ‘choice’ narrowed the groups’ possibilities to go beyond this model and come up with more elaborated models.

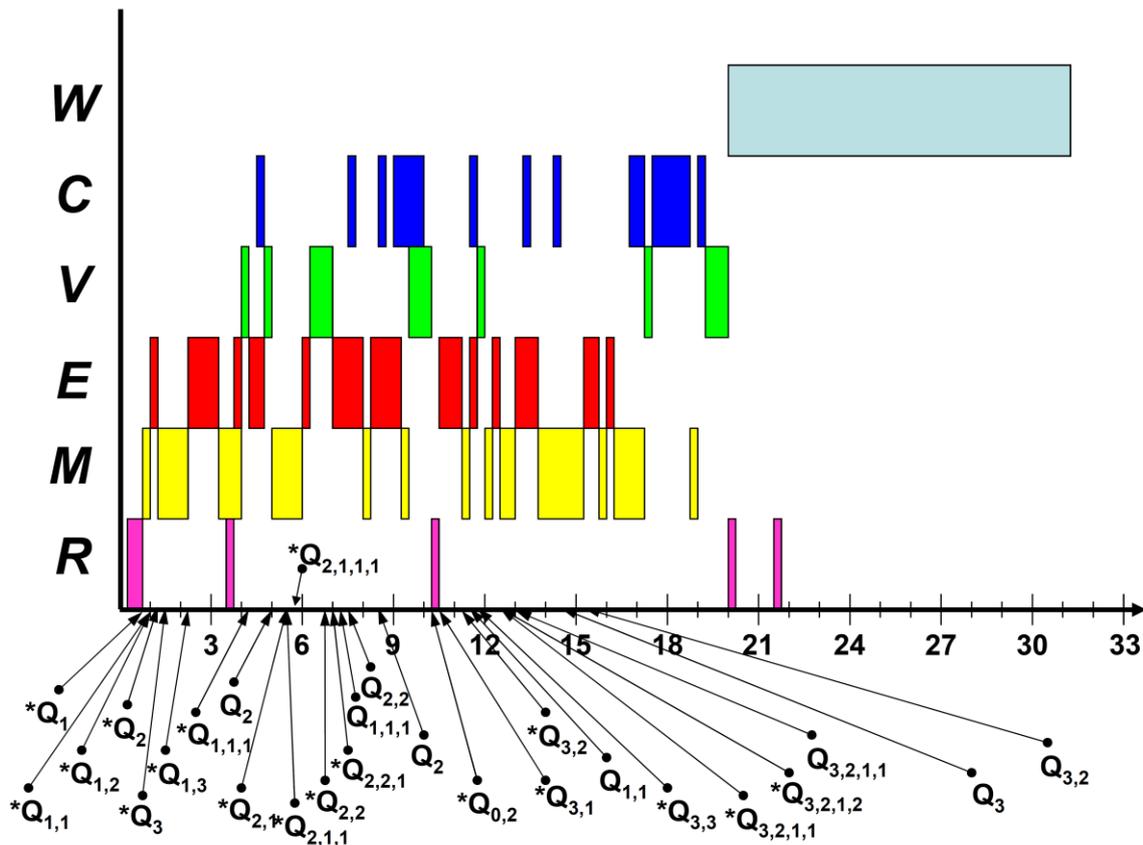

Figure 4: The Modelling Activity Diagram (Ärlebäck, 2009c, s. 346) extended with the order and dynamics of the derived questions in the RSC.

A majority of the praxeologies the students developed made use of estimation as the *technique* to resolve the *tasks* originating from all (but $Q_{2,1,1,1}$ and Q_3) of the derived questions the students engaged in. All these praxeologies have underdeveloped logos and the *technologies* and *theories* invoked to justify and verify the estimates are based on personal and often anecdotal experiences. This is most probable due to the feature of realistic Fermi problem to not provide the students with any explicit numbers to work with. It should be noted that one of the *technologies* applied and made use of to validate the estimate in some of these praxeologies are the same mathematical model as used as the *technique* in addressing $Q_{0,1}$ and $Q_{0,2}$; $v=s/t$.

The result suggests that there are some often used mathematical models, here exemplified by $v=s/t$, which are taken for granted used without second thought and reflection on underlying assumptions, limitations or alternatives. An explanation might be found in the different institutional conditions and constrains where these models are taught, learnt, practiced and applied. In particular, it would be interesting to study the didactical transposition of the notions and use of mathematical models

and modelling to see where these conditions and constraints arise. Though it has proven productive and useful to use realistic Fermi problems for the introduction of mathematical modelling at the upper secondary level, the challenge for the future is to design generative questions in the RSC so that also more advanced mathematical praxeologies are invoked and developed. The RSC ‘allows’ for the teacher to intervene, comment and make suggestions during the course of study, and this presents a possibility to achieve more, and perhaps specific, advanced mathematical content

NOTES

1. For a critical discussion of this interpretation and its possible consequences see Ärlebäck (2009b).
2. For a discussion on the relations between realistic Fermi problems and other characterisations of problems (such as modeling eliciting activities, numerosity problems etc.) see Ärlebäck (2009c).

HYPOTHESES AND ASSUMPTIONS BY MODELLING – A CASE STUDY –

Roxana Grigoraş

University of Bremen, Germany

By going through the mathematical modelling process, students often generate hypotheses and assumptions, in order to follow their strategies and to come to a solution. This generation of hypotheses is investigated by using the Scientific Discovery and Dual Search (SDDS) model. The design of the “Africa task” for a case study aims at stimulating students’ work with hypotheses in an a-priori non-mathematical setting. The students’ mathematical works are investigated with a modification of the SDDS model. This somewhat untypical task leads to assumptions and hypotheses of quite different nature than those one might be used to thinking of, that is, in more traditional tasks within mathematical modelling.

INTRODUCTION

During the mathematical modelling process, students go through distinct phases in the modelling cycle. However, some of these phases interfere with the others (Crouch and Haines, 2004) and some of them are even missing. In this study, we are interested in the process of mathematisation, and particularly in the means by which students express their thoughts and ideas in order to accomplish a mathematical modelling task. Mathematising, as part of mathematical modelling, is the process addressing the transition from a real model to mathematics. The modelling process students go through can be regarded as a path scattered with generation of hypotheses and assumptions, while following certain problem solving strategies.

The emerging hypotheses in students’ work are essentially of different nature than hypotheses in scientific research; like in physics, for example, where stated hypotheses are followed by experiments, and afterwards evaluated, therefore sustained or rejected. Here the students do not check many of these hypotheses, but simply state them and take them as granted. They are either led by intuition or the use of their background knowledge. It could also be that the means for proving does not stay at the students’ disposal, but the agreement in the group and intuition encourage them to go further with their stream of thoughts and ideas. Assumptions represent on the other hand another main component in modelling (Galbraith and Stillman, 2001; Ikahata, 2007), and according to the specificity of the task environment, in this study, their character is more or less mathematical. The model used as framework is applied here on a mathematical modelling task, and the procedure of testing hypotheses, as well as experimental space have atypical behaviour and form, closely dependent on the contextual situation, not following standardised hypotheses checking practices.

Since the current investigation concerns assignments where mathematics is somewhat hidden and no direct calculations are to be performed, the emphasis falls on elaborating strategies for pursuing with the task. Under these circumstances, collaborative working in groups appears fruitful, and students must proceed by loudly expressing their ideas. Assumptions are sometimes not easy to differentiate from hypotheses, thus working definitions for both are formulated in advance.

THEORETICAL FRAMEWORK

On the one hand, the scientific acquisition of knowledge is seen as a complex form of problem-solving, where the problem-solving search takes place in two spaces: in the hypothesis-space and in the experiment-space (Simon, 1981). The SDDS model (Klahr, 2000) supports a structured description of hypotheses in the two spaces, as well as the evaluating evidence that comes in addition to these. On the other hand, the process of mathematical knowledge construction can be described with the help of the epistemic actions (Hershkowitz, Dreyfus & Schwarz, 2001).

SDDS

The Scientific Discovery and Dual Search (SDDS) model is widely used in the area of scientific education; as a “general framework within which to interpret human behaviour in any scientific reasoning task” (Klahr, 2000). A special concern of the SDDS model is the evidence-based description of all aspects in the scientific acquisition of knowledge by the initial hypothesis statement, through the later acquisition of experimental evidences in order to check a hypothesis, and then ends up with a decision as to whether there is enough evidence for checking the hypothesis (Hammann, 2007). The scientific acquisition of knowledge begins with the searching in the hypothesis space, which also assumptions can be part of. Building hypotheses is described as a form of problem-solving, where initially domain-specific knowledge about a phenomenon or process following to be described, are provided. The final product is a tested hypothesis, explained with certain plausibility. Testing hypothesis has as output the description of evidence which sustains, respectively contradicts the hypothesis.

When predicting the finding of some research based on a theory or a logical common sense, a theoretical hypothesis is drawn. When a temporary conclusion is drawn, which will be validated with more data, it is handled with an empirical hypothesis. If an objective reasoning is important, in order to avoid bias, and if data is computed, a statistical hypothesis is formulated (Latief, 2009). More precisely, a theoretical and logical hypothesis can be defined as

[...] a tentative proposition suggested as a solution to a problem or as an explanation of some phenomena. It presents in simple form a statement of the researcher’s expectation relative to a relationship between variables within the problem (Ary, Jacobs and Razavieh 1979, p. 72).

Accommodated for our purposes, context and circumstances, the following working definitions are the basis for our identifications. We denote an *assumption* as being a proposition by means of which a certain thinking path is enabled. Reasons behind the generation of assumptions could be various; the need for pushing forward a stream of thoughts, reducing complexity of a situation, insufficient mathematical literacy or methods and algorithms near at hand, imposing conditions while smoothing the course of some solving. We denote a *hypothesis* as being any statement which is meant to answer a complex question, given a sophisticated situation and whose argumentation requires going through an unpredictable number of steps. Hypotheses differ from assumptions basically in their coherent and self-explanatory action containing it, meaningful by its own, with or without a succeeding proof.

RBC model

The epistemic actions model of abstraction in context (AiC) aims at providing a framework for a micro-level description and analysis of processes of abstraction (Dreyfus, Hershkowitz & Schwarz, 2001). Empirically, abstraction can often be seen in the following “epistemic actions”: *recognising* (R), *building-with* (B) and *constructing* (C) (in the sense of vertical reorganisation of knowledge). These are mental actions by means of which knowledge is reconstructed. Conforming to the RBC, recognising takes place when students detect that a certain piece of knowledge is relevant for the context (s)he is dealing with. Building-with is the action where recognised constructs are combined in order to achieve a specific goal. Constructions are those activities indicating epistemic actions towards mathematical abstraction. The RBC model is used here to verify to which extent knowledge construction was realised by the students. The found constructions were finally embedded in the hypothesis space, that is, some of the hypotheses were identified as constructions.

EMPIRICAL SETTING

A task on a predator-prey situation was designed with the purpose of encouraging students to make statements during argumentation and generate hypotheses and assumptions. Slightly different versions of this task have been developed over time, and the latest version of this Africa task (Grigoraş and Hoede, 2008) is:

In Africa there are territories consisting of three areas. On one side of a river there is an area with grass and trees. On the other side there are two areas, one only with grass, and one only with trees. These two areas are separated by mountains.

There are seven species of animals: antelopes (A), crocodiles (C), Gnus (G), elephants (E), lions (L), monkeys (M) and panthers (P).

Grass and trees grow depending on the rain fall, grass serves as food for antelopes and Gnus, trees give food to monkeys and elephants. Lions feed on antelopes and Gnus, panthers feed on monkeys, and crocodiles feed on Gnus whenever these pass the river.

Gnus pass the river if there is not enough grass.

Working Group 6

Elephants can also pass the river if they want to get to another area with trees, without being threatened by crocodiles.

- 1. In which areas do you think will the species be living? Make a drawing of the situation and indicate by letters where grass, trees, as well as each species is to be found.*
- 2. Group the animals according to properties.*
- 3. Suppose that there is no rain in the area where there grass and trees are. By this, the amount of grass and the number of trees are going down.
 - a. Investigate what is happening with all the species in the three areas.*
 - b. What happens if the rain stops falling in the area where only grass grows?*
 - c. What happens if the rain stops falling in the area where only trees grow?**
- 4. In case the grass is disappearing in the area where there is only grass (case 3.b), Gnus will cross the river and start eating the grass on the other side.*
- 5. Now focus upon grass, antelopes, Gnus and lions: describe your expectation of what will happen with the amount of grass and each of these three species.*

Students – aged 13-16 – of a secondary school worked on the given task, while being organised in groups, in a classroom environment. 7th graders were mainly chosen for the analysis, with some 9th graders also involved, in order to check whether significant differences in their approaches can be observed. Teams of three students were video-taped during working and the teacher had no intervention on the content, unless students had to clarify issues concerning task formulation.

Data analysis

Given the complexity of the task, a fragmentation in smaller pieces of data contained in the formulation or inferred from students' reasoning was realised. The following categories were developed, which distinguish sources of knowledge as follows:

Text information belongs to the real world, and is extracted from the task's text. For reasons of space, just several pieces of the text information are given here, the others can be found in the assignment statement, presented in the previous section. For an easier manipulation in our analysis, the task was fragmented in nineteen pieces (T's):

T₁: In Africa there are territories consisting of three areas.

T₂: On one side of a river there is an area with grass and trees, and so on.

Knowledge of biology/geography/etc. (B's) belongs to real world and represents information showing relationships between concepts used in the task, being mainly background knowledge. It is also possible that some B's overlap or sometimes even contradict with some T's given in the formulation task. Some examples of B's are:

B₁₃: When the grass is gone, then the grass feeding animals are dying, and herewith other animals feeding from the grass feeding animals.

B₁₅: When it stops raining in the area where only grass grows, then all animals die, except monkeys, elephants and panthers.

B₁₆: If it stops raining in the area where trees and grass grow, then after a while they will all get dry.

B₁₇: If it stops raining in the area where only grass grows, then antelopes will also cross the river to the area where grass grows, like the Gnus, and therefore lions will go to that area, too.

We remark at this point that the difference between text information (T's) and biology information (B's) is basically that the text information may trace certain changes, by means of some actions, so that connections between different parts can make sense to be set up. The distinction between some T's and B's (which might be very similar) is done by the context in which B's were expressed.

Logical clauses (L's) belong to the mathematical world and act as kind of 'operators', by means of which logical inferences are achieved:

L₁: $A \rightarrow B$

L₂: Negation

L₃: If " $A \rightarrow B$ " and " $B \rightarrow C$ ", then " $A \rightarrow C$ "

L₄: $x \rightarrow y \rightarrow x$ (if x influences y , then y will influence, in turn, x)

A statement counting as construction in our analysis does not have to necessarily look or sound abstract in the sense of being intangible or imaginary difficult, but realised on a meta-level, so that further cognitive processes are enabled through it.

Constructions: (for reasons of space, just few of the ten C's are enumerated here)

C₅: When there are fewer lions, then there are more Gnus, but then there are again more lions.

C₆: Less rain causes less grass, and therefore also fewer herbivores, namely antelopes and Gnus.

C₇: When grass gets dry off, then Gnus and antelopes do not have food anymore and die off. Then lions and crocodiles die off, too,

The list of suggested knowledge (B's and L's) gets longer with the number of subjects participating in the investigation. The present B's and C's resulted from gatherings of five teams (7th and 9th graders). An increased number of students, more advanced in background knowledge might easily produce considerably more items in number and quality, than the B's and C's delivered in the existing analysis.

There is no space to give all the hypotheses and assumptions found in students' results. Nevertheless, their dialogues abound in hypotheses, while assumptions are significantly less. 'Typical' hypotheses and assumptions produced by students are:

Hypotheses:

Student 1: The lion is by grass and trees, because the antelopes go on the other side, when not having grass there.

Student 2: I would say, by grass – only antelopes, and by grass and trees – Gnus are also coming, because the lions can eat sometimes...

Working Group 6

- Student 3: I would rather write... here... eat grass, eat things from trees... eat Gnus and eat antelopes and make then cross... it is much practical.
- Student 4: The grass gets dry, and then Gnus and antelopes do not have food anymore and die off. When G and A are gone, then L and C die off.
- Student 5: When it does not rain, the trees are getting fewer, and thus fewer trees feeding animals.

Assumptions:

- Student 1: It must be so, that some... to be free from those which do not eat them... this is the feeding dynamic chain.
- Student 2: No, we have to describe that somehow... first by x... remains nothing more to eat, then by y no more food, then by z no more eating...
- Student 3: Yes, but we should restrict only to A, G and L. We should not do with the crocodiles, but only with antelopes, Gnus and lions.

Findings

In the following, we present a scheme to depict the hypotheses and assumptions generated by the students in form of figures, corresponding to every team under investigation. The entire dialogue is part of the hypothesis space, which contains, in turn, experiment spaces as subsets. Combinations of T's, B's and L's, seen as elements of the experiment spaces, lead to hypotheses, some of which are linked to each other, while assumptions act sometimes as junctions. When a certain direction can be defined, either in meaning or time, arrows are also coming along. A possible way to start reading the scheme is, for example, by taking time as backbone (the sense is here inverse clock-wise). The size of the experiment spaces spheres differs just in that they contain more or less dense clustered T's, B's, respectively L's.

Figure 1 displays a rather typical view of an overall picture for the work performed by the young students for the Africa task. The four hypotheses (Hy_1, \dots, Hy_4), which in this case happen to be constructions (C_1, \dots, C_4), are connected in meaning, as it is illustrated in the diagram. Where the main subject of the statements expressed by students gets changed, no edge in the figure appears. If a certain assumption is related to a hypothesis stated previously or afterwards, then this can also be seen in the drawing. But it must not necessary be the case; there could be assumptions whose statements do not come in the logical reasoning of some previous hypothesis, and also do not directly yield the emergence of other hypothesis. A characteristic of this team is the weird way of communicating between students, sometimes the topic changing spontaneously, or some students ignoring the opinion of other colleagues. This is reflected in the 'solitary' hypotheses/assumptions, having no edges with others. It could also be that other peers just manifest the wish of immediately sharing a new idea, and thus a previous discussion gets abandoned. This can be seen in the

diagram, namely where even more isolated tiny systems lie. This particularity is independent of the quality of students' reasoning or the correctness of their answers.

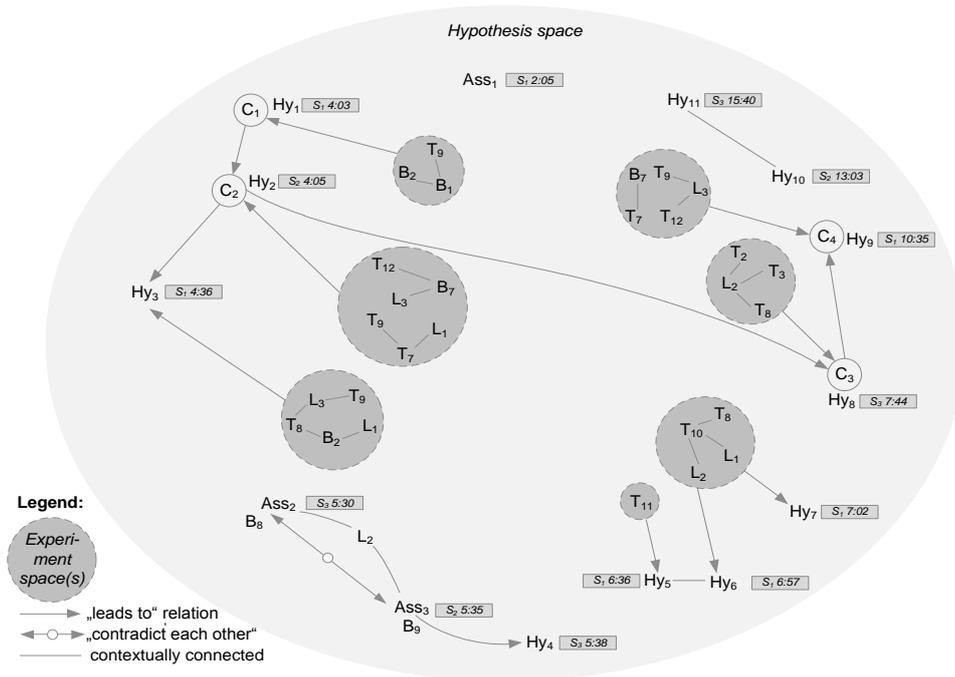

Fig. 1: Hypotheses and assumptions in the 9th graders' team work

As it can be seen in Figure 2, a considerable number of hypotheses are stated, having quite intensive discussions behind (many B's, L's, T's and dense connections between them in most of the spheres).

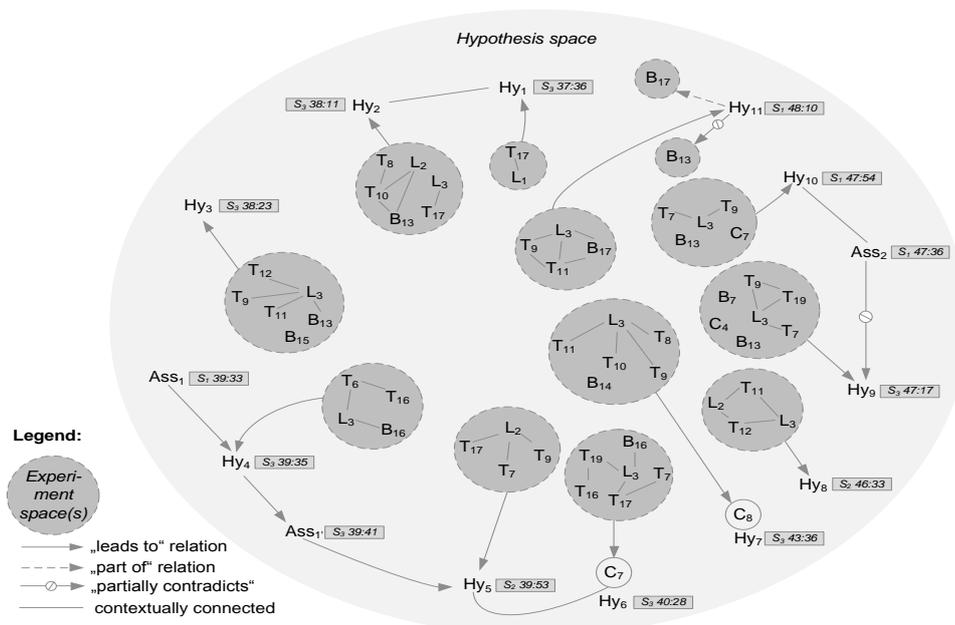

Fig. 2: Hypotheses and assumptions in the 7th graders' first team

The communication between students is well-established and efficiently maintained. Though sometimes certain misunderstandings are occurring in incipient phases of

some key-points of the conversation, they are thoroughly worked out and better ideas are emitted, approved and successfully implemented. The manner in which assumptions are produced, how they relate, sometimes contradicting to each other, as well as the way of leading to hypotheses are clear indications for students working carefully and likely to have previously experienced mathematical challenges. The constructions occurring here do not necessary seem to be decisive for the quality of the team, though some beliefs could speak about a direct proportionality in this regard. The overall work was performed in a rather mature manner and quite some complexity in elaborating strategies emerged, as far as the task allows.

The third team carries, as others as well, features of its quality peers communications. The work was often taken as a game, at least by the leading person. This influenced the results by preventing students from treating the task more thoroughly, and eventually to perform better. Four hypotheses and one assumption needed to be reformulated or rephrased, sometimes more than twice, and this indicates on the one hand uncertainty, but on the other hand consistency and the wish to make things better.

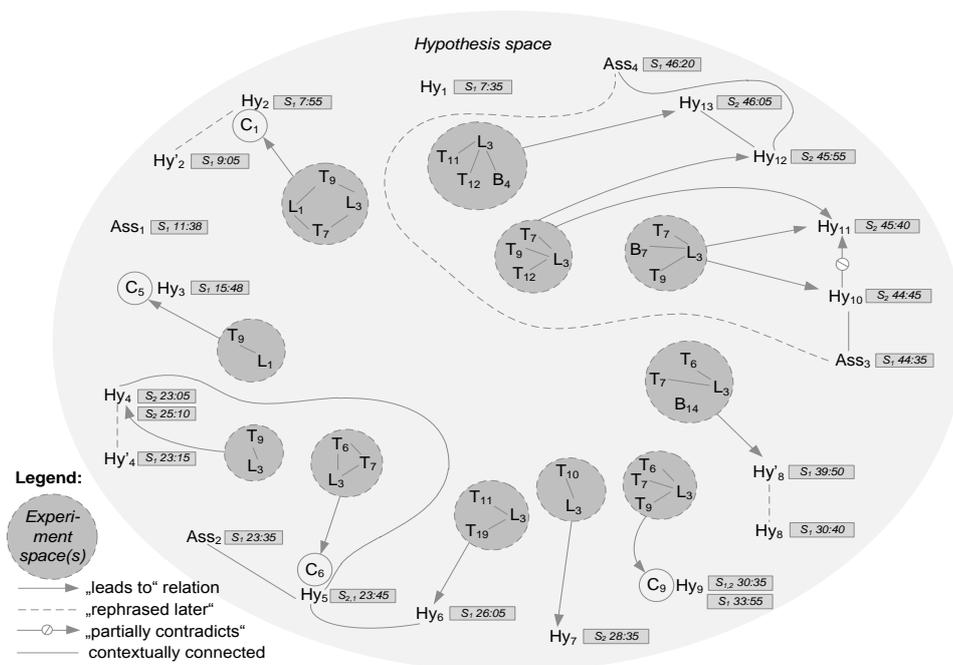

Fig. 3: Hypotheses and assumptions in the 7th graders' second team

The discussions between students are quite intensive; many hypotheses are stated, meaning that ideas are generated, but reasoning is not realised by means of an extensive number of assumptions. It is also the nature of this particular task, which does not necessary ask for imposing special conditions, in order that the reasoning process follows smoothly, and the answers to the posing questions to be found. The emitted hypotheses are tested through repetition, then expecting feedback, respectively confirmation from the other colleagues of the team. Quite particular in the working of this group of students is the way how they approached the last

question of the problem, and namely how they understood to discuss what happens “only with the three species of animals”. The specification given in the formulation, that just the three species (antelopes, Gnus and lions) are the object of investigation, created some confusion and efforts of handling the problem, because the requirement could not be achieved without involving other aspects, namely that crocodiles influence what happens with the Gnus. On the one hand, the impossibility of answering the question without considering other aspects was continuously sustained by one student. On the other hand, another colleague argued loudly for the denial of even mentioning other pieces of information than the required ones. These two opposing ideas met in a conflict, highly voiced, but nevertheless students maintained their collegial relationship. It was in fact controversy content versus form, and the noisiest ‘advocate’ finally won, namely the supporter of the second idea.

DISCUSSION

Since hypotheses are sometimes hardly distinguished from assumptions, the SDDS model does help pointing this distinction while following the groups’ dynamics. When trying to map the empirical results to a SDDS diagram, some conclusions can be drawn, specific to the particular task it is worked with. The entire path covered while coming to a solution is a continuous hypotheses launching, which would fit to a searching hypotheses space. This seeking is done concomitantly with experimenting, i.e., testing hypotheses by continuously checking given information, as well as information obtained from these (T’s and B’s). The experimental space is formed by the logical block (mainly having at least one L), where the generation of hypotheses allows going deeper in the logical world, and staying in the same space. When nothing more in the direction of a hypothesis can be done by the students, then new interpretations take place and new logical constructs are attempted. These logical considerations are not always concluded as constructions (in the sense of the RBC theory), thus not all the hypotheses are regarded as constructions.

The assumptions are being conceived when changes in the model space are implicitly required, meaning that discussions get to such a point where no decision seems to be possible or agreed on. Sometimes assumptions opposing to each other are pronounced, then one of them is adopted, and afterwards a next hypothesis follows. Many hypotheses are tightly linked, like students’ thoughts rowed in a chain. The search hypotheses space cannot be separated from the space where testing hypotheses is acquired and hopefully achieved. The first space is containing the other space, since the components which help finding the hypotheses are the same by means of which hypotheses are tested, namely T’s, B’s and L’s. In fact, testing takes place through posing rhetorical questions, a proper combination of the background knowledge, which permits drawing satisfying (from a students’ point of view) conclusions. Evaluating evidence seems to be part of the testing hypotheses, and in

case agreement on certain hypotheses is performed, then no later contradictions, as result of evaluating evidence, are met.

Since operating with hypotheses is basically part of researchers' scientific work, one can ideally say that within every student lies a possible future scientist. 7th graders produced more elaborated results than the 9th graders, collaboration within the team being the main reason for it. They manipulate their own statements in no predefined and much more elaborate manner, but mainly on intuitive basis. Nevertheless, surprises in this regard are not excluded; novices are handling empirical and theoretical hypotheses (according to Latief's typology), and if properly challenged, it might be surprising how mature and constructive students' approach could become.

INTRODUCTION TO THE PAPERS OF WG 7: MATHEMATICAL POTENTIAL, CREATIVITY AND TALENT

Leaders: Roza Leikin (Israel) rozal@construct.haifa.ac.il
 Demetra Pitta-Pantazi (Cyprus),
 Florence Mihaela Singer (Romania),
 Andreas Ulovec (Austria)

SCOPE AND FOCUS OF THE WORKING GROUP

The purpose of the WG was to raise the attention of the mathematics education community to the field of mathematical potential, creativity and talent, and to promote empirical research that will contribute to the development of our understanding of the field.

The WG aimed at international exchange of ideas related to the didactics of teaching highly able students as well as the promotion of creativity in all students. Part of the discussion was focused on the ways that lead students to discover and realize their mathematical talents and develop their mathematical creativity. Special attention was devoted to activities which are challenging, fundamentally free of routine, inquiry-based, and rich in authentic mathematical problem solving.

The WG addressed the ways of identifying mathematically gifted and creative students as well as the relationship between exceptional mathematical abilities, motivation and mathematical creativity. The WG participants paid special attention to teacher education aimed at mathematics teaching that encourages creativity and fosters mathematical talent.

Finally WG members discussed interculturally- and culturally- related aspects of creativity and giftedness.

Twenty-five participants from 14 countries took part in the Working Group.

In what follows we describe the main topics for discussion that were suggested by group leaders and some outcomes of these discussions.

Topic 1: Theoretical foundations of mathematical talent and creativity

Discussion on *theoretical foundations of mathematical talent and creativity* attended definitions and origins of creativity and of mathematical talent. Additionally, this session was devoted to questions of how to identify mathematically creative and talented students.

The study by Kontoyianni et al. served as a basis for the discussion of modelling mathematical giftedness through the design of a theoretical model. This model, which was based on previous theoretical works, was put into practice using large-scale empirical research. The paper by Leikin and Kloss offered a starting point for discussing theoretical models of creativity and their implications for empirical

research. The choice of a research paradigm for empirical investigation was found to be a basic element in the performance of empirical research. Brandl's model of mathematical giftedness was designed based on a variety of educational theories and paradigms. This work led to discussion of whether each theoretical model should be tested empirically and to what extent empirical investigation performed by a researcher should be analysed by means of the theoretical model he/she designed.

Discussion outcomes

There was general agreement among group participants that the definitions of creativity usually depend on the context. Giftedness and creativity are expressed in extraordinary performance in problem solving. At the same time, problem posing can be a powerful tool for identifying mathematical creativity and giftedness. Moreover, problem posing can be considered as an essence of mathematics and, in contrast to problem solving, it facilitates better evaluation of elaborative acts.

The participants suggested that a characterisation of mathematically gifted students can be devised by asking expert mathematics teachers to distinguish between children who are good in math and those who are absolutely amazing. The teachers can be asked:

- What is the essence in this child that a teacher remembers for years?
- What is it that makes one certain student so special?

The group agreed that mathematical talent can rarely be identified using one (relatively short) specific test. Our assumption was that a combined test (e.g., combining achievements, personal traits and creativity) would have to be employed. We assumed that good questions and unique ideas raised by the students are probably indicators of their giftedness. However, the following question remains open:

- What are the predictors of mathematical giftedness and talent?

Topic 2: In-depth empirical studies on creativity and its development

Three papers served as starting points for the discussion of empirical studies on creativity, its development and investigation of giftedness. This session ended up with more questions than answers.

The paper of Kattou et al. presented a complementary part of the study presented by Kontoyianni. This study presented empirical testing of a theoretical model in which mathematical creativity is considered as a predictor of mathematical ability. The results of testing 359 elementary school students in Cyprus using two instruments showed that mathematical ability may be predicted by mathematical creativity.

Levenson introduced the concept of collective creativity that was devised through empirical investigation of problem-solving directed at the development of creativity in elementary school students. We asked:

- How can this construct be used by other researchers?

Working Group 7

- Does it characterise the work of professional mathematicians, or is it useful just on the level of elementary school mathematics?

We assumed that collective creativity does not necessarily lead to construction of shared mathematical meaning by a group of students since only few students can be participating at one time in this collaborative process.

Based on the paper by Levav-Waynberg et al. participants discussed the possibility of developing creativity in groups of students with varying abilities. The studies in Levav-Waynberg et al. demonstrated that development of mathematical creativity is significant not only in groups of high-achievers but also in groups of mid-achievers. Based on this study the following question was raised:

- What is a reasonable balance between qualitative and quantitative studies in the field of creativity and giftedness that can lead to a better understanding of these phenomena?

Other questions emerged from the discussions:

- What is the relationship between high ability and creativity?
- How can creativity be developed in each and every student?

Topic 3: Mathematical activities aimed at developing creativity and promoting mathematical giftedness

Two sessions of the WG were devoted to the mathematical activities that are aimed at Development of Creativity and Promoting Mathematical Giftedness. We discussed papers by Aizikovitsh-Udi and Amit; Kyriakides; Maj; Novotná and Sarrazy; Singer, Pelczer and Voica; and Sophokleous and Pitta-Pantazi. We also learned about the NRIC project that was presented by Hewson and McClure.

A variety of creative ideas about developing mathematical creativity and the ways of working with gifted students were presented during two sessions of the WG. The discussion focused on ways of realizing students' mathematical potential including:

- teaching high-achieving students,
- promoting and fostering creativity in the mathematics classrooms,
- presenting mathematically challenging activities: non-routine, inquiry-based, and authentic mathematical, problem posing; and
- enhancing teacher education.

When discussing didactical principles of working with highly able students the participants made distinctions between the affective, social and cognitive domains. Among others, the following issues were found extremely important in discussion of the education of students with high mathematical abilities:

- When designing programs for highly able students, mathematics educators should be concerned with the social consequences of treating able children

Working Group 7

differently. If these children are offered the same curriculum as everyone else, there is no point in placing them in separate groups. Ability grouping requires offering a qualitatively different curriculum.

- The interdisciplinary and multidisciplinary nature of the curriculum for mathematically gifted students is an important principle in the education of the gifted, since spending a majority of the time on mathematics could inhibit them from doing well in other subjects which they might otherwise excel at.
- The culture of the classroom/school for highly able students must have very well trained teachers and a culture in which ability is celebrated.
- Acceleration and in-depth programs have to be suited to individual differences among students, especially concerning the affective dimension.

Still, several questions were asked which require further discussion:

- Should the teacher of gifted students be gifted, or is it enough to be highly competent?
- What kind of didactical contract can best fit the needs of high ability students in mathematics?
- What kind of didactical contract can best promote creativity in all students?

Topic 4: Culturally dependent and intercultural aspects related to the development of creativity in school mathematics and supporting mathematical giftedness:

Following the paper by El Yacobi “Mathematical Creativity: Impediments and Challenges for Africa”, the group devoted one of its sessions to discussions concerning ways for developing creativity and fostering mathematical giftedness in schools in different countries. Participants developed a system of criteria for analysis and comparison of national school policy, the role of textbooks, management of special frameworks, and teacher education. We hope that this system of criteria will serve as a starting point for the international study in which the group participants take part.

INTEGRATING THEORIES IN THE PROMOTION OF CRITICAL THINKING IN MATHEMATICS CLASSROOMS

Einav Aizikovitsh-Udi, Miriam Amit

Ben Gurion University, Beer-Sheva, Israel

The present paper addresses the question of whether critical thinking can be most successfully taught in specialized courses (known as general skills approach) or by way of integration in the curriculum of regular courses (known as the infusion approach). Arguing in favour of the infusion approach, the paper discusses the possibility of integrating this approach with taxonomies of critical thinking. The qualitative data analyzed in the paper were obtained in a two-year experimental teaching of the learning unit "Probability in Daily Life." The unit was specially modified for teaching critical thinking in the infusion approach, while using as well as actively teaching Ennis' taxonomies.

Key words: teaching critical thinking, critical thinking taxonomy, infusion approach, teaching probability

INTRODUCTION

The field of education has recognized for decades the need to concentrate on the promotion of critical thinking (CT) skills. The question is how this can be best accomplished. Some educators feel that the best path is to design specific courses aimed at teaching CT, which is called the *general skills approach*. By contrast, integrating the teaching of these skills in regular courses in the curriculum is known as the *infusion approach*. The question at the heart of the argument is, whether CT skills are general or depend on content and on the system of concepts specific to that particular content. According to Swartz (1992), the infusion approach aims at teaching specific CT skills along with different study subjects, and instilling CT skills through teaching the set of instructional material. Swartz also emphasizes that the students should not only employ CT skills in class, but also be able to activate them in real-life situations and to recognize situations when these skills should be used. For this, an appropriate motivation should be fostered; otherwise these skills will remain passive.

The study on which this paper is based was conducted according to the infusion approach. We have combined the mathematical content of an existing learning unit "Probability in Daily Life" (Lieberman & Tversky, 2001) with CT skills according to Ennis' taxonomy, and restructured the curriculum. Further we tested different learning units and evaluated the participants' CT skills, to examine whether the modified learning unit "Probability in Daily Life," taught in the infusion approach, does indeed develop CT (Aizikovitsh & Amit, 2009).

The Defining Components of the Theoretical Framework

This section presents the three fundamental components that this research is based on: Ennis' taxonomy, the modified "Probability in Daily Life" learning unit, and the infusion approach.

The Infusion Approach

In light of the evidence that has accumulated in the field of teaching thinking, the question arises whether thinking skills are general or content-dependent (Perkins & Salomon, 1989). Out of this question there developed four major approaches: the general approach, the infusion approach, the immersion approach, and the mixed approach. The general approach teaches thinking skills as a range of general skills detached from other study subjects, as a separate course in the curriculum. In the infusion approach the skills are taught in the framework of a specific study subject, and thinking turns into an integral part of teaching specific materials, while general principles and terminology of thinking are explicitly emphasized. In the immersion approach, the study material is taught in a thought-provoking way and the students are "immersed" in the topic of study, without explicit reference to the principles of thinking. The mixed approach combines the general and the infusion approaches

Ennis' Taxonomy

Ennis (1987, 1991) claims that CT is a reflective and practical activity aiming for a moderate action or belief. There are five key concepts and characteristics defining CT: practical, reflective, moderate, belief and action. In accordance with the categories this definition employs, Ennis developed a taxonomy of CT skills that include both an intellectual and a behavioural aspect. In addition to skills, Ennis' taxonomy also includes dispositions and abilities. In this study, we focus on students' abilities rather than their dispositions. We have chosen to use Ennis' definition and taxonomy of CT because it distinguishes between abilities and dispositions, and because teaching thinking skills according to a taxonomy suits the hierarchical structure of our learning unit in probability studies.

The Learning Unit "Probability in Daily Life"

This unit in probability studies is part of the formal high school curriculum of the Israeli Ministry of Education. It was chosen because its rationale is to make the students to "study issues relevant to everyday life, which include elements of critical thinking" (Lieberman & Tversky 2001, Introduction p.3). In this unit, students must analyze problems using statistical instruments, as well as raising questions and thinking critically about the data, its collection, and its results. Students learn to examine data qualitatively as well as quantitatively. They must also use their intuitions to estimate probabilities and examine the logical premises of these intuitions, along with misjudgements of their application. The unit is unique because it explores probability in relation to everyday problems. This involves CT elements

such as tangible examples from everyday life, evaluating reliability of information, accepting or dismissing generalizations, rechecking data, doubting, and comparing new knowledge with the existing knowledge. This unit is characterized by questions such as “Define the term ‘critical thinking’,” “Give examples of a problem while using a controlled experiment,” “Give examples of failures and misleading commercials,” and “Give examples of a scientific truth that was dismissed.” While studying the subject, the connection is checked between statistical judgment and intuitive judgment, and intuitive mechanisms that produce wrong judgments are explored (Aizikovitsh & Amit 2009). While studying the unit, students are expected to acquire the tools for CT. In the beginning, students learn the mathematical tools necessary for performing calculations, and later on they use the probability part: causal connection, and mechanisms of intuitive judgment, which are considered more of a psychological projection.

METHOD

The instructional model consisted of a learning unit (30 hours) that focused primarily on statistics in everyday life situations. This unit was first implemented in an interactive and supportive environment for a class of mathematically gifted youth participating in the *Kidumatica* project at the Ben Gurion University of the Negev.

Seventy-one students between the ages of fifteen and sixteen participated in the first round of the experiment, an extra-curricular program aimed at enhancing the CT skills of students from different cultural backgrounds and socio-economical levels. Probability lessons were combined with CT skills, taught by several teachers, with most teaching done by the presenting author. Among the topics taught were bi-dimensional charts, Bayes’ formula and conditional probability. CT skills, such as raising questions, searching for alternatives and doubting, were evaluated quantitatively, using Cornell tests (Ennis, 1996, 2005) and the CCTDI test (Facione, 1992), as well as qualitatively. The present paper discusses the qualitative findings.

As sources of qualitative data, we used students’ products (papers, homework, exams etc.), pre and post questionnaires, personal interviews, and class transcriptions. Five randomly chosen students were interviewed individually at the end of each lesson and again one week after the final class of the course. The personal interviews were conducted in order to identify any changes in the students’ attitudes throughout the academic year. All lessons were video-recorded and all public dialogue was transcribed. The teacher also kept a journal (log) on every lesson. Data was processed by means of qualitative methods intended to follow the students’ patterns of thinking and interpretation with regard to the material taught in different contexts.

QUALITATIVE FINDINGS

Twenty-seven interviews related to critical thinking were conducted with the students towards the end of our course, in order to closely examine their personal

attitude towards mathematics, critical thinking and the development of thinking, and to reveal the students' thinking patterns in their interaction with "Probability in Daily Life" and mathematics. The interviews allowed to create a direct, open and flexible dialog with the students, which provided an additional source of information for evaluating their critical thinking abilities. An additional body of findings is derived from the group discussions aroused by the learning unit, which shows the centrality of critical thinking in everyday life. With this set of findings, as with the others, the purpose of the analysis was to examine the students' patterns of critical thinking in the mathematical, social and cultural contexts. In the course of teaching the unit, we have interviewed a number of students and asked them a number of questions concerning critical thinking. During the interviews we have identified a number of recurrent elements presented below. The interviews were of two kinds: closed/structured interviews, where questions were composed in advance, and open/semi-structured interviews, where questions were also composed in advance but selected and/or modified according to the interviewee's answers. In all of the interviews, three main elements recurred throughout the students' answers: the usefulness of critical thinking as an instrument for life and learning; the importance of critical thinking as a more empowered attitude towards authoritative sources of information and opinion; and finally, the role of critical thinking in promoting the students' general understanding of the world.

The Findings of the Structured Interviews

To the question, "*What is critical thinking?*" or the prompt "*Critical thinking is...*," the students gave the following answers, which define critical thinking in three main dimensions: as a tool they can use in life and studies, as an attitude towards authority and sources of information, and as a way to improve their general understanding of the world. The answers that define critical thinking as a useful tool would say, for example:

It's something for which you need to use your brain properly. Something about critique. For instance: an ad in a newspaper that is not true. [B536]

To know how to check findings, opinions, reliability; to research, to doubt. [R505]

Not to trust everything [you hear], to check before you decide. Not to believe any odd survey [right away]. To think about every thing. [A847]

The latter definition brings forward a strong aspect of critical attitude towards authoritative sources of information, as does the following one: "In my opinion, the importance of critical thinking is that you don't take everything they tell you for granted, but check whether it's true and whether it's possible that the person who is explaining is wrong, and you accept mistakes."

Working Group 7

Yet another extensive definition focuses on the critical attitude towards information sources, but also makes a strong emphasis on the role of critical thinking in learning to understand the world better:

Often I used to see only the external aspect of things and wouldn't really see what they are about. All of a sudden things become explicit, something lights on me, and it has to do with understanding. When I understand something, it also helps me to understand myself better. I have a greater power. When we studied investigation, I felt that my voice was becoming strong. [I could ask,] Who is doing the research, how many people, what are the purposes? I got power out of understanding, to understand more things better. [E886]

The aspect of empowerment acquired by mastering critical thinking should be noted here as well.

Also the following definition, "Every time I study, I discover new things, things are becoming clearer to me" [A427], focuses on the aspect of improved general understanding that critical thinking provides. Another student says, "If we didn't have critical thinking we wouldn't be able to understand well" [Y318]. Finally, one student defined critical thinking as "A way of life" [E886],

While the students' answers elude going into a detailed analysis, they do capture the all-encompassing influence of acquisition of critical thinking on the students' lives and perception of the world.

To sum up, *the main elements in the students' definitions of **critical thinking*** are as follows:

- (i) Openness to a variety of opinions and ideas;
- (ii) Serious consideration of other points of view;
- (iii) Suspension of judgment when evidence and arguments are insufficient;
- (iv) Consolidating or changing an opinion when evidence supports doing so;
- (v) Looking for precision in information, searching for reasons and arguments, examining all the possibilities.

Answers to the question "*Who is a critical thinker?*" are closely related to the definitions of critical thinking itself, but also add an important dimension of personal wisdom and intelligence as traits closely associated with critical thinking, as, e.g., in the following answers:

A critical thinker knows how to examine things, put things into question, to go deep and think about what s/he sees. [R505]

A critical thinker for me is an intelligent person, with a lot of world knowledge and life wisdom, which they can draw on when they are thinking critically about what they read or what they get. They also need mathematical thinking. [S210]

Working Group 7

To sum up, *the main elements of the students' definition of the **critical thinker*** are as follows:

- (i) Someone who tends to shape, correct and change their beliefs in light of convincing arguments.
- (ii) Someone who is capable of understanding at least two opposing, well-defined points of view on the same subject while maintaining one's own standpoint regarding the subject.

In answering the question "*In what ways can critical thinking be developed?*" the students emphasized learning from other people, reading, and the importance of patience and perseverance. One student said it can be "learned from reading books, criticisms, articles, listening to other people's opinions. In researches they discuss methods that one can examine" [R505]. Another student emphasized the challenge that learning and practicing critical thinking poses, and the importance of insistently pursuing it:

What's interesting about critical thinking is that at first everything is very difficult and complicated, and then, when you peel off leaf after leaf, you discover some little treasure; at first it seems very complex, so you need to remember that all the time you need to keep exploring, because as long as we go on it becomes more and more beautiful. [E886]

In their answers to the question about the ways of developing critical thinking, the students named three main abilities that need to be developed:

- (i) The ability to distinguish between opinion and fact: the difficulty of distinguishing between utterances expressing the position of the speaker/writer on a certain reality, and the expressions of facts/events comprising this reality.
- (ii) The ability to identify information intended to influence the reader emotionally, such as using emotional manipulation as a means for presenting an argument and persuading the reader.
- (iii) The ability to recognize stereotypes and avoid using them: it is difficult to identify overgeneralization that leads to stereotyping and is likely to create bias and acceptance of a stereotype as a scientific fact.

DISCUSSION

Acquisition and construction of higher-order thinking skills by students in general and mathematics students in particular has become one of the main targets of the education system widely accepted by educators around the world. The acquisition of these skills will enable the student to function as an active and productive citizen, and the challenge at present is to find ways of teaching and developing this approach not only in the excellent students but in the total population of students in schools.

Working Group 7

Higher-order thinking involves applying many different criteria that frequently contradict each other, as well as self-regulation of thinking processes (independence of others at every stage of thinking). With the qualitative methodology we have chosen for this research, it was possible to examine these different aspects from several perspectives that enabled observation and interpretation of the educational reality in each group and conducting direct dialogue with the research participants (Tsabar Ben Yehoshua, 2000). Thus it became possible to point out several tendencies that became apparent during the research.

Analyzing the findings, we have arrived at the following insights regarding the process of critical thinking skills construction and teaching:

- (i) It seems that critical thinking skills do not develop spontaneously and that even good students acquire them by means of explicit instruction. This finding is in direct opposition to Zohar's claim (2000) that learning skills and learning strategies develop in the student spontaneously, without direct instruction. The findings suggest that being familiar with the taxonomy of critical thinking skills has a potential to improve the students' success at acquiring and perfecting them.
- (ii) To a large extent, the construction and teaching of critical thinking skills are determined by specific contents and tasks the teacher uses. This finding corresponds with other researches, such as Bransford (2000). In this research, Ennis' taxonomy of skills enabled the researchers to choose skills most suitable to be taught at each stage of the course, with respect to the contents and the increasing difficulty level of the learning unit.
- (iii) It is possible to significantly influence and change the mathematical discourse in the classroom and the students' language of critical thinking, by providing appropriate conditions and terminology as well as using appropriate instruction methods. In the literature, this finding applies not only to older and/or more successful students, but also to younger and/or underachieving ones (Weinberger, 1992).
- (iv) Excellent students (the *Kidumatica* group) were capable of operating a greater number of skills automatically, quickly, utilizing a minimal degree of conscious effort. However, this automatic application of thinking has only been acquired after much practice and exposure to different learning contexts. What is more, even expert learners are likely to return to a much slower and more conscious way of learning when confronted with unfamiliar tasks or connections.

However, it has to be recognized that providing a systematic terminology for describing thinking skills is far from exhausting the problematics of teaching critical thinking. For instance, Resnick (1987) expresses a different view, namely, that it is difficult to define higher-order thinking skills, but easy to recognize them when used by someone. She believes that higher-order thinking is not algorithmic, and that thinking patterns are not clearly defined in advance. This type of thinking often

concludes with multiple solutions, each of which has its advantages and disadvantages, but does not yield a single clear solution. High-level thinking has to do with skills in solving problems, asking questions, thinking critically, making decisions and assuming responsibility (Ben-Chaim, Ron & Zoller, 2000; Zoller, 2001).

Decision is an essential part solving a problem that involves a gap between an initial situation and a final goal and there is no easy, well-known way of finding a solution. Nonetheless, based on the findings of this research, it seems that conscious learning and explicit discussion of thinking skills in the context of mathematics enables the students to more efficiently develop these skills by way of solving probability problems. This type of learning emphasizes the development of specific skills in the process of solving mathematical problems. The small-scale research described here constitutes a small step in the direction of developing additional learning units designed to develop critical thinking skills within the traditional curriculum.

CONCLUDING REMARKS

This paper has focused on the qualitative findings of our research, which are supported by quantitative findings presented elsewhere (Aizikovitsh & Amit 2008, 2010). The analysis of CT skills and dispositions tests and math tests the students took revealed the following improvements

- (i) In all three iterations of this research design, a moderate improvement has been detected in the critical thinking dispositions of all experimental groups. This improvement may be attributed to maturation and accumulating life experience as well as learning proper. All of these are significant factors affecting the development of the students' critical thinking, particularly within the framework of probability.
- (ii) Throughout these iterations, a moderate improvement was also detected in the students' critical thinking abilities. As in the case of dispositions, this improvement can also be ascribed to maturation, accumulating life experience, knowledge in other mathematical fields (e.g. geometry contributes to the development of deductive skills), and learning proper.

Thus, the findings of this research suggest that when teachers consistently and explicitly emphasize specific critical thinking skills, the students are more likely to succeed in developing them.

HIGH ATTAINING VERSUS (HIGHLY) GIFTED PUPILS IN MATHEMATICS: A THEORETICAL CONCEPT AND AN EMPIRICAL SURVEY

Matthias Brandl

Chair for the Didactics of Mathematics Faculty of Philosophy University of Erlangen-Nuremberg

There is a big difference between high attaining and (highly) gifted pupils in mathematics: first, being gifted in mathematics does not necessarily lead to high assessment in this subject; second, being high attaining in mathematics does not necessarily mean being mathematically gifted – depending on the context in which the notion of mathematics and the concept of mathematical giftedness is socially constructed. Based on a conceptual approach from systems theory, a model for the causality of giftedness and assessment is presented and supported by an empirical survey among teachers at a higher secondary German boarding school for high attaining pupils.

Keywords: mathematical giftedness, high attaining, systems theory, teacher interview

INTRODUCTION

For the purpose of fostering gifted pupils, the identification of those comes first. There has been done plenty of research emphasizing the quantitative aspect of different kinds of tests that historically range from a solely IQ-test over bringing in school marks up to modern multidimensional settings (Heller et al., 2000; Pfeiffer, 2008). However, in day-to-day school life there is one dominant (non-) identifier and fosterer of giftedness, for example, in mathematics: the teacher – and because of the viability of the construct, the teacher's idea of mathematical giftedness (MG) may differ from that of parents or professional mathematicians.

In order to make up a custom-made material-based program that suits the predominant concept of mathematical giftedness at a specific German school for high attaining pupils, the manifestation of the construct MG at this specific school and its difference to high assessment in mathematics were investigated by qualitative teacher interviews. Furthermore, a suitable theoretical model of mathematical giftedness is provided. Within that, MG is constructed by an ambivalent environment. As this environment on the one hand consists of (the viable notion of) mathematics and on the other hand, amongst others, of the educational system with its specific schools and mathematics teachers, the degree of being gifted in mathematics depends strongly on the maths teachers notion of mathematics.

Both exceeding and specifying the research question of identifying mathematically gifted pupils hitherto, is another question addressed here, too: How can the really

mathematically gifted ones be identified in a group of just and indeed mathematically high attaining pupils? Are there any characteristics that – again, in the teacher’s eye – distinguishes the gifted from the (just) high attaining ones? Those aspects that can be found out by qualitative single case interviews (as it was done here), may deliver aspects for the development of more quantitative orientated tests for samples already containing only high attaining test persons.

MATHEMATICAL GIFTEDNESS

There are several concepts on giftedness. Mathematical giftedness (MG) is even more controversial as on the one side there are authors objecting to the existence of a specific MG (a. o. Fölsch, 1977; Treumann, 1974) and on the other side other authors testify this specific disposition based on empirical evidence (a. o. Greenes, 1981; Kruteskii, 1976; Kießwetter, 1992; Käpnick, 1998). We stick to the latter ones and see MG as a synergetic potential that consists of two different aspects: a) abilities specific to mathematics and b) general personality traits. An incomplete list of items is given in figure 1.

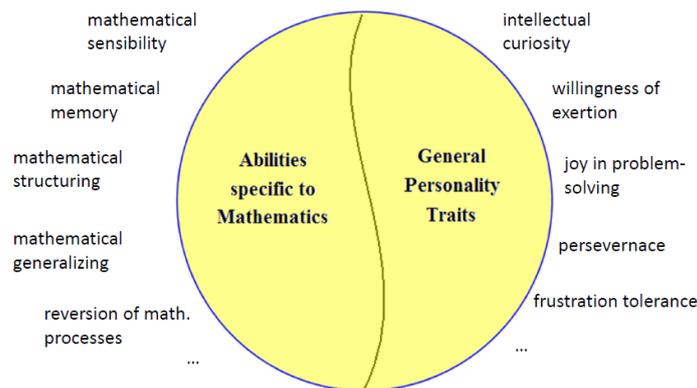

Figure 1: Mathematical Giftedness: abilities and traits.

An approach via Systems Theory

Because of the apparently vagueness of the concept MG, a conceptual approach by terms of systems theory was given in Brandl (2010) that is based on the “Law of cultural differentiation“ (Irvine & Berry, 1988) and the so-called anthropological approach (Sternberg, 1996). Therein the system MG is seen as an open mental disposition construct surrounded by the environment mathematics which features necessary structural couplings between the system and its environment that describe the influence of predominant philosophical notions about mathematics on a conception of mathematical giftedness. Mathematics represents “environment 2” that “is the world that creates sense for the system.“ (Krieger, 1996, p. 81). The further environmental factors that affect the system MG in a competitive way, too, but which do not necessarily endow the system with meaning or sense, are collected in „environment 1“ (figure 2).

Working Group 7

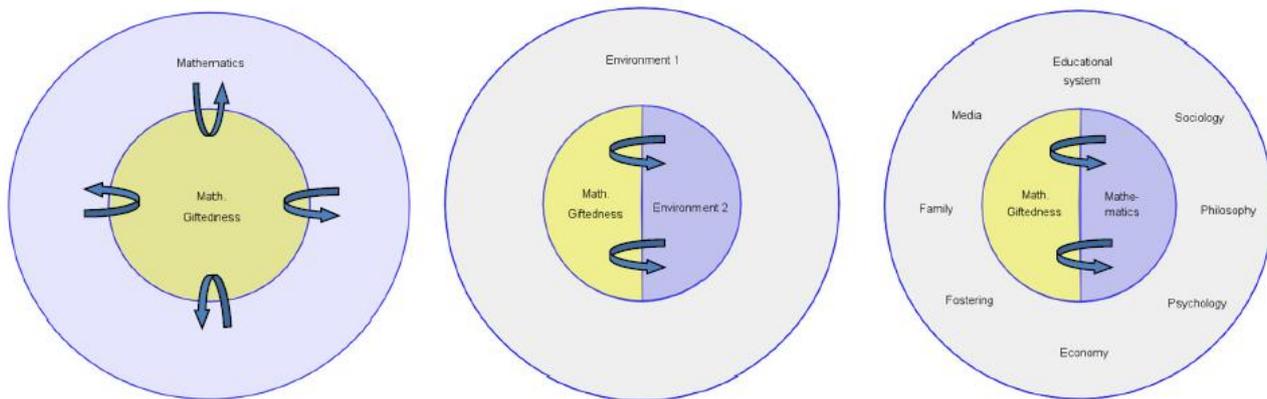

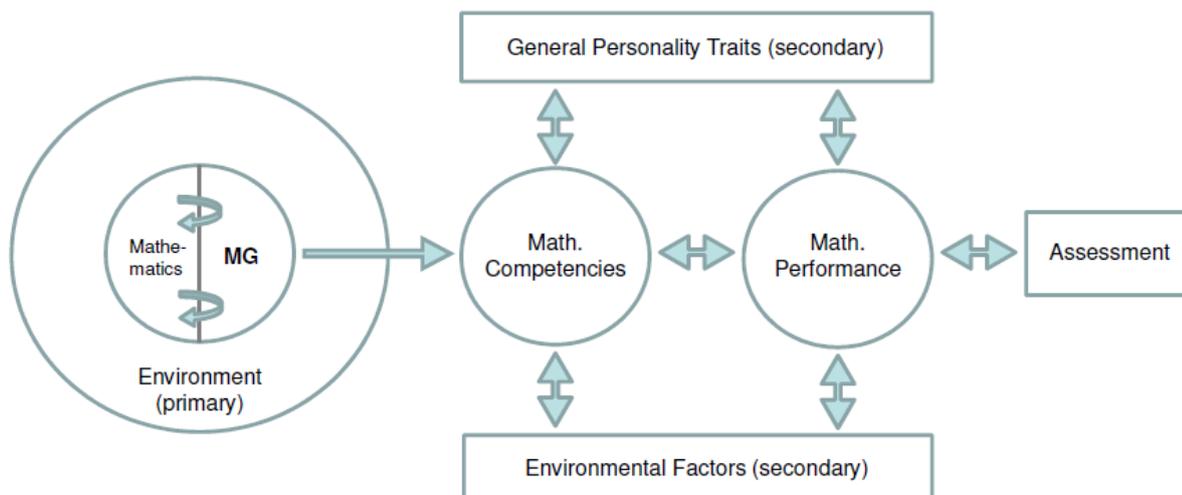

Figure 2: System MG and environment(s) interacting by structural couplings.

So MG manifests in different kinds and shapes depending on the notion about mathematics and the current state of the discourse concerning the authorities in environment 1. These items can only be detected by entering the field, like a certain school, and investigating the predominant notions and characteristics by qualitative and quantitative methods. Hence, the question “Is this person mathematically gifted?” should be altered to the question “Is this person mathematically gifted *within this specific environment(s)?*”.

Causality of Giftedness and Assessment

In general, the system MG – as illustrated in Figure 1 and 2 – is seen as an individual potential for excellent assessment (Heller et al., 2002; Ulm, 2010). According to Ziegler (2009) a high attaining pupil is a person that fulfils a fixed criterion of achievement. So, in the first place, excellent assessment of a pupil in mathematics is measured by the teacher via recognizing very good marks in mathematics, for example.

A further developed model coming from the models in Heller et al. (2002) or Ulm (2010), respectively, for the causality between pupils’ MG and assessment which includes the systemic character, is given in Figure 3. The open mental construct MG that already contains some primary general personality traits (figure 1) depends on a predominant notion of mathematics in a certain situation which is located in a primary environment, the so-called environment 1. A person that possesses that kind of MG can develop mathematical competencies which may lead to mathematical performance and assessment. The actual formation of an observable performance as well as competencies is influenced by some secondary general personality traits (such as learning and working strategies, learning and working motivation, ability to concentrate, stress coping skills, ...) and secondary environmental factors (such as familial learning environment, teaching quality in class, atmosphere in school and class, peer group, critical personal experiences, ...) which operate as moderator variables.

Fig

Figure 3: Causality between MG, competencies, performance and assessment.

As indicated in figure 3 there is no equivalence between performance and MG: the arrow from MG to mathematical competencies only points in one direction. However, a well-known example for the fact that all dependences must not be seen as absolute but rather as possible is the (gifted) underachiever: he or she is MG, but his or her secondary moderators let him or her show no performance. On the other hand a high attaining pupil does not need to be (highly) gifted. The environment in his or her school can allow for very good grades in exams and the A-levels, for example, but does that mean that the pupil is a gifted mathematician? Perhaps the tasks the pupil had to solve only aimed at computational skills and did not stress on any kind of creative approaches at all. Of course, this implication depends on how MG is constructed in that specific environment. Therefore in the following paragraph an example from an empirical survey at a German school for high attaining pupils is sketched that gives insight to

- a) the manifestation of MG at this specific school and
- b) the different notions of being high attaining or highly gifted in mathematics from the view of teachers at this specific school.

AN EMPIRICAL SURVEY

Description of field and sample: The school is a German boarding school for higher secondary education. So the pupils at this school are about between 15 and 18 years old. The classes are small and consist of 16 pupils with equally distributed gender. All pupils that want to apply for the school must have at least the mark “good” in the main subjects German, Mathematics, one foreign language and one natural science. Furthermore the average mark in the last two school reports has to be at least “good” as well. Pupils that fulfil the requirements with respect to marks have to pass a further selection process that consists of the intelligence structure test I-S-T 2000 R (Liepmann et al., 2007) and a two-day assessment centre concerning the social skills.

In the intelligence structure test pupils must have a total score that makes sure that the pupils finally selected are gifted in the sense of achieving very high IQ levels¹.

All (eight) mathematics teachers were interviewed in an individual, problem-centred and episodic way with focus on their beliefs concerning their notion of mathematics, mathematical giftedness and the pupils at their school.

RESULTS AND CONCLUSIONS

Transcript excerpts show the predominant concept of MG and different characteristics of high attaining versus (highly) gifted pupils in mathematics.

Quotations from the individual interviews

Within this paper we limit ourselves to the presentation of quotations from two male mathematics teachers and denominate them as A and B. Teacher A is 47 and teacher B 59 years old. Both have worked at the school for six years. Teacher A earned a PhD in a non-math subject and had a several years experience of working with gifted pupils before entering the current school. Teacher B had worked as a teacher abroad. Both of them had worked at different secondary schools before entering the current school. The interviews lasted 55 and 26 minutes, respectively. Quotations from teacher A and B were chosen out of the eight interviewed ones for presentation in this paper because of their relative similarity, openness and extensiveness. But as there is no right or wrong but only *the* specific and viable construct of MG this is no restriction according to the theoretical background.

Teacher A: notion of mathematics

When it comes to their notion of mathematics, teacher A addresses several aspects. His answers can be separated according to different topics. So, the themes are listed, followed up by some quotes stemming from the interviews²:

- leisure: “[...] thinking it over relaxed and quietly, this and then concentrating on it, that gives a better return”
- philosophical thoughts: “[...] it must make sense. I mean that philosophically, too. Because you said what pupils should answer to what is mathematics. Yes. (.) That is a matter of taste either way, but that it makes sense somehow.”
- communicative process: “Mathematics is a communicative process.”
- logically clearly defined and also communicative intellectual game: “I hope they don’t see mathematics as deterrent but as (.) a logically clear defined (.) and also (.) communicative intellectual game.”
- intellectual appealing world of thought: “[...] as an appealing, intellectually appealing, but that’s also a matter of taste, intellectual appealing mhh (..) world of thoughts”

Working Group 7

- also applications: “That is a matter of taste either way, but that it makes sense somehow. ((hm)) (..) Either just cognitively or by application“
- intellectual joy, happiness: “The goals? ((yes)) Well, that the pupils have intellectual fun [...] Joy, actually that’s the highest goal.“

Teacher A: manifestation of MG

When teacher A is asked for his idea of mathematical giftedness, the interview again delivers some main points:

- intuition; sensing the overall train of thoughts: “Well, I see that in fact that they actually sense the point of it all without that I would have spent many words about the problem. [...] a kind of intuition, aha, so now there is this and that and this. That they sense the overall train of thoughts where the method will lead us”
- interest in alternative definitions and the corresponding consequences: “[...] it is the permanent attempt (.) can’t we play differently? ((yes, yes)) And if yes, where would this lead us to? If no, why doesn’t it work out?”
- aesthetical sensation and joy: “Those have more fun than usual. [...] Over the fact that this is a beautiful construction of the theory ((ah, yes, certainly)) Or: what a wonderful exactness! ((mhm)) So this joy over a good construction [...] they really feel it.”

Teacher A: looking at the structural coupling

Teacher A has a very high-level and sophisticated notion of mathematics. So, for example teacher A emphasises leisure, the communicative process, exactness and intellectual joy. Because of the structural couplings between the system MG and its environment of mathematics this leads to strong correlations with teacher A’s idea of MG. These correspondences are pointed out by colours and arrows in table 1.

<i>Notion of Mathematics</i>	<i>MG</i>
<ul style="list-style-type: none"> • leisure • philosophical thoughts • communicative process • logically clearly defined and also communicative intellectual game • intellectual appealing world of thought • intellectual joy, happiness • also applications 	<ul style="list-style-type: none"> • intuition: sensing the overall train of thoughts • interest in alternative definitions and the corresponding consequences • aesthetical sensation and joy about that

Table 1: Notion of mathematics and MG of teacher A; coloured text parts correspond to each other as also indicated by arrows.

Teacher B: notion of mathematics and manifestation of MG

For the sake of completeness the next summarized quotations give insight to the notion and manifestation of mathematics (first quotation) and MG (second quotation) of teacher B; the main topics are underlined:

Maths: “[...] mathematics brings in a certain kind of systemization. [...] Mathematics: to search for, to see and to analyse structures. [...] They should (.) see that mathematics (.) is the art of looking at the complicated in an easy way. [...] Well, that knowledge to have, or are able to gain, an instrument by which we understand how the modern world operates. [...] But, of course, this is a bit of disenchantment. [...] this balancing act between the two different approaches to mathematics, on the one hand (.) I don’t need illustration at all ((mhm)) in order to design mathematics as just a glass bead game [...] and the other hint that I want to give the pupils: mathematics always was the answer to concrete questions. [...] I think either is important to get across. [...] Yes, it is inspiration and a bit of chaos, of course. Yes ((yes, yes)). And, of course, it is also the possibility, the frustration tolerance, to begin and to throw away ideas, to have ideas. ((yes)) (.) And from this, to see structures suddenly coming out of this confusion, so you can again throw away things and arrange them in a new way ((yes, yes)) Of course, there is a certain kind of joy, too. In this respect then there is something like mathematical beauty, too, of course.”

MG: “[...] those really were satisfied with this (.) highly abstract chapter about vector spaces ((ok)) they took part in and saw some good connections [...] I don’t know if somebody is mathematically gifted. Well, of course, creativity, curiosity (.) plays a role, the ability to think out of the box or to see connections. Hence, the opposite to being uninspired/dutiful [...] what happens really often is that they find solutions to problems that I didn’t expect. [...]”

Teacher A: high attaining pupils

When teacher A speaks of the pupils at his school he gives a good profile of these high attaining ones and their difference to the mathematically gifted. Again, the answers are sorted by main topics followed up by short quotations:

- want mathematics lessons to be done in detail and precisely: “The pupils often say (.) fully convinced: when we do it very accurately then we understand it best. ((mhm, yes, yes.)) This is a very clear statement which I get over and over again every year ((ok)) In all grades. That means (.) mathematical precision for these pupils leads to a better and not a worse understanding”
- want to be active: “In case of doubt they want to be active ((ok)) not hanging around, they are motivated.”

Working Group 7

- are motivated (mainly intrinsic): “Actually, I think it is mainly intrinsic motivation ((hm)) just want to be intellectually active. That’s for sure.”
- are able to work in teams: “Able to work in teams, social cooperation ((yes)) in a positive sense”
- impose an introjected pressure to perform on themselves: “[..] it is a somehow introjected pressure to perform which they impose on themselves, too.”
- have extreme requirements on themselves: “[...] often it is a very high requirement on themselves [...] There are pupils weeping, because they only have the grade “good” [...] That means it is an internal pressure to perform on oneself ((hm)) I wouldn’t say that this is the classical grade pressure ((mhm)) but that these are pupils that partly have extreme requirements on themselves.”
- don’t dare to work independently: “I offer the pupils (.) that when they say they don’t want to take part in class to work independently about this or that mathematical aspect in the library (..) that’s what I offer them, and then do a short talk about it ((yes)) in order to differentiate. I offer that, also in other subjects, I offer that and who doesn’t make use of it? The pupils!”
- don’t want to isolate themselves: “They don’t want to isolate themselves”
- don’t want to miss anything in class: “[...] and, of course, they don’t want to miss anything in class. [...] They somehow don’t dare.”
- do well in all subjects: “The good and very good pupils from advanced math courses at normal schools would do well here especially in maths ((hm)) However, the pupils here do well in all subjects ((ok)) more or less.”
- are less non-conformistic: “Well, the pupils here are not more non-conformistic than at other schools. Not for sure. [...] It’s just the opposite.”
- are interested: “They are interested, they are motivated ((ok)) Let it be whatever it is, just make sure that it is interesting ((ok, hm)) It has to make sense and it has to be interesting”
- are very polite, respectful, sensitive and thus reserved: “On the interpersonal level they are (.) very polite, very respectful, very sensitive ((mhm)) and thus very reserved [...] just because they are so nice and respectful ((yes)) they don’t rebel so straightforward”
- are distinctively stubborn on an emotional an cognitive level: “[...] they are distinctively stubborn [...] in order to convince them to do something in different way or that something is better, you really need telling arguments. They have to be absolutely convincing [...] on the emotional level concerning something, but, of course, just as well when it comes to cognitive things ((ok)) [...] And the same with motivational questions in class. A problem is not interesting as a pseudo problem, it really has to be interesting [...] In this respect: a global stubbornness”

Working Group 7

- are less qualified to be subordinates: “Actually they are less non-conformistic than at other schools ((ok)) but they are less qualified for being subordinates. ((mhm)) Yes. That’s the point”

Teacher B gives some more aspects:

- are teacher-orientated: “I experience the pupils here as interested, teacher orientated, committed [...] The pupils’ expectation is more significant than elsewhere that the teacher is the one, who knows the things and (.) has to find an appropriate way to teach it to the pupils. What I want to say is that they more often are less independent than I would actually wish. [...] They have the potential to work independently, but they don’t dare. [...] On the evaluation sheets that I hand out in every course, I always ask on which content we should have had more concentrated on or what else they imagine. And then surprisingly often there is the answer that I would never have heard at other schools: you will know it best, or, that’s what the curriculum says after all. [...] Well, that objects my experiences which I made at other schools.”
- are very dutiful: “We have many dutiful ones at this school. ((ah, ok, aha)) Probably too many dutiful [...] Many (...) do mathematics, because they know that one needs it and also has to at this school ”
- are resistant to psychological strain: “ [...] and they are (..) resistant to the psychological strain. They take on very much ((ok)) don’t show it as much as at other schools ((ok)) how much they suffer”
- are eager for reliability: “They want the teacher to take the lead, because he knows what’s going on. ((yes)) Especially with ours, who are eager for reliability”
- want to write good exams: “They want to write good exams. [...] they definitely want to do good A-levels.”

Teachers A and B: high attaining versus (highly) gifted in mathematics

We chronologically list the important items that refer to the high attaining pupils at this specific school in table 2 and contrast them to the mentioned (not necessarily additional) characteristics of MG seen by these two teachers.

<i>High attaining pupils</i>	<i>MG pupils</i>
<ul style="list-style-type: none"> • want mathematics lessons to be done in detail and precisely • want to be active • are motivated (mainly intrinsic) • are able to work in teams • impose an introjected pressure to perform on themselves • have extreme requirements on themselves 	<ul style="list-style-type: none"> • have mathematical intuition: sensing the overall train of thoughts • are interested in alternative definitions and the corresponding consequences • feel aesthetical sensation and joy about that more than others • are satisfied with highly abstract

Working Group 7

<ul style="list-style-type: none"> • don't dare to work independently • don't want to isolate themselves • don't want to miss anything in class • do well in all subjects • are less non-conformistic • are interested • are very polite, respectful, sensitive and thus reserved • are distinctively stubborn on an emotional and cognitive level • are less qualified to be subordinates • are teacher-orientated • are very dutiful • are resistant to psychological strain • are eager for reliability • want to write good exams 	<p style="margin-left: 20px;">objects</p> <ul style="list-style-type: none"> • are creative • show curiosity • are able to think out of the box • “see” inner-mathematical connections • find unexpected solutions to problems • are the opposite of being uninspired/dutiful
---	---

Table 2: Characteristics of high attaining and gifted pupils in mathematics as described by teacher A and B opposed to each other.

Conclusion

The comparison of the two columns in table 2 shows well the difference between a high attaining and a (highly) gifted pupil in mathematics the way it is seen by those two exemplary teachers. Most of the aspects listed in the MG column correspond to the items listed in figure 1 both for abilities specific to mathematics and general personality traits. But especially when it comes to the latter ones, there is an overall theme that separates the gifted from the high attaining ones. In the eyes of both teachers, a pupil who is a brilliant mathematician features a specific characteristic that opposes the description of the typical high-attaining pupil: where a less non-conformistic, reserved, stubborn, dutiful and teacher-orientated attitude is typical for high attaining pupils, mathematical excellence results from creativity, curiosity, out-of-the-box-thinking, flexibility and the “opposite of being uninspired/dutiful”. This stands in line with the following quotation from the teacher Carol Fertig at Prufrock’s Gifted Information Blog: “Flexible thinkers go beyond the bounds of orthodox thinking and look for alternatives others fail to see. While rules are used as guidelines, they are not used as straightjackets that curb thinking. Flexible thinkers are those who are creative problem solvers. Flexibility requires that people escape from ruts and try new things. These thinkers are able to shift gears easily. They look for new ideas everywhere. They are not afraid of change.” (Fertig 2007)

Connection to the theoretical background

By the exemplarily examination of two teacher interviews at this specific school for high attaining pupils we could give an answer to the actual manifestation of MG in this special context: both teachers have a very high-level and sophisticated notion of mathematics. Furthermore it was illustrated in the case of teacher A, how the notion of mathematics influences the notion of MG. In system theoretical termini this fact shows the structural coupling between the two systems. Concerning the difference between gifted and high attaining pupils, the interviews clearly showed that there are more and/or other aspects that stand for being gifted in mathematics. Just looking at a very good performance in the subject does not mean that the pupil looked at is a gifted mathematician: the left horizontal arrow in Figure 3 is not reversible! Those aspects may be considered in tests to identify mathematically gifted pupils.

NOTES

1. The fact that a psychologically defined numerical IQ exceeds a certain value does not necessarily imply that this person is mathematically gifted.
2. All quotations from the interviews and discussions have been translated from German into English by the interviewer and author of this paper.

DOES MATHEMATICAL CREATIVITY DIFFERENTIATE MATHEMATICAL ABILITY?

Maria Kattou, Katerina Kontoyianni, Demetra Pitta-Pantazi, Constantinos Christou
Department of Education, University of Cyprus

This paper focuses on the development of a theoretical model in which mathematical creativity constitutes a predictor of mathematical ability. Furthermore, we examine the existence of groups of students that differ across mathematical ability and investigate whether these groups present differences in their mathematical creativity. The study was conducted among 359 elementary school students in Cyprus, using two instruments. The results revealed that mathematical ability may be predicted by mathematical creativity. Moreover, the sample can be grouped in three distinct categories according to mathematical ability. The categories of students also present statistically significant differences in their mathematical creativity, suggesting that the level of mathematical ability depends on the level of mathematical creativity.

Keywords: creativity, cognitive abilities, mathematics.

INTRODUCTION

Creativity has been proposed as one of the major components to be included in the education of the 21st century (Mann, 2005). Therefore, contemporary curricula emphasize the development of students' creative thinking (Lamon, 2003). However, the conceptualization of creative learning varies due to the diversity of the proposed definitions of creativity. In particular, several definitions have been proposed for the concept of creativity; some of the definitions focus on process, while others emphasize the creative product (Haylock, 1987). For instance, creativity has been defined as a continuum of actions, as a process of bringing something new into being (Best & Thomas, 2007). In regard to the definitions that refer to the creative product, fluency, flexibility and originality are some of the commonly accepted characteristics that describe the outcome of the creative action (Torrance, 1995). In contrast to general creative ability, as has been defined previously, Gardner (1993) proposed that every individual has creative potential in a specific domain. Due to this fact, research literature makes a distinction between general and specific creativity (Piiro, 1999), whereas specific creativity "is expressed in clear and distinct ability to create in one area, for example mathematics" (Leikin, 2008).

THEORETICAL FRAMEWORK

Defining mathematical creativity

The lack of a uniform definition of general creativity consequently leads to the dearth of a commonly accepted conceptualization of mathematical creativity (Haylock, 1997). In some cases, researchers move away from mathematics to search ideas associated with creativity in general and then to select those which are the most

relevant to mathematics (Haylock, 1987). For example, the definitions given by Krutetskii (1976), Ervynck (1991), Silver (1997), Gil, Ben-Zvi and Apel (2007) are based on the concepts of fluency, flexibility and originality (Torrance, 1995) in the content of mathematics. In this case, fluency refers to the ability of producing many ideas, flexibility refers to the number of approaches that are observed in a solution and originality refers to the possibility of holding extraordinary, new and unique ideas (Gil, Ben-Zvi & Apel, 2007).

Moreover, several attempts have been made to generate definitions of mathematical creativity. These definitions include the abilities to solve problems and to develop thinking in structures (Ervynck, 1991), to observe patterns (Laylock, 1970), to abstract and generalize mathematical content (Krutetskii, 1976), to discern or choose (Hadamard, 1945), to understand which patterns are acceptable (Birkhoff, 1969) and to make connections between unrelated ideas (Haylock, 1987).

Mathematical creativity and mathematical ability

As Silver (1997) suggested, “creativity is closely related to deep, flexible knowledge in content domains” (p. 750). However, there are conflicting results that describe the relationship between mathematical creativity and mathematical ability: could creativity affect an individual’s mathematical ability or mathematical knowledge may enhance mathematical creativity? According to Meissner (2000), solid mathematical knowledge is essential for the development of mathematical creativity. One important reason for this necessity is the fact that excellent knowledge of the content helps individuals to make connections between different concepts and types of information (Sheffield, 2009). Therefore, students who are characterized by mathematical accuracy and fluency are more able to think creatively in new mathematical tasks by providing original and meaningful solutions (Binder, 1996). Moreover, “creative work involves a certain amount of pre-existing domain knowledge and its transformation into new knowledge” (Nakakoji, Yamamoto, & Ohira, 1999). More specific, prior knowledge constitutes the backbone on which new information will be organised and determines the extent to which these information will be explored (Sheffield, 2009). On the contrary, other researchers proposed that creative potential contribute to the improvement of mathematical knowledge. In Starko’s words (1994) “students who use content in creative ways learn the content well”. The ability to solve a problem with several strategies or the ability to reach different answers in a specific task are valuable evidences of the development of mathematical reasoning (NCTM, 2000). In other words, mathematical creativity “is an essential aspect in the development of mathematical talent” (Mann, 2005, p. 29). The importance of mathematical creativity to mathematical ability is also proposed by Hong and Aquino (2004). In this research, Hong and Aquino (2004) studied the differences between high academically and high creative students in mathematics. The results verified that creative students in mathematics were more cognitively resourceful than their peers who achieved high

grades in school mathematics. On the basis of these results, Sternberg (1999) acknowledged that the essence of mathematics is to apply knowledge creatively in specific circumstances.

PURPOSE OF THE STUDY

Despite the fact that the definitions referring to mathematical creativity suggest important abilities that may consist this construct, there is a lack of corresponding research regarding to the relationship between mathematical creativity and mathematical abilities. Therefore, the purpose of the present study is threefold: (1) to examine the relationship between mathematical creativity and mathematical ability, as they are projected in a theoretically driven model; (2) to trace groups of students that differ across the components of mathematical ability; (3) to investigate differences in creativity between the groups of students that vary in mathematical ability.

METHODOLOGY

Sample

The sample for this study consisted of 359 Grade 4, Grade 5 and Grade 6 students from eight elementary schools in Cyprus. One hundred and forty three students attended 4th grade, while 118 and 98 students attended 5th and 6th grade, respectively.

Instruments

Each student completed two instruments: the mathematical abilities instrument and the mathematical creativity instrument (examples of tasks are presented in Figure 1). The mathematical abilities instrument consisted of 29 tasks measuring the following abilities: manipulation of quantities (quantitative ability), causal relationships (causal ability), visualization and spatial reasoning (spatial ability), processing of similarities and differences (qualitative ability), inductive/deductive reasoning (inductive/deductive ability). Students' answers were assessed as right or wrong. The mathematical creativity instrument included five tasks in which students were required to provide: (a) multiple solutions, (b) solutions that were different between them, and (c) solutions that none of his/her peers could provide. The assessment of students' creativity was based on the distinction of students' fluency, flexibility and originality (Torrance, 1995). A task from the mathematical creativity instrument is presented in Figure 1. In this example, fluency referred to the number of correct responses that students presented. For flexibility, the different types of responses were measured (e.g. whether students used additive or multiplicative structure). Originality was calculated by comparing a student's solutions with the solutions provided by all students and the rarest correct solutions received the higher score. Every component of the mathematical creativity instrument was converted to a score ranging from 0 to 1, with 1 being the highest score.

Working Group 7

	<p>Observe carefully the following solid.</p> <div style="text-align: center;">  </div> <p>If you rotate the solid shown above, which of the following solids could be the result?</p>	
Spatial Task	<div style="display: flex; justify-content: space-around; align-items: flex-start;"> <div style="text-align: center;">  <p>A</p> </div> <div style="text-align: center;">  <p>B</p> </div> <div style="text-align: center;">  <p>C</p> </div> <div style="text-align: center;">  <p>D</p> </div> <div style="text-align: center;">  <p>E</p> </div> </div> <p>A. A B. B C. C D. D E. None of the previous</p>	
Qualitative Task	<p>Twenty passengers travel to Larnaca Airport by bus. Twelve of them carry a travel bag, eleven a computer bag and six people both types of suitcase. How many passengers carry only a computer bag?</p> <p>A. 5 B. 6 C. 8 D. 11 E. 17</p>	
Quantitative Task	<p>George's marbles are three times as many as Spiro's marbles. Andreas has 20 marbles less than George. If Spiros has S marbles, how many marbles does Andreas have?</p> <p>A. $\frac{S}{3}-20$ B. $3S+20$ C. $S+50$ D. $S-50$ E. $3S-20$</p>	
Inductive/ Deductive Reasoning Task	<p>If the suitcase has stripes, then it belongs to Emmanuel. If the bag is yellow, then it does not belong to Emmanuel. The suitcase is yellow. Therefore,</p> <p>A) The suitcase has stripes. B) The suitcase does not have any stripes. C) The suitcase belongs to Emmanuel. D) I cannot decide.</p>	
Causal Task	<p>Inside a vase there are four balls: one yellow, one red, one green and one blue. If I want to pull out of the vase only three balls, by pulling out one at a time, how many different possible combinations do I have? Write down all the possible combinations. (For example I can pull out a red, a yellow and then a green ball or a green, a yellow and then a red ball. These are only two possible combinations, but there are more).</p> <p>A. 6 B. 12 C. 18 D. 24 E. None of the above</p>	
Creativity Task	<p>Look at the following number pyramid. All the cells must contain only one number. Each number in the pyramid can be computed by performing always the same operation with the two numbers that appear underneath it. Fill in the pyramid, by keeping on the top the number 35. Try to find as much solutions as possible.</p> <div style="text-align: right;">  </div>	

Figure 1: Examples of tasks from the mathematical abilities and mathematical creativity instruments.

The two instruments were given in electronic form and students worked individually in the laboratory of their school in order to complete them. The administration time ranged from 40 to 80 minutes.

Data Analysis

The objectives of the analysis were first to verify a theoretical model regarding to the relationship between mathematical creativity and mathematical ability, secondly to trace groups of students that differ across the components of mathematical ability

and finally to examine differences between the groups of students. In regard to the first objective, confirmatory factor analysis (CFA) was conducted in order to assess the fit of the theoretically driven model to the data of the present study. More specific, CFA was used to test whether several observed variables (e.g. fluency, flexibility, originality) may define a latent construct (e.g. creativity). For the purposes of this analysis, the statistical modeling program MPLUS (Muthen & Muthen, 2007) was used. The evaluation of model fit was based on three fit indices: The comparative fit index (CFI), the ratio of chi-square to its degree of freedom (χ^2/df) and the root mean-square error of approximation (RMSEA). According to Marcoulides and Schumacker (1996), for the model to be confirmed, the values for CFI should be higher than 0.90, the observed values for χ^2/df should be less than 2 and the RMSEA values should be close to or lower than 0.08. For the accomplishment of the second objective, latent class analysis was used to explore whether there were different categories of students in our sample whose achievement could vary according to mathematical ability. Once the latent class model was estimated, subjects classified to their most likely class by mean of recruitment probabilities. Afterwards, analysis of variance (ANOVA) was conducted, in an effort to investigate differences between groups of students on mathematical abilities (spatial ability, quantitative ability, qualitative ability, causal ability, inductive/deductive reasoning ability) due to their different degree of mathematical creativity (fluency, flexibility, originality).

RESULTS

The Validation of the Model

A-priori we hypothesized that mathematical creativity, composed by fluency, flexibility and originality, could predict mathematical ability. Regarding to mathematical ability, we assumed that it was composed of five components: spatial ability, quantitative ability, qualitative ability, causal ability, inductive/ deductive reasoning ability. Figure 2 presents the structural equation model with the latent variables (mathematical creativity and mathematical ability) and their indicators.

The results of the analysis revealed that the theoretical model matched the data set of the present study and determined the “goodness of fit” of the factor model (CFI=0.990, $\chi^2=29.269$, $df=19$, $\chi^2/df= 1.540$, RMSEA=0.039). The analysis revealed that the statistically significant loadings of fluency ($r=.833$, $p<.05$), flexibility ($r=.925$, $p<.05$) and originality ($r=.793$, $p<.05$) consist a first order factor, that of mathematical creativity. Moreover, the five cognitive abilities, namely spatial ability ($r=.306$, $p<.05$), quantitative ability ($r=.667$, $p<.05$), qualitative ability ($r=.625$, $p<.05$), causal ability ($r=.475$, $p<.05$) and inductive/deductive reasoning ability ($r=.725$, $p<.05$) can model the performance of students in mathematics. Mathematical creativity contributes to the prediction of mathematical ability ($r=.610$, $p<.05$).

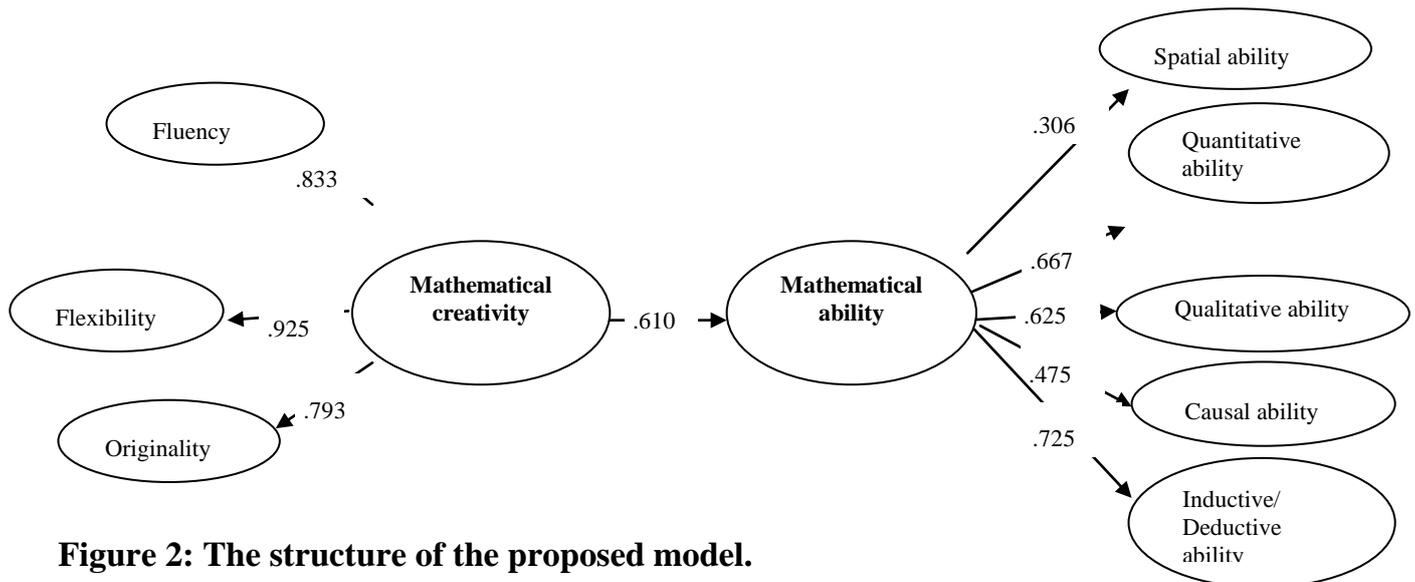

Figure 2: The structure of the proposed model.

Categories of students and differences on mathematical abilities and creativity

The second aim of the study concerns the extent to which students in the sample vary according to their mathematical ability. To this end, we examined whether variation on mathematical ability leads to discrepancy on mathematical creativity components. The latent class analysis (LCA) used a stepwise method-that is, the model was tested under the assumption that there are two, three, and four groups of subjects. The best fitting model with the smallest AIC (6366.99) and BIC (6467.96) and the largest entropy (0.733) indices (Muthén & Muthén, 1998) was the one with three groups.

Taking into consideration the average group probabilities as shown in Table 1, we may conclude that categories are quite distinct, indicating that each class has its own characteristics. The means and standard deviations of the three categories of students on the specific mathematical abilities are presented in Table 2.

	Category 1	Category 2	Category 3
Category 1 (N=111)	.878	.122	.000
Category 2 (N=189)	.102	.861	.037
Category 3 (N=59)	.000	.083	.916

Table 1: Average Latent Class Probabilities.

Table 2 reveals that students in Category 3 outperformed students in Category 1 and Category 2 across all mathematical abilities. Students in Category 2 outperformed their counterparts in Category 1. It is important to note that across the three categories of students, there are statistically significant differences ($p < 0.05$) among all mathematical abilities.

Due to the differences on mathematical abilities across the three categories of students, it can be deduced that our sample can be grouped in three distinct levels of

Working Group 7

abilities; Category 1 (N=111) consists of low mathematical ability students, Category 2 (n=189) consists of average mathematical ability students and Category 3 (n=59) consists of high mathematical ability students.

	Category 1 \bar{X} (SD)	Category 2 \bar{X} (SD)	Category 3 \bar{X} (SD)	Total \bar{X} (SD)
Spatial ability	1.02 (0.88)	1.32 (1.09)	2.07 (0.96)	1.35 (1.07)
Quantitative ability	0.80 (0.81)	1.54 (1.04)	3.34 (1.03)	1.61 (1.28)
Qualitative ability	0.65 (0.82)	1.25 (0.94)	3.14 (0.96)	1.37 (1.23)
Causal ability	1.02 (0.76)	1.74 (0.83)	2.34 (0.71)	1.61 (0.91)
Inductive/Deductive ability	1.11 (0.59)	2.57 (0.67)	3.56 (0.65)	2.28 (1.07)

Table 2: Means and Standard Deviations of the three Categories of Students in mathematical abilities.

Regarding to mathematical creativity, Table 3 presents the differences between the three categories of students across the three components of mathematical creativity, namely fluency, flexibility and originality.

	Category 1 \bar{X} (SD)	Category 2 \bar{X} (SD)	Category 3 \bar{X} (SD)	Total \bar{X} (SD)
Fluency	0.93 (0.44)	1.46 (0.57)	2.04 (0.63)	1.39 (0.66)
Flexibility	1.37 (0.42)	1.83 (0.46)	2.21 (0.38)	1.75 (0.52)
Originality	1.67 (0.66)	2.20 (0.79)	2.76 (0.73)	2.13 (0.82)

Table 3: Means and Standard Deviations of the three Categories of Students in mathematical creativity.

In particular, students with high mathematical ability (Category 3) are the high creative students as well. Likewise, average mathematical ability students (Category 2) have an average performance across fluency, flexibility and originality, while low ability students (Category 1) have low creative potential in mathematics. The differences on fluency, flexibility and originality are statistically significant across the three groups of students ($p < 0.05$).

DISCUSSION

Creativity is currently discussed as an essential component of the aim “mathematics for all” (Pehkonen, 1997). Given the importance of creativity in school mathematics, several researchers investigated the relationship between mathematical creativity and

school mathematics (e.g. Mann, 2005), but few of them examined the impact of the former to the latter. Hence, the first goal of this study was to articulate and empirically test a theoretical model, in which abilities in mathematics may be predicted by creative potential. In the theoretical model, spatial conception (spatial ability), arithmetic and operations (quantitative ability), proper use of logical methods (inductive/deductive reasoning), formulation of hypotheses concerning cause and effect (causal ability) and the ability to think analogically (qualitative ability) constitute mathematical ability, as has been proposed by Krutetskii (1976). With respect to mathematical creativity, fluency, flexibility and originality were its three components as recommended by Torrance (1995) and adopted by researchers on mathematics education (e.g. Silver, 1997). The model extended the literature in a way that mathematical creativity is a predictor of mathematical ability.

Therefore, it appears that the assessment of mathematical creativity can provide useful information in regard to students' profile and more specifically to their mathematical performance. Unfortunately, mathematical tests which are used in schools value mainly speed and accuracy and neglect creative thinking abilities (Mann, 2005). For this reason, creative tasks should be included in the assessment methods of mathematics, in order to capture not only students who do well in school mathematics and are computationally fluent but also students who have the potential but have not manifested their abilities yet.

The second aim of the study concerned the extent to which students in the sample vary according to their mathematical ability. The analysis illustrated that three different categories of students can be identified. Category 1 students had low mathematical ability, Category 2 students had average mathematical ability and Category 3 students had high mathematical ability. This distinction between the three categories of students appeared across the five mathematical abilities. With respect to the third aim of the study, an investigation of differences in mathematical creativity components, due to the differences in mathematical ability took place. The results of the present study verified that the three categories of students varying in mathematical ability, reflect three categories of students also varying in mathematical creativity. To this end, it can be assumed that creativity is one of the components that contribute to the development of mathematical abilities. These results are in accordance with Hong's and Aqai's study (2004).

To sum up, creative applications of mathematics in the exploration of problems and in the teaching of mathematical content are essential (Pehkonen, 1997). Encouragement of mathematical creativity in combination with computational accuracy is important for students to further develop their mathematical ability and understanding (Mann, 2005).

UNRAVELING MATHEMATICAL GIFTEDNESS

Katerina Kontoyianni, Maria Kattou, Demetra Pitta-Pantazi, Constantinos Christou

University of Cyprus

This study purports to develop a multiple criteria identification process for mathematically gifted students, in an effort to clarify the construct of mathematical giftedness. The study was conducted among 359 4th, 5th and 6th grade elementary school students in Cyprus, using four instruments measuring mathematical ability, mathematical creativity, self-perceptions of mathematical behaviour and fluid intelligence. The results revealed that mathematical giftedness can be described in terms of mathematical ability and mathematical creativity. Moreover, the analysis illustrated that although self-perceptions and fluid intelligence do not consist mathematical giftedness, they could predict it. Implications for researchers and teachers are discussed.

Keywords: giftedness, mathematical ability, creativity, self-perceptions, intelligence.

INTRODUCTION

To meet the challenges of the new millennium, the field of giftedness research has to expand its conceptions with revised models and approaches (Ziegler, 2009). Despite the number of publications that introduced several conceptions of giftedness, only a small number of them have been empirically examined (Stoeger, 2009). Thus, the need for more empirical studies in the future is evident. The field-dependent character of giftedness was pointed out by Csikszentmihalyi (2000). However, prior research in the field of giftedness focused on the examination of general giftedness rather than domain-specific giftedness. As a result, there is limited focus on theoretical models of mathematical giftedness as well as specially designed procedures and instruments for students' identification.

This study attempts to complement the lack of empirical studies in giftedness and the lack of studies, models and identification processes focused on mathematical giftedness. Specifically, the present study aims to investigate the construct of mathematical giftedness in students aged 10-12 years old (4th-6th grades) and to develop an identification process based on a multiple criteria approach.

THEORETICAL FRAMEWORK

Conceptualizations of giftedness

Although IQ was for decades considered as the only and predominant index of giftedness, a major shift was later noted in the research field. Namely, environmental influences were acknowledged resulting to the decrease of the influence of intelligence (Hartas, Lindsay & Muijs, 2008). At the same end, there were studies which have questioned the validity and liability to cultural and social bias of

standardized measures such as IQ (Black, 2001). Despite the criticism, Silverman (2009) claims that instruments with the richest loadings on general intelligence, such as the Wechsler scales, are the most useful for identification for giftedness. Turning away from intelligence as an indicator of giftedness, among the conceptualizations of giftedness that have been proposed over the years, a widely accepted definition was proposed by Renzulli (1978), emphasizing above-average ability and creativity as characteristics of gifted individuals. In the area of mathematics, the relationship between mathematical giftedness and creativity has also been documented by a number of researchers (e.g., Sriraman, 2005).

Identification of giftedness

Due to the lack of conceptual clarity as to the nature of giftedness, identification processes have varied widely. Identifying gifted individuals raises important issues regarding the types of evidence of giftedness and the validity of assessment processes, since gifted children will be provided with opportunities not accessible to others.

For gifted children to be identified, researchers should decide upon their discriminating characteristics and assess their ability in the specific domain, in our case mathematics. In addition to above average mathematical ability and mathematical creativity, researchers suggested that gifted students can also be identified by examining students' learning pace, depth of understanding and interests (Maker, 1982). According to other researchers (Hartas, Lindsay & Muijs, 2008), information about certain students' personality characteristics (e.g., persistence, perseverance, resilience), motivation and interests should be collected. Equally prevalent is the desire to understand students' perceptions with respect to these characteristics and behaviours.

Particularly in the case of mathematically gifted students, researchers should pay attention to mathematical abilities of highly able students and characteristics related to mathematical reasoning. For example, Krutetskii's work (1976) revealed a number of characteristics and abilities that mathematically able children possess: ability for logical thought with respect to quantitative and spatial relationships, number and letter symbols; the ability for rapid and broad generalization of mathematical relations and operations, flexibility of mental processes and mathematical memory. Moreover, a number of characteristics of mathematical giftedness have been proposed by several researchers (Benbow & Minor, 1990; Feldhusen, Hoover, & Sayler, 1991; House, 1987; NCTM, 2000; Olszewski-Kubiliyus, Kulieke, Shaw, Wilhus, & Krasney, 1990; Sriraman, 2005; Stanley, 1993; Wiczerkowski & Prado, 1993), such as high spatial ability, the ability to develop unique relations, produce original, insightful solutions/methods for solutions or formulate imaginative questions and the ability to organise data in such a way to consider patterns or relationships.

Following, this wide variety of characteristics of gifted individuals calls upon the use of a multiple-criteria approach during their identification, employing a combination of valid and reliable tools and multiple sources of evidence (Hoeflinger, 1998). Among other instruments, tests, self-report questionnaires, teacher rating scales, checklists and inventories have been introduced as measures of the identification of giftedness. To sum up, both evaluation of academic performance and cognitive abilities are used (Naglieri & Ford, 2003), despite their conceptual differences in combination with evidence of students' perceptions.

PURPOSE OF THE STUDY

Having in mind the abovementioned considerations, the purpose of this paper is twofold. Firstly, the study attempts to investigate the construct of mathematical giftedness which comprises of mathematical ability and mathematical creativity. To clarify this concept, the relationship between students' self-perceptions, fluid intelligence and mathematical giftedness is investigated. Secondly, the study purports to develop a valid and reliable identification process for identifying mathematically gifted students based on multiple measures. These measures assess mathematical ability, mathematical creativity, students' self-perceptions with respect to mathematical behaviour and fluid intelligence.

To fulfil the purpose of the study, a theoretical model was a-priori created (see Figure 1). In this model, we hypothesized that mathematical giftedness consists of mathematical ability and creativity. Furthermore, we assumed that self-perceptions regarding students' behavioural characteristics in mathematics and fluid intelligence would contribute to the prediction of students' mathematical giftedness.

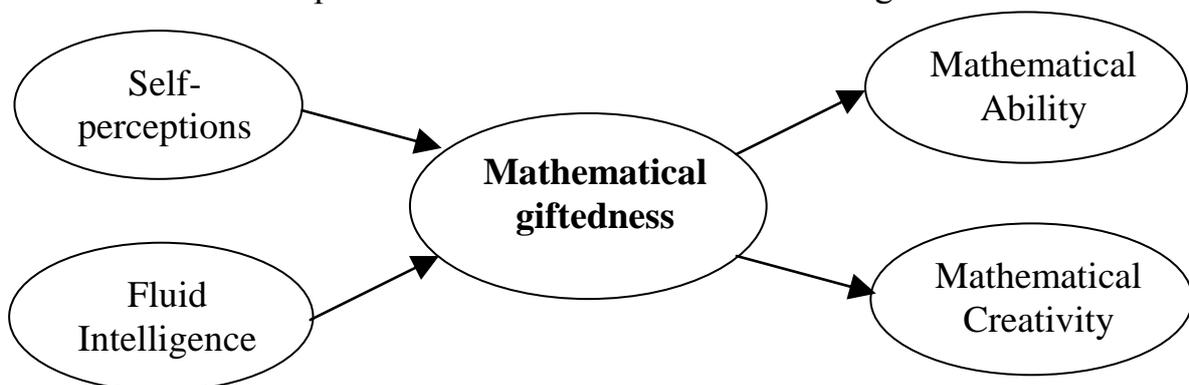

Figure 1: The proposed model.

METHODOLOGY

Sample and instruments

To fulfil the aims of the study, four instruments were administered to 359 students ranging from 9 to 12 years of age; the mathematical abilities instrument, the mathematical creativity instrument, the self-report questionnaire and the fluid intelligence instrument. The mathematical instrument comprised of 29 mathematical

items measuring spatial, quantitative, qualitative, causal and inductive/deductive abilities. The creativity instrument included five open-ended mathematical tasks. The self-report questionnaire consisted of 20 statements describing behaviours with special focus on mathematics. Students responded on a 5-point Likert scale regarding the frequency of each behaviour observed. To measure fluid intelligence, we used the subtest Matrix Reasoning Scale from the Wechsler Abbreviated Scale of Intelligence (WASI) (Wechsler, 1999). The WASI Matrix Reasoning Scale provides a measure of nonverbal fluid abilities using 32 tasks for students of 9 to 11 years old and 35 tasks for students older than 11 years. All instruments were group administered in electronic form except from the WASI Matrix Reasoning Scale which was completed in a hard-copy form.

Data analysis

For the analysis of the data confirmatory analysis was employed using the statistical package MPLUS. In this study, confirmatory factor analysis (CFA) was used to investigate whether the proposed model for the identification of mathematically gifted students fits our data. In order to evaluate model fit, three fit indices were computed: The chi-square to its degree of freedom ratio (χ^2/df), the comparative fit index (CFI), and the root mean-square error of approximation (RMSEA) (Marcoulides & Schumacker, 1996). For the model to be confirmed, the values for CFI should be higher than 0.9, the observed values of χ^2/df should be less than 2 and the RMSEA values should be close to zero.

RESULTS

For the construct validity of the model to be evaluated, a confirmatory factor analysis (CFA) was employed. CFA showed that all tasks and statements of the four instruments loaded adequately (i.e., they were statistically significant, because the z values were greater than 1.96) on each factor (see Figure 2). Figure 2, presents the structural equation model with the latent and observed variables and their indicators. CFA also showed that the observed (students' responses to each task and statement) and theoretical factor structures (the components of the theoretical model) matched the data set of the present study and determined the "goodness of fit" of the factor model (CFI=0.923, $\chi^2=566.627$, $df=366$, $\chi^2/df= 1.626$, RMSEA=0.039). Therefore, the analysis suggested a model representing distinct components that should be considered during the identification of mathematical giftedness. Thus, (a) spatial abilities, (b) quantitative abilities, (c) qualitative abilities, (d) verbal abilities and (e) causal abilities constitute mathematical abilities, while fluency, flexibility and originality comprise mathematical creativity. Both mathematical abilities and mathematical creativity constitute mathematical giftedness. In addition, the analysis revealed that fluid intelligence and self-perceptions of mathematical behaviour could predict mathematical giftedness. Moreover, with regard to students' self-perceptions about mathematical characteristics the data illustrated that they can be organised

across five dimensions and should be considered during the identification of mathematically gifted students.

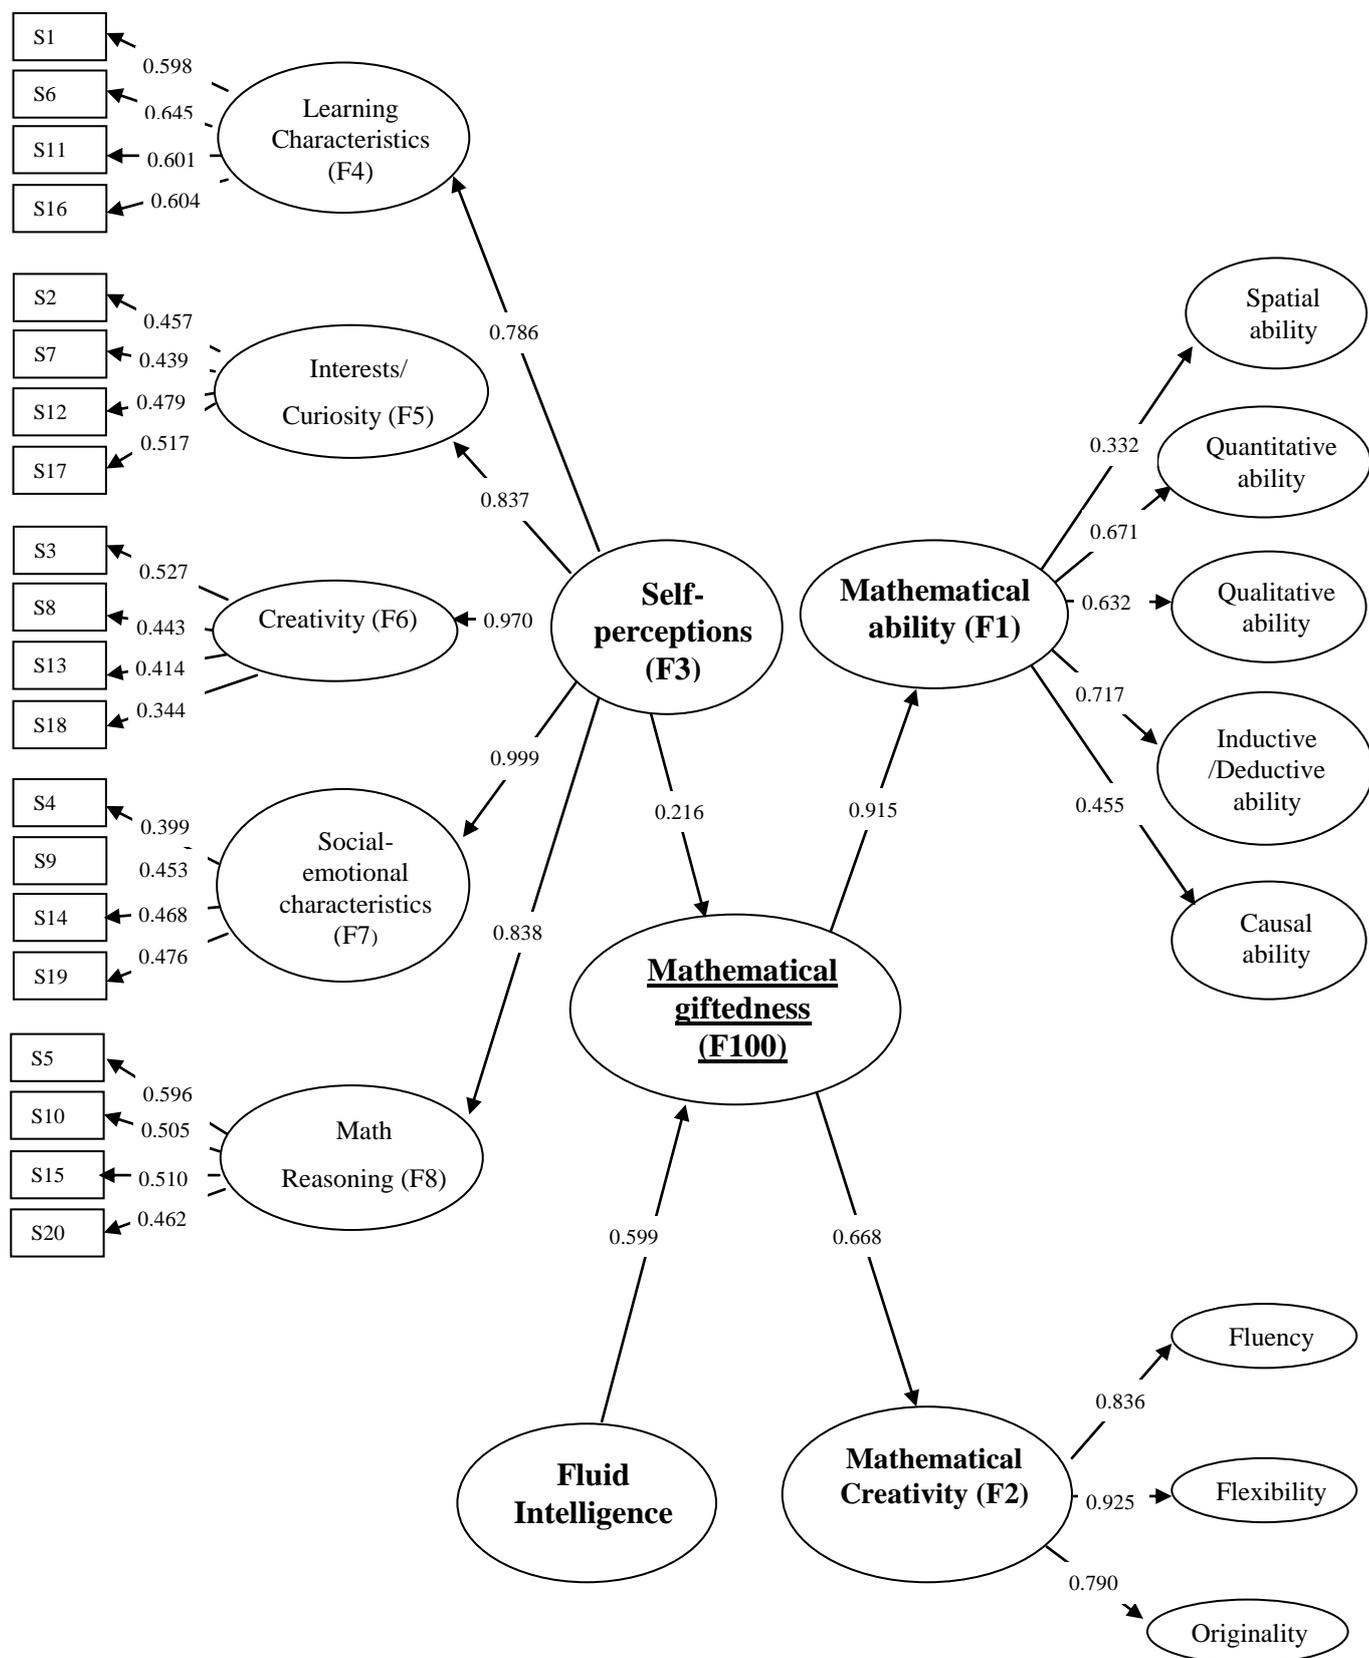

Figure 2: The structure of the proposed model.

In particular, students' descriptions in regard to their (a) learning characteristics, (b) interests/curiosity, (c) creativity, (d) social-emotional characteristics and (e) mathematical reasoning are important for the identification of mathematically gifted students.

Specifically, the analysis revealed that the five types of mathematical abilities measured by the mathematical instrument constitute one general factor, that of mathematical ability (F1). In particular, the statistically significant loadings of spatial abilities ($r=.332$, $p<.05$), quantitative abilities ($r=.671$, $p<.05$), qualitative abilities ($r=.632$, $p<.05$), inductive/deductive abilities ($r=.717$, $p<.05$), and causal abilities ($r=.455$, $p<.05$) verify that these abilities constitute general mathematical ability. The data suggest that for this age group the quantitative, qualitative and inductive/deductive abilities contribute more than the causal and spatial abilities to mathematical abilities. Likewise, the loadings of fluency ($r=.836$, $p<.05$), flexibility ($r=.925$, $p<.05$) and originality ($r=.790$, $p<.05$) suggest that these three first order factors constitute the second order factor of mathematical creativity (F2). Furthermore, one general factor, that of mathematical giftedness (F100), was generated from mathematical ability ($r=.915$, $p<.05$) and mathematical creativity ($r=.668$, $p<.05$) as shown by their statistically significant loadings.

In addition, students' self-perceptions of their characteristics with regard to mathematics comprise of five factors (F4-F8) with statistically significant loadings; learning characteristics ($r=.786$, $p<.05$), interests/curiosity ($r=.837$, $p<.05$), creativity ($r=.970$, $p<.05$), social-emotional characteristics ($r=.999$, $p<.05$) mathematical reasoning ($r=.838$, $p<.05$). The data suggest that according to students' responses for this age group, characteristics describing social-emotional characteristics and characteristics describing creative behaviours contribute more than learning characteristics, interests/curiosity and mathematical reasoning to their self-perceptions.

The structure of the proposed model also addresses that students' perceptions and fluid intelligence are able to significantly predict students' mathematical giftedness ($r=.216$, $p<.05$ and $r=.599$, $p<.05$, respectively).

DISCUSSION

Given the controversy prevailing in the field of giftedness, reflected both in the variety of concepts and identification processes proposed, the identification of mathematically gifted students is considered to be extremely challenging (Hoeflinger, 1998). Hence, this study comes to complement the lack of empirical studies in giftedness as well as the lack of studies, models and identification processes focused on mathematical giftedness. Firstly, the study attempts to investigate the construct of mathematical giftedness. Namely, it was expected that the relationship between students' self-perceptions, fluid intelligence and mathematical giftedness, composed by mathematical ability and creativity, would be

clarified. Secondly, the study aims to develop a valid and reliable identification process based on multiple criteria and instruments. This process is focused on the identification of mathematically gifted students at the upper grades of the elementary school.

To fulfil the purpose of the study, a theoretical model was conceived and it was later empirically tested and confirmed. With respect to the first objective, data analysis revealed that mathematical ability can be defined in terms of five abilities; spatial conception (spatial ability), number relationships (quantitative ability), the ability of analogical thought (qualitative ability), experimentation skills (causal ability) and logical reasoning (inductive/deductive abilities), confirming the abilities suggested by Krutetskii (1976) as characteristics of mathematically able children. Mathematical creativity can also be described in terms of fluency, flexibility and originality, as proposed by Torrance (1974). Moreover, the findings showed that mathematical ability and creativity constitute a more general factor, that of mathematical giftedness.

The model extended the literature to include two specific measures that may predict mathematical giftedness, complementing the other two measures, the mathematical ability and the mathematical creativity instruments. Specifically, it was shown that although fluid intelligence and self-perceptions of mathematical behaviour are not components of mathematical giftedness, they could predict it. The finding for the predictive power of self-perceptions about mathematics is in accord with other researchers who claim that self-efficacy of gifted students contribute to the prediction of math performance (Pajares, 1996). Moreover, data analysis revealed that students' responses to the self-report questionnaire can be organized across five distinct factors; (a) learning characteristics, (b) interests/curiosity, (c) creativity, (d) social-emotional characteristics and (e) mathematical reasoning. These characteristics have been mentioned by researchers listing the traits of gifted students (e.g., Hartas, Lindsay & Muijs, 2008; Maker, 1982).

The findings imply that the identification process of mathematically gifted students should include multiple measures in order to capture the variety of characteristics that these students present. Since we aim to identify mathematical and not general giftedness, instruments measuring mathematical ability and mathematical creativity are fundamental. Furthermore, the use of self-report questionnaires such as the one reported in this study and a measure of fluid intelligence could be used as supplementary means to collect information about mathematical giftedness, since they have been found to predict it. In particular, the self-report questionnaire addresses a variety of characteristics focusing in mathematics. Therefore, it may complement the lack of domain-specific identification instruments for gifted students, in this area. At the same time, the fluid intelligence instrument sheds light on the relationship between intelligence and giftedness.

Working Group 7

From the theoretical point, the model may inform the controversial concepts of intelligence, giftedness and domain-specific abilities. This model suggests valid evaluation of mathematical giftedness could be made both with processes where general and domain-specific abilities and processes are measured. In practice, the model is expected to facilitate the identification process of mathematically gifted students and to afterwards promote the nourishment of students' mathematical talent. Namely, teachers could identify gifted students through the identification instruments which encompass the components of the theoretical model proposed. Certainly, further research is required in order to introduce and examine additional instruments that might contribute to the identification of mathematical giftedness.

QUESTIONING ASSUMPTIONS THAT LIMIT THE LEARNING OF FRACTIONS: THE STORY OF TWO FIFTH GRADERS

Andreas O. Kyriakides

European University Cyprus

Dedicated to the memory of my colleague Georgia Kyriakidou

While standard procedures associated with learning to compute fractions could be quickly and easily memorized, many students appear highly vulnerable in cases they need to explain aspects of knowledge they had not discerned before. In this article, the author provides a window on his own teaching practice and explores the story of two fifth-grade students as they try to work out how to perform fraction subtraction using diagrams. Analysis of data suggests that familiarity with a limited class of examples of computations could be responsible for the constraint of learners' perception of the possible values a fractional difference might take. Implications for the role diagrams could play as tools to occasion students to discover their mathematical potential are discussed in light of these findings.

Key words: Fractions, elementary school mathematics, computations, diagrams

INTRODUCTION

Learning of fractions has traditionally been one of the most problematic areas in school mathematics. The most comprehensive analyses of fractional meanings stem from the work of Kieren (1988, 1993) and the Rational Number Project (Behr, Harel, Post, & Lesh, 1992; Behr, Harel, Post, & Lesh, 1993; Lesh, Behr, & Post, 1987). This body of research suggests that transition from fractions as operators to fractions as numbers is a major hurdle for young learners. Many have no idea what they are doing when they are combining fractions and, thus, appear highly vulnerable when they forget or misremember an algorithm they had learned to apply but not to re-construct for themselves.

In this paper, I provide a window on my own teaching practice to highlight some of the themes which have struck me as a teacher and researcher of a group of twenty-two fifth-grade Cypriots (10-11 yr.). What is to be recounted is part of an ongoing work studying the complexities of learning to compute fractions as revealed from the use of diagrams. Knowing about diagram use and being able to use that knowledge appropriately is a component of visual literacy, which, in the words of Hortin (1994), is “the ability to understand [read] and use [write] and to think and learn in terms of images” (p. 25).

The story zooms in on two students (Marvin and Mina) as they try to work out how to perform fraction subtraction using rectangular areas. This research is particularly important because is based in a cultural context in which students have poor individual experiences in using diagrams to compute fractions.

THEORETICAL BACKGROUND

The key theory that has guided and shaped the direction of this work is variation theory. It has developed from and is grounded in phenomenographic research, which accounts for how the same thing or the same situation could be seen, experienced or understood in a limited number of qualitatively different ways (Marton, 1981; Marton & Booth, 1997; Bowden & Marton, 1998). Central to this theory is the object of learning, that is, there is no learning without something being learned. How this something is experienced is constituted by the simultaneous discernment of certain aspects or features of what is experienced. Those aspects of an object that come to the forefront of our awareness are called dimensions of variation.

While variation seems to be an important condition for learning, Runesson (2006) stresses that it is variation in the critical aspects of the object of learning that is significant and not any variation. For students to appreciate or see a mathematics concept in a certain way, it is essential to be at least subliminally aware of what is exemplary about an example: what aspects, what dimensions can change and still the example remains an example of the concept (Mason & Watson, 2005; Watson & Mason, 2005). This hints at the kernel of the notion of *dimensions of possible variation* which according to Johnston-Wilder and Mason (2005) underpins all conceptual development. The adjective possible is added because different people may be aware of different possibilities. Teachers, for instance, are usually aware of aspects which can be varied but have not yet occurred to learners. Johnston-Wilder and Mason (2005) also note that the variation permitted in each dimension might be referred to as *range of permissible change* because learners may think that the range of change is more constrained than is actually the case. Understanding grows when they become aware that the range of permissible change is greater than previously thought.

My sense is that the power of variation theory lies in exemplifying what it is possible to learn, in terms of what could be discerned, and in locating which conditions/aspects are necessary to be present in the learning environment. Worthy underlining is that none of these necessary conditions for learning something should be perceived as absolute since these “are relative to the individuals and the situation. Nor is there a guarantee that the students will learn if the necessary conditions exist” (Runesson, 2005, p. 84).

METHOD AND METHODOLOGY

Two methodological traditions have contributed to the design of this study: phenomenography and action research. Because the ultimate aim of phenomenographic research was made clear through the analysis of variation theory, I will now elaborate on how action research has also contributed to the development of the methods I used.

Mason (2002) notes that action research has become a label for a form of research with many different interpretations in practice: it “has an enormous literature and a wide range of detailed methods of implementation, whether for socio-political critique or for effecting change in some complex situation” (p. 199). For the purpose of this work, I consider only one of its variants: teacher research.

My personal understanding of teacher research is built upon Ainley’s (1999) perspective. As she explains, assuming the role of the teacher or the role of the researcher simply refers to ways of behaving, perceptions and expectations other people have of that behaviour (Ainley, 1999). The notion of roles is, thus, used “as a deliberate device to recognize and label choices, and to allow me to re-enter experiences imaginatively in order to explore other choices which I could have made” (Ainley, 1999, p. 45).

During the time my teacher research took place, though I followed the fraction-related content outlined in the syllabus, I digressed from the way this was presented in pupil’s textbooks because I did not want standard algorithms to dictate my practice. My desire to avoid a direct exposure of my students to procedural rules along with the low status of diagrams in Cypriot curriculum (Kyriakides, 2009, 2010), led me to implement a visual component. This was ensured by asking learners to produce and partition diagrams as a response to the tasks or by inviting them to comment on given diagrams. I intentionally chose the rectangular area instead of the circular one as a diagrammatic form because drawing equal parts inside a circle is technically difficult. In the words of Ball (1993),

this difficulty makes it harder to determine whether a child intends to divide the circle equally –and just does not know how- or whether the child is even considering the importance of equal parts (p. 180).

Another limitation of the circular model is that it might provide

a source of simple examples for adding and subtracting, maybe even for other numerical operations with fractions, but becomes unwieldy for denominators that are not closely related multiplicatively (Watson & Mason, 2005, p. 95).

Considering the suggestion made by Adams and Sharp (2006) that “classroom research requires an intricate question precisely because the ebb and flow of the classroom is taken into account” (p. 16), I set out to explore the subsequent research question: What are the complexities (if any) of learning fractions as revealed by students’ use of diagrams? The foregoing was an important issue to study because

though in Cypriot culture school mathematics textbooks introduce the concept of fraction with images of partitioned rectangles and circles, they make little or no use of diagrams when they show students the way to compute (Kyriakides, 2010, p. 1003).

Thus, the use of diagrams in the process of coming to understand and learning to calculate with fractions promised to be fruitful in revealing complexities beneath the surface of students' facility, and lack of it, in calculating with fractions.

During the analysis conducted on transcripts of single tasks and classroom discussions, I became aware that there were some students, whose voices were heard more than others across the entire collection of tapes, suggesting that these learners could serve as subjects of individual case studies. I have deliberately chosen Marvin and Mina to be the focus of the current paper because Marvin's sophisticated reasoning, which seemed to rise above others with an evident persistence, in the long run made it possible for Mina to discover and realize her mathematical potential.

Using as analytic frames the variation theory as well as personal reflections on pedagogy, my goal in the current paper is not only to assess critically two fifth graders' growth of understanding but to demonstrate, through their story, how it is possible for any student to question early constraints and experience the extension of personal "example spaces" (Watson & Mason, 2005, p.60). This likelihood is important because it could lead to a shift in perspectives and change of individual's thought with regard to the learning of fractions. As Watson and Mason (2005) explain, "no one has access to all possible elements and features of a potential example space associated with a specific topic. ...example spaces prevalent at a given time may be extended or altered in the future" (p. 60).

CLASSROOM FINDINGS

In this section, I have chosen to present part of a classroom discussion on subtraction of fractions. The quoted transcript has been intentionally split into Episode A (lines 318-333) and Episode B (lines 413-453). This division is absolutely artificial and it does not imply any lack of succession in terms of time or place. Rather, it is meant simply to organize structurally the data and facilitate the development of commentary later on. The discussion starts with a reference to the example of four sevenths minus one half and then shifts to the example of three sixths minus one half. What counts in both episodes is not only the content and structure of the mathematics itself but also the ways in which it is talked about, perceived and assimilated by the involved learners.

Episode A

318 Teacher: Now, we will do something different...I would like you all to think what will happen if we have four sevenths minus one half. Who would like to come on the board and show us?

[Bob comes to the board]

319 Bob: I did one area model and I divided it into seven vertical equal parts and I took the four. Then I drew another area model and I divided it into two vertical parts and took one... [Then Bob erases his second drawing]

Working Group 7

- 320 Teacher: Why did you erase it?
- 321 Bob: It should have been divided horizontally not vertically because here it is vertical and here it should be horizontal.
- 322 Teacher: Why?
- 323 Bob: To be able to add?
- 324 Teacher: To add?
- 325 Bob: No, to subtract...we should make it the same...you know, to transfer these rows to the columns here and vice versa because if they were the same all columns, for example, I wouldn't be able to see it when I would exchange.
- 326 Marvin: Can I say something sir?
- 327 Teacher: Marvin would like to add something, let's hear.
- 328 Marvin: No sir I don't want to add anything I just want to tell you something in person.
- [I approach Marvin's seat and he whispers to me]
- 329 Marvin: To confuse them sir I have an idea: how about showing them three sixths minus one half?
- 330 Teacher: And why do you think this will confuse the class?
- 331 Marvin: Well, maybe there will be someone who doesn't know.
- 332 Teacher: Will he not know?
- 333 Marvin: That one half for instance is half.

Episode B

- 413 Teacher: Now, who would like to come up to the board and show us how we can find three sixths minus one half by using rectangular areas?
- [Mina is coming up to the board and developing the first rectangle of Figure¹ 1]
- 425 Mina: I will draw another area model for one half but instead of a horizontal line I will draw a vertical line to divide the area into two equal parts.
- 426 Teacher: Mina could you show us what you are talking about?
- [Mina is developing the rest of Figure 1]

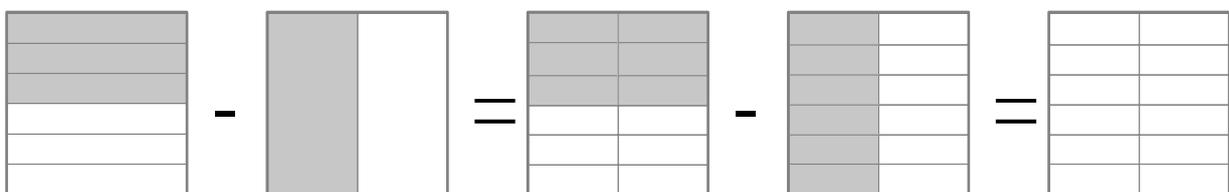

Figure 1: Mina's diagrams for $3/6 - 1/2$

- 427 Mina: I draw a second area model and divide it into two vertical columns and shade one.
- 428 Teacher: Yes and then?
- 429 Mina: Then I take the rows of the first area and shift them to the second and the columns of the second I'm shifting them to the first one.

Working Group 7

- 430 Teacher: So Mina has exchanged the rows with columns and vice versa. What do we have now Mina?
- 431 Mina: We have the same denominators, 12ths. We have $6/12$ in the first area model and $6/12$ in the second.
- 432 Teacher: Can this happen?
- 433 Richard: No.
- 434 Teacher: $6/12$ minus $6/12$, what's the result Mina?
- 435 Marvin: It was my idea, I caused you difficulty.
[Mina is smiling]
- 436 Mina: Hm...nothing.
- 437 Teacher: That is?
- 438 Mina: $0/12$, zero?
- 439 Teacher: So the answer is zero. Well, class I have to say that Marvin asked me to work on this example.
- 449 Mina: Sir in the beginning I felt a bit strange. I thought that the answer was $0/12$ but I found it strange to be true.
- 450 Teacher: Could you tell us why you found it strange?
- 451 Mina: Hm...because sir I haven't come across such a fraction before.
- 452 Teacher: So what did you learn today?
- 453 Mina: That it happens...it's possible to find zero.

DISCUSSION

What Marvin proposed confidentially to me in line 329 might have sounded like a jump to his classmates -if they listened to what he had said- or as something disconnected to the ongoing discussion. However, a deliberate attempt to explore the line of thinking that stands behind Marvin's words could suggest that when he saw one half drawn by Bob, Marvin possibly noticed connections between alternative images of one half, predicted how these might be achieved and, in turn, constructed a class-like mental object, including all equivalent fractions occupying half of a whole. Worthy of consideration here is that in Greek language the fraction $1/2$ is not read as one half but as one second. This cultural clarification is meant to elucidate any triviality or vagueness likely assigned to Marvin's statement that one half is half (line 333).

The first part of the discussion (lines 318-333) explicitly shows that Marvin does not see learning as an absolute event but prefers, instead, to engage himself in the "eventing" (Mason, 2002, p. 228), by increasing the possibilities and potential he recognizes through the structure of his own attention, as he participates in the moment by moment flow of unfolding events. The boy does not only integrate what he hears, but also consciously searches to extend his own and peers' "example space" (Watson & Mason, 2005, p. 60) of the difference of two fractions.

When I posed Marvin's suggestion to the whole class, insightful verbal exchanges (lines 413-453) were brought to the fore. As it stood, the case of zero was not an ordinary difference of two fractions for the rest of his peers. The case of Mina suggests an example. The girl appears competent in drawing and manipulating diagrams to show the fractions three sixths and one half (see Figure 1). Evidence also exists with regard to her fluency in explaining her actions to secure common denominators and thus subtract (lines 413, 425-431). The problematicity lies in the interpretation aspect since Mina is observed (face, gestures, tone of voice) to be somehow hesitant (lines 434-438) to acknowledge the validity of zero as the difference of three sixths minus one half. Her reference to "nothing" (line 436) could suggest, on the one hand, an image of "emptiness" for the concept of zero which "is, quite reasonably but probably unconsciously, influenced by the common language meaning of nothing" (Pirie & Martin, 2000, p. 136). This, in conjunction with her expressed confession (lines 449-453) of what she experienced while standing in front of the board, could serve as evidence of an internal struggle, which in turn gave rise to an awareness that the "range-of-permissible-change" (Watson & Mason, 2005) of the difference of two proper fractions is greater than previously thought (line 453).

An associated implication is that learners make sense of fractional computations from what is available to them. This is frankly implied in Mina's words: "I found it strange to be true (line 449)... because sir I haven't come across such a fraction before (line 451)". In terms of variation theory (Johnston-Wilder & Mason, 2005; Runesson, 2006), familiarity with a limited class of examples of fractional computations could hence be responsible for the constraint of learners' perception of the possible values a fractional sum, difference or product might take. Lakatos (1976) notes that mathematics develops as people question the implicit assumptions that limit the examples offered or that come to mind. The story of Marvin and Mina comes to suggest that placing learners in the situation of board presentation might have its ebbs and flows but it could also occasion individuals who, on their own, may lack the persistence or courage to try something new (Movshovitz-Hadar, 2008), to think creatively.

What has been described here is a new kind of practice of teaching and learning for the participants. Rather than attempt to isolate or emphasize diagrams artificially, I came more and more during this paper to note how diagrams could function naturally with words, numbers and other symbols used on board, or perhaps in children's heads. I found that my students moved among these multiple representations in an interwoven, fluid process to embody and communicate their growing sense of the concept of fractions and the operation of subtraction. This, of course, should neither be regarded as an unproblematic, linear task nor as something that can be certain (Kieren, 1988, 1993). Watching the gradual change in Mina's notion of zero revealed complexities but also allowed me to capture a useful description of resolving challenges as well as celebrating advantages of my students' encounter with

Working Group 7

diagrams. The contribution of this paper lies, therefore, in exemplifying the relationship between diagrams and the process of coming to understand fractions, as well as, the roles diagrams could play in promoting individual mathematical creativity and supporting students to question the status of an example.

NOTES

1. The initial form of Figure 1 was drawn on the classroom's board. Soon after it was made, the teacher-researcher hastily copied it (by hand) on a piece of paper. Afterwards, based on his handwritten rough sketches he constructed a clearer and more accurate copy with the use of technology.

MATHEMATICAL CREATIVITY OF 8TH AND 10TH GRADE STUDENTS

Roza Leikin and Yona Kloss

University of Haifa, Israel

One hundred and fifty-eight 8th graders and one hundred and eight 10th graders were asked to solve four multiple solution tasks (MSTs). Creativity is evaluated using Leikin's (2009) model that employs MSTs. Problem solving performance of 8th and 10th graders is compared with respect to correctness of the solutions, and the three components of creativity: fluency, flexibility and originality. While success in problem solving is highly correlated with fluency and flexibility, originality is shown to be a special mental quality. Consistent with other studies, we demonstrate that originality determines creativity stronger than fluency and flexibility do. This study once again demonstrates the validity of the model for evaluation of mathematical creativity by means of MSTs.

Key words: Mathematical creativity, relative creativity, problem solving, multiple solution tasks.

EVALUATION OF MATHEMATICAL CREATIVITY IN THIS STUDY

The study presented in this paper is one of a group of studies that evaluate relative mathematical creativity in different groups of school students using Multiple Solution Tasks. A *multiple-solution task (MST)* is an assignment in which a student is explicitly required to solve a mathematical problem in different ways (see the definition and various examples of MSTs in Leikin, 2006, 2009, Leikin & Levav-Waynberg, 2008). The model utilises the notion of *solution spaces* (Leikin, 2007). *Expert solution spaces* include the most complete set of solutions known for a problem at a particular time. They can be conceived as a set of solutions that expert mathematicians can suggest to the problem. These spaces include both *individual solution spaces*, which are collections of solutions produced by an individual to a particular problem, and *collective solution spaces*, which are a combination of the solutions produced by a group of individuals. Solution spaces are used here as a tool for exploring the students' mathematical creativity.

There is no single, authoritative perspective or definition of creativity (Mann, 2006; Sriraman, 2005; Leikin, 2009). There is a diversity of views on creativity and they keep changing over time. Based on research literature, Mann (2006) argues that there are more than 100 contemporary definitions of creativity.

We view creativity as personal creativity that can be developed in schoolchildren. This view requires drawing a distinction between *relative* and *absolute* creativity (Leikin, 2009, p. 151).

Working Group 7

Absolute creativity is associated with “great historical works” (in Vygotsky’s terms, 1982, 1984), with discoveries at a global level. Examples of absolute creativity may be seen in the inventions of Fermat, Hilbert, Riemann, and other prominent mathematicians (Sriraman, 2005). *Relative creativity* refers to discoveries by a specific person within a specific reference group, to human imagination that creates something new (Vygotsky, 1982, 1984).

Mathematical creativity in school mathematics is usually connected with problem solving or problem posing (e.g., Silver, 1997). Kwon, Park, and Park (2006) proposed two major criteria for mathematical creativity: the creation of new knowledge and flexible problem-solving abilities. Chiu (2009) connected mathematical creativity with the students’ ability to solve routine and non-routine problems and to approach ill-structured problems.

The current study represents uses of a multidimensional creativity scoring scheme that takes into account the relative nature of creativity and links creativity with problem solving. It draws on the views of Ervynck (1991), Krutetskii (1976), Polya (1973), and Silver (1997) that solving mathematical problems in multiple ways is closely related to personal mathematical creativity, and suggests evaluating mathematical creativity by means of Multiple Solution Tasks (MSTs).

The model presented herein (Leikin, 2009) makes possible not only an evaluation of the students’ personal mathematical creativity but also of the efficiency of MSTs in evaluating such creativity (see Figure 2). The model contains operational definitions and a corresponding scoring scheme to evaluate creativity based on three dimensions (originality, fluency, and flexibility), as suggested by Torrance (1974). To evaluate originality it uses Ervynck’s insight-related levels of creativity in combination with the conventionality of the solutions. *Conventional solutions* are usually determined by the curriculum, displayed in textbooks, and usually taught by the teachers, while *unconventional solutions* are based on strategies usually not prescribed by the school curriculum. Conventionality of the solutions refers also to the individual student’s educational history.

Fluency (Fl) is detected by the number of solutions in the individual solution space. To evaluate *flexibility* (Flx), we established groups of solutions for the MSTs. Two solutions belong to separate groups if they employ solution strategies based on different representations, properties (theorems, definitions, or auxiliary constructions), or branches of mathematics. With respect to the corresponding solution spaces, we evaluated flexibility as follows (see Figures 1 and 2): $Flx_1 = 10$ for the first appropriate solution (see an explanation of this scoring in the section on scoring creativity). For each consecutive solution $Flx_i = 10$ if it belongs to a group of solutions different from the solution(s) performed previously; $Flx_i = 1$ if the solution belongs to one of the previously used groups but has a perceptible minor distinction; $Flx_i = 0.1$ if the solution is almost identical with a previous solution. A student’s

total flexibility score on a problem is the sum of the student’s flexibility on the solutions in his/her individual solution space. We evaluate *originality* (Or) in written settings as follows: If P is the percentage of students in the group that produces a particular solution, then (*relative evaluation*): $Or_i = 10$, when $P < 15\%$ for an insight-based or unconventional solution; $Or_i = 1$, when $15\% \leq P < 40\%$ or for a model-based or partly-unconventional solution; $Or_i = 0.1$, when $P \geq 40\%$. A student’s *total originality score* on a problem is the sum of the student’s originality on the solutions in his/her individual solution space. (For the explanation of decimal basis we use in the scoring and the decisions about 15% and 40%, see Leikin, 2009).

The *creativity* (Cr) of a particular solution is the product of the solution’s originality and flexibility: $Cr_i = Flx_i \times Or_i$. Producing flexibly non-original solutions and producing repeatedly original solutions is less creative than flexibly producing (different) original solutions. The total *creativity score* on an MST is the sum of the creativity scores on each solution in the individual solution space of a problem:

$$Cr = \sum_{i=1}^n Flx_i \times Or_i .$$

	Flu-ency	Flexibility	Originality	Creativity
Scores per solution	1	$Flx_i = 10$ - for the first solution $Flx_i = 10$ - solutions from a different group of strategies $Flx_i = 1$ - similar strategy but a different representation $Flx_i = 0.1$ - the same strategy, the same representation	$Or_i = 10$ $P < 15\%$ or for insight / unconventional solution $Or_i = 1$ $15\% \leq P < 40\%$ or for model-based / partly unconventional solution $Or_i = 0.1$ $P \geq 40\%$ or for algorithm-based / conventional solution	$Flx_i \times Or_i$
Total score	n	$Flx = \sum_{i=1}^n Flx_i$	$Or = \sum_{i=1}^n Or_i$	$\sum_{i=1}^n Flx_i \times Or_i$

n is the total number of appropriate solutions

$P = (m_j / n) \cdot 100\%$ where m_j is the number of students who used strategy j

Figure 1. Scoring scheme for the evaluation of creativity

THE STUDY

Population

The target population in this study consisted of 108 tenth-grade students and 158 eighth grade students. The students were from families with a similar socio-economic level and similar ability levels. The tenth-grade participants, when they were eighth-graders, learned according to textbooks identical to those with which the eighth-grade participants of the study were learning.

Tasks in the experiment

The tenth-grade and eighth-grade students were asked to perform identical tests. There were 4 different variants of the tests distributed in different classes. The variants differed in the order of problems and in slight changes in the problems themselves (e.g., different numbers in the system of equations – see below, or a different context for the word problem). Figure 2 depicts tasks in one of the variants.

<p>1. System of equations</p> $\begin{cases} 3x + 4y = 14 \\ 4y + 3x = 14 \end{cases}$	<p>4. Algebraic expressions</p> <p>Given: $a + b = 1, a > b,$ What is bigger $a^2 + b$ or $b^2 + a$?</p> <p style="text-align: right;">From Maison (2010)</p>
<p>2. Jam problem</p>	<p>Mali produces strawberry jam for several food shops. She uses big jars to deliver the jam to the shops. Once, her workers distributed 80 liters of jam equally among the jars. She decided to save 4 jars and to distribute the jam from these jars equally among other jars. She realized that she had added exactly $\frac{1}{4}$ of the previous amount to each one of the jars. How many jars did her workers prepare in the beginning?</p>
<p>3. Rectangle problem</p>	<p>When the sides of rectangle ABCD were enlarged by 2 cm, its area enlarged by 24 cm^2. Find the perimeter of rectangle ABCD.</p>

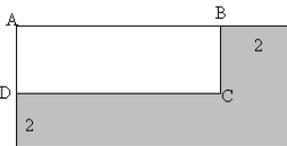

Figure 2: The test

The test was combined from the problems that 8th graders had studied before the test was administered. Thus, for 10th grades these problems were definitely solvable. The problems were taken from different mathematical topics: Task 1- Systems of linear equations (SE), Task 2 and 3 - word problems: Task 2 – Jam Problem (JP) according to the curriculum could be solved using equations with fractions, Task 3 – Rectangle Problem (RP) could be solved using linear equation, Task 4 – algebraic expression (AE) – required manipulations with algebraic equations using reduced multiplication formulas. Clearly, all the tasks had additional solutions (see Figures 3a, 3b for JP and AE).

The test design also included preliminary evaluation of the creativity embedded in the tasks. In our previous research (Leikin & Lev, 2007; Leikin, 2009) we concluded that the tasks with higher "embedded creativity" are better tools for the comparison of creativity in different groups of students. Thus we searched for those problems in which embedded creativity was higher than 200. Figures 3a and 3b display calculations of the embedded creativity for JP and AE tasks.

Figures 3a and 3b demonstrate that an expert problem solver can receive a higher creativity score on the AE task than on the JP task. However, when school students solve MSTs they rarely receive maximal flexibility and originality scores. In the next section of the paper we describe the problem-solving performance of the participants in our study.

FINDINGS

Differences in the problem solving performance of 8th and 10th graders

Tenth-grade students achieved significantly higher scores in both correctness and fluency, on all four tasks in the test, than eighth-grade students (see Tables 1). This finding was not expected since the topics from which the tasks were borrowed are

learned in eighth grade. Tenth-grade students were significantly more flexible than eighth-grade students on three of four tasks (JP, RP and AE tasks). At the same time eighth-grade students were significantly more flexible than tenth-graders when solving the system of equations. Eighth-grade students produced significantly more original and creative solutions than tenth-grade students when solving the JP task whereas tenth-graders were significantly more original and creative than eighth-graders when solving the AE task (see Table 1). No significant differences were found with respect to students' originality and creativity on two of the tasks (SE and RP). However, there were non-significant differences in students' originality and creativity on the RP task, which were similar to significant differences found for another word problem in the test (i.e., JP task).

*p<0.05; **p<0.01; ***p<0.001

Whereas tenth-grade students were significantly more successful and fluent when solving all the tasks, the differences between tenth-graders' and eighth-grader' flexibility, originality and creativity appear to be *task dependent* (see Tables 1 and 2). Tenth-grade participants performed significantly better on all the examined criteria when solving AE task. Eighty-three percent of tenth-grade students solved this task successfully; 31% of these students found more than one solution to this problem. At the same time only 69% of eighth grades managed to solve this task, and only 3 of 158 (2%) students managed to solve this problem in 2 ways. We found that, first, the algebraic manipulations that the task required appeared to be difficult for the eighth-graders and, second, they did not connect this problem to the topic of

reduced multiplication formulas. Tenth-graders performed rarer (more original) solutions and used more different strategies (i.e., were more flexible) when solving the task.

Our findings pertaining to students' problem-solving performance on the SE task are different. As on the other tasks tenth-grade students were more successful: 100% tenth-graders vs. 98% eighth-graders produced appropriate solutions to the system of equation. Though students from both groups were more successful when solving this task, the differences between the students from tenth and eighth grades were statistically significant (taking into account the correctness of the solutions). As on all other tasks tenth-graders were more fluent when solving the SE. However, tenth-grade students produced more "repeating" solutions when solving the SE, while eighth-grade students were more flexible: by presenting both algebraic and graphical solutions (e.g, 60 of 158 (38%) eighth-graders solved the system graphically vs. only 10 of 108 (9%) tenth-graders). Higher flexibility of eighth-grade students on the SE task was quite surprising since tenth-grade students have more available tools for solving the system. A symmetry-based solution was produced by 3 (2.7%) tenth-grade students and by 6 (4%) students from 8th grade. These solutions contributed to the differences in originality of the solutions which appeared to be non-significantly better for eighth grade students.

Summary

Although the differences between eighth- and tenth-graders appeared to be significant on many criteria for different problems in the test, the ranges of the scores on all the criteria were similarly low for all the participants. The highest scores received by eighth- and tenth-grade students were equal on all the tasks and all the criteria except fluency and flexibility scores for SE and AE tasks. Only tenth-graders produced 4 and 5 solutions to SE while the solutions varied mainly within the space of algebraic solution strategies. Only 2 tenth-graders produced 3 solutions for the AE task, of which 2 were based on different solution strategies. Moreover, flexibility mean-scores for all the tasks except SE task are lower than 10. This finding reflects the fact that only a small number of students produced more than 1 solution to a particular problem. Additionally, when the students produced several solutions most of them were repetitive.

Based on these findings we argue that Israeli school mathematics teaching is not directed towards the development of mathematical creativity. Both for eighth- and tenth-graders we expected better results with respect to all the criteria presented here. Moreover, while students in tenth grade are more successful and fluent in solving the problems than eighth grade students, this success and fluency can be attributed to the additional tools that students have attained during 2 more years of school. We cannot say that students from tenth grades are consistently more flexible than eighth grade students.

CORRELATIONS BETWEEN THE DIFFERENT COMPONENTS IN THE MODEL

One of the most interesting findings in this study is related to the examination of correlations (by Pearson correlation coefficient) between different criteria in the scoring scheme on each one of the problems. Table 2 demonstrates correlations received for the four tasks in the test.

Table 2: Pearson correlation coefficient for correctness and different components of creativity

N=266		Fluency	Flexibility	Originality	Creativity
SE	Correctness				
	Fluency				
	Flexibility				
	Originality				
JP	Correctness				
	Fluency				
	Flexibility				
	Originality				
RP	Correctness				
	Fluency

	Originality				
AE	Correctness				
	Fluency				
	Flexibility				
	Originality				

* $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$

First we find that correlations among the three components of creativity, as presented in the model, are significant and, thus, we consider the model reliable. Second, while correlations between correctness, fluency and flexibility are significant for all the tasks, correlations between originality and correctness are not necessarily significant. Moreover, even when significant, correlations between correctness and originality are low (see Table 2). That is, students who solve mathematical problems in multiple ways more successfully than other students are not necessarily more original. This observation is consistent with the findings that follow a comparison between problem solving performance of eighth and tenth grade students on 3 of 4 tasks: SE, JP and RP.

Correlations between fluency and flexibility are always significant at different levels. For the tasks in this study, the Pearson correlation between fluency and flexibility varies from 0.53 to 0.85. This finding allows us to argue that fluency and flexibility are strongly related to each other, and very reasonably, students who produce more solutions also have a chance to produce more solutions that are different. However,

on some problems fluency does not necessarily lead to flexibility. Both the values of Pearson correlation for SE task (Table 2) and the comparison of tenth-graders' and eighth-graders' problem-solving performance on the SE task support this observation (Table 1).

Interestingly, correlations between originality and flexibility and between creativity and flexibility are significant but low. At the same time, originality and creativity are highly correlated (Table 2). While our model suggests an identical scale for scoring flexibility and originality, and the calculation of creativity includes flexibility and originality symmetrically (Figure 1), originality (in our model) appears to be the main criterion for determining creativity. This finding is consistent with the common view of creativity as production of novel ideas (both on relative and absolute levels), and thus it proves the validity of the model presented in this paper.

EMPLOYING MULTIPLE SOLUTION TASKS FOR THE DEVELOPMENT OF MATHEMATICAL CREATIVITY: TWO COMPARATIVE STUDIES

Roza Leikin⁽¹⁾, Anat Levav-Waynberg⁽¹⁾, Raisa Guberman^(1,2)

⁽¹⁾ University of Haifa, Israel

⁽²⁾ Achva Academic College of Education, Israel

The paper presents two empirical studies that examine employment of multiple solution tasks (MSTs) for the development of creativity. Based on the findings of the two studies we compare development of fluency, flexibility and originality in two different learning environments: a problem-solving workshop for pre-service mathematics teachers and a geometry course for high school students. The two studies compare development of creativity in groups of participants with different attainment levels. Similarities in the findings of these studies led us to several theoretical hypotheses. Students' flexibility and fluency significantly increased in both studies. Students' originality decreased non-significantly. We demonstrate that originality appears to be the strongest component in determining creativity.

Key Words: mathematical creativity, multiple solution tasks, developing creativity

THEORETICAL BACKGROUND

The studies presented in this paper consider creativity as a dynamic characteristic that can be developed if appropriate learning opportunities are provided to learners (Vygotsky, 1930/1984; Sheffield, 2009; Subotnik et al., 2009; and Yerushalmy, 2009). According to Leikin (2009) we distinguish between absolute and relative creativity as follows: *Absolute creativity* is associated with “great historical works” (in Vygotsky’s 1930/1984 terms), with discoveries at a global level. *Relative creativity* refers to discoveries by a specific person within a specific reference group, to human imagination that creates something new (Vygotsky, 1930/1984). Whereas absolute creativity is quite easy to identify, we lack tools for the identification of relative mathematical creativity.

Our conception of creativity utilizes the views of Ervynck (1991), Krutetskii (1976), Polya (1973) and Torrance (1974). Following the perspective suggested by Torrance (1974) we consider three categories: *Fluency* relates to the continuity of ideas, flow of associations, and use of basic and universal knowledge. If time is unlimited it refers to the pace of solving a procedure and switches between different solutions. If time is limited it refers to the number of solutions generated by a solver. *Flexibility* is associated with changing ideas in producing a variety of solutions and refers to the number of different solutions generated by a solver. *Originality* is characterized by a unique way of thinking and unique products of a mental activity. Additionally, we accept Ervynck's (1991) position that an insight-based solution is an indication of

creativity. Based on these definitions Leikin (2009) proposed a model that evaluates mathematical creativity by means of multiple solution tasks (see also Leikin & Kloss, in the proceedings of this conference, Levav-Waynberg & Leikin, 2009). A multiple-solution task (MST) is an assignment in which a student is explicitly required to solve a mathematical problem in different ways. We use the notion of solution spaces (Leikin, 2007) which enables us to examine the various aspects of problem-solving performance using MSTs. *Expert solution spaces* include the most complete set of solutions to a problem known at a particular time. Expert solution spaces include *conventional* and *unconventional* solution spaces. *Individual solution spaces*, which include all the solutions displayed by an individual, are used here as a tool for exploring the students' mathematical creativity and for assessment of the potential of a task to evaluate mathematical creativity. *Collective solution spaces* include all the solutions produced by a group of students.

We will shortly explain the model and demonstrate its use in the two studies.

DESCRIPTION OF THE RESEARCH INSTRUMENT

To analyze students' performance on a certain MST, the first step is to construct its expert solution space, which is the collection of solutions proposed by researchers and students. The scoring scheme for the evaluation of creativity of an individual solution space is borrowed from Leikin (2009). The number of all the appropriate solutions in one's individual solution space indicates one's *fluency*. *Flexibility* is measured by the differences between appropriate solutions in one's individual solution space. To carry out the analysis of flexibility, solutions of a specific MST in an expert solution space are divided into groups according to the level of differences between the solutions. The first solution presented in a certain solution group is scored 10 even if it is the only solution in the individual solution space. Additional solutions from the same, already represented, group receive a score of 1 or 0.1, depending on the degree of difference between the two solutions.

The originality of a student's specific solution is measured by how rare its solution group is in the mathematics class to which the student belongs. Solutions from a solution group that recur in more than 40% of the individual solution spaces of a certain class are scored 0.1. Solutions from less frequent solution groups (15%-40%) are scored 1. Solutions are considered to be most original if they belong to groups with a frequency lower than 15%. The originality of these solutions is scored 10. The originality score for the same solution group may vary in different classes as a result of its different rate of recurrence in those classes. The border values of 15% and 40% for different levels of originality were established based on experimentation (Leikin, 2009).

The decimal basis of the flexibility/originality scores makes it easy to interpret the total flexibility/originality score. For example, a total flexibility score of 21.3 means that the individual solution space contains two solutions belonging to different

solution groups, one solution that uses a solution strategy similar to one of the previously used ones but different in some essential characteristics (e.g., representation), and three solutions that are repetitive. If the total originality score is 21.3 for a solution space, this means that the solution space includes two original solutions, one solution that is partly original, and three conventional (non-original) solutions.

The data analysis of the two studies described in this paper employed the model, and we compared development of fluency, flexibility and originality in two different learning environments: a problem-solving course for pre-service mathematics teachers (PMTs) and a geometry course for high school students. Similarities in the findings of these studies have led us to several theoretical hypotheses which will be presented in this paper.

STUDY 1: EMPLOYING MSTs IN A PROFESSIONAL DEVELOPMENT COURSE

This study examines development of problem-solving expertise in PMTs through employment of MSTs at a professional development course (Leikin & Guberman, in preparation). Problem-solving expertise in this study was determined by correctness of PMTs' solutions and their mathematical creativity (as defined above).

Setting

Twenty-seven pre-service mathematics teachers (PMTs) who were studying towards their B.Ed. in elementary school mathematics participated in the research. They took part in the Problem-Solving course during the 3rd or 4th year of academic studies. One of the researchers conducted a teaching experiment focusing on MSTs.

When coping with MSTs during the course, PMTs were encouraged to compare their individual solution spaces and discuss the quality and aesthetics of different solutions in the collective solution spaces. We analyzed changes in teachers' mathematical creativity and their success in solving MSTs. The pre-test was given to PMTs during the 2nd lesson of the 56-hour courses and the post-test during the last lesson of the course. Each test lasted approximately 90 minutes.

We compared the development of problem solving expertise in two groups of PMTs who participated in the course: HA (high achievers) and LA (low achievers). For this purpose we examined PMTs' achievements at three elementary mathematics courses (Arithmetic, Algebra and Euclidian Geometry) which were central to the professional development program in which participants of this study took part. The division of the PMTs into two groups -- HA and LA -- was based on the mean score (M_m) they received in the three courses. The HA group included participants with M_m between 85 and 97, whereas the LA group included participants with M_m between 70 and 84. This division generated an approximately equal number of PMTs within the groups (13 LA and 14 HA).

Mathematical tasks in the study

The problems used in the study were chosen based on the following considerations:

- The tasks are non-conventional with respect to the standard Israeli textbooks while their solutions require knowledge from elementary school mathematics curriculum only. Thus we assumed that study participants were able to approach the problems in at least one way.
- The problems belong to different mathematical topics and require knowledge of different mathematical concepts.
- Each of the problems allows performing at least 2 different solutions.

Task: Solve the following problem in as many ways as possible

Two gears, one with 15 teeth and the other one with 20 teeth, fit together as shown in the figure. Each gear has a marked tooth as indicated in the figure. After how many rotations of the gears will the marked tooth be together again for the first time?

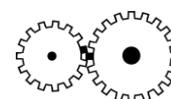

Figure 1: Example of a task used in this study

Data analysis

Each individual solution space in the pre- and post-test was scored for correctness, fluency, flexibility, originality and creativity. The tool reliability of the model was confirmed by the significant high correlations between all the criteria. We compared scores for the participants' problem-solving expertise on the pre-test and post-test for all the criteria for each of the two groups – HA and LA. We also compared problem solving performance of HA and LA on the pre-test and post-test. The comparison was performed using T-tests and Repeated Measures ANOVA.

Findings

Table 1: Changes in success and creativity – Study 1

	Success			Fluency			Flexibility			Originality			Creativity		
	HA Mean (SD)	LA Mean (SD)	t	HA Mean (SD)	LA Mean (SD)	t	HA Mean (SD)	LA Mean (SD)	t	HA Mean (SD)	LA Mean (SD)	t	HA Mean (SD)	LA Mean (SD)	t
Pre-test	66.2 (20.2)	62.9 (26.9)	0.35	2.25 (.8)	2.1 (.9)	.57	21.7 (8.3)	21.3 (9.9)	.09	3.3 (4.5)	3.1 (4.7)	1.27	30.6 (45)	38.9 (62.3)	.386
Post-test	100 (0)	86.6 (22.8)	2.26*	6.8 (1.4)	4.7 (1.4)	2.81**	51.1 (12.3)	35.1 (14.7)	3.0**	1.2 (.8)	.5 (.4)	2.70*	48.5 (36)	15.8 (18.3)	3.06**
t	5.8***	3.13**		9.47***	4.2***		5.63***	3.28***		1.53	2.12		.92	1.4	
ΔT	33.8	23.7	F= 1.03	4.55	2.6	F= 5.93*	29.4	13.8	F= 5.54*	-2.1	-2.6	F= .005	17.9	-23.1	F= 2.63

During the course we observed meaningful changes in PMTs' problem-solving expertise. Contrary to pre-test at which PMTs' solutions were non-systematic, mainly based on trial and error strategy, at post-test, when solving the problems, PMTs used

systematic mathematical concepts and rules. Only at post-test PMTs employed a variety of representations, e.g., algebraic expressions, tables, number line, diagrams.

HA and LA began their participation in the course with similarly low results on all the examined criteria: correctness, fluency, flexibility, originality. The differences between these two groups on all the criteria were not significant.

Both HA and LA significantly improved their *correctness, fluency and flexibility* through their participation in the course. Changes in fluency manifested in the number of solutions produced by PMTs to each one of the problems: from 0, 1 or 2 solutions at pre-test to 2 to 8 solutions at post test. The flexibility changed from one type of solution to each of one of the problems on the pre-test to four types of different solutions on the post-test. At the same time, the improvement of correctness, fluency and flexibility in HA was higher than in LA. The differences in the increase of fluency and flexibility between HA and LA were significant. As a result, on the post-test, correctness, fluency and flexibility in HA became significantly higher than in LA. These differences [probably] explain teachers' [mistaken] belief that MSTs are appropriate for implementation with high achievers only. However, as noticed above, our study clearly demonstrates that MSTs are an effective tool for the development of PMTs' problem-solving expertise both in HA and LA.

Contrary to the findings related to fluency and flexibility, originality in both groups of participants decreased non-significantly from pre-test to post-test. We assume that the increase of flexibility caused the decrease in the numbers of original solutions that PMTs were able to produce. The decrease in originality was [non-significantly] lower for HA and, as a result, originality in HA was significantly higher than originality in LA.

Correlation between originality and creativity was higher than correlations between fluency and creativity and between flexibility and creativity. Additionally, the changes in creativity were similar to changes in originality and different from changes in fluency and flexibility. Thus, we hypothesize that originality is the major component that determines creativity.

STUDY 2: MSTs IN SCHOOL GEOMETRY

This study explores systematic implementation of Multiple Solution (Proof) Tasks (MST) in school geometry (Levav-Waynberg, in progress; Levav-Waynberg & Leikin, 2009, submitted). In addition to the development of a mathematical creativity compound of fluency, flexibility and originality, in this study we examine development of the connectedness of students' geometry knowledge as reflected in the multiple proofs that they produce. We compare the changes in geometric creativity and knowledge on high level (HL) students versus regular level (RL) students.

Setting

Three hundred and three tenth-grade students from 14 instructional groups participated in this study. The classes were divided between experimental and control groups HL and RL. In this paper we address the study involving the experimental group only.

Students in the experimental group were consistently encouraged to perform and discuss various proofs to geometrical statements during a whole school year. The students were given a pre-test (at the beginning of the school year) and a post-test (at the end of the school year). Each test included 2 proof problems and lasted 60 minutes. Students were asked explicitly to perform as many proofs as they could for each one of the problems.

**Example: AB-diameter, O-center of the circle
OD||AC, Prove: DB=CD**

OD is a midline of the triangle EAB: ED=DB. We need to prove CD=DB

<p><u>Proof 2.1</u> Construct – AD –median, $\angle ADB=90^\circ \Rightarrow$ $\triangle EAB$-isosceles AD bisect angle EAB $\Rightarrow CD=DB$</p>	<p><u>Proof 2.2</u> Construct – CB OD midline in $\triangle ACB$ $\Rightarrow OD$ bisects CB $\Rightarrow CD=DB$</p>	<p><u>Proof 2.3</u> Construct – CB $\angle ACB=90^\circ$ $OD \parallel AC \Rightarrow OD \perp CB$ $\Rightarrow CD=DB$</p>	<p><u>Proof 2.2</u> Construct – OC $\angle DOB = \angle EAO = \alpha$ $\Rightarrow \angle ACO = \alpha \Rightarrow \angle COB = 2\alpha$ $\Rightarrow \angle COD = \alpha$ $\Rightarrow CD=DB$</p>
<p><u>Proof 2.3</u> As in proof 2.1 EAB-isosceles triangle As in 2.2 – calculation of the angles \Rightarrow $\triangle CDE$ is an isosceles triangle</p>	<p><u>Proof 2.7</u> Construct – OC $\angle DOB = \angle EAO = \alpha$ $\Rightarrow \angle COB = 2\alpha$ (central angle) $\Rightarrow \angle COD = \alpha \Rightarrow CD=DB$</p>	<p><u>Proof 2.6</u> Construct – CB $\angle ACB=90^\circ$ rests on the diameter $\Rightarrow \angle ECB=90^\circ$; $ED=DB$ CD –median in the right angle triangle ECB $\Rightarrow CD=DB=ED$</p>	

Figure 2: Example of a MST in Study 2

Data analysis

Each individual solution space was scored for correctness, connectedness, fluency, flexibility and originality. Connectedness was scored according to the number of concepts and theorems in the individual solution space relative to the total number of concepts and theorems in the corresponding expert solution space. Fluency, flexibility, originality and creativity were scored according to the scoring scheme described earlier in this paper. Repeated measures MANOVA was performed in order to compare the development of the different criteria (for the experimental and

Working Group 7

control groups of HL and RL). The tool reliability was confirmed by significant correlations between all the criteria. High correlations were found between correctness, connectedness, fluency and flexibility, on the one hand, and between originality and creativity, on the other hand. Originality appeared to be the strongest component in determining creativity

Findings

Table 2: Changes in success and creativity – Study 2

	Success			Fluency			Flexibility			Originality			Creativity		
	HL Mean (SD)	RL Mean (SD)	F(1,165)	HL Mean (SD)	RL Mean (SD)	F(1,165)	HL Mean (SD)	RL Mean (SD)	F(1,165)	HL Mean (SD)	RL Mean (SD)	F(1,165)	HL Mean (SD)	RL Mean (SD)	F(1,165)
Pre-test	83 (23)	67 (30)	45.3 *** (Time)	3 (1.5)	2 (1)	88.1 ***	23 (9)	18 (8)	45.4 ***	2.4 (4.5)	1.2 (2.9)	0.4	55 (129)	19 (52)	0.002
Post-test	96 (14)	88 (21)		4.8 (2.3)	3.1 (1.5)		30 (10)	23 (9)		1.6 (3.5)	1.5 (3.7)		48 (164)	24 (62)	
(Time× group level) F (1,165)	2.8			4.6*			1.1			1.5			0.16		

Students of HL and RL improved significantly the *correctness* of their solutions, without significant differences between the participants of RL and HL. *Connectedness* of students' knowledge improved non-significantly in groups of both HL and RL, but in contrast to the changes in correctness, changes in connectedness were significantly higher in HL than in LA. All the groups improved their *fluency* and *flexibility* over time. These findings also show that fluency and flexibility are strongly based on knowledge. Students of HL demonstrated a significantly higher change in fluency in comparison with the students from RL group.

There was no significant effect of the experimental intervention on originality. For HL students the mean originality score decreased while there was a slight increase in originality for RL students (although this difference between HL and RL was not significant). We explain this phenomenon by the relative nature of the evaluation of originality in our study: when students become more fluent they have less chance to be original.

When focusing on the most original solutions produced by the students in this study we found that these solutions were produced by HL students only.

DISCUSSION

The two studies presented in this paper examined employment of MSTs in two different educational settings. In Study 1, we used MSTs in the problem-solving course for pre-service mathematics teachers (PMTs), comparing development of PMTs' creativity in high achievers (HA) and low achievers (LA). In Study 2 we

Working Group 7

implemented MSTs in school geometry; we compared development of geometry knowledge and creativity in high level (HL) and regular level (RL) students. These two studies demonstrate several common phenomena (see Figure 3).

The graphs in Figure 3 show the changes in correctness, fluency, flexibility and originality found in the two studies for the different groups of participants (LA versus HA groups for Study 1 and RL versus HL in Study 2).

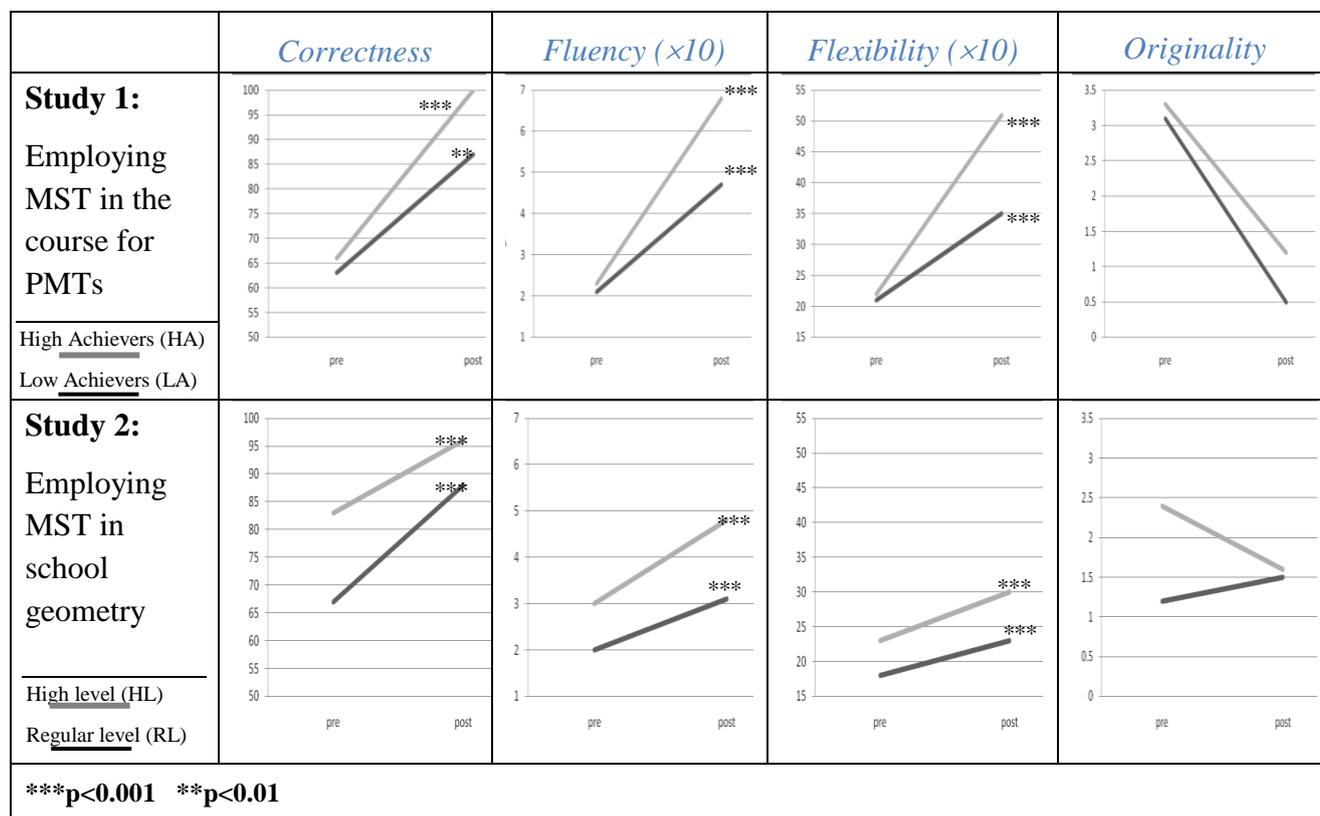

Figure 3: Developing problem-solving expertise by employing MSTs: Two studies

We found that in both studies:

- a. Participants at both levels significantly improved their problem solving correctness, fluency and flexibility.
- b. The improvement in all the criteria was shown for participants of both levels: high level (HA/HL) and lower level (LA/RL).
- c. The improvement of fluency (in both studies) and flexibility (Study 1) was significantly greater for the high level participants than for participants of lower level. (In Figure 2 this is depicted by a bigger slope for HA/HL than for LA/RL).
- d. Originality of the solutions decreased non-significantly in high level participants (in Study 1 also in low level participants).

- e. Correlations between the three combined components of creativity (fluency, flexibility and originality) and the creativity outcome are significant.
- f. Correlations between fluency and flexibility as well as between originality and creativity are high.
- g. Correlations between originality and creativity are higher than 0.9

Figure 3 summarizes the changes in all the examined components in the two studies.

The consistency of the findings concerning the increase of fluency and flexibility along with the decrease in originality validates the model. The two studies demonstrate that MSTs are an effective didactical tool. The comparison between control and experimental groups in Study 2, which was not the focus of this paper, strengthened this assertion by the findings that experimental HL group, which systematically employed MSTs, improved significantly higher on its connectedness, fluency and flexibility than the control group.

We hypothesize that in the fluency-flexibility-originality triad, **fluency and flexibility** are of a **dynamic nature**, whereas **originality is a "gift"**. We demonstrate that **originality** appeared to be the strongest component in determining **creativity**.

The strength of the relationship between creativity and originality can be considered as validating our model, being consistent with the view of creativity as an invention of new products or procedures. At the same time, our studies demonstrate that this view is true for both absolute and relative creativity.

Based on the research findings, we hypothesize that, one of the ways of identifying mathematically gifted students is by means of originality of their ideas and solutions. Systematic research should be performed to examine our hypotheses.

Finally, we assume that developing mental flexibility and fluency in and of themselves is of great importance. Probably other types of activities, such as problem posing (which includes elaboration and generalization) and mathematical explorations, are also effective in developing originality, but this assumption requires a different empirical investigation. The model presented in this paper can be useful for such an investigation.

MATHEMATICAL CREATIVITY IN ELEMENTARY SCHOOL: IS IT INDIVIDUAL OR COLLECTIVE?

Esther Levenson

Tel Aviv University

This study combines theories related to collective learning and theories related to mathematical creativity to investigate the notion of collective mathematical creativity. Collective learning takes place when mathematical ideas and actions, initially stemming from an individual, are built upon and reworked, producing a solution which is the product of the collective. Referring to characteristics of individual mathematical creativity, such as fluency, flexibility, and originality, this paper examines the possibility that collective mathematical creativity may be similarly characterized. The paper also explores the possible relationship between individual and collective mathematical creativity.

Key words: mathematical creativity, elementary school mathematics, individual creativity, collective creativity.

Many studies have investigated ways of characterizing, identifying, and promoting mathematical creativity. Haylock (1997), for example, and more recently, Kwon, Park, and Park (2006) assessed students' mathematical creativity by employing open-ended problems and measuring divergent thinking skills. Leikin (2009) explored the use of multiple solution tasks in evaluating a student's mathematical creativity. What many of these studies had in common was that they focused on the mathematical creativity of individuals. This study focuses on the collective, not as the aggregation of a few individuals, but as a unit of study. Although some of the studies mentioned above acknowledged the effect of classroom culture on the development of mathematical creativity, and others considered the creative range of a group of students, these studies did not necessarily investigate mathematical creativity as a collective process or as the product of a collective endeavour.

This study combines theories related to collective learning and theories related to mathematical creativity to investigate the notion of *collective mathematical creativity*. The notion of collective creativity has been used to investigate creativity in several contexts including the work place (Hargadon & Bechky, 2006) and the global community (Family, 2003). In those cases, collective creativity was considered to occur when the social interactions between individuals yielded new interpretations that the individuals involved, thinking alone, could not have generated. Can the notion of collective creativity also be applied to mathematics education?

THEORETICAL BACKGROUND

Two main issues are at the heart of this study, the nature of mathematical creativity and the collective nature of mathematical learning. This section begins by describing

three key components of mathematical creativity: fluency, flexibility, and originality. These components are mentioned in several studies which view creativity as “an orientation or disposition toward mathematical activity that can be fostered broadly in the general school population” (Silver, 1997, p. 75). The section then describes the collective nature of mathematical learning.

Fluency, flexibility, and originality

Silver (1997) related fluency to “the number of ideas generated in response to a prompt” (p. 76). He claimed that the use of ill-structured and open-ended problems in instruction may encourage students to generate multiple solutions developing fluency. Leikin (2009) referred to fluency as the pace at which solving proceeds and measured the number of solutions produced by a student.

Flexibility, according to Silver (1997) refers to “apparent shifts in approaches taken when generating responses to a prompt” (p. 76). Leikin (2009) evaluated flexibility by establishing if different solutions employ strategies based on different representations, properties, or branches of mathematics. At times, it helps to think of flexibility in relation to its counterpart, fixation. In problem solving, fixation is related to mental rigidity (Haylock, 1997). Flexibility is then shown by overcoming fixation or breaking away from stereotypes. Haylock further differentiated between content-universe fixation and algorithmic fixation. Overcoming the first type of fixation requires the thinker to consider a wider set of possibilities than at first is obvious and extend the range of elements appropriate for application. The second type of fixation relates to when an individual adheres to an initially successful algorithm even when it is no longer appropriate. Originality is related to creating new ideas. For example, the systems model of creativity suggests that when an individual employs the rules and practices of a domain to produce a novel variation within the domain content, then that individual is being creative (Sriraman, 2009). With regard to mathematics classrooms, this aspect of creativity may manifest itself when a student examines many solutions to a problem, methods or answers, and then generates another that is different (Silver, 1997). Leikin (2009) measured the originality of a solution based on its level of insight and conventionality according to the learning history of the participants.

The collective nature of mathematical learning

Different studies have taken into account the social context of mathematical learning. For example, Yackel and Cobb (1996) introduced the notion of sociomathematical norms to describe “normative aspects of mathematical discussions that are specific to students' mathematical activity.” (p. 458). They were interested in how normative aspects of mathematics discussion are developed, such as what counts as mathematically different, mathematically efficient, and mathematically elegant. While these norms are important for guiding interactions between individuals, they are not necessarily indicative of the individuals acting as a collective.

According to Martin, Towers, and Pirie (2006) collective mathematical understanding emerges from coactions. Coactions describe particular mathematical actions carried out by an individual but which are “dependent and contingent upon the actions of the others in the group” (p. 156). Collective understanding does not necessarily occur whenever two or more people collaborate or interact. Instead, “coacting is a process through which mathematical ideas... initially stemming from an individual learner, become taken up, built on, developed, reworked and elaborated by others...” (p. 156).

Research aims

According to Haylock (1997) there are two main approaches to recognizing creativity. The first is to consider the cognitive process which is indicative of creative thinking. Overcoming fixation is one such process. The second approach is to consider the product which indicates creative thinking has taken place. An original solution would be one such product. The first aim of this study is to explore both the process involved in collective mathematical creativity as well as the product of collective mathematical creativity.

The three key components of creativity discussed above, fluency, flexibility, and originality, are sometimes related to the process (Shriki, 2010) and sometimes related to the product (Haylock, 1997). The second aim of this study is to examine if and how the notions of fluency, flexibility, and originality used when describing individual mathematical creativity may also be used to describe collective mathematical creativity. That is, is it possible to speak of collective fluency, collective flexibility, and collective originality?

Finally, although the aim of this study is to explore the emergence of collective mathematical creativity and describe its nature in elementary school mathematics classes, it also acknowledges the significance of individual mathematical creativity. Thus the third aim of this study is to explore the interrelationship between individual mathematical creativity and collective mathematical creativity.

METHODOLOGY

One fifth grade and one sixth grade class participated in this study. The sixth grade teacher had 14 years experience teaching fifth and six grades. The fifth grade teacher had eight years experience teaching fifth and sixth grades. Both teachers taught according to the mandatory mathematics curriculum using state approved textbooks. The teachers did not collaborate with the researcher and were not explicitly implementing a program aimed at promoting creativity. During the school year, each class was observed approximately ten times. During classroom observations, the focus was on students’ interactions with materials, other students, and teachers and the ways in which “ideas are picked up, worked with, and developed by the group”

(Martin, Towers, & Pirie, 2006, p. 152). All lessons were video recorded and transcribed by the researcher who also took field notes during the observations.

RESULTS

In this section I describe three classroom episodes that illustrate different aspects of mathematical creativity. The first episode was taught by the first teacher. The second and third episodes were taught by the second teacher. For each episode I describe the main aim of the lesson, the classroom interactions, and the mathematical creativity, individual and collective, observed.

Episode 1: Collective fluency and collective flexibility?

This episode was taken from a sixth grade class, in the middle of the school year, where the main topic of the lesson was multiplication of decimal fractions. The class had already been introduced to this topic and had already practiced the procedure for multiplying decimal fractions during previous lessons. The teacher put the following problem on the board, $_ \times _ = 0.18$, and asked the class, “What could the missing numbers possibly be?” Many children raise their hands while the teacher comments, “There are many possibilities.” She then calls on one at a time:

Gil: 0.9 times 0.2.

Teacher: Another way. There are many ways.

Lolly: 0.6 times 0.3.

Teacher: More.

Tammy: 0.90 times 0.20.

Teacher: Would you agree with me that 0.2 and 0.9 is the same [as 0.90 and 0.20]? I want different.

Miri: I’m not sure. 9 times 0.02.

Teacher: Nice. Can someone explain what she did?

(The teacher and students then review the rules for multiplying decimal fractions.)

First, we note that although Gil and Lolly gave different answers both answers may be considered similar in that they consisted of two numbers with one digit after the decimal point. The teacher does not acknowledge their similarity. However, when Tammy attempts to break the mould, the teacher does not accept the answer because 0.9 is equal to 0.90. This relates to sociomathematical norms and the establishment of what it means for solutions to be different. In this case, the teacher is establishing that merely expanding a number from 0.9 to 0.90 does not qualify for difference. She then requests a different solution, which is supplied by Miri.

Tom: What about 0.18 times 0.1?

Tad: No.

Working Group 7

Gad: 0.18 times 1.

Toby: 18 times 0.1?

Many students: 18 times 0.01.

Teacher: Let's move to another problem

This episode illustrates how one child may have the germ of an idea but another child may develop it. In the first vignette, Gil, factoring 18 into 9 and 2, comes up with one solution. Tammy attempts to use the same factors as Gil, but is not successful. Miri then follows up on the idea, producing an additional solution. The same scenario occurs in the second vignette. Tom has the idea of factoring 18 into 1 and 18 but comes up with an incorrect solution as witnessed by Tad. Gad follows up on the idea and comes up with a correct solution. Toby also attempts to find a solution with the same basic factors which is then corrected by other students in the class.

In this episode we also see an illustration of collective fluency which seems to have been promoted by the teacher. The teacher has the class working together to produce many different solutions to the same problem. Up until this point in the lesson, the class came up with five different correct solutions. Perhaps, if more time was available, the class may have produced more solutions.

Regarding flexibility, we note that the second solution, 0.6×0.3 followed more or less the same strategy as the first solution 0.9×0.2 . The last three solutions, 9×0.02 , 0.18×1 , and 18×0.01 , may also be considered similar to each other. Each example consists of one factor which is a whole number and a second factor which is a decimal fraction with two digits after the decimal point. Thus, it seems as though this problem promoted collective fluency but not necessarily collective flexibility. Only one student, Miri, was successful in employing a different strategy, a sign of flexibility. And yet, Miri's solution came after Tammy's suggestion. Although the teacher did not accept Tammy's solution as being different from the first, it was Tammy who attempted a solution with two digits after the decimal point. Perhaps, the flexibility manifested in Miri's correct solution was the result of working on Tammy's suggestion. Perhaps, Miri understood what was meant by a solution being different and had the courage to think flexibly after Tammy paved the way. In other words, it is possible that in this case collective flexibility refers to a collective process and not necessarily that the group, as a whole, produced solutions based on different strategies.

Episode 2: Individual or collective originality?

This episode took place in the fifth grade classroom with the second teacher. The students had previously been introduced to decimal fractions, had learned to convert back and forth between decimal fractions and simple fractions, and had recently learned to add and subtract decimal fractions. The main topic of the current lesson

Working Group 7

was reviewing addition and subtraction of decimal fractions. The following problem, taken from the classroom textbook, was given as a homework assignment, and, at the request of one of the students, was reviewed in class.

Complete the following sequence: $\frac{5}{100}, \frac{30}{100}, \frac{\quad}{100}, \frac{\quad}{100}, \frac{\quad}{100}$

The following discussion ensues:

Teacher: After 30/100, mmm hundredths, and again, mmm hundredths, and again. They want a sequence. What is a sequence?

Oren: It continues with jumps.

Teacher: Equal jumps. The jumps must be equal. What types of jumps are there?

(A few students say out loud different numbers: 25 and 25/100.)

Teacher: That's the size of the jump. You mean to add 25/100.

Oren: Can the jumps be in multiplication?

Teacher: Wonderful. That's exactly what I mean. If I jump by adding 25/100 then the next will be 30/100. Now, you mentioned another type of jump. We didn't learn that yet...it's part of next year's syllabus. But, there are also multiplication jumps. Who said that going from 5/100 to 30/100 means that I added 25 [hundredths]. I can also multiply...

Sam: By 6.

Sarah: 180.

Teacher: 180 hundredths.

At this point it is worthwhile to note that although multiplication of simple fractions and decimal fractions had not yet been introduced, Oren came up with this idea by himself. Furthermore, although it is technically part of next year's curriculum, the teacher does not dismiss this idea. Finally, two more children contribute to the idea by carrying out the actual multiplication

Oren: That's what I did at first. But I thought it was a mistake.

Teacher: Is that allowed?

Tina: I thought that it would be a mistake.

Noam: But then you get big numbers.

Teacher: So, you can use a calculator.

Note that at least two children thought of multiplying but ended up dismissing the possibility for various reasons. Noam, who claims that he would end up with "big numbers", shows signs of content fixation. This may have been brought on by previous textbook examples which refrained from using 'big' numbers. The teacher

Working Group 7

is quick to negate this excuse, keeping the door open for additional possibilities. Noam then takes Oren's idea one step further, by considering division.

Noam: Then you can also divide.

Teacher: You can divide, but not here (referring to the jump from $5/100$ to $30/100$).

Noam: You can multiply by 6 and then divide by 3.

Teacher: Ok. That's also a type of sequence. Multiply by 6, divide by 3, and then again multiply by 6 and divide by 3.

Tina: But, that's not good. You need equal numbers.

Teacher: This is a different type but it is certainly acceptable. Let's try it.

Tina: But, it won't come out. You need equal numbers.

Teacher: Let's just say that when the textbook requests a sequence, they generally don't mean this type. They usually mean jumps that are the same each time. But, this is definitely a sequence.

Tina: But, they are not all equal.

Aaron: You can also have more than two types of jumps. Multiply, divide, and add.

Noam expands on the idea of multiplication and division jumps by including both in the same sequence. This is a novel idea, which the teacher accepts. Yet, the teacher does not succeed in convincing Tina that two types of jumps may also be considered a sequence. While conceding that this type of sequence may not be the norm, the teacher attempts to legitimize thinking that may be outside the norm. At the end of this vignette, Aaron, who has previously remained silent, but apparently has been listening, joins in and adds yet another novel idea.

Looking back, it is apparent that several children displayed original ideas. First, we have Oren. The children had not yet learned multiplication of fractions and yet, he considers the possibility. Then there is Noam who suggested employing both multiplication and division in the same sequence and raises the possibility that the jumps do not have to be equal. Recall that the teacher had previously said that a sequence consists of equal jumps. Finally, Aaron suggests employing three mathematical operations at once in the same sequence. Perhaps, employing multiplication and division may be allowed because they are essentially inverse operations. But to consider addition in the same sequence is indeed novel. So, who displayed original thought? Certainly, Oren, Noam, and Aaron suggested novel ideas. Yet, looking at the sequence of events, it also seems that each student built on the previous student's idea. So, was Oren the only student to display original thinking? Perhaps, taken together, we can say that this is an illustration of collective originality.

Episode 3: Individual or collective flexibility?

Working Group 7

This episode is actually a continuation of the previous episode. The teacher presents another problem from the book.

Teacher: Let's look at another problem. Build a sequence that has in it the numbers 0.2 and 1.1.

(Four children raise their hands.)

Aaron: Add 0.9.

Teacher: You're saying to place them next to each other and then the difference is 0.9. Then what would be the next number?

Judy: 2.

Teacher: And then?

Mark: 2.9.

Teacher: But who says that the two numbers have to be next to each other?

Tali: You can do 0.3.

Teacher: Jumps of 0.3. (The teacher writes on the board 0.2, 0.5, 0.8.)

Aaron: You can put the sequence in backwards order and do subtraction.

Teacher: Ok. You can start with 1.1.

In this episode, the class is working on an open-ended or ill-defined task. Unlike the previous task in the previous episode where the first two numbers in the sequence were given, in this task, two numbers are given but are not placed in any specific order. The teacher takes advantage of the situation in order to promote flexibility. In other words, she seems to be less interested in promoting fluency and more interested in trying to encourage the students to think of various ways of placing the numbers. She then raises another suggestion, moving in an entirely different direction than the ones suggested by the students.

Teacher: I have another idea. You can expand the numbers. (The teacher writes on the board 0.20, leaves a lot of space, and then writes 1.10.)

Tomer: 0.9.

Shay: Nine and a half.

Teacher: 0.90 so the expansion is by 10 and then I can do jumps of 0.45. Is that allowed?

Tomer: Yes.

This last part is interesting because it seems that the teacher is also displaying flexible thinking and joining the collective effort to come up with various ways of placing the two numbers in a sequence. If we look at the different solutions to this problem, we may count four solutions where each solution stems from a very

different way of combining the numbers into a sequence. Perhaps, we can call this collective flexibility.

DISCUSSION

When reviewing the episodes presented in this paper, it is possible to discern both the process and product of collective mathematical creativity. Regarding the collective process, we focus on the interplay of ideas put forth by individuals which is then woven together. When describing the product of collective mathematical creativity, we look not only towards the individual solutions but towards the end product of the collective process. For example, in the first episode, one student put forth an idea, another expanded it, another assessed the correctness of a solution, and the teacher clarified boundaries. The end product consisted of five solutions brought forth by the collective. On the one hand, this is similar to the notion of a collective solution space which is “a combination of the solutions produced by a group of individuals” (Leikin, 2009, p. 134). On the other hand, rather than looking at each solution as the product of one person’s creativity and then merely collecting them together, we look at the five solutions as the product of the collective.

Throughout this paper fluency, flexibility, and originality were used to describe mathematical creativity related to the collective. In the first episode, we reflected on collective fluency as a product of the collective effort and pondered the possibility of discussing collective flexibility. Can we talk about a collective being flexible? Perhaps collective flexibility may refer to the dynamic process by which one student leads the group in one direction which then reminds another student about the possibility of another direction. Together, the group tries out various strategies and possibly produces solutions based on different mathematical properties or different representations. Thus collective flexibility may be used to describe a process as well as a product. Regarding originality, it seems almost far fetched to talk about collective originality. Originality presumes a unique or novel idea. If the idea is unique, is it not individual? Leikin (2009) suggested that originality is relative, that a solution’s novelty is relative to the solutions produced by the group. And yet, although a solution may be unique, it may be the product of a collective process of creativity. Which brings us to the question, what is the relationship between individual and collective mathematical creativity?

Although the focus of this study was on collective mathematical creativity, one cannot help but notice the many instances of individual mathematical creativity. Raising the idea that the jumps of a sequence do not have to be equal, illustrates how one student was able to break away from a stereotype. By focusing on collective mathematical creativity this study does not claim that individual mathematical creativity is not important. On the contrary. As noted by Martin, Towers, & Pirie (2006) a musical performance, such as a jazz improvisation, is highly dependent on the creativity of each individual player. Yet, together, the musicians create a

performance that is more than the sum of its parts. So too, individuals, working on a mathematics problem, may each contribute insights, ideas, and directions building eventually to a collective idea. At the end of the second episode, one student came up with the original idea of creating a sequence that employed three mathematical operations. This idea was not put forth in a vacuum. Before him, there was a student who introduced the idea that a sequence may employ two operations and before him a student who introduced the idea that the jumps in a sequence do not have to be equal. In other words, the students built on each other's ideas coming up with many different solutions as well as some very novel solutions. So, can we say that the final original idea was only that of the one student? Or, might we say that the final original idea was the product of the collective?

In considering the relationship between individual mathematical creativity and collective mathematical creativity, we might also consider affective issues. On one's own, a student may lack the persistence sometimes necessary for creative mathematical thinking or the courage to try something new (Movshovitz-Hadar, 2008). Working as a collective may actually encourage students to keep at it and try new ideas. In other words, by promoting collective mathematical creativity we may also be promoting individual mathematical creativity.

This paper combined two fields of study, collective learning and mathematical creativity, in an initial investigation into the notion of collective mathematical creativity in elementary school classrooms. Many questions remain. What is the teacher's role in this endeavour? Will the same types of tasks used to promote individual mathematical creativity promote collective mathematics creativity as well? What are the ramifications of the age of the students? Additional research is necessary in order to answer these as well as other questions.

DEVELOPING CREATIVE MATHEMATICAL ACTIVITIES: METHOD TRANSFER AND HYPOTHESES' FORMULATION

Bozena Maj

University of Rzeszow

This paper describes a series of workshops conducted among mathematics teachers. The aim of the workshops was to develop creative mathematical activities among the teachers. The analysis of the transcripts is focused on two kinds of such activities: transfer of a method and hypotheses' formulation and verification. The results show a considerable improvement in the teachers' ability and their attitude towards creative mathematical activities.

Keywords: creativity, hypotheses' formulation and verification, transfer of a method

INTRODUCTION

Mathematics education should harmonize with the socio-economical need of preparing people to everyday life. In many professions creativity, ingeniousness and a creative attitude to problems are required even from a young person who just entered the field. At the same time, that creative side of education is almost absent at school. Mathematics teaching very often has an imitative and reproductive character. It is focused on elementary activities and skills leading the students to learn schematic behaviours. This is because the teachers are not sufficiently prepared to promote creativity in mathematics among their students. They do not have sufficient knowledge, skills, experience and didactical tools to develop creative mathematical activities among their students (Klakla, 2008; Maj, 2006). The essential condition for the development of the skills needed for different kinds of creative mathematical activities among students is the deep understanding of those issues by the mathematics teachers. Only then the teachers can effectively form and develop these activities in their work with the students. According to Nęcka (2005) "a creative teacher will educate creative pupils, a not much creative teacher will rather discourage pupils from unconventional thinking" (p. 201).

THEORETICAL BACKGROUND

According to Ervynck (1991) mathematical creativity is the ability of problem solving and/or developing structural thinking by taking into consideration the logical and deductive nature of mathematics. He gives some examples of creativity in mathematics: the ability to formulate a valuable definition by using the concepts which ensure the usefulness of the defined object in a later theory; the mathematization of basic ideas taken from a real context which were initially the base of a mathematical problem. Therefore, according to him mathematical creativity is both the ability of creating mathematical objects and discovering mutual relations between them. Ernest (2008) sees creative mathematical activity as solving

problems, using mathematical methods or performing investigative work; this usually includes the formulation of more complex tasks. It requires a novelty and an insight into the choice of transformations and the choice of the elements of a task that could be used in order to create a sequence of such transformations. For Lakatos (2005) mathematics is not predictable, you cannot create it step by step in a specific direction. You can rather compare it with discovering a new territory during which the 'trip' could be pointless. It is similar to mathematical thinking, which contrary to ready-made knowledge is a creative activity which allows the possibility of mistake.

From the above we can conclude that mathematical creativity is related to different kinds of creative mathematical activities. A detailed description of such activities has been worked out by Klakla (2002) who distinguishes seven kinds of creative mathematical activities, which are present in an essential way in activities of mathematicians. These are: (1) hypotheses' formulation and verification; (2) transfer of a method; (3) creative receiving, processing and using mathematical information; (4) discipline of thinking and critical thinking; (5) problems' generation in the process of the method transfer; (6) problems' prolonging; (7) placing the problems in open situations. These activities can be formed through multistage tasks which consist of series of tasks, problems and didactic situations which have a specific structure. They are based on problematic situations and connect different kinds of creative mathematical activities with each other in complex and rich mathematical-didactic situations.

From the previous activities, the transfer of a method, which is described in literature also as 'analogical transfer', is for some researchers the main (or even the only) means to solve novel problems (Reeves & Weisberg, 1994; Polya, 1957). In order to undertake the transfer of a method, firstly you have to familiarize with a problem's solution based on an idea. The analysis of the solution makes you realize the essence of that idea by abstracting any unimportant data or context. This leads to the awareness of the class of tasks for which the idea of the solution will function. For this class that idea becomes an effective method of reasoning. Sometimes the trials of a method's transfer can be made beyond the class of the tasks, i.e. in similar, analogous or general situations. Then the method requires some modifications and the trials can be successful or not (Klakla, 2002). It is very important to put students in a situation in which the transfer of a method fails.

Another important aspect of creative work in mathematics is formulating and verifying hypotheses. The creative mathematician puts hypotheses in situations when s/he has some premises but does not have a sufficient proof. Such situations may occur in the work of both a mathematician and a student. The difference lies in the cautiousness of the mathematician which is based on previous experiences. By working on some mathematical situations one can perform various empirical investigations: calculations in some concrete cases, experimentations with drawings or reasoning based on analogies. However, accepting that the discoveries are not

enough to state that they are true is not easy for the students. There is a need for formal and conscious evaluating of all stages of reasoning (Klakla, 2002).

METHODOLOGY

In this paper we present a part of a wider research (Maj, 2009) carried among a group of mathematics teachers. We mainly analyse fragments of the workshops, which show the work of the teachers in the direction of the transfer of a method and hypotheses' formulation and verification.

A group of seven teachers of mathematics (of gymnasium and high schools) took part in a series of workshops from March to September 2006. The workshops were organised as part of the Professional Development of Teachers Researchers (PDTR) project, during the mathematics course. The main content of that course was solving different kind of mathematical problems which were supposed to be challenging for the teachers. The workshops were organised around three multistage tasks. They consisted of solving some chosen tasks – open-ended problems and discussing the possibilities of introducing the students to the particular problems. The main aims of the workshops were:

- developing the skills of undertaking creative mathematical activities among mathematics teachers,
- raising the mathematics teachers' awareness of the need to develop creative mathematical activities among students.

We will present an analysis of four fragments of the workshops; these fragments are related to the first and the second multistage task. The analysis was conducted in the direction of answering the following questions:

- Did the teachers gladly engage in working on multistage tasks (emotional aspect)?
- Did the teachers use the transfer of a method or the transfer of a method with modifications?
- Did they formulate some problems, put questions, hypotheses and did they verify them? Were the formulated problems non-trivial?
- Were discipline of thinking and critical thinking evident in the way of verifying the hypotheses?
- What was the role of the instructor during working on multistage tasks?

The data collected comprised of an audio recording of the workshops (24 lesson hours) and notes. After this, a full transcription of the audio recording and analysis of this transcription was made.

Example of the multistage tasks used at the workshops

Task 1 – ‘Lengthening the sides of a triangle’

An acute triangle ABC is given. Construct the triangle A'B'C' by lengthening each side of the given triangle ABC by its own length in the same sense of circulation. Compare the area of the triangles A'B'C' and ABC. Give the ratio of their areas.

- What happens with the ratio of the areas when you make 2-times, 3-times, n-times ($n \in \mathbb{N}_+$) longer the sides of the triangle ABC?
- Consider analogous situation for a convex quadrilateral ABCD.

Task 2 – ‘Butterfly’

An acute triangle ABC is given. Through any point P which belongs to the inside of the triangle, three lines parallel to the every side of the triangle are drawn. The lines divide the triangle ABC of the area S into six parts. Three of them are triangles of areas S1, S2, S3. The figure which is comprised of these three triangles with the common vertex P is called ‘butterfly’. The three triangles are called the ‘wings’ of the ‘butterfly’ (Figure 1).

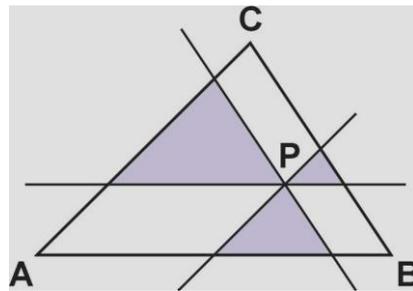

Figure 1. The initial situation of the task ‘Butterfly’.

Without any suggestions on the direction of enquiry the teachers were asked by the instructor: “What questions would you like to ask to that situation?”.

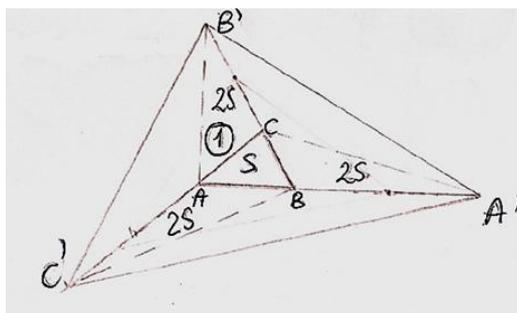

RESULTS

Four fragments of the workshop will be analysed. The dialogs were realised either between the instructor (I) conducting the workshops and the teachers (T) or between the teachers.

The ‘Lengthening the sides of a triangle’ task was the first to be considered at the workshops. During the work on the task three methods of solving were used: proper ‘cuttings’, use of a particular formula of the triangle’s area and use of triangles of the same areas. Then the teachers had the task to prolong the initial situation by changing the number of lengthening into 2-times, 3-times and n-times:

- 1 I: So we have the task: we are lengthening 2-times the triangle’s sides...
- 2 T2: Lengthening 2-times ... (on the blackboard):

Working Group 7

The height is the same (ACB' and ABC) and the base is 3-times longer (the triangle ABB').

- 3 T1: 2-times.
- 4 T4: But it depends on which triangle we are talking about...
- 5 T2: Exactly, maybe we're talking about this one (he is showing the triangle ACB') and here the base is 2-times longer.
- 6 I: So write the area.
- 7 T1: $2S$.
- 8 I: And now what?
- 9 T2: Now...
- 10 T3: Where else is $2S$?
- 11 T2: And now here... Here it will be the same (the triangle ABC'), won't it be?
- 12 T1: Yes.
- 13 T2: Because there is the base AC and the height here (he is showing). And the third connection (he is drawing a triangle CBA'), here is again the same, I mean $2S$. Now, what about these ones? (the other triangles: $CA'B'$, $AB'C'$, $BC'A'$).
- 14 I: Yes, what about it?
- 15 T1, T3: It is 2-times bigger (the triangle $AB'C'$).
- 16 I: When I told you about this student, what I said about this and this? (ACB' and $AB'C'$) [the story of a 12-year old student who solved that problem]
- 17 T2: I must have missed it... what is happening here? (he is thinking)
- 18 T1: I also... I must have missed it too.
- 19 I: He compared this one with this one (ABC and ACB') and then this with this one (ACB' and $AB'C'$).
- 20 T4: And then he turned this situation and there he had the same heights (ACB' and $AB'C'$).
- 21 T2: So he compared this with this, the heights are the same, so it has to be $4S$.
- 22 T1: Once again!
- 23 T2: It will be $2 \cdot 2S$ – because of that (he is showing on the drawing).
- 24 I: He is now comparing this triangle and this triangle (she is showing).
- 25 T2: The height is the same (showing) and the base is 2-times longer, so the area is 2-times bigger than this one ($2S$), so $4S$.
- 26 T1: I see now!

Working Group 7

27 T2: The same is here 4S and 4S (he is writing the areas for the triangles which are left).

28 I: So the previous ratio was 1/7, what is now?

29 T2: Now we have 3 times 4 and 3 times 2, so 18 plus one, so 1/19.

Comment. In spite of the fact that the third solution ('triangles of the same areas') was introduced by the instructor (by giving some clues) as an alternative solution, the teachers liked that way the most. Probably it was because of its elegance and simplicity. And they chose that method for solving the next problems. Although that method seemed to not require advanced knowledge, when the teachers wanted to transfer it on the analogous task they had difficulties.

Analysis. The example of that task shows that by solving an analogous problem you can develop an important creative mathematical activity – transfer of the method (Klakla, 2002). Although the method was quite easy, using it in the next problem was challenging for the teachers. They started asking questions by themselves, explaining to each other and after such discussions we can say that they really familiarised themselves with this method and understood it. The important fact was that group work gave them the opportunity for such common discussions.

The other prolonging of the task contained a quadrangle instead of a triangle:

30 I: Let's work on the next task: a quadrangle.

The teachers are working silently; they are drawing, cutting the figure into triangles. Then they are discussing in pairs (or triads) trying to use the method of triangles of the same areas:

31 T7: These ones are for sure equal, these also, but I have too many of these Ps...

32 T4 and T1 (they obtained the result 1/5 and are happy like children): I have it, hurray!!!

33 T3 asks T4: How to calculate this?

34 T4: You have to only notice that $S_2+S_4=S_1+S_3$.

35 T3: How nicely you wrote it!

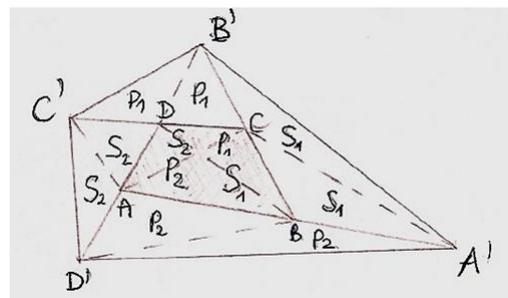

36 T2 (drawing):

37 T7: It can't be in 2, you have to do it in 4 (divide the quadrangle in triangles).

38 T5: You should do it in 4 from the beginning.

39 T1: In 4? Aha! I also did it in 2.

40 T2: $2P_1+2P_2+2S_1+2S_2 = 2P+2P$ plus P –that initial one, that is 5P.

Comment. This time the teachers did not have any problems with the transfer of the assumptions of the task. They started working in small groups. Their strategy was to divide the initial quadrangle into triangles and this was done in two ways. In both cases the teachers were searching for triangles of the same area with these which arose as the result of the division of a triangle. Therefore they modified the previous

Working Group 7

method of solving and they transferred it into the new problem. But not all managed to do it so easily (e.g. T7 in [31] or T3 in [33]). After T2 presented his solution on the blackboard a discussion on how many triangles should a quadrangle be divided into started.

Analysis. In this fragment the teachers undertook a creative mathematical activity – transfer of the method of solution on an analogous task (Klakla, 2002). They did it by themselves without any suggestions. They tried to transfer the method which they used in the case of triangles. When it showed that it cannot be transferred directly they modified it in such a way to use it also in the case of a quadrangle. It is worth noting the joy that the solution of this task gave them [32]. It is also important to underline the special role of the instructor who only initiated the problem and then backed out and let the teachers decide by themselves how to solve it.

The next two fragments are related to the second multistage task called ‘Butterflies’:

- 41 I: What more can we ask about that situation?
42 T4: Maybe what is the ratio of the painted areas to the non-painted?
43 T3: No, if they are similar triangles, we can ask...
44 I: Similar triangles... So the wings of the butterfly are similar triangles to ...?
45 Everybody: To the initial one.
46 I: To the initial one... Are they?
47 Everybody: the property (of similar triangles) Angle – Angle – Angle (corresponding angles are the same), because they are lines parallel to the sides.
48 T3: Are they similar to each other?
49 I: Exactly, are they?
50 T1: If all of them are similar to the initial one, then they are similar to each other.
51 I: Yes, and on what base we can conclude it?
52 T1 and T3: On transitivity.
53 I: Of the relation?
54 T1 and T3: Relation of similarity.
55 I: Ok. In what scale are they similar to each other? The same scale, different scales?
56 T4: Probably it can be done to be the same scale.
57 T3: It depends on the point P.
58 T6: It depends on the position of the point P.
59 I: On the position of the point P... Listen, where would have to be the point P in order for those scales to be the same? Is it possible to answer that question?

Teachers are discussing...

- 60 T3: The centroid of the triangle?
61 T4: Maybe in the equilateral triangle?

Working Group 7

Comment. After formulating and solving some problems proposed by the teachers, the instructor asked another question [41] that made the teachers put other questions and hypotheses. The first one [42] could be connected with the first multistage task, but the next question of T3 [43] is related to the property noticed on the drawing. Actually, most questions of the teachers were not specified that is why the instructor's interventions were needed. This resulted in discipline of thinking and critical thinking of the teachers (Klakla, 2002).

Analysis. In this fragment the teachers showed an ability of putting hypotheses and the need of verifying them. They had the ideas on what directions can be taken during considering that task. They formulated non-trivial problems, they were engaged in investigation (Ernest, 2008). Their language was characterized by a lack of precision, thus their talk had to be complemented by the instructor. But eventually the teachers started supplementing each other's talk.

In the next fragment the teachers continued the work on the task “Butterfly” by searching another relation in the initial situation:

62 T2: T3 has something.

63 I: T3, show us what you have.

64 T3: But I'm not sure if it is true, it's a question for now...

65 T2: Put a hypothesis!

66 Everybody: Put a hypothesis!

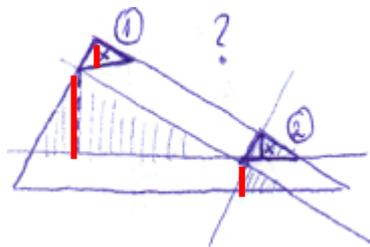

67 T3: But it's not a theorem!

68 T2: A bold hypothesis and a good hypothesis is precious by itself.

69 T4: I'm not sure if it can be related to the point P – that the sum of the heights of the small triangles equals the height of the big one.

70 I: T3, show us what you have.

71 T3: I don't know if it is so. For now it is only a conjecture (she draws on the blackboard):

For sure those heights (red lines) give us the height of the triangle ABC. The question is if it is x – if that height and the height of that triangle (1 and 2) are equal!

Comment. In this fragment we can observe how the workshop participants forced one of them to put a hypothesis. The reaction of the teachers showed us on the one hand the willingness of searching a hypothesis and on the other hand the joy of putting it [68]. It also proved that the participants of the workshop became aware of undertaking mathematical activities and their significance. Putting a hypothesis

resulted immediately in a trial of its verification. T3 knew that the sum of the heights (in red) is equal to the height of the triangle ABC, but she had doubts if the heights of the triangles 1 and 2 had the same length. Although the drawing suggested that it is so, the teacher was careful in formulating the theorem. Her reasoning was characterized by discipline of thinking (Klakla, 2002).

Analysis. The described fragment showed us that the teachers noticed that the work on the task makes sense when you put other hypotheses and try to verify them. The teachers had a need of prolonging the task and this explains the fact that when one of them made an observation, the others forced her to present it and then everybody was working on its verification (in the later part of the workshop). When they finished working on a previous problem they started searching for new relations and new ways of prolonging the task by trying to use the whole potential of the given situation. In the short presented fragment many kinds of creative mathematical activities appeared: putting and verifying hypotheses, prolonging the task and discipline of thinking (Klakla, 2002). Moreover, the work was accompanied by intense emotions.

CONCLUSIONS

The presented fragments reveal the character of the teachers' and the instructor's work. The first multistage task 'Lengthening the sides of a triangle' had the aim to introduce the teachers to creative mathematical activities. Already during solving that task the first tentative attempts of independent thinking and undertaking different kind of creative mathematical activities appeared. The teachers tried to transfer the method of 'triangles of the same areas' into an analogous problem. This made them aware that firstly you have to familiarize with a problem's solution in order to realize the essence of the idea. Only then you can use that method to solve another problem even if it needs some modification (Klakla, 2002). That leads to noticing the whole potential of a task and developing mathematical methods.

Later, we observed a greater freedom in putting questions, hypotheses' formulation and verification. The teachers decided by themselves what they want to work on, what they want to discover and what relation they want to investigate, which all fit in the frame of mathematical creativity according to Ervynck (1991). The formulated hypotheses were non-trivial; the teachers made a progress in expressing their thoughts, in being more careful during verifying their hypotheses and in transferring their reasoning into analogous problems. Additionally, we could observe the satisfaction that teachers felt when they succeeded in solving the tasks. The role of the instructor was minimalized to the only necessary actions: delicate suggestions of the directions of searching, small numbers of clues, evaluating discipline of thinking and critical thinking of the teachers.

Creative mathematical activities do not develop spontaneously. The conscious attitude of the teacher can be formed through the personal experience of different

forms of such activities. Creativity requires conscious didactical methods and tools on every educational level (Maj, 2009). The multistage tasks used during the workshops support the development of activities such as transfer of a method and hypotheses' formulation and verification (Klakla, 2002; Maj, 2009). In order to transfer a method of solution or reasoning, the teachers have to have the opportunity to work with such series of tasks, try to use the worked out methods, experience the situations in which they cannot be used or the situations in which in order to use them, they have to modified them. Open-ended problems and rich mathematical situations favour the formulation of hypotheses. The actions of the instructor should make the teachers aware of the need for verifying them. At the same time, the participants of the workshops have to feel that they can stand on their own feet and they do not need the help of the instructor any more. That confidence can improve their professional development.

DIDACTICAL VS. MATHEMATICAL MODELLING OF THE NOTION COMPETENCE IN MATHEMATICS EDUCATION: CASE OF 9-10-YEAR OLD PUPILS' PROBLEM SOLVING

Bernard Sarrazy, Jarmila Novotná

Université Victor Segalen Bordeaux 2, Charles University in Prague

In the paper, the authors investigate experimentally the notion of “competence” applied to mathematical education, more precisely the idea by which teaching cognitive and metacognitive strategies could allow pupils to learn mathematics better. They first identify the psychological model of this perspective and then underline the insufficiency of that approach, showing that pupils’ solving strategies are not independent of situations and solving contexts.

Key words: competence, cognitive strategies, meta-cognitive strategies, didactical situation.

Key competences for lifelong learning are a combination of knowledge, skills and attitudes appropriate to the context. They are particularly necessary for personal fulfilment and development, social inclusion, active citizenship and employment. [...]Mathematical competence is the ability to develop and apply mathematical thinking in order to solve a range of problems in everyday situations, with the emphasis being placed on process, activity and knowledge.

Recommendation of EU from December 18, 2006 ²²

INTRODUCTION

The notion of competence is often used for explaining differences in the levels in mathematics; but the origins of these differences are never explained. Nowadays, the competence is used in relationship with talent for explaining the differences in creativity.

The recent notion of “competence” reintroduces the ancient idea that teaching cognitive and metacognitive strategies will allow pupils to solve problems in a better way and hence to learn mathematics more efficiently. As a result of evolution of this perspective, a didactical model based on a psychological model with origin in information processing was developed. This model focuses on the development of pupil’s mathematical thinking (Novotná & Sarrazy, 2009).

The model supposes that for being efficient, the taught strategies have to be independent of situations and contexts of solving. The aim of this paper is to challenge this hypothesis.

²² http://europa.eu/legislation_summaries/education_training_youth/lifelong_learning/c11090_en.htm

THEORETICAL FRAMEWORK AND QUESTIONS

The psychological model referred to in this paper is a theoretical follow-up of works of W. Kintsch, J.G. Greeno (1985), M.-C. Escarabajal (1986) (among other) built on the theory of scheme developed in artificial intelligence: either the scheme is identified and thus allows interpretation of information contained in the assignment (processing from the scheme to its components), or the subject transfers elements from the task to the scheme which allows integrating pieces of information. In this perspective, solving a problem consists of application of a solving scheme. To understand a problem means to make it calculable. In reality, the pupil has to identify useful elements in the wording of the assignment and find a sequence of relationships from the surface characteristics in order to end in a numerical operation. In this point of view, a mistake is considered as selecting an inappropriate scheme or as a “shift of meaning”.

Three invariants structuring psychological models can be found. Our observations suggest they inspire teachers to use various lesson plans (see e.g. Roiné, 2009):

1. *Apply a scheme*: In order to understand a problem the pupil must construct a representation of the problem from the pieces of information that he/she selects and that he/she interprets in a conceptual scheme. He/she must refer to knowledge that allows him/her to apply the solving scheme corresponding with the problem to be solved.
2. *Develop heuristics*: The pupil should be able to check validity of his/her interpretation. When looking for a suitable solution, he/she must develop heuristics: select the operation, control the validity of his/her result, e.g. by using the so called “analogical transfer” of a solving procedure already known to be efficient for a problem with whose solution the pupil is familiar, to the solution of a new problem which he/she is supposed to solve.
3. *Make the pupil become aware of the used procedures*: The teacher must make the pupils realize what procedures of checking have been used. The pupils should also be able to adapt these procedures to use in other contexts.

Even if the principles allow *description* of what “experts” (good pupils) do, nothing guarantees that these pupils will use the procedures efficiently. The idea of teaching competences lies in the implicit principle by which teaching cognitive strategies allows to prefer the transfer of knowledge from one solving context to another. This is the principle that we will call the *principle of transversality*. This principle will be investigated in the following text in the framework of the Theory of Didactical Situations (Brousseau, 1997).

METHODOLOGY²³

The experimental protocol is relatively simple: The same task is assigned to 9-10-year old pupils in four different situations. What makes this task unusual/special is the fact that it involves an unusual use of multiplication, not common in school practice. In fact, the pupil has to use his/her knowledge of multiplication to discover that the assigned task does not involve this operation. We call such problems “pseudo-multiplicative”; in the text they are labeled as “PPM”.

The problem can be formulated simply: If the pupil is able to distinguish between PPM and usual problems in a given context, then, according to the principle of transversality (inherent in the psychological model), he/she should manifest it also in other similar contexts. If not, we can conclude that this principle is not valid and therefore it is wrong to expect any improvement if cognitive and metacognitive strategies are taught.

Four PPM were presented in four different school situations:

1. “*Evaluation by the experimenter*”

If we know that one car covers the distance between the town A and B in 6 hours, how long will I take before 3 cars cover the same distance?

2. “*Mathematical competition*”

A ship covers the distance between Marseille and New York in 6 days. How long will it take 3 ships to cover the same distance?

3. “*Evaluation by the teacher*”

A snail is at the bottom of a well. He decides to leave the well. We know that it will take him 6 days to get out of the well. How long will it take three snails to get out of the well?

4. “*Warning*”

If we know that one biker covers the distance between the towns A and B in 6 hours, how long will it take 3 bikers to cover the same distance if they set off together?

Each of these four target problems was assigned to pupils from seven classes in four different situations ($N = 155$). All these situations are situations of evaluation because in each of them the pupil must demonstrate that he/she is able to carry out what is requested. These situations differ in the degree of analogy to common situations in three aspects: their level of formality, the types of input linked to them (individual vs. collective; the result of evaluation taken into consideration by the teacher or not) and the position of the proposer of the assignment.

However, each of the situations may be described in many more details:

²³ Experiments for this research were carried out in France by B. Sarrazy.

Working Group 7

- *Situation 1* (“a researcher’s practice”): It is the experimenter who proposes the assignment; the pupils were informed in advance that the test would not be marked; intentionally other information about the test was not disclosed (Will the teacher, the parents be informed about the results? Will the results be communicated publically in the classroom to other pupils? ...)
- *Situation 2* (explicit frame “a mathematical competition between classes”): This test is presented to pupils as a competition between classes in which each class chooses which of the posed problems will be assigned to the other classes. The test was divided into two phases: in the first phases the rules of the competition were presented and then each pupil posed a problem and then submitted it to the experimenter. The test itself was carried out in the second phase, a few days later, and the researcher posed his own problems. Here, the nature is not individual as in the other situation but collective.
- *Situation 3* (explicit frame “summative evaluation at the end of term”): Each teacher was asked to carry out such evaluation that they would normally use in the end of the term. This evaluation should in addition include the target problem. Here, the nature of the activity is clear to pupils: individual and marked by their teacher.
- *Situation 4* called “warning” (frame “experience of a researcher”): The aim of this situation is to verify that pupils are able to correct a “defective” problem assignment. That is why the pupils were informed of presence of both non-calculable and calculable (classical) problems in the given set of problems. Below is an example of the two forms:

Non-calculable form: If we know that one biker covers the distance between the towns A and B in 6 hours, how long will it take 3 bikers to cover the same distance if they set off together?

Calculable form: A decorator paints one wall of a building in 6 hours. How much time will 3 decorators need for painting the same wall if they decide to work together?

Note: In case of all four situations, the target problems were included in a longer set of problems with both unusual problems (e.g. incomplete assignments ...) and classical problems.

RESULTS AND ANALYSES

Table 1 and Figure 1 present detailed results of the types of answers to PPM (in percentages) for each school level in mathematics in the four situations.

Working Group 7

	Good pupils				Average pupils				Weak pupils			
	S1	S2	S3	S4	S1	S2	S3	S4	S1	S2	S3	S4
Exact	20,5	32,6	43,5	91,1	14,3	31,1	33,3	73,8	10,0	20,8	14,6	71,1
No answer	0,0	0,0	8,7	8,9	1,8	1,6	8,3	14,8	2,5	4,2	10,4	13,3
Calculation	79,5	67,4	47,8	0,0	83,9	67,2	58,3	11,5	87,5	75,0	75,0	15,6
N	39	46	46	45	56	61	60	61	40	48	48	45

Table 1: Frequency (in %) of types of answers to PPM

- “Exact”: The student provides the answer included in the assignment without doing any calculation
- “No answer”: No answer provided.
- “Calculation”: The pupil multiplies (6x3)

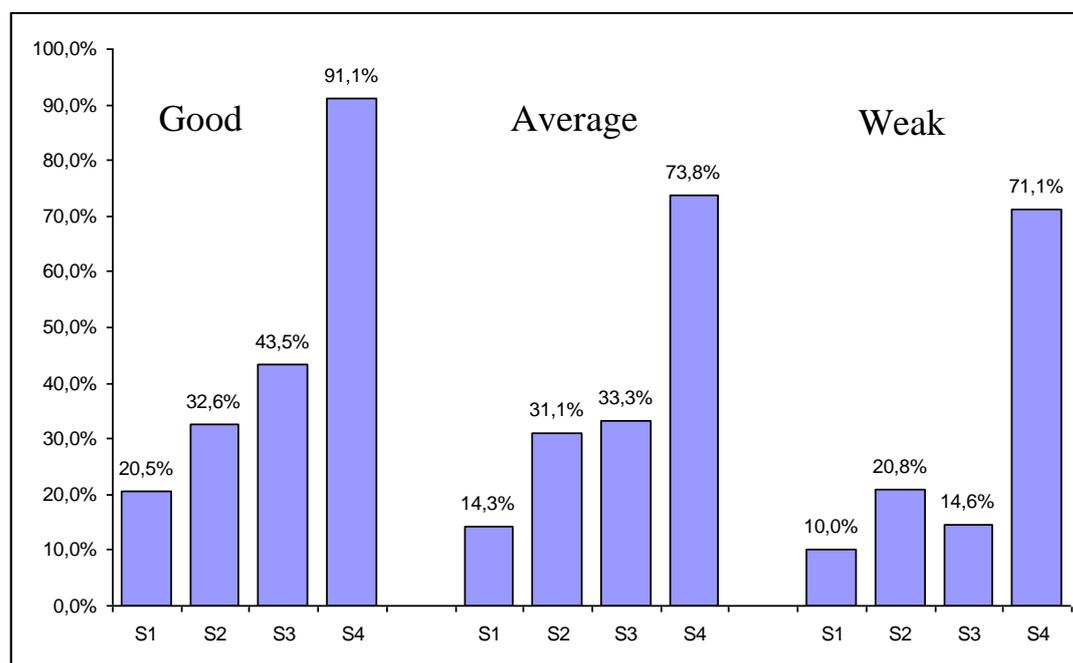

Figure 1: Histogram of success in PPM for each situation and with respect to pupils' age levels

1) It is clear that in all four situation pupils find PPM difficult. These difficulties on the one hand reveal insufficient mastering of multiplicative structures, but they can also be interpreted as the effect of *didactical contract* (for this notion

see Brousseau, 1997; Sarrazy & Novotná, 2005) connected to the proximity of classical multiplicative problems; it is highly probable that the problems are caused by both of the factors.

2) The results for situation 4 clearly show that pupils are able to distinguish between “non-calculable” and “calculable” problem (ϵ ; s.; $p < .001$).

3) Frequency of success increases with the pupils’ school level ($\chi^2 = 7,89$; s.; $p < .02$); This phenomenon is more evident when the degree of formality increases and when the evaluative nature is strong (as in case of situation 3).

4) Finally, a similarity of profiles of results can be observed in case of all three school levels in all four situations; one can conclude that the difference is a difference in degree but not in situational competences (because the profiles are similar).

These two last results (3 and 4) seem to confirm our hypothesis but in a reverse direction, good pupils get better results regardless of the situation. Factor analysis of correspondences allows us to assess the role the two factors (level of competence and type of situation) play in handling of the task and to examine what the most valid statement is; see Figure 2.

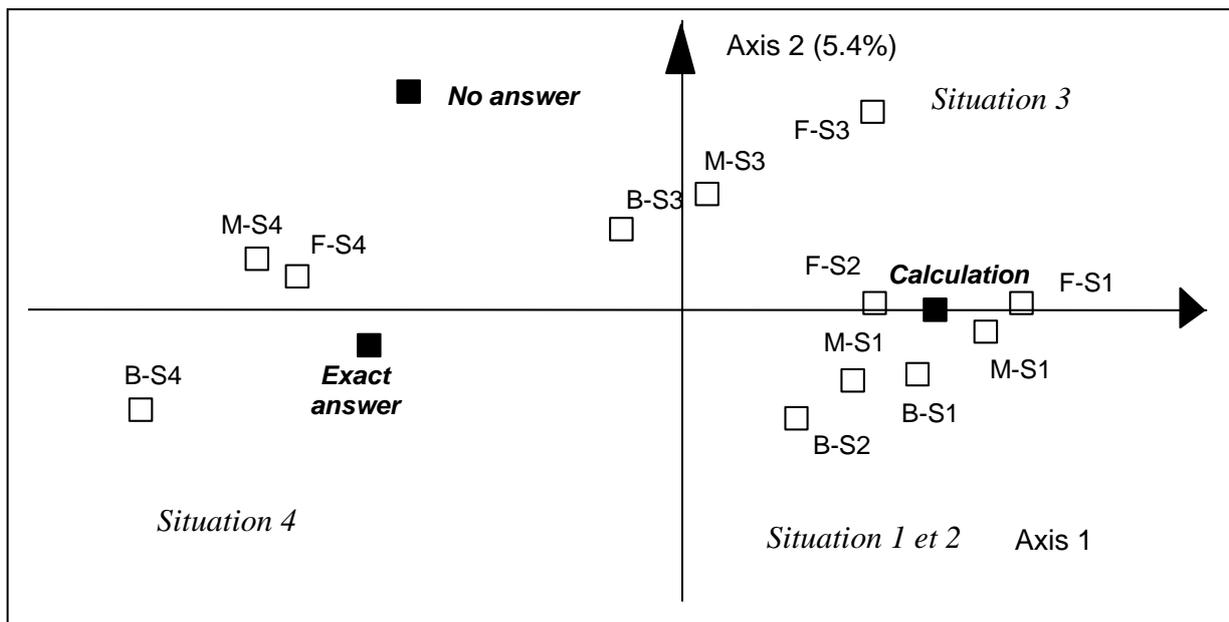

Figure 2: Simple factor analysis of correspondence. Types of answers to PPM, types of situations and pupils’ school level

The results of factor analysis of correspondence clearly show that production of answers to the same problem is, regardless of the pupils’ school level, more strongly linked to the situation than to mathematical abilities: in the set of pupils $\chi^2 = 88,01$; s.; $p < .001$.

Situation 4 is not typical (because it is a situation where pupils are warned about the possible presence of untypical problems). The analysis verifies that the result holds if we do not consider the three first situations $\chi^2 = 8.19$; s.; $p. < .02$.

This result allows to contradict the initial hypothesis that production of an answer to the same task is independent on the solving context. Pupils' decisions are more determined by the type of situation than by their competences in mathematics. In other words, the notion "task", central in cognitive psychology, fails to provide meaningful feedback on the pupil's work. The principle of transversality is not valid here and consequently cannot be classified as one of the constituents of the base for cognitive improvement enabling development of pupils' mathematical thinking.

CONCLUSION

In specific situations, a considerable proportion of pupils do not find themselves capable of providing an answer that does not require any numerical calculation if they are not warned of this possibility before they start work. Thus, although it was the same assignment, pupils from S1, S2, S3 and S4 did not solve the same problem. Our results show that the reasons are not to be looked for in the pupil's psychology but in the situation that, by the limitations that define it, imposes certain forms of attitudes. The "official" relationship, aimed at this type of the task, is not present in majority of primary school pupils. However, it cannot be concluded that this relationship cannot be established as the results obtained in situation 4 confirm.

This research also highlights the didactical weaknesses of those approaches that come out from a limited conception of the situation (the situation of the system "subject-task"). This definition does not correspond to the observation reported in this paper: the observed variations from one situation to the other – that must not be regarded as simple artefacts – are not comprehensible if the situational dimension of pupils' activities is overlooked.

As one of the authors has already demonstrated (Novotná, 2009), models guided by psychological modelling of the activity often result in the situation when pupils regard problems as mere tools of evaluation, not as an occasion to learn mathematics. Consequently, problems tend to be conceived as tools that enable division of pupils between those who succeed and who fail.

What we propose is to proceed in the opposite direction than described in the previous paragraph by re-centering teacher's and pupils' activities on problems themselves (see Novotná, 2009, Sarrazy, 2002). We need tools that would allow the pupils to develop a living culture of problems and that would change pupils to "experts in problems". Only then will they regard problems as tools necessary for their learning and as an opportunity for mutual visits to some regions of mathematics.

Working Group 7

This means we must develop a less didactically narrow relationship towards mathematical problems in pupils, guide them to regard problems as work, and, let us stress this again, not merely as an instrument used by the teacher for instruction and for evaluation. This form of problem knowledge could develop in pupils some kind of mathematical culture that would trigger, among other, a more homogeneous behaviour of classes.

PROBLEM POSING AND MODIFICATION AS A CRITERION OF MATHEMATICAL CREATIVITY

Florence Mihaela Singer

University of Ploiesti
Romania

Ildikó Pelczer

École Polytechnique
Canada

Cristian Voica

University of Bucharest
Romania

We explore different types of behavior during the problem posing process by looking at the ways students value the problem data in solving and extending their own posed problems. Based on the outcomes of these analyses we explain the differences in students' success and failure in the problem posing approaches in relation to the level of understanding the solution of a problem and the novelty of the posed problems. We notice that the more the student advances in the abstract dimension of the problem and its context, the more mathematically relevant are the newly obtained versions. The abstraction level of the solution process determines the novelty of the newly posed problems and it seems to be a good predictor of the child's creative potential.

Key-words: problem posing, problem reformulation, novelty, creativity

INTRODUCTION

Mathematical creativity raises special interest due to its links with mathematical giftedness and advanced mathematical thinking. Once considered a valid research subject only in relation with professional mathematicians, the focus on mathematical creativity has shifted in the last decade towards the creativity of schoolchildren in classroom settings. However, there is an ongoing controversy about how to define it and what tasks allow identifying creative behaviors. A source of such tasks is problem posing (PP). In this study, we focus on the key elements students use in the problem posing process. More specific, we explore how students value the problem data in solving and extending their own posed problems. We compare students' behaviors during the process of modification of a posed problem in order to identify the differences among them. Based on the outcomes of these analyses, we try to explain the differences in students' success and failure in PP approaches in relation to their potential for mathematical creativity.

There are different terms that are used in reference to problem posing, such as problem finding, problem sensing, problem formulating, creative problem-discovering, problematizing, problem creating, and problem envisaging (Dillon, 1982; Jay & Perkins, 1997). In the present study, we adopt Silver's (1994) position, in accordance to which „problem posing refers to both the generation of new problems and the re-formulation, of given problems”.

The literature on PP shows that this activity is important from various perspectives and emphasizes connections between PP and creativity. For example, Jensen (1973) considers that for being creative in mathematics students should be able to pose mathematical questions that extend and deepen the original problem as well as solve the problems in a variety of ways; therefore, exhibiting PP capacities is a condition of mathematical creativity. From another perspective, Silver (1997) argued that inquiry-oriented mathematics instruction which includes problem-solving and problem-posing tasks and activities can assist students to develop more creative approaches to mathematics.

The question still remains: To what extent the production of problems validate or not students' creative capacities? Some studies are reserved in this respect. For example, Yuan & Sriraman (2010) conclude that "there might not be consistent correlations between creativity and mathematical problem-posing abilities or at least that the correlations between creativity and mathematical problem-posing abilities are complex". Silver's (1997) statement suggests that any relationships between creativity and problem posing might be the product of previous instructional patterns. Other studies, for instance Haylock (1997) and Leung (1997), who did not agree that there was correlation between creativity and problem posing in mathematics, did not take instruction into consideration. To answer the question, thus involving us into the existent controversy in the literature, we have analyzed the problems devised by students who voluntarily responded to a PP task.

Before entering the details of our study, we have to face another, related question: how do we identify creative behavior in students, or, a more tackled one: how do we define creativity? In a large sense, creativity is defined as «the ability to make or otherwise bring into existence something new, whether a new solution to a problem, a new method or device, or a new artistic object or form» (Encyclopædia Britannica). The definition of creativity benefits of a large spectrum of studies, going from broad characterizations to particular aspects about problem identification, problem posing and problem solving (e.g. Csikszentmihalyi, 1998). The topic of mathematical creativity also received much attention from researchers who focused on defining, characterizing it, or establishing criteria for its assessment (see for example, Ervynck, 1991; Freiman & Sriraman, 2007; Silver, 1997; Sriraman, 2004).

In this paper, we will step out of adopting a certain definition of mathematical creativity. We prefer to specify some aspects of creativity by exemplifying situations in which student's behavior is certainly non-creative. Through comparison, behaviors that are situated at distance from these examples will shape certain features of creativity.

METHODOLOGY

Usually, in the Romanian schools, students are not asked to pose problems. They are trained in problem solving, and once the problem is solved, it is not even followed by a heuristic stage that could lead to modifications of the initial text. Consequently, because there is not a PP practice in the common Romanian classes, we can undoubtedly consider that PP is a task with creative potential.

The participants in the study were 120 students from grades 3 to 6 who voluntarily answered to a call for problems, from a total of 220 students who participated to a mathematical summer camp. The students in the camp were selected from 89,872 students via a two-round national competition; therefore their experience in problem solving was high. During the camp, the students were asked to create two problems – one easy and one difficult, and to deliver their proposals, including the problems solutions, after a few days.

Subsequently, we have chosen and interviewed 40 respondents. The choice was made depending on the nature of the problems posed by the students and their proposed solutions.

We structured the protocol interviews around questions such as: Can the given data of your problem be changed? (And, if yes, can you devise new data that fit your problem?) Are there redundant/ insufficient data in your proposal? Can you define a more general situation? Is there any interesting particular case? What happens if you change a smaller/larger part of the problem?, etc.

During the interview session, the students had about 15 minutes to re-read their initial proposals and to think to the addressed questions. After this reflection time, the discussion started individually and followed children's ideas until the interviewer had a clear image of the student's approach. Along each interview, other questions have been addressed, suggested by the students' answers.

DATA ANALYSIS

In the next sections, we present some of the students' reactions that are relevant for the different contexts identified in the gathered data. From the database of 240 of problems posed by the children of our sample, we first selected the problems that were likely to be far away from common, usual and conventional school problems. The term conventional has been used in the literature in relation with solution spaces (Leikin, 2007), to express that a solution respects the recommendations made by curriculum and it can be found in textbooks. Here we use it in the same spirit, as an expression of what it is expected, usual and habitual at a given grade, in the context of a given school curriculum.

In order to better explain the selection strategy, we start the presentation with a standard conventional problem, proposed by a 5th grader, Sorin:

Working Group 7

What are the values of x if:

(a) $7+x \leq 40-5x+30$

(b) $x-4+7 \geq 30+5-20:4$

The problem posed by Sorin is a classic exercise in each textbook or workbook. In addition, the text is elliptic: we realized from his solving that Sorin's presumption was to solve the inequations in the set of natural numbers (He gives for (a) the solution $x \in \{0,1,2,3,\dots,37,38\}$, and for (b): $x \in \{27,28,29, \dots \infty\}$). For these reasons, this problem was framed in the category conventional, even if one can say that it is "too algebraic" for the student's age (12 years old).

Other students, however, posed problems that, although they might be recognized as conventional, they were put in a context that made them interesting. This is the case, for example, for one of the problems proposed by Patricia (grade 6):

Martha and Helen invented a game: "maximal sums". Martha tells Helen:

"- We have two numbers a and b . Knowing that $[a, b] \cdot (a,b) = 34$, find the maximal sum!"

Help Helen by solving this problem!

Patricia's problem resorts to a conventional situation that evokes the formula $[a, b] \cdot (a, b) = a \cdot b$. However, some features of the problem: game style, characters that have a conversation, the case-analysis necessary for solving, and the invitation addressed to the reader to get involved in the solving are mostly unusual in the common teaching strategy. Therefore, we take these features as testimonies in favor of Patricia's originality in posing this problem.

While we use the term originality in relation with a person's behavior, we shall use the term novelty as a quality of the outcome of the process (for example, as quality of the problems resulting from the posing process). Novelty might be defined as surprising connections between the concepts or elements involved within a problem. As in the case of the term "conventional", we define the habitual connections between concepts as the ones promoted by the school curriculum and by the problems found in the textbooks. Surprising connections are not habitual. From this perspective, the smallest common multiple is strongly connected to product of numbers, factors and prime numbers. The vast majority of the textbook problems related to this concept will involve in some way the product between the numbers. Taking into account the students' age, we generally considered as a sign of novelty the cases when symbols and mathematics formula were not presented in the problem text, although they contributed to the solving.

Going back to Patricia's problem, we can say that her proposal displays novelty, since she asks a question about the sum of the numbers, while we would be expecting something about their product.

Working Group 7

As far the relationship between originality and novelty of the results is concerned, we observe that all combinations are possible (maybe except the one no originality – novel result). Nevertheless, we had to distinguish between originality and training. To clarify this aspect, we analyze the solution given by Claudia (grade 6) to the problem she proposed:

I am 13 years old and my sister is 3 years younger than me. What will be the difference of ages between us 5 years later?

The problem can be considered a mathematical charade (the difference between the ages remains constant!). However, the solution given by Claudia shows that she was not aware of this fact:

“Let’s note by x the difference of ages between the two sisters.

$$x=13+5-(13-3+5)$$

$$x=18-(10+5)$$

$$x=18-15$$

$$x=3 \text{ (years)}”$$

In Claudia’s case, the problem text moves away from the conventional style. However, is it the result of a creative capacity or just the consequence of intensive training? Silver (1994) connects problem re-formulation to problem solving: „when solving a nontrivial problem a solver engages in this form of problem posing by recreating a given problem in some ways to make more accessible for solution”. From Claudia’s solution, we can see that she does not understand an essential fact in the logic of a problem: a problem should not be formulated only for the sake of the algebraic game, but its data should have consistency. The algebraic mechanism mobilized by Claudia in solving the problem is not consistent; it is just a way to encrypt what one can deduce through a brief analysis of the text.

This example is an argument in favor of the assumption that the degree of conventionality of a problem is not enough to decide whether the student acts or not creatively when devising a problem. At this stage of argumentation, some explanations are needed. Because the sample is composed of students who participated at a very selective contest, they are familiar with the problems vehiculated during previous competitions. This is why, although some students’ proposals look non-standard, these problems are, in fact, similar to problems belonging to the sets used for training. From this point of view, the respective problems are considered already known, conventional.

It was obvious in our sample that, in achieving the problem posing task, many of the students were influenced by „problem models” they knew, and they actually proposed re-formulations of these models. For this reason, in order to refine the

Working Group 7

analysis, we looked closer at the “distance” between the posed problem and the possible model from which the student seemed to start.

We further analyze students’ proposals from this perspective.

Consider, for example, one of the Teona’s (grade 6) problems:

On a 20x20 square table colored in 2 alternative colors (like a chess table) one must position rectangular tiles that cover exactly 2 squares. The tiles can be positioned vertically or horizontally. Can we fill in the table with 199 tiles, if the squares from the ends of one of the diagonals were cut?

In its „classical” shape, the problem was about a chess table (8x8), from which two squares from diametrically opposite corners were cut. Teona gave a more general case of this problem, keeping the same context, but varying the dimensions of the table. The starting model is quite obvious since she even refers to 2 color-squares, albeit this information is not needed in the text of the problem (but, it is an important reference point for the solving).

Another example is the one of Stefan (grade 6):

Andrei and Bogdan play the following game. Each of them has a candy box. They alternatively take a number of candies from 1 to 6 inclusively, and put them into an urn. The one who first puts the 100th candy wins. Andrei is starting. How many candies should he put into the urn for the first time, in order to secure his victory?

Stefan’s proposal is closely connected to a known game (called „Who tells first 100?”), where two children successively say numbers from 1 to 9, which they add to the previous sum. The winner is the one who first arrives at 100. By changing the data and the context (which is no more purely mathematical but related to daily life), Stefan manifests flexibility in thinking. Stefan, as well as Teona, has built analogies of already known problems.

In general, what we noticed is that the students reacted to the problem posing task by resorting to analogies that reflect a near transfer (Salomon & Perkins, 1989) even if they had complete freedom in processing the task, including the non-compulsory reporting of the task.

However, we also found some situations of what we considered to be far transfer.

For example, Paul (grade 6) proposed the following problem:

Andrei goes to the shop and buys 10 chocolates. For each chocolate he gets a ticket and with two tickets he can buy a new chocolate [and, of course, a new ticket – a.n.]. How many chocolates does Andrei get?

This problem seems not to start from a previous model (fact confirmed during the interview). We account that this problem moves away from both conventional and training problems because the student combines the idea of equivalent exchange with successive iterations.

A general conclusion of the previous paragraphs is that when facing a problem posing task, the students proceed through analogy. They start from a known problem and vary one or more parameters, obtaining a re-formulation of the starting model.

Thus they resort to a transfer, usually near transfer, most frequently based on analogy. However, a more restrained category of students tries to create novel contexts within the problem posing task.

A MORE FOCUSED ANALYSIS

In the second part of the study, we wanted to see how deeply the students entered the philosophy (and the mathematical mechanisms) of the problems they proposed. More precisely, because the re-formulation can be done on various tiers of understanding of the solving, we have analyzed the relationship between the deep understanding of the solution and the quality of the final problem. We thus realized that the degree of novelty of a problem is not enough to conclude that the student is mathematically creative.

We first discuss below some answers given by Teona (see the problem above) during her interview. In order to have an insight into the mechanisms used by Teona when she moved from the “model problem” to her proposal (mainly characterized by new dimensions of the table), we asked:

- a) What would happen for a 13x13 table?
- b) What would happen for a 20x20 table? Is it possible to cover such a table (from which 2 squares have been cut) with 1x3 tiles?

Although Teona found relatively easy the argument for 13x13 (the answer is **no** because of the odd number of squares), she failed to find the answer for the 1x3 tiles (which is based on divisibility and which, also, constitutes the deeper argument for the **no** answer for the odd number of squares). Thus, she unnecessarily restricted the range of numbers she could use to make up a new problem. The term *unnecessarily* expresses the fact that those restrictions originate from the student, internally, and not from the situation described in the problem’s text. In the terms of Haylock (1997), she remained “prisoner” of a content-universe fixation.

Nevertheless, this was not the case for Stefan (see his problem above). The questions in his interview have been focused on the relevance of the numbers 6 and 100 for his problem. He not only was able to explain accurately his solution, but he was also able to give the following generalization:

”Let’s say that each child can take away between 1 and n candies and the winner is the one who puts the candy number m into the urn. Then the first player wins (no matter how the second proceeds) if $n+1$ does not divide m , and the second may win (no matter how the first plays) in the opposite case.”

This generalization witnesses deep understanding of the way in which the variation of the parameters can influence the result.

Paul's case (see above the text of his problem) is even more interesting. Although his proposed problem is novel, the interview showed us that Paul remains at a superficial, concrete and numerical level of understanding. For example, Paul was not able to propose any new situation in which after all the possible exchanges are made, the child in the story has no ticket at all.

We have now a list of examples to point out to the question: How does the transfer made by some students in problem posing process relate to creativity?

The deep understanding of a problem determines flexibility in devising new problems, because deep understanding allows exploring the relationships between the elements of the problem at different levels. Thus, the level of understanding of the solution is decisive for the variety of the new problems developed by the students.

In order to clarify this aspect we resort to a complexity-abstraction scale, in which a gradual progression from operating with concrete objects to operating with symbols and symbol systems is seen as a spiral development with different tiers of abstraction. Constructing abstraction implies reorganizing previous knowledge by incorporating it within new systems, which are hierarchically structured (Singer, 2007).

At an immediate, superficial level of understanding, we will find students that keep the problem at a concrete tier, just changing, for instance, the numerical data. For example, on such scale, Teona remains anchored of the chess table and she is not able to climb up on the spiral to a more abstract level, where she would use divisibility without physical support. This means a minimal understanding of the connections among the elements from the problem text (numerical data, parameters, constraints – Singer & Voica, 2008).

In order to better illustrate the way in which this scale functions, we return to the problem posed by Sorin. Although his problem looks abstract, he is at a low level on the scale because he cannot satisfactorily operate with that abstraction.

At a higher level are situated the students that modify large parts of the problem model and advance in the direction of abstraction-generalization. In this last case, the newly posed problems are similar to the “models” only at an abstract tier – that of the mathematical structures that describe the problem. For example, Stefan makes a clear jump in abstraction, because he gives a strong algebraic generalization.

CONCLUSIONS AND FURTHER RESEARCH

We included in this paper examples of problems proposed by students of 11-13 years old. On this gamut of ages, we found that students of our sample are at different

levels of abstraction capabilities, although all of them were selected via complex mathematical tests. We noticed that the more the student advances in the abstract dimension of the problem and its context, the more mathematically relevant are the newly obtained versions. Supplementary evidence in sustaining this claim is offered by Paul's case: his problem is surprising, original, but because he does not master the abstracting possibilities beyond his proposal, he cannot make variations. We see this – namely, the role of abstraction ability in creative output – as a potential avenue for further research about the differences between mathematical creativity and creativity in general.

In conclusion, if the student is able to construct coherent and novel variations in problem posing activities by changing some parameters of his/her posed problem and he/she understands the consequences of these changes, then he/she proves capability for deep transfer creative approaches.

By assessing the distance between the conventional model of a problem – frequently met by the students in their solving activity – and the final problem emerged along the interviews, we noticed that in some cases there is a considerable leap. This advancement can indicate disposition toward mathematical creativity. In all the cases we analyzed, it is connected to student's capacity to effectively operate with abstract information. Therefore, this capacity might be a feature of mathematical creativity.

CREATIVITY IN THREE-DIMENSIONAL GEOMETRY: HOW CAN AN INTERACTIVE 3D-GEOMETRY SOFTWARE ENVIRONMENT ENHANCE IT?

Paraskevi Sophocleous & Demetra Pitta-Pantazi

Department of Education, University of Cyprus

This paper reports the outcomes of two empirical studies undertaken to investigate the creative abilities of sixth grade students in three-dimensional (3D) geometry and to analyse the way in which an interactive 3D geometry software environment enhanced that abilities of two students. The analysis indicated that students' creative abilities in terms of fluency, flexibility and originality were very low in both studies. But the interactive 3D geometry software improved the creative abilities of students who worked in this environment. The interactive geometry environment offered opportunities to students to imagine, synthesize and elaborate. It appears that enhancing students' ability to imagine, synthesize and elaborate may be a way to enhance students' creative abilities.

Key-words: 3D geometry, interactive environment, creativity, imagining processes, synthesizing skills, elaborating skills

INTRODUCTION

Creative performance is an essential part of doing mathematics (Pehkonen, 1997). This recognisable value of creativity in mathematical thinking led a number of researchers to define, assess and promote creativity in various mathematical concepts such as problem solving, problem posing and two dimensional geometry (e.g., Pehkonen, 1997; Leikin & Lev, 2007; Levav-Waynberg & Leikin, 2009; Pitta-Pantazi & Christou, 2009). Technology was proposed by a number of researchers as a tool that promotes students' mathematical creative abilities (Mevarech & Kramarski, 1992; Dunham & Dick, 1994; Clements, 1995; Subhi, 1999). However, although substantial work has been done in this area, little attention has been given to the ways in which technology can enhance mathematical creative abilities and processes. In this paper, we tried to examine the impact of an interactive 3D geometry software environment on students' creative abilities and processes in 3D geometry.

THEORETICAL BACKGROUND

Creativity and mathematics

Creative thinking is an essential aspect of the Integrated Thinking Model and involves "using and going beyond the accepted and reorganised knowledge to generate new knowledge" (Iowa Department of Education, 1989, p. 7). In the same line, Ervynck (1991) argued that creativity is an important factor of advanced

Working Group 7

mathematical thinking and refers to it as process of creating new knowledge, in other words “making a step forward in new direction” (p. 42), based on previous knowledge.

The creation of new knowledge is not simply a process, but it is a multicomponent process. More specifically, the new knowledge is created by imagining, synthesizing and elaborating processes with accepted or reorganised knowledge (Iowa Department of Education, 1989). In other words, creative thinking involves imagining processes which require original ideas through intuition, visualisation, prediction and fluency. Creative thinking also involves synthesizing skills which depend on the abilities to combine parts to form a new whole using analogies, summarizing main ideas in one word, hypothesizing and planning a process. Elaborating skills refer to the abilities to develop an idea fully by expansion, extension and modification (Iowa Department of Education, 1989). In the same line, Levav-Waynberg and Leikin (2009) describe mathematical creativity as the act of “integration of existing knowledge with mathematical intuition, imagination, and inspiration, resulting in a mathematically accepted solution” (p. 778).

A number of researchers characterised and evaluated creative responses in mathematics mainly by fluency (the number of acceptable responses), flexibility (the number of different ideas or categories of responses used) and originality/novelty (the relative infrequency of the responses) (Torrance, 1974; Leikin & Lev, 2007).

Creativity, mathematics and technology integrated environment

In the literature we come across two conflicting views regarding the relationship between creativity and technology (Clements, 1995). One view is that technology enhances only uncreative, mechanistic thinking. The second view is that technology is a valuable tool of creative production (Clements, 1995). This is in line with the argument of the National Advisory Committee on Creative and Cultural Education (1999) on the role of technology who suggests that technology enables students to find new modes of creativity. The results of empirical studies showed that technological environments enhance students’ creative abilities too. More specifically, Mevarech and Kramarski (1992) found that students who participated in problem solving activities using the Logo environment had higher creative scores in specific parts of the Torrance Test of Creative Thinking (TTCT) than students who participated in Guided Logo environment. Subhi’s (1999) research extended these results and indicated that problem solving via the Logo environment can enhance creativity in all figural and verbal domains of TTCT. Furthermore, in a study by Dunham and Dick (1994) students who used graphing calculators appeared to be more flexible problem solvers.

We could argue that most of the studies conducted until now on the impact of technology in students’ creative abilities are “results oriented”. They concentrate only on whether a specific software environment may enhance or not students’

creative abilities. In this study, we try to examine the ways in which 3D geometry environment enhances students' creative abilities and processes while being engrossed in the task.

THE PRESENT STUDY

Purpose

The purpose of this paper was to investigate students' creative abilities in 3D geometry and to examine the impact of an interactive 3D geometry environment on these abilities. More specifically, we address the following questions:

- (a) What were students' creative abilities in 3D geometry in terms of fluency, flexibility and originality?
- (b) Can an interactive 3D geometry environment enhance students' creative abilities?
- (c) How did an interactive 3D geometry environment enhance students' creative abilities and processes in 3D geometry?

Participants and procedure

To answer the first research question, we conducted two empirical studies on two kinds of 3D geometrical abilities that young students are expected to perform according to the Cypriot mathematics curriculum: 3D rectangular arrays of cubes (Study 1) and nets (Study 2).

In Study 1, a hundred and twenty one 6th grade primary school students (54 males and 67 females), ranging from 11 to 11.5 years of age completed two 3D rectangular arrays of cubes tasks. The first task required students to create as many constructions with nine cubes as possible (9-cubes constructions). The second task called students to create as many constructions as possible with four cubes and surface area equal with 18 square units (4-cubes constructions). In Study 2, a hundred and twenty eight 6th grade primary school students (59 males and 69 females) completed two nets tasks. These tasks required from students to create as many cube nets and cuboid nets as possible. It needs to be stressed that all tasks used in both studies asked students to find multiple solutions, a characteristic of creative mathematical activity (Leikin & Lev, 2007). To evaluate students' mathematical creative abilities we measured: fluency (number of correct constructions), flexibility (number of different types of constructions or categories of constructions) and originality (extraordinary, new and unique constructions) (Torrance, 1974). Every response in the two 3D arrays of cubes tasks and in the two nets tasks was given a score from 0 to 4 for each one of these three dimensions (fluency, flexibility and originality). These scores are relative and based on the categories raised from all of the students' answers.

To answer the second and third research questions, we used a case study approach because it was the most appropriate to respond to the "how" research questions according to Yin (2003). In addition to this, this approach offers in details the

description of a specific situation and provides an example of “real people in real situations” (Cohen, Manion & Morrison, 2000, p. 181). We selected two sixth grade students who participated in the two studies with creative tasks. These two students worked for two sessions, one hour each, on four 3D geometry activities, which were the same with those that they worked in paper. They used two applications of an interactive 3D software environment, DALEST; a powerful tool in the teaching of 3D geometry which provides conditions of observation and exploration (Christou et al., 2007). The first application, Cubix Editor, can be used by students to “create 3D structures built of unit-sized cubes” (Christou et al., 2007, p. 4). The second application, Origami Nets, can be used by students to create different nets of various 3D geometric figures. The two students were asked to read again the task instructions that they solved earlier on paper and this time solve them with the use of the software. The students’ work on DALEST applications was videotaped and at the same time the researcher was taking notes. The researcher was recording the students’ comments during the time that they were working on the software, their strategies and constructions on each task.

This second part of the paper was conducted in the frame of the European project InnoMathEd (this project is funded with the support of the Lifelong Learning Programme of the European Union).

Data analysis

To investigate students’ creative abilities in 3D geometry, we conducted descriptive analysis on both studies. To examine the ways in which DALEST applications environment enhances students’ creative abilities and processes in 3D geometry, we analysed students’ strategies in the creativity tasks which they solved with the software and tried to underline the different creative thinking skills which arose from students’ solutions. The presentation and discussion of students’ solutions to the four creativity tasks are organised around three phases: (a) the phase before students express creative abilities (before students give numerous, different and unusual responses), (b) the creative phase and (c) the expansion phase.

RESULTS

Creative abilities in 3D geometry in paper

Table 1 presents the mean and the standard deviation of students’ performance in the creative tasks in both studies in terms of fluency, flexibility and originality. The means of students’ performance shown in Table 1 are all smaller or equal to one, since scores of students in fluency, flexibility and originality were divided by four (the maximum score).

CREATIVE TASKS	FLUENCY \bar{X} (SD)	FLEXIBILITY \bar{X} (SD)	ORIGINALITY \bar{X} (SD)	TOTAL \bar{X} (SD)
STUDY 1 (N=121)				
9-cubes constructions	0.49 (0.30)	0.48 (0.30)	0.45 (0.30)	0.47 (0.29)
4-cubes constructions	0.25 (0.22)	0.23 (0.20)	0.23 (0.20)	0.24 (0.20)
STUDY 2 (N=128)				
Cube nets	0.48 (0.29)	0.44 (0.29)	0.44 (0.27)	0.45 (0.27)
Cuboid nets	0.22 (0.19)	0.19 (0.15)	0.19 (0.14)	0.20 (0.15)

Table 1: The means and standard deviations of students' performance in creative tasks on study 1 and 2 in terms of fluency, flexibility and originality

According to Table 1, the total mean performance of students in creative tasks in both studies was below 0.5. These tasks appear to be very difficult and complicate to solve on paper and students probably did not have the opportunity to solve similar tasks in their mathematical textbooks in the past. However, it seems that students' creative abilities are better in some tasks than others. More specifically, the total mean of creative performance of sixth grade students in Study 1 in the task with 9-cubes constructions ($\bar{X}=0.47$) was double the mean of performance in the task with 4-cubes constructions ($\bar{X}=0.24$). The same pattern appears in Study 2 where students' mean performance in cube nets task ($\bar{X}=0.45$) was double the mean performance in cuboid nets task ($\bar{X}=0.20$). We hypothesise that students provided a larger variety and more unique solutions in tasks which are given to them without any "limitations" than in tasks with certain "limitations". Specifically, in the 9-cubes constructions task students were free to create constructions without any limitations in regard to the size of the surface area. On the other hand, in the 4-cubes constructions task, students were asked to create constructions with a specific size of surface area (18 square units). Similarly in Study 2, students were more creative while working with the cube nets, since all the faces were equal, instead of working with the cuboid nets where not all faces were equal.

Moreover, students in both studies had a higher mean score in fluency rather than in flexibility and originality. Therefore, it appears that students tended to be more fluent than innovative. They provided a number of answers but not always were these of a great variety or unique. More specifically, almost all students of Study 1 made at least one 9-cubes construction. This was usually a nine cubes tower or a cuboid 3X3X1. Many of them provided one to four 9-cubes constructions and only twenty students made more than five constructions with nine cubes. Therefore, the mean score in fluency was 0.49. In addition to this, many of the students of Study 1 created one to four different types of 9-cubes constructions and only fourteen students produced more than five different types of 9-cubes constructions. Thus, their total mean score in flexibility was 0.48. Students' originality score was also under 0.50 ($\bar{X}=0.20$), since only a small number of students created 'irregular' constructions

(with small base or to have a specific shape). In the task where students asked to create 4-cubes constructions with surface area 18 square units, sixty students could not create such as construction. Almost all students who created a correct 4-cubes construction had as one of their constructions a tower (an alignment of four cubes). Only eight students created more than five 4-cubes constructions and the rest of them created up to four constructions (fluency). In addition to this, only three students build four different types of 4-cubes constructions and the rest of the students, who responded correctly, gave up to three different types of constructions (flexibility) which were not very unique (originality). Thus, students' fluency ($\bar{X}=0.25$), flexibility ($\bar{X}=0.23$) and originality scores ($\bar{X}=0.23$) were very low.

From table 1, it can be deduced that students of Study 2 were more able to construct many, different and unique cube nets than cuboid nets. All students that completed these creativity tasks in Study 2, produced at least one cube net and this was the cross-net, but only twenty four students produced more than five cube nets. This is why students fluency score was under 0.50 ($\bar{X}=0.48$). Many of the students created up to four different types of cube nets, but only thirteen students constructed more than five different types of cube nets (flexibility), which however were not unique (originality). Thus, students' flexibility ($\bar{X}=0.44$) and originality scores ($\bar{X}=0.44$) were under 0.50. In the cuboid nets tasks, more than half of the students did not create any net and only five students produced more than five cuboid nets. The rest of the students created at least one cross cuboid net and this is why their fluency score was very low ($\bar{X}=0.22$). Students who produced cuboid nets were able to construct at the most three different types of cuboid nets. Only five students created more than four different types of cuboid nets (flexibility). In addition to this, students' cuboid nets were not innovative, since many of them were either the cross-net or T-net (originality). This is why the flexibility ($\bar{X}=0.19$) and originality scores ($\bar{X}=0.19$) were very low.

Creative abilities in 3D arrays of cubes in an interactive 3D geometry environment

The phase before creativity. In this phase, students explored the functions of the software by creating the constructions they already drew on paper. More specifically, for the task with the 9-cubes constructions both students created a tower of nine cubes and a cuboid 3X3X1. These were the most “popular” constructions in students' paper solutions. For the task with 4-cubes constructions, both students constructed only a tower of four cubes. These explorations allowed students to *visualise* the constructions that they had already created on paper. They could *see* their constructions from different perspectives by rotating them and *check* their solutions with the use of the “statistics window”. The “statistics window” shows the number of cubes used and the surface area of the constructions.

The creative phase. Through the visualisation processes and the checking potential that the software environment offers, both students provided six different types of 9-

cubes constructions. It was notable that students built these constructions by *expressing their ideas fluently* and without any assistance from the researcher. Sample of students constructions are given in Figure 1. These 9-cubes constructions appear to be difficult to be drawn on paper. In addition to this, students selected to build construction with “big base” (the number of cubes at the base is more than the number of cubes of other layers of the constructions).

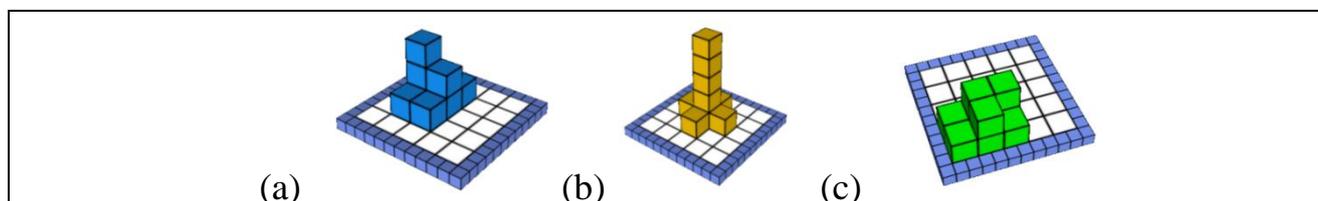

Figure 1: Students’ 9-cubes constructions

In the task where students were asked to create 4-cubes constructions with 18 square units surface area, both students started making *hypothesis* about which cube to move from the original tower (their first construction) to transform it to a different 4-cubes construction and *checked* simultaneously their solutions using the “statistics window”. They repeated this *procedure* (see Figure 2) until they provided a number of constructions. Student A provided nine 4-cubes constructions and Student B made five 4-cubes constructions. They stopped this step-by-step procedure when they realised that they could not find any other solution.

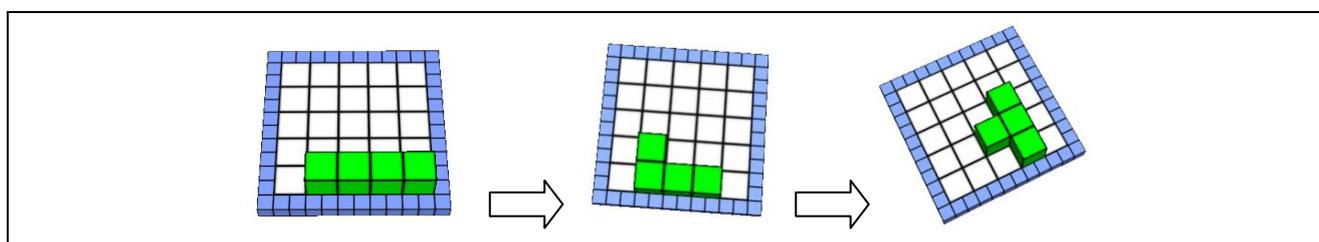

Figure 2: A step-by-step procedure for providing 4-cubes constructions

The expansion phase. In this phase, students appeared to use their *intuition* and *imagination* to extend their constructions. They tried to provide unique constructions employing a *modified* version of their previous constructions. More specifically, Student A constructed an additional 9-cubes construction by *removing* some cubes from the base of his previous construction and *adding* them on other layers above (see Figure 3(a)). Student B constructed another 9-cubes construction by *removing* cubes from the top of his previous construction and extending it horizontally (see Figure 3(b)). Similarly, in the 4-cubes constructions task both students created two further constructions without depending on the step-by-step procedure (see Figure 3(c) and Figure 3(d)). The step-by-step procedure, which characterised their way of processing during the creative phase, was replaced in the extension phase by their intuition and imagination.

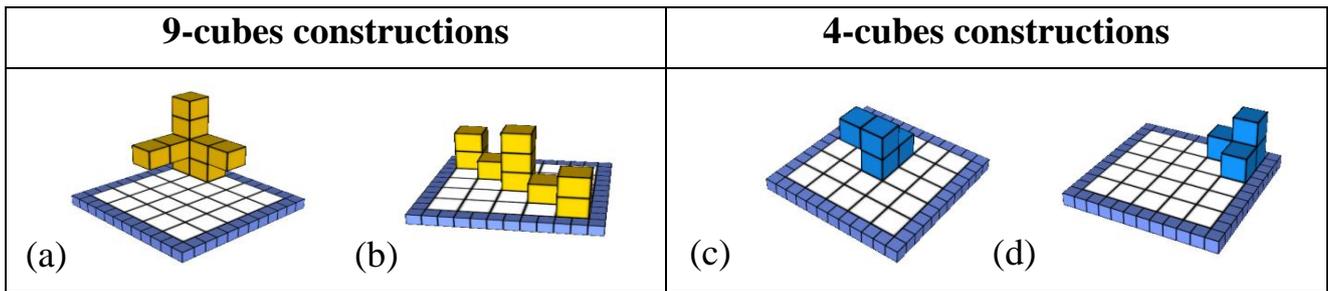

Figure 3: Students’ constructions in the expansion phase

Creative abilities in nets in an interactive 3D geometry environment

The phase before creativity. The two students when solved the nets tasks on paper produced only the cross-net for cube and cuboid. This cross-net, according to Stylianou, Leikin and Silver (1999) is considered as the easiest since it can be straightforwardly “opened up” whereas other nets need more transformations. Students claimed that they remembered it from their mathematical textbooks. In this phase, students *created* a cross cube net and a cross cuboid net in the software application, Origami Nets and *checked* whether these nets could be folded.

The creative phase. In this phase, both students *observed* and *explored* unfolded cross-net of cube and cuboid and tried to *plan a process*. In both tasks, students kept four squares or rectangles attached together in a row and moved the other two squares around that row (see Figure 4). Similar process was used by students in the study by Stylianou et al. (1999) and was characterised as systematic. With the above procedure, both students managed to construct 6 cube nets and 4 cuboid nets.

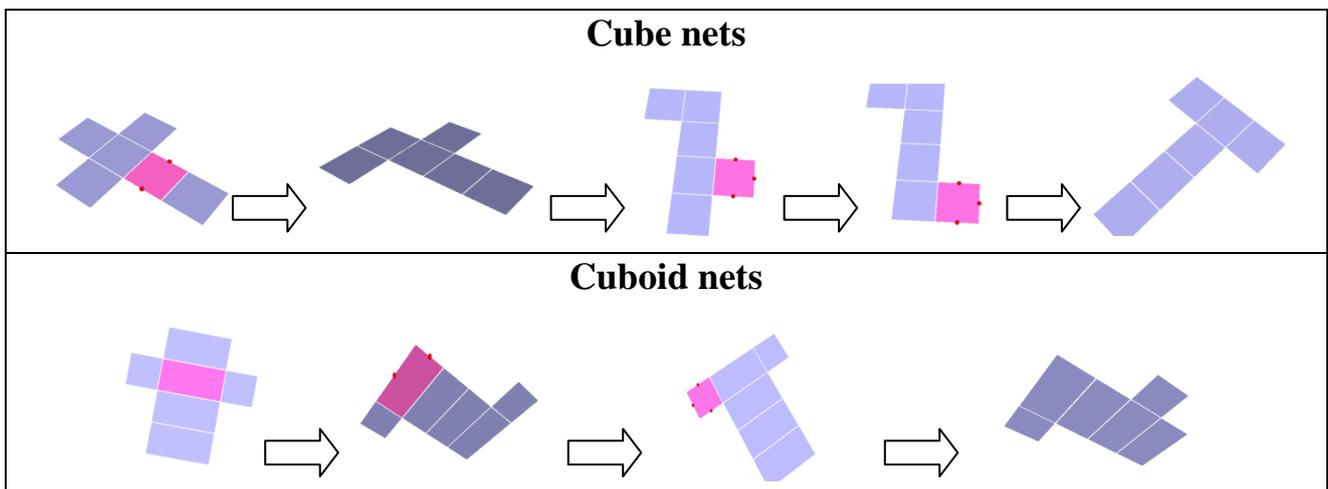

Figure 4: A step-by-step procedure for creating cube nets and cuboid nets

The expansion phase. In this phase, both students used their *intuition* to extend their constructions of cube nets and cuboid nets which were created previously during the creative phase. Students tried different combination of squares by *adding* or *subtracting* squares or rectangles and tried fold them up. Students employed this

strategy and succeeded in “extending” their answers by providing three extra solutions for the cube nets and one extra solution for the cuboid nets. Students’ “extended” constructions of cube nets and cuboid nets are given in the Figure 5.

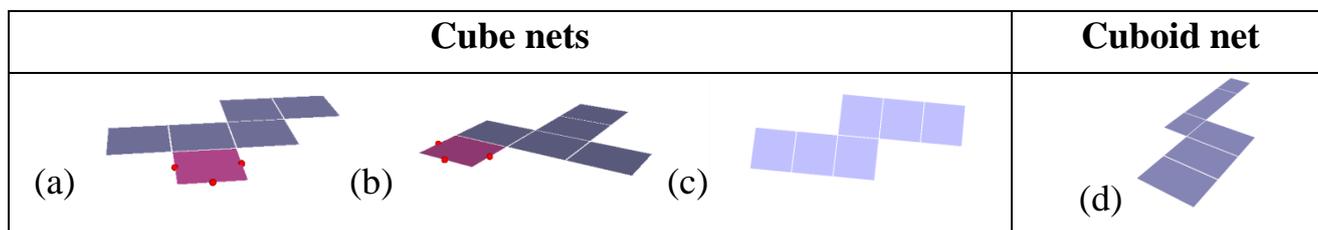

Figure 5: Students’ cube nets and cuboid net in the expansion phase

It is important to note that during the creative phase as well as in the expansion phase, the two students justified their solutions and at the same time they worked in the interactive environment. Their approach was not at all mechanistic (i.e. give an answer by chance, check and correct it).

Overall, the two students were able to construct many, different and unique solutions in the four creativity tasks in the interactive 3D geometry environment. They expressed a more creative performance in this interactive 3D geometry environment, by visualising their ideas and using their intuition and imagination (imagining skills), by planning a step-by-step procedure and hypothesizing (synthesizing skills) and finally by extending and modifying their previous solutions (elaborating skills).

DISCUSSION

The current paper examined sixth grade students’ creative abilities in 3D geometry and the ways in which an interactive software environment enhanced their creative abilities and processes.

Overall, the results of the two studies indicated that students’ creative abilities in terms of fluency, flexibility and originality were very low. But the interactive 3D geometry software environment enhanced the creative abilities of students who worked in that environment, by facilitating them to provide more, different and unique solutions. This finding confirms previous studies results about the value of technology as a tool for creative production (Clements, 1995; Subhi, 1999). Moreover, we found through the two case studies that the interactive 3D geometry environment forced and also enhanced students’ imagining, synthesizing and elaborating thinking skills. More specifically, it seems that during the phase before creativity, students used mainly imagining processes, while during the creative phase they used a combination of imagining and synthesizing skills. During the expansion phase, they used a combination of imagining, synthesizing and elaborating skills. These processes appear to have empowered students’ creative performance.

MATHEMATICAL CHALLENGING TASKS IN ELEMENTARY GRADES

Isabel Vale & Teresa Pimentel

School of Education of the Polytechnic Institute of Viana do Castelo, Portugal

Mathematics teaching and learning should include much more than routine tasks, which appeal to memory and drill, being complemented by others, mathematically more rich and challenging, as problem solving and investigations, that push for reasoning, creativity and connections. So teachers must have the ability to choose, formulate and adjust tasks according to their intended objective. In this paper we present some mathematical pattern tasks to use in elementary mathematics classes that, intending to be challenging, can develop students higher order thinking and creativity.

Key words: Challenging tasks, investigations, teacher education, elementary teachers

INTRODUCTION

The new Portuguese curriculum proposes a different perspective about the learning and teaching of school mathematics, with great challenges for both teachers and students. Despite of being well written and transparent about its aims, pathways for implementing these changes in real classroom settings are not fully defined and can be very complex and difficult to accomplish by the teachers when they haven't innovative instructional materials, and in fact only a few are available yet. More than ever we only can have students engaged in knowledge and critical citizenship if school and teachers promote creativity in their own classroom - being creative both in developing curriculum to get higher levels of students understandings through adequate tasks and in promoting creativity in students work. In this setting we are designing a two-year project to develop a research-based professional development curriculum focused on mathematics tasks, which will assist teachers in their practices and teachers in their initial preparation of grades k-6. Our attention is directed not only to mathematical themes of the curriculum but also to cross-mathematics processes - communication, problem solving and reasoning. Thus we intend to draw sequences of tasks, materials, expectations for each, and methodological notes about their use, and in particular selecting illustrative episodes of students' creative solutions of the tasks and teachers' creative ways of exploring them.

THEORETICAL FRAMEWORK

Teacher education and school mathematics

Literature identifies the major obstacles to reforms as teachers' lack of familiarity with innovative instructional practices and tools, teachers' lack of understanding of

mathematics they teach and their inability to communicate mathematics with students in ways other than direct instruction; and teachers' reluctance to conform to new methods of teaching due to their beliefs about what students need to know (Heibert et al., 2007). Several researchers (Raymond, 1997; Remillard & Bryans, 2004; Schoenfeld, 2008) suggest that teachers' knowledge, beliefs and attitudes influence their actions in the classroom and their interactions with students. Towards a mathematics preparation, Ma (1999) claims that teachers must have a profound understanding of fundamental mathematics to provide teaching and learning processes. In this pathway reflection plays an important role as the reconstruction of the teachers' experience and knowledge (Hodgen, 2003). Actually, teachers with more explicit and organized knowledge tend to use with their students more conceptual connections, appropriate representations and active student discourse (Warren, 2006).

Nowadays, widespread tendencies in mathematical education suggest that effective learning requires that students be active and reflexive when they are involved in significant and diversified activities. This idea follows a way of thinking where higher order and critical thinking skills are privileged, where lectures are substituted by dialogue and discovery methods. According to Boaler (2002), different teaching methods are not just vehicles to produce more or less knowledge, they shape the nature of knowledge production and define the identity of students toward mathematics through the practices in which they involve. As such, teachers must have an in-depth understanding of the mathematical thinking of their students. In doing so, they can support the development of their mathematical competence (Franke et al., 2007). Further, they need an understanding of how to mobilize this knowledge for their students' learning. We believe that students' mathematical thinking must support teachers' practice so teachers must construct or adapt good mathematical tasks to use in the classroom. They should have the capacity to be creative for themselves in the tasks they propose but be also mathematically competent to analyse their students solutions.

Research shows that learning heavily depends on teachers. They must make a set of decisions during the instructional process that depend on various factors affecting their actions, including how to interpret the curriculum and select curricular materials and strategies to use in the classroom. Within this context we as teacher educators have to design *good* mathematical tasks that should be used to achieve a variety of goals, in particular further mathematical understanding and creative thinking in order to motivate students to learn. So we have the dual responsibility of preparing mathematics teachers, both mathematically and didactically, and discuss the way tasks can be designed and refined for the purposes of promoting mathematical understanding.

Mathematics tasks and the development of mathematical knowledge

Having an explicit understanding of how and why mathematical tasks are used in teacher education gives us insight into what qualities a *good* task must have. However, it does not automatically provide us with the ability to design *good* tasks. The designing of *good* tasks requires an interface between the theoretical and the practical, between the intended and the actual, between the task and the student. The process of designing mathematical tasks is a recursive one that applies to the creation of entirely new tasks as well as it does to the adaptation (or refinement) of already existing tasks (Liljedahl et al., 2007). Serpinska (2003) regards the design, analysis and empirical testing of mathematical tasks, whether for the purposes of research or teaching, as one of the most important responsibilities of mathematics education.

What students learn is largely influenced by the tasks given to them (Stein & Smith, 1998). In fact, the tasks used in the classroom provide the starting point for the mathematical activity of students (Doyle, 1988) and the way of implementing a task determines its cognitive level. Its nature significantly influences the type of work that is done in math class; they should be diverse in nature and in context, giving rise to a variety of representations, using different resources and promoting discussion. Discussion that focuses on cognitively challenging mathematical tasks, namely those promoting flexible thinking, reasoning and problem solving, is a primary mechanism for promoting conceptual understanding of mathematics (Smith et al., 2009). Such discussions give students opportunities to share ideas and clarify understandings, develop convincing arguments, develop a language for expressing mathematical ideas and learn to see things from other perspectives (NCTM, 2000).

Although discussions about higher-level tasks provide important opportunities for students to learn and to promote creativity in their solutions, they also present challenges to the teacher who must determine how to organize discussion built from a diverse set of responses. The teacher must decide what aspects of a task to highlight, how to organize the work of students, what questions to ask to challenge those with different levels of expertise and how to support students without taking over the process of thinking for them and thus eliminating the challenge (NCTM, 2000). Giving students too much or too little support or too much direction can result in a decline in the cognition demands of the tasks (Stein et al., 1998). On the other hand, mathematical challenging tasks are not just difficult tasks or with a higher level of mathematization (Holton et al., 2009; Stillman et al., 2009) but much of the challenge may be provided by the teacher.

Patterning tasks are a specific kind that allows a depth and variety of connections with all topics of mathematics leading to consider patterns as cutting across all of mathematics education, both to prepare students for further learning and to develop skills of problem solving and communication (NCTM, 2000; Orton, 1999; Polya, 1945; Vale et al., 2009). Thus we will give special attention to this kind of tasks,

mainly for representations they raise (very different and usually taking the shape of analogies, drawings, manipulative or tables). Research shows that the use of multiple representations is beneficial in the teaching and learning of mathematics (Tripathi, 2008). Our previous research analyzed the impact of an intervention centred on the study of patterns in the learning of mathematics concepts (Vale et al., 2009; Barbosa, 2009). Since patterns are powerful in the mathematics classroom and can suggest numerical, visual and mixed approaches (Orton, 1999) and exploring growing patterns in elementary levels lays in the foundation for the algebraic reasoning (e.g. Usiskin, 1999; Rivera & Becker, 2008) we designed a didactical experience grounded on figural patterns as a suitable context to get expression of generalization and contribute to approach algebraic thinking.

The research has also shown that pattern tasks are a fruitful focus to support teacher inquiry and students learning towards the implementation of the current curriculum orientations. Moreover, patterning tasks challenge for different representations and to look for creative ways to reach the solutions; for instance, if students look for different ways of counting a collection of elements in figures, or a general rule of a growing figurative pattern. We identify the five different interconnected representations proposed by Clement (2004) for the mathematical ideas: pictures, manipulative, written symbols, spoken language and relevant situations. They must be used in mathematics lessons in order to provide a lens for making sense of students' solutions and responses and can be a guide for teachers to plan their lessons. We privilege problem tasks that require manipulative because, in doing so, specially young students seem to create a more significant and long-lasting experience, becoming involved in their own learning (NCTM, 2000; Weiss, 2006; Vale, 2003).

Challenge and creativity in the mathematics classrooms

We can read in ICMI Study 16 (Barbeau & Taylor, 2005) that mathematics is engaging, useful, and creative. The sentence itself was a challenge for us in the way that it conducted us to wonder what can we do to make it accessible to our students. In the last decades we developed our work and research around problem solving which led us to believe that it can be a fruitful context to engage both students and teachers to perceive those mathematics characteristics. A problem solving approach can reflect the creative nature of mathematics and give students opportunities both to learn mathematics and to feel the way in which mathematicians develop mathematics.

Learning mathematics is much more than facts, memorizing and mastering rules, techniques and computational algorithms, despite their importance and role. It entails incorporating experiences and conceptual understanding to solve different tasks like problems, investigations, games and puzzles, that promote mathematical knowledge in a reflective way, and developing creative processes to get solutions.

We only can be creative if we are attracted and challenged by the task. Challenging situations provide an opportunity to think mathematically. Holton et al. (2009) defend the importance of challenge in mathematics classroom when they state: “Students can become unmotivated and bored very easily in “routine” classroom unless they are challenged and yet it is common to hold back our brightest students” (p. 208). A mathematical challenge occurs when the individual is not aware of procedural or algorithmic tools that are critical to solve the problem and seems to have no standard method of solution. So he/she is required to engage in some kind of reflection and analysis of the situation, possibly putting together several factors, therefore having to build or invent mathematical actions to get the solution. Those challenges must respond to the situation with flexibility and imagination (Barbeau & Taylor, 2005; Powell et al., 2009).

Challenging tasks usually require creative thinking. Creativity begins with curiosity and involves students in exploration and experimentation drawing upon their imagination and originality (DFES, 2000). Creativity is typically used to refer to the ability to produce new ideas, approaches or actions and manifest them from thought into reality. The process involves original thinking. According to the *Wikipedia* creative thinking is a mental process involving creative problem solving and the discovery of new ideas or concepts, or new associations of the existing ideas or concepts, fuelled by the process of either conscious or unconscious insight. For Meissner (2000) there are several descriptions for creative thinking having not a standardized answer. But this author claims that creative thinking may develop as a powerful ability to interact between reflective and spontaneous *internal representations*. An examination of the research that has attempted to define mathematical creativity found the lack of a consensual definition. According to several researchers (Leikin, 2009; Polya, 1981), we also believe that creativity can be developed if we provide students with tasks that, allowing autonomous approaches, can generate new insights in underlying mathematical ideas. As we said before we are timely in the new national curriculum, so we designed some mathematics tasks fitting 1-6 grades, admitting multiple approaches and providing the development of creative processes of solution. We hope that we can motivate students to involve in class and challenge them for mathematics activity.

EXAMPLES OF CHALLENGING MATHEMATICAL TASKS FOR THE CLASSROOM

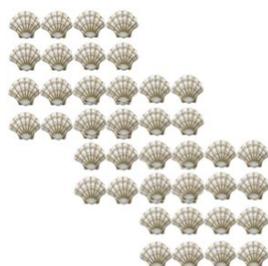

In a constructivist perspective the exploratory tasks in several contexts increase the development of students’ knowledge and mathematical skills. In this setting, while mediator between students and mathematical knowledge, the teacher must offer students diversified tasks that allow them to access mathematical content as well as to highlight and develop mathematical processes such as to experiment, conjecture, investigate, communicate and create, contributing to a more effective learning of

mathematics. On the other hand, good tasks must call for mobilization, integration and application of different knowledge. According to NCTM (2000) a task is a good one when it deals or serves as an introduction to fundamental mathematical ideas that constitutes an intellectual challenge to students and allows different approaches.

We present four examples of tasks included in the research plan, of different nature and designed to different grades. Some of them intend to develop number sense while others stress algebraic thinking or geometric and spatial reasoning. However, they have a common objective: to develop new approaches and creative ideas. That is, the tasks must provide multiple solutions in order to raise the student flow of mathematical ideas, flexibility of thought and originality in the responses. According to students' age, the teacher may encourage the use of manipulative materials so that children can have an useful involvement in the task.

We briefly discuss possible ways of exploration of the tasks.

Task 1. Visual Counting - The shells

The sea girl organized this way the shells she caught yesterday.

Can you find a quick process to count them?

Fig 1: Shells

We claim that a previous work with counting tasks in figurative settings can be a particularly good way to develop skills of *seeing* (identification, decomposition, rearrangement) to facilitate similar processes in growing pattern tasks. In fact, in the exploration of growing patterns in figurative sequences it is crucial for students to see the relations among successive terms in order to translate visual patterns into numerical expressions conducting to the generalization process - the heart of algebraic thinking.

Numerical expressions translating students' thinking in seeing the collection of shells arranged in this manner must be explained. For instance

$$40 = 4 \times 4 + 4 \times 6 = 3 \times (4 \times 4) - 2 \times (2 \times 2) = 2 \times (4 \times 4 + 2) + 4 = \dots$$

“Four rows of four shells and four rows of six shells” or “Three 4x4 squares minus two overlapping 2x2 squares” or “A 4x4 square plus two above, its reflected image and 4 shells more in the reflection axis”.

The horizontal representation stresses the equivalence of the numerical expressions and allows a new meaning of the equal sign. Our expectations of students' creativity in this task lay in the different original ways of seeing/counting the number of shells.

Task 2. Figurative growing patterns - Trucks

Observe the pattern.

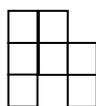

Fig. 1

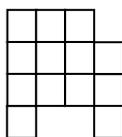

Fig. 2

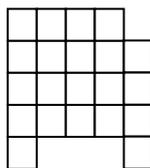

Fig. 3

Fig 2: Trucks growing pattern

1. Sketch the next figure.
2. What is the area of each figure if the little square is the unit? Write a numerical expression translating a way to calculate that number.
3. Describe with a written explanation how you could construct the figure 25.
4. Describe with words how you could determine the area of any figure of the sequence.
5. Explain, to a fellow that doesn't believe in your rule, why does it work.

We intend that students look for a pattern, describe it, and produce arguments to validate it using different representations. The previous work with visual counting may help to see a visual arrangement that changes in a predictable form and write numerical expressions translating the way of seeing, in order to make it possible the generalization to distant terms.

Students must be encouraged to observe and see the figures in different ways and to register those several modes in a table looking for a functional relation (Table 1) using more or less formal representation. Creativity can be revealed in the search of different ways of seeing the arrange, in order to choose the best way to get an expression of far generalization.

Number of the figure	Area
1	$2 \times 3 - 1 + 2 = 3 + 2 \times 2 = \dots$
2	$3 \times 4 - 1 + 2 = 4 + 3 \times 3 = \dots$
3	$4 \times 5 - 1 + 2 = 5 + 4 \times 4 = \dots$
...	...
25	$26 \times 27 - 1 + 2 = 27 + 26 \times 26 = \dots$
...	...
n	$(n + 1) \times (n + 2) - 1 + 2 = (n + 2) + (n + 1) \times (n + 1)$

Table1: Registration of modes of seeing

Task 3. The Euclid's Game

Number of players:2

Material: - a hundred chart

- overhead projector pens or translucent marks

Working Group 7

Development:

Toss who is player 1. The 1st player chooses a 1-100 number and marks this number on the chart. The 2nd player chooses and marks any other number.

In turn, the player subtracts any two marked numbers in order to find a difference that has not yet been selected. The players play alternately until they cannot choose a chart number. The player who can mark the last number wins.

Play the game several times. Try to discover a winning strategy.

Throughout games students can develop a greater motivation for mathematics work. The links between the game and mathematics are sometimes surprising and unexpected: the fact that a game has a simple mathematical explanation and its knowledge may entail the possibility of gain provides a good way to enjoy mathematics, its beauty and power. The Euclid's game is a numerical one in which, with a few persistence, students will be able to discover patterns in the numerical structure and relations in a flexible manner in order to reach a winning strategy. The fluency of basic knowledge to relate the numeric data collected must give insight to the underlying mathematical concepts in the task and associate them to produce the bright idea of the solution.

The hundred chart may be replaced by a table of 6x6, for example, to facilitate and not becoming boring to perform several calculations.

The general conclusion about the game is complex and may be presented as follows: Let n and s the numbers chosen, respectively, by the 1st and the 2nd player. Let $d = \text{gcd}(n, s)$; Let $m = \text{Max}\{n, s\}$. Then the game ends after m/d steps.

It is the evenness of m/d that determines the winner. So if the 2nd player knows how to play, the 1st hasn't any possibility of winning: if the 1st chooses an even number, it is enough for the 2nd to choose its half to take immediate winning; if the 1st chooses an odd number, it is enough for the 2nd to choose its double, to take immediate winning, or then the successive even number to warrant victory after a number of steps equal to the chosen number.

However, students can take partial conclusions based on particularization with various numbers resulting from several games. For this purpose it is useful to ask questions such as:

Compare the patterns of numbers marked in each game. Can you explain why some games have so few numbers marked and others so many?

If the first player chooses the number 26, what number should I choose to be sure of winning?

If I start the game by choosing an odd number can I win? How?

Task 4. The Cube Problem

From a square sheet of paper, draw the net of a cube with the largest possible volume. Then build the cube by folding.

This problem involves geometric and spatial reasoning.

Many nets can be drawn in a square sheet of paper but there is only one that fits the condition. Fig 3 shows some different attempts students may do to get the solution. This one – the last drawing in Fig 3 – may be achieved either by drawing or by folding. It is necessary insight and divergent thinking to admit one face of the cube divided into four triangles. This requests a novel idea. However, the evolution in the consideration of the different nets as suggested by Fig 3, as well as the intuitive notion of balance and symmetry, may provide this good idea.

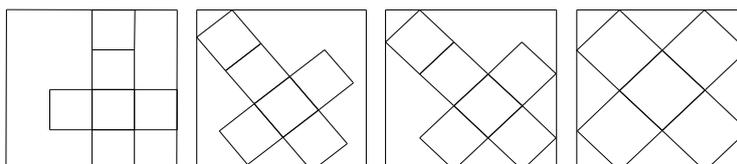

Fig 3: Different attempts to optimize

Another promising exploration for elder students is the relation between maximum volume/area. The construction of those successive figures with dynamic geometry software may be a good tool to discover the solution and to verify that it is indeed the optimal one.

TO CONCLUDE

Mathematics tasks are not the only feature in promoting mathematical challenge. In this endeavour, the teacher has a critical role in the process of fostering mathematical learning of students. To provide students with challenging situations is in itself a challenge for teachers. They have to choose adequate tasks and help students to carry on with appropriate assistance. This implies a wide and deep knowledge of the mathematics they teach and also a didactical one, in order to interpret students discourse and support students who are working on in new situations.

Creativity is new for us as a research field. We expect some results about the impact of teaching and learning elementary mathematics students with the support of these tasks and about if they are real opportunities to obtain creative solutions that contribute to the learning process. To check these goals we privilege classroom communication including questioning, oral presentations, written work and discussions, as well as focusing on the analysis and comprehension by the teachers of their students' mathematical thinking.

Wolfgang Schloeglmann, Universität Linz, Austria

INTRODUCTION

Affect has been a focus of increased interest in mathematics education for the last fifteen years. At Cerme 7, Working Group 8 was as stimulating and interesting as it had been in previous years with once again an atmosphere of collaboration between the 20 participants of the group. 13 research papers were submitted to the group and 12 were accepted for presentation after the review process. In the proceedings, 11 papers and two poster presentations were included, each of which investigated the multifaceted world of Affect.

The coordinators scheduled the seven conference sessions so that each participants paper could be presented to and discussed within the group. Fruitful discussion was encouraged by presenters also taking the role of responder to another paper, allowing the interactions between the papers to be highlighted. The program was scheduled in such a way as to enable the discussion to go beyond the papers, to a reflection on the structure and dynamics of the affective domain in an attempt to develop and expand the field in new directions. To this end, the first five sessions, based on the presented papers, were organized around five thematic topics: 1) Attitudes, 2) Beliefs, 3) Affect in mathematics thinking and learning, 4) Beliefs and Attitudes-Change, and 5) Other issues on Affect. In the two last sessions the work presented in the group was further discussed and possible new directions in the field were highlighted. Specifically the group discussed how to get a deeper insight into the affective constructs based on the questions: (a) How are the different constructs related to each other? What are the similarities and differences? (b) The different role of qualitative and quantitative approaches in the development of the Affective Domain. (c) The affective domain and other areas in the sphere of mathematics education. (d) Ideas for further studies.

The structure of the affective domain

Research into affect has always been accompanied by a discussion of the various definitions of the affective concepts (e.g. Di Martino & Zan, 2010). Therefore the goals of this working group on affect remained the clarification of the definitions used, the introduction of new concepts in order to broaden the field and the elucidation of the relation between the affective constructs. A starting point for this discussion was McLeod's (1992) first categorization of the affective constructs. McLeod (1992) introduced the categories of beliefs, attitudes and emotions, each

Working Group 8

distinguished by certain characteristics. Beliefs were seen as the one end of a continuum, more cognitive, more stable and less intense and emotions to be at the other end, affective, less stable and more intense. The context of the discussion of the group took a socio-constructivist perspective on learning continuing from the previous two working groups. This theoretical framework is characterized by its focus on the situatedness of learning and problem solving and by the close interaction between (meta)cognitive, motivational and affective factors in students' learning (Op't Eynde et al., 2006).

The concept of attitudes was presented to the group (Pepin; Pezzia & Di Martino). The authors moved beyond the simple definition that is attitude as the positive or negative degree of affect in relation to mathematics, to the model proposed by Di Martino and Zan (2010). The two studies investigated students' and teachers' attitudes shifting from the normative approach, measuring students' and teachers' attitudes towards mathematics, to an interpretive approach investigating causes that may shape students' and teachers' attitudes towards mathematics. An issue raised in the discussion was the nominalization in comparative studies (Pepin), the same statement may be used with different meaning in different context. The poster presentation by Vankúš was also related to students' attitudes towards mathematics.

Other concepts discussed in the group referred to self related beliefs, particularly self-concept and self-efficacy beliefs (Kleanthous; Panaoura et al.; Tuohilampi). In an attempt to clarify the concepts used and establish the relation between them, the discussion concluded that both self-concept and self-efficacy beliefs include individuals' evaluation of their ability in a domain, their confidence and how they see themselves in comparison to others. Kleanthous investigated students' self-efficacy beliefs and their dispositions to study mathematically demanding courses. Panaoura investigated differences in primary and secondary students' self-concept, self-efficacy beliefs and actual performance. Tuohilampi drawing from self beliefs and motivational theories (achievement goals) investigated the discrepancy between real and ideal self, a new direction in the field of affect. In the same realm and in the context of achievement motivation (Elliot & Church, 1997) the fear of failure was introduced as a self-evaluative framework (Pantziara & Philippou). In this study the authors investigated the causes of students' fear of failure by considering students' characteristics, family background and teachers' practices, once again revealing the complex world of affect.

New concepts were introduced and discussed in the group such as Personal Meaning. Vollstedt investigated the impact of context and culture on the different kinds of students' personal meaning in two different countries. Another new issue in the group was Resilience. Lee and Johnston-Wilder investigated ways to develop a mathematically resilient community of learners, who were confident enough to recruit other pupils to their way of thinking about effective ways to learn mathematics and to communicate those ways to teachers. Identity (Heyd-

Working Group 8

Metzuyanım & Anna Sfard) was also introduced to the group as a collection of narratives that are told by or about individuals, narratives that are *reifying, endorsable, and significant*.

In an attempt to interpret the nature of affect in the social context of mathematics classrooms, new theoretical frameworks were presented. Lewis introduced the Reversal Theory. The foundation of this theory is the structure of the motivational landscape, and its eight constituent motivational states. Students experience the world as they move or reverse, between opposite states. Commognitive theory (Heyd-Metzuyanım & Anna Sfard) was also presented. This framework recognizes the centrality of communication in all our activities, including uniquely human forms of learning and thus mathematical learning. In the same vein, Edwards' poster presentation referred to the impact of friendship groups on mathematical reasoning.

Intentionally changing affect was an important issue in this group's discussion as in the previous two affect groups. The studies by Pezzia and Di Martino and by Stylianides and Stylianides described intervention programs specifically designed to change teachers' and student teachers' affect.

Research methods for investigating affect

Various research methods were presented designed to investigate the multifaceted and complex affective domain. Some of the studies introduced qualitative approaches, such as observations and interviews (e.g. Heyd-Metzuyanım & Anna Sfard; Vollstedt) and others used quantitative approaches (questionnaires) (e.g. Tuohilampi). The trend in the group was for their research methods to combine qualitative and advanced quantitative approaches (e.g. SEM, Chic, Rasch) (Kleanthous & Williams; Lee & Johnston-Wilder; Panaoura et al.; Pantziara & Philippou) and also to use both teachers' and students' narratives (Peppin; Pezzia & Di Martino; Stylianides and Styliades).

Discussion and further considerations

The discussion of the results focused on the development and clarification of the concepts and instruments in the domain. The contribution of a combination of qualitative and quantitative methods to this development was stressed. Clarity of the concepts within the domain was further enhanced by an increasing unity in the language used. The new concepts introduced may develop and refine existing concepts but the definitions of these new concepts must combine with or grow out of the existing ones. A second focus was the relation between different constructs in the affective domain and their connection to other areas in the realm of mathematics education such as problem solving and students' achievement in geometry, algebra etc. Several different relations have been revealed, such as the relation between students' negative/positive affect and achievement. The complex nature of these relations was also stressed, revealing that students characterized by the same affective constructs may behave differently in a mathematical learning context.

Working Group 8

A third focus was the change in teachers' and students' affective constructs, considering how change can happen and how to instigate lasting change. Through the discussion different approaches to the stability of affective constructs emerged. The difference between state and trait was discussed and also the issue of the resistance to change in teachers' and students' affect. In addition, the distinct characteristics of intervention programs that changed affect in teachers were revealed. A last issue was whether the change in teachers' affect is also mirrored in their practices.

A last focus was the need to deepen our knowledge of the structure and dynamics in the affective domain. To this aim we followed Hannula's new theoretical framework on affect (Hannula, 2011). The framework is based on the integration of emotions with cognition and motivation, providing a dynamic approach to affect by using different angles. The broad distinction between affective states and traits is approached through an angle of motivation, cognition and emotion and at the same time through a psychological, psychological and social angle emphasising the dynamics of the different constructs involved.

The concluding remarks of the group included the necessity of continuing the research in the affect field using multi-method approaches; qualitative analysis of structures could describe patterns in students' engagement in the learning process while quantitative analysis of structures could focus on affective traits. Collaborative research between the members of the group was discussed. The work will go on.

NOTES

1. We would like to acknowledge the contribution of Clare S. Lee in proof-reading the final version of the introduction.
2. Special thanks to the members of our group, Clare S. Lee, Gareth Lewis, Julie-Ann Edwards, Karen Skilling and Sue Johnston-Wilder for proof-reading the papers of the group.

SELF – BELIEFS ABOUT USING REPRESENTATIONS WHILE SOLVING GEOMETRICAL PROBLEMS

Areti Panaoura*, Eleni Deliyianni, Athanasios Gagatsis**, Iliada Elia****

* Department of Primary Education, Frederick University, Cyprus

** Department of Education, University of Cyprus, Cyprus

The purpose of the present study was to investigate students' self-beliefs about using representations as a useful tool for understanding geometrical concepts and for solving geometrical tasks. The interest was concentrated on finding the differences between primary and secondary education in respect of students' self-concept beliefs, their self-efficacy beliefs about using representations and their real performance in geometry. Results indicated that, as was expected, secondary school students' performance is higher in all the dimensions of geometrical figure understanding. There is a coherent model of self-concept dimensions about the use of representations for understanding the geometrical concepts, which becomes more stable across the educational levels.

Keywords: representations, self-beliefs, self-efficacy, self-concept, geometry

INTRODUCTION

Students experience a wide range of representations from their early childhood years onward. Mathematics textbooks use of variety of representations in order to enable students to better understand mathematical concepts. In geometry, the understanding of mathematics requires that there is not any confusion between mathematical objects and the respective representation (Duval, 1999). In education it is important to investigate how pupils use and react to each teaching tool or procedure and what beliefs or conceptions develop. The present work correlates the students' beliefs about the use of representations in the learning of geometry with their respective performance on using them. Researchers embrace the belief that the development of geometrical concepts is multifaceted (Walcott, Mohr, & Kastberg, 2009) and agree that concept formation in geometry is potentially different from concept formation in other mathematics disciplines. We consider the present study to be a contribution to the extension of theoretical approaches of the cognitive and affective processes that underlie understanding in the learning of geometry.

Representations and the teaching of geometry in mathematics education

The importance of studying and teaching geometry is well established in the literature and is stressed in contemporary mathematics curricula not only as an autonomous mathematics field, but also as a means to develop other mathematical concepts. Through the study of geometry, students are expected to learn about geometric shapes and structures and how to analyse their characteristics and relationships (NCTM, 2000), building understanding from informal to more formal thinking and passing from recognizing different geometric shapes to geometry

Working Group 8

reasoning and geometry problem solving. Geometry is typically regarded as a difficult branch of mathematics for many students. As a mathematical domain, geometry is to a large extent concerned with specific mental entities, the geometrical figures. At a mathematical level, geometrical figures are mental entities, which exist only based on their definitions and their properties. But, a distance is identified between the geometrical-mathematical meaning of these specific concepts and students' personal meanings of geometrical figures, since, in students' minds, they are often related to real objects or are dealt with as pictures.

During the past twenty years, several mathematics educators have investigated students' geometrical reasoning based on different theoretical frames. For example, van Hiele (1986) developed a model referring to levels of geometric thinking, Fischbein (1993) introduced the theory of figural concepts and Duval (1999) reported the cognitive analysis of geometrical thinking. Duval distinguishes four apprehensions for a geometrical figure: perceptual, sequential, discursive and operative. Each has its specific laws of organization and processing of the visual stimulus array. To function as a geometrical figure, a drawing must evoke perceptual apprehension and at least one of the other three dimensions. Each has its specific laws of organization and processing of the visual stimulus array. Particularly, perceptual apprehension refers to the recognition of a shape on a plane or in space. It indicates the ability to recognize, in the perceived figure, several sub-figures. Sequential apprehension is required whenever one must construct a figure or describe its construction. Discursive apprehension is related to the fact that mathematical properties represented in a drawing cannot be determined through perceptual apprehensions.

In geometry, three registers are used: the register of natural language, the register of symbolic language and the figurative register. In fact, a figure constitutes the external and iconical representation of a concept or a situation in geometry. It belongs to a specific semiotic system, which is linked to the perceptual visual system, following internal organization laws. As a representation, it becomes more economically perceptible compared to the corresponding verbal one because, in a figure, all the relations of an object with other objects are depicted. However, the simultaneous mobilization of multiple relationships makes the distinction between what is given and what is required difficult. At the same time, the visual reinforcement of intuition can be so strong that it may narrow the concept image (Mesquita, 1998). Geometrical figures are simultaneously concepts and spatial representations. According to Mesquita (1998), an external representation has the nature of an object when the geometrical relationships utilized in the construction of the representation can be reutilised. In this case, it is possible to infer geometrical relationships from the construction of the figure; these geometrical relationships, such as parallelism, right angles etc. may be used in geometrical reasoning and proof. In the case when the representation has the nature of an object, the visual perception of the figure is consistent with the verbal statements of the problem. On the contrary,

when the external representation has the nature of an illustration, it is then impossible to directly extract a geometrical relationship from the construction of the figure and in this case the figure seems to “mislead”.

Self-concept and self-efficacy beliefs in mathematics

Cognitive development of any concept is related with affective development. Affective domain in mathematics education is an area to which considerable research attention continues to be directed (Leder & Grootenboer, 2005). The relationship between affective factors and learning in mathematics is not simple, linear or unidirectional; rather it is complex and convoluted (Grootenboer & Hemmings, 2007). The relationship between cognition and affect has attracted increased interest on the part of mathematics educators, particularly in the search for causal relationships between affect and achievement in mathematics (Panaoura, Gagatsis, Deliyianni & Elia, 2009). Marsh and Craven (1997) maintain “enhancing a child’s academic self-concept is not only a desirable goal but is likely to result in improved academic achievement as well” (p. 155). The anticipated improvement of student performance is based on the existence of a reciprocal relationship between self-concept and academic achievement (Marsh, Trautwein, Ludtke, Koller & Baumert, 2005).

The literature suggests that there is an influential connection between affective mathematical views and performance in mathematics (Ai, 2002; Schreiber, 2002). One’s behavior and choices, when confronted with a task, are determined by one’s beliefs and personal theories, rather than one’s knowledge of the specifics of the task. Beliefs is a multifaceted construct, which can be described as one’s subjective “understandings, premises, or propositions about the world” (Philipp, 2007, p. 259). In the present study, attention is concentrated on the self-beliefs and their relation to the performance.

According to Pajares (2008) “self-efficacy should not be confused with self-concept, which, as a broader evaluation of one’s self, is often accompanied by the judgments of worth or esteem that typically chaperone such self-views” (p. 114). Self-efficacy beliefs refer to matters related to one’s capability and revolve around questions of “can”, whereas self-concept beliefs refer to matters related to being and reflect questions of “feel”. Academic self-concept is referred to as self-perceptions of ability, which affects students’ effort, persistence, anxiety (Pajares, 1996), and indirectly their performance. Self-concept includes beliefs of self-worth associated with one’s perceived competence (Pajares & Miller, 1994). Besides an individual impression, students could develop their academic self-concept externally through a comparison with their classmates (Wang, 2007). People who believe that they are capable of performing academic tasks use more cognitive and metacognitive strategies, and, regardless of previous achievement or ability, they work harder, persist longer, and persevere in the face of adversity. People with a strong sense of efficacy approach difficult tasks as challenges to be mastered rather than as threats to

be avoided. They have greater intrinsic interest in activities and they set themselves challenging goals and maintain a strong commitment to them (Pajares, 2008).

Based on the above, the purpose of the present study was to investigate students' self-beliefs about the use of representations for solving geometrical problems in relation to their self-efficacy beliefs, their self-concept beliefs and their real mathematical performance in primary and secondary education. The main purpose of the study was twofold: (1) to identify the statistically significant differences between primary and secondary school students concerning their understanding in the various geometrical figure dimensions and (2) to propose and validate a framework which describes the components of students' self-beliefs to solve tasks involving different geometrical figures and mainly the interrelations between those different types of beliefs.

METHOD

The study was conducted among 1086 students, aged 10 to 14, of primary (Grade 5 and 6) and secondary (Grade 7 and 8) schools in Cyprus (250 in Grade 5, 278 in Grade 6, 230 in Grade 7, 328 in Grade 8). A test with 12 tasks (Deliyianni et al., 2009) was constructed and a questionnaire with 23 items was developed. The test consisted of three groups of tasks: (1) the first group of tasks includes two tasks concerning students' geometrical figure perceptual ability and their recognition ability, (2) the second group of tasks includes area and perimeter measurement tasks, which examine students' operative apprehension of a geometrical figure. Three other tasks require a reconfiguration of a given figure, while a task demands to synthesize two given figures in a new one, (3) the third group of tasks includes verbal problems that correspond to discursive figure apprehension.

A questionnaire (Table 2) was developed for measuring students' beliefs about the use of different types of representations for understanding geometrical concepts such as the area and the perimeter. Items were created with responses using a 5-point Likert scale ranging from 1=strongly disagree, to 5=strongly agree. The reliability of the whole questionnaire was high (Cronbach's alpha was 0.807 and 0.856 for primary and secondary education respectively).

RESULTS

In respect of the first objective of the study, we present the results of the multivariate analysis of variance in order to identify the significant differences between primary and secondary school students concerning their performance in the different aspects of geometrical figure understanding. Then the collected data of the questionnaire about self-concept beliefs were first subjected to exploratory factor analysis in order to examine whether the factors that guided the construction of the questionnaire were presented in participants' responses. We present the statistically significant differences for self-beliefs factors in respect of students' grades. Finally we present the results of the confirmatory factor analysis, indicating the structure of the specific

Working Group 8

affective factors, their main interrelations and the differences between primary and secondary education.

In order to determine whether there are significant differences between primary and secondary school students concerning their performance in the different aspects of geometrical figure understanding, a multivariate analysis of variance (MANOVA) is performed. Overall, the effects of students' educational level (primary or secondary) are significant ($F_{6,1079}=34.43$, $p<0.001$). The presentation of the results in Table 1 is indicative.

		\bar{X}	SD	\bar{X}	SD
Geometrical figure perceptual ability	$F_{1,1079}=79.51$, $p<0.001$	0.62	0.38	0.45	0.41
Students' recognition ability	$F_{1,1079}=38.81$, $p<0.001$	0.62	0.26	0.72	0.27
Operative apprehension of a geometrical figure	$F_{1,1079}=74.34$, $p<0.001$	0.49	0.35	0.32	0.31
Place value modification tasks	$F_{1,1079}=36.03$, $p<0.001$	0.45	0.42	0.31	0.38
Verbal problems (7,8)	$F_{1,1079}=105.38$, $p<0.001$	0.63	0.40	0.38	0.4
Verbal problems (9,10,11)	$F_{1,1079}=0.03$, $p=0.85$	0.25	0.31	0.24	0.21

Table 1: Means and standard deviations of students' (primary and secondary education) performance on specific types of geometrical tasks

The principal component analysis of students' responses to the items of the questionnaire revealed five factors ($KMO=0.887$, $p<0.001$) with eigenvalues greater than 1. Varimax rotation was used and as a consequence uncorrelated factors were revealed (Costello & Osborne, 2005). The eigenvalues, percentages of variances explained by factors and the factor loadings of the items are presented in Table 2.

The first factor corresponded to students' beliefs about the use of representations and materials for the better understanding of mathematical concepts (F1). The items at the second factor expressed students' self-efficacy beliefs in using representations for the understanding of geometrical concepts (F2). The third factor represented their self-efficacy beliefs about solving problems of area (F3), while the fourth factor represented their self-efficacy beliefs about solving problems of perimeter (F4). The fifth factor corresponded to students' self-concept beliefs about the use of diagrams, figures and representations in understanding mathematical concepts and their beliefs in using them as useful tools for explaining their geometrical thinking.

Analysis of variance (ANOVA) indicated that there were statistically significant differences in respect of grades for the factors F1, F2, F3 and F5. Those results depended on post-hoc analyses by using Scheffe. Specifically in the case of F1, there were differences at the means ($F_{3,1060}=4.943$, $p<0.001$) of the Grade 5 with the Grade 7 and the Grade 8 ($\bar{X}_5=3.62$, $\bar{X}_6=3.73$, $\bar{X}_7=3.92$, $\bar{X}_8=3.88$). In the case of the students' self-efficacy beliefs about using representations (F2), the statistically significant differences ($F_{3,999}=7.349$, $p<0.001$) were found between the Grade 5 with Grades 7 and 8 ($\bar{X}_5=3.66$, $\bar{X}_6=3.84$, $\bar{X}_7=3.95$, $\bar{X}_8=3.92$). The results were

Working Group 8

different in the case of students' self-efficacy beliefs about solving geometrical problems of area ($F_{3,1057}=4.237$, $p<0.005$). The differences were between Grade 5 and Grade 8 with Grade 6 and Grade 7 ($\bar{X}_5=3.84$, $\bar{X}_6=3.76$, $\bar{X}_7=3.72$, $\bar{X}_8=3.59$). In the case of self-concept beliefs about using representations in order to solve or explain problems ($F_{3,1034}=4.377$, $p<0.005$), the differences were between Grade 7 with all the other Grades ($\bar{X}_5=3.60$, $\bar{X}_6=3.71$, $\bar{X}_7=3.83$, $\bar{X}_8=3.64$).

Item	F1	F2	F3	F4	F5
The diagrams (e.g. circle area, rectangle area, number line) are useful tools for the problem solving in mathematics	.53				
The use of materials (e.g. fraction circles, dienes cubes) is important for the primary school students.	.62				
The construction of a figure or a diagram is useful for the problem solving in mathematics.	.67				
I prefer solving problems which present the data at a schema.	.70				
I can easily solve area problems.	.78				
I can easily explain the solution of a perimeter problem verbally.	.79				
I can easily solve problems which present the data at a schema.	.70				
I can easily solve problems which present the data verbally.	.56				
If someone asks me to explain the solution of an area problem, I prefer to do it verbally.	.69				
I can easily indicate the data of a perimeter problem at a geometrical schema.	.59				
I prefer solving problems perimeter problems which present the data only verbally.	.73				
I can easily solve the problems of area which need the construction of a schema.			.68		
I am very good in solving area problems.			.69		
The schemata help me in solving area problems.			.64		
I can easily solve the problems of perimeter.				.55	
I can easily explain to my classmate the solution of a problem of a perimeter by using a schema.				.65	
I can easily find the perimeter of a figure.				.59	
I can easily use formulas for solving problems of perimeter (e.g the perimeter of a rectangle is $2X(\text{length} + \text{width})$).					.65
The good student in mathematics can present his/her solution and explain it by using many different ways.					.48
For the correct solution of a mathematical problem, the use of an equation is necessary.					.59
I find it easy to explain at my classmate how I have solved an area problem by using a formula (e.g. rectangle area=widthXlength).					.67
When I solve an area problem I construct a schema.					.47
If someone asks me to explain the solution of a perimeter problem I prefer to do it by using a schema.					.51
Eigenvalues	7.87	5.28	2.92	1.85	1.45
Percentage of variance explained	30.1	16.7	8.77	6.01	4.20
Cumulative percentage of explained variance	30.1	46.8	55.5	61.5	65.7

Table 2: Factor loadings of the factors against the items associated with participants' beliefs

Working Group 8

In order to confirm the structure of students' self-concept beliefs in respect of the use of geometrical representations, a CFA (Confirmatory Factor Analysis) model was constructed by using the Bentler's (1995) EQS programme. The tenability of a model can be determined by using the following measures of goodness of fit: $\chi^2/df < 1.95$, $CFI > 0.9$ and $RMSEA < 0.06$. Firstly, a first-order model was examined within the structural equation modeling framework. This model involved only one first-order factor, which associated all the items involved. This model did not have a good fit to the data and therefore, could not be considered appropriate for explaining students' behavior.

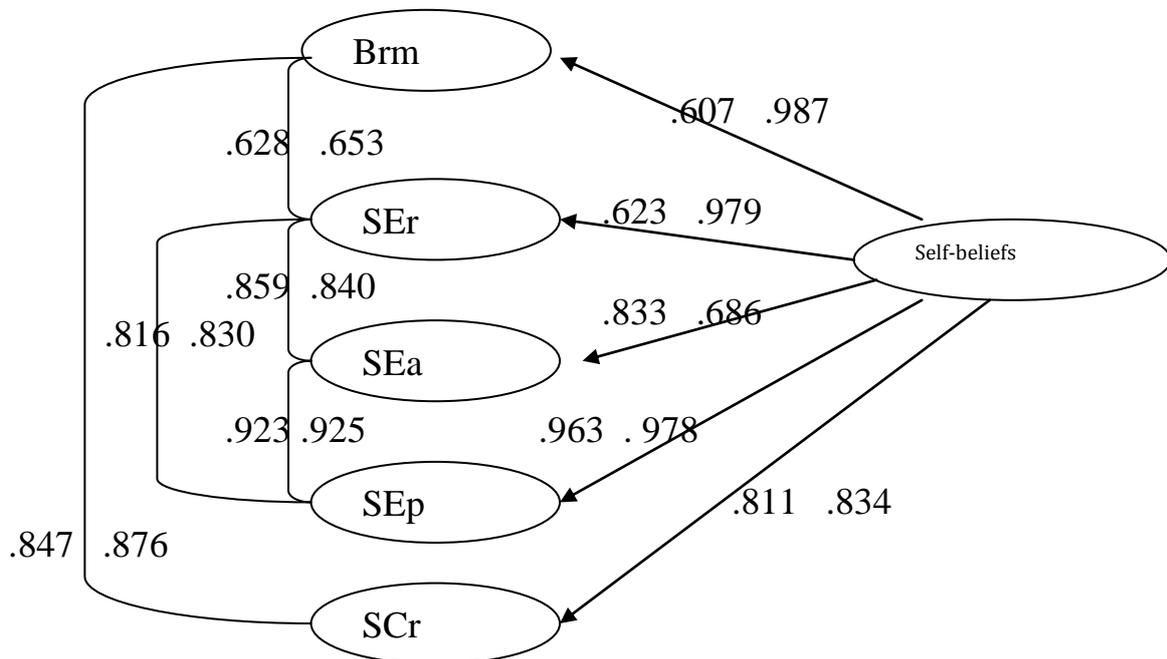

Figure 1 presents the results of the model that fits the data reasonably well for both the levels of education (primary education: $\chi^2/df = 1.14$, $df = 208$, $CFI = 0.972$ and $RMSEA = 0.020$, secondary education: $\chi^2/df = 1.45$, $df = 209$, $CFI = 0.949$ and $RMSEA = 0.03$). The second-order model, which is considered appropriate for interpreting students' self-representation beliefs, involves the 5 first-order factors, which were the results of the above exploratory factor analysis and one second-order factor. The first order factors regressed on a second order factor explaining the students' self-beliefs about using geometrical representations for solving geometrical tasks and understanding geometrical concepts, indicating that those factors are not independent.

The loadings of the whole model are higher in the case of secondary education almost in all cases. It is an integrated model of self-beliefs factors concerning the use of representations for solving geometrical tasks which becomes more stable across the educational levels, as a result of the continuous experiences in the teaching procedure and the more precise self-representation about the cognitive and affective performance. Students realize which tools and external or internal procedures help them to understand better the geometrical concepts.

There is a high statistically significant interrelation between the students' beliefs about using representations and their self-concept beliefs about using them for solving or explaining the solution of geometrical tasks [primary school (0.847), secondary school (0.876)], indicating that students who believe that representations are useful tools for understanding geometrical concepts tend to use representations in order to solve tasks and in order to explain to someone else the solution of a problem. At the same time students who use representations have already positive beliefs about the usage of this learning material. As was expected, the highest statistically significant interrelation is between students' self-efficacy beliefs for solving tasks concerning the concept of area with their self-efficacy beliefs for solving tasks concerning the concept of perimeter [primary school (0.923), secondary school (0.925)]. Students develop similar self-efficacy beliefs for both the concepts because in primary education they solve many problems, which ask them at the same time to find the area and the perimeter of a geometrical figure. Students with high self-efficacy beliefs about their ability to use representations, express positive beliefs about the use of representations on teaching and learning. The relation is higher in

Working Group 8

secondary education (0.853) than in primary education (0.728) where students have more experiences with Euclidean geometry, they have more positive beliefs about the usefulness of representations and they have more positive self-efficacy beliefs.

Notes: 1. Brm= beliefs about the use of representations and materials, SEr= Self-efficacy beliefs about using representations, SEa= Self-efficacy beliefs about using representations for the concept of area, SEp= Self-efficacy beliefs about the using representations for the concept of perimeter, SCr= Self-concept beliefs about using and explaining geometrical representations, 2. The first and second coefficients of each factor stand for the application on the model of primary and secondary education.

Figure 1: A confirmed model of students' self-beliefs about using representations in solving geometrical tasks

DISCUSSION

The first objective was to identify the statistically significant differences between primary and secondary school students concerning their understanding of the various geometrical figure dimensions and the second was to propose and validate a framework, which describes the components of students' affective performance to solve tasks involving different geometrical figures and mainly the interrelations between those factors. In respect of the first objective, differences existed in the geometrical figure understanding performance of primary and secondary school students. Particularly, secondary school students' performance was higher in all the dimensions of the geometrical figure understanding relative to the primary school students' performance. The performance improvement can be attributed to the general cognitive development and learning taking place during secondary school. In fact, the secondary school curriculum in Cyprus involves many concepts already known and mastered during primary school. This repetition of concepts leads to higher performance even though primary and secondary school instructional practices differ.

Working Group 8

Students' self-efficacy beliefs in using representations are lower in primary education. The results were different in the case of the self-efficacy beliefs about solving geometrical problems with the concept of area where the means are lower in secondary education. Students at Grade 7 have high self-concept beliefs about using representations in order to explain solutions of geometrical tasks. Actually there is an increase up to this age and then there is a decrease. It seems that students start having a more precise self-image about their abilities and do not overestimate their abilities.

Confirmatory factor analysis indicated that there is a stable coherent model of affective dimensions about the use of representations for understanding the geometrical concepts. It becomes more stable across the educational levels as a result of the continuous experiences. General beliefs about the use of representations are related to the self-concept beliefs about using them as a tool to explain geometrical tasks problem solving. Students seem to connect the concept of area with the concept of perimeter and for this reason they have similar self-efficacy beliefs. It seems that there is a need for further investigation into the subject with the inclusion of a more extended qualitative and quantitative analysis.

A COMPARATIVE STUDY OF NORWEGIAN AND ENGLISH SECONDARY STUDENTS' ATTITUDE TOWARDS MATHEMATICS

Birgit Pepin

Sør-Trøndelag University College, Trondheim, Norway

This presentation reports on a comparative study of English and Norwegian pupils' attitude toward mathematics, using a mainly qualitative questionnaire to develop a deeper understanding of the factors that may shape and influence pupil attitude. Albeit based on a small statistical sample, in both countries students' attitudes has very similar trends between grades 7/8 and 10/11. However, pupils' qualitative comments showed that the most influential factors were due to pupils' experiences in their respective mathematics classrooms and larger school environments. It is argued that by comparing it was possible to deepen our understanding of pupil attitude as a socio-cultural construct, and as a 'lived' construct influenced by the meanings that are made in different contexts.

Keywords: pupil attitude towards mathematics; comparative study; situated-ness of pupil attitude.

INTRODUCTION

Much research has been conducted in the area of 'affect in mathematics education': in terms of the role of emotions in mathematical thinking in general; in terms of the role of affect in learning; and of the role of affect in social contexts such as the classroom (Hannula, Evans, Philippou & Zan, 2004). Particular attention has been given to the influence of socio-cultural context on the formation of beliefs, and it is generally accepted (e.g. Op 't Eynde, De Corte & Verschaffel, 2006) that students' mathematics-related beliefs are "more complex, personal and context-specific ... than is generally thought." (p. 68) They argue that students' previous experiences in instructional environments were closely associated with beliefs.

Whilst the definitions of, and relationships between, constructs such as 'belief', 'attitude', 'emotions' and 'values' have been an area of great concern (Zan, Brown, Evans & Hannula, 2006), it is also unclear how to measure these, what influences them and how they are comparable across countries or cultures. Comparisons of how these constructs are 'lived' in different contexts and cultures (or countries), can not only identify similarities and differences, but are likely to deepen our understandings of what we mean by 'affect in mathematics education'.

THEORETICAL FRAMEWORK

Without making judgement on any particular constructs and frameworks, for our comparative study where culture is likely to play a significant role, the socio-constructivist view of learning and emotions appears most appropriate, as it stresses

Working Group 8

the situatedness of learning activities and connects the ‘cognitive, conative and affective factors in students’ learning’ (Op ‘t Eynde et al., 2006).

The theoretical framework of ‘attitude’ used in this study builds on Zan and Di Martino’s work (2007) who had investigated this construct for many years in an Italian project. Students are asked three ‘questions’ (see fig 1) and given the opportunity to “tell their own story with mathematics through an autobiographical essay” (p.163). Analyses of their data identified three core themes:

Emotional disposition towards mathematics expressed with “I like/dislike mathematics”;

Perception of being/not being able to be successful in mathematics, expressed with “I can/cannot do mathematics”;

Vision of mathematics expressed with “mathematics is ...”

(Zan & Di Martino, 2007, p.163)

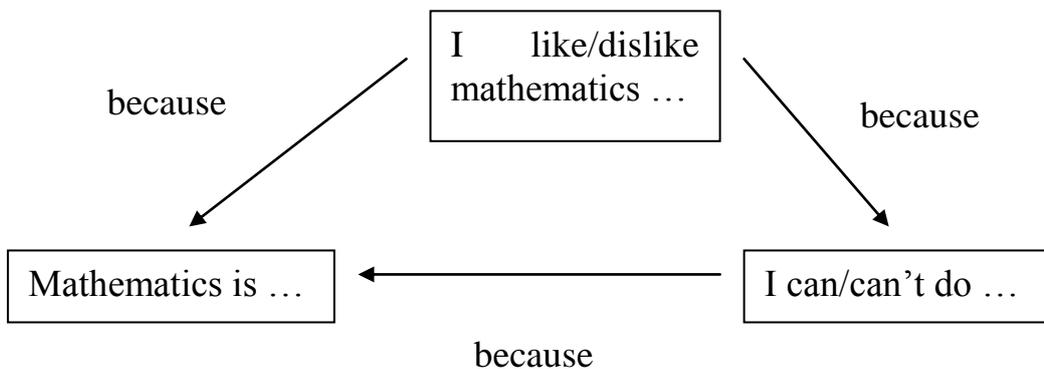

Fig. 1: Triad of Zan and Martino (2007)

The rationale for choosing this scheme is that the scheme provides a strong link to practice and the educational experiences of pupils. Moreover, students are given the opportunity to narrate their story (Bruner, 1990), and it is not important whether the story is ‘likely’ or ‘true’, but students’ perceptions of what they have done, the underlying reasons, and the types of situations they encountered are at the core of this frame. This is of interest. According to Bruner (1990) the narrative is concerned with the explication of the person’s intentions ‘in the context of action’ and through the telling of stories, one is likely to be able to make sense of events, or work out meanings of actions and processes.

THE STUDY

In previous studies the author developed an understanding of identity and ‘culturally figured worlds’ (Holland, Lachicotte, Skinner, & Cain, 1998) in mathematics classrooms in England (and other countries) and it emerged that national educational traditions are a large determinant and influence on teacher pedagogic practice and

Working Group 8

classroom culture. More recently, she investigated Norwegian and English classrooms, in particular with respect to ‘attitude towards mathematics’. The collected data (for this study) consisted of qualitative questionnaires and selected lesson observations. The qualitative questionnaire was based on three questions/statements (‘I like/dislike mathematics because ...’; ‘I can/cannot do mathematics because ...’; ‘Mathematics is ...’) where pupils could add their comments, describe their experiences and generally tell their story. The questionnaires were administered to 307 Norwegian pupils in grades 6 to 11, altogether to 13 groups/classes (distributed over several schools), and the same (translated) questionnaires to 194 English pupils in grades 7 to 11, altogether to nine groups/classes.

It is acknowledged that the data sets are too small and are not likely to be representative for England or Norway. However, in terms of catchment areas and situation of schools, they are comparable: the English data were taken mainly in one inner city comprehensive school in a large city in the Mid-North of England; and the Norwegian data were taken mainly in one ‘inner city’ school of the largest city in the Mid-North of Norway. Considering that the population of the whole of Norway is only half of the population of London, it may not be appropriate to talk about ‘inner city schools’ in Norway; but by Norwegian standards the schools was situated in a large city environment.

Moreover, and in terms of the validity of the data, the data were analysed on the basis of the author’s understandings of the construct of ‘attitude toward mathematics’ and its potential influences. The main questions addressed are:

- (1) How do students perceive their learning of mathematics, and what are the aspects of their attitude towards mathematics?
- (2) What are the main influences which appear to shape pupil attitude towards mathematics?
- (3) What are the similarities and differences in the different settings, and how does that influence our understandings of the ‘attitude’ construct?

In terms of analysis the main emphasis was on discovery rather than testing of theory, and the analysis involved category generation and saturation based on *constant comparison* as advocated by Glaser and Strauss (1967). Concepts emerged from the data, they were checked and re-checked against further data, compared with other material, strengthened and refined, similar to a procedure described by Woods (1996). Di Martino and Zan (2010) used a related way of analysing their data.

Moreover, the author tried at one level to maintain the coherence of the groups’ responses in schools, by analysing the responses with respect to selected observations. At another level s/he analysed across cases with each country, using the conceptual framework of ‘attitude’ and testing the hypotheses offered by the literature, and building explanations and theorisations grounded in the data. On a

third level, she looked for similarities and differences of pupil attitude towards mathematics across the two countries and contexts. However, due to the additional cross-cultural dimension, it was important to address the potential difficulties with cross-national research, in particular issues related to conceptual equivalence, equivalence of measurement, and linguistic equivalence (Warwick and Osherson, 1973). Particularly important were the validity checks with respect to the ‘questionnaires’, and considerable time was spent amongst researcher colleagues to ensure ‘equivalent’ meanings and constructs. In this respect, it was important to locate and understand mathematics classroom practices and the classroom cultures in England and Norway, and it was useful to draw on knowledge gained from previous research conducted by the author, which highlighted the complex nature of classroom practices and environments in the two countries. In addition, national curriculum documents and guidelines (including textbooks) were analysed in order to study the contextual background of mathematics classrooms and the potential influences of these texts in each country.

THE FINDINGS

Albeit based on a small sample, it is interesting to compare the two data sets quantitatively: interestingly more students like mathematics in Year 8 in Norway than in Years 7 or 9 in England, and especially the English Year 9 data (which are comparable in terms of age) ‘stick out’ there. At school leaving age (Year 10 for Norway, Year 11 for England) slightly more pupils like mathematics in the Norwegian schools than in English ones. It is also interesting to note that the same trend that Hodgen, Küchemann, Brown and Coe (2009) claimed, namely the drop of interest in mathematics from age 12 to 14, can also be claimed in both the Norwegian and the English data. However, after age 14 it seems that the interest increases again, and this is evident in both countries’ data sets: in Norway the positive attitude toward mathematics in Year 10 even overtakes the Year 8 ‘marks’. Thus, it is suggested that Hodgen et al. (2009) may have found a similar increase in interest, had they surveyed older children. Perhaps the most interesting finding here is that the ‘trends’ in attitude, going from Years 7 to 11, are similar in both countries’ data sets. The pupil comments appear to suggest that this was the case because students had accepted that, given the right conditions, they were ready to work at this subject in order to get good grades in their (compulsory) school leaving examinations, which in turn were likely to give them more opportunities in life. Thus, the ‘exchange value’ of mathematics, and this is linked to the assessment system, appears to influence pupils’ attitude towards mathematics.

Working Group 8

England			
(194 pupils)	Like mathematics	Indifferent	Dislike mathematics
Y7 (age 11/12) 74 pupils- 3 classes	(31/74=) 42%	9 %	49%
Y9 (age 13/14) 57 pupils- 3 classes	(22/57=) 39%	16%	46%
Y11 (age 15/16) 63 pupils- 3 classes	(26/63=) 41 %	22 %	37%
Norway			
(278 pupils)	Like mathematics	Indifferent	Dislike mathematics
Y8 (age 13/14) 41 pupils- 2 classes	(18/41=) 44%	22%	34%
Y9 (age 14/15) 158 pupils- 6 classes	(51/158=) 32%	23%	45%
Y10 (age 15/16) 79 pupils- 3 classes	(36/79=) 46%	16%	38%

Table 1: Pupil attitude (%) per year group and country

Analysing the qualitative comments, this paper argues in support of ‘pupil attitude toward mathematics’ as a socio-cultural construct that connects the cognitive, motivational and affective factors in students’ learning of mathematics. Leaning on the work of Op ‘t Eynde et al. (2006) the author contends that pupil attitude is embedded and shaped by the context in which it develops. Looking across pupils’ comments (on the questionnaires) there were seven themes that emerged from the data:

- (1) Mathematics for jobs and ‘later life’;
- (2) Mathematics is interesting, but hard and challenging for some, and boring and frustrating for others;
- (3) Repetitive nature of mathematics in classroom lessons;
- (4) Importance of working in groups (also for thinking) and support of friends;

Working Group 8

- (5) The role of the teacher;
- (6) The support of the family and primary school for being able to do mathematics;
- (7) Examinations play an important part, both in terms of individual success as well as what doing mathematics means.

Taking the example of Theme 1 (Mathematics for jobs and ‘later life’), and looking across pupils’ comments, it appears that in terms of liking/disliking mathematics most students stated that ‘mathematics is necessary for life’. In Norway, this is supported by curricular guidelines. Large scale international comparative studies in mathematics and science (TIMSS; PISA) have shown that Norwegian pupils perform relatively poor and significantly lower than the mean of other countries (e.g. Grønmo & Onstad, 2004), and there has also been noted a decrease in recruitment to science related studies (Schreiner, 2008). This, together with the low performance on international achievement tests, is likely to have influenced the Government in terms of increasing the emphasis on sciences and mathematics education.

Many pupils in the study had dreams of particular professions and needed mathematics to fulfil those dreams.

”You get to learn new skills and it will help you later on in life ... because algebra etc can help you in jobs such as an accountant...” (EY7-SO)

“... Maths can be tiring, but it opens opportunity doors.” (EY11- U8)

“... I struggle with any work ... my dream is to become a police officer and you need to have a GCSE in maths.” (EY9- JF)

However, this emphasis on the utilitarian aspect of mathematics, in the sense of using it as a means to achieve their own particular ‘distant’ goal, was more evident in English pupils’ comments than in Norwegian answers (from the questionnaires). This can be understood in the light of the different contexts in which pupils were working and living. In particular, the education system in England expects pupils to direct their studies very early, and pupils have to decide latest at the GCSE level (age 16) what kind of line they want to pursue at A level, which in turn has implications for further study (e.g. Higher Education) and hence for job opportunities. This also means that depending on their A level choices, they may not have any mathematics instruction after GCSE. In Norway every child has the right for upper secondary education regardless of their grades at the end of compulsory schooling (grade 10), and they have to continue mathematical studies for at least another two years after age 16. More than 95% of students in Norway continue with upper secondary education, either in ‘professional’ (e.g for apprenticeships) or ‘theoretical’ (e.g. traditional upper secondary mathematics and science) tiers.

Theme 2 (Mathematics is interesting, but hard and challenging for some, and boring and frustrating for others) and theme 3 (Repetitive nature of mathematics in

Working Group 8

classroom lessons) are interrelated. Approximately half of the pupils, in particular those who seemed to succeed in mathematics (according to their comments), talked about mathematics as a ‘challenging’, ‘interesting’ but ‘hard’ subject to learn. Others characterised it as ‘boring’, ‘non-creative’ and ‘confusing’. These perceptions went right through all classes, ages, and achievement groups.

“It is fun and easy and very interesting subject ... I like being made to think in maths ... I also like to be made to write and do many activities in maths. I love maths so much that I make sure I don’t forget a calculation ...” (EY7- TO)

“... it is boring and it does not allow you to be creative. ... mathematics is also very complicated as you have to use many different formulas... it is stressful..” (EY11-U12)

Pupils’ perceptions were often linked to particular classroom practices and atmospheres. For example, many Norwegian pupils commented that it was a very theoretical subject where topics build on and connect to one another, and where very little practical work was done.

“I don’t like mathematics because it is such a theoretical subject. If you miss one theme the class works on, you don’t get the next theme. Mathematics builds upwards. And it is some calculations I don’t get so I have given up, so now I’m lost in mathematics classes. In addition, I have fear of failure in this subject, so I don’t give a crap about anything called mathematics.” (NY9- GN1)

English pupils perceived the nature of mathematics more rigidly as ‘getting the right answer’, and where little creativity is encouraged.

“... I find it easy to understand and because it is the same wherever you go. Numbers are always the same in every country, so anyone can do it. With maths, the answer is either right or wrong, whereas with other subjects like English and History, there are many different answers.” (EY11- DB)

“There is always a key book so there is always just one correct answer.” (NY9- GN5)

“... it is boring and it does not allow you to be creative. ... mathematics is also very complicated as you have to use many different formulas....” (EY11- U12)

In terms of classroom practices, and particularly in Norway, pupils commented on the repetitive nature of lessons, with textbook work and teacher presentation playing the main role.

“ ... mathematics could be funny if it was varied and not just writing ... I don’t like mathematics because it is too much of the same thing.” (NY9- GN2)

“... it is not an interesting subject. There is nothing fun towards this subject and a lot of it just feels like you’re doing the same thing all the time. I like the class I am in and how we really understand things ...” (EY11- U13)

Working Group 8

“.. once you learn how to work out an equation or formula, you keep repeating the same method and there is always one correct answer. ...” (EY11- U14)

However, pupils wanted to work ‘differently’, in a problem solving way and with more open questions (than provided by textbooks), in order to develop a better understanding of the mathematics.

“I like problem solving. I think it is fun. I like to think and reflect long, because I then have a better chance of understanding. I become really happy when I manage to solve the problem. With Pascal’s triangle it was quite fun and I got the system, but when we went back to calculating arithmetic problems again I became bored. ... there should be more variation in the teaching. All we do is star down in to a book all the time. I find it a total waste of useful time.” (NY6- GN10)

Whilst not being able (for limited space) to explain all themes, the seventh theme (Examinations play an important part, both in terms of individual success as well as what doing mathematics means) provided evidence of examinations influencing pupils’ attitudes.

“I’m good at it and I like it because it’s good trying to work it out. But sometimes I don’t like it, because of exams ...” (EY7- DB)

“.. good because when you leave school you will have good exam results and you will be brainy. Also if you go to university you will get really good grades, and if you get good exam results in university then you will get a really good job.” (EY7- GE)

It seemed that the assessment system played a crucial role in pupils’ perceptions of what mathematics is and how to become a ‘proficient’ mathematics learner. For example, in both countries, but more in England, pupils practice on examination questions several months before the examination. This means that nearly all curriculum teaching is suspended, and pupils and teachers go over past examination papers- ‘teaching to the test’. Examinations appear to define whether a pupil is ‘good at maths’ or not.

CONCLUSION

This article argues in support of ‘pupil attitude towards mathematics’ as a socio-cultural construct that connects the cognitive, motivational and affective factors in students’ learning of mathematics. Leaning on the work of Op ‘t Eynde et al. (2006) the author argues that pupil attitude is embedded and shaped by the context in which it develops. Furthermore, and looking at the qualitative data, one can conclude that the main dimensions identified by Op ‘t Enyde et al. (ibid) are represented: beliefs about self; beliefs about social context; and beliefs about social norms in pupils' own classes.

Interestingly, whilst there are differences which can be seen to be accounted for by differently ‘figured’ environments, there are also many similarities. For example, it

Working Group 8

was interesting to see that, albeit based on a small sample, in both countries students had a positive attitude towards mathematics in year 7/8, which dropped in Year 9, and increased again in years 10/11. The pupil comments appear to suggest that this was the case because students had accepted that, given the right conditions, they were ready to work at this subject in order to get good grades, which in turn were likely to give them more opportunities in life. Thus, the 'exchange value' of mathematics, and this is linked to the assessment system, appears to influence pupils' attitude towards mathematics.

In terms of differences it was interesting to see how pupils 'lived' their mathematics worlds, in school and 'at home'. Pupil attitude appeared to be influenced by several factors which in turn were influenced by the different contexts in which pupils (and teachers) were working. For example, most pupils in both countries perceived mathematics as 'non-creative' and 'theoretical'. However, the perceptions that underpinned these notions were different. In Norway 'theoretical' was explained as connected and topics logically building on each other. In England, however, the connotation was that it was theoretical if one could 'understand the workings out and how numbers and statistics work', in short a more formulaic approach - different from making connections in mathematics. This is likely to be influenced by how mathematics is perceived, also by teachers.

In theoretical terms, it is argued that the seven before mentioned themes influence and shape pupil attitude towards mathematics. Whilst not being entirely new constructs, the identified influences emphasise the situatedness of 'pupil attitude towards mathematics' within a 'meaningful' environment. Furthermore, it has been shown how these constructs are intrinsically interwoven, and come together in 'attitude towards mathematics', when pupils write about their experiences. Thus, it is claimed that it is not enough to identify the factors that may shape and influence pupil attitude, but more importantly to study how these are 'lived' by pupils, what meanings are made in classrooms and in different contexts, and how the factors interrelate and can be understood.

THE PUPILS' VOICE IN CREATING A MATHEMATICALLY RESILIENT COMMUNITY OF LEARNERS

Clare Lee and Sue Johnston-Wilder

Open University and University of Warwick

We report on our work with one school to develop a mathematically resilient learning community. Pupils acted as Ambassadors to take the ways of working developed together into their mathematics classes and to bring the voice of all the pupils to our meetings. We describe our work within the school and what the pupils told us about the way that they learned mathematics and the way that they felt their learning could be improved. The knowledge we gained was shared with the teachers in the school. Some staff welcomed the ideas; others felt threatened by the notion of working in different ways. We argue that in order for the school to develop into a mathematically resilient learning community a change in thinking is needed by many mathematics teachers.

Keywords: Mathematical Resilience, community of learners, pupil voice

INTRODUCTION

In this paper, we report on a single cycle within an ongoing action research project undertaken in one school to facilitate formation of a mathematical learning community, where pupils learned from teachers and from each other, and teachers sought to learn from each other and the pupils. The intention behind the development of this community was to start to work towards increasing the overall attainment of the school's pupils in mathematics examinations taken at age 16. Schools in England are increasingly concerned about their pupils' attainment in mathematics as they can be judged to be 'failing to meet the needs of their pupils' if examination results in mathematics fall below an arbitrary measure. There is also an agenda, driven by government agencies, to increase the number of students studying STEM (science, technology, engineering, and mathematics) subjects at University (Roberts, 2002).

THE CONTEXT

We work regularly alongside teachers of mathematics, and recently began an action research project focussed on the notion of mathematical resilience (Johnston-Wilder & Lee, 2010a), the first cycle of which was reported in Johnston-Wilder and Lee (2010b). The first cycle indicated that, in addition to raising mathematical resilience, working in this way also raised attainment of the pupils in a difficult situation.

The cycle of action research presented here took place in an all-girls school in an urban setting in the West Midlands region of England. The school is considered a 'high attaining school', as it is always towards the top in school league tables. However, the managers saw a problem; the overall results in English examinations were always higher than in mathematics. As a result of our previous work, the

Working Group 8

Advanced Skills Teacher in maths invited us to work with the mathematics department in order to see whether we could help to narrow this gap. The cycle reported in this paper focused on introducing pupils and selected teachers to strategies for engaging and empowering pupils in learning mathematics, building their understanding of mathematical resilience and using them as conduits for change. We worked with pupils in Year 8 (aged 12-13 years) to change their stance towards learning mathematics and thereby raise their attainment (Dweck, 2000).

Our particular role was to enable the pupils to have an informed mathematical voice and to allow that voice to be heard. We were concerned that, when we asked the pupils how their mathematical learning could be improved, most pupils would give stereotypical or naive answers because they had not experienced different ways of learning mathematics. We knew from the theoretical considerations discussed below that, for example, increasing the pupils' ability and opportunity to take part in mathematical discussions, and encouraging them to work collaboratively, would enable them to surmount some of the barriers that learning mathematics often presents and to become more mathematically resilient. The results clearly showed that many of the pupils already knew this.

Typically for an English school, the school had grouped its pupils into classes for mathematics according to their attainment in internal examinations. The teacher of each of these 12 classes or 'sets', chose two girls to take part in the project as 'Ambassadors'. The girls were chosen because of their ability to speak out and take a lead within their own group. We had, in the community of Ambassadors, a mixture of girls in terms of mathematical attainment and mathematical confidence.

THEORETICAL BASIS

The way that we worked in the school was based on the ideas of building mathematical resilience that we have published elsewhere (Johnson-Wilder & Lee, 2010a, 2010b). Our underlying intention was to encourage the teachers to act to make the classroom a more positive place to be and one where barriers to learning mathematics could be overcome. If mathematics is difficult to master, and we see that it often is, then pupils need to develop a positive adaptive stance towards mathematics which will allow them to continue learning despite barriers and difficulties. This positive adaptive stance towards mathematics we have named as *mathematical resilience* (Johnston-Wilder & Lee, 2010a). Characteristics of mathematical resilience as we have described it include perseverance when faced with mathematical difficulties, working collaboratively with peers, having the language skills needed to express mathematical understandings and having a growth theory of mathematical learning (Dweck, 2000). Any learning may require resilience at times and can be actively promoted (Newman, 2004); however, we argue that pupils particularly require resilience in order to learn mathematics because of various factors that include: the type of teaching often used (Nardi & Steward, 2003; Ofsted,

2008), the nature of mathematics itself (Mason, 1988; Jaworski, 2010) and pervasive beliefs about mathematical ability being ‘fixed’ (Dweck, 2000, Lee, 2006).

It has been established that emotions have an important role in mathematical thinking generally (McLeod, 1992) and that powerful affective structures are a key factor for effective mathematical learning (Goldin, 2002). We see resilience as an important positive affective construct. Resilience enables pupils to make positive use of their affective domain and is built when teaching takes account of the four aspects of affect: emotions, attitude, beliefs and values (Hannula, Evans, Philippou, & Zan, 2004). We consider that building mathematical resilience offers a way to counter the well-known global affective structures that impede mathematical learning, commonly called “maths anxiety” (Richardson & Suinn, 1972). We see teaching for resilience as facilitating a positive self-belief or self-efficacy in pupils learning mathematics, which have been shown to be influential factors determining the interpretation and appraisal processes constituting their affective responses and emotions (McLeod, 1992).

In this study, we wanted to develop a mathematically resilient community of learners, who were confident enough to recruit other pupils to their way of thinking about effective ways to learn mathematics and to communicate those ways to teachers, thereby including both teachers and pupils in the purpose of improving mathematical learning in the school. Communicative aspects of resilience were particularly important to us in this project. We aimed to promote dialogic interaction, thereby enabling intra-mental ideas to subsequently become inter-mental (Vygotsky, 1981). The strategies that we asked pupils to use arose from work such as Vygotsky (ibid) and Lee (2006), which show that thinking and communicating are intricately intertwined. For example, we invited the pupils to try making mathematical videos and peer teaching. We have previously demonstrated (Lee and Johnston-Wilder, 2010) that video-making is a device that can be used in mathematics departments to increase pupil articulation and autonomy, so we incorporated video-making into this cycle. Peer teaching has also been demonstrated (Lee, 2006) to increase articulation, change pupils’ mathematical identities and increase agency.

what we Did

Our work with the school consisted of three days over half a term spent with the mathematics Ambassadors and additional time emailing and meeting three times with representatives of the teachers in order to plan and review the days. We were joined by a drama teacher from Creative Partnerships (www.creative-partnerships.com), whose role was to inform about and model the use of drama to support mathematical learning. Drama can be seen as enabling dialogic communication and therefore this expert practitioner added to our expertise in building a mathematically resilient community. We used the three days in two distinct ways. Firstly, we introduced the pupils to different ways of learning about mathematics. Secondly, we used the days

Working Group 8

to enable the pupils to collect and analyse data about the ways that Year 8 pupils in the school felt would be effective in enabling them to learn mathematics.

On the first day, we introduced a questionnaire to examine how pupils felt about the way school encouraged them to learn maths. The questions we asked derived from the work of Dweck (2000) on fixed and incremental theories of learning and the work of Fennema and Sherman (1976) on assessing attitudes to mathematics. We asked the Ambassadors to examine the questionnaire and to suggest changes to make questions more accessible to their peers and any extra questions that may be needed. The original questionnaire was changed in the light of the Ambassador's suggestions and they administered the questionnaire to their mathematics groups. We collated pupils' responses before our next day in school, when we asked the Ambassadors to analyse the response data and identify points that seemed important to them. They reported finding this both challenging and interesting. We also asked Ambassadors to keep journals describing their feelings about, and reactions to, the mathematics they were learning and the way that they were learning it, both in lessons and during our days with them. The Ambassadors were asked to focus in their journals on their own and their peers' feelings and reactions and that their journals were not to critique teachers or record any negative personal reactions other than to learning mathematics. These journals were brought to the second and third day workshops and each pupil drew attention to important points in their journal.

Therefore our data on the way that the mathematics learning community developed in this school consisted of: field notes about our plans for the days and the reasons for revisions of the plans, field notes about our discussions with the teachers in the school and the drama teacher, evaluations from the pupils from the day workshops and notes from our discussions with them, the results from the questionnaire on attitudes to mathematical learning and the Ambassadors' journal entries along with the pupils own analyses of both the questionnaire results and the journal entries.

What we found out

The Questionnaire Results

The Ambassadors distributed the questionnaire to all the pupils in their mathematics classes, collected the completed questionnaires and posted them to us for analysis. Therefore the responses we have represent the views of all the Year 8 girls in 2010. We entered the responses into a spreadsheet, created pie charts and asked the Ambassadors to tell us what the results indicated to them. Thus our analysis of the questionnaire results is informed by the Ambassadors. The results showed that many of the attitudes to learning displayed by the Year 8 girls in this high-achieving school corresponded to those that we would see as resilient. For example, 78% said that they worked hard in mathematics lessons and 80% agreed with the idea that 'I can get smarter at maths if I work hard'. However, 16–20% of the girls were rather more

Working Group 8

disaffected; it appears that the school will need to work with this cohort and engage them in mathematics in order to raise the school's attainment in mathematics.

We were struck by how resilient in general our respondents appeared to be; 94% reported being sure that they would be able to learn new work in all subjects. This level of confidence dropped by 6% when pupils were asked specifically about mathematics; nevertheless, 88% of the girls were confident in their ability to learn more mathematics. The resilient stance of the majority extended to their willingness to undertake tasks even if they knew that they might not 'do well' at the task; only 17% said that they would not engage with such tasks.

This resilient stance was not so evident when we asked if they "... sometimes would rather get good marks than understand the work." Only 40% agreed and a further 33% were not sure, leaving 27% valuing understanding over good marks. A further 78% said that they preferred getting a good mark to being challenged. Such results may indicate that the majority of pupils in the school are currently motivated by the idea of 'good marks' rather than understanding mathematics. This attitude is further emphasised by the fact that 53% disagreed with the statement "In addition to getting a right answer in maths, it is important to understand why the answer is correct." and 58% did not disagree with the statement "It does not really matter whether you understand a mathematics problem if you can get the right answer."

The answers also showed that for many of the pupils mathematics is 'a chameleon' (Johnston-Wilder & Lee, 2010a). 24% of the girls were not sure that studying mathematics would help them earn a living and 23% thought studying mathematics might be a waste of time; for such girls, mathematics lessons did not help them to distinguish how mathematics appears or is useful in the world outside school.

The data showed that 28% of Year 8 girls enjoy mathematics all the time, 55% some of the time but 17% not at all. It is to be expected that the girls did not all indicate that they enjoyed mathematics all the time; however, that 17% of the girls do not enjoy mathematics at all in the early years of their secondary school careers is rather worrying and, we suggest, underlies the relatively lower attainment in mathematics.

The Workshop Days

The tasks that we used during the workshop days involved learning with ICT using Grid Algebra (Hewitt, n.d.) and Autograph software, making videos (see Johnston-Wilder and Lee (2010b) for a description of this in another context) to explore where mathematics can be found in the real world, some drama activities as well as data analysis. Our notes from the days, and the pupil's own evaluations, show that all 24 girls enjoyed making the videos: the particular elements that they mentioned about the days were the team work, being able to go outside, using ICT in the form of video recorders, the boost that the activities gave to their confidence and the fact that the activities were more interesting and fun than they had expected. One of the pupils who worked with Grid Algebra wrote in her evaluation of the day: '*something like*

Working Group 8

nth term is usually boring but we understood it'. After being asked to show the class their work on Grid Algebra, one girl wrote *'I enjoyed making the presentation as I learned more about algebra. I would like to do something like this in my lessons as we could perform to each other and learn more'*.

Pupils particularly valued finding out some mathematics as part of a group and they enjoyed both working with friends and working with people that they had not worked with before. A pupil wrote: *'we brought our confidence out, writing and really being creative'*. The elements of choice they were offered were also important, as were using visual aids and sharing work. Another pupil wrote: *'all the projects were interesting and my thoughts about maths have really changed'*. The pupils also mentioned enjoying the more active way of learning that they were offered and that they would like to do such activities more often in their mathematics lessons.

The Journals

The pupils gave us permission to take their journals away for analysis. We noticed ideas in the data that informed us about the pupils' learning; we collected like ideas together and reflected on the import of what they were saying. From this we devised 'stable categories' (Cohen, Manion & Morrison, 2007) that reflected the key ideas discussed by the pupils. A draft letter to the teachers was constructed from this information. This letter was discussed with the Ambassadors during the third day workshop and the quotes given below either come directly from the pupils' journals, were recorded during the discussions of the letter or are from the wording of the letter agreed with the Ambassadors.

We discovered that these pupils intuitively knew ideas about effective teaching and learning of mathematics that were supported by research literature. For example, they either knew or had discovered that, in the best lessons, teachers talk less and consequently pupils talk more. Many of the journals mentioned that mathematics teachers talk too much. *"When we are not involved enough we lose focus so we would like less teacher talk, more pupil work and more expectation of effort."*

It is important that pupils feel able to ask their teachers when they do not understand and that the teachers *"explain and help if we are stuck"*. Peers are also important to learning; the Ambassadors said that classmates should be allowed to help one another and recognised that pupils learn best when they can support each other and *'have a laugh occasionally'*. Contrary to the questionnaire results, the Ambassadors' descriptions of lessons valued understanding and reported that pupils liked lessons where all are given a chance to understand the essential elements. The timing of the lessons was important; according to the pupils, lessons should be well timed and not involve *"sitting still for too long and being bored"*. The pupils are aware that they do not do well in an environment where the work is *"boring and repetitive"*.

The journals also made clear that the pupils *"would like teachers to have higher expectations of us"*. They wanted more challenge and felt they would be more

Working Group 8

engaged when challenged. *“We don’t mind hard work. We are not afraid to work hard.”* They liked teachers to be sufficiently strict in lessons to ensure that pupils learn, but not so severe that they discourage questions and problems. Pupils stressed that they like teachers who set high expectations and expect them to do well. Pupils enjoy working on difficult questions *“that will help us in the long run.”*

These pupils would like more variety in mathematics lessons, less book work, a diversity of tasks and more group work. They do not believe they learn or remember when working solely from books. They like to be active, interacting with other people, giving presentations, working independently and completing projects or extended work. They said such activities boosted their confidence and helped them learn to work independently. They enjoyed it when a pupil prepared and taught part of a lesson; they said it is useful when pupils work at the board for the rest of the class to consider and question. They see value in complex tasks, using a range of skills in a lesson. Similarly, they would like projects and extended work.

“We would like more interactivity, more games and interesting activities, more practical work and creative tasks, like making and testing helicopters as some did this term. We like more fun activities and we like adventures ... We like maths we can recognise in the real world”.

The pupils like to learn using computers and said computers are not just for playing games. They felt that work such as making presentations using ICT helped them to learn and those who had opportunity to use Grid Algebra recognised its value. They also suggested that they should be given optional ICT tasks for homework.

Pupils would like to support each other more; they asked for more group activities, team work and collaborative work. *“For example, one day this term, we did a GCSE problem and had to work as a group. It went well and everyone enjoyed it and began to work as a team.”* Sometimes, teachers could split the class into *“those who can do it and those who can’t.”* The pupils pleaded: *“Make sure all pupils understand the topic”.* They recognised that they needed to be proficient in using the mathematics register if they were to fully understand and become confident in using mathematics. *“We would like teachers to give us more help on the meaning of words.”*

The working environment was important; the pupils liked the room to be not too hot so that they could concentrate well and they liked interesting wall displays. The ethos of the class was crucial; pupils needed a relaxed environment where they could feel trusted and allowed to talk to one another whilst working. They do not enjoy working in silence: *“we don’t like the atmosphere of silence and it makes us feel locked in. We like it when people are talking, getting on with interesting work and able to ask questions with a helpful teacher.”* They also told us that they did not like to be asked if they did not know – it made them feel *“dumb.”*

CONCLUSION

We were struck by the extent that the pupils' ideas resonated with research about learning mathematics and our own research about how pupils become more mathematically resilient. Pupils understood the importance of collaborative learning (Wiliam, 2008; Mercer & Littleton, 2007) and how important it is for the pupils to use the language of mathematics (Vygotsky, 1981; Lee, 2006). They also understood the importance of variety in keeping them motivated and interested.

There was a contradiction in the data concerning the importance of understanding. In the questionnaire, only 27% unequivocally valued understanding over getting good marks, whereas the Ambassadors' journals clearly plead for the teachers to "*Make sure all pupils understand the topic*". This could be a false dichotomy; it is likely that the pupils appreciate that, when they understand their work, they get good marks in examinations. It seems more likely from the questionnaire results that the dialogue in school values marks over understanding and that the pupils' plea about understanding should be listened to, if attainment in mathematics is to be improved.

The majority of pupils were willing to form a learning community in order to learn more about succeeding in mathematics. Most of them willingly presented their views about what they thought best helped them to learn mathematics. Those few who were less willing told us that they did not expect to be listened to and hence considered the process a waste of time. They became more willing as it became clear that the data they provided was recorded and considered. However, their conviction that teachers would not listen was partly supported. The teachers themselves, who had all been willing participants at the start of the process, became divided along a continuum by the second workshop. There were some who dropped in on the pupil days to see what was going on, discussed ideas with us and invited their pupils to demonstrate new ideas. However, others were deeply suspicious; they came to share lunch with us but were reluctant to talk and did not allow pupils write in their journals during lessons. Other mathematics teachers varied between these two extremes.

Why the divergence of attitudes on behalf of the teachers who had agreed to take part in the project in the first place? We know, from teachers who have discussed the ideas with us, and from the completed journals, that the reluctant teachers have a view of teaching that conforms with the stereotypical teaching described by Nardi and Stewart (2003). Therefore, the changes that were being promulgated may have appeared to deskill these teachers, possibly making them feel incompetent.

The data collected from the Year 8 ambassadors conformed to the way research defines 'effective' teaching: active, reflective, collaborative and grounded in the real world (Askew & Wiliam, 1995). Many of the pupils said firmly that they were not afraid of 'hard work'; they enjoyed being challenged, and working on complex, tractable problems. This view is far from the atomised practice of mathematics teaching prevalent in many schools in England. However, from our data, based in the

pupils' experience, we argue that part of enabling the school to develop into a mathematically resilient learning community will be a change in identity (Holland, Skinner, Lachicotte, & Cain, 1998) on the part of some of the mathematics teachers; moving from practices that tend to be repetitive, and focussed on techniques, to working with the pupils to develop mathematical understanding; moving from teacher as deliverer of knowledge, to pupil as an active, resilient participant in the learning process.

The pupil data clearly confirms our previous research that, if pupils are to become sufficiently mathematically resilient to overcome the barriers presented in learning mathematics, they must be more involved at all stages in the learning process. They must feel that they have the ability, opportunity, time and confidence to work to overcome any obstacles that are presented in learning mathematics. Therefore, they must feel supported by teachers and their fellow pupils, be challenged by the activities used and have time to fully engage in and succeed with their mathematical learning. Their questions must be fully answered and understanding should be valued over everything else. Above all pupils must not be made to feel “dumb”.

"YOU UNDERSTAND HIM, YET YOU DON'T UNDERSTAND ME?!" - ON LEARNING MATHEMATICS AS AN INTERPLAY OF MATHEMATIZING AND IDENTIFYING

Einat Heyd-Metzuyanin and Anna Sfard

Haifa University

Leaning on commognitive theory, we attempt to demonstrate how affective, social and cognitive aspects of learning can be treated with the same set of theoretical concepts and analytical tools. This will be done by developing the basic idea of learning mathematics as interplay between activities of mathematizing (talking about mathematics) and subjectifying (talking about the participants of the discourse). We shall exemplify our proposed tools of analysis on a group of usually successful 7th grade mathematics students whose ability to benefit from significant opportunities for learning is shown to be highly sensitive to how they identify themselves and their peers.

Keywords: identity, social interactions, affect, commognitive theory, discourse analysis.

Affective aspects of learning mathematics such as attitudes and beliefs have been studied extensively both for discovering differences between groups and for finding relations between those aspects and mathematics achievement (i.e. McLeod, 1992). However, emotional reactions during mathematics learning have received less attention (Leder & Forgasz, 2006), and, in particular – their interaction with the cognitive processes of mathematics learning have seldom been researched. Social aspects such as status and positioning in class has received growing attention in recent years (Lerman, 2000), yet less work has been done about the links between social interactions and the emotional and cognitive processes going on within the individual student in class.

Most probably, the lack of studies dealing with the interaction between 'affective' reactions, cognitive processes and social interactions stems from the fact that very specific, dissimilar conceptual frameworks and research tools have been used for studying each of these three arenas. Therefore, the long term goal of our research is to contribute to the effort of creating a unified framework, where cognitive and affective, as well as individual and social aspects of learning would all be seen as members of the same ontological category, to be studied with one integrated system of tools, grounded in a single set of foundational assumptions. In what follows, we report on the conceptual tools we have developed, while trying to address this challenge. We also exemplify the usage of these tools in an interesting episode of social, emotional and cognitive conflict in class.

The proposed conceptual framework leans on the 'commognitive' theory, which recognizes the centrality of communication in all our activities, including the

uniquely human forms of learning. This theory, stemming from participationist (Lave & Wenger, 1991) and discursive theories (Harré & Gillette, 1994), maintains that thinking can be viewed as an interpersonal form of communication and mathematics, being a particular way of thinking, turns out to be a special form of discourse (Sfard 2008).

Learning mathematics can be seen as interplay between two concomitant activities: that of *mathematizing* – communicating about mathematical objects; and that of *subjectifying*, that is, communicating about participants of mathematical discourse. Of all subjectifying activities, the most consequential for learning seems to be that of identifying – the activity of talking about the properties of persons rather than about what the persons do. Scrutinizing the activity of mathematizing is the commognitive counterpart of cognitive analysis, whereas studying the activity of identifying means attending to all those phenomena that other researchers label with adjectives such as affective, interpersonal or social. The empirical material presented in this article demonstrates how the activity of identifying may interfere with the activity of mathematizing, and thus with the learning of mathematics.

The Study

The study was held over a period of 5 months, in an extra-curricular program, where one of us taught three groups of 7th grade students: students with very high scores in mathematics, with moderate-to-high scores, and with low scores. In each group there were 4 students, 12 students overall (7 boys and 5 girls). The episode discussed here occurred during the 11th lesson with the moderate-to-high achievers group. This group included two boys - Ziv and Dan, and two girls - Edna and Idit. Generally speaking, Ziv and Dan had a history of high achievement in mathematics, Idit was generally successful though in some areas she encountered problems, and Edna had usually moderate scores.

The lessons were video filmed by 3 stationary cameras, directed at the student's fronts. Additionally, all written material performed during the lesson was collected. The recordings were transcribed in Hebrew, and the examples given here were translated into English by the authors.

The episode was chosen for deep and thorough analysis because of the very high occurrence of subjectifying utterances that accompanied what appeared to us as an inexplicable block in the advancement of the group towards a solution of a given mathematical problem. The students were presented with a worksheet containing a problem called the Chocolate Factory Problem (Figure 1). Its purpose was to help students to advance toward a discourse on fractions (though fractions were not explicitly mentioned).

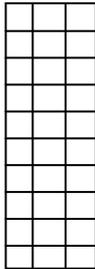

What mystified us was the fact that the participants seemed impervious to one student's (Ziv) seemingly lucid and cogent explanations and that the eventual eye-

Working Group 8

opening effect came from what looked to us as a much less coherent and quite opaque argumentation of another student (Dan). In what follows we show that much more than scrutinizing the flow of the "mathematical content" of the conversation is necessary in order to understand what blocked the learning process.

The Chocolate Factory

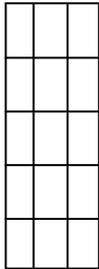

The chocolate factory produces four different types of chocolate bars, all of the same size, as shown in the drawing.

When bars get damaged, the factory can't sell the chocolate in its original package. The factory donates the damaged bars after repacking them in bags. Each bag contains the amount of chocolate equal to one type-D piece and two type-B pieces.

1. In how many different ways can one pack such a bag?
2. What are these ways?
3. How can you be sure you have found all the possible ways?

Fig. 1: The Chocolate Factory problem

Mathematizing

While participating in mathematical discourse, interlocutors combine mathematical keywords and mediators into mathematical objects. Indeed, to act as a competent participant in mathematical discourse, one has to realize (translate) words such as *numbers*, *functions* or *sets* with the help of other mathematical words and mediators. A *mathematical object* is a mathematical signifier together with its *realization tree*, a hierarchically organized set of all the realizations of the given signifier, together with the realizations of these realizations and so forth.

One way to analyze the activity of mathematizing is to follow the flow of mathematical objects, that is, to try to identify the ways in which the participants realize the focal signifiers at different points in the process of solving the problem. One important question that can be answered on the basis of this information is that of the effectiveness of communication: We can decide in a systematic, testable manner whether two interlocutors are speaking of the same object while using the same words.

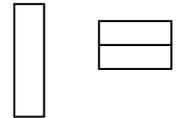

Working Group 8

Let's take a close look at how two of the students, Ziv and Dan, realized the signifier *a bag[containing] the amount of chocolate equal to one type D piece and two type B pieces* (which we shall shortly term 'the required bag', or simply 'bag') while trying to solve the Chocolate Factory problem.

Dan's first try

As evidence by numerous utterances during the first minutes of the episode, Dan and the two girls had considerable difficulty trying to understand the question. Apparently, they were unable to unpack the complex 'bag' signifier so as to be able to start thinking about any realization procedure. After grappling with the question for three minutes, a breakthrough occurred and Dan offered an idea:

Dan: so it's actually they say that they mean this.. that one like this,
each piece of one type, of type D, equals two of type B
[pieces] right? (lines 233-235)

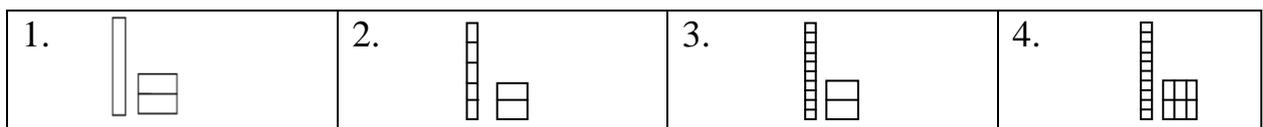

Dan had arrived at the (wrong) impression that the word *equal* in the description of the task signify the relation between the amount of chocolate in a type-D piece and the amount of chocolate in two type-B pieces (in other words, $1/3 = 2/5$). Not surprisingly, this interpretation stymied his further attempts at solving the problem. Indeed, from here, it was not clear what the words "number of different ways to pack such bag" could possibly refer to. His idea was questioned by the teacher, who encouraged Ziv to offer his alternative solution.

Ziv's try

Ziv remained silent throughout the conversation between Dan, the girls and the teacher. During the first 10 minutes of the episode he worked on his own solution. When he eventually spoke up, his proposals flowed one after another, contributing to the gradual emergence of a coherent realization tree for the requested 'bag'.

Ziv: O.K. (..) the first way (.) is the way they showed us, which is one stripe from here (*points to Bar D*) and two from here (*Bar B*, see fig 2. No. 1), that's the first way²⁴. The second way is to take all these (*Bar C*) and two from here (*Bar B*, see No. 2). A third way is to take a=ll²⁵ these (*Bar A*), two from here (*Bar B*, see No. 3). Now let's move here (*points to Bar C*). A third way is to take a=ll these (*Bar A*), and all this part (*Bar C*, see No. 4), all the six-, all the-, these

²⁴ The visual realizations of the students' words are *our* interpretations, based on the way the students pointed on the worksheet

²⁵ The transcription signs are as follows: = marks - a prolongation of the syllable; (.) marks a very short halt.

Fig 2. Ziv's realizations of the requested 'bag'.

In spite of the ostensive clarity of Ziv's explanations (supported by suggestive pointing), his classmates claimed they were unable to understand what he was saying. This left space for Dan's new take on the problem.

Dan's second try

After his $2B=D$ proposal was rejected by the teacher, Dan went back to coping solitarily with the problem, hardly paying attention to Ziv's solution. He then volunteered to explain his own solution to the girls and set out into a long and somewhat muddled explanation.

Dan: Uh- the chocolate factory did, um- things-, ah like, did a defected [pack], and did that the defected chocolates pack, will be this size, O.K? (*Pointing up and down a D rectangle, see fig. 3-1*) .. and in this size (*fig 3-2*). Right? Wait. (*Turning the worksheet towards himself*) If it's actually in this size, then why? Ah, I got it. 'nyway he did in this size, O.K? (*pointing to D, fig 3-1*) And in this size (*pointing to B, fig 3-2*). Two different packs. Now, they have a few types of packs, and they wanted actually, each, each pack of the defected [packs] they wanted actually to make it into such a pack (*pointing to D, fig 3-1*). They only have two types of packs, that they can get, and they can't change the size of the packs, so they have to insert [it]. Now, here (*pointing to bar A, fig 3-3*) there are many small ones, so they can actually divide them so they be put into such [a pack] or such [a pack] (*fig 3-1 and 3-2*). That's why they asked you here, if you can pack such a bag with squares of type A alone, so yes... So actually you can divide them so they'll be in this (*pointing to bar D, fig 3-1*), or like this (*bar B, fig 3-2*) because they are bi-, they're small. (Lines 536-554).

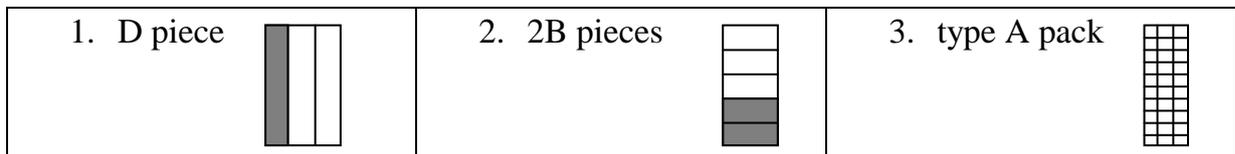

Fig 3 – The diagrams Dan was pointing to (the pointed parts are shaded gray)

Apparently Dan had arrived at a realization of a 'bag' he was quite content with (though it was wrong, again). He figured there are two 'legitimate' types of chocolate bars: one of the size of a single D piece, and one of the size (shape) of two B pieces. Thus, his realization tree for the requested 'bag' was as depicted in fig 4.

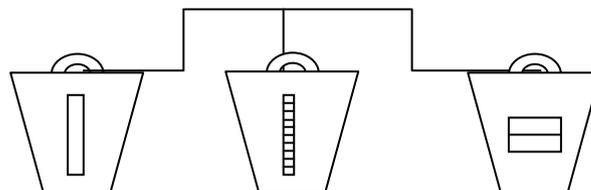

Fig 4 – Dan's realization tree for the signifier 'bag containing the amount of chocolate equal to 1 type D piece and 2 type B pieces'

Working Group 8

Surprisingly enough, the girls, who earlier insisted they 'don't understand a thing', now showed signs of comprehension. Idit claimed she understood Dan, and Edna offered: "and then it's like ten cubes" (line 557).

What was happening here? These students seemed to be learning from the participant who himself was struggling for understanding, and who offered a realization which was much too blurred and ambiguous to be helpful. All this happened after they let the obvious opportunity for learning slip away – after remaining unimpressed by a solution which, according to the observers, was not only correct, but also presented quite clearly and convincingly. Although nobody seemed to doubt the correctness of Ziv's solution, no visible effort was made to find out what his proposal was all about. We found no evidence for the other students being even interested in Ziv's explanation.

In order to understand what was happening, it was necessary to look into what we claim is a process that always runs in parallel to 'mathematizing', the process of 'subjectifying' and, in particular, 'identifying'.

SUBJECTIFYING

Subjectifying could be about oneself (1st person subjectifying), about others (3rd person subjectifying) or stated explicitly toward the subject of the communication (2nd person subjectifying). Following Sfard & Prusak (2005) we shall denote every subjectifying utterance with a specific notation that will clarify who the informer, the subject and the receiver of the communication are. Thus the notation $_{Edna}Ziv_{Teacher}$ will signify an utterance about Ziv, made by Edna and directed at the Teacher.

Subjectifying acts can be verbal or non-verbal (such as in gestures, facial expressions or meaningful intonation of the voice). They can also be direct or indirect. *Direct* subjectifying utterance refers directly to the subject (such as Dan (to Ziv): "no one can understand you"). *Indirect* subjectifying acts are acts that can be interpreted as being about one of the participants, even if the object of the act is not stated explicitly (such as when Ziv says about the other student's failure to comprehend "so they should try harder", indirectly stating he himself is superior to the others in his mathematical performance: in other words, this utterance may be marked $_{Ziv}Ziv_B$).

Moving from subjectifying to identifying

By using the term 'identity', we refer to Sfard & Prusak's definition of *identity as a narrative*. More specifically,

"identities may be defined as collections of stories about persons or, more specifically, as those narratives about individuals that are *reifying*, *endorsable*, and *significant*" (Sfard & Prusak, 2005, p. 16)

Sfard & Prusak made the distinction between narratives of *current identity* which consist of stories about the actual state of affairs, and *designated identity* "consisting of narratives presenting a state of affairs which, for one reason or another, is

Working Group 8

expected to be the case, if not now then in the future." (p. 18). This distinction will serve us when we look at different designated identities the participants are attributing to one another during this episode, and how such designated identities might conflict with the current 1st P identities the participants hold.

One of the most problematic obstacles for studying the mechanisms of identity building is the inaccessibility of some of the 'identity narratives' during a non-intrusive observation of students in class. Our first task, therefore, was to prepare an operational means for extracting 'identifying processes' (processes of identity building) from the natural discourse of the students in class and, in particular, for deciding which subjectifying utterances could count as identifying. We did this by assessing how general the subjectifying message is. At the lowest level of generalization we placed utterances in which an interlocutor evaluates what she just did or is about to do (e.g., Idit: "I didn't understand a thing"). A remark about a general characteristic of the speaker's or other person's participation (such as Edna: "When Ziv speaks I never understand him") was classified as representing a higher level of generalization. We decided that the highest level of reification occurs when rather than assessing the participation (what people do), the speaker evaluates properties of a person (what the person *is* or *has*) or of this person's memberships (with whom the person belongs), e.g., Dan (to Ziv): "You'll never be a teacher". Such reifying utterances are *identifying* by definition. However, *general participation* evaluation and even *specific participation evaluation* utterances can sometimes add up to form a coherent identifying narrative, provided they are *recurring* and *consistent*.

Most researchers interested in students' identities rely in their analysis exclusively on students' verbal 1st person identification, such as those obtained in interviews. And yet students of this age seldom talk extensively about themselves, and thus these are the non-verbal and indirect subjectifying actions which may often be a major, sometimes the only, 'window' to students' first-person identities. In our analysis, we found that when examined in the context of verbal direct identity narratives, *repetitive, consistent non-verbal* and *verbal indirect* subjectifying actions may often provide the most valuable information about how the students view themselves and others.

Additionally, emotional declarations and gestures are key signs of significance, and thus indicate which narratives and activities are important for the interlocutors. It can be reasonably assumed that whatever an emotionally loaded statement is, it has something to do with the student's identity – with how the student sees herself in the longer run. For instance, when Ziv solemnly hides his face behind his worksheet, avoiding eye contact and sitting ubiquitously quiet after remarking that Edna has 'understood' Dan and not him, we may assume he's emotionally hurt and that 'being understood', and 'explaining better than Dan' is important for his 1st P identity.

Working Group 8

To summarize, we will define identifying utterances (which may be either verbal or non-verbal) as *those subjectifying acts that signal that the identifier considers a given feature of the identified person as permanent and significant.*

Technique of analyzing identifying actions

In order to understand the identifying processes going on in this episode, we extracted all the subjectifying verbal and non-verbal acts made by the participants. These utterances were inserted into four tables (one for each student), each table containing all the group member's references toward the subject of the table. Looking at the tables, it appeared immediately that most of the subjectifying actions were made about Ziv. His table was the richest in subjectifying utterances in general, and in 2nd and 3rd P utterances in particular. In other words, not only was Ziv the participant who talked directly about himself the most, he was also the one who got the most attention from the other participants. As we shall shortly see, this attention was far from being positive, at least on the part of the other students.

In the following table²⁶, we bring examples of the most telling subjectifying acts from Ziv's table, those which can be classified as 'identifying' according to the definition made above.

Looking at this table, and from the analysis of all the subjectifying acts in the transcript, a clear picture of the identifying processes going on in this episode emerged. Let's first look at Ziv's 1st P identifying. It included a few main themes: First, Ziv made it clear that he thought himself superior to the others (especially to Idit and Edna). Second, he was very competitive with Dan (for instance by trying to 'beat' Dan and insulting him when he attempted to catch up). Finally, he seemed to get very hurt when the girls failed (or refused) to understand him conveying that 'being a leader of the mathematical discussion' was an important part of his identity.

The Teacher's 3rd P subjectifying of Ziv was very consistent, verbal and direct, and thus it could safely be claimed she was identifying Ziv as the most competent participant (mathematically speaking) in the group, and as one who could, and should, help the others understand the task.

The girls (both Edna and Idit) consistently identified Ziv as an "Incapable teacher" who may be smart but does not know how to explain. He was identified directly by Edna as condescending and admittedly complied with this identity, for instance by rolling his eyes at Edna's disability to comprehend him (though all the students had long histories together, thus it might be that the interaction seen here was rooted in the long past of their acquaintance).

²⁶ Out of space restrictions, the structure of this table is different from the one used for our analysis. The analysis table used a column for each participant, where all his/her utterances about Ziv were documented.

Table 1 – Ziv's subjectifying acts

Speaker, object and addressee	What is said (<i>and how</i>)	Subjectifying category
TeacherZIV _{Ziv}	Teacher: [explain your solution to the others] because you're the only one who understood [the question] (line 99)	Verbal 2nd P specific participation evaluation
DanZIV _{Ziv}	Dan (<i>quietly, while Ziv starts explaining again</i>): Enough, Ziv, you won't be a teacher. (line 678)	Verbal 2nd P designated identifying
EdnaZIV _{Ziv+Teacher}	Edna (<i>to the Teacher, in an annoyed voice</i>): He just- he talks to me like I'm his [little] girl! (<i>to Ziv, mummifying angrily a 'teaching voice'</i>) Ziv, you understand that if it's ^so and so^ than it's this and that? Yeah?! (<i>Turning back to the teacher</i>) That's how he talks to me! (line 704)	Verbal and Non-verbal identifying of a complex type: Edna speaking of how she thinks Ziv is identifying her.
IditZIV _{Teacher+Others}	Idit: No [I didn't understand Ziv]. Ziv talks to himself and he thinks everyone is listening to him so he (<i>mummifying a 'babbling' voice</i>) >pa pa pa pa pa, wa wa wa wa wa< (line 443)	Verbal 3 rd P General participation evaluation and non-verbal identifying
ZivZIV+DAN _{Edna}	Ziv (<i>to Edna, in an annoyed voice</i>) Ah! Like you understand him [Dan], and me you don't? (<i>sits back and looks hurt: covers part of his face with the worksheet, avoids eye contact and seems to 'close up'</i>) (line 555)	Verbal + Emotional-Non-Verbal 2nd P specific participation evaluation, highlighting the rivalry between Ziv and Dan.

It can be reasonable to conclude that the combination of Ziv's arrogant behaviour and 'superior' 1st P identity as enacted by him during the lesson - combined with the "he's the competent leader" 3rd P identity afforded to him by the Teacher - created a clear resistance from the girls to learn anything from him. Look at Edna, for instance, at the point when Ziv was trying to explain his solution to her (the 3rd time around) and she aggressively rejected it (see table 1, line 3). From her point of view, at this particular moment, she was offered a very undesirable identity by Ziv, and indirectly by the teacher - that of the 'little, inferior', perhaps even 'incapable' student. If she had cooperated by 'understanding' Ziv, she would have simply approved this identity, something she probably very much wanted to avoid.

Dan, on the other hand, being confused himself and showing no condescending behaviour, was much less threatening. In other words, his acts offered no endangerment for the girls designated identities as 'intelligent learners'.

To conclude, what we see here is a *struggle of identities*. As a result of this struggle, something very basic was missing from the students' discourse which would enable a useful learning process: a *teaching-learning agreement*. Sfard (2008, p. 283) coined this term for the implicit understanding, formed between two or more interlocutors, that one of them is the 'teacher' who has the authority to determine what is 'true', and the others are the 'students' who 'learn'. In our case, it is clear that the teacher believed such an agreement should exist, and as Ziv was making signs he had solved the problem, it was natural from her point of view, that he would take the role of the

'teacher'. However, as this agreement would endanger the designated identities of the girls, they strongly rejected it, even at the price of blocking their advancement in solving the presented problem.

CONCLUSIONS

This case shows how powerful processes of identifying may be in hindering mathematical discourse. The way the student chooses to participate in the mathematical discourse is affected not only, and perhaps even not mainly, by her mathematical competence, but also by her 1st P identity. Of principal importance here are her designated identities constructed by herself and by other participants.

It should also be noted that it is not always the 'weak' or peripheral students who pay the social price during participation in mathematical discourse. As Ziv's behaviour shows, it is the strong student who would sometimes be hurt.

Finally, teachers' actions, even if well-intended and performed in the attempt to advance the mathematical discourse in the class, can fuel and shape counterproductive identifying interactions among the students. As we have shown, such identifying interactions may hinder the learning process, achieving an effect exactly the opposite to the one intended by the teacher.

AN INTERVENTION ON STUDENTS' PROBLEM-SOLVING BELIEFS

Gabriel J. Stylianides

University of Oxford, UK

Andreas J. Stylianides

University of Cambridge, UK

Many students have certain beliefs about problem solving that tend to impact negatively on their engagement with problem solving. Previous interventions that achieved a positive impact on some of these student beliefs lasted over extended periods of time, thereby producing research knowledge that cannot be easily replicated in other settings. Findings from a 4-year design experiment in an undergraduate mathematics course suggest that it is possible to achieve a notable positive impact on 4 common and counter-productive student beliefs about problem solving with an intervention of duration as short as 75 minutes.

Keywords: beliefs, problem solving, classroom interventions, design experiments

INTRODUCTION

Students' ability or willingness to engage with the important mathematical activity of *problem solving* is shaped by students' *beliefs*, "the set of understandings about mathematics that establish the psychological context within which individuals do mathematics" (Schoenfeld, 1985, p. 5). According to Schoenfeld (1985), "[o]ne's beliefs about mathematics can determine how one chooses to approach a problem [...] and how long and how hard one will work on it" (p. 45).

Many students believe that those who understand the content can solve assigned problems in five minutes or less (Schoenfeld, 1992). Students with this belief tend to "give up working on a problem after a few minutes of unsuccessful attempts even though they might have solved it had they persevered" (Schoenfeld, 1992, p. 359). Also, many students tend to believe that "[t]here are always numbers in formulations of math problems" (Callejo & Vila, 2009, p. 116) or other clearly identifiable mathematical referents such as formulas. Students with this belief tend to give up working on problems that do not fit in with their expectations, because they cannot see how to make progress on these problems (see, e.g., Callejo & Vila, 2009).

These student beliefs not only interfere with students' ability to engage productively with problem solving, but also often lead to low success rates and negative reactions to mathematics more broadly (e.g., Furinghetti & Morselli, 2009). Previous studies (e.g., Perrenet & Taconis, 2009; Philippou & Christou, 1998; Swars et al., 2009) developed interventions that impacted positively on students' problem-solving beliefs, and identified specific features of the respective interventions that seemed to have played major role in their success (e.g., an emphasis on the history of mathematics). Despite the significance of these interventions, their success cannot be easily replicated in other settings due to their long duration and the associated large number of variables that were not explicit parts of the interventions but

possibly influenced their outcomes (the interventions lasted from 10 weeks to several years). Would it be possible to develop interventions of short duration in mathematics classrooms that would impact positively on students' problem-solving beliefs? Such interventions would be more easily replicated in other settings than long-term interventions, for they would allow more control over confounding variables. Evidence from a 4-year design experiment we conducted in an undergraduate mathematics course suggests that a notable positive impact on students' problem-solving beliefs can be achieved with an instructional intervention of duration as short as 75 minutes. With this intervention we targeted specific student problem-solving beliefs that tend to impact negatively on students' problem-solving engagement. Specifically, we aimed to promote the following 4 learning goals. Help students:

1. Recognize that some problems they perceive to be “unsolvable” can actually be solvable and within their capabilities (Goal 1);
2. Realize that effective problem solving requires perseverance (Goal 2);
3. See that the formulation of a mathematical problem can include more than just clearly identifiable mathematical referents (numbers or formulas) (Goal 3); and
4. Appreciate that problem solving can be a satisfying or enjoyable activity (Goal 4).

THEORETICAL FRAMEWORK

“[B]elief systems are composed mainly of ‘episodically’-stored material” and episodic memory “is organized in terms of personal experiences, episodes or events” (Nespor, 1987, p. 320). Thus, beliefs can often be traced back to vivid memories of highly influential episodes that shape people's interactions with subsequent events. Following Nespor's work, we aimed to engineer a dramatic and positive episodic memory for our students that would overpower their earlier episodic memories. This new episodic memory would be engineered by means of purposeful implementation of a carefully-designed problem. Below, we discuss design and implementation features of such a problem that can be used to impact positively on students' beliefs, with a focus on the 4 learning goals. Our theoretical framework has 2 components, which emerged both from prior research and knowledge from our design experiment.

Component A: Problem design features

The problem should have a memorable name (feature A1) so that students can more easily store in and retrieve from their episodic memory their engagement with the problem. The remaining design features relate explicitly to the 4 learning goals.

To promote Goal 1, the problem should initially appear to be unsolvable to students and, of course, should be presented to the students in a way that leaves open the possibility that it can actually be unsolvable (feature A2). At the same time, however, the problem should be within students' capabilities (feature A3a): if the students persevere, they should be able to solve the problem within reasonable time

Working Group 8

by working in small groups and by receiving (perhaps) limited scaffolding from the instructor. If under these conditions students solve the problem, Goals 2 and 4 are also promoted: students are expected to see that their perseverance paid off (Goal 2) and feel satisfaction/accomplishment for solving an “unsolvable” problem (Goal 4). To further promote Goals 1, 2, and 4, the problem’s solution should involve achievement of multiple milestones (feature A3b). If it involved only one milestone, then, once a student in a small group had an insight into the solution, the other students would be deprived of opportunities to: (a) offer something substantial to the solution of a problem they originally perceived unsolvable (cf. Goal 1), (b) see their own perseverance as a contributive factor to the solution (cf. Goal 2), or (c) experience personal satisfaction from their engagement with the problem (cf. Goal 4). To promote Goal 3, the problem should include few clearly identifiable mathematical referents, which should offer by themselves insufficient data for the problem’s solution (feature A4). The fact that students will need to consider other kinds of referents can help expand their view about what counts as a legitimate referent.

Component B: Problem implementation features

The problem implementation should involve a set of conceptual awareness pillars (CAPs; Stylianides & Stylianides, 2009) that aim to help students become more aware of specific beliefs that are to be challenged or formed during students’ engagement with the problem (feature B1). CAPs is a “construct that ... describe[s] instructional activities that aim to direct students’ attention to their conceptions [understandings, beliefs, etc.] about a particular mathematical topic [such as problem solving]” (ibid, p. 322). CAPs at the beginning of the intervention can help students become more aware of their original beliefs, while CAPs at the end can help them reconsider these beliefs in relation to new beliefs provoked by the intervention.

The assumption underlying feature B1 is that the more aware students are of their existing beliefs, the more likely they will be to problematize and potentially change these beliefs when they engage in a problem-solving situation that challenges their existing beliefs and encourages the formation of alternative beliefs. This assumption finds support in the literature. For example, Nespor (1987) noted the following:

[Trying to change or shape teachers’ beliefs] would mean helping teachers and prospective teachers become reflexive and self-conscious of their beliefs and, as Fenstermacher [1979] suggests, presenting objective data on the adequacy or validity of these beliefs. However, this can result in transformations of teachers’ beliefs and practices only if alternative or new beliefs are available to replace the old. (p. 326)

The features we discussed in Component A, along with the experience of solving the problem, are expected to provide students with objective data that they can use to judge the validity of their original beliefs and begin to develop new ones. Feature B2 concerns the instructor’s critical role in the implementation of the problem (Stylianides & Stylianides, 2009). We view the instructor as the representative of the

mathematical community in the classroom and thus as the guarantor that the development of new knowledge will be consistent with conventional understandings (feature B2a). Also, the instructor organizes and facilitates social interactions among the classroom participants so that new knowledge in the classroom (including solutions to mathematical problems) is interactively constituted (feature B2b). Related to the latter aspect of the instructor's role is the implementation by the instructor of scaffolding strategies and CAPs.

METHOD

The findings we report in this paper were derived from the last research cycle of a 4-year *design experiment* (e.g., Cobb et al., 2003) we conducted in a semester-long mathematics course for prospective elementary teachers in the United States. The design experiment included 5 research cycles of implementation, analysis, and refinement of a set of instructional interventions that aimed to promote students' mathematical knowledge (including beliefs). The students pursued different majors and tended to have weak mathematical backgrounds. Our overarching objective was to develop effective instructional interventions to promote hard-to-achieve goals and also theoretical frameworks that would help explain how the interventions achieved their goals. Only one of the interventions explicitly aimed to promote the 4 goals we focus on here. This intervention was implemented toward the middle of the course.

The problem used in the intervention: a solution outline and design features

Below is the problem we used in the focal intervention, called the Blonde Hair Problem (BHP). This is a slightly modified version of a problem we found in Philippou and Chiristou (1995, p. 132). Next we outline a solution to the problem that our students develop by the end of their engagement with the problem.

The Blonde Hair Problem

- 1 After having many years to see each other, two friends who really loved math, Hypatia and
- 2 Pythagoras, meet again. They have the following conversation:
- 3
- 4 *Pythagoras:* Are you married? Do you have any children? How many? How old are they?
- 5 *Hypatia:* Yes, I am married! I have three children and the product of their ages is 36.
- 6 *Pythagoras:* (After doing some thinking.) I cannot figure out their ages. I don't have
- 7 enough clues.
- 8 *Hypatia:* Right! What if I told you that the sum of their ages is the same as the number
- 9 of your address?
- 10 *Pythagoras:* (After doing some thinking again.) I still can't figure out their ages. I need
- 11 another hint.
- 12 *Hypatia:* Well done! I also tell you that the oldest has blond hair.
- 13 *Pythagoras:* Aha! Now I can, without any doubt, figure out the ages of your children.
- 14
- 15 What are the ages of Hypatia's children? (their ages can only be natural numbers)

The first hint (line 5), together with the fact that the ages are natural numbers (line 15), reveals that there are 8 possibilities for the children's ages. With regard to the second hint (lines 8-9), although we are not told the number of Pythagoras' address, we can infer that Pythagoras knows this number since he is trying to see how this hint could be useful to him (line 10). Eventually, Pythagoras concludes that he is still unable to figure out the children's ages (lines 10-11). This suggests that there are at least 2 possibilities in which the sum of the ages is equal to the number of

Working Group 8

Pythagoras' address; the only two possibilities in which this happens are 1, 6, 6 and 2, 2, 9. In the final hint (line 12), the hair color is a distraction; the relevant information is that there *is* an oldest child. So the ages of Hypatia's children are 2, 2, and 9. (Given that the ages can only be natural numbers, for a child to be recognized as older than another child their ages should correspond to different natural numbers.) The BHP fulfills features A1-A4 of our theoretical framework. Regarding feature A1, it has a memorable name, which includes a color referent that is not only atypical for names of mathematical problems but also a distraction to the problem's solution. The BHP provides only 2 numbers (3 and 36), which are the only clearly identifiable mathematical referents in the problem and by themselves offer insufficient data for a solution (feature A4). Also, it includes some distractive information (e.g., the hair color) and some "mystifying" information, which however turn out to be crucial for its solution (e.g., that Hypatia had an oldest child). Thus, the problem may initially appear to be unsolvable (feature A2). Features A2 and A4 are further satisfied by the fact that the BHP cannot be solved by application of a formula and does not fit in any traditional domain (algebra, geometry, etc.). Regarding feature A3, the BHP can be solved using only basic concepts and systematic listing/elimination of cases, and so it can be accessible to students of varied backgrounds (feature A3a). Also, its solution involves 3 milestones, each corresponding to one of the hints (feature A3b).

Implementation plan for the problem in research cycle 5

The problem's implementation was done according to a highly refined lesson plan (outlined below) that we developed during our design experiment. The lesson plan derived from: critical comparison between different versions of the plan over the 5 cycles of the design experiment and the relative success of these versions in promoting Goals 1-4, relevant literature, and our emerging theoretical framework.

1. The instructor presents a PowerPoint slide entitled "Blonde Hair Problem" that includes the problem statement, without commenting on whether the problem is solvable or not. The students read the BHP and think about it individually. After a few minutes students are expected to start laughing or wonder whether the instructor is joking with them by presenting to them such a "weird" problem.
2. When the students do that, the instructor maintains a serious tone and asks the students to respond individually and in writing to the following prompts (CAPs).

CAP 1: Describe your initial reactions to the BHP.

CAP 2: Does this problem differ in any way from most of the other problems you encountered in mathematics classes before? If so, how?

The instructor is careful not to say anything that could influence students' responses to the CAPs (e.g., that the problem is solvable). CAPs 1 and 2 aim to help make students more aware of their original thoughts about the BHP, including their current beliefs about problem solving (cf. feature B1).

Working Group 8

3. The instructor collects the students' responses to CAPs 1 and 2. At this point, he assures the students that the BHP can be solved mathematically, encourages them to think carefully about the information that each hint may give them, and asks them to continue their work on the problem (first individually and then in their small groups). Telling the students at this point that the BHP is solvable is important because, otherwise, many students would give up on the problem. This instructional move is consistent with our view of the instructor as the representative of the mathematical community (cf. feature B2a) and the fact that students need some scaffolding (in this case encouragement/reassurance) in order to overcome their original conviction that the BHP is unsolvable (cf. feature B2b).
4. The small groups work on the BHP independently until all of them come up with a solution. It is important that all groups solve the BHP prior to a whole group discussion, because, otherwise, the groups that would not solve the problem would not benefit from the experience in regard to Goals 1, 2, and 4. The instructor provides necessary scaffolding only to those groups that really need it.
5. The whole class discussion focuses on the mathematics of the BHP, not on students' experience with solving the problem. One of the small groups is asked to present first its solution for the consideration of the rest of the class. Other groups present alternative solutions as appropriate. Based on our experience, most groups will come up with all 8 possibilities for the first hint, but few will list these possibilities in a systematic way to show that these are all the possibilities. The issue of systematic enumeration is brought up for discussion by the instructor.
6. The instructor provides some historical remarks on the 2 characters in the BHP and asks the students to respond individually and in writing to a new CAP.

CAP 3: Describe your experience with working on the BHP. CAP 3 is intended to help students reconsider their original reactions to the BHP in relation to their subsequent experience of working on and solving the problem.
7. The instructor collects the students' responses to CAP 3 and the class period ends (time elapsed: about 60 minutes). At the beginning of the next period, the instructor returns students' responses to CAPs 1-3 and poses a new CAP:

CAP 4: (A) Read your responses and compare what you wrote at the beginning of your work on the BHP [cf. CAPs 1 and 2] and at the end [cf. CAP 3]. (B) Share your observations with the other members of your small group.

Activity A aims to help the students reflect on the anticipated sharp contrast between their reactions to the BHP at the 2 different stages of the problem's implementation. In communicating these observations to the other members of their small group in Activity B, the students are expected to become more aware of possible changes in their beliefs, thereby making it more likely that students' engagement with the BHP will become an influential episodic memory for them.

Data and analytic method

The data come from the implementation of the focal intervention in research cycle 5, which was conducted in 2 sections of the course taught by the first author and attended by a total of 39 students. The implementation in each section lasted approximately 75 minutes. We used videos of the focal seminars and field notes of students' small-group work in order to create an account of how the BHP was implemented and examine whether it matched the lesson plan we outlined earlier. Also, we coded written data from all 39 students to assess their learning related to the 4 goals. Students' responses to CAPs 1-3 offered data for examining the short-term impact of the intervention. Their responses to a question in the last homework assignment of the course (2 months after the implementation of the BHP) offered data for examining its possible long-term impact. In that homework question, we asked the students to individually consider all the activities done in the course (more than 40 activities), identify 3 activities they felt contributed the most to their learning, and write a paragraph for each activity explaining what they found useful about it. A notable methodological consideration is the open phrasing of the questions. By not directly eliciting student comments related to the 4 goals in CAPs 1-3 and the homework question, we aimed to obtain valid data about the possible effectiveness of the intervention. We coded independently all responses, compared codes, and discussed disagreements until we reached consensus. We did not code students' responses to CAP 4, for these were based on their responses to CAPs 1-3.

Coding students' responses to CAPs 1-3

Regarding Goal 1, the relevant data came from the combined consideration of students' responses to CAPs 1 and 3. We coded students' responses to CAP 1 using 2 codes: (a) "the problem is unsolvable" and (b) "do not know how to solve the problem." Although it was possible for a student to produce a response that fitted neither code, all responses ended up receiving one of the 2 codes. A precondition for us to say there was evidence a student made progress in Goal 1 was that the student's response to CAP 1 received code a. No claim could be made for responses that received code b. For the subset of students whose responses received code a, we also examined their responses to CAP 3 to see whether there was evidence to suggest they got any insights related to Goal 1. Such evidence included comments that a problem they originally perceived to be unsolvable was actually within their capabilities. Regarding Goals 2 and 4, we examined students' responses to CAP 3. Depending on whether there was evidence for one or both goals, each response to CAP 3 could receive a code for one or both goals. Regarding Goal 3, the relevant data came from the combined consideration of students' responses to CAPs 2 and 3. Given that no student explicitly wrote in response to CAP 2 that the BHP was a legitimate or a solvable problem, students' responses to CAP 2 could not provide by themselves sufficient support for learning related to Goal 3. There needed to be also some evidence in their responses to CAP 3 to indicate an expansion in their conceptions of

the nature of referents a (legitimate) mathematical problem can have. A student's response to CAP 3 could potentially provide by itself sufficient evidence for Goal 3.

Coding students' responses to the homework question at the end of the course

We analyzed students' responses to the homework question at 2 levels. At the first level we identified all the students who included the BHP in their list of 3 activities and we examined whether there was evidence in their responses to suggest understanding related to each goal. A response could receive up to 4 codes (one corresponding to each of the 4 goals). At the second level we focused on the students we identified in the first level, and we examined whether a student's response to the last homework assignment got any of the same codes that the student got for his/her responses to CAPs 1-3. Repeated codes were considered as evidence for sustained (long-term) student learning related to the goals that corresponded to those codes.

RESULTS

The implementation of the intervention in the 2 sections of the course played out in almost identical ways, and was faithful to the lesson plan. So below we discuss together our findings based on data from all 39 students in the two sections.

Short-term impact of the intervention: Responses to CAPs 1-3

For each goal, students' responses to CAPs 1-3 offered evidence that more than 35% of them developed understanding related to that goal: 36% for each of Goals 3 and 4, 54% for Goal 1, and 77% for Goal 2. Regarding Goal 1, out of the 26 students who had originally deemed the BHP unsolvable (thereby setting 67% to be the maximum possible percentage for Goal 1), 21 of them ended up recognizing that a problem that appears to be unsolvable can actually be solvable and within their capabilities.

Long-term impact of the intervention: Responses to the last homework question

Given that the students could choose from more than 40 activities in the last homework question, we can say that the number of students who included the BHP in their list of 3 activities was a lower bound of the actual number of students who found the BHP important for their learning: for some students, the BHP could come, for example, 4th or 5th on their lists, but they could only list 3 activities (the data do not allow us to investigate this issue further). Also the fact that the question was asking students to identify and comment on the influence of individual activities rather than on collections of activities that had a specific effect on their learning helped address the issue of the possible contribution activities other than the BHP had on students' problem-solving beliefs. The lower bound we identified for the long-term impact of the intervention was markedly high: 13 students. The responses of 77% of these students offered evidence of understanding related to each of Goals 1 and 2. The corresponding percentages for Goals 3 and 4 were 54% and 46%.

Working Group 8

To explore sustained learning, we checked whether a student's response to the last homework assignment got any of the same codes the student got for his/her responses to CAPs 1-3. The percentages of repeated codes for each of Goals 1-4 were 88%, 82%, 57%, and 100%, respectively. Thus, we may say that the intervention had a rather long-lasting effect on students' learning. In their explanations about why they chose the BHP in their list of 3 activities, students articulated broader implications of their engagement with the BHP for their problem-solving beliefs, which is a positive outcome of the intervention. For example, Aleara (all names are pseudonyms) noted that her engagement with the BHP changed her "whole outlook on how to solve problems" and learnt that one does not "need specific numbers, or even variables, when solving a problem." ira said she used to get angry and give up when she was given a problem she did not think she could solve; she "either didn't do it or waited for someone else to solve it and copied their answer." Her experience of independently solving the BHP was fulfilling and helped challenge her prior way of thinking about problem solving. Finally, Evans noted that the BHP taught him the importance of perseverance.

DISCUSSION

The combined evidence for the short- and long-term impact of the intervention was more robust for Goals 1 and 2. The similar outcomes in relation to these 2 goals might be explained in terms of their possible relationship. Students who hasten to conclude that certain problems are "unsolvable" are likely to lack perseverance with working on such problems. The converse can also be true. Although the impact of the intervention in Goals 3 and 4 was not as powerful as in Goals 1 and 2, the positive results are encouraging given the short duration of the intervention and the difficulties encountered by research and practice in promoting Goals 3 and 4. A possible explanation for the lower impact in Goal 3 is that changes in students' beliefs about the legitimacy of different referents in a problem would require students to carefully examine the referents in the BHP. For methodological reasons, we avoided channeling students' activity to any particular direction (cf. the open phrasing of CAPs), and so we did not guide students to conduct such an examination. Regarding Goal 4, the lower impact of the intervention might be attributed to the challenges involved in getting university students who tend to have negative attitudes towards mathematics to explicitly say that problem solving can be enjoyable. The contribution of the paper is not limited, however, to showing that the focal intervention "does" or "can" promote the 4 learning goals. Consistent with the 2 primary intents of design experiments, our design experiment had, in addition to the pragmatic concern to promote the 4 goals, a theoretical concern to explain how the intervention supported the goals. Due to the lack of a randomized controlled experiment, we could not establish the specific contribution of each design and implementation feature in promoting each goal. However, we identified a "package" of design and implementation features whose collective function can yield the

desirable outcomes. The multiple research cycles of our design experiment enabled us to compare different versions of the intervention, thereby allowing us to identify weaknesses of the early versions of the package and generate possible explanations for what provoked these weaknesses that informed subsequent refinements. Regarding the issue of replicating the intervention in other settings, the following aspects of the intervention suggest its potential to be successfully incorporated into different educational programs at both the school and university levels: (a) it has a short duration and a stand-alone nature; (b) it involves ideas that are accessible to a wide range of student populations; (c) it targets beliefs that prevail in a wide range of student populations; and (d) its design and theoretical underpinning were not contingent upon special characteristics of the research participants in our study.

AUTHOR NOTE

The two authors contributed equally to the preparation of this paper. The research was supported by funds from the Spencer Foundation (Grant Numbers: 200700100, 200800104). The opinions expressed in the paper are those of the authors.

A REVERSAL THEORY PERSPECTIVE ON DISAFFECTION USING TWO EXAMPLES

Gareth Lewis

School of Education, University of Leicester

In this paper arguments are presented for a qualitative approach to researching affect in order to illuminate a richer, more complex and more dynamic motivational and emotional landscape in relation to children's experience of school mathematics. Reversal Theory is introduced as an approach to motivation and emotion which can provide a richer description of the phenomena than has been done hitherto. Data from the literature is re-analysed using Reversal Theory as a lens to provide insights. Conclusions are drawn about the implications for future research.

Keywords: Disaffection; Motivation; Attitude to School Mathematics; Reversal Theory

INTRODUCTION

Disaffection

Disaffection with school mathematics education is a major problem. It is not just an educational problem, but an individual tragedy as well as having social and economic consequences. In the last 30 years there has been a great deal of research on attitudes to mathematics, much of it documenting and quantifying the worryingly high level of negative attitudes to mathematics amongst young people (Underwood, 2009).

A recent report into mathematics education by the Royal Society notes the widespread nature of current concern, 'no decade since the 1970's has seen so much being written about the disaffection young people appear to have for science and mathematics' (The Royal Society, 2008, p.171). The report points out that there has not been enough quality research into this area, and cites only three studies in relation to mathematics.

Affect and Attitude

In order to understand disaffect, it is important to understand affect. However, this is not easy to accomplish as the field is fragmented and confusing (Hannula, 2006; Zan & Di Martino, 2007). Theorisation of affect has been strongly influenced by the framework suggested by McLeod (1987), and this has informed the CERME working model of affect (Hannula et al., 2010). However, research to date on affect has been dominated by attention to attitude. Although the study of attitude has helped to identify and document disaffection with school mathematics, and has provided useful comparative data across countries, gender and social class, it has not provided explanatory evidence for achievement (Furnham, 2009; Ma & Kishor,

1997). Thus there is strong evidence of a consensus that real insight and explanation will only come with a widening of the study of affect.

Schorr and Goldin (2008) argue :

‘We share with other researchers the need to study affect more deeply than the study of attitude permits....But it is increasingly clear that the functioning of affect is far more complex than is suggested by considerations of positive versus negative emotions and attitudes.’(p.132)

WIDENING THE STUDY OF AFFECT : MOTIVATION AND EMOTION

To investigate disaffection more fully, I propose that a focus on motivation and emotion, and a widening of the methodologies used will provide a deeper, richer and more dynamic picture of the landscape, and thus create new insights. More recently, there have been studies giving a more fine-grained picture of motivation and affect in educational settings (Op't Eynde, De Corte, & Verschaffel, 2006; Zan & Di Martino, 2007).

It has been argued that classroom contexts, pedagogy and teacher attitude and behaviour are critical to engaging the motivation of students (Boaler, 2010; Pintrich, 2003; Zembylas, 2005). But there is a need to understand more fully the motivational factors that influence how students engage or disengage in mathematics. One such study was conducted by Nardi & Steward (2003). They used the acronym TIRED to describe the factors identified.²⁷ Yet underneath these broad factors there are motivational mechanisms and needs involved that need further investigation.

Much of the literature on motivation has focused on achievement goals, but it has been argued that a broader research focus is required to capture the richness of motivational impact (Weiner, 1990). To do this, it is necessary to delve more deeply into aspects of motivation and emotion to find exactly what is going wrong for disaffected individuals. Vygotsky (1986) argued that cognition and affect are indivisible, and that emotion, motivation, attitude and beliefs all interrelate in a seamless web. He advocates a more holistic approach, as does Zembylas (2005), arguing that we can understand the inter-relatedness of motivation, emotion, values, goals and beliefs (in addition to cognition) - what Vygotsky called the ‘fullness of life’ – via the use of ethnographic methodologies which he believes create space for the voices of those studied.

Aside from achievement goals, there are other formulations of motivational needs. One such influential formulation is that the basic needs are for competence, autonomy and relatedness (Deci & Ryan, 1985). However, as research has begun to develop a more detailed, qualitative picture of motivation and emotion, a good deal of complexity has been encountered. At the same time, a range of motivational

²⁷ TIRED stands for : Tedium; Isolation; Rote learning; Elitist; Depersonalisa

factors and motivational and emotional phenomena that do not fit neatly into current theorisations have emerged, as the following makes clear.

Evidence of Motivations :

Schorr and Goldin (2008) point out that the complexity of affect in the social contexts of mathematics classrooms is exceptionally difficult to characterise for the purposes of research. The variety of emotions they report was substantial, including: curiosity, anticipation, frustration, anger, fear, excitement, pride, pleasure, elation, satisfaction. They note a number of important aspects of the motivational climate that encourages students to engage with the mathematics. These include an emotionally safe environment; the central importance of social interactions; relationships based on dignity and respect. Important as these are, it is not clear how they relate to motivational needs.

Swain (2005) studied the complex and multiple motivations of adult underachievers adopting mathematics education later in life, and found that ‘to help my children; to prove that I can do it; for understanding, engagement, enjoyment’ were more frequent and important motivators than utility. Swain also reports evidence of the excitement and pleasure of these adults in being able to do mathematics, “*It’s exciting.*” “*I enjoy doing it...*” “*It gives you a buzz....it’s exciting.*” Again we come across evidence that mathematics can be a source of pleasure and satisfaction for its own sake. Such evidence is also reported in Buxton (1981, p.132).

Theorising about emotions in the literature has been dominated by attention to anxiety or a limited set of negative emotions, and yet a whole range of other emotions has been reported, as referenced above. It has proved difficult to provide any theoretical or explanatory framework for many of these emotions, and they are rarely related to other aspects of motivation or affect. For instance, how does anger occur? How does excitement relate to motivation? These are important questions that need to be explored in a research setting. The CERME working group has set the agenda:

‘One apparent main focus for research and practice in this domain has been to develop richer theoretical frameworks using aspects and develop better concepts and instruments, preferably combining qualitative and quantitative methods. The frameworks should recognise the close relation between beliefs, motivation and competence.’ (Hannula et al., 2010, p.32)

One such framework that addresses these challenges is Reversal Theory. In the rest of this paper I set out some key aspects of the theory, and an analysis of data sources from the literature that evidence the application of the theory in the context of mathematics education.

REVERSAL THEORY

Reversal Theory was developed over 30 years ago as a way of trying to explain and illuminate problematic behaviour of young people. This led to a focus on the subjective experience and the meanings ascribed by children to their own behaviour. The foundation of the theory is the structure of the motivational landscape, and its constituent eight motivational states. Time and space will not allow a detailed exposition of the theory, but a full description can be found in the literature, and is perhaps summarised best in Apter (2001). A motivational state is defined as a distinctive orientation to the world based on a fundamental psychological value. Methodologically, Reversal Theory is a structural phenomenological approach, in that it begins with subjective experience, but seeks to find structure in the complexity of that experience. Our experience is ordered into four fundamental domains:

- means-ends, about directionality or purpose;
- rules, including expectations, conventions, norms, customs, and the constraints put on us by social contexts of various sorts;
- transactions, which is those people or things we interact with; and
- orientation, which is a focus on self or identification with external entities – ‘the other’.

One of the key insights of Reversal Theory is that we can experience each of these four domains in two, entirely opposite ways. So, for instance, with the means-ends domain, we can experience it as focusing on the goal or outcome, or we can experience it as focusing on the journey rather than the destination. The former is defined as the telic motivational state (or *serious* in everyday language). The latter is defined as the paratelic or *playful* state. In the case of the former, we are interested in goals or outcomes, and progress towards them. The latter involves doing things for their own sake – in effect, for the pleasure and excitement for its own sake.

This aspect of our motivational make-up has strong resonance in many aspects of human experience, but it is not well represented in current theorisations of motivation. Specifically in the educational context, there is significant evidence that fun and excitement (both associated with the paratelic state) are important. The evidence from (Buxton, 1981; Swain, 2005) and others, above confirms this. One of the advantages of Reversal Theory as a framework for studying motivation in an educational context is that it does account for phenomena that are evidenced in research, but which resist classification in terms of current theorising. Examples include :

- the notion that high arousal can be experienced in a pleasant way (as excitement or thrill). This runs counter to the notion, often adopted in mathematics education research, that high arousal is always experienced negatively (as fear or anxiety).

Working Group 8

- That motivationally, goals do not always drive our experience and behaviour.
- Reversal Theory proposes motivational needs that are poorly explained or absent from current motivational research in education. These include: rebelliousness and anger; altruism – the need to help others. It will be instructive to see if there is evidence of these in mathematics education contexts, and to widen the theoretical base to include them.
- The theory gives an account of primary emotions and their relationship to motivational states.

What Reversal Theory states is that one will always (at any one moment) experience the world as either serious (telic) or as playful (paratelic), but never both at the same time. What is very different about this treatment of motivational states (as opposed, for instance to trait descriptions), is that we frequently reverse between states.

The other domains and states describe aspects of our motivational experience. The domain of rules can be experienced as conformity or negativism. The domain of transactions can be experienced as mastery or sympathy, and relationships can be experienced as self-oriented (autic) or other-oriented (alloic). When we are in a state, it colours every aspect of our felt experience – from what we are paying attention to, to what we value, to how we view events, and the emotions we experience. More specifically, each motivational state has associated a value, a feeling, a way of experiencing, and associated emotions. People move between states (and combinations of states) frequently. And since these states are opposites, not only are we bi-stable, but we are multi-stable. That is, we can literally, be different people at different times. In this way, Reversal Theory captures the dynamic and changeable (and even contradictory) aspects of our personality, emotions and motivation.

In summary, we can see that our motivation shifts around (by reversals and by changes of focus) in a dynamic flow. There is strong evidence to show that motivational efficacy and psychological health requires that we have available and experience all eight states in the daily course of our lives, and psychological dysfunction caused by inability to do this is well documented (Apter, 2001). It is very interesting to speculate how, and to what degree these eight states are available to students (or not) in typical mathematics lessons.

REVERSAL THEORY IN MATHEMATICS EDUCATION: TWO EXAMPLES

Reversal Theory has been applied successfully as an explanatory framework in many areas of human experience, such as child guidance, psychotherapy, drug addiction, anti-social behaviour, smoking cessation, sporting performance (Apter, 2001). In educational terms it has been used much less. In the UK the Learning and Skills Council evaluated a psychometric instrument based on the theory very positively, and stated: ‘There is an impressive amount of empirical evidence which supports

Working Group 8

Reversal Theory ...which has major implications for how we think about learning styles.’ (Coffield, Moseley, Hall, & Ecclestone, 2004, p.54)

The first step in my own research has been to identify data and evidence for the constructs set out In Reversal Theory. Two examples will be briefly described here.

Reversal Theory perspective on the case of Frank

The case study of Frank (Op't Eynde & Hannula, 2006) was addressed by the contributors to the issue of Educational Studies in Mathematics, devoted to affect. An alternative analysis is presented here.

Perhaps the most interesting data about Frank is the map of his dynamically changing emotions. Using the ideas from Reversal Theory we can use the sequence of his emotions to infer the motivational states. Frank is reported as being a little nervous about the task, and this suggests that he is in the serious state. In fact, in subtask 1 we see that he is worried, which suggests serious/high arousal. This is likely to be caused by the problems he encountered in his progress. However, he then finds a solution, arousal decreases, and he becomes relieved. Reversal theory predicts that in the serious state the emotion will move from anxiety to relaxation/relief as arousal lowers (as the solution is found).

In subtask 2 he again encounters a problem and gets stuck. This time he panics. I interpret this to be a stronger form of anxiety, due presumably to his perception of the depth of his ‘stuckness’. That is, he can’t see a way to progress. The panic causes him to reach for the calculator, which is seen as a strategy to make progress. It is possible that the panic is amplified by the fact that using the calculator brings him into conflict with other aspects of his motivational system (e.g. possibly a mastery-based self belief that if you are clever, you don’t need it). Without the data, we can only speculate. However, he does invoke a sound learned strategy for dealing with problems (and unpleasant high arousal) in mathematics contexts – stop and think. This seems to work, as he says ‘I know again what I have to do’. The emotions map shows that at some stage the panic changes to frustration/anger. This indicates that a reversal has taken place. His inability to make progress in the serious-conforming state has triggered a reversal from conformist to rebellious state, and the anxiety has now changed to anger. He now seeks to move outside of his own norms – to break the rules (whatever they are perceived to be). Is this where he impulsively reaches for the calculator?

When he finally reaches the end the emotion reported is pride. This suggests a shift of focus from the serious (which appears to have been the operative state so far) to that of self-mastery with the felt transactional outcome being experienced as winning. This analysis enables us to evidence the dynamic flow through motivational states within the problem-solving process, and more specifically we are able to relate states to the associated emotions. We can see also evidence of reversals, and change of focus of motivational state.

Quiet disaffection revisited

The qualitative research by Nardi and Steward (2003) is one of the most influential analyses of disaffection with school mathematics. Below is a summary of the analysis of one of the interviews conducted with two 14- year old girls. Clearly, the interviews were not conducted with the intention of examining the complete motivational and emotional landscape for each participating individual. Nonetheless, it is possible to determine, even from this short extract, some key aspects of individual motivational factors. I identified in the interview transcript any motivationally or emotionally significant statements or segments. There were approximately thirty such statements. For each one the implied motivational inferences were tabulated.

Examples include :

“I don’t like being shouted at”	“I need things explaining”
“I like it when it’s fun”	“I remember it better when it’s fun”
“I need to know why it’s important	“I need to know the rules”
“Not knowing the answer makes... ..me feel stupid”	“I enjoy it more when I understand it”
“Maths makes me panic. (then)... ..I don’t know what to do”	“I need to do it my own way”
“Talking to friends helps me to understand”	

If I use Reversal Theory as a framework or as a lens to refract the data through, I encounter these points:

(Self)Mastery. The need to understand is a very strong focus for the interviewees. There are many statements here reflecting that. Having something explained to us is an important component of being able to understand. When I understand it I can do it, and when I can do it I enjoy it more. Not understanding can leave us feeling powerless (*‘oh my god I can’t do it’*), or humiliated. There are a numerous comments about feeling stupid. There is also evidence here of the issue of agency. For student J, there is clearly a power tussle in which she obviously needs to assert her own way of doing things.

Seriousness. Many of the comments here are about the lack of a sense of purpose. They demonstrate that both girls need to know why they are doing this. Comments like *‘what’s the point in it?’* and *‘I don’t see what it would help us with’* can be viewed as cries for a sense of purpose and direction.

Playfulness. Playfulness is not about play in the everyday sense of the word, but about enjoyment in the moment. It is related to fun, but also to excitement, intrigue, curiosity. It is arousal-seeking, and so is also often associated with risk-taking.

Working Group 8

However, when arousal is low, playfulness will be experienced as boredom or sullenness, and there is good evidence of that here. It is interesting to note that ‘fun’ is mentioned a number of times by both girls. They make the association with being more interested, paying more attention and remembering better. Activities that were ‘different’ (i.e. not following the book) sparked playfulness, as did practical activities like looking through catalogues.

Conformity and rebelliousness. Conformity is about fitting in – complying with the norms, expectations and rules of the socio-cultural environment. There are quite specific and distinct rules and expectations that operate in mathematics classrooms (even though they may not be explicitly codified), and students will want to know what they are. Comments like *“I don’t get most of maths. It’s really weird.”* *“I do everything differently to Mrs R because I don’t understand how most of the time”*, give away the discomfort caused by the students not understanding the ‘rules of the game’. And even when they do, it is sometimes not sufficient to create mastery (*“you remember how to write it out but not how to do it.”*) This is particularly interesting, because there is often a received notion that all pupils need to do in school mathematics is to follow the rules and the correct answer will follow. This evidence shows that even disaffected students (or maybe especially disaffected students) know that this is not the case. In contradiction to this, all healthy individuals will also spend time in the rebellious state, and will need to express this in some way. This is rarely legitimised in a school setting, and perhaps in mathematics classrooms least of all. Unfortunately, this is an opportunity lost, as constructive cognitive and behavioural rebelliousness can be extremely creative, and is a requirement for mathematicians at a higher level.

In these sequences, we do see evidence of rebelliousness operating. For student C, boredom or sullenness creates the need to raise arousal levels, and when associated with the rebellious state, involves doing something ‘naughty’ (*“winding up my little brother”*) to raise arousal. Playfulness + rebelliousness + low arousal can cause problems when expressed in a classroom (as every teacher knows!). What is interesting is that C knowingly chooses to express this outside of the classroom, which demonstrates an element of mature self-regulatory behaviour. An element of rebelliousness is also expressed later by C in her rejection of the teacher’s way of doing things, and her assertion of her need to do it her own way.

Sympathy and other. There is some evidence here of the importance of relationships, and the need for affinity. Many comments refer to the need to have friends around. But friends also play a quite specific role in terms of being able to discuss, and the need to ask questions and receive explanations.

There is also evidence of interesting motivational sequences reported here. One is: ‘Maths makes me panic. When I panic I don’t know what to do. When I don’t know what to do I feel stupid.’ Motivation here shifts from serious to self-mastery (losing). Another sequence goes: ‘I need to understand. When I understand, I can do it. When

Working Group 8

I can do it, I enjoy it more.’ The sequence moves from self-mastery (winning) to paratelic enjoyment. It will be interesting to find evidence of other such sequences in further research.

So we can see from this interview evidence of all states being operative in the mathematical experience of these two girls. Of course, because we are in a state, does not mean we experience it positively or gain the satisfaction from the state, and that is often the case here.

CONCLUSION

Recognising the agenda of the CERME working group on affect, ideas have been presented from a wider point of view than the study of attitude and beliefs, and I have presented a theoretical framework that offers one answer to the call for a more holistic approach that relates motivation to emotion and other aspects of affect.

Reversal Theory has significant potential to provide an explanatory framework for mapping the motivational and emotional landscape of students in mathematics classrooms, and to provide a coherent basis for integrating theory about different aspects and constructs in the affective field.

The next stage of my research is to apply a multi-method approach to investigating how these phenomena manifest in the experience of young people in mathematics classrooms.

STUDENTS' DISPOSITIONS TO STUDY FURTHER MATHEMATICS IN HIGHER EDUCATION: THE EFFECT OF STUDENTS' MATHEMATICS SELF-EFFICACY

Irene Kleanthous and Julian Williams

University of Manchester

The present study aims to investigate what factors affect students' dispositions to study further mathematics in Higher Education (HE) and the role of students' maths self-efficacy in particular. A questionnaire was designed for the purposes of this study and was distributed to 563 adolescent students in Cyprus. The validity of the scales designed to measure students' dispositions and maths self-efficacy was investigated using the Rasch model. It was found that students' maths self-efficacy had a statistically significant effect on students' dispositions to study further mathematics but when students' mathematics course was included in the model maths self-efficacy was not statistically significant anymore. Possible reasons for the non-significant effects are discussed drawing on some qualitative data from this study.

Keywords: dispositions, further mathematics, HE studies, mathematics self-efficacy

LITERATURE REVIEW

The problem of students dropping out of mathematics, especially advanced mathematics has become one of the major contemporary concerns of educators, parents and politicians (Ma, 2001). Students' dispositions towards mathematics influence their decisions to choose advanced mathematics at school and to pursue further studies in mathematically demanding courses in Higher Education (HE). A considerable number of studies have investigated the role of students' mathematics self-efficacy in students' decision making for choosing a major course (e.g. Betz & Hackett, 1983; Hackett & Betz, 1989; Pajares & Miller, 1994). Most of these studies support Hackett's argument (1985) which highlights the critical role self-efficacy beliefs play in the academic and career choices of students.

The importance of considering students' self-efficacy beliefs, in addition to test scores is stressed in recent research findings, mainly because of its positive effect on students' academic choices (e.g. Pajares & Miller, 1997; Chen & Zimmerman, 2007). Chen and Zimmerman (2007) argue that perceived academic self-efficacy positively influences students' academic choices, academic performance, effort and persistence as well as choices in careers related to mathematics and science. Nevertheless, the relationship between self-efficacy and outcome expectations is not always consistent. According to Usher and Pajares (2009) "a student reasonably confident in her mathematics capabilities may choose not to take an advanced statistics course" (p.89).

Working Group 8

Bandura (1986) initially defined the notion of self-efficacy as "people's judgments of their capabilities to organize and execute courses of action required to attain designated types of performances" (p.391). With regards to mathematics, Hackett and Betz (1989) defined mathematics self-efficacy as "a situational or problem-specific assessment of an individual's confidence in her or his ability to successfully perform or accomplish a particular [mathematics] task or problem" (p. 262). Mathematics self-efficacy has been assessed broadly in terms of individuals' judgments of their capabilities to solve specific mathematics problems, perform math-related tasks, and succeed in math-related courses (Betz & Hackett, 1983).

Bandura (1986) cautioned that, because judgments of self-efficacy are task and domain-specific, "ill-defined global measures of perceived self-efficacy or defective assessments of performance will yield discordances" (p. 397). As Pajares and Miller (1995) point out measures of self-efficacy should be specifically tailored to the criterial task being assessed. They argue that mismatch between self-efficacy and criterial task assessment is a recurring theme in educational research, often producing confounded relationships and ambiguous findings.

Pajares and Miller (1995) also remarked that the confidence assessment should consist of students' judgments of their confidence to solve specific problems rather than of global confidence statements infused with personal judgments of self-worth. In addition, they argued that such global statements decontextualise efficacy beliefs and transform the construct of self-efficacy into a generalized personality trait rather than the context-specific judgment Bandura (1997) suggested it should be.

In a recent study in England, called "*Keeping open the door to mathematically demanding courses in Further and Higher Education*", Wake and Pampaka (2007) reported the use of contextualised questions with mathematics problems to measure students' mathematics self-efficacy and to investigate its effect on students' dispositions to study further mathematics. They argue that students' mathematics self-efficacy is a multidimensional construct which could be measured separately for applied and pure mathematics. Furthermore, Pampaka, Kleanthous, Hutcheson and Wake (in press) found a positive effect of students' mathematics self-efficacy on students' dispositions to study further mathematics in HE, and they noted the effect of gender and mathematical attainment on students' mathematics self-efficacy.

The present study aims to investigate the effect of students' mathematics self-efficacy on their dispositions to study further mathematics in HE in a different cultural context, namely Cyprus. We build on previous research by Williams et al. (2008) for the ESRC-TLRP project "*Keeping open the door to mathematically demanding courses in Further and Higher Education*" which investigated students' dispositions to study mathematically demanding courses in HE and the effects of different socio-cultural backgrounds. We hypothesise that students' mathematics self-efficacy will have a positive effect on students' dispositions to study further mathematics as the literature in different educational contexts suggests.

METHODOLOGY

For the purposes of this study a questionnaire was designed and distributed to 563 students aged 16-17 years old, attending four different upper secondary schools (lyceums) in Cyprus (boys N=266, girls N=297). Additional semi-structured interviews were conducted with a subset of 22 students, who were selected according to the year group and mathematics course they were attending. We drew on previously validated instruments from the ESRC-TLRP project for designing the questionnaire used in this study. We used the same scale designed for the ESRC-TLRP project, to measure students' dispositions to study further mathematics in HE (DISP.MATHS). The DISP.MATHS scale consists of 5 items aiming to capture information on students' dispositions to studying mathematically demanding subjects in the future in HE. This scale was translated into Greek and revalidated using the Rasch model. Cronbach α for this scale is $\alpha=0.93$. An indicative item of the DISP.MATHS scale is the following:

My preferred options for any future study will include:

- a lot of mathematics
- quite a lot of mathematics
- a moderate amount of mathematics
- as little mathematics as possible
- no mathematics
- Don't know

In order to measure students' mathematics self-efficacy we used some items from the mathematics self-efficacy (MSE) scale designed for the ESRC-TLRP project, which consists of contextualised questions with mathematics problems (Wake & Pampaka, 2007). Additional items were designed according to the mathematics curriculum for each year group. These were again contextualised questions with mathematics problems drawn from the national textbooks of mathematics for lyceum. The items for the MSE scale were presented by the question: "*How confident are you in your ability to solve each maths problem?*". Students were asked to rate their confidence in solving sixteen mathematics problems ranging from 1= Not confident at all to 4= Very confident, without actually solving the problems.

A total of thirty-one items were developed with twenty items drawn from the national mathematics textbook for lyceum and a further eight items drawn from the MSE scale used in the ESRC-TLRP project. Three additional items were included in the scale in "pure" mathematics areas because most MSE items drawn from the ESRC-TLRP project dealt with modeling and applying mathematics (Wake & Pampaka, 2007). The thirty one self-efficacy items (sixteen on each questionnaire) were organised into four different versions of the questionnaire, which were

Working Group 8

appropriately adjusted according to the year group and mathematics course the students were attending (Advanced or Core mathematics). Cronbach α for the MSE scale was $\alpha = 0.91$. Examples of a ‘pure’ and an ‘applied’ MSE item are given in Figure 1.

Figure 1: An ‘applied’ (bottom) and a ‘pure’ (top) item from the MSE scale

In summary, therefore, our MSE instrument meets Pajares and Miller’s (1995) urge for specificity in assessment when measuring students’ mathematics self-efficacy, due to its contextualised questions for eliciting students’ self-efficacy in solving specific mathematics problems.

FINDINGS

The validity of the scales was investigated separately using Rasch analysis. According to Bond and Fox (2007) Rasch analysis provides indicators of how well each item fits with the underlying construct. Model fit statistics and item analysis was carried out for each scale using Winsteps, a software application for carrying out Rasch analysis (Bond & Fox, 2007). Tests of fit showed acceptable fit suggesting that our instruments could be used to measure the desired constructs, since there were no statistically significant misfitting items in any of the scales.

Once the Rasch analysis was conducted to check scalability, a step-wise model selection procedure was adopted to build generalized linear models (GLM) in the statistical software ‘R’. Students’ mathematics self-efficacy (MSE) was used as an explanatory variable to model students’ dispositions to study further mathematics (DISP.MATHS). Other variables used in these models were background variables

Working Group 8

such as gender, socio-economic status (SES) measured in terms of their parents' occupation, and students' mathematics course (Advanced or Core mathematics).

The model in table 1 shows the effect of MSE on students' dispositions to study further mathematics in HE (DISP.MATHS). Clearly the F-value ($F=9.886$, $p=0.00$) shows the model below is statistically significant although it can only explain 6% of the variance of DISP.MATHS ($R^2= 0.061$). In this model MSE and gender were statistically significant for predicting students' dispositions to study further mathematics but students' SES was not.

$$\text{DISP.MATHS} \sim \text{MSE} + \text{SES} + \text{GENDER}$$

Coefficients				
	Estimate	Std. Error	t-value	p-value
(Intercept)	-0.76231	0.26335	-2.895	0.00395 **
MSE	0.30183	0.05924	5.095	4.82e-07 ***
SES[T.low]	-0.42433	0.27809	-1.526	0.12762
SES[T.medium]	-0.25212	0.26469	-0.952	0.34127
Gender[T.Male]	0.49288	0.16640	2.962	0.00319 **

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Table 1: Generalised linear model (GLM1) for predicting DISP.MATHS.

In table 2 a second generalised linear model (GLM2) is presented with mathematics course (MATHS.COURSE) included in the model as an explanatory variable. When MATHS.COURSE was introduced in the model MSE and GENDER were no longer statistically significant. In the model below the F-value ($F=54.5$, $p=0.00$) shows the model is statistically significant and it explains 33% of the variance of DISP.MATHS ($R^2=0.3284$).

Surprisingly, when mathematics course was introduced in the model MSE was no longer statistically significant. In all the models built, students' mathematics course (MATHS.COURSE) was a statistically significant predictor for DISP.MATHS which might explain why the relationship between MSE and DISP.MATHS is not statistically significant. Apparently, students who are more self-efficacious in mathematics tend to choose Advanced mathematics at school so the effect of MSE is 'hidden' in students' choice of mathematics course.

Table 2: Generalised linear model (GLM2) for predicting DISP.MATHS.

Further analysis showed that students who attend Core mathematics have lower mathematics self-efficacy (MSE) and are negatively disposed towards studying further mathematics in HE (DISP.MATHS). On the contrary, students who attend Advanced mathematics are more self-efficacious in mathematics and are positively disposed to studying mathematically demanding courses in HE. These differences are illustrated by the boxplots in figure 2.

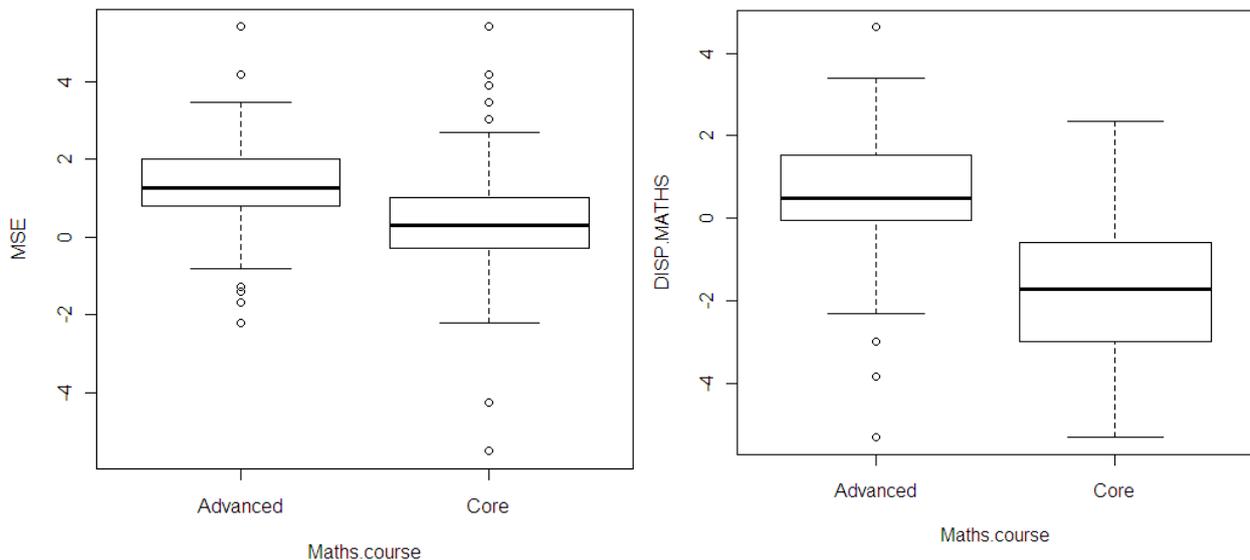

Figure 2. Students' mathematics self-efficacy and dispositions by mathematics course

Insights from the qualitative data of the study

In order to interpret the non-significant effect of students' mathematics self-efficacy on their dispositions to study further mathematics in HE, we draw on the qualitative data of this study. We chose to present here two case studies of students who were interviewed twice over a period of one year, because these two students were considered to be representative cases of students with high and low mathematics self-efficacy. They are both taking Advanced mathematics at school: a male student (Charalambos) and a female student (Chryso). They both aspire to study mathematically demanding courses in HE; Charalambos aspires to study Civil Engineering and Chryso wishes to study Computer Science. Although they are both attending Advanced mathematics at school their self-efficacy in mathematics differs tremendously.

When Charalambos was asked where he will rank mathematics in terms of difficulty comparing to his other subjects he seemed quite self-efficacious about mathematics:

Interviewer: Where will you rank mathematics?

Charalambos: For me? For me it's the easiest.

Similarly, when he was asked about the contextualised questions with mathematics problems for the MSE scale he responded quite confidently:

Interviewer: Is there something you saw on the questionnaire that you would like to comment on?

Charalambos: I think it is important if we can think about general exercises, like say there were some exercises which weren't part of the school curriculum but we can solve them. This is important because based on our knowledge regardless if we had never seen them before we could, if we thought about them, solve them.

On the contrary, Chryso seems less confident about mathematics and she uses the word 'phobia' when she refers to mathematics:

Interviewer: I wanted to ask you about your relationship with mathematics in general, what do you think about maths? If you want to you can go back to primary school or gymnasium. What experiences have you had with mathematics?

Chryso: In previous years, in primary school I was very good. But then when I went to gymnasium, I don't know I had a phobia, I didn't do so well. At gymnasium I had B but sometimes I had C. So it was a bit harder for me. I didn't like it much either but ok now I think it is useful and it's worth the effort to try.

The reason for this 'phobia' were not her mathematics teachers she argues, but her low self-efficacy in mathematics made her feel stressed and worried about mathematics.

Working Group 8

Interviewer: What was the reason maths gave you a hard time at gymnasium? Do you think it had something to do with your teachers or with the curriculum that is being taught?

Chryso: No the teachers, all right they played a role but ok sometimes... They were good, the teachers I had, but I don't know, I was a bit stressed and scared.

Interviewer: Only in mathematics or in other subjects as well?

Chryso: Yeah basically mathematics because I didn't like it much and I don't know sometimes I was afraid I won't do well and things like that.

During their interview both students seem to have chosen Advanced mathematics to enable them to study mathematically demanding courses in HE. Chryso explains:

Interviewer: You said you have chosen advanced mathematics although you are afraid of maths?

Chryso: Yeah.

Interviewer: What led you to this decision?

Chryso: Because I liked computer science and I wanted to pursue it, I knew it required [of you] to know maths and physics, you needed them. OK I can't say I didn't like mathematics at all, I liked it but not as much as some other subjects.

Students were also aware that they would have to face challenging mathematics during their studies. Charalambos seems to be quite confident about the mathematics he will have to do at university:

Interviewer: Do you think that Civil Engineering will have lots of maths for the degree?

Charalambos: Yes.

Interviewer: Are you prepared for that? To face lots of mathematics during your studies?

Charalambos: Ok (laughs). I feel I can do it, but I don't know what I have to face exactly. I saw more or less what subjects are being taught. Maths and Physics but I don't know exactly.

On the other hand, Chryso's low mathematics self-efficacy almost made her change her mind about which studies to follow in HE. This indicates the effect students' mathematics self-efficacy can have on their decision making for future studies in HE.

Chryso: Last year when we were about to make our choices I was thinking not to choose computer science because the other subjects would be difficult for me despite the fact that I was good at computer science. I was thinking that maybe the other subjects will be difficult for me physics, mathematics...

DISCUSSION AND CONCLUSION

In this study we sought to explore students' dispositions to study further mathematics in Higher Education and the effect of students' mathematics self-efficacy. Our

Working Group 8

statistical analysis showed that students' mathematics self-efficacy is statistically significant for predicting students' dispositions to study further mathematics, which aligns with previous research findings (Betz & Hackett, 1983; Hackett & Betz, 1989; Pajares & Miller, 1994). Nevertheless, when students' mathematics course was introduced in the model students' mathematics self-efficacy was no longer statistically significant. This is probably because the mathematics course 'masks' the effect of MSE; more self-efficacious students in mathematics tend to choose Advanced mathematics at school.

Moreover, we argue that students' mathematics self-efficacy is an important factor influencing some students' decision making for future studies in HE and we have illustrated this with some qualitative data from this study. We also found that students' mathematics self-efficacy varies across the spectrum of confidence in mathematics to math-phobia.

A possible explanation for the non-statistically significant effect of students' mathematics self-efficacy on their dispositions to study further mathematics could be students' inaccurate ratings of their self-efficacy in mathematics. This aligns with Chen and Zimmerman (2007) who argue that students are generally not well calibrated or accurate in prejudging their capabilities to solve mathematical problems. Chen and Zimmerman (2007) also argue that researchers should examine the difficulty of the tasks that elicit students' judgments. Although our instrument was validated using Rasch analysis students might still have overestimated or underestimated their self-efficacy in mathematics.

Another plausible explanation why students' mathematics self-efficacy was not statistically significant in some models could be the multicollinearity between the explanatory variables of the model. This serves as a warning to studies that adopt correlational designs in this complex, multi-collinear field. It should be noted that previous research in the area of mathematics self-efficacy is mostly quantitative in nature. Apparently, students' mathematics self-efficacy needs to be further investigated by integrating quantitative and qualitative research methods.

AN EXAMINATION OF THE CONNECTIONS BETWEEN SELF DISCREPANCIES' AND EFFORT, ENJOYMENT AND GRADES IN MATHEMATICS

Laura Tuohilampi

Helsinki University

Research studies show that there is a connection between individuals' behavior and the discrepancies between their perceived, self-related skills and ideals: for example, high expectancies without success may lead to mathematics anxiety. In this study a hypothesis of a quadratic connection between self-discrepancies and desired learning action is formulated: an ideal level of discrepancy will associate with desirable action, whereas too large or too small a discrepancy will associate with undesirable action. The connections between examined variables were found to be non-linear, statistically significant associations; some evidence in support of the hypothesis was found.

Keywords: self discrepancy, effort, enjoyment of mathematics, self concept, self beliefs.

INTRODUCTION

Research in mathematics-related attitudes has put emphasis on studying linear relationships between different dimensions of affect and achievement. In this article, some theoretical elaboration and empirical results about a more complex model will be presented. This examination is a continuation of the investigation by Tuohilampi (2011), in which the threats and possibilities of internal discrepancies in one's self-concept were presented.

self-concept

Self-concept seems to be a compendious and essential, but intricate, construct. It has been divided into *the material self*, *the social self*, *the spiritual self* and *the pure Ego* by James (1890). Later on, it is said to contain certain essential ingredients: self-related beliefs, which may or may not be valid (self image), the emotional and evaluative connotations around those beliefs (self-esteem), and a consequent likelihood of responding in a particular way (behavior) (Burns, 1982). Self can be viewed from two very different angles: self as a subject (I) and self as an object (me) (Harter, 1999). According to Bandura (1986), self-concept is a composite view of oneself that has formed through direct experience and evaluations adopted from significant others.

Burns (1982) has identified three roles of self-concept: to maintain inner consistency, to interpret experiences, and to determine a set of expectations. Self-concept is powerful and resilient, which is mostly a consequence of maintaining inner consistency. The strength of one's self-concept affects the interpretations of the

experiences of a person. Further, the self-image determines the expectations of a person's experiences and the expectations of his / her success. A person with poor self-image does not expect any success, which leads to either behavior or the adoption of an interpretation of circumstances that fulfills the prediction in order to maintain inner consistency. A person not only has certain beliefs within him/herself which need to be fulfilled, but also the perceived beliefs of other people in their social environment.

self-perceptions and behavior

Perceptions of one's self-concept inspire, or cause, an individual's behavior (Burns, 1982). The connection between self-perceptions and behavior has been confirmed by empirical research. For example, mathematics anxiety is determined by outcome expectancy and outcome value (Kyttälä & Björn, 2010). In view of the effects of self on behavior, achievement and self-esteem, what perception of self should we be striving to instil in ourselves and others?

According to Bandura (1986), competent functioning requires both *skills* and *self-beliefs of efficacy* to work out effectively, and further, perceived self-efficacy is a judgment of one's capability to accomplish a certain level of performance, whereas an outcome expectation is a judgment of the likely consequence such behavior will produce. A circle of production can thus be described: good achievement implies better self-image (Marsh, Byrne & Shavelson, 1988), better self-image implies better performance (Bandura, 1986; Korpinen, 1990), which again leads to better self-image.

According to Harter (1999), self-concept has three types of functions. Firstly, there are *organizational functions* to provide expectations and to give meaning to life. Secondly, there are *protective functions* to maintain and maximize the pleasure. Thirdly, there are *motivational functions* to “energize the individual to pursue selected goals”, and to “identify standards that allow one to achieve ideals in the service of self-improvement” (Harter, 1999, p. 10).

real self and ideal self

An individual not only has perceptions of the *real self*, but also of the *ideal self*. An initial idea of the relationship between real self and ideal self was presented as early as 1890 by James' formula of self-esteem as a ratio of success and pretensions. The idea is that self-esteem can be enhanced by increasing the nominator (success, which can be seen as real self) or reducing the denominator (pretensions, which can be seen as ideal self) (James, 1890). The difference between real and ideal selves is then something to work on, as unrealistic pretensions can be risky: it is important for an individual not to fail when pursuing the ideal self; failure will result in negative outcomes, such as anxiety and depression. Further, the discrepancies between the *success* of pursuing an ideal and the *importance* of that ideal is a determinant of one's level of self-esteem (Harter, 1999).

Other discrepancies emerge from the *disparity* between real and ideal selves. The idea of the magnitude of the disparity between ideal and current self was first explored in the work of Rogers and his colleagues (Rogers & Dymond, 1954). In Roger's view, this disparity was the main cause of an individual's maladjustment. The idea of inequalities was operationalized, for example Butler and Haigh (1954) designed Q-sort task to measure the difference; subjects were instructed to sort cards to describe themselves on the day (self-sort) and to describe their ideal person (ideal sort).²⁸

The disparity between real and ideal selves seemed to have some negative effects, such as poor self esteem (Harter, 1999). However, Harter writes that Rosales and Zigler have argued that the disparity could also be considered as an inspirer of desired action. Thus, the function of the disparity would be positive. In addition, Rosales and Zigler have presented that at some point the significance of the disparity might start to decrease. This suggests a quadratic function: diminutive difference would not provide any positive effect onto motivation, nor does large difference, whereas a suitable difference would generate a motive for the desired behavior. From that point of view, the increased disparity developed with age is not necessarily detrimental; it can also be seen as a more effective way of encouraging motivation.

Quite apart from considerations of the magnitude of the disparity, the same discrepancy, when associated with a negative sense of one's real self, may produce more distress than if it is associated with a more positive evaluation (Harter, 1999). As Bandura (1986) wrote, self theories have had difficulty explaining how the same self-concept can give rise to diverse types of behavior. By examining the disparity, its magnitude, its sign (whether the value of the discrepancy is negative or positive), and its starting point (the degree of the basis of the discrepancy, i.e. the degree of the real self), some improvements to the self theories might follow.

Aims and hypotheses

As Tuohilampi (2011) has pointed out, the idea that the connection between self-discrepancy (disparity between the real self and the ideal self) and desired action can be quadratic needs to be examined. The association between these variables is quadratic, if both large and small discrepancies connect with minor action, whereas moderate discrepancy connects with good action. If the connection does appear quadratic, one needs to determine the best conditions, i.e. the optimum amount of discrepancy to ensure good action. This requires the direction of the connection to be from discrepancy to action; otherwise one has to study the possible benefits of connection in the opposite direction, i.e. from action to discrepancy.

²⁸ Q-sort (or Q-method, Q-technique), developed by William Stephenson, in which the items are put in an order of representativeness or significance for the individual (Block, 1961).

Working Group 8

Based on the previous studies, the hypothesis is that the connection is from discrepancy to action, and that if the discrepancy is too large or too small, the motivation to bridge that gap is depressed. In the case of the discrepancy being too large, this is because the goal appears unattainable, and this leads to academic frustration; in the case of the distance being too small, it is because of the lack of a perceived challenge. If the distance between the real self and the ideal self is a negative number, i.e. the value of the ideal self is smaller than the value of the real self, no hypotheses as to how this may affect action are available from previous studies. However, an educated guess is that in that case the motivation to act as desired is potentially destroyed.

The study presented in this paper concentrates on the type of the connection when discrepancy is considered to be independent variable, and *effort*, *enjoyment of mathematics* and *last grade in mathematics* are considered to be dependent variables. The direction of the connections, however, cannot be revealed in this study, as this requires longitudinal analysis.

Specific research questions are: 1. Are there any associations between discrepancy and a) effort, b) enjoyment of mathematics (referred to as: EoM), and c) the last grade awarded in mathematics (referred to as: grade)? 2. If the association exists, what sort of is it regarding a), b), and c)? 3. What numerical value of discrepancy is connected to best values of a), b), and c)?

Method

The present analysis is based upon data collected from December 2009 to January 2010 in Finland. The participants were aged 13 to 15 years. The data was collected in four local authority areas (*kunnat*; singular: *kunta*), and the numbers of participants in each *kunta* was 120 (598), 100 (472), 186 (540), and 0 (373); the sample size for each *kunta* is given in parentheses, giving a response rate of 20 %. The total number of participants was 406.

Data was collected as part of a research project, the aim of which is to investigate the affects of a learning environment called *Opit*. The *kunnat* differ in their application of *Opit*: some have used *Opit* for a long time; some started to use *Opit* at the time of the first data collection (three collections were carried out altogether); some have not used *Opit* at all. *Opit* is a Finnish learning environment that consists of a variety of tools, such as basic applications, customer service, technical support and teacher training.

In the questionnaire that was used to collect data, there were questions from several existing instruments. In this study, the following instruments were applied: *Students' view of learning mathematics*, developed by Rösken, Hannula, Pehkonen, Kaasila and Laine (2009), with sections on competence, effort, enjoyment of mathematics, difficulty of mathematics, and confidence; *Patterns of Adaptive Learning Scales* (PALS), developed by Midgley & al. (2000), with sections on mastery goal

Working Group 8

orientation, performance-approach goal orientation, performance-avoidance goal orientation, avoiding novelty, classroom mastery goal structure, classroom performance-avoidance structure, parent mastery goal, and parent performance goal; and *Self-Regulation*, developed by Schwarzer, Diehl and Schmidz (as cited in Diehl, Semegon, & Schwarzer 2006).

In this study, the data was used to find out exploratory results concerning the hypothesis. In the data, there were items that measured perceptions of present skills and abilities (students' competence, confidence and self-regulation). These items were used to formulate mean variable of perceived self, representing students' *real self*. Items for mastery goal orientations (MGO) represent students' *ideal self*, as they measure how students wish to act. Discrepancy is then defined as the distance between perceived self and their ideal goals (MGO minus mean variable of perceived skills). The justification for choosing these items comes from previous theory: mastery goal orientations can be seen as pretensions (James, 1890); or as ideal self (Burns, 1982); the sum of competence, confidence and self-regulation can be seen as perceived skills, i.e. real self (e.g. Rogers & Dymond, 1954; Harter, 1999; Burns, 1982).

Results

The analysis started by looking at the distributions of 'discrepancy', 'effort', 'EoM' and 'grade'. All distributions, except the 'grade', could be interpreted as normal according to their histograms and absolute values of skewness and kurtosis (all absolute values < 1) albeit the tests gave an alternative result (e.g. Nummenmaa, 2009). The parameters were: discrepancy ~ N (0.18 ; 1.05²), range [-3 ; 3.5]; effort ~ N (3.25 ; 0.84²), range [1 , 5]; and EoM ~ N (2.93 ; 0.96²), range [1 , 5]. Grade had a near normal distribution, but the absolute value of the kurtosis was slightly over 1. Mean of the 'grade' was 7.88, variance was 1.36², and range was [4 , 10].

Reliability of all the factors were examined by Cronbach's alpha, though discrepancy had to be disassembled into perceived skills (confidence + competence + self-regulation) and into mastery goal orientation. The values of the alphas were: skills=.91, MGO=.84, effort=.77, EoM=.87. None of the reliabilities could be improved significantly by removing items.

The second phase of the analysis was to examine the scatter plots. When taking 'discrepancy' as the independent variable and other variables as dependent, none of the connections (discrepancy-effort, discrepancy-EoM, discrepancy-grade) seemed linear. On the contrary, when allowing the "fit line" to be loose ("loess" in SPSS-program), the connection seemed rather quadratic in nature, as expected by the hypothesis. This was the case for all the connections, except the connection between discrepancy and grade. However, the connections were not very clear.

How to examine the quadratic connection? According to Kendrick (2005), one way to better see whether two variables are quadratically connected is to view their

contingency table. This is what was done next. The variables were categorized, the contingency tables formulated and the distributions of percentages were interpreted (Kendrick, 2005). This time one could clearly see that the connection was either quadratic or at least curvilinear in two of the cases, discrepancy-effort, discrepancy-EoM (see tables 1, 2, and 3).

The significance of this result can be determined statistically by using the χ^2 -independence test for a null hypothesis “There is no association between independent variable ‘discrepancy’ and dependent variables ‘effort’, ‘EoM’, ‘grade’”. To satisfy the conditions of the test, the number of categories of variables was decreased: only about 20% of the cells may have frequency of less than 5, while the frequencies of all cells ought to be more than zero (e.g. Nummenmaa, 2009). At this point, the variables ‘effort’, and ‘EoM’ were condensed into three categories: -1=not at all or not very much, 0=neither a lot nor a little, 1=quite a lot or very much; ‘grade’ was also distributed into three categories: 1=poor grade, 2= moderate grade, 3=good grade; and ‘discrepancy’ into 5 categories: -2=orientations much less than interpreted skills, -1= orientations less than interpreted skills, 0=orientations in line with interpreted skills, 1=orientations higher than interpreted skills, 2=orientations much higher than interpreted skills.

For all the variable pairs (discrepancy-effort, discrepancy-EoM, discrepancy-grade), the null hypothesis “there is no association between” was rejected. The exact results were: discrepancy-effort $\chi^2(8)=19.99$, $p=.01$; discrepancy-EoM $\chi^2(8)=14.92$, $p=.06$; discrepancy-grade $\chi^2(8)=107.28$, $p=.00$. Although the p-values were not all under .05, the trend was similar in all cases. Whether the null hypothesis got rejected incorrectly in any of the cases seems unlikely because of this trend as well as the theory behind what has been tested.

To view the connections, see the tables below. To make interpretation easier, the highest percentages have been bolded if the value is very high or remarkable: these values bend the connections from clearly linear.

Finally, a comparison was made between the linear and quadratic models linking the variable pairs. When discrepancy was an independent variable and effort was dependent variable, the results were: $p=.35$ in linear model, $p=.07$ in quadratic model, $R^2_{\text{linear}}=.00$, $R^2_{\text{quadratic}}=.01$. When enjoyment was dependent variable, discrepancy again independent, the results were: $p=.02$ in linear model, $p=.00$ in quadratic model, $R^2_{\text{linear}}=.01$, $R^2_{\text{quadratic}}=.047$. When grade was dependent variable, and discrepancy independent, the results were: $p=.00$ in linear model, $p=.00$ in quadratic model, $R^2_{\text{linear}}=.16$, $R^2_{\text{quadratic}}=.18$. The differences were not very obvious; neither of the models seemed very suitable in any of the connections. However, the coefficient of determination (R^2) is not a reliable measure if the connection is not monotonic, i.e. for example, quadratic (e.g. Nummenmaa, 2009).

Interpretation

As far as the first connection, discrepancy-effort, is concerned, we can clearly see that the discrepancy should be negligible or negative rather than positive. However, the interplay is complicated to explain. If discrepancy causes effort, it is because

Working Group 8

those whose skills are perceived as poor or who have high aspirations start to put in more effort. If effort causes discrepancy, it is either because those putting in a lot of effort without reaching their goals may revise the interpretation of their skills downwards, or those who like working hard set themselves too high aspirations as a realistic vision. The causations may even be circular. To be exact, those having large positive discrepancy are more likely to be connected with no effort, those having moderate positive or negative discrepancy or large negative discrepancy are more likely to be connected with moderate or strong effort. Counter to the hypothesis, negative discrepancy does not connect to putting in nonexistent effort. The result in the case of large positive discrepancy, however, supports the hypothesis that aspirations which are too high in relation to one's perceived skills do not result in increased effort.

In the second table, the connection seems to be curvilinear, to the point of being quadratic, but the cause-result relationships are hardly clear: the high frequency in cell_{1,1} can be explained by claiming either that dislike of mathematics has led to lowered orientations or that lowered orientations has led to the dislike, whereas the high frequency in cell_{1,5} may be explained by claiming that the non-fulfillment of high orientations has led to dislike but it can hardly be claimed that dislike has led to high orientations. Again, those having moderate positive or negative discrepancy are more likely to be connected with moderate or strong enjoyment of mathematics, but, this time large negative discrepancy is more likely to be associated with no enjoyment of mathematics, which is supported by the hypothesis.

The third connection seems to be somewhat similar. Moderate discrepancy connects with good or moderate grades, whereas large positive discrepancy clearly connects with poor grades. However, this time the connection between large negative discrepancy and poor grades is not obvious. The causation is again complicated: either poor achievement has led to high orientations (the wish to do better) or too much discrepancy has led to poor achievement.

The results printed above were subjected to further comparison by carrying out checks on the connections of all the independent variables (effort, EoM and grade) with 1) mean variable of competence, confidence and self-regulation (referred to as: skills), and 2) MGO. All the connections were clearly linear, and most of the correlations were quite strong and positive: $R_{\text{skills} - \text{effort}} = .61$, $R_{\text{skills} - \text{EoM}} = .66$, $R_{\text{skills} - \text{grade}} = .62$, $R_{\text{MGO} - \text{effort}} = .59$, $R_{\text{MGO} - \text{EoM}} = .57$, $R_{\text{MGO} - \text{grade}} = .23$, wherein $R = \text{Pearson correlation}$. This means, that although high orientations correlate positively with examined variables *and* perceived skills correlate positively with examined variables, the effect changes if *the distance* between the two variables (perceived skills and orientations) is taken into account. Thus, there is strong evidence for the importance of this kind of perspective.

However, the analysis did not give a good model for the connections. This may be due to the fact that the number of subjects examined turned out to be on the low side.

Working Group 8

Consequently, there was only a small number of cases showing large positive or large negative discrepancy (i.e. extreme cases), which limited the possibilities for statistical analysis. In future studies, this has to be taken into account: one has to pay attention to the number of participants.

Discussion

Previous studies of self discrepancies show that there are connections between perceptions of the self and behavior (e.g. Burns, 1982; Kyttälä & Björn, 2010). The results of this study confirm this connection: perceptions of self can be separated from aspirations, and the disparity between the two gives an interesting perspective to examine the self. However, even a small discrepancy was connected with poor behavior, which was against the suggestion that some degree of the disparity would be necessary to emerge motivation, brought out by Harter (1999).

The results in this study linked the best connection to either small negative discrepancy or to no discrepancy at all. This means that those students who have high feelings of their skills, as well as those students who do not feel so competent but can set their goals very moderately, can enjoy mathematics, put effort on it and are able to get better grades. This suggests that it is good for a student to either be able to trust on own abilities, or to have realistic view on own skills and proceed step by step rather than trying to take huge leaps.

What are the causations of the connections? Bandura (1986) argues that competent functioning requires skills and self-beliefs of efficacy to work out effectively, but how can these efficacy feelings be improved? Perhaps those students, who tend to set their goals realistically, experience feelings of success more often, which again strengthens their ability feelings. If so, is the large discrepancy one cause for losing ability feelings? Do some students protect their *inner consistency* (Burns, 1982) by setting unrealistic aspirations to make sure they are not able to achieve them? If this is the case, students' *protective functions* (Harter, 1999) seem to overrun *motivational* and *organizational functions*. This suggests that the discrepancy is rather a protection of self than an initiation of desired behavior.

This study gives some preliminary results in the field of self-discrepancy's connections in mathematics, and builds the basis for further hypotheses.

THE IMPACT OF CONTEXT AND CULTURE ON THE CONSTRUCTION OF PERSONAL MEANING

Maïke Vollstedt

Leibniz-Institute for Science and Mathematics Education at the University of Kiel,
Germany

What impact do context and culture have on the kinds of personal meaning constructed by students of the lower secondary level in the context of learning mathematics at school? To answer this question, this paper takes the perspective of students from Germany and Hong Kong as examples for cultures from the West and the Confucian Heritage Culture in East Asia. The concept of personal meaning will be developed denoting the personal relevance a person assigns to an object or action. Personal meaning is put in a concept framework of didactics and educational psychology and the relation to context and culture is shown. Finally, exemplary results from a qualitative study enriched with exploratory statistical analyses suggest the cultural impact on the construction of different kinds of personal meaning.

Keywords: personal meaning, culture, context, learner's perspective, East/West

INTRODUCTION

Humans have a “need for meaning” and “[a]lthough meaningful learning and meaningful life seem to be different concepts, it is quite possible that they have the same origin” (Vinner, 2007, p. 6). If meaningful learning is a special case of “man's search for meaning” (ibid), this specific human attitude does not disappear before entering the classroom. Meaning is also sought inside the classroom when students engage in learning and dealing with subject contents. Thus, the demand for meaning in education has been detected for many years, and meaningful learning has been identified as one of the major goals of education (ibid, p. 10).

Meaning seems an important topic when considering learning processes in school in general, and in learning mathematics in particular. But what exactly do we mean when we talk about *meaning*? Do students and educators intend the same thing when using this term? And taking the students' perspective, which meaning do students construct when dealing with mathematics in a school context? Does culture play a significant role for the construction of (personal) meaning? The last two questions are answered in the qualitative study reported on in this paper.

The study is included in the context of research on Educational Experience and Learner Development, which focuses on the learners' perspective of their own educational process. The paper's main focus is the development of the theory of personal meaning and hence, first presents different interpretations of the term *meaning*. The concept of *personal meaning* is then developed with regard to the perspectives of German and Hong Kong students. The two countries represent

cultures from the West and the Confucian heritage in East Asia. The theoretical part of the paper concludes with the relation of personal meaning with context and culture. The theory then is illustrated with exemplary results of the study presenting the influence of culture on the construction of meaning.

FROM MEANING TO PERSONAL MEANING

A review of the relevant literature shows that the term *meaning* is used in very different contexts denoting different concepts. In education, we think about meaningful learning, and, even within the field of mathematics education, the term *meaning* can be used in different ways. The absence of a commonly accepted interpretation of *meaning* has resulted in a diversity of interpretations. This is due to a mixture of philosophical and non-philosophical interpretations as Kilpatrick, Hoyles, and Skovsmose (2005a, p. 2) point out: “on the one hand, we may claim that an activity has meaning as part of the curriculum, while students might feel that the same activity is totally devoid of meaning”. Different kinds of meaning can also be reconstructed when we turn to the students’ perspective (Kilpatrick, Hoyles, & Skovsmose, 2005b, p. 9):

Some students find it pointless to do their mathematics homework; some like to do trigonometry, or enjoy discussions about mathematics in their classrooms; [...] other students are told that because of their weakness in mathematics they cannot join the academic stream.

Although many interpretations of the term *meaning* relate to very different aspects, Howson (2005, p. 18) distinguishes two different aspects of *meaning*:

those relating to relevance and personal significance (e.g., ‘What is the point of this for me?’) and those referring to the objective sense intended (i.e., signification and referents). These two aspects are distinct and must be treated as such.

In this paper the terms *personal meaning* denotes the personal relevance of an object or action, and *objective meaning* a collectively shared meaning of an object or action (Vollstedt, 2010) [1].

To maintain the productive range of interpretations, the criterion of *personal relevance* here defines the term *personal meaning* of an object or action (Vollstedt & Vorhölter, 2008, pp. 29–31). It comprises the following aspects: objective meaning, usefulness, goal, purpose and value. Therefore, depending on the context, personal meaning can have an intentional as well as functional character. In addition to these aspects, I assume that personal meaning is subjective and individual, that the construction of personal meaning is context bound and that personal meanings can, but do not have to be reflected on (Vollstedt, 2010).

RELATIONAL FRAMEWORK OF DIDACTICS AND EDUCATIONAL PSYCHOLOGY

Working Group 8

The concept of personal meaning can be found in a relational framework of different concepts from mathematics didactics, the didactics of Educational Experience and Learner Development, and educational psychology. These concepts are understood to have an impact on the construction of personal meaning as they denote aspects which are personally relevant for the students. Let us assume we have a context in which an individual is dealing with a certain situation. In school, this might be a learning context in which a student deals with a mathematical problem. This student, let us call him Toby, judges the situation solely with respect to his personal attributes and goals. Toby automatically answers the question whether dealing with the situation makes sense to him, i.e. whether it is personally relevant, or not. He also considers in which way a possible following action might affect his personal goals.

Appraisal of the situation requires different concepts from mathematics didactics, the didactics of Educational Experience and Learner Development, and educational psychology. Toby might judge differently depending e.g. on his mathematical beliefs (Op ‘t Eynde, Corte, & Verschaffel, 2002). He might also be influenced by his interpretation of the developmental tasks he is dealing with at that point in time (Havighurst, 1972), a concept prominently discussed in the research context of Educational Experience and Learner Development. In addition, judgement is influenced by different aspects of learning motivation; a concept from educational psychology (Wild, Hofer, & Pekrun, 2001). The academic self concept, i.e. Toby’s judgement of his abilities in mathematics and how he perceives them (Möller & Köller, 2004), is relevant for the process of constructing personal meaning. Also, the three basic needs for autonomy, competence, and relatedness (Ryan & Deci, 2002) are believed to play a decisive role.

PERSONAL MEANING IN RELATION TO CONTEXT AND CULTURE

Personal meaning cannot be constructed in a vacuum but is related to context. In this study, the term *context* covers both situational context (i.e. the context of the learning situation in terms of topic and the situation in the classroom) and personal context. The personal context may consist of the student’s personal traits (i.e. aspects which concern the student’s self like his/her self-concept, motivation, or beliefs) and his/her personal background (i.e. aspects regarding the world around the student like his/her socio-economic status, migration background, or learning and cultural environment) (Vollstedt & Vorhölter, 2008). Mercer (1993, pp. 31–32) takes the student’s perspective when he describes context in the following way:

What counts as context for learners [...] is *whatever they consider relevant*. Pupils accomplish educational activities by using what they know to make sense of what they are asked to do. As best they can, they create a meaningful context for an activity, and the context they create consists of whatever knowledge they invoke to make sense of the task situation. (Italics in original, MV)

Working Group 8

According to Mercer, the students decide which information and experiences are relevant to deal with the posed task.

In my study, Mercer's description is interpreted in a broad way. In a learning situation not only knowledge but also beliefs, goals or other kinds of personal traits or background may be relevant for the students. According to Leung, Graf, & Lopez-Real (2006), these are subject to cultural influence as culture has a strong impact on how learning takes place in any learning situation. This is consistent with Mercer (1993, p. 43), who states that learning in the classroom depends both on culture and context as it is:

- (a) culturally saturated in both its content and structure; and (b) accomplished through dialogue which is heavily dependent on an implicit context constructed by participants from current and past shared experience.

Both culture and context of a learning situation differ greatly in the Confucian Heritage Culture of East Asia and the Western traditions, as they are based on Chinese/ Confucian and Greek/Latin/Christian traditions respectively (Leung, 2001). As students from East Asia outperformed Western students in large scale comparative studies, it is interesting to see whether cultural differences can provide an explanation for these significant differences. Therefore, Leung (2006) examined a number of different characteristics of the Chinese/Confucian culture. He shows that:

there are indeed different cultural values pertinent to education that may explain the differences. This is of course no proof that differences in student achievement are caused by cultural differences. But in the absence of clues from variables at other levels, it is probable that culture does matters [sic]. (Leung, 2006, p. 44)

Therefore, one can stress that "the impact of cultural tradition is highly relevant to mathematics learning" (Leung, Graf, & Lopez-Real, 2006, p. 7) and therefore, also for personal meaning constructed in the context of learning mathematics at school.

Leung (2001) describes six features relevant for mathematics education distinct for East Asian and Western cultures. These features are not understood as dichotomies but as continua on which the relative position of countries from East Asia or the West differ. They are product (content) vs. process, rote learning vs. meaningful learning, studying hard vs. pleasurable learning, extrinsic vs. intrinsic motivations, whole class teaching vs. individualised learning, and pertaining to the competence of teachers: subject matter vs. pedagogy. All these aspects relate to complex underlying cultural differences and not just different kinds of established practice (Leung, 2001; for detailed discussion of the differences cf. Vollstedt, 2011). As the aspects given above are relevant for the learning context of mathematics, they are supposed to influence the students' processes of constructing personal meaning. Accordingly, the aim of this study is to contrast different types of personal meaning constructed in Germany and Hong Kong.

THE STUDY

Working Group 8

The study is based on 34 guided interviews conducted in Germany and Hong Kong with students of the lower secondary level (about 15-16 years old). Seventeen students participated from each country; all attended the highest school type in the respective educational system. In Hong Kong, I collaborated with schools using English as medium of instruction so as to conduct the interviews in English.

The guided interviews lasted for about 35 to 45 minutes and began with a sequence of stimulated recall (Gass & Mackey, 2000). For this, the students were shown a five to ten minutes video abstract of the last lesson they attended. Their task was to verbalize and reflect on the thoughts they had during the lesson. The interviews then tackled various topics inspired by the relational framework of personal meaning (see above) to come as close as possible to the aspects related to learning mathematics which are personally relevant for the students in a school context. Students were for instance asked about their associations of the words *mathematics* and *mathematics lesson*, they were interrogated about their beliefs with relation to mathematics, mathematics lessons and their learning of mathematics as well as about their feelings, their learning strategies, their goals and so on.

The data was coded in the style of Grounded Theory (Strauss & Corbin, 1996) by developing concepts directly from the interview material as well as theory-governed, taking the theoretical framework of the study as sensitising concepts into account. The coding was done partly in teamwork, partly independently but together with a team member so that the results could be discussed afterwards, and – after having received consistent results – partly on my own. By comparison and by using a coding paradigm, relations between concepts were disclosed so that core categories were developed denoting 17 different kinds of personal meaning. They vary in their orientation towards mathematics and the self so that a broad range is covered from the fulfilment of duty and the wish for cognitive challenge when dealing with mathematics to the experience of social relatedness. They can be grouped in seven different types of personal meaning.

Strictly speaking, the model of personal meaning presented above is also a result from the study as the concept and the relational framework were specified and developed further throughout the research process. To assure validity, the results as well as aspects which lacked clarity from my Western perspective were later discussed with Hong Kong professors of mathematics education as well as Hong Kong mathematics teachers.

After reconstructing the kinds and types of personal meaning, they were analysed with respect to the students' cultural background. Bound to the reconstructive framework, I opted not to generate hypotheses concerning cultural differences or similarities on a theoretical basis with relation to the relevant literature. Instead, I conducted exploratory statistical analyses using the software SPSS (version 15) to generate culture-specific hypotheses from the data. Hence, the unspecific and undirected hypotheses used in the *t*-tests of my study are strictly speaking not 'real'

hypotheses. On the contrary, I only checked whether differences exist between the two places to generate hypotheses about similarities and differences between the two places from empirical data. Statistics therefore acted as a means to conduct exploratory analyses instead of making general statements about Germany and Hong Kong.

To obtain a measure of the students' personal preferences, the relative frequency of every kind of personal meaning was coded for every student. In order to achieve this, the codings of every kind of personal meaning were counted. Then, the percentage of codings of one kind of personal meaning was calculated from all codings of personal meaning of this student. These relative frequencies formed the basis for the calculation of *t*-tests. From these results, empirically grounded hypotheses were generated for the relation between different kinds of personal meaning and the students' cultural background. The results are rather tentative as each sample only includes 17 students. Therefore, to support these results with a non-parametric test, the Mann-Whitney-*U*-test was calculated. This paper only includes the results of the *t*-tests, because the results from the two tests were comparable (for further information cf. Vollstedt, 2011).

DISCUSSION OF EXEMPLARY RESULTS

As described above, seven different types of personal meaning could be generated. Here, example discussions include the type *fulfilment of societal demands*. The characteristics for this type of personal meaning are that it is personally relevant for the students to deal with mathematics and to learn mathematics to gain appreciation by other people due to their achievement, as well as to fulfil certain requirements for their intended future profession. The type consists of four different kinds of personal meaning. In *examinations*, it is important for the students to prepare themselves for examinations as passing the exams may result in opportunities in their personal future or their education. In addition, the students intend to create a *positive impression* and impress others through their achievement in mathematics. With respect to their future vocation, students must fulfil *vocational prerequisites* to ensure admission e.g. to their chosen field of study. Regarding *duty*, it is personally relevant for the students to meet the demands perceived as unavoidable as well as to deal with performance pressure.

When looking at *fulfilment of societal demands*, no significant differences could be found between Germany ($M_{\text{Ger}} = 12.91$, $SE_{\text{Ger}} = 5.21$) and Hong Kong ($M_{\text{HK}} = 12.70$, $SE_{\text{HK}} = 4.99$), $t(32) = .12$, $p = .905$, Cohen's $d = .04$. This, however, does not automatically imply that underlying kinds of personal relevance do not show significant differences as opposite results may cancel each other out. Similar as with the type itself, no significant differences could be found for *duty* and *vocational prerequisite*. The differences between results from Hong Kong and Germany for *positive impression* and *examination* turned out to be significant as will be shown in more detail below.

Working Group 8

As no significant differences could be found with the two kinds of personal meaning *duty* ($M_{\text{Ger}} = 4.17$, $SE_{\text{Ger}} = 2.33$, $M_{\text{HK}} = 4.08$, $SE_{\text{HK}} = 2.44$; $t(32) = .10$, $p = .918$, $d = .04$) and *vocational prerequisite* ($M_{\text{Ger}} = 4.94$, $SE_{\text{Ger}} = 2.73$, $M_{\text{HK}} = 5.08$, $SE_{\text{HK}} = 3.06$; $t(32) = -.14$, $p = .891$, $d = -.05$), it seems personally relevant for Hong Kong as well as German students to learn mathematics either because it is a school subject or due to other's expectations of them. In both countries students also consider some mathematical competencies relevant for their desired future vocation. Therefore, learning mathematics appears meaningful in preparation for future vocational demands.

When looking at *positive impression* and *examinations*, the results of the two countries are quite different. On the one hand, creating a *positive impression* of oneself in others seems more important for German students ($M_{\text{ger}} = 3.57$, $SE_{\text{Ger}} = 2.54$) than for those from Hong Kong ($M_{\text{HK}} = 0.78$, $SE_{\text{HK}} = 1.80$), $t(32) = 3.70$, $p < .01$, $d = 1.27$, as the value of the effect size Cohen's d is positive and bigger than 0.8. At first glance, this result seems surprising, as keeping face, acting according to others' expectations and worrying about others' opinions are aspects of social orientation and, therefore, part of the Confucian Heritage Culture (Leung, 1998).

The differences between Germany and Hong Kong can be traced back to the category of appreciation by other people with the appreciation of the teacher being the focal aspect for German students. A possible interpretation of these results with respect to (lesson) context and culture might be found in the different importance of oral participation in class, and examinations respectively. Oral participation is highly important in German lessons as it comprises a great share in the overall mark students get for a subject. In addition, performance measurement is continuous and dependent on the teachers' judgement rather than on examination boards (Kaiser, 1999). Therefore, it is of great importance for German students to continually create a positive impression of themselves for their teachers. In Hong Kong the focus lies on whole class teaching instead of individualised learning (Leung, 2001). Hence, oral participation in lessons is not as important. Accordingly, in the Hong Kong educational system, great importance is placed on results of examinations – an aspect which may historically be related to the prevalent belief in the Confucian heritage culture that practice makes perfect (Li, 2006). This goes along with the historic role of examinations in China. As early as 597 AD examinations were designed to choose savants for government positions. Therefore, it was possible to further social advancement by taking examinations (Leung, 2008). This attitude is still prevalent today. Today particularly the *Hong Kong Certificate of Education Examination* (HKCEE, similar to GCSE in the United Kingdom) is of great personal relevance for students. At the time of interview, students were going to take it in one to two years time, but already this early on it was governing their thoughts. Therefore, studying hard, practising a lot (rote learning as a necessary step towards deep understanding of the contents), and extrinsic motivation resulting from the importance of the results

from HKCEE are crucial aspects for Hong Kong students (Leung, 2001; Vollstedt, 2010). This, then may be an explanatory approach for the differences detected with *examinations*: examinations seem to play a more important role in Hong Kong ($M_{HK} = 3.71$, $SE_{HK} = 3.16$) than in Germany ($M_{Ger} = 0.47$, $SE_{Ger} = 0.90$), $t(18.6) = -4.06$, $p < .01$, $d = -1.39$ as the value of Cohen's d is negative and $|d| > .8$. A similar situation did not arise in Germany with relation to the *Abitur* (University Entrance Examination) or other kinds of regular examinations. Two possible explanations are suggested here: On the one hand, as stated above, oral participation has a stronger weight for marks in Germany than regular examinations have. On the other hand, the *Abitur* exams are taken one year later than the HKCEE so that they may not have been as acute for the students during the interviews as for the Hong Kong students.

CONCLUSION

When considering meaningful learning in a school context, it makes sense to take the perspective of the students as they are the people focused upon. Therefore, one must ask what is personally relevant for them when learning and dealing with mathematics. Characterizing personal meaning with the help of the criterion of personal relevance encompasses the range of interpretations denoted by the blurred concept of meaning. Theoretical coding of interview data from Germany and Hong Kong led to 17 different kinds of personal meaning covering aspects such as fulfilment of duty, cognitive challenge, and social relatedness. All these are personally relevant for students to deal with mathematics or learn the contents. Varying in degrees of relation to mathematics and the self, the 17 kinds of personal meaning could be grouped into seven types.

The paper discusses exemplary results including the four underlying kinds of personal meaning of the type *fulfilment of societal demands*. As shown above, no sound statements can be made on type level, as the results of the underlying kinds of personal meaning may be oppositional and cancel each other out. Therefore, only the results from the kind level were discussed in more detail. Here, no differences could be found for *duty* and *vocational prerequisite*, whereas differences became apparent for *examination* and *positive impression*. The students' cultural backgrounds were considered as a possible explanation for the differences detected in the last two kinds of personal meaning. Some instances of lesson culture as well as cultural beliefs were related to the results suggesting possible explanations: the cultural belief that practice makes perfect and the historic role of central examinations is prevalent in Hong Kong whereas in Germany oral participation in lessons plays a greater role. Therefore, the results of the qualitative study reported on in this paper suggest that a connection may be drawn between some personal meanings and the context, as well as the culture in which they had been constructed. In the East Asian and Western culture other kinds of personal meaning seem universal. This of course does not prove that culture is the reason for these differences. However, it may provide a

Working Group 8

partial explanation. To provide more conclusive evidence, the hypotheses developed in this study will be tested on a broader field of data.

NOTES

1. The German term for *personal meaning* we use in our research is *Sinnkonstruktion*. *Objective* or *collective meaning*, on the other hand are equivalent to *Bedeutung*.

THE EFFECT OF A TEACHER EDUCATION PROGRAM ON AFFECT: THE CASE OF TERESA AND PFCM

Maria Pezzia* & Pietro Di Martino**

* University of Naples Federico II – Italy

** University of Pisa – Italy

Affective factors are strictly intertwined and have a strong influence on teachers' professional practices. Literature underlines that primary teachers often have a negative attitude towards mathematics. For these reasons it is fundamental that professional development programs in primary mathematics teaching consider affective issues. In this study we analyze – describing the case study of Teresa, an experienced primary teacher with negative attitude towards mathematics – the effect of a Portuguese in-service program in mathematics and its teaching for primary teachers that includes, among its goals, the development of a positive attitude towards mathematics and its teaching.

Keywords: attitudes towards mathematics, primary teachers' education, beliefs, emotions, teachers' professional development.

INTRODUCTION AND THEORETICAL BACKGROUND

Many researchers have underlined the influence of several factors on teachers' effectiveness: Shulman (1986) highlights the role of subject matter knowledge, pedagogical knowledge and pedagogical content knowledge, others scholars (for example Ernest, 1989) underline the role of affective factors. As Tsamir and Tirosh (2009) claim, mathematical subject knowledge, pedagogical knowledge and affective factors are strictly intertwined and have a strong influence on teachers' professional practice. Therefore a professional development program in mathematics teaching limited to cognitive and pedagogical issues is “doomed to failure unless placed within an affective frame in which teachers have space to question mathematics and mathematics teaching” (Hodgen & Askew, 2006, p.41).

Literature shows that the common traits shared by many primary teachers (they are non specialist in mathematics and have often had negative experiences with mathematics as students) could generate uncertainty, low perceived self-efficacy as a teacher (Tschannen Moran et al., 1998), negative emotions such as shame (Bibby, 2002) and anxiety (Hannula et al., 2007) and produce “deep seated beliefs [that] often run counter to contemporary research on what constitutes good practice” (Liljedahl, 2007, p.320).

Adapting the model proposed by Di Martino & Zan (2010) for *attitude towards mathematics*, we characterize *attitude towards mathematics and its teaching* by three strictly interconnected dimensions: emotional disposition towards mathematics and its teaching, vision of mathematics and its teaching, and perceived competence in teaching mathematics. According to this theoretical framework, primary teachers'

Working Group 8

common traits could generate a negative attitude towards mathematics and its teaching.

For these reasons it appears to be very important, both for the teacher as a person and for the quality of mathematics teaching and learning, that education programs for primary teachers focus on the several aspects that characterize the affective side. Nevertheless there are few professional development programs focalised on affective aspects (above all for what concerns in-service primary teachers) and “there has been little theoretical or empirical research exploring teachers’ emotional relationship with mathematics” (Hodgen & Askew, 2007, p.470).

Reporting some major trends in teacher education research, Krainer and Goffree (1999) stress the increasing importance of “teaching stories”, seeing case studies as:

an outcome of teachers’ efforts to investigate into their own teaching (...) for them as an additional circle of reflection, for other colleagues and researchers as an insight into teachers’ challenges and change. (Krainer & Goffree, 1999, p.230)

The issue of our study is related to the theme of understanding, by means of small scale qualitative research, teachers’ opportunities to change their attitude towards mathematics.

We focus on PFCM (Programa de Formação Continua em Matemática): a Portuguese in-service primary teacher education program that includes among its goals the need to develop a positive attitude towards mathematics and its teaching in order to improve mathematical learning in primary school. Some studies on PFCM and its effects on teachers have been conducted by Portuguese researchers, above all teacher educators directly involved in the program (e.g. Menezes, 2008; Canavarro & Rocha, 2010). These studies underline the good results of the program together with some obstacles (usually organizational difficulties).

Our study is different from the others mentioned above, mainly for two fundamental aspects: first, it is focused on teachers’ change related with the affective domain of mathematics education; second, it offers an external point of view (the authors are not Portuguese and they are not involved in the PFCM program). This aspect can be of some relevance: most research on mathematics teacher education is conducted by teacher educators studying the teachers with whom they are working and “*we do need more external research*” (Adler et al., 2005, p. 371).

In this paper we will briefly describe the PFCM’s structure and, through the analysis of one case (Teresa), we will evaluate what elements of PFCM either hinder or promote change in an experienced teacher with a deeply seated negative attitude towards mathematics.

methodology

This paper is based on the analysis carried out for the first author’s doctoral thesis. Four teachers have been involved in the research, chosen according to two common

Working Group 8

features: their declared negative attitude towards mathematics and their feeling that, consequently to their involvement in PFCM, *something* changed in their attitude towards mathematics and its teaching. In this paper - due to the limited space - we only describe the case of Teresa. It seems to us particularly interesting because we recognized in Teresa all the common and critical traits highlighted by the literature on primary teachers; moreover her declared attitude towards mathematics and previous experiences with mathematics as a student are particularly negative. These elements, in our opinion, make of Teresa a real challenge for PFCM's efficacy.

We used a qualitative and interpretive approach. This methodological choice follows our attention to the processes below the teacher's change and not only to the certification of the possible change. We believe that qualitative analysis can highlight these processes. As Bruner (1986) states, narrative is the primary way in which we organize our own experience, trying to give it a meaning. Furthermore, the meanings given by teachers to their own professional development experience has an influence on their practice. For these reasons the main focus of the analysis has been on Teresa's narratives.

Data collection was realized during the second year of Teresa's participation in the program. It included two observations of two-hours school lessons (two hours each) and a semi-structured interview a week after each observation. Each interview went on for about two hours. The first observation was in the first term, while the second observation took place in the third term. Moreover our first author could see Teresa's first-year portfolio: it is a 45-pages document including an introduction, her reflections upon two activities carried out in the first year and her conclusions.

Context

PFCM (Programa de Formação Contínua em Matemática) is a national in-service program started in 2005, as a response by the Education Ministry to the Portuguese students' worrying results in mathematics emerging from PISA 2003 survey. The main aim of the program is to improve the quality of mathematics teaching in 1st-6th grade through teachers' professional development in mathematics and didactics.

From 2009/2010 PFCM has also had the goal of helping teachers to implement the new Mathematics Curriculum (Ponte et al., 2007). PFCM and the new Curriculum are oriented by a socio-constructivist model of teaching and learning processes, where mathematical knowledge is built in the classroom mainly through problem solving and "investigation" activities. As Ponte (2001, p.1) claims "there is a parallel between the activity of the research mathematician and the activity of the pupil in the classroom". The author describes investigation activity in the classroom as follows:

"A mathematical investigation stresses mathematical processes such as searching regularities, formulating, testing, justifying and proving conjectures, reflecting, and generalizing. When one starts working on an investigation, the question and the conditions are usually not completely clear and making them more precise is the first part

Working Group 8

of the work. That is, investigations involve an essential phase of problem posing by the pupil—something that in problem solving is usually done by the teacher. However, investigations go much beyond simple problem posing and involve testing conjectures, proving, and generalizing.” (Ponte, 2001, p.3)

The new Mathematics Curriculum and the PFCM are proposing a neat break with “traditional methods” of Portuguese primary schools. These were mainly based on knowledge transmission, with a central focus on drilling exercises and learning by heart definitions or procedures. In order to make this *revolution*, teachers need to acquire new pedagogical and mathematical competences. As the national coordinators of the program recognize²⁹, primary teachers’ professional development needs to be based on the improvement of pedagogical content knowledge, reflective attitude about professional practice and, in many cases, on a change of “attitude” towards mathematics and its teaching.

PFCM’s goal is to promote professional development starting from teachers’ reflection on their own practice. Indeed, the main features of PFCM are its close relationship with teacher practice and school context and the long duration. The training program lasts two school years and it is composed by two typologies of sessions: (i) Group sessions (two per month, three hours each) involving 8-10 teachers and held in the school after the curricular school-time. In these sessions, teachers and tutor discuss the mathematics curriculum, wondering about the content and pedagogical knowledge needed to plan lessons and possible obstacles in their classes. They also discuss questions arising from supervision; (ii) Individual supervision sessions of classroom work (about ten hours per year), where the teacher, with the trainer’s help, implements selected tasks explored in the previous whole-group working sessions.

The development of the teacher’s reflective attitude is also promoted through the editing of a portfolio.

Teresa’s story

In the first meeting, Teresa (a very experienced teacher) introduces herself saying “I have never liked maths”. Her story with mathematics is a story of difficulties. In the first interview she tells that, when she was a pupil, she was terrified by multiplication tables and counting:

Teresa: I did not like tables and I was afraid...I was afraid of counting money. I was terrified of counting money. I got stuck on it, I got stuck! I am not able to count money!

Maria: According to you why did you get stuck on counting?

²⁹ Comissão de Acompanhamento, 2005. Programa de Formação Contínua em Matemática para professores do 1.o Ciclo, unpublished document.

Working Group 8

Teresa: My father had a grocery shop...At that time there were many coins. He knew that I did not like to count the coins and he obliged me to count and I failed! Then he beat me (she laughs).

The emotional charge of this story is clear. It is interesting and surprising, at the same time that, in Teresa's view, this experience has not had any impact on her difficulties in mathematics. She strongly rejects Maria's hypothesis about the relationship between her experiences at home and her attitude towards mathematics. She explains that, in her family, two brothers out of four have their father's *maths genes*. Describing her father, she says that he "adored" maths and that he had an extraordinary intelligence in this field. She seems to suggest that if she were as gifted as her brothers she would not have been beaten.

Teresa tells about her aversion towards memorization (and towards all topics that she links to memorization like tables, numbers...) and, vice versa, her appreciation for visualization in mathematics. Her very few positive marks in mathematics as student (in grade 8) are linked to particular topics like geometry:

Teresa: When I got those marks, I do not know the reason. But I remember that I was able to see everything quickly! I discovered all. I don't know...I adore geometry!

The discovery of visual strategies in mathematics represented a turning point for Teresa: in her experience as a student they were accepted only in few topics and contexts. Starting from the new approach to mathematics met in PFCM (based on the use of multiple problem solving strategies including visual ones, not limited to geometry) Teresa thinks back to her experience as a student. This reflection, together with the experience in PFCM, convinces her about the need, for students, to use different strategies in mathematics and to seek their preferred ones and, for teachers, to give prominence to all the different strategies used by the students.

In grade 10 Teresa chose a humanistic course of study and "turned away from mathematics". Three years later, she enrolled in a university course necessary for becoming primary teachers in Portugal and during the first two years she took mathematics courses. She describes this experience with mathematics as very difficult but positive. Teresa was enthusiastic of her teacher:

Teresa: I had a wonderful mathematics teacher. Even now I love him, he is my life! (...) I had again good marks with him and I did not like maths at all!

In spite of this last positive experience as a student, Teresa seems to be still confined in the role of someone who does not like maths. In her long teaching experience (almost thirty years) Teresa had never been involved in a significant mathematics development program before PFCM.

TERESA and the PFCM

In the first interview, Maria asks Teresa why she decided to enrol in PFCM.

Working Group 8

Maria: Why did you decide to enrol in PFCM last year?

Teresa: First of all we are obliged³⁰ to enrol in some teacher development program. Then I thought that I had to follow something new related with maths...I haven't done mathematics for too long, I do not like mathematics and I think I have to learn something more because we have to start with the new Curriculum. So I thought that I had to enrol. And I like it very much.

Maria: Did you enjoy it?

Teresa: I enjoyed it. I liked my trainer very much, I think that he has been wonderful, he taught much. He has been excellent!

From this excerpt it emerges that, although Teresa decided to enrol in a teacher development program for an extrinsic reason, it was nevertheless her need to be ready for starting with the new Curriculum that addressed her towards the PFCM. Moreover, Teresa underlines the role of the trainer in triggering her enthusiasm for the first year of the project. Afterwards she gives more details about what she had learned from her trainer, also observing him to put his suggestions into practice.

Teresa: F. taught us...taught me...if I noticed that then the others noticed too...simple and practical words: “look, look again, try to explain with your words, pay attention, reflect, how did you do this thing? Are you able to explain how you did that? Ah explain! Try to write it down”. Because many students are not motivated to write and explain what they know, what they have done (...) F. taught me this way to ask students to explain how they have done something. We used to order them: “not like this! Not like this!!” But this is not the right way to teach this thing! (...)

F.'s suggestions about the way to interact with students during maths lessons (“the simple and practical words”) and his behaviour in the classroom are related with a view of mathematics in which error is not the focus. Arguing skills and comparison between different strategies become the main points. This new way of viewing mathematics seems to cause a radical change not only in Teresa's beliefs towards mathematics, but also in her emotions and attitude. It seems that now mathematics “is totally different” for her:

Teresa: I think that [mathematics] is difficult, I keep thinking that it is difficult, anyway I like it much more. I think that...it is totally different.

Maria: Why do you like it now and before you disliked it?

Teresa: Sure. Because...how can I explain that? Why do I like it much more now? Because there is not a unique way to do things!

³⁰ Actually it is not compulsory, but it is needed to have career progression.

Working Group 8

At the beginning of the second year of the PFCM two significant events happened: Teresa was assigned another tutor and the new Curriculum started in its first implementation. As the first interview shows, Teresa lives *dramatically* the change of tutor. She feels that the significant path started with F. is definitely interrupted:

Teresa: I need to learn much more about mathematics. Do you understand? Much more! It is what F. did with us: he taught maths.

Maria: Then do you need to continue this path?

Teresa: Exactly! Because, after all, we have done all on the surface. Do you understand? On the top! Now we need to go in depth!

She attributes that to the inexperience of J. (the new tutor): unlike F., J. is not a school teacher and Teresa thinks she cannot deeply understand teachers' needs and difficulties. Moreover, the overlap of commitments linked to the start of the new Curriculum caused the lack of time for reading and studying in depth mathematical or teaching-related issues. According to Teresa, the previous year she positively faced the changes in her practice, because it was a gradual change and teachers had the time to both share and manage this change. Moreover, she recognizes some aspects of disorganization in the start of the new Curriculum, for instance there were no texts or handbooks ready for the new Curriculum. The work load, the uncertainties and the lack of an adequate support cause negative emotional reactions in Teresa and, according to her, in her colleagues. She claims: "we cry"!

The second interview is carried out in May, at the end of the second year of PFCM. The stress period has gone, Teresa is surely more relaxed and she shows a renewed enthusiasm towards the experience in PFCM. She is conscious that she changed her practice from the traditional way towards an inquiry oriented mathematics teaching. This change gave such unexpected results with students, that Teresa tells Maria with emphasis, underlying her happiness:

Teresa: Students from a school on the mountains getting A mark! I was admired! I was so happy! (...) I think that the few things made the last year have opened their minds and perspectives and they got A in maths!!!

She has not a definitive idea about the validity of her new method to teach maths:

Teresa: Perhaps this way to do maths is easier. Or rather it teaches to work better and then the students do everything more easily. I am not able to discover that! I need time to understand. Perhaps they understand more and if they understand they do better. Perhaps this new way makes it easier to understand.

She keeps attributing this success principally to the action of F.:

Teresa: He gave me a different perspective about mathematics, completely different. More practical, I do this in my classroom now. It is all a discovery! All, all, all! And I don't know how I can be so ahead with mathematics now.

Working Group 8

The enthusiasm of Teresa is not only justified by the good marks of her students but also by the changes in pupils' attitude towards the mathematical activity:

Teresa: It is very nice that they [students] realize that one answers in one way, another in a different way, another in a further way...but all the ways are right! "teacher, I have done it different from you!" I find it funny!

Due to these results Teresa's perceived self-efficacy as mathematics teacher grew:

Teresa: Now I think that I would be able to orient a group of teacher, do you understand? Help other colleagues! Now I feel that I have the capacities to do that! Now I know how to explain the new Curriculum.

She reports an episode in which other primary teachers recognized her as an expert in mathematics and she is aware that her beliefs about mathematics have changed:

Teresa: Some days ago a colleague told me: <Teresa, you that are learned in maths, explain that thing to me>. He said that and I thought I have never been learned in maths, they wouldn't believe that I didn't like maths! But it is true! Now I think that I view maths in another way and in another form.

This professional change makes Teresa more confident about possible results with pupils in the future. She is now convinced about her ability to obtain the expected goals of the new curriculum. Teresa concludes the second interview showing her awareness that with PFCM and the implementation of the new curriculum she has started a path towards autonomy in teaching maths and she wants to continue it:

Teresa: This year has been an experience. Now we have to begin to get organized.

In this growth, Teresa changes also her consideration of the textbook: from the feeling of being discouraged without it, to the idea that the textbook is only the starting point to develop teaching ideas individually.

Conclusions

Teresa is a difficult case: she has a personal history with mathematics full of difficulties and her emotions towards mathematics are strongly negative; moreover, she is a very experienced teacher with very deep-seated beliefs about mathematics and its teaching. The analysis of her case shows that, despite these difficulties, at the end of the two years of PFCM Teresa, her emotions and beliefs have changed radically. It is true that the main reason to enrol in PFCM was extrinsic (the need for career progression), but this decision gives Teresa the chance to engage in an unexpectedly significant developmental path:

Teresa: Sometimes we leave for a journey and we don't know why! But when we discover new things during the journey, we find new perspectives on life!

Teresa's change happens as a consequence of the encounter with a "*different mathematics*", introduced by the tutor, that Teresa implements both in the group sessions and in the classroom (the tutor in this phase represents a model and also a

Working Group 8

facilitator). The change in Teresa's view of mathematics is relevant also because it elicits an emotional change: Teresa begins to appreciate mathematics ("now I like it because I see that there are many ways to do the same thing"). In PFCM Teresa has had the possibility of developing a new idea of mathematics, to learn aspects of mathematics that she ignored and to appreciate a more open method to teach mathematics (related and consistent with her new view of mathematics). This possibility has originated a virtuous process in which Teresa develops the pleasure to do and teach maths, increasing her perceived self-efficacy towards mathematics and its teaching. In this process Teresa changes her attitude towards mathematics and she is rewarded and also comforted by students' reactions (and results) to her new way of teaching mathematics.

It is a process and, like all processes, on the one hand it is full of crossroads and on the other hand it needs time (we cannot expect to get radical changes without time expense). The structuring of PFCM (through the group sessions where the teacher can explain his/her doubts and the continuous support of the tutors) provided a great help to Teresa in overcoming the crossroads she met; concerning the time variable, in our analyses we could notice how the second year was crucial to realize the change in Teresa's attitudes and practices (it is important to underline that PFCM is one of the few in-service teachers programs lasting for two years).

We are aware that our analysis is limited to a single case, nevertheless we think that this case has the strength of an *existence theorem* in mathematics: a radical change of in-service teachers' attitude towards mathematics and its teaching is possible also when it appears to be very difficult to be realized.

Furthermore, as emerges from our analysis, the change we observed is due to PFCM's specific features, that provided the necessary conditions to overcome the teacher's difficulties, by paying attention to content, to teachers' practice and to the affective side of teaching at the same time. We think that Teresa's case sheds light on the great potential of this teacher education model for the professional development of in-service teachers.

FEAR OF FAILURE IN MATHEMATICS. WHAT ARE THE SOURCES?

Marilena Pantziara^{1,2} and George Philippou²

Cyprus Pedagogical Institute¹ –University of Nicosia²

This paper presents some results of a larger study that concern the causes of students' fear of failure in mathematics. Data was collected from 321 sixth grade students through a questionnaire comprising five-point Likert-type scales measuring among other constructs students' fear of failure and self-efficacy beliefs: An observation protocol was developed to identify teachers' practices fostering students' fear of failure. Findings revealed that fear of failure is a complicated affective construct based on several sources such as family context, students' characteristics and teachers' practices. The implications of these findings for understanding and improving students' behaviour in the mathematics classroom are discussed.

Keywords: primary students, fear of failure, self efficacy, teachers' practices.

INTRODUCTION

Research on achievement motivation provides empirical data about the nature and consequences of fear of failure (FF) (Conroy & Elliot, 2004; Macgregor & Elliot, 2005). Particularly, in Educational Psychology, achievement motivation theory emphasizes FF as a determinant of students' behaviour and performance (e.g. Elliot & Church, 1997), however there is little research on reasons why individuals are fearful of and motivated to avoid failure in mathematics. In recent studies the origins of FF were found in students' family context (parental socialization) and in students' associated feelings of shame (Macgregor & Elliot, 2005). In mathematics education, negative feelings have been reported by researchers such as fear, anxiety and frustration and their relation to students' mathematics performance (Ho et al., 2000) has been established. However, there is a need to investigate causes of students' FF in the mathematics classroom.

In this respect the present study investigates variations in students' internal and family characteristics and focuses on teachers' practices in the mathematics classroom that may cause students' FF. By raising awareness of the negative consequences of students' FF on their mathematical performance and on their stance towards mathematics, we believe that the results of the study will shed some light on factors that may lead to the development of FF in mathematics and inform teachers about desirable and undesirable practices in the classroom.

THEORETICAL BACKGROUND AND AIMS

Fear of Failure in Educational Psychology

Working Group 8

Research on motivation identified the motive to avoid failure or more commonly fear of failure, as an energizing means for human behaviour (Conroy & Elliot, 2004). McGregor and Elliot (2005, p.219) state that FF is a self-evaluative framework that influences how the individual defines, orientates to, and experiences failure in achievement situations. More explicitly, an individual with a high FF perceptually and cognitively orientates to failure-relevant information and thus encounters anxiety prior to, and during, task engagement. He/she seeks to avoid failure by avoiding the situation, by quitting or withdrawing effort, or by trying hard to succeed and thus avoid failure. The core emotion of FF is most likely shame, a devastating emotion that entails a sense of one's global incompetence. Other origins underlying students' FF mentioned by these researchers were students' relationship with their parents and social background. Specifically, students' high in FF had mothers who punished failure but reacted neutrally when the students were successful or they had mothers who set high standards for achievement but believed that their children could not reach them. Among other causes of students' FF identified by researchers is the experience of embarrassment, the devaluation of one's self-esteem and also that important others may become upset, Conroy, Poczwardowski and Henschen, 2001 (in Conroy & Elliot, 2004). In the context of the hierarchical achievement goal framework proposed by Elliot and Church (1997), motive-based and goal-based variables appeared to be an integral part. Elliot and Church (1997) assert that FF negatively predicts adaptive behaviour. Particularly, FF is found to negatively predict mathematics performance and interest through achievement goals (e.g. Zusho, Pintrich & Cortina, 2005) and it is negatively correlated to self-efficacy beliefs (Pantziara & Philippou, 2006).

Fear of failure in Mathematics Education

In mathematics education, a term that is close in meaning to Fear of Failure is mathematics anxiety (Ho, et al., 2000). Mathematics anxiety has been investigated as a two dimensional construct, in a two factor model comprised of affective and cognitive dimensions. Affective anxiety refers to an emotional component of anxiety such as fear, feelings of nervousness, tensions etc. Cognitive anxiety refers to the worry component of anxiety which is often displayed through negative expectations, preoccupation with failure and self-deprecatory thoughts (Ho et al., 2000, p.2). The conceptual nature of fear of failure as developed in the realm of Educational Psychology we believe is closer to the cognitive anxiety as described above.

Similar results to the ones in Educational Psychology have been reported in mathematics education with mathematics anxiety correlating negatively to students' mathematics performance and behaviour. The indirect effects of mathematics anxiety are worth noticing, even in cases when the negative correlation with performance is poor, such as students' negative attitudes to mathematics, avoidance of mathematics classes and elementary school teachers spending less time in teaching mathematics. (Ho et al., 2000; Pantziara & Philippou, 2006).

We limited our attempt to investigate multiple sources underlying FF in mathematics to the context of a socio-constructivist perspective on learning (Op't Eynde, De Corte & Verschaffel, 2006). More specifically Op't Eynde et al. (2006) recognised the close relation between (meta) cognitive, motivational and affective factors in students' learning and problem solving. They believed that students' understanding of, and behaviour in the mathematics classroom is a function of the interaction between who they are (their identity), and the specific classroom context. Students' identity, their values and what matters to them and in what way is revealed to them through their emotions (Op't Eynde et al., 2006). In this respect, students' attitudes toward mathematics are the outcomes of a conscious or unconscious personal evaluation of mathematics, the students' self and their mathematics learning situations.

Based on this theoretical framework and in an attempt to inform educators as to the factors creating students' FF, we investigated variables regarding students' mathematical performance and self-efficacy beliefs, mothers' and fathers' educational background, as well as variables referring to the context of learning mathematics (teachers' practices) that may influence students' FF for mathematics.

Self-efficacy beliefs

Friedel, Cortina, Turner, and Midgley (2007) refer to academic self-efficacy as children's confidence in their ability to master new skills and tasks, often in a specific academic domain such as mathematics. In this study we consider self-efficacy beliefs in relation to broader types of tasks (mathematics tasks) and not to specific ones (e.g. fraction tasks) to attain broader results; but not seeking to establish a general competence construct.

Numerous studies have found that students with high self-efficacy beliefs are more devoted, show intense interest, work harder, persist longer and have fewer adverse emotional reactions when they come across difficulties, than students who doubt their capabilities (Zimmerman, 2000). Also self-efficacy beliefs were found to be related to mathematical performance (Zimmerman, 2000; Pantziara & Philippou, 2007).

Students' self-efficacy beliefs which manage the demands of academic tasks were found to have an emotional influence by decreasing their stress, anxiety and depression, Bandura, 1997 (in Zimmerman, 2000). Moreover self-efficacy beliefs were found to be more predictive of mathematical performance than students' mathematics anxiety, Pajares and Kranzler, 1995 (in Zimmerman, 2000). These results suggests that educators should focus more on fostering positive characteristics in students, like self-efficacy rather than merely diminishing negative characteristics like anxiety and FF.

Instructional practices

Working Group 8

Elliot and Church (1997) draw attention to the role of teachers' practices in the classroom; they note that if the setting is strong enough, it alone can establish situation-specific characteristics that lead to different motivational constructs, either in the absence of a priori propensities or by overwhelming such propensities. Earlier studies in the context of achievement motivation and mathematics education specified various classroom instructional practices that contribute to the development of different patterns of motivation and achievement outcomes (e.g. Ames, 1992; Patrick, Anderman, Ryan, Edelin & Midgley, 2001; Stipek et al., 1998).

Achievement motivation theorists, relying on a large literature on classroom environments, proposed six sources that contribute to the classroom motivational environment represented by the acronym TARGET (Task, Authority, Recognition, Grouping, Evaluation and Time). All these sources have been examined with regard to teachers' specific practices. Several studies in classroom environments have shown that teachers' different practices in each of these sources ended in different levels of students' motivation in the classroom. In the mathematics education domain, Stipek et al.'s (1998) study, referring to instructional practices and their effect on learning and motivation, found that the affective climate was a powerful predictor of students' motivation and mastery orientation.

The various and vital consequences of students' FF in the mathematics classroom together with the absence of studies investigating the sources of their FF obliged us to identify the origins of this construct by investigating students internal and contextual characteristics. In this respect, the purpose of this study was:

- To test the validity of the measures of the factors, fear of failure and self-efficacy, in a specific social context.
- To identify students' characteristics (mathematical performance, self-efficacy beliefs, mothers' and fathers' educational background) which affect the level of their fear of failure.
- To identify teachers' practices that trigger students' fear of failure, using an observational protocol that includes convergent variables referring to instructional practices in the classroom.

METHOD

The participants were 321 sixth grade students (136 males and 185 females) from 15 intact classes and their 15 teachers. All student-participants completed a questionnaire reflecting among other motivational constructs (achievement goals, interest), fear of failure and self-efficacy beliefs.

We further collected information about the students' parents, including their educational background. We measured students' mathematics performance through a specially constructed mathematics test on fractions. Most of the tasks comprising the test were adapted from published research and specifically concerned students'

Working Group 8

understanding of fraction as part of a whole, as measurement, equivalent fractions, fraction comparison and addition of fractions with common and non common denominators (Lamon, 1999).

Herman's Fear of Failure scale (Elliot & Church, 1997) was used to measure students' FF; Herman's 27-item Fear of Failure scale was revised by Elliot and Church (1997) who tested its reliability (Cronbach's $\alpha=0.88$) and construct validity. A specimen item from the nine items we used in the study was "I often avoid a task because I am afraid that I will make mistakes". Students' self-efficacy beliefs were measured using the five scale measure of the Patterns of Adaptive Learning Scales (PALS) (Midgley et al., 2000). The items measured students' perception of their competence to do their work in the classroom. A specimen item was "I'm certain I can master the skills taught in mathematics this year" which the researchers reported had a reliability of $\alpha=0.78$. We adjusted the items in the scale to measure students' perception of competence in the mathematics classroom.

For the analysis of teachers' instructional practices we developed a protocol for the observation of teachers' practices in mathematics in the 15 classes. The observational protocol was based on the convergence between instructional practices described by Achievement Goal Theory and the Mathematics education reform literature. Specifically, we developed an inventory of codes around six constructs, based on previous literature (Ames, 1992; Patrick et al., 2001; Stipek et al., 1998), which were found to influence students' motivation and achievement. These six constructs were: task, instructional aides, practices concerning the task, affective sensitivity, messages to students, and recognition.

The construct *task* included algorithms, problem solving, teaching self-regulation strategies, open-ended questions, closed questions, constructing the new concept on an acquired one, generalizing and conjecturing. We also checked whether teachers made use of instructional aides during their lesson. *Practices concerning the task* included the teacher giving direct instructions to students, asking for justification, asking multiple ways regarding the solution of problems, pressing for understanding by asking questions, dealing with students' misconceptions, or seeking only for the correct response, helping students and rewording the question posed. Behaviour referred to *affective sensitivity* included teachers' possible anger, using sarcasm, being sensible to students, having high expectations of the students, teachers' interest towards mathematics or teachers' fear for mathematics. *Messages to students* included learning as students' active engagement, reference to the interest and value of the mathematics tasks, students' mistakes being part of the learning process or being forbidden, and learning as receiving information and following directions. Finally, *recognition* referred to the reward for students' achievement, effort, behavior and the use of external rewards by the teachers. During two 40 minute classroom observations for each teacher, we were able to identify the occurrence of each code in each structure.

RESULTS

Since we have conducted an exploratory factor analysis involving 302 students concerning the same scales (Pantziara & Philippou, 2006), in the present study we have proceeded with Confirmatory Factor Analysis using structural equation modelling and the program EQS (Hu & Bentler, 1999) in order to identify the factors corresponding to fear of failure and self-efficacy beliefs. To this end, we followed a process including the reduction of raw scores to a limited number of representative scores, an approach suggested by proponents of Structural Equation Modelling (Hu & Bentler, 1999). Particularly, regarding FF, some items were deleted because their loadings on the factor were very low and some items were grouped together because they had high correlation with each other. The reliability for the factor FF was Cronbach's $\alpha=.726$ and for the factor Self-efficacy was Cronbach's $\alpha=.710$. The correlation between the factors was $-.609$.

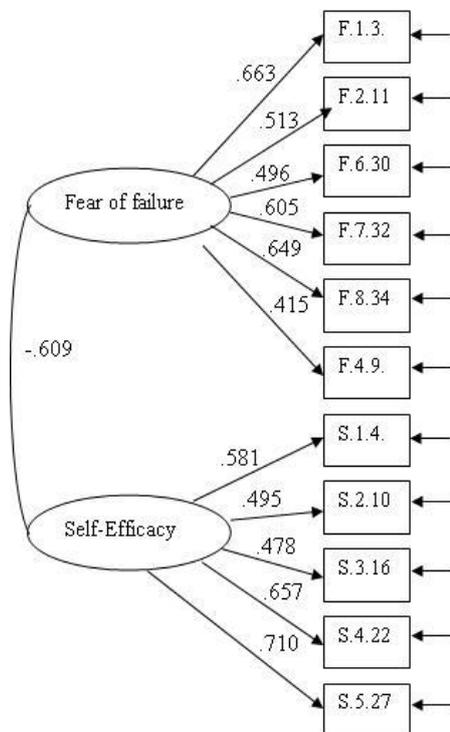

Fig 1: Two factor measurement model

To assess the fit of a two factor measurement model with correlation between the factors (FF and self-efficacy) we used maximum likelihood estimation method and three types of fit indices: the chi-square index, the comparative fit index (CFI), and the root mean square error of approximation (RMSEA). The chi square index provides an asymptotically valid significance test of model fit. The CFI estimates the relative fit of the target model in comparison to a baseline model where all of the variable in the model are uncorrelated (Hu & Bentler, 1999). The values of the CFI range from 0 to 1, with values greater than .95 indicating an acceptable model fit. Finally, the RMSEA is an index that takes the model complexity into account; an RMSEA of .05 or less is considered to be as acceptable fit. The fit indices supported good fit of the model as

Figure 1 shows ($\chi^2 = 68.908$, $df = 43$, $p < 0.000$; $CFI = 0.961$ and $RMSEA = 0.044$). In order to investigate the second aim of the study, regression analysis was performed to determine which of the antecedent variables (self-efficacy beliefs, students' mathematics performance) predicted students' FF. Multiple regression analysis revealed that self-efficacy beliefs and students' performance were negative predictors $\beta = 4.346$, $F(36.413)$, $p < 0.001$ of students' FF. Specifically, the regression equation was:

Students' FF = $4.346 - 2.18 \times \text{self-efficacy} - 3.52 \times \text{mathematics performance}$.

Working Group 8

One-way ANOVA (GLM1) indicated a statistical significant difference between the FF of students whose fathers had different educational background, $F(5, 290) = 2.569, p < 0.05$. Hochberg's GT2 post-hoc test revealed that students whose father had low educational background (gymnasium) reported a higher fear of failure ($M=2.584$) than students whose father had higher educational background (postgraduate studies), ($M=1.996$). No statistical significant difference was found between students' FF whose mothers had different educational background.

Investigating the third aim of the study, we used one-way ANOVA (GLM1) to identify possible significant differences between students' FF placed in different classes. The analysis showed significant differences between classrooms in students' FF, $F(14, 300) = 2.545, p < 0.05$. Gabriel post-hoc test identified that students in class 11 and in class 13 had non-significant means. Specifically students in class 11 declared the highest FF in mathematics (Mean=2.93) and students in class 13 the lowest FF in mathematics (Mean=2.06). Worth noticing is that students in class 11 performed better in mathematics (Mean=10.20) than students in class 13 (Mean=9.11).

Analysis of the teachers' observations

To assess teachers' practices we calculated the mean score of each code for the two observations using the SPSS and creating a matrix display of all the frequencies of the coded data from each classroom. Each cell of data corresponded to a coding structure. Being aware that FF constitutes a complicated construct, a first analysis of the observational data involved isolating the two classes at the highest and lowest extremes of specified motivational construct and comparing the means of each code in the six structures to identify commonalities and differences in teacher behaviours and instructional practices in the two classes. This approach is similar to the one used by Patrick et al. (2001).

T11 (the teacher in class 11 where the highest FF appeared) had 15 years of experience, a strong background in mathematics and a master's degree in mathematics education. T13 (the teacher in class 13, where the lowest FF appeared) had 29 years of experience, and lower qualifications in mathematics. As far as it concerns the *task*, T11 used more problem solving activities than T13, while T13 used more routine activities than T11. Teacher 11 used less open-ended questions and more closed questions than T13. During the observations teacher T11 taught problem solving strategies, while T13 did not. T11 did not connect new mathematical knowledge with the students' existing knowledge and he/she did not make connections between the mathematical ideas while T13 did so. T11 did not give students the opportunity to generalize or conjecture while T13 did so. T11 made use of visual aids in the mathematics lesson, while T13 did not. Relating to *practices concerning the task*, T13 was observed giving direct instructions to students while T11 did not. T11 asked the students to provide reason for their choices and solution plans more than T13 while T13 was observed asking for multiple solutions for a

Working Group 8

problem and pressed students for understanding more than T11. Dealing with misconceptions was observed in T11's class while in many cases T13 accepted the correct responses from students without any explanation. While both teachers gave individual help to their students, T11 gave more individual help than T13. As far as practices of *affective sensitivity* were concerned T11 was observed in some instances showing anger and using sarcasm while T13 did not. None of the other affective variables were observed. With respect to *messages* sent to students, both teachers informed students that erroneous answers were part of the lesson with T11 doing so with greater frequency than T13. Concerning *recognition*, both teachers rewarded students for their mathematical performance, while T11 also verbally rewarded the students' for their efforts. T11 gave rewards publicly to the students.

CONCLUSION

Regarding the first aim of the study, data revealed that factors referred to the two motivational constructs (FF and self-efficacy beliefs) were confirmed as present in a different social context. The data referred to the second aim of the study revealed that a source of FF could be traced to students' family context (Macgregor & Elliot, 2005). The explanatory factors for these findings were the fathers' job, social status and the consequences of these factors (e.g earnings) or the help students receive whilst engaged in their work at home. In addition, students' mathematics performance and their self-efficacy beliefs were found to predict negatively their FF. Numerous studies (e.g. Ho et al., 2000; Pantziara & Philippou, 2006; 2007) revealed that students' mathematics performance negatively predicts students' FF. Naturally students with low mathematics performance may more often experience feelings of shame and incompetence in the mathematics classroom, both feelings were found to be implicated in students' FF (e.g. Mcgregor & Elliot, 2005). Moreover, other studies (Pantziara & Philippou, 2007) revealed the negative relation between students' self-efficacy beliefs and their FF. Students' positive self-efficacy beliefs concerning their ability to manage academic task demands, influence them emotionally and thus decrease their stress, their anxiety and depression. In addition the positive relation between students' self-efficacy beliefs and their mathematics performance may contribute to a limitation of their FF. Instructional and social influences are found to be the most influential source of students' self-efficacy (Zimmerman, 2000). Therefore this study indicates that educators who work in such a way that students' self-efficacy beliefs are raised will help the students confront unpleasant situations.

Regarding the third aim of the study, we uncovered that students' FF in mathematics is sensitive to the classroom context, finding statistically significant differences in students' FF from different classes. We found that teachers' practices contributed to students' different motivational constructs (e.g. FF) in line with other studies (Patrick et al., 2001; Stipek et al., 1998). Here we discuss these practices in parallel with the findings of other studies, being aware that the identification of teachers'

practices is not easy to attempt. Students in the class with the highest FF had higher average mathematics performance than students in the class with the lowest FF. This complexity may be due to the close interaction between teachers' practices and students' other motivational and cognitive factors (Opt' Eydne et al., 2006).

Our results indicate that affective *sensitivity* is the most predictive structure for students' FF, which is in line with the results of Stipek et al. (1998). Stipek et al. (1998) revealed that teachers' positive affect was the most predictive variable in students' positive emotions. Our conclusion was based on observations showing that in a class with high FF, the teacher had knowledge of and used practices that have been shown to raise students' positive affect (use of problem solving activities, giving help, errors part of the lesson). However even the traces of anger and sarcasm in the classroom might have proved to be stronger than these positive practices in affecting students' FF. Anger and sarcasm may bring shame and embarrassment to students, which are both found to be origins of students' FF. Similarly, Patrick et al. (2001) described classes characterized by negative motivation in which teachers insulted students. Another practice found to affect students negatively belongs in the category *recognition* and refers to making rewards to students public. Rewarding publicly may raise competition between students affecting them negatively (Ames, 1992). Practices from the category *task*, such as the use of open – ended questions, making conjectures, and connecting new knowledge to existing knowledge were observed in the class with low FF. These practices were found by researchers (Patrick et al., 2001; Stipek et al., 1998) to raise students' motivation and our results indicate also may be considered as diminishing students' FF. From category *procedures concerning the task*, discussing multiple solutions of a problem and pressing students for understanding were also observed in class with low FF. Lastly giving individual help to students was also a practice observed in the low FF class.

Fear of failure is found to be a multiphase and complex structure with various consequences in students' performance and behaviour. More research is needed to illuminate origins of students' FF especially in the educational setting. Such information will guide teachers so as to avoid certain practices that increase students' FF and therefore use practices that raise students' motivation to learn mathematics.

INTRODUCTION TO THE PAPERS OF WG 9: LANGUAGE AND MATHEMATICS

Maria Luiza Cestari, University of Agder, Kristiansand, Norway

Alain Mercier, Université de Provence, Marseille, France

Pier Luigi Ferrari, Università del Piemonte Orientale, Italia

Konstantinos Tatsis, University of Western Macedonia, Greece

INTRODUCTION

Maria Luiza Cestari

The presentations and discussions based on written papers submitted to Working Group 9 focusing on language and mathematics reveal a multiplicity of theoretical backgrounds and, at the same time, the use of methodologies from different areas of research, particularly from social sciences. The mathematical topics and the way in which they have been analysed demonstrate that this area of research in Mathematics Education continues to be in constant expansion. This fact reflects the intersection of disciplines from different areas of knowledge which contribute to illuminating the complexities observed in mathematical lessons.

In connection with the structure and group dynamics, the sections were divided into time slots of 40-45 minutes for each presentation and had as a basic schedule the following steps: 1. Authors presented the main ideas of their papers including research questions, theoretical framework, methods and main findings. Some have also showed a video or introduced transcriptions of the empirical material. 2. Clarifications requested by the audience; 3. First discussant commented on the paper and raised questions or issues for discussion; 4. Small group (2- 3 participants) discussed together in order to point out issues which caught their attention; 5. A whole-group discussion. 6. Second discussant made central remarks and gave feedback to the author. On many occasions, at this point, the author responded to the comments, and included new insights concerning the understanding of his work.

For the presentation of posters we organized a special conference section: the authors displayed their posters before the section began, participants had the opportunity to read them and during the section a short time slot was allocated to every author. Participants were invited to comment and discuss special issues and contribute new ideas.

In relation to the topics approached by the authors, as has been observed and pointed out in earlier Working Groups, the variety of mathematical concepts and ways to treat them in discourses has been remarkable. From a total of 10 papers, four have focused on mathematical concepts, four on ways in which mathematics has been treated in classrooms conversations and two related to teacher's identity and

Working Group 9

bilingual students. It is important to mention that in the majority of studies, empirical material – in general from classrooms – is included. This fact has facilitated the group discussions particularly with respect to the focus on the object analysed and implications for theoretical development.

In the first group of papers the mathematical concept has been the focus, for example the one by Rønning analysing 8-year-old pupils engaged in activities related to different aspects of symmetry: reflection (design of symmetric pictures in various ways) and rotation (building three dimensional objects and being encouraged to talk about them using mathematical words). Coppola, Mollo and Pacelli also analyse episodes involving children from primary school. They show convincingly how “*actions* of shortening the language sentences and checking the equivalence between two sequences in two activity systems, allowed the children to *construct the concept of equivalence*”.

Morgan and Alshwaikh in a teacher experiment with students from a secondary school in year 8 (ages from 12 to 13 years) that includes the class teacher, the researchers and a student teacher are concerned with “the evolution and use of a system of gestures for communication about movement in three dimensional space”. They make distinctions between movements related to 2D and 3D space showing the contrast between everyday vs. specialised resources, using the concept of rotation.

Another study where the mathematical concept has been the focus is the one by Bardelle. From a pragmatic perspective, particularly the functional linguistics and a semiotic approach, she analyses how the concept of infinite and unbounded sets is used among seven second-year undergraduate mathematics students. The author pointed out that they do not recognize the importance of mathematical definitions. Her data showed also that different systems of representation evoke different meanings related to “bounded/unbounded” and “finite/infinite” sets.

Among the second group of papers, four of them focus on the social interaction in the classroom. The first one by Brandt and Höck analyse transcribed interactions by dyads using a framework provided by conversation analysis. Two collaborative processes are identified and compared illuminating chances and as well impediments in problem solving situations. They pointed out the possibilities of a collective cognitive convergence being productive and also provoking limitations to the moment when the problem is not anymore perceived as the focus of conversations. The second one by Gellert presents an exemplary episode between a teacher and two students discussing the decimal place value system in a class of fourth graders at a primary school. The concept of contention is used to locate a point which presents different possibilities for interpretation. One of the concluding remarks is related to the fact that “the engagement in the point of contention and the arguments seem to be difficult and unfamiliar” especially at these pupils’ age. The third study by Ingram, Briggs and Johnston-Wilder focuses on turn-taking in secondary mathematics lessons including pupils aged 12-13 years, also with a conversation analysis

Working Group 9

approach. In all lessons it has been observed that turn-taking is controlled by the teacher. Three situations have been identified from the turn-taking analysis, all of them involving self-selection of a pupil as the next speaker. Ingram and colleagues locate the first when pupils ask their own questions; the second when they initiate or perform repairs related to the teacher's previous turn or a peer's turn and the third when they respond to indirect teacher questions. At the end of this study, the author elaborates on an open question related to the effectiveness of this kind of interaction compared to the more "traditional" interactions between teacher and pupils. We could say that this question has been open for a quite long time in this area of research. And the fourth study by Planas and Morera is related to two theoretical constructs: revoicing ("re-telling") and collective mathematical argumentation. Data from secondary mathematical classrooms are analysed by a group of mathematics teachers and researchers. Some of the data shows how students' use of revoicing can reinforce mutual understanding. The authors exemplify this phenomenon when "a student partially explains an argumentation, and another in the group uses revoicing to emphasize particular aspects of that argumentation..." This additional information is recognized as a facilitator for a more adequate mathematical understanding.

The third group of studies includes the works by Tatsis and Ní Ríordáin. Tatsis presents a study where language is conceived as a tool for shaping teachers' identity. Data consists of a collection of narratives registered during an in-service training course. Typical examples show how the notion of identity as narrative can be more operational than the beliefs and attitudes approach to teaching. Ní Ríordáin introduces a working model for improving mathematics teaching and learning for bilingual students. This model has been elaborated basically from data generated in the Irish context. The focus is on the transition from Irish language Gaeilge-medium mathematics education to English-medium mathematics education in Ireland. The description of the working model includes Mathematics Understanding, Pedagogy and Culture and the so-called quartet: Mathematics Understanding, Bilingual Factors, Conceptions of Mathematics and Language Use.

From the brief presentation of papers above we can identify three main research focuses: 1. the mathematics content and how it is conveyed in communication; 2. the interaction in the classroom; and 3. new topics emerging from recent theoretical and methodological developments, for example, mathematics teachers' identity. Even though the group of participants in this Working Group 9 has been changing from conference to conference, we still have a stable commitment to advance knowledge in this research area of mathematics education.

INFINITE AND UNBOUNDED SETS: A PRAGMATIC PERSPECTIVE

Cristina Bardelle

University of Eastern Piedmont ‘A. Avogadro’, Alessandria, Italy

This paper explores some of the ambiguities inherent in the notions of finite/infinite sets and bounded/unbounded sets for what concern Euclidean spaces. The study, carried out with seven mathematics students, shows that wrong attitude towards mathematical language is a major source of misconceptions about cardinality and boundedness. In particular, everyday use of mathematical terms combined with a lack of coordination of different representations proves to be a hindrance in the conceptualization of basic properties of subsets of Euclidean spaces.

INTRODUCTION

In the last years research in mathematics education has pointed out the central role of language in the learning of mathematics and has addressed this topic from a variety of perspectives.

The complexity of ‘mathematical language’ does not depend on the symbolic component only, but on all of the semiotic representations used in mathematics, such as symbolic notations, diagrams, figures, and verbal texts as well.

From the point of view of semiotics many studies stressed the importance of both treatment within the same semiotic system and conversion between different representations of mathematical objects as well (Janvier et al., 1987; Duval, 1993).

From a pragmatic perspective, and in particular within the functional linguistic framework some studies (e.g. Pimm, 1987; Morgan, 1998; Ferrari, 2004) provided ideas to interpret some language-related difficulties in the learning of mathematics. For example Ferrari (2004, p. 384) claimed “that students’ competence in ordinary language and in the specific languages used in mathematics are other sources of troubles”. In particular some studies pointed out difficulties arising from the overlapping of everyday language and mathematical language (see e.g. Tall, 1977; Cornu, 1981; Mason & Pimm, 1984; Ferrari, 2004; Kim, Sfard & Ferrini-Mundy, 2005; Bardelle, 2010). But not enough attention has been paid to the fact that most of mathematical terms are borrowed from everyday language and used with meanings different from everyday-life usage. The aim of this paper is to focus on this topic. In particular here we deal with the concept of boundedness and infiniteness of subsets of Euclidean spaces. The study of metric spaces and their properties is basic in the curricula of mathematics undergraduate students and the concept of boundedness is fundamental for the learning of other topological properties such as compactness.

Research questions

This research is aimed at investigating some typical students' behaviours concerning the recognition of bounded or unbounded subsets of Y^n , endowed with the Euclidean distance. For example, some students seemingly justify that 'a set is unbounded because it has infinite elements'. In particular, the study explores the interplay of pragmatic aspects with the flexibility in switching between different representations of bounded/unbounded sets and finite/infinite sets. In particular the research questions are:

- How the everyday meanings of the words 'finite/infinite' and 'bounded/unbounded' influence students' behaviour in the resolution of problems involving such words?
- What is the role of the formal definition of 'bounded/unbounded set' and 'finite/infinite set'?
- What are the factors (problem formulation, system of representation of the set, context, etc.) that might influence the way words like 'bounded/unbounded set' and 'finite/infinite set' are interpreted and used by undergraduate students?

THEORETICAL FRAMEWORK

The functional linguistics approach

Functional linguistics is a theoretical perspective (in the frame of pragmatics) that studies language in relation to its functions rather than to its form. According to this framework, the main functions of language are the *ideational*, *interpersonal* and *textual* ones (Halliday, 1985). In particular, the interpersonal function involves social and cultural aspects of language and language use, including the processes of dynamic and negotiated meaning generation through interaction.

Here I adopt the pragmatic notion of *register*, which has been thoroughly discussed from a functional linguistics perspective by Leckie-Tarry (1995). A register denotes a linguistic variety based on use that is a conventional pattern or configuration of language that corresponds to a variety of situations or contexts. Ferrari (2004), following Leckie-Tarry (1995), distinguishes between 'colloquial registers' and 'literate registers'. The former refer to the linguistic resources adopted in spoken communications prevalently but also in informal written communication such as sms messages, e-mails, etc. whereas the latter refer to written-for-others texts mainly such as books but also to formal spoken communication such as in academic lectures. Ferrari (2004, p.387) argued "that the registers customarily adopted in advanced mathematics share a number of features with literate registers and may be regarded as extreme forms of them" and provided evidence to corroborate this claim.

Semiotic approach

As mentioned before, registers used in mathematics are highly literate; in fact, the development of mathematics but also its teaching and learning requires the introduction of a variety of representations such as symbolic notations, verbal texts, geometrical figures, diagrams and so on. According to Duval (1993) *there cannot be noésis without sémiosis*, where *sémiosis* denotes the production of a semiotic representation and *noésis* denotes the conceptual learning of an object. Moreover Duval states that the cognitive functioning of human thought needs multiple semiotic systems and he applied his ideas to the learning of mathematics where very different representations occur. Duval makes a distinction between *treatment of a representation*, which is a transformation (manipulation) within the same semiotic system, and *conversion* (translation) between different semiotic systems³¹. For example, computing the sum of two fractions is an example of treatment, whereas translating a fraction into an equivalent decimal expansion is an example of conversion.

THE EXPERIMENT

The research involved seven second year undergraduate mathematics students at the University of Eastern Piedmont in Italy. The students were attending a Geometry course focused on point set topology and on introductory algebraic topology. Students had already dealt with the concept of finite/infinite set and of bounded/unbounded set in Y^n , endowed with the Euclidean metric, in their first year classes. In this second year course the definition of finite/infinite set is supposed as well known, whereas the definition of boundedness of a set is generalized to an arbitrary metric space, paying particular attention to Y^n with Euclidean metric. This study focused on Euclidean spaces only. The data have been collected from individual interviews. The interviews were semi-structured and based on two different kinds of questions.

Q1-questions

The first kind of questions were aimed to recognize if a given set in Y^n with Euclidean metric is unbounded and infinite. The sets were given by their graphical representation or by symbolic notations and in this case, whenever it was useful and possible, students were encouraged to represent it in the Cartesian coordinate system. Some examples of given sets are $\{1/n, n \in \mathbb{N} \setminus \{0\}\}$, $\{(x,y) \in Y^2 : x^2+y^2=1\}$,

$\{(x,y) \in Y^2 : y=x\}$, $\{(x,y) \in Y^2 : xy=1\}$, $\{(x,y,z) \in Y^3 : x^2+y^2=1, z=3\}$, $\{(x,y,z) \in Y^3 : x^2+y^2=3\}$, $\{(x,y) \in Y^2 : y=\sin x\}$, etc.

³¹ Duval used the term ‘register’ referring to a semiotic system; here ‘register’ is used with its pragmatic meaning only.

Q2-questions

The second kind of questions were aimed to understand the meaning of ‘finite/infinite set’ and ‘bounded/unbounded set’ used to answer to Q1-questions. Students were asked to say what is an infinite and unbounded set or to produce some examples.

The interviews were carried out in order to help students to achieve a proper understanding of the subjects as well as to identify their behaviours and the *concept images* (Tall & Vinner, 1981) they were adopting. The term ‘concept image’ is used “to describe the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes” (Tall & Vinner, 1981, p. 152). The generation of the concept image of an individual can be influenced also by the *concept definition* that is “a form of words used to specify that concept” (Tall & Vinner, 1981, p. 152). The concept definition can be different from the *formal* concept definition, i.e. a definition accepted by the mathematical community at large. Moreover Tall and Vinner introduced the *evoked concept image* as the portion of the concept image which is activated at a particular time. The concept image may have conflicting aspects that may be evoked at different times. When such conflicting aspects are evoked *simultaneously* they cause a cognitive conflict. In particular, Q2-questions investigated the concept definition and Q1-questions were aimed to study the influence of the symbolic and graphical representation on the concept image. The interviews were conducted, when appropriate, in order to cause cognitive conflicts helping students to understand the concepts involved.

SELECTED FINDINGS

Just two students (students A, E) out of seven showed no kind of problems dealing with the topic of this study. The remaining students presented difficulties that seem, as we shall see shortly, to be due to their lack of skills for the treatment of symbolic expressions, lack of coordination of representations of subsets of \mathbb{Y}^n ($n=1,2,3$) and also to the improper adoption of colloquial registers.

In what follows only the responses about the sets $\{(x,y) \in \mathbb{Y}^2 : x^2+y^2=1\}$ and $\{1/n, n \in \mathbb{Y} \setminus \{0\}\}$ are presented. This choice is due to the fact that the students were familiar with them and their conversion into the related graphical representation was within their reach and did not require a previous treatment of the symbolic representation, which would have been beyond the purpose of this study. Some results concerning more examples of sets, which were provided ad hoc to some of the students in order to better recognize their concept image, are also presented.

Table 1 summarizes the students’ answers concerning the boundedness of the set $\{(x,y) \in \mathbb{Y}^2 : x^2+y^2=1\}$.

Working Group 9

Student	$\{(x,y) \in \mathbb{R}^2 : x^2+y^2=1\}$	Explanation
A	Bounded	" $\{(x,y) \in \mathbb{R}^2 : x^2+y^2=1\} \subseteq [-1,1] \times [-1,1]$ "
B	Unbounded	" $x^2+y^2=1$ has infinite solutions, therefore the set is unbounded"
C	Bounded	"It is a circumference, it is bounded"
D	Bounded	"It is a circumference and hence it is bounded"
E	Bounded	" $\{(x,y) \in \mathbb{R}^2 : x^2+y^2=1\} \subseteq [-1,1] \times [-1,1]$ "
F	Bounded	"It is a circumference, it is bounded"
G	Bounded	"It is a circumference, it is bounded"

Table 1: Answers to the question on the boundedness of $\{(x,y) \in \mathbb{R}^2 : x^2+y^2=1\}$

The first thing to say is that all students, except B, recognized at a first glance that $\{(x,y) \in \mathbb{R}^2 : x^2+y^2=1\}$ is a circumference in the plane and were able to represent it graphically. Students A and E showed a literate use of mathematical language (literate register) and preferred the symbolic representation. The remaining students, except B, could not explain why the set is bounded. Therefore such students, among the others, were encouraged to say when a set is bounded/unbounded.

The set $\{1/n, n \in \mathbb{N} \setminus \{0\}\}$ revealed itself to be more troublesome for students. Table 2 summarizes the answers about its boundedness.

Student	$\{1/n, n \in \mathbb{N} \setminus \{0\}\}$	Explanation
A	Bounded	" $\{1/n, n \in \mathbb{N} \setminus \{0\}\} \subseteq [0,1]$ "
B	Unbounded	"It is unbounded because n varies in ∞ "
C	Unbounded	"It is unbounded on the right...the naturals are infinite and hence there is no end for this set"
D	Unbounded	"It is unbounded because there are infinite n "
E	bounded	"It is contained in $[0,1]$ "
F	bounded	"The set is bounded from above and below"
G	Unbounded	"It is not bounded because you get infinite fractions"

Table 2: Answers to the question on the boundedness of $\{1/n, n \in \mathbb{N} \setminus \{0\}\}$

Only three students (A, E and F) answered correctly. Since the explanation of student F, even if correct, seemed to be not so usual as a topologic argument, some investigations were conducted in his interview (see below). The remaining four students, among the others, were encouraged also after this question to give the definition of bounded/unbounded set and of finite/infinite set. In this case some students evoked a concept definition which was different from the one evoked after

Working Group 9

the first question. Table 3 summarized the responses of students about their concept definition of the boundedness of a set.

Student	What is a bounded/unbounded set in Υ^n ?	
A	“A set X is bounded if there exists a ball B such that $X \subseteq B$ ”	
B	She was not able to give a definition but she gave the closed interval $[0,1]$ as an example of bounded set in Υ and the interval $]0,1[$ as an example of unbounded set in Υ . She could not come up with an example in Υ^2	
C	“A set X is bounded if there exists a ball B such that $X \subseteq B$ ”	
D	She answered “An unbounded set is an infinite set” when she referred to sets that she could not visualize	She answered “A bounded set is a set placed in a limited space” when she referred to sets that she could visualize
E	“A set X is bounded if there exists a ball B such that $X \subseteq B$ ”	
F	“A set X is bounded if there exists a ball B such that $X \subseteq B$ or a product of intervals that contains it”	
G	She answered “An unbounded set is an infinite set” when she referred to sets that she could not visualize	She answered “A set is bounded when, from the drawing, it is in a narrow space” when she referred to sets that she could visualize

Table 3: Answers to the question on the concept definition of bounded/unbounded set

For what concern the concept of finite/infinite set all students grasped its correct meaning. All students did not give the formal definition but used a more colloquial (colloquial register) but effective argument as showed in Table 4.

Student	What is a finite/infinite set in Υ^n ?
all	All students answered that a finite set is a set with a finite number of points (or elements)

Table 4: Answers to the question on the concept definition of finite/infinite set

Data shows that students use an everyday meaning for the boundedness of a set even if their concept definition is correct and given with a literate register. Such a meaning is sufficient to give an answer to problems where the set is already drawn in the Cartesian coordinate system or students can sketch its graphical representation. In this case the definition of ‘bounded’ used in the everyday meaning in Italian language that is “something that has limits referring to space or time” clearly fits with the concept definition of students D and G. Moreover, it seems that also students C, F adopted this colloquial meaning since they are not able, at least

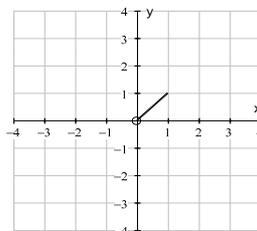

Working Group 9

apparently, to provide an explanation to the boundedness of the circumference (Table 1) even if their concept definition coincide with the formal one (Table 3). One has to highlight that this everyday meaning is not more sufficient in order to answer to problem $\{1/n, n \in \mathbb{N} \setminus \{0\}\}$ (Table 2). In this case all the students who gave an incorrect explanation (B, C, D, G) did not think of sketching the set, neither of working within the symbolic system to find an appropriate ball of \mathbb{Y} containing it. The symbolic aspect of the representation of this set seemed to evoke in these students the idea of infinite elements connected to the set of natural numbers, indeed a set that tends to infinity and hence with no upper bound. Here the matter is not that students did not understand the concept of ‘infinite set’. Rather, the first evoked meaning of ‘infinite’ in this context is colloquial, that is “something that never ends with reference to space and time” indeed something which is unbounded. The problem is not even that they could not represent it graphically. Indeed, the students were asked to sketch it and they did it correctly (sometimes with some help). After that they recognized that they were dealing with a bounded set. Notice that student B seemed to apply this reasoning also for the circumference since she could not sketch it (Table 1). During the interview students were asked to explain their apparently incoherent behaviour. Some examples of responses are:

- G: I used I used ‘infinite’ in order to justify that a set was unbounded because I imagined an infinite set as a set stretching to infinity.
- C: I think more to the idea of infinity in order to decide about the boundedness of a set.

The research proves also the everyday usage of the term ‘finite’ by student D, as one can see from the following transcript:

- 1 I: Is $\{(x,y) \in \mathbb{Y}^2 : x^2+y^2=1\}$ unbounded?
 2 D: It is a circumference [she draws it] ... it is bounded
 3 I: It is infinite?
 4 D: It is closed, not infinite.
 5 I: What does it mean that a set is finite?
 6 D: It is limited in space.
 7 I: Is the set [in its graphical representation]

- bounded?
- 8 D: Yes, it is
 9 I: It is infinite/finite?
 10 D: It is finite

Working Group 9

- 11 I: Can you find points belonging to it?
12 D: yes, for example $(1/2, 1/2)$, $(1/3, 1/3)$, etcetera, $(1/n, 1/n)$ no, then it's infinite!
13 I: Why did you answer finite before?
14 D: Because it seems finite from the drawing.

Also in this case the use of the colloquial register (colloquial definition of 'finite') prevailed on the literate one (mathematical definition of 'finite'). When she was asked to convert the set in the symbolic system she immediately could give the proper answer. This behaviour as the previous ones show that students are not aware of the role of mathematical language and of its functions.

Finally the research highlights another kind of behaviour due to a misleading interpretation of mathematical language. Student F showed no kind of problems with sets like in Table 1 and 2. Problems arose with sets like $\{(x,y) \in \mathbb{R}^2 : y = \sin x\}$, $\{(x,y) \in \mathbb{R}^2 : xy = 1\}$, $\{(x,y) \in \mathbb{R}^2 : y = \arctg x\}$, etc. where functions are involved. In this case the recognition of well known functions (both graphical and symbolic representations) evoked a meaning of 'boundedness' related to functions rather than sets. The following transcript shows this fact:

- 1 I: Is $\{(x,y) \in \mathbb{R}^2 : y = \sin x\}$ bounded or unbounded?
2 F: Bounded because it can assume values between -1 and 1

After some explanation about his wrong answer he declared

- F: I think that the set $\{(x,y) \in \mathbb{R}^2 : y = \sin x\}$ was in \mathbb{R} if I see something simple like $8^x = 8^y$ or $y = \sin x$ I don't see the other particulars.

Finally, the formal concept definition of bounded/unbounded set was showed to the students (B, D, G) that did not manage to provide it and they were asked if they remembered it. Student B answered that she could not remember it and the other two that they knew it but they did not think to use it.

DISCUSSION AND TEACHING IMPLICATIONS

This paper provides an example of a wrong use of mathematical language by some Italian mathematics undergraduate students. In particular, these students do not recognize the importance of mathematical definitions. Mathematical terms, such as 'bounded/unbounded' and 'finite/infinite', evoke different meanings at different times. This is a typical thinking habit that concerns the everyday-life language. In mathematical language, as well as scientific languages in general, terms are usually coined with one meaning only in order to avoid interpretative problems. This purpose should be shared with the students in order to prevent improper use of mathematical language. Moreover, since data showed that different systems of representation evoke different meanings of 'bounded/unbounded' and 'finite/infinite', another goal of mathematics education should be promoting flexibility in switching from one representation to another. By 'promoting flexibility'

Working Group 9

I mean, helping students not just to learn *how* to shift from a representation to another, but also to *think* of doing so, that is to work at metacognitive level. Actually, the students involved in this experiment, when prompted, were able to switch between the symbolic representation of sets and their graphical representation. Finally, we have to add that most of the students involved have great difficulty in the manipulation of symbolic representation (or ‘treatment’ in the sense of Duval (1993)). This issue has not been investigated in this research but it might be interesting to explore causes and connections between weakness in the treatment within the symbolic system and lack of awareness of the role of language in mathematics.

In my opinion a good practice of teaching, in order to promote the learning of the concept of boundedness of sets, should include not only the formal definition, but also examples of sets satisfying the definition as well as examples of sets that do not verify it. The choice of examples has to be done in order to evoke possible cognitive conflicts, for example like those presented in this paper. Some examples related to other topics can be founded in Tall and Vinner (1981). Moreover, when possible, following the idea of Duval (1993), sets have to be presented in at least two kinds of semiotic representations. Finally, a good practice should include the assignment of exercises requiring students to make explicit their concept definitions in order to help them to focus on the proper meaning of concepts.

MATHEMATICAL JOINT CONSTRUCTION AT ELEMENTARY GRADE - A RECONSTRUCTION OF COLLABORATIVE PROBLEM SOLVING IN DYADS

Birgit Brandt and Gyde Höck

Elementary dyads solving arithmetical problems have been the focus within this study. With regard to an interactional theory of learning mathematics, the exploratory focus are the students' acts and how these acts function on the emerging joint construction. Analysing the structure of individual participation brings light into joint construction mechanisms, described as different 'types' on the basis of Christine Howe's research project (Howe 2009). The micro-analytical analysis of transcribed discourses will highlight significant differences in the participation of one child interacting in two different dyads as well as in the emerging types of joint constructions.

INTRODUCTION

On the basis of social interaction as a fundamental element for individual learning, joint construction is giving a great chance of supporting each others ideas in the process of problem solving. Considering international studies aiming at the complex structure of interaction in peer group work, there are two main trends to mention. On the one hand, these studies focus on asymmetric peer group constellations, where there is one advanced group member taking the lead, to support the zone of proximal development (Vygotski 1978). On the other hand, they point out mainly symmetric dyads or groups, which are moving towards a new (mathematical) understanding in a more balanced way, by resolving socio-cognitive conflicts, emerging by different perspectives or strategies in peer interaction (e.g. Bearison, Magzamen, & Filardo 1986). Coordinating the different perspectives, the result of a joint constructed process can become more than an addition of different ideas or propositions.

TYPES OF CO-CONSTRUCTION IN PEER INTERACTION

Howe (2009) has been looking into the processes of joint construction in the developed collaborative settings for 8 to 12-year-old pupils, exploring motion under different conditions. In many years of research, Howe has focused on collaborative learning processes, collecting data from various group settings, and their way of creating an idea for a reasonable solution. Throughout these years, Howe has been following the question of how the underlying processes can transform the individual knowledge of each group member. In an extensive re-analyses, she concentrates on finding certain structures in the problem solving process of groups, to gain some hints of how the learners can progress by taking part in collective problem solving processes. Howe's analyses lead to two main forms of co-constructive processes, named as Type 1 and Type 2 joint construction (p.217).

Working Group 9

Type 1 indicates a discourse, where there are different group members involved in the process of problem solving, in a very balanced way. Everyone participates individually with their own ideas and, as a group, coordinate all contributions “into a relatively advanced whole” (p. 217). Given the fact that there are different ideas to consider, it needs a “coordination of competing perspectives” (p. 217) within the group. In the quoted study, Howe concentrates on “groups where members were different as regards ideas expressed at pre-test” (p. 223). Thus her examples are mainly considering the phenomenon of coordinating competing perspectives, although she does not restrict this Type 1 to situations where different opinions are discussed. The basic idea of this type is a relatively equal allocation of substantive contributions among the group members, which is consistent with a symmetric group constellation.

Type 2 describes a constellation where “only one idea has to be considered” (p. 218), as one group member is suggesting one idea which is accepted by the others. In this context, Howe underlines that “less advanced children progress when they work with more advanced peers” (p. 219). That does not mean that this type excludes constellations where the main idea is presented by a less advanced pupil, but “relatively advanced children are likely to be the source of appropriate ideas whose acceptance results in Type 2 joint construction” (p. 219). Thus, Type 2 can be characterized by unequal distributed substantive contributions of different members to the joint construction, which often goes along with asymmetric group constellations³²

The types represented by Howe serve us as a basis for our own reconstructions, on the empirical data of elementary pupils, solving mathematical problems. During our research, we found Type 1 and Type 2 in different variations and mostly in the allocation to asymmetric and symmetric constellations, as assigned above. We will expose this allocation in two different dyadic constellations, where one child is involved in both. In addition, we encountered a phenomenon of joint construction which in its whole dimension could not be classified by the existing types.

THE EMPIRICAL STUDY: COLLECTIVE PROBLEM SOLVING

As above mentioned, this paper is focused on the general idea of an interactional theory of learning mathematics and deals with everyday classroom interactions. Particularly, we analyse videotaped peer interactions, which originate from the project “Collective problem solving”³³ and has been based on the concept of learning by participating in collective argumentation processes (Krummheuer 2007). relying on the capability of the others leading to a result.

³² A more or less active participation in a problem solving process is not to compare with a “freeriding-effect“, where there are members of the group not been focussed on the shared task and only

³³ The project was sponsored by the Zentrum für Lehrerbildung, Schul-und Unterrichtsforschung of the Goethe-Universität Frankfurt (Feb. 2009 – Jan. 2010).

Methodological and analytical Background

In this study, collaborative learning will be discussed as a theoretical question, concerning a general understanding on how children learn. The research is design-based, which means that the object of investigation is the real-world-practice, which reverts to theoretically founded learning materials. In our study, the theoretically deduced collaborative learning settings were prepared by the involved teachers, for the application in their classrooms. Therefore, "...design-based research is concerned with using design in the service of developing broad models of how humans think, know, act, and learn." (Barab & Squire 2004, p. 5). We will not evaluate the settings, but we will explore the execution of them in the peer interaction. Given the fact that this empirical study occurs in every day classrooms, moments of collaborative learning environment can be accomplished, which render the possibility of collective problem solving.

We adopt qualitative methods for the analysis of transcribed interaction processes. The basic analysis method is a turn-by-turn reconstruction of the interaction processes that originate from ethno-methodological conversation analysis (basically pointed out in Sacks 1998). In addition, we reconstruct the participation structure by decomposing the everyday concept 'speaker' into more detailed analytical elements (cf. Krummheuer 2007). We included the production design in our analysis to trace the responsibility for the ideas emerging in the (joint) construction. Following Goffman's (1981) idea of decomposing, each utterance consists of three analytical aspects:

a) gestical or acoustical appearance, b) formulation and c) idea/motive. For instance, person A can introduce an idea to the discourse and person B can repeat the utterance more or less literally (e.g. as a kind of ratification), or can express the idea with their own words (e.g. to establish a common understanding). Taking into account the responsibility these aspects have, there are four ways of participation for the speaker of the actual utterance (+ gestical/acoustical appearance):

Role of the actual speaker	Idea	Formulation
author ³⁴	+	+
ghostee	+	-
spokesman	-	+
relayer	-	-

The last two forms (spokesman and relayer) ensure a stabilization of the negotiation of meaning, while the other two forms (author and ghostee) are challenging that negotiation, in the sense of enrichment as well as in the sense of threat to communication. Each interactive process is kept alive by balancing the two elements

³⁴ The denominations are adopted from Levinson (1988, p. 172).

Working Group 9

– and the success of group work among pupils depends on the fact how the differing ideas can be associated with each other in the interactive process.

Design of the study

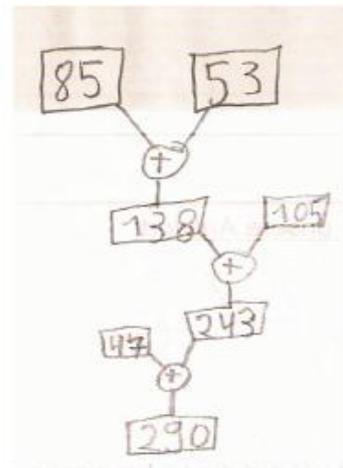

The research project took place in two elementary schools in Frankfurt a.M./Germany. At the beginning of the project, the two classes were joining the third grade, and after the summer holidays we continued with both classes during the first half of the fourth grade. The mathematic lessons we filmed were held by their mathematic teacher. Together with both teachers, we were developing four different main themes of arithmetical problem solving:

Theme	Form of cooperation	Start	Grade
written subtraction	think – pair – square	individual	3 rd
division with remainder	math-conference ³⁵		
number sequences	pair – double-pair	collaborative	4th
word problems	pair – cross-over-pair		

Over the whole period of the project, rules for cooperation were asked in classroom discussions and matched to the currently passed collaboration (cf. the “thinking together project”, e.g. Mercer & Littleton 2007). The above mentioned pairs were kept in the same combination together during the whole project (cf. Edwards 2007). It was interesting to follow the development of how two partners, who had to discuss considerably about the organisational way of co-operating, became dyads who were then able to better focus on the task itself, given the fact that there was less distraction from collaborating within the process of joint construction.

In this article we are concentrating on two transcripts of the last set of lessons, where two pupils are constantly working together on word problems. The first three lessons of this last theme were based on long-term constellations of dyads, trying to discover the arithmetical structure of a word problem and designing a diagram³⁶ of their strategy, as the following example is representing:

Your class teacher has asked you to bring some lego bricks to school, because you have to build something with it. All the children of your class are putting their lego bricks on the table. On table one there are 85 bricks, on table two there are 53, on table three there are 105 and on the last table there are 47 bricks displayed.

³⁵ In a small group of four pupils, each has to present their individual solution they worked out beforehand

³⁶ This diagram is called “Rechenbaum” in German.

Working Group 9

In the last lesson of this subject, the dyads were split and arranged into new pairs, by changing the partners (cross-over method). The main focus of our analysis is now on a dialog of a long-term dyad in the last setting: *Josefine and Janina and the remaining money*. We will contrast their dialog with an excerpt of the subsequent cross-over phase: *Josefine and Belen and their cookie-task*. By contrasting these two dyads, we encountered significant differences between the work flow of a long-term dyad and the interactional approach of a complete new collaboration. Following Howe, the joint constructions of the partnership between Josefine and Belen could be clearly classified as Type 2, in an asymmetric constellation (whereas Josefine is the ‘better mathematician’). The collaboration between Josefine and Janina, instead, does show some interesting characteristics which could not be found clearly classified within the two main types described by Howe.

Collaboration Process A: Josefine and Janina and the remaining money

Josefine and Janina are two female pupils which have been observed by the teacher as children with very similar performances in mathematics. Generally, both are able to resolve mathematical problems in the normal lessons, without further support. Their grading is usually quite high and they are seen as more competent in calculating and solving problems than most of the other children in their class. In the beginning phase of their team work they still had to discuss a lot about their way of organising the work flow. But during the lessons, the understanding towards each other was increasingly growing, to a point where many elements were resolved in a non-verbal way, by taking for granted that the other one understands and thinks similarly. For somebody supervising the two pupils, one got the impression of a dyad which collaborates on a very harmonic and equal basis, being productive and target-oriented, as you can see by the following extract of transcript:

86 M1 who is calculating/
87 Jo both
88 <³⁷ Ja [*pushes Josefine*] thirty-nine divided by >three
89 <Jo >three yes

One girl from another group, next to them, is asking who is responsible in their dyad for calculating the result. There are actually quite a number of teams, where the group members are dividing the tasks between themselves, such to have a clear responsibility of who is writing, reading, calculating or supervising the time. In this case, the spontaneous answer is “both”, and it goes to show how serious the participants take on the instructions from the teacher of really working together. This a typical sequence which characterizes their way of collaborating, and it will be highlighted by the following transcript.

60 Jo well once again\ *reading the word problem*. You have been saving your

³⁷ < signals simultaneously voiced utterances. In the utterances the overlapping is marked with >.

Working Group 9

- 61 pocket money for quite a while to be able to buy some presents.
62 Altogether you own 39 Euros. You want to keep one third. With the
63 leftover (Rest)³⁸ you spent 8 Euros on your parents.
65 Ja well then we have to calculate
66 Jo well this divided by three somehow/ but then there is
67 a remainder\ (Rest)
68 Ja yes remainder (Rest) is (incomprehensible) no with the leftover (Rest)
69 you spend eight Euros
70 Jo yes
71 Ja well thirty-nine Euros divided equals by divided³⁹ ...no one third divided
72 thirty-nine Euros divided by three
73 Jo yes

First of all, Josefine starts the problem-solving process by reading the task out loudly one more time. By reading the word problem out loud, she shares the information with her partner and provides some structure to a concrete beginning of the problem-solving process<60-63>. This starting point is implying the minimum which is required for a co-constructive process, as both are focused on the same problem. Janina is taking the next turn and makes the point of seeing the need to calculate <65>. She also demonstrates her interest to deal with the problem together with her partner by using the personal pronoun “we”. It is not clear if she would have completed her remark, but Josefine is offering the first idea how to translate the word problem into an arithmetic operation. Josefine’s idea is paraphrasing an important part of the word problem “one third”, into a concrete division by using “divided by three” <66>. Both seem to agree on this translation offered by Josefine, because there is no debate arising – this sequence is actually demonstrating a first mathematical idea shared between each other as a joint construction.

In the following lines, the word “leftover/remainder” (Rest) is shifting into the centre of attention as Josefine brings this point into consideration <67>, and Janina is at first assenting, but then feeding back the word “leftover/remainder” to the text, to underline the fact that with the “leftover” you spend eight Euros <68/69>. Josefine does agree with Janina’s point of view, by saying “yes” <70>. Her affirmation could be also interpreted as a signal for only listening and letting the partner keep the turn, but in both interpretations no contradiction emerges on the stage of interaction. The next turn is taken by Janina, with the attempt of translating their ideas into a first mathematical term. At first, it seems quite confused what Janina is trying to express in line<71>, but in the end she brings up the term $39 : 3$ <72>, and Josefine does

³⁸ In the original transcript, the girls were using the German word „Rest“ which stands for both left over and remainder. This caused the problem of mixing the meaning of the ‘leftover’ in the word problem with the understanding of division with remainders.

³⁹ “Divided by“ is translated as “geteilt durch“ in German and sometimes just the word „durch“ is representing the meaning of division in an everyday language: <71-73-German> also 39 Euro geteilt ist durch...nein ein Drittel durch 39 Euro geteilt durch 3.

Working Group 9

agree without having any problems of understanding <73>. In a similar way, they agree on having a remainder for this term, but after calculating the term, they assert:

95 Ja no there is no remainder (Rest)

96 Jo that's right, there is no remainder (Rest) ... this will be thirteen

After a short pause, Josefine proposes minus as a new operation to get a kind of “remainder/leftover” (Rest). Janina contributes with a new first calculation for the word problem and they finish the problem in the following way:

102 Ja thirty-nine minus eight

106⁴⁰ Jo minus eight equals thirty-one\ ..and now

109 Ja divided by three

113 wait a moment this will be ten but now you have one Euro leftover (übrig)

114 Jo yeah this will be ten remaining one

At the end, both are happy of having achieved a “remainder” (Rest) and they do not doubt their solution, even though they tie their result to the situation presented in the word problem <113, 114>. They close this word problem with the written answer: *She has got 10 remaining 1 for herself*. Thus, by starting with 39 minus 8, they jointly ‘produce’ a number (31) which ensures a remainder taking 3 as divisor.

The prompt way of supporting the input of the partner is characteristic of their joint constructions, and during the whole problem-solving process their way of communicating grows from this supportive answering to an overlapping conversation, where the last word or two are repeated by each other, before completing the sentence, up to a collective cognitive convergence⁴¹ where the ideas and sentences are merging into each other. Thus, only by taking utterances of both partners together, a substantive contribution to the joint construction will occur. The detailed analyses of their participation leads to the perception of having two equal “authors” within this problem-solving process, as they are both carrying forward their partner’s ideas and joining their input into one whole joint construction, where in the end they can sign their result to the word problem on a working sheet, agreeing that they both understand their approach to the solution.

Collaboration Process B: Josefine and Belen and their cookie-task

In contradistinction to Josefine and Janina’s highly symmetric joint construction, we are going to show another sequence of team work between Josefine and another female pupil of her class, named Belen. This dyad is a new constellation; these two

⁴⁰ Missing lines refer to a side dialogue.

⁴¹ The phenomenon of collective cognitive convergence in groups of people, who are interacting frequently together, has been discussed by several studies. For different aspects of collective cognitive convergence in cooperative learning see Teasley et.al. (2008). In particular, van Dyke Parunak, is engaged in this development between group members who work together over quite a long period of time, losing the capability of questioning themselves and being aware of the advantage of differing and contrasting ideas (e.g. Parunak et.al 2009).

Working Group 9

pupils did not work together on mathematic problems before this lesson. Belen is usually having some problems in solving mathematical tasks alone, which requires a lot of support by the teacher in the everyday lessons. Alike the dyad we have analysed above, this new team is taking the task as a problem which has to be resolved together – joint construction has also been built by these two pupils, but in a complete different approach than before.

Again, Josefine is setting up a joint focus by repeating the task as a spokesman of the teacher “well now we have to think up of a word problem” <45>. Belen throws in immediately an idea where Tom and Kim own respectively 55 and 50 clothes. Josefine’s reaction shows a sceptical attitude which is demonstrated by her way of questioning Belen’s input. After rejecting Belen’s first idea, Josefine phrases the following:

- 51 Jo .. well wait let’s do it rather let’s do it well mhmh on Sunday a
52 Christmas market takes place at the Opernplatz \ (square in front of the
53 opera) there\ there Belen sells Belen has– has got a
55 <Jo stall - has got hund red >eigh ty cookies
56 <Be >eighteen
57 Jo of these she sells ninetyfive\ so Josefine has got also a stall.. she has..
58 Be three. fourhundredfifty

Josefine induces her contribution as something new, not related to the former idea of Belen <51>. After rejecting Belen’s input, she places emphasis on the idea of working together: Within her new attempt of creating a word problem, she integrates Belen as a protagonist <53>. This could be seen as a kind of a face-saving act towards Belen after face-threatening her by rejecting Belen’s idea (cf. Brandt & Tatsis 2009). Furthermore, she reverts to the underlying structure of Belen’s suggestion, using two people (Belen and Josefine) and a certain amount of objects (cookies). But Josefine doesn’t leave it to the additional term Belen verbalised, as she is bringing in the subtraction by selling the objects <55>. At several stages, Belen contributes single numbers at the right moment <56-58>, such that Josefine can integrate them into their word problem while creating it. Later, Josefine prompts Belen to calculate:

- 110 Jo Belen now strain your head do you know what this plus that is
111 [*pointing at the work sheet*]
112 Be this is (incomprehensible)
113 Jo threehundredfive plus hundredninety
114 Be becomes than fourhundredninetyfive

Belen is also joining the process of developing the task, by calculating an addition problem which Josefine confers on her <113-114>. By analysing this new dyad, it highlights that Josefine, after taking on Belen’s first idea as a ghostee, is leading the team work process like a tutor, as she is the more capable one. She takes on the part of being the “author” of the word problem structure and of the final result. Belen

takes part as a “spokesman” and “relayer”. Thus, she is integrated in the joint construction of Josefina’s idea.

COMPARING AND CONCLUSION

Collating the two dyads, there is a special form of joint construction to emphasize: In the interaction between Josefina and Janina there is not even one moment of misunderstanding and there is no antithesis to the suggestion of a single person (like the direct rejection of Belen’s idea). They collectively reject their first joint construction (39 : 3) without even questioning each others ideas. Another interesting phenomenon is how the turn-taking is accepted by both partners in all moments of their problem solving. There is never a dissent between them which leads to a conflict or even a contradictive discussion. They are both responsible for creating their solution in a complete balanced way. This means that the joint constructions in their word problem solving process could not be classified as Type 2 – there may be one idea considered through the collaborative process of Josefina and Janina, but it is not a “relatively advanced contribution of one child becom(ing) a group product” (Howe, 2009, p.217, 218). Instead the two partners show a complete equality of how they develop and coordinate their resolution. Considering Type 1 as a coordination of substantive contributions from more than one child into a relatively advanced whole (Howe, 2009, p.217), it also does not encompass the complete phenomenon of Josefina’s and Janina’s joint constructions process, although it may fall under the category of Type 1, being a very special subcategory. It is a conjointly creation of a common idea, where the single turns of both partners gear into each other – and both partners are aware of this common idea just from the first glow in the interaction. Thus, this subtype involves elements of collective cognitive convergence and can be described as follows: Joint construction of one united idea, in complete symmetry, as one idea has to be considered from both partners from the beginning.

Something new is constructed, a new idea unfolded without any dissent, but resolving a ‘joint problem’ – even if the solution is not responding ‘correctly’ to the problem. In our example, the ‘mistake’ Josefina and Janina do is underlining the singularity of their joint construction – there is actually a real ‘problem’ to solve together and they find a collaborative way to surmount the difficulty.

This example of Josefina’s und Janina’s collaboration is highlighting the chances and impediments of working in dyads over a longer period of time, as collective cognitive convergence can be very productive on the one hand, as there are less misunderstandings between the team members, but on the other hand it can lead to such closeness that problems are not perceived anymore (cf. Parunak et. al 2009). Using the cross-over method as well as pair-square to bring in new ‘experts’ with new ‘ideas’ from outside, can help to detect these ‘blind alleys’ and offer new incitements for working more productively.

THE CONCEPT OF EQUIVALENCE IN A SOCIALLY CONSTRUCTED LANGUAGE IN A PRIMARY SCHOOL CLASS

Cristina Coppola, Monica Mollo, Tiziana Pacelli

Università degli Studi di Salerno - Italy

We analyze two episodes of a teaching experiment involving children of primary school. The children, handling a procedural language they previously constructed, single out equivalence rules. So they construct the concept of equivalence intuiting a semantic equivalence in the language. We adopt a qualitative approach mainly based on observational and ethnographic methods. We present a data analysis regarding how the children, in interaction, co-construct the solutions to the tasks, according to the activity theory and the epistemological triangle.

Key words: procedural language, equivalence, interaction

INTRODUCTION AND THEORETICAL BACKGROUND

The study we are presenting is part of a wider research, whose main aim is to analyse the relationship between language and the development of logical tools through linguistic-manipulative activities, in primary school classrooms. By *logical tools* we mean the skill to find and choose different strategies to solve problems regarding logical tasks. The activities regard both assertive and procedural aspects of the language. Both aspects play a fundamental role in the development of child's mathematical thinking (Gerla et al., 1990). In this paper we refer to a simple procedural language.

Our theoretical background refers on the one hand to the social-genetic constructivism (Perret-Clermont, 1979; Iannaccone, 2010) and to the contributions of the soviet cultural-historical school (Vygotskij, 1934; Leont'ev, 1978), on the other hand to formal logic [1] (Kneale, 1962). The latter can represent a basic point of reference for the study of the development of mathematical thinking provided it is seen as the explicit expression of the strong relationship among the language, the construction of mathematical objects and the development of mathematical concepts. Mathematical objects arise not only through abstraction processes from the direct experience, but also through the language objectification, through the singling out of manipulation rules of linguistic objects and through the intuition of the equivalence among different procedures. According to the Vygotskian theories, the use of the symbols deeply affects the cognitive functioning. Thinking cannot be traced back only to abstract processes of knowledge and reasoning, but it is feed with motor and sensory processes; the tools, intended as "mediation devices" between the individual and the social context, modify the whole flow and the structure of the mental functions, transforming and affecting the actions (Anolli, 2005). Symbols are intended as "tools" supporting the accomplishment of the actions required by the context and the activities which the individuals are engaged with (Radford, 2000).

Working Group 9

Concerning signs in the *Activity Theory* Leont'ev agrees with Vygotskij in that tools mediate activity. Psychological processes are based on the *activity*. It represents the reference global unit, which is naturally social and so it implies necessarily the interaction among the different actors. Activities consist of goal-oriented conscious *actions*. The actions consist of automatic *operations* which are independent from the nature of the activities (Anolli, 2005). In the subsequent developments of the activity theory Leont'ev includes the rules and the division of the work inside the community (*activities' systems*), maintaining that an activity and its progress require a social coordination and a meanings' sharing (Ligorio, 2010). According to the socio-genetic constructivism, on some conditions the peers interaction represents the key for a cognitive progress and moreover the cognitive activity cannot be studied without considering the social and cultural contexts in which this activity is carried out (Perret-Clermont, 1979; Iannaccone, 2010). Thinking, and so mathematical thinking, cannot be considered as an individual information processing, but "thinking is a form of *social praxis*" (Wartofsky, 1979; Radford et al., 2005). The construction of new mathematical knowledge is based on the relations built in the classroom interactions between *signs/symbols* and concrete or abstract *objects/reference contexts*. Signs themselves do not have an isolated meaning, which has to be constructed by the learner. The meaning given to the not yet familiar systems of symbols is continuously enriched by the mediation with suitable reference contexts (Steinbring, 2000).

The use of the symbols in the culture of mathematics teaching is constituted in a specific way, giving social and communicative meaning to letters, signs and diagrams during the course of ritualized procedures of negotiation (Steinbring, 1997).

An important theoretical tool to describe and analyze the processes through which the children, in an activity system, construct new mathematical knowledge is the *epistemological triangle*.

[...]the epistemological triangle is used for modeling the nature of the (invisible) mathematical knowledge by means of representing relations and structures the learner constructs during the interaction (Steinbring, 2006).

The characteristic of the epistemological triangle consists in the mutual relations among the three vertices of the triangle, "sign/symbols", "object/reference context", "concept". These relations are not fixed a priori, they constitute a balancing system. As the knowledge develops in an interactive way, the interpretation of the systems of signs and the corresponding reference contexts modify (Steinbring, 2000; 2006).

RESEARCH PURPOSES

Our research hypothesis is that activities based on the creation and the handling of simple procedural languages, in a context of social interaction, can spur in the children a reflection about the language functions and the use of symbols. The aim is to lead the children, by group activities, to a change in the representation and in the

use of the language, from being only a communication tool to being also an object to manipulate. We believe that such a change could be an important process in the development of mathematical thinking and that through manipulation the construction of new mathematical knowledge could be facilitated. With regard to the activities we describe in this paper, we expect that the children would carry out interactive processes of constructing the concept of equivalence.

THE METHODOLOGY AND THE PARTICIPANTS

The participants were 24 children, aged 9-10 years, from a fourth grade class on a primary school, working in small groups in a period of about three months. We adopted a qualitative approach mainly based on observational and ethnographic methods. The activities referred to the “poor informatics paradigm” [2]. During the activities our role was to ask questions in order to stimulate thought processes without correcting any errors. We collected a corpus of data consisting of videotapes, audio recordings, “observable traces” (Vermersch, 1994) [3], initial and final tests and narrative interviews (ongoing and at the end of the activities). We analyzed: 1) how the children, in interaction, co-constructed the solutions to the tasks; 2) the cognitive representation of the tasks’ solution that the children, individually, developed during and after the activities. In this paper we present only some results of the data analysis regarding point 1), according to the activity theory (Leont’ev, 1978; Engeström, 2001) and the epistemological triangle (Steinbring, 2000; 2006).

DESCRIPTION AND ANALYSIS OF THE ACTIVITIES

We identified different situated activity systems (Leont’ev, 1978; Engeström, 2001) by analyzing the video recordings and by transcribing the communicative interactions among the children in the activities progress. We transcribed the communicative exchanges using a lightened version of the Jeffersonian system (Jefferson, 1985). We analyzed the *systems* according to the three levels of the *activity theory* (Leont'ev,1978; Engeström, 2001): the level of the goal-oriented *activity* (the given task); the level of the *actions* the children carried out to solve the task; the level of the *operations* underlying the performed actions.

In this work we focus on two activity systems that are part of a teaching experiment starting with a problematic situation in which there is a “child-robot” in a room. The other children have to “invent” the instructions in order to make the child-robot move. After several discussions and negotiations, the children create a language constituted by letters. The *interpretation* of each letter is a basic movement of the robot. Therefore, a word of the language is a “program”, since it is a sequence of elementary instructions. The invented language with its (translated) interpretation is: *A is Forward; I is Backward; N is Turn to the north; S is Turn to the south; E is Turn to the east; O is Turn to the west; L_O is West side step; L_S is South side step; L_N is North side step; L_E is East side step; F is No-moving* [4]. This first phase ends with

Working Group 9

R1 draws the group's attention to the fact that the task is "to replace" instructions and not only "to remove" them

8 R1: what can we put instead of Forward and Backward? What do Forward and Backward correspond to?

9 S5: to nothing (0.5) (*looking at the billboard with the instructions*) to No-moving

In this example, the activity is built collaboratively by the children, which in turn (lines 1, 2, 3) try to find a solution to the questions asked by the researcher. The strategy pursued by the group is to remove the instructions. The operations are the specific modalities of execution by which the action is performed: in this example they correspond to the use of the sheet as a mediation device. For example, in lines 1 and 3 the children point at the sheet on which the instructions are written. In line 5, two children answer in choir to the researcher stating that "by forward and backward" it is possible to come back on the same tile. This verbal formulation is the result of the previous interaction with the other children. The researcher reminds the children of the task: it is about "replacing" and not only "removing". So a child (line 9) says that "Forward and Backward" can be replaced with "nothing". The operation "looking at the billboard" moves the attention of the group to the language. The children answer that "Forward and Backward" can be replaced with "No-moving". In the development of this first action it seems that the group is approaching to an insight of a semantic equivalence in the language (lines 5, 9). After the response of the child about the "No-moving" (line 9), the group goes on with the activity, interacting with the researchers, *making marks on the sheet, simulating the movements of the robot* and referring to the context in which they are working. Afterwards a child sums up trying to answer the questions. The group asserts that the initial sequence can be simplified.

10 S4: (*reading again the task*) which instructions can be replaced? Backward and Forward (.) we have replaced with No-moving (.) then (.) with what? With No-moving and we said it (.) How come?

11 S3: because (.) forward and backward is always the same thing so you might as well keep still (.)

The group receives the second sequence. In the following excerpts there is the construction of the rule " $L_E L_O = F$ ". After the negotiation of the task inside the group and with us, a child *crosses* by the pencil the instructions $L_E L_O$ on the sequence. Another child asks for an explanation

12 S2: why did we remove them?

13 S4: because (.) no look at=look at! (*pointing the worksheet*) Wait! As before (.) see (.) we said orally (.) because at the end we always come back to the same point

14 S2: ok (0.5)

15 S4: so these [instructions] here can be removed

Working Group 9

R2 asks for explanations about the abbreviations and about the marks on the sheet

16 S4: These as before (0.5) which actually get [us] reach always the same point

17 R2: So we can replace them (.) with what?

18 the group: [[nothing]]

19 R2: and which is the instruction for nothing?

20 the group: [[No-moving]] (*looking at the billboard with the instructions*)

Finally, as for the first sequence a child sums up in order to answer the questions

21. S4: which have to be replaced? (0.5) East side West side North East (0.5) (*looking at the sheet with the task*) with what? (.) with No-moving (.) and then (.) how come? Because (.) because you always come back to the same point

The other members of the group nod and confirm. S4 while giving us the sheet

22.S4: 'cause then (.) at the end (.) if it is really how we did (.) the solution (.) we can do differently (.) that is on the contrary (.) in the way that (0.5) that we have to lengthen the path (.) as for example (.) like here (.) but we have to get it longer

23.R1: longer (.) but always reaching the same point?

24.S4: yes (.)

The previous excerpt shows that the children are constructing the concept of equivalence step by step. At every step every child spontaneously recovers what the other children have built. The children, after they have understood and internalized the rule, try alternately to solve the task. At the same time they reflect on the answers given by the others (lines 12 to 15). Furthermore, they construct new rules referring to how the other rules have been previously constructed by other children (line 13, lines 16 to 20). We cannot claim that in another situation or educational context the same interactional situation would arise. It is interesting to notice that the activity of rules' creation is a *socially constructed* culturally situated (lines 19, 20, 21) activity. Besides it is mediated by both materials and linguistic cultural artefacts.

The use of the equivalence rules

The second activity we analyze follows the singling out of the equivalence rules, which have been institutionalized by writing them on the blackboard. The task is to verify if the two symbols sequences of the language $SAAIAEEAFL_S L_N L_N AAANN$ and $SAFAEAFL_N 3AN$ are equivalent, using only the equivalence rules. Only afterwards the groups have to verify the task by drawing the corresponding paths. We report an excerpt regarding the communicative exchanges of the resolution process of a different group from the one of the previous activity. We identify the *operations* and the *tools*. A child *reads the task aloud* and *reads the two sequences*. At first the group concentrates on the instructions.

Excerpt n.2

Working Group 9

- 1 S1: Turn to the south (.) then there is Forward (0.5) it is replaced with No-moving (0.5) because it stays in the same point (0.5) then AA then E (.) Turn to the east (0.5) then it always stays in the same point (*pointing EE in the sequence*) (0.5) Forward (.) Backward [...] they aren't equivalent (.) because there is South side and here there isn't (*moving from a sequence to the other one touching the sheet*) (0.5) but let's see now (.) we have to check it yet

Hurriedly the group states that the sequences are not equivalent and soon it passes to verify the answer *representing* the corresponding paths. Nevertheless, using the drawing the children get confused, they don't succeed in reaching a correct solution and there is not agreement.

- 2 S3: they always arrive at the same point (0.5) no (.) they don't always arrive at the same point
- 3 S4: yes (.) they are equivalent (0.5) look (.) it's the same tile
- 4 S2: it's not true look that this is the yellow tile (0.5) and this (.)
- 5 S1: ok let's revise the path

At this point the researcher suggests reading the task again. Then the group goes back to the symbols dropping the drawing. After a discussion the children conclude

- 6 S2: (*looking at the two sequences in the first of which there is $L_S L_N L_N$, in the second one there is L_N*) the robot takes a step south side (*pointing by his hand the wall labeled with the south-card*) and then it takes a step north side (*pointing by his hand the wall labeled with the north-card*) if then you write North side (.) it's the same thing because here there is one instruction more (.) but they always are equivalent
- 7 S3: so are they equivalent?
- 8 S2: wait (.)
- 9 S1: N (0.5) South (.) Forward (.) it's ok (.) No-moving it's ok (0.5) it's ok
- 10 S3: is it ok?
- 11 S2: the instructions are ok

In the excerpt the group applies the equivalence rules, previously constructed, to the two sequences given in the task. At first (line 1) the children's action is oriented to the solution of the task in the shortest time. The "hurry" is due to the competition among the groups and it leads the children to mistake. The operation in this case is "reading the task" hurriedly and not carefully and "representing the paths" on the sheet. In lines 2-5 we can observe how the children, debating one another, realize that their solution does not fit the task. The discussion seems to activate a real *awareness* of the error. The researcher by a *guidance action* leads again the group to a deeper reflection about the task. The action of "reading again the task" changes the initial goal of the children from giving a solution in the shortest time to giving a

correct solution. This action involves new operations: a child represents the movements of the robot “pointing out the cardinal points” fixed on the walls (lines 6-10). Again the interaction in the group allows the co-construction of the solution and also the awareness of the initial error.

The concept of equivalence

The process of constructing the concept of equivalence can be described by the epistemological triangle (Fig. 2). In the activity systems different kinds of signs are produced (Steinbring, 2006). There are *verbal formulations* (in both the activities): the children use everyday language expressions, which can represent preliminary forms of interactively produced signs useful to construct mathematical concepts; *“touching deictics”* (above all in the first activity): the children touch the small squares on their worksheet simulating by the fingers the robot’s movement; *“pointing deictics”* (above all in the second activity): the children point out by their hands the walls labeled with the cardinal points; *drawings*: the children use graphical representations as a support in the task resolution. Besides the children produce and handle the language’s symbols. Really the latter turn out to be the most useful to gain the goal of the activities. Indeed, especially in the second activity, when the children use the drawing they do not succeed in solving the task, while they are successful when they use and handle the symbols of their language. The meaning of the signs is produced by the children in a continuous reference to what they employ as *reference context*, that is, *the worksheet with the task, the billboard with the symbols of the language* (in the first activity), *the blackboard with the rules* (in the second activity) and *the walls labeled with the cardinal points*. Through the continuous mediation between signs and reference context they construct the concept of “equivalence”.

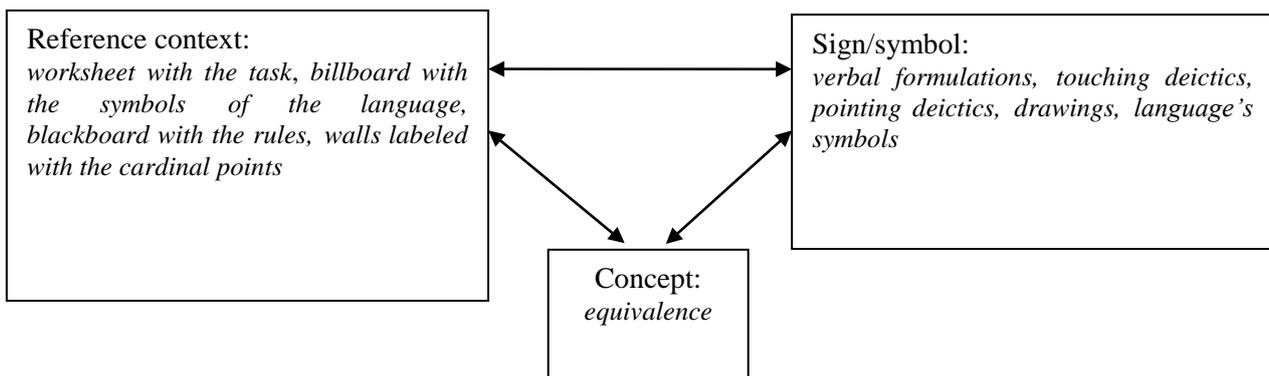

Figure 2

In both activities the concept of equivalence comes out in the repeated use of expressions like “is the same thing”. The use of expressions like “it remains always on the same point”, “it comes back to the same tile”, “you come back always to the same point” points out that the first step of the construction is the singling out of simple equivalence rules (as an example $AI=F$). Showing that the composition of some instructions is “the same” than the composition of other ones, the children

Working Group 9

“construct mathematical knowledge”, because in doing this they identify an equivalence relation. The produced signs are “mathematical signs” because they denote a semantic equivalence relation in the language. The understanding of the equivalence is not an end in itself, since it is basic for the construction of the “mathematical objects”, which arise just from unifying equivalent “words” [8].

In the collective discussion among the groups, taking place after the activities, it emerges how the children’s previous knowledge strengthens the mediation between signs and reference context and the whole construction process of the “new” concept. “The signs have to be interpreted, and this interpretation requires experiences and implicit knowledge-one cannot understand these signs without any presuppositions” (Steinbring, 2006). Indeed the children refer to the already known notion of equivalence regarding weights and measures. Besides it is interesting the comparison they do with the “synonymous” words in the Italian language. In their “new language” two syntactically different words are two sequences with different symbols. These words are “equivalent” if, even though they are different, they have the same meaning where the meaning is the robot’s movement.

CONCLUSIONS

According to our research hypothesis, the shared creation of a language and its manipulation allowed the children to acquire the awareness that symbols depend on the context of use and that they presume an agreement in the community of the receivers (Ferrari, 2002). Moreover the language, seen as a manipulation object as well as a communication device, was a basic tool in the knowledge construction, an “amplifier” of the intellectual capabilities (Bruner, 1996). Although the activities don’t deal with argument strictly linked to mathematical school topics, they aim to stimulate linguistic skills which are basic for the mathematical knowledge construction. By the analysis of the activity systems it comes out how in a particular educational situation the children, freely interacting, were able to co-construct a socially shared meaning of the concept of equivalence. The actions were negotiated and shared by the groups. So the underlying operations became common and understandable. The *actions* of shortening the language sequences and checking the equivalence between two sequences, in the two activity systems, allowed the children to *construct the concept of equivalence*. The *operations* generated by the actions spurred a continuous mediation between *reference context* and *signs/symbols* produced and handled by the children (Leont’ev, 1978; Steinbring, 2006). The repeated use of expressions like “is the same thing” highlights that the children *intuit* a semantic equivalence relation in the language. They arrive *gradually* to the concept of equivalence, through the *singling out* of simple equivalence rules.

NOTES

1. Formal logic is seen as the expression of an historical path bringing to a change of the language’s role in mathematics. This path starts with the passage from the rhetorical algebra to the symbolic one and keeps up to modern logic.

Working Group 9

2. According to this paradigm it is possible to develop abilities near to a data processing frame by means of simple and “poor” materials. The children become “inventors” (they code a language), “interpreters” (they decode a language), “manipulators” and users of “programs” in the language (Gerla et al., 1990).
3. According to Vermersch (1994) the traces are the material signs produced by the children during the activities, such as intermediate and final written notes and outcomes.
4. As an example, *AAIS* is a word corresponding to the temporal sequence of actions: take a step forward, take a step forward, take a step backward, turn to the south.
5. We call *equivalent* sequences representing paths which, starting from the same initial position, allow the robot to arrive at the same end position. An example of an “equivalence rule” is $AI = F$ since both the words represent “no-moving”. So as an example, the sequence *AIA* is equivalent to the sequence *A*.
6. The squared sheet simulates the classroom’s tiled floor and N,O,S,E represent the cardinal points labelling the walls.
7. In the excerpts we denote by *S1, S2,...* the students and by *R1, R2,...* the researchers involved in the activities
8. This is the point of view of formal logic which shows how mathematical models can be constructed starting from the used language (closed terms) and from a suitable equivalence relation.

CONTENTION IN MATHEMATICAL DISCOURSE IN SMALL GROUPS IN ELEMENTARY SCHOOL TEACHING

Andrea Gellert

University of Duisburg-Essen

Abstract. The paper presented refers to the elaboration of the theoretical construct called “focusing teaching strategies” within the research project “Probing and Evaluating Focusing Instruction Strategies in Elementary Mathematics Teaching (ProFIT)”. By teachers’ interventions an attempt is made to create a learning situation, in which the joint attention is focused on a critical feature of a mathematical problem. Especially the following two perspectives are investigated: How can the teacher make a mathematical reasoning need more accessible for students and in which way can the needs be developed in the common discourse? And: How can pupils understand a mathematical reasoning need and how are they able to agree on it?

Keywords: interpretative discourse analysis, focusing teaching strategies

INTRODUCTION: CONTENTION IN MATHEMATICAL DISCOURSE

Mathematical classroom interaction is a complex process. In the research project “Probing and Evaluating Focusing Instruction Strategies in Elementary Mathematics Teaching (ProFIT)”, the interaction competence of mathematics teachers will be worked out by means of videotaped small group discussions with four pupils and one teacher. The five participating teachers are from one school so the video data consists of 40 videos of group discussions and the associated school lessons. Selected sequences, in which a contention or disagreement is evolved interactively, will be interpreted by theory-based analyses for further elaboration and differentiation of the theoretical construct “focusing instruction strategies”. The project is related to social, interactionist and epistemological theories, which are associated with discursive learning and the construction of new mathematical knowledge.

Furthermore, it will be analysed for how focusing teaching strategies affect concrete discourse situations and pupils’ learning processes with an aim of a deeper understanding of the nature of mathematical classroom discourses. This is also elaborated by means of interpretation of the students’ reaction in the selected video episodes. The special analysis refers to the interaction evolved by the contention to the apparent mathematical content and to the interplay between them.

THEORETICAL BACKGROUND

Mathematical Discourse and discursive learning

The particular mathematical discourse is part of the social teaching and learning activity in school. It especially attends to clarifying jointly identified problems and statements, which are related to the mathematical content of a task on which not all participants agree. From a sociologist perspective, discourses are subjected to certain rules determining who can say what in which way and under which circumstances. Nevertheless, these rules are not rigid. They can be changed and indeed are changed frequently (Miller 2006, 202f.). The teaching practice of mathematics in elementary schools often does not comply with these changes. For example in the pattern of the “thematic procedure of mathematization” elaborated by Voigt (1990, 305), the teacher tries to achieve a pretended uniqueness in the interpretation of ambiguous mathematical classroom objects. However, the ambiguity of these objects admits numerous initial points for classroom discussions (e.g. Voigt 1990; Steinbring 1994; Söbbeke 2005).

The communicative classroom exchange about these different views and the development of intersubjectivity through the participants’ negotiation processes are fundamental for the learning of mathematics in social interaction (Voigt 1994). So the pupils involved in these learning processes depend on communication with other people, e.g. classmates, parents, teachers or others, because fundamental learning demands constructing actively and negotiating dialogically new general relations between already existing segments of knowledge. Miller (1986) speaks about “basic theories” to acquire applied knowledge. Moreover, discourses are a necessary condition for them to emerge.

In his epistemological research, Steinbring speaks of “new mathematical knowledge”, which “has to exceed the old knowledge systematically” (Steinbring 2005, 61). Thus, new mathematical knowledge is understood as an extension of the old knowledge at the same time. Hence, the construction of new knowledge in mathematics lessons takes place in a tension between consistent base knowledge and new knowledge relations, which is in need of fundamental reorganisation and enhancements of knowledge systems. For “mathematical knowledge” being negotiated interactively, the subject “mathematics” cannot be understood as a predetermined matter but has to be interpreted in accordance with the epistemological conditions of their dynamic, interactive development (compare Steinbring 2005, 34f.).

Interaction patterns and routines in the mathematical classroom

From an interaction-theoretical and epistemological point of view, teaching and learning processes are seen as dynamic and reflexive. In this process, teachers and students jointly constitute the classroom’s reality by interaction. So the situation is necessarily influenced by interaction and communication patterns (Mehan 1979;

Working Group 9

Bauersfeld 1988; Wood 1994). They are mutually produced by the routines of teachers and students (Bauersfeld 1988). The teacher reverts to a functioning repertoire of procedures of acting and communication patterns, which are internalized by his/her own school and teaching experiences (Bauersfeld 1980) and from which he/she can hardly diverge. The students adapt their behaviour and over the time, teacher and students jointly and interactively produce particular regularities in their behaviour and their way of communicating. Finally, they form steady routines for the behaviour in different classroom situations. So future situations become predictable for the students, the focus of their attention can be conducted to unknown or problem oriented mathematical situations (Voigt 1984; 1990). Thus, routines are important and useful: they are responsible for classroom interaction being as trouble-free as possible.

However, if these routines become patterns, by which teacher and students are so well-attuned to each other that a deeper mathematical understanding is not possible, learning can be delayed. The tripartite exchange (teacher's question – student's response – evaluation by the teacher) as well as the often-discussed funnel pattern described by Bauersfeld (1988) show in their analyses only an unsatisfying mathematical understanding by the students. Often, it is sufficient to follow the signals given by the teacher to react to the teacher's question adequately. Thus, Steinbring demands:

The intended uniqueness of communicative, mutual understanding on the layer of interaction through the funnel pattern or the interactive negotiation of significance has to be absorbed, referring to the epistemological content of mathematical knowledge, by establishing theoretical ambiguity (Steinbring 1994, 205; Translation: AG).

If there are any created possibilities for producing theoretical ambiguity and if they are embedded in the interactive process, discourses are developed, in which mathematical meaning is negotiated and the understanding of mathematical strategies is supported.

Contention in mathematical discourse

Discourses constitute a basic method to solve interpersonal problems of coordination (Miller 2006, 13). The first aim of discourse is that a controversial question, the *Quaestio*, is answered by the persons communicating together (Miller 1986, 143). According to Miller, these negotiations of contention are fundamental for learning. For Kamii (1986) too, conflicts (cognitive as well as social) are central, because social influences probably lead to conflicts. Thus, children have to try to approximate their divergent perspectives and by this learning processes can be initiated. In the presented project episodes from small group discussions are interpreted, in which a *res controversia*, a controversial question or statement, can be observed. The video episodes are selected by sequences in which there is a kind of irritation, initiated by a student or the teacher.

The focusing pattern

In several aspects, the teacher's role is decisive. He has to apprentice, whereas teaching in this case is not meant as transporting subjects, but arranging favourable learning conditions (see also Cooney 1988; Mason 1987):

The teacher's role is seen as providing learning situations in which students have to contribute their own potential for actively reconstructing knowledge, for establishing a personal relationship towards his knowledge (Steinbring 1994, 91; Translation: AG).

Thus, it is in question how new mathematical knowledge can be developed in classroom discourse and how the teacher can make his/her contribution to accompany children on their way to autonomous learning. Bromme et al. (1990, 2f.) speak of an epistemological dilemma in the teacher's role and in his/her activities. The teacher moves steadily in an intermediate field between his/her own knowledge of mathematics science and the already existing students' knowledge. Thus, it is also in question, to what extent teachers are able to dissociate from their own ideas and intentions and to what extent they are open to the children's knowledge structures. However, this openness is equated neither with an unreflective orientation towards the students nor with the exploratory character used in clinical interviews. The teacher's openness is understood with regard to the interpretation of the children's constructions and reasoning attempts.

Wood (1998) characterized this teaching practice with the concept of the *focusing pattern*. She highlights the importance of involving the children in the teachers' process of interaction and structuring: The teacher gives the students the possibility to make the mathematical content as well as making the discourse accessible for them. He provokes them to explaining and reasoning, and to discussing their ideas with other students. Thus, the teacher's intention is different: focusing the students' attention on a critical aspect of the problem, raising a question that turns the discussion back to the students leaving him/her with the responsibility of clarifying the situation (Wood 1994).

For example, this is possible by demanding them to write down his/her statements or reasons. The notation can probably help to clarify his/her own reasoning, because supported by the possibility of pointing to something he/she is perhaps able to explain more decidedly. On the other hand, for the students listening it affords an opportunity to follow up the given explanations and reasons. Additionally, this course creates possibilities of connecting their informal explications with the formal, in their cultural setting. Students start to realize that the symbols have a mathematical meaning. The teacher has to anticipate which aspects are critical or rather controversial, and he/she has to focus on clarifying questions, for example. One aim is to draw the joint attention to important aspects, so that these aspects do not fade out nor that the topic is changed without having been clarified. The students should be aware of the teacher's expectation that they are responsible for understanding the

explanations and reasons given by their classmates and that they are responsible for asking upcoming questions, and thereby creating an opportunity to clarify a mathematical aspect (Wood 1994).

In his investigations of argumentation processes, Schwarzkopf (e.g. 2000) also pointed out that classroom discussions can be structured by the teacher through guiding the students' attention to a reasoning-needed and/or a discussion-worthy statement. Thus, a reasoning need must be demanded explicitly by the teacher. The objects, on which the attention is focused, are jointly produced in the interactive process in spite of different functional parts:

Thus, argumentations are not arbitrarily opened by the teacher, but they arise from the interaction between teacher and students (Schwarzkopf 2000, 588; Translation: AG).

As students should have the opportunity to hold their own point of view, they also should accept others'. In meetings with the teachers being involved in the project ProFIT, an attempt was made to create awareness for this kind of learning as well as to sensitize these teachers to their own routines.

RESEARCH QUESTIONS AND FIRST IDEAS OF AN ANALYSIS

The preliminary analyzing aspects *interaction*, *mathematical content* and the *interface* between them arise from these theoretical considerations:

The interaction

In a first analysis of the discursive context, three different types of context are distinguished: *Report Ways*, *Inquiry* and *Argument*. This distinction is based on a grid developed by Wood and Turner-Vorbeck (2001). They used this grid for structuring and planning discursive contexts on the basis of their own research, experiences, and analyses. The context type *Report Ways* is mainly related to the *comparing* and *contrasting* of mathematical students' solutions in classroom discussions. The *Inquiry*-Type implies *reasoning* and *questioning* based classroom discourse, while for the *Argument*-Type, *justifying* and *challenging* is central. A first pre-analysis within the project ProFIT showed that the grid is useful for a first pre-structuring of the episodes on an interaction level. Using the grid as an instrument for reconstruction, in particular the following questions arise: How does the teacher develop opportunities for different students' responses during the interaction? When does a firstly *reporting* context exceed to an *inquiring* or an *argumentative* context?

The mathematical content

The tasks together with the mathematical learning environments are the indispensable base of autonomy in teaching, but the interface of the teacher's and students' activities are fundamental, too (Bromme et al. 1990, 2f.). As already mentioned in the theoretical part, the fundamental assumption from an interaction-theoretical perspective on teaching is that the objects of discourse should be

“ambiguous”, i.e. open to different interpretations by the participants (Voigt 1994, 77). As it provides numerous opportunities for discourses in classroom, this ambiguity can produce arguments. But this is only possible if the teacher is aware of that ambiguity and if he/she incorporated it as a constitutive element in the mathematical discourse. The richness of mathematical structures is a possible basis for explaining, reasoning and perhaps also for clarifying contentions. Thus, the following research questions are of interest: To what extent does the ambiguous mathematical content comprise something structural in its topic, its presentation, its visualization, etc., what is interpreted in the classroom interaction by the students as well as by the teacher? What kind of understanding of the ambiguous mathematical content becomes explicit by each participant?

The interface between interaction and mathematical content

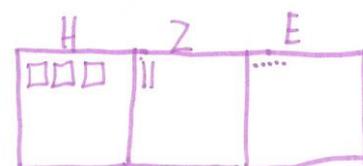

Within an interpretative analysis, neither the mathematical content nor the interaction can be considered in an isolated way. This is because of the teacher’s consideration to create learning situations by maintaining a collective focus on a critical feature of the mathematical content. Thus, the investigation is about how a joint collective focus can be conducted on the mathematical content. Questions related to this analytical focus are: Where is the interface, which determines if students follow a social or a mathematical logic in teaching-learning-processes? Where does the inquiry, which refers to the mathematical content, start; is there even a trigger? And is this particular interface a barrier, which one has to overcome? How far is it possible to interrogate, in a special manner, the fact that contention is clarified by statements related to the mathematical content? Which role do the students’ interpretations, hypotheses and reasons play?

ANALYSIS OF AN EXEMPLARY EPISODE: DISCUSSION ABOUT 20 TENS

The exemplary episode originates from a small group discussion between four fourth graders (Ferdinand, Frank, Kevin and Laura) and their mathematics teacher in primary school during the research project ProFIT. For all involved participants it was the first small group discussion within the research project. The teacher has several years of teaching experience and conducted eight small group discussions during the project.

Choice of the scene – epistemological description of the point of contention

The episode was chosen because a point of contention develops during the interaction. This controversial point displays the different possibilities for the interpretation of a depiction produced by the pupils during class (see image).

The ambiguity of the representation of the number is the reason for the potential point of contention. The epistemological point of view can be interpreted, according to the point of view, an empirical-concrete or a relational. If

Working Group 9

the visual depiction with squares, strokes and dots has an *empirical-concrete* interpretation, the concrete use of the working material consisting of a hundreds board, a tens bar and a unit cube come to the fore. These materials, or rather the iconic depiction of the materials is used conventionally and “collected” in the referring boxes – labelled H, Z, E (English: H, T, U). This interpretation of the representation of the number can be described as a classified accumulation of objects in 3 boxes: 3 H-boards, 2 Z-bars and 5 E-cubes.

If the interpretation is *symbolic-relational*, the labelling is not interpreted as names for the boxes but rather depict place values in a place-value-table. In this case the decimal relation between the different place-values is important: 10 E equals 1 Z and 10 Z equals 1 H. So the quantity of symbols in one column of the place-value-table shows how many of the according place values have to be chosen.

This interpretation of the representation of the number can be described as a relational arrangement of units in three columns of place-value-tables: 3 symbols in the H-column, 2 symbols in the Z-column and 5 symbols in the E-column.

Obviously, in the symbolic-relational interpretation there might be the conflict that it has to be abandoned from the “additional” characteristics of the symbols, i.e. the iconic meaning connected with the symbols: hundreds board, tens bar and units cube.

Which forms of the mathematical point of contention can arise in this setting? First, it could be questioned which point of view is appropriate, the *empirical-concrete* or the *symbolic-relational* interpretation? (In a discussion with young pupils the differences are not named systematically and explicitly, but they have to be reconstructed afterwards from the descriptions and explanations of the pupils.) A further mathematical point of contention might be how to deal with the representation of the number as a place-value-table with filled-in symbols: Is the special iconic aspect of signification abandoned, or does it frequently play a role in the discussion and so leads to a different interpretation of the “place-value-table” to “sorting boxes”?

The exemplary episode

Before the episode starts the children explain why this figure can only represent the number 325 and no other. They explain it only using the symbols square, stroke and dot. After that the following episode starts:

- 1 Teacher: But, like I said, this is not obvious to me. So that...without the place value table, that's clear. Over there I see, ok I know one square we said equals a hundred, doesn't it? ... A stroke you said
#equals #and a dot equals one.
- 2 Ferdi: #equals ten. #dot. What about?

Working Group 9

- 3 Teacher: It doesn't equal but it's similar. We agreed on this in the second or third grade. Now, if I see that, ok (*covering the place-value-table*). But now I also have my place-value-table.
- 4 Frank: (..) But there is also written tens. You can say you've got zero tens. For example that the tens mean a zero. It also might be that the tens mean 100. The number over there. (.)
- 5 Kevin: Yes, but when... This is, it is written there. One stroke is a ten and then when we, if there is a ten above it, then we know that stroke needs to be put in there, if there are tens. And therefore a stroke is one ten and so on.
- 6 Teacher: But these are twenty, right? (*pointing on the two strokes*)
- 7 Kevin: Yes, these are twenty.
- 8 Teacher: But twenty tens. And twenty tens are#
- 9 Kevin: #No. Two strokes are two, two strokes are two strokes, which are on the ten's place 20.
- 10 Teacher: But these are twenty tens. (*first pointing at the two strokes than at the Z for the tens*) 20 times 10 don't equal 200?
- 11 Kevin: This is not about multiplication.

Description of the episode

The teacher says that for her it is not obvious to read only the number 325 in the figure and she refers to the convention introduced in the second and the third grade that one square means 100, one stroke ten and a dot one, without reference to the frame and the letters H, Z and E (in English: H, T, and U). Further, she describes this particular frame and the caption as a place-value-table and points at the combination of both. Frank and Kevin comment on the teacher's contribution. Then, she refers only to the two strokes and asks whether these are 20. Kevin agrees. The teacher refers to the place-value-table and says that they are 20 tens. Kevin negates this. The teacher repeats her statement referring to the Z as a caption for the tens and asks whether 20 multiplied by 10 equals 200. Kevin disagrees referring to the actual act of the arithmetic operation and the topic changes.

The coping with the mathematical point of contention in the interaction during the episode – a summarizing interpretative analysis

Already at the beginning of the presented episode the teacher indicates a reasonable point and tries to conduct the collective focus to the contention of the combination of frame and letters in terms of an interpretation as place-value-table on the one-hand with the symbols inside on the other hand interactively (She says that the pre-given explanations are not obvious for her (l. 1)). By this, she reveals her own more symbolic-rational mathematical interpretation of the whole presentation, as she

Working Group 9

labelled it as a place-value-table (l. 1). Without observing the students' reaction, probable interpretations are: The teacher tries to make her own mathematical interpretation obvious for the students or she is aware of the ambiguity of the mathematical object and tries to conduct the joint attention focus to this point. Related to the interpretation of the symbols inside, she repeats the classroom convention referring to an agreement in passed grades: "We agreed..." (l. 3).

Frank and Kevin take the teacher's statements as a cause for clarifying their interpretations in more detail and react with new explanatory statements for their interpretations (l. 4, 5). The participants do not comment on Frank's statement, wherefore it is not interpreted any more. Kevin "reads" his interpretation of symbols once again: "it is written there" (l. 5). In doing so, his interpretation is bound to everyday life situations. He probably interprets the frame as a kind of case, an assortment box, which has to be filled: "if there is a ten above it, then we know that strokes need to be put in there". What has to be put in is indicated to him by the Z. Probably frame and caption assist in the sorting. He does not indicate seeing any relation to the place-value-table.

This is followed by another question from the teacher, in which she interprets the two strokes differently. She considers the two strokes isolated and describes them as 20, instead of two tens. She asks whether the students agree that these two strokes are 20. In her statement she does not mention the two strokes explicitly, but with "these" she gives a deictic reference and points on the two strokes, so that this interpretation seems to be plausible (l. 6). Kevin agrees on the convention that one stroke is a tens (l. 5) and two are twenty (l. 7). So, from an interactional point of view, these first lines of the episode can be labelled as an inquiry context.

Related to the mathematical content, the ambiguity of such a representation becomes obvious. The teacher has a rather symbolic-relational point of view. She probably is aware of the ambiguity and tries to conduct it to the supposedly joint attention focus. Kevin has a more empirical-concrete point of view and for him only one interpretation seems to be possible: the interpretation of a kind of case, a kind of assortment box.

Initiated with the word "No" in line 9 Kevin disagrees and contradicts the teacher's statement, and discussion becomes more challenging. For him, the two strokes lying on the tens' place are 20, the quantity of strokes (two) lying on the tens' place is crucial. Here, he changes his reasons. His statement is not consistent with his statements before. He uses a more symbolic-rational understanding, without taking the place-value-table explicitly into consideration. This was not carried out at this point; the teacher does not follow this interpretation up.

The teacher's introducing "But" in line 10 also gets another, more justifying emphasis. The discussion's context changes more to the direction of an argumentative context (l. 8-11). She repeats her general statement in line 8 related to

a concrete reference to the figure (l. 10, once again deictic, supported by pointing on the figure) and connects the presentation of strokes with the Z by using multiplication, analogous to the place-value-table. She puts into question whether 20 times 10 equals 200. For Kevin it is not to be debated whether 20 times 10 equal 200, at least he does not react to it. But he does not accept the operative connection between 20 and 10 in the form of multiplication, which for him seems not to be permitted at this moment (l. 11). For him, the contention is originated in the interaction on the mathematical content. The presentation of the number 325 is not controversial for him, but the teacher's statements are worth discussing. The teacher's constant attempt to focus on another possible interpretation of the mathematical content fails (l. 11); the discussion moves onto another topic.

Specific communicative elements within the cause of small group interaction

If one follows the special communication in dealing with points of contention in this setting it can be seen that the teacher tries different measures to put the point of contention into the focus of all participants; i.e. she initiates the point of contention. First, she questions the obviousness of the children's explanations (l. 1). Then, she tries to focus on the controversial point by referring to known conventions and to contrast different points of view by hiding and showing the labels (l. 3). Later, she tries to provoke the pupils with her remarks by bringing single elements of the representation into discussion again (ll. 6-10).

In the exemplary episode the pupils deal very differently with the teacher's strategies. First, they feel asked to give new explanations (Frank, l. 4; Kevin, l. 5). Next, only Kevin communicates with the teacher. Here, Kevin agrees on some of the teacher's remarks and contradicts others. They do not reach a consensus.

CONCLUDING REMARKS

The interpretations at that early time of the research project led to the conjecture that it is possible to initiate and discuss mathematical contention with children at the elementary school age, but it is challenging to focus the attention on special aspects of the interpretation. In the exemplary episode, the pupils engage in a new way of communication and discussion, but deal with it in different ways. The engagement in the point of contention and the arguments seem to be difficult and unfamiliar.

The research questions mentioned in the article are the leading questions for the presented research, which cannot be answered yet. So it is still in question as to whether and to how far it is possible to interrogate in reference to the mathematical content. This barrier could not be overcome in this episode. So for the teacher's role two challenges become obvious: On the one hand the release of his/her own interpretation of mathematical signs and symbols and on the other hand the teacher's consideration to create a joint collective focus interactively, including the discourse about a cooperatively identified contention. The interest in this research has been

shown through the discussed episode and points out the difficulties of a change of the established classroom discourse to new forms of discourse. It is the concern of the research project ProFIT to work out more exactly what and where the key points discussed above are.

TURN-TAKING IN THE MATHEMATICS CLASSROOM

Jenni Ingram, Mary Briggs and Peter Johnston-Wilder

University of Warwick, UK.

This paper focuses on turn-taking in secondary mathematics classrooms. Sixteen lessons in four mathematics classes for pupils aged 12-13 years were observed and video recorded and then analysed using a conversation analysis approach. The analysis of the data reveals differences in the patterns of turn-taking from those discussed in the thorough analysis by McHoul (1978). In particular, three types of situation arise where pupils self-select as next speaker: to ask a question; to initiate or perform a repair; and finally to respond to an undirected teacher's question. The last of these in particular raises some important questions about the teaching and learning of mathematics.

INTRODUCTION

Classroom interactions between pupils are widely held to be an important feature of the mathematics classroom, and a large number of existing studies have explored specific features such as how questions are asked and answered, and when and how pupils participate (Sfard & Kieran, 2001; Yackel & Cobb, 1996). The aim of these studies has often been to develop an understanding of the relationship between these interactions and learning. We do not yet know what interactional features of classroom discourse result in successful learning, though we may have strong opinions about the value of explanation, argumentation and discussion. We do however know that the structure of interactions play an important role in how pupils perceive and learn mathematics (Wood, Williams, and McNeal, 2006). There are also observable differences between pupils in the extent to which they participate in whole class discussions (Ball 1993; Boaler, Wiliam, & Brown, 2000). The vast majority of these existing studies focus on the content of the interactions, particularly on how teacher's support or scaffold pupil's interactions. In this study, we examine instead the structure and local management of turn-taking which constrain the content of interactions.

THE ALLOCATION OF TURNS

Turn-taking has received considerable attention in the research literature (Maroni, Gnisci, & Pontecorvo, 2008; Sinclair & Coulthard, 1975), in particular as one of the notable differences between natural conversational discourse and classroom discourse. There are rules that govern who can speak, for how long they can speak for and also constrain what can be said. Whilst there are rules that characterise all conversational interactions, there are often more constraints on formal interactions, such as those that take place in classrooms. These rules are often unsaid, yet by analysing interactions between participants we can find evidence that these rules are

Working Group 9

being oriented to by participants; this is particularly clear when these rules are violated (a deviant case) and participants are sanctioned.

In this paper, we particularly focus on the systematic rules that govern whole class discourse. Sacks, Schegloff and Jefferson (1974) outline the rules for the construction of turns in natural conversation and McHoul (1978) develops these for formal classroom discourse. Features common to both systems include the rules that only one speaker speaks at a time and that a change of speaker occurs and often reoccurs. Where natural conversation and classroom discourse differ is in the allocation and management of speakers.

In Sacks et al.'s (1974) rules for governing speaker change in natural conversation, at a point where it would be relevant for the speaker to change (a transition-relevance place), the current speaker can select the next speaker and thus the turn belongs to the selected participant. If the current speaker has not selected the next speaker, then another speaker can self-select. If neither of these two scenarios occur, the current speaker can continue the turn. These rules apply to any transition-relevant place. McHoul's (1978) analysis of discourse from geography classrooms results in an adaptation of these rules, highlighting the different roles of the teacher and the pupils.

When the teacher is the current speaker, then the teacher can select the next speaker. If the teacher does not select the next speaker, then the teacher must continue the turn. When a pupil has been selected by the teacher to speak and becomes the current speaker, they then can select the next speaker and the teacher takes the next turn. (It is worth noting that in McHoul's data there are no instances where the pupil selects anyone except the teacher as next speaker). If the pupil does not select the teacher as next speaker, then other speakers can select as next speaker with the teacher having the right to self-select first. If the teacher does not self-select at the transition relevance place then the current speaker (the pupil) may continue.

McHoul's systematic analysis of turn-taking makes it clear that the pupils are restricted in their roles in the local management of turn-taking and that it is the teacher who controls and manages the allocation of turns. The teacher participates in the interactions with some preformed idea of what should be said and done during the lessons; they have a lesson plan that the pupils are expected to follow. Discussion occurs within well-established norms of participation between teachers and their pupils (Yackel & Cobb, 1996). Furthermore, the interactions often begin with some additional instructions to the pupils about the nature of their participation that will be considered acceptable, such as "put up your hands" or "you need to explain why". These rules which govern turn-taking in the mathematics classroom determine the ways in which different activities are performed. For example, the teachers' control of turn-taking determines the topic of interactions.

Working Group 9

The rules which govern turn-taking in natural conversation provide an “intrinsic motivation for listening” (Sacks et al. 1974, p.43). Participants need to monitor the interaction for possible transition relevance places for opportunities to take the next turn and for information concerning what will be acceptable in that next turn. As turns are pre-allocated, then this need to listen and monitor what is being said is lost. Teachers can circumvent this problem to some extent by nominating the next speaker at the end of their turn, but more frequently the next speaker is selected following the pupils bidding for the next turn by raising their hand.

Turns can be allocated by the current speaker nominating by name, gesture or by eye gaze. They can also be more generally solicited where the next speaker is not selected but the current turn has been constructed such that it places constraints on the next turn. In this situation, it is possible that more than one participant may take the next turn, violating the rule that only one participant speaks at a time. The number of participants in a classroom context means that some form of allocation of turns is needed. Traditionally the teacher nominates the next speaker, again often following bidding for a turn by the pupils raising their hands.

THE STUDY

The data for this paper is taken from a collection of lessons video recorded in the UK. This collection includes a total of sixteen mathematics lessons delivered by four different teachers. For each teacher, one class of 12-13 year olds is video recorded between three and six times over a period of six weeks. The extracts presented below each feature just one of these teachers, though with only one exception, the accompanying discussion applies to all the teachers in the sample.

The videos were transcribed using Jefferson’s (2004) system, with [] indicating overlapping speech, (1.1) indicating a pause of 1.1 seconds and underlining indicating emphasis. These transcripts were analysed alongside the video recordings using a conversation analysis approach (Seedhouse, 2004), focusing on the local turn-by-turn organisation of the interaction. This means that the analysis is based on what is evidenced as relevant to the participants through their interactions. In other words, “analysing the interpretations that participants display, rather than creating their own” (Barwell, 2003, p. 201). Consequently, social identities and roles, such as pupil or teacher, are only attributed to speakers where it is clear from the interaction that the participants themselves are orienting themselves to these roles and identities. In this paper, the roles of teacher and pupil are used as the allocation of turns, number of turns and length of turns all indicate that the participants are adopting the roles of teacher and pupil in these interactions.

For the purposes of this paper, only whole class interactions are analysed. Interactions that occur when the pupils are working as individuals or in small groups are ignored.

ANALYSIS

McHoul's analysis does not include pupils selecting the next speaker, as in his data this is always the teacher; McHoul also claims that a pupil only speaks when the teacher has allocated the turn to them. In this paper, we examine instances in mathematics lessons where pupils have self-selected as next speaker and this is not sanctioned by the teacher or by other pupils. Within these instances, there are also occasions where pupils have selected another pupil as next speaker.

There are three types of situation in the data where pupils self-select as next speaker. The first of these is when pupils are asking their own questions.

- 231 Teacher: one in eight. ok. if I cancel them down, that and that cancels. that and that cancels I'm left with (0.7) a tenth. so,
- 232 Pupil1: how do you know that cancels with that
- 233 Teacher: how do you know that this cancels down
- 234 Pupil1: yeh
- 235 (1.1)
- 236 Teacher: if I multiplied it out you'd see tha- that (0.3) I have a factor of eight on the top and a factor of eight on the bottom.

In these situations, the pupil is also changing the topic of the interactions. In the current data, pupils rarely ask questions during whole class interactions; the number of questions asked in these instances only ranged from zero to two. On each occasion, the pupil's question is asked at a transition relevance place, so that the teacher's current turn is not interruption. In the above example, the teacher often uses the discourse marker 'so' to mark a change in the topic of conversation, thus whilst offering a gap in which an opportunity for the current speaker to change exists, it is clear that the teacher is intending to keep the current turn.

The second situation is when the pupils are initiating or performing a repair (see McHoul, 1990 for more detail on repair in classrooms).

- 29 Teacher: one in ni:ne. so has that gone up or gone down
- 30 Pupil1: gone down
- 31 Teacher: probability's gone
- 32 Pupil1: u[p]
- 33 Pupil: [up]
- 34 Pupil: up
- 35 Teacher: probability's gone up, it's more likely now that you're going (.) to get (0.3) the (.) red cross. so Miles (.) choose one

In the above extract, both of the teacher's turns are directed at pupil1, whose immediate answer, 'gone down', is incorrect. Whilst the teacher offers pupil1 the opportunity to self correct by re-asking the question and gesturing the correct

Working Group 9

answer, his peers also self-select to give the correct answer. These situations are very rare in the data and the above extract is the only example where the pupils are not sanctioned for taking the turn. However, in this case, the pupil who had the right to the turn also gave the ‘correct’ answer and the teacher maintains eye contact with this pupil throughout the exchange, thus the other pupils have been ignored.

The final situation where pupils self-select is in response to an undirected question from the teacher. This occurs whenever the teacher requires a response but has not selected the next speaker, either by name or gesture.

131 Teacher: what’s the probability?

132 Pupil1: a hal[f]

133 Pupil2: [[a ha]lf]

134 Pupil3: [fifty fifty]

135 Teacher: fifty fifty, a ha:lf, good.

In the extract above, three pupils offer an answer, virtually simultaneously, and the teacher accepts both variations of the answer offered. In the extract below, both correct (seven) and incorrect answers are given:

176 Teacher: what total will go (5.4) ((draws diagonal boxes on the board))

177 Pupil1: seve[n]

178 Pupil2: [si]x

179 Teacher: what total would go diagonally across the [board]

180 Pupil3: [six]

181 Pupil4: seven

182 Teacher: seven good. seven would be the most likely and ...

In both these situations, the pupils have the right to speak as the teacher has elicited a response yet no specific pupil has been nominated to speak. Any or all of the pupils can choose to answer, possibly simultaneously. This seemingly violates the rule that only one participant may speak at once. However, these types of teacher questions are usually followed in the data by simultaneous ‘correct’ responses suggesting that they are used when a large number of the pupils, but not necessarily all, are expected to know the answer. Consequently, if we view the interaction as between the teacher and the class of pupils as one participant, the rule is not violated. Additionally, the control over the interactions by the teacher is maintained.

Where different pupils offer different answers, as in the second extract above and the extract below, these are often given so that a different answer ‘interrupts’ a previous answer. In the extract below, the two contrasting answers result in a discussion, lasting over three minutes, in which several pupils self-select as next speaker. The pupil turns with an asterisk are the only pupil turns where there teacher has selected the pupil as the next speaker.

Working Group 9

- 255 Teacher: which ticket would you prefer?
- 256 Pupils: second one
- 257 Teacher: why
- 258 Pupil: cause it's got
- 259 Pupil1: it doesn't [matter]
- 260 Pupil: [it doesn't] matter
- 261 *Pupil1: because ((inaudible)) you've still got a chance of winning, cause those numbers could come out.
- 262 Teacher: but which one's got a greater chance of winning.
- 263 Pupils: same one/they've both got the same chance/the second one/same
- 264 Pupil: they're both the same
- 265 Teacher: good.
- ...
- 270 Teacher: ok. both these this is the thing about probability people (0.4) don't necessarily always think mathematically they think about (.) what they see. these have exactly the same chance of winning on the lottery
- 271 Pupil: yeh
- 272 Pupil: yeh [but]
- 273 Teacher: [exact]ly (.) the same chance.
- 274 Pupil2: it's not a very good ch[ance.]
- 275 Teacher: [what?]
- 276 *Pupil2: it's not a very good chance
- 277 Teacher: for both of them equally
- 278 *Pupil2: for that (.) one two three four five six
- 279 Teacher: it has exactly (.) the same chance (.) of winning
- 280 *Pupil2: but there's more chance of that one winning cause there's a different array of [numbers]
- 281 Teacher: [ok] ((inaudible)) listen again. ...
- ...
- 296 Pupil2: that one's got more chance
- 297 Teacher: why
- 298 *Pupil2: because it's a different variety of numbers
- 299 Pupil: and
- 300 Pupil: don't and him
- 301 *Pupil2: you never ever get one two three four five six. [you might] get three [((inaudible))]

Working Group 9

Here, the pupils are initially asked which lottery ticket they would prefer, one with the numbers one, two, three, four, five and six or one with the numbers three, seven, twelve, thirty eight, thirty nine and forty six. This initial question is not specifically directed at a particular pupil and several pupils give the answer “the second one”. The teacher’s following question, “why” continues to be directed at the class as a whole and three different pupils offer an answer.

So far, all the pupils have had the right to speak and stop talking as soon as the teacher begins to gesture to the pupil in line 261 that the turn is theirs. This offers further support for the suggestion that the rules that only one participant can speak at a time is not in fact violated if we treat the pupils in the class as one participant. Additionally, McHoul’s assumption that pupils do not self-select is also not contradicted as the question was directed to the class and the class has responded. However, in line 299 a pupil, not only self-selects as the next speaker but also her turn is directed towards pupil2 and a response is expected from pupil2. So, here is an example where a pupil has both self-selected for the current turn and selected the next speaker which is not the teacher.

This extract is then followed by several pupils both talking concurrently and directing their turns towards other pupils. Unfortunately, several pupils talking concurrently makes the content undecipherable for transcription. However, whilst these interactions clearly deviate from the rules governing turn-taking in the formal classroom environment (McHoul 1978), close examination of the video indicates that the pupils are not in fact violating the rules for turn-taking in natural conversation (Sacks et al. 1974). Whilst there are several pupils talking at once, their talk is not directed to the class as a whole but to an individual pupil elsewhere in the class.

We would argue that there are now several interactions occurring simultaneously, each with the same topic. Analysing groups of interacting pupils individually, the rules of turn-taking are adhered to. For example, observing the two pupils who spoke in lines 299 and 300, their later turns are directed towards each other, there is minimal overlap in their turns, with one cutting off their turn if they both begin talk at the same time, and the gaps between their turns are minimised. The two pupils compete for the floor and attempt to persuade the other that their answer is ‘correct’ whilst not violating the rules for turn-taking. Here the roles of teacher and pupil are not evident until the teacher takes a turn and the pupils end their turns.

In all the lessons in this study, turn-taking is tightly controlled by the teacher. All the teachers in this study control the topic through their turns and the questions that they ask and the pupils are constrained to answer these question (Barwell, 2003, p. 205). Many of the answers rely on pupils remembering facts, procedures or tasks undertaken in previous lessons. A few questions require pupils to offer explanations for their previous answers. The teacher from whom the extracts in this paper have been taken differs from other teachers in the study in that the majority of questions asked by him in the lesson are not followed by the nomination of a pupil to answer;

instead, they are directed to the class as a whole. Where questions are not directed at a particular pupil (or small group of pupils) the possibility arises for multiple respondents and multiple answers. In the lessons of the teacher discussed in this paper, when different answers are offered by different pupils an argument between pupils often ensues; the teacher often encourages these debates by asking the pupils to justify their answers. In these arguments, each pupil offers justification for their own particular answer and attempts to convince other pupils that their own answer is correct. Whilst pupils in all the lessons in the study are remembering, describing and explaining during whole-class interactions, only in these arguments are pupils using mathematical argument to justify, refute and convince others (Barwell, 2003; Mason, Burton, & Stacey, 2010). In this study, such discussions occur only in the lessons of the teacher used in this paper, though they do occur in the majority of his lessons.

We know from Mercer and Littleton's (2007) work on the *Thinking Together* approach that the classroom environment and culture have a significant impact on the extent to which pupils will dispute or disagree with their peers. Further analysis of these discussions from a conversation analysis approach is needed to identify which features of the classroom environment and culture the pupils are in fact orienting to.

CONCLUSIONS

In this paper we have outlined three types of situation in mathematics classroom interactions which are not considered by McHoul's (1978) systematic analysis of turn-taking. All three situations involve the self-selection of a pupil as next speaker. The first occurs when pupils ask their own questions, something we as teachers ourselves value in our lessons. If we consider the self-selection of a pupil in order to ask questions within McHoul's rules of turn-taking, some interesting questions are raised about the pedagogic relationship between encouraging pupils to ask questions and the implications this might have on classroom management. Pupils also self-select to initiate or perform repairs, either on the teacher's previous turn or a peer's turn and repair in mathematics classrooms is an area of further investigation elsewhere.

Finally, pupils self-select in order to respond to undirected teacher questions. We make the suggestion that when teachers ask questions that require a response but an individual is not selected to make this response, by treating the whole class as a single participant, the rules that govern turn-taking in natural conversation are in fact not violated.

In the situations where self-selection by different pupils results in an 'argument' or a point of contention (Gellert, 2011) between pupils raises further questions. It is clear from the videos and the transcripts that there is something qualitatively different in the justification given by pupils when they are attempting to persuade a peer in an 'argument' that their answer is correct, than when a teacher has asked them to justify

their answer. The motivation to provide a justification is intrinsic to the pupil when they need to convince a peer, and is often done passionately, as can be seen from the emphasis placed on the words in the transcript above. When justifying an answer to a teacher, the motivation often appears to be extrinsic as the justification is given in response to a request from the teacher. We believe that these ‘arguments’ are a positive feature of mathematics classrooms but are they actually effective in terms of learning. Is there any difference in the understanding and the depth of mathematics considered as a result of these discussions compared to the more ‘traditional’ interactions between the teacher and their pupils?

COMMUNICATING EXPERIENCE OF 3D SPACE: MATHEMATICAL AND EVERYDAY DISCOURSE

Candia Morgan¹ and Jehad Alshwaikh²

Institute of Education, University of London, UK¹ and Birzeit University, Palestine²

In this paper, we consider data arising from student-teacher-researcher interactions taking place in the context of a teaching experiment making use of multiple modes of communication and representation to explore three-dimensional shape. As teachers/researchers attempted to support student use of a logo-like formal language for constructing 3D trajectories in a computer microworld, a system of gestures emerged to represent the various types of turn in 3d space. We focus on the ways students coordinated the multimodal resources available in the classroom. In particular, we discuss how this system of gestures was adopted and adapted by teachers and students, drawing on both mathematical and everyday discourses.

Keywords: everyday discourse, gesture, multimodality, three dimensional space

INTRODUCTION

As human beings living in a three-dimensional world, we continually experience shape and motion within that world. Yet the mathematical description and analysis of these aspects of our experience appear to be exceptionally difficult for learners. In particular, we note issues identified by research in relation to identification and operation with angles (Clements & Battista, 1992) and recognition of connections between the physical contexts of corner, turn, and slope (Mitchelmore & White, 2000). A common approach to explaining such difficulties has been to identify conflicts between students' intuitions, built on their everyday experiences, and formal mathematical definitions of such concepts and operations on them.

Our experience of the world, however, is not purely physical but is mediated by language and other semiotic resources (Vygotsky, 1986). Mathematics teachers attempt to structure the mediating resources available to students by providing forms of language, visual and physical resources, digital technologies, etc. that are designed to offer mathematical ways of experiencing the world. In this paper, we draw on data from a teaching experiment, part of the ReMath project¹, focussing on three-dimensional shape. The sequence of lessons was designed to provide students with multiple modalities of mediating resources. We aim to consider the ways students coordinated the resources provided in the classroom with those brought from their everyday discourses. In particular, we focus on the development and use of a system of gestures to represent the various types of turn in three-dimensional space.

EVERYDAY AND MATHEMATICAL LANGUAGE

Although mathematical discourse is perhaps most notably characterised by its use of formal notations and uniquely mathematical vocabulary, this is only part of the story. As in many other specialised domains, the mathematics register incorporates considerable use of what may be termed ‘ordinary’ or everyday language in order to make mathematical meanings (Halliday, 1974). While some parts of this ‘ordinary’ language are used in ways compatible with everyday usage, others diverge subtly or, in some cases, radically. Rather than interpreting failure to use such language in ‘correct’ mathematical ways as evidence of lack of mathematical understanding, it is possible to see it as a consequence of students continuing to make use of ‘everyday’ linguistic patterns in circumstances when specialised usage is more appropriate. Students draw on the resources of an everyday discourse while their teachers expect them to be situated within a specialised school mathematics discourse.

MULTIMODALITY – DIFFERENT MEANING POTENTIALS

The bulk of existing research into mathematical communication has focused on the semiotic systems of language and algebraic notation. Research concerned with students’ use of diagrammatic, graphical or gestural forms has tended to approach these as vehicles for access to students’ ‘understanding’ or ‘representation’ of mathematical concepts rather than as forms of communication (though there are exceptions to this, e.g. Chapman (2003), Alshwaikh (2010)). There is, however, a major trend towards recognising the multimodal nature of communication and the importance of studying the contributions made by different modes of communication and representation. Each of the various available semiotic systems provides a different range of meaning potentials (O’Halloran, 2005). In investigating the meanings that students make within such a multi-semiotic environment, it is thus important to consider their use of all these modes and the relationships between them.

Moreover, wherever mathematical communication takes place in face-to-face contexts, gesture and actions also play a part. Kress, Jewitt, Ogborn & Tsatsarelis’ (2001) multimodal analysis of communication in science classrooms shows teachers and students making use of a “complex ensemble” of modes, including gesture alongside speech, writing, images, etc. There has been recent research interest in the use of gestures in mathematics teaching and learning. Much of this has focused on the gestures used by students, analysing the contribution made by gesture to learning and mathematical meaning making (e.g. Radford, 2009). In considering gestures used by teachers, studies have shown teachers and students making shared use of gestures initiated by student communication efforts (Arzarello, Domingo, Robutti, & Sabena, 2009; Maschietto & Bartolini Bussi, 2009) and teachers using deictic gestures as mediating resources (Bjuland, Cestari, & Borgersen, 2009).

In this article, we consider the evolution and use of a system of gestures for communication about movement in three-dimensional space, focussing on how these gestures related to other semiotic systems in use. Our particular interest is in how students adopted a system of gestures offered by the teacher/researcher team.

EMERGENCE OF A NEW SEMIOTIC SYSTEM: PLAYING TURTLE IN 3D

The episodes we discuss here arose during a teaching experiment involving a multi-semiotic interactive learning environment, MachineLab Turtleworld (MaLT). This environment, designed by the University of Athens Educational Technology Lab (ETL) ReMath project partners, incorporates a 3D turtle geometry, driven by a Logo-like language (see Figure 1). It also includes variation tools for direct manipulation of variables, though we do not discuss this component of the software in this

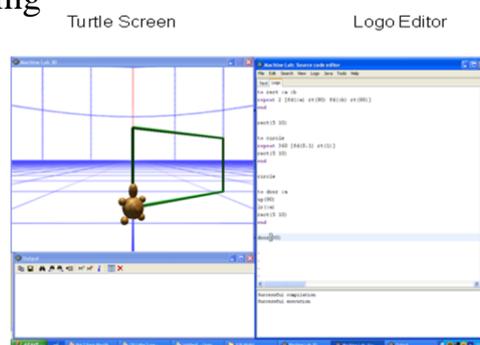

Figure 3: MaLT screenshot

paper (see Kynigos & Latsi, 2007). The pedagogical plan used in the London-based teaching experiment was designed to allow us to investigate the meanings students would make in relation to 3D geometry through their semiotic activity in the multimodal context. In addition to the resources offered by MaLT itself, the social environment of the teaching experiment was intended to allow, and indeed encourage, communication through talk and various paper-and-pencil based forms of representation and the use of physical manipulatives as well as through the computer software itself.

The teaching experiment was conducted in a state secondary school in London with a Year 8 class (aged 12-13 years). The students had no previous experience with MaLT or other forms of Logo. A sequence of nine lessons was taught collaboratively by the class teacher, the researchers and a student teacher attached to the class. In each lesson a video record was made, focusing on the teacher or researcher during whole class interaction and on a selected student or group of students during individual or group tasks. The video aimed to capture gestures and the various visual and physical resources available, including the computer screen when in use. Microphones similarly captured teacher talk and most student contributions during whole class interactions and talk within a group of students or between students and teacher during group or individual work. Episodes in which use of multiple semiotic modes was evident were selected for transcription. See Morgan & Alshwaikh (2009) for details of the transcription methods used with such multimodal data.

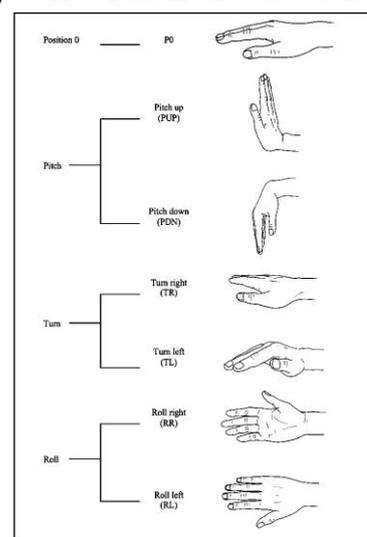

Figure 4: MaLT gesture codes

As we started to view the video data collected during use of MaLT, it was noticeable that the teachers and researchers made extensive use of gestures in an apparent attempt to support students' planning and execution of constructions. One significant type of gesture was a set of stereotyped hand and arm movements, often associated with use of the terms turn, pitch and roll and the associated Logo instructions (see Figure 2). This set of gestures constitutes a new semiotic system, linked with, but not identical to, both the linguistic description of movement and the symbolic system of Logo. They may be considered iconic gestures (McNeill & Levy, 1980; Roth, 2001), in that each bears a visual resemblance to the anticipated trajectory of an object moving in 3D space (or a turtle moving in the simulated 3D space of MaLT). Students also made use of these and other gestures to support their communication about turtle movement. Although the students used 'these' gestures to indicate that their hand and arm movements resembled those used by the teachers/researchers, we believe, as will become apparent, that the students made use of them in different ways, thus construing different meanings.

For the teachers and researchers, using these gestures as ways of thinking and communicating seemed to emerge as a natural consequence of our experience with two-dimensional versions of Logo. In Papert's seminal *Mindstorms* (1980), he argued that turtle geometry is useful for learning because it is body syntonic, "firmly connected to children's sense and knowledge about their own bodies" (p.63). This connection to personal bodily knowledge may be operationalised through 'playing turtle', either literally by walking along a path, enacting the instructions given to the turtle, or metaphorically in the imagination. Encouraging and supporting students to 'play turtle' has become a standard part of Logo pedagogy. The metaphor of 'playing turtle' thus formed part of our experience of 'Logo culture' and constituted for us a more or less implicit theory about learning with Logo.

Our partners ETL incorporated the idea of body syntonicity as an explicit theoretical justification for their own pedagogical plan, implemented in Athens, suggesting manipulating a model of an aeroplane to help students connect with the 3D logo commands (<http://remath.itd.cnr.it>). We adopted a similar initial activity in introducing MaLT to London students, using a model aeroplane to demonstrate a trajectory of turns and moves as described in Episode 1 below. We then substituted gestures (hand and arm movements without holding a model) for the movement of the aeroplane and incorporated these into our communications about three-dimensional movement throughout the teaching experiment. As students moved on to drawing 3D objects, no longer connected with the context of aeroplane trajectories, the hand and its movements came to be used as representations of the Logo turtle.

We now present two episodes from the teaching experiment in which the teachers and researchers modelled use of gestures to 'play turtle'. Then we present an analysis

Working Group 9

of an episode of a student's use of similar gestures. Finally, we discuss differences in the ways gestures were used by teachers/researchers and by the students.

Episode 1: In the introductory session with MaLT, the first author (CM) introduced the notion of turtle movement using a toy aeroplane. She accompanied the physical movement of the aeroplane with a verbal description, using and stressing the terms pitch (up/down), roll (right/left) and turn (right/left) in synchrony with the associated movement. After this initial introduction, students were set the task of using the 3D Logo language to construct the trajectory of an aeroplane taking off. On observing how we and other members of the teacher/researcher team supported students' attempts at this task, we noticed that we made use of iconic gestures in which the movement of the hand resembled the desired movement of the 'aeroplane'/3D Logo turtle. Sometimes a gesture was used synchronously with an 'equivalent' word or Logo symbol; at other times a gesture appeared to be used, without equivalent verbal or symbolic language, in order to elicit such language from the student. Although this use of gesture had not been planned, in the course of the lesson a system of gestures emerged, supplementing the planned use of everyday and formal language.

Episode 2: In a later lesson, recognising that some students were still having difficulty distinguishing between the different kinds of turn, we planned an activity to make more explicit links between the gestures and the language of 3D movement. At this stage, the system of gestures had become a code for us, mapping each change in the relationship between hand and arm in a one-to-one relationship to the language of 3D turns and hence to the formal Logo terms as shown in Table 1.

Hand/arm relationship	3D turn language	Logo formalism
	Down (more fully 'Pitch down')	PD 90

Table 1: Mapping gesture-language-Logo formalism

In this activity the class teacher (GD) used her arm and hand to act out the role of the turtle drawing a 'door' under instruction from the class. Once a movement was agreed to be correct, the corresponding instruction was entered into Logo and the consequent figure displayed. GD was careful to follow the conventions of the gesture system in order to emphasise the relative nature of turtle movement.

	<p>CM Ok. Look at the way that Miss's hand is pointing. Which way has she got to turn it now?</p> <p>S1 Down</p> <p>CM OK. Would you turn your hand down please?</p>
---	--

Working Group 9

	S1	No
	Ss	[laugh]
	CM	Was that right?
	S1	No

Table 2: ‘Down’ doesn’t mean ‘down’

Thus, for example, she turned her hand in a pitch down gesture when given the instruction to go down, even though this resulted in her hand pointing horizontally (see Table 2). Although student S1 used a term down that was part of the code system, he used it in an everyday sense to indicate movement towards the ground. This resulted in conflict for students between their intended outcome and the visual feedback provided. The conflict was resolved as shown in the following extract.

- CM It wasn’t was it? So which? Can you think about which way to turn?
- S2 [indecipherable]
- GD What did you say S2?
- S2 Sideways
- GD Sideways? Which way? Right or left? [GD uses her left hand to point to the right and left sides of her right hand]
- S2 Right
- CM Ok, everybody agree with that? [GD turns her hand TR] Does that look right?
- Ss Yeah

It is worth noting that student S2 again used an everyday term sideways, though in this case a term that was not also part of the formal system. The teacher GD revoiced this instruction, offering the terms right and left – terms with formal places in the code system as well as everyday meanings. GD’s additional deictic gesture, pointing to the right and left sides of her hand, served to indicate the desired plane of reference for right/left. This deictic gesture might be considered to serve as a form of scaffolding for developing the formal code, as all terms in the code must be interpreted relative to the current plane of the hand. On the other hand, by offering students a choice of just two acceptable answers, their attention may be focussed very narrowly on that choice, rather than on the underlying principle.

Working Group 9

1	here	<i>whole rt arm vertical P0, palm facing away from body, moves up in direction of fingers</i>	
2	turn here	<i>TR, arm moved in direction of fingers (maintaining TR position)</i>	
3	turn here	<i>attempt to move rt hand TR again (too difficult?)</i>	
4		<i>switch to lt hand, arm horizontal pointing rt, hand PDN (fingers pointing down)</i>	
5	turn here	<i>moves forearm clockwise, hand still PDN (fingers pointing left)</i>	
6	but I want it to come forward	<i>turns arm (awkwardly) so that, hand still in PDN position, fingers point towards body</i>	

Table 3: T draws a wall

Episode 3: T, having constructed one rectangular wall, was trying to construct a second wall perpendicular to the first. She explained what she was trying to draw using language and gesture. Her words are shown in Table 3, together with a verbal description and a sketch of the accompanying gesture. The switch (lines 3 - 4) between right and left hands appears to be a response to the physical difficulty of achieving the desired position with the right hand (see Figure 3). It allows T to maintain the direction the fingers are pointing (down). This may be taken to represent the turtle heading within the vertical plane parallel to the screen. However, in switching arms, she changes the relationship between arm and hand from a turn to a pitch gesture. We use turn and pitch within the conventions set up by the teachers/researchers and the Logo language, not to suggest that T associates her gestures with these terms. On the contrary, she does not appear to attach significance to the distinction, using turn in a generic, everyday way, focusing solely on the position of her hand and the direction in which her fingers are pointing in order to describe the intended turtle movement. While she is to some extent ‘playing turtle’ with her hand, she defines the turtle’s movements using position and heading at the corners of her imaginary wall rather than by using turn and distance as required by the Logo language. The use of the turn and pitch gestures is thus not supporting her move into using Logo code and may indeed have made her communication with teachers/researchers less effective.

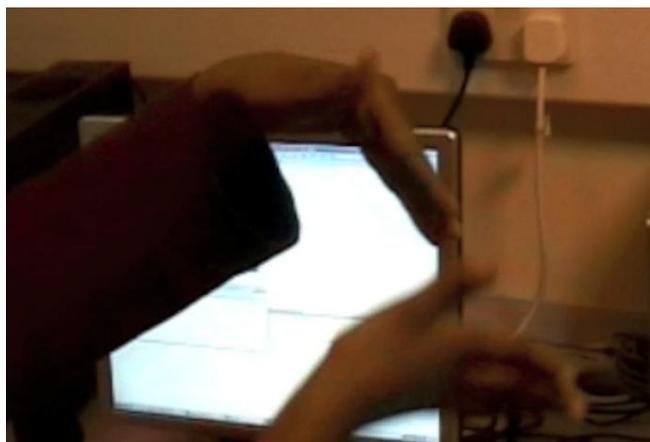

Figure 5: T switches hands

CONTRASTING GESTURES: IMAGING VS. IMAGINING

In Morgan & Alshwaikh (2008) we considered the difference between the ways in which teachers/researchers and students were using the ‘same’ gestures, and distinguished between the two notions of imaging and imagining. We defined imaging as using an iconic gesture to create an image of the construction of the turtle path. The movement of the hand mimics the movement of the turtle: the forearm is held parallel to the current heading of the turtle and the hand is moved to define the next heading. In contrast, for student T the relationship between forearm and hand did not appear to have significance: she was willing to substitute a pitch down gesture with her left hand for a turn right gesture with her right. We characterise her use of gesture as imagining, referring to her mental image of the desired outcome. Such use appears to have both iconic and deictic characteristics. In this episode, as in several other episodes within the data set, the student’s gesture points to the desired direction of movement, rather than mimicking the required type of turn. Our conclusions related to a disjunction between students’ everyday experience of 3D space and the movement of a turtle in MaLT, interpreted as a cognitive difficulty in imagining one’s body moving freely in that space. We noted at that time the possibility that students might be drawing on everyday communicative resources rather than on the formal systems proposed by the teacher-researcher team and by the Logo language. We now develop our analysis of the relationship between everyday and specialised discursive resources for describing 3D turning.

DISCUSSION: EVERYDAY VS. SPECIALISED RESOURCES

When movement is restricted to a 2D space, rotations are only possible around an axis perpendicular to (and outside) the plane. Our everyday experience is most commonly confined to movement experienced as more or less within a plane (i.e. travelling on the surface of the earth) and everyday English language reflects this, using the single word turn to denote any form of rotation. Even when rotations out of this plane are experienced they are generally referred to using the generic turn, modified by a description of the sense of the rotation (e.g. clockwise) or of the heading following the rotation (e.g. up or down).

In contrast, in 3D space rotations are possible around any line in the space, though any rotation may be defined as a combination of rotations around a set of three mutually perpendicular axes². Consequently, in order to specify rotations in 3D, three different words are required. In English (and Logo) the terms pitch and roll are adopted in addition to turn. Turn itself acquires a specialised use, referring to rotation around an axis perpendicular to the plane in which the moving object is currently located, while maintaining its everyday generic use. Thus it is possible to say: “In 3D space there are three types of turn – pitch, roll and turn.” As everyday discourse does not systematically distinguish different types of turning, it is common

Working Group 9

to omit specific reference to the process altogether, simply providing the heading following the turn.

Another difference between everyday language and the formal language of Logo and of the introduced gesture system lies in the ways that directions are used. In Logo and the gesture system, right/left and up/down are always defined relative to the current heading. In everyday discourse while right and left are usually used in a similar, relative way, up and down are more commonly used to refer to absolute directions relative to the earth. Gestures used to indicate turns in everyday discourse may also tend to be deictic – pointing in the direction of the turn – or hybrid like student T's gestures, rather than purely iconic – mimicking the trajectory of the movement.

As students talked about their work on tasks such as drawing a room, constructing a revolving door, etc., they tended to use only directions to describe their turtle turns, omitting the verbs that would define the type of turn. Thus, rather than saying turn right or pitch down they would say simply right or down (or possibly use an indeterminate verb go right or go down). Such elision is compatible with everyday usage in which down and right are unambiguous: down towards the centre of the earth; right relative to the vertical axis of the body and the direction in which the whole body is facing. Alternatively, as seen in Episode 3, students would coordinate everyday language and gesture, using only the word turn while indicating the direction of the turn by a gesture.

A particular source of difficulty in coming to use the Logo formalism lies in the fact that the formal terms turn and roll are both modified by right and left. It was noticeable that, even as students became more familiar with the formal language, roll was used less frequently than either pitch or turn. This is consistent with the everyday focus on direction rather than type of movement. Students talked about their desire for the turtle to go up or down, right or left, then associated these directions with the formal pitch and turn but had no distinct everyday way of referring to the desired outcome direction of roll.

Unlike the situation described by Arzarello et al, where “the teacher uses the same gestures as the students and rephrases their sentences using precise mathematical language” and thus “supports the students towards a correct scientific meaning” (2009, p.106), in the situation presented in this paper the teachers/researchers themselves developed and then used a new set of gestures in an attempt to support students' development of new formal language, an attempt that appears justified according to Roth's review of studies of gesture in teaching (2001). On the other hand, Roth also suggests that students may interpret teachers' metaphoric gestures as iconic, with negative consequences for their understanding of scientific concepts (p.377). In the case presented here, students adopted the teachers/researchers' iconic gestures as if they were deictic. We have argued that this adaptation is likely to be related to the characteristics of students' everyday language and gesture use and

Working Group 9

mismatches between these and the formal descriptions provided by the introduced system of gestures and the formal languages of mathematics and Logo. As a consequence the intended use of ‘playing turtle’ as scaffolding to support students’ development of the formal description of motion in 3D was less effective than hoped.

NOTES

¹The ReMath project (Representing Mathematics with Digital Technology), was funded by the European Commission Framework 6 Programme IST4-26751.

²In fact, two axes is the minimum required but can result in more complex sequences of turns.

A WORKING MODEL FOR IMPROVING MATHEMATICS TEACHING AND LEARNING FOR BILINGUAL STUDENTS

Máire Ní Ríordáin

Head of Education, St. Patrick's College, Thurles, Ireland

The role of language in teaching and learning mathematics has been well documented amongst mathematics educators (e.g. see Barwell, 2009; Clarkson, 2007) and those in the fields of social science, sociology and linguistics (e.g. Cummins, 2000). However, there is a need for the development of a model for improving the teaching and learning of mathematics for bilingual students. A number of theoretical models have been developed (see Ellerton, 1989; Gawned, 1990) over the years that have proved useful for investigating language related issues in the teaching and learning of mathematics but the model presented in this paper is concerned with issues that mathematics teachers who have bilingual students in their classrooms need to take into consideration.

INTRODUCTION

Mathematics is made meaningful through the use of language and students should be enabled to communicate adequately the language of mathematics. Consequently, the role of language in teaching and learning mathematics has been well documented amongst mathematics educators (e.g. see Barwell, 2009; Clarkson, 2007) and those in the fields of social science, sociology and linguistics (e.g. Cummins, 2000). However, there is a need for the development of a model for improving the teaching and learning of mathematics for bilingual students. A number of theoretical models have been developed (see Ellerton, 1989; Gawned, 1990) over the years that have proved useful for investigating language related issues in the teaching and learning of mathematics but the model presented in this paper is concerned with issues that mathematics teachers who have bilingual students in their classrooms need to take into consideration. The working model presented in this paper is derived from data generated by a variety of methods in the Irish context. The authors' research is concerned with Gaeilgeoirí (students who learn through the medium of Gaeilge (Irish)) *in the transition* from Gaeilge-medium mathematics education to English-medium mathematics education in Ireland. This transition can take place at the primary to secondary interface or at the secondary to third level interface. Data generated from the second to third level transition is utilised for the development of the working model. It is anticipated that other English as an additional language (EAL) students would present comparable similarities when encountering the English mathematics register for the first time. Thus, the working model presented in this paper can provide a basis for investigation within other mathematical learning contexts in which EAL students are present. This research is the first of its kind to be undertaken in the Irish context and accordingly significant contributions have

been made both nationally and internationally to this area of mathematics education (see Ní Ríordáin & O' Donoghue, 2009).

THE IRISH CONTEXT

Ireland has two official languages – Gaeilge (Irish) and English. Consequently, primary and second level education is provided through either language medium, dependent on the location of the school (all-Irish speaking region) and if it is a designated Gaelscoil (Gaeilge-medium primary level school) or Gaelcholáiste (Gaeilge-medium second level school). This rise in popularity of attending Gaeilge-medium education is significant with approximately 8% of primary school children and 3% of second level students studying through Gaeilge (Gaelscoileanna Teo., 2008). However the majority of these Gaeilgeoirí (students who learn through the medium of Gaeilge) face an imminent transition to English medium mathematics education, be it at second or third level education in Ireland. The integration of these students into English-medium mathematics classes is of concern to the author and consequently a working model has been developed exploring the issues that teachers of bilingual mathematics students need to take into consideration when engaged in mathematics education.

THE STUDY

Because of the diverse nature of the topic, a co-ordinating framework that exposed the various components of the field was needed. Both Ellerton's (1989) and Gawned's (1990) frameworks provided a theoretical structure for the design methodology. Ellerton's (1989) model shows the need to link the various aspects of language factors in mathematics learning and it demonstrates that culture occupies the entire classroom, and that communication within this culture is of key importance. Communication and language become central factors in issues such as socio-linguistics, natural language, psycho-linguistics, problem solving and classroom discourse which intersect with each other, and with most parts of the framework. Gawned (1990) acknowledges that the language of the classroom has a very important influence on students' understanding of mathematics, and that each classroom has a unique culture of its own. Gawned (1990) also discusses the discourse patterns found in mathematics classrooms. They tend to be dominated by rules, function within strict relationships and are teacher centred. Thus, this framework reflects the nature of mathematics classrooms and how language plays a key role in learning, particularly the language of the teacher and the textbook, while also highlighting the cultural influences on mathematics education. These models establish the need to link the various aspects influencing language and mathematics learning, while depicting the centrality of the teacher.

Fifteen Gaeilgeoirí, who had studied mathematics entirely through the medium of Gaeilge (13 years of schooling) until they began third level education, took part in

the study. All Gaeilgeoirí completed a detailed questionnaire and follow-up semi-structured interviews were undertaken with seven of the Gaeilgeoirí. During the interview completed a language-use survey (Clarkson, 2007), along with responding to questions based on specific themes. The primary aim of the questionnaire was to gain an insight into how language has impacted on the transition from Gaeilge-medium to English-medium mathematics education from a pedagogical, cultural and personal perspective. The purpose of the interview was to obtain an understanding of the language employed by Gaeilgeoirí when immersed in mathematical problem solving, to establish their perceptions of mathematics and of mathematical learning, while appraising their experiences of the transition to English-medium mathematics education. Analysis of the questionnaire and interviews involved both quantitative (SPSS, Version 15) and qualitative aspects (NVivo), which is in line with the mixed methods approach employed in this study.

DESCRIPTION OF THE WORKING MODEL

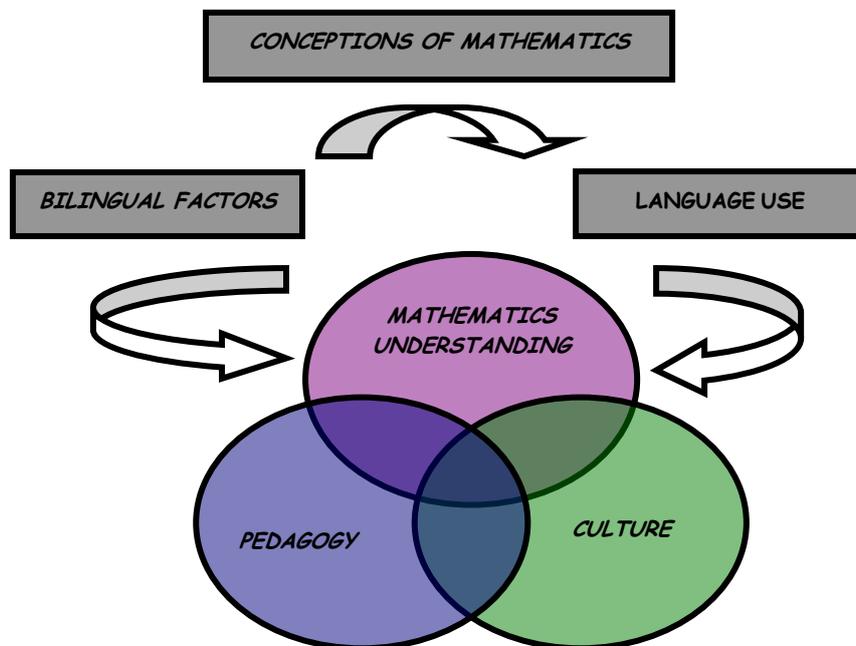

Figure 1: A model for improving mathematics teaching and learning for bilingual students.

The first relationships to be discussed are that of the triad of Mathematics Understanding, Pedagogy and Culture. They are examined in pairs initially with a final discussion on the group as a whole.

Mathematics Understanding - Pedagogy

The general consensus when questioned on what they believe ‘understanding mathematics’ to be was one of an instrumental perspective (Skemp, 1978). Being able to solve mathematical problems using mathematical formulae and correct procedures reflected one’s ability at understanding mathematics. Granted

instrumental understanding plays a significant role in mathematics learning but none of the participants interviewed relayed an importance of knowing ‘why’ (Skemp, 1978). However pedagogical aspects need to be taken into consideration when engaged in a discussion on learners’ perspectives of mathematics. Through discussion it became obvious that the participants’ lecturers/tutors place an emphasis on procedural knowledge for the learning of mathematics and little time is given to the development of conceptual understanding. Because of this emphasis Gaeilgeoirí’s learning strategies revolve around the continual practice of tutorial questions and previous exam papers. Rote learning is relied on and fostered through success in examinations. So for Gaeilgeoirí, their acuity for procedural methods in learning and understanding mathematics is rewarded by a system that instinctively promotes this type of knowledge.

Mathematics Understanding - Culture

Gaeilgeoirí entering Irish third level education are emerging from a learning environment immersed in the Irish language and culture. They are required to adapt to a learning environment steeped in the English language and cultural practices. Therefore Gaeilgeoirí are required to use mathematical tools within this new environment with little regard given to previous language/cultural practices. The assumption is that all students have done mathematics through English. Cultural differences played a significant role in the transition for these students. Many felt that the other students in their courses perceived them as being different

Tomás: Sometimes when in class I stand out a little bit because of my English isn’t up to their level...they’d know like because my accent and stuff that I’m different.

This in turn prevented them from engaging in discussions that arose during tutorial times. They lacked confidence in their ability to partake in mathematical discussions and ask questions through the medium of English. The lack of use of Gaeilge for academic, cultural and social purposes hindered their progression at third level education.

Pedagogy - Culture

Too often mathematics students are required to use procedures of the discipline without acquiring and embracing the culture of the discipline (Brown, Collins & Duguid, 1989). All Gaeilgeoirí interviewed highlighted the didactical approach employed by many lecturers/tutors at third level education in Ireland. Gaeilgeoirí were presented with abstract concepts and independent examples. Thus Gaeilgeoirí were exposed to the procedural tools of mathematics but lacked ‘authentic activity’ in order to truly understand the conceptual tools being employed (Brown, Collins & Duguid, 1989). The culture of third level institutions is to promote independent autonomous learners which Gaeilgeoirí found difficult to adapt to and they felt that lecturers/tutors were unapproachable. Consequently, there appeared to be a fear of

being perceived as ‘different’ and ‘weak’, with Gaeilgeoirí rarely seeking help with any mathematical difficulties they were encountering.

Mathematics Understanding - Pedagogy - Culture

Mathematics understanding, pedagogy and culture are interdependent in the triad – neither can be understood without the other. In order for Gaeilgeoirí to develop mathematical understanding, pedagogical practices are of key importance, which in turn are evocative of cultural influences. Mathematics is a product and a function of culture and unfolded through pedagogy.

The next sections will look at the upper section of the working model which consists of the quartet of Mathematics Understanding, Bilingual Factors, Conceptions of Mathematics and Language Use. The relationships between each pair will be discussed.

Mathematics Understanding – Bilingual Factors

Colm: Going from Gaeilge to English is hard at times...it has made the transition to college maths difficult for me but I’m getting used to it.

Although the majority of Gaeilgeoirí interviewed found the general transition from second to third level education relatively easy, having to transfer from learning mathematics through Gaeilge to learning mathematics through English impacted on their learning and understanding of the subject. The main source of difficulty was the actual ‘language of mathematics’ i.e. the mathematics register. They all referred to problems they encountered with mathematics terminology they had acquired at primary and second level through the medium of Gaeilge but were unaware of the English equivalent on entering third level. For example, basic operations such as addition (simiú), subtraction (dealú) and division (roinnt) caused problems for Gaeilgeoirí. Gaeilgeoirí were also confused by similar words in English e.g. “multiple” and “multiply” and may have been unsure of the difference in meaning. Whereas in Gaeilge two dissimilar words are used – “iolraí” (multiple) and “meadú” (multiply), thus lessening the confusion when interpreting and answering a question. Similarly, the syntax and semantics of the Gaeilge language lends itself to a clearer understanding of what is being described. For example, in Gaeilge a passage reads “It is called the Highest Common Factor the number that is highest, which is 4” (directly translated) compared to “The highest of these, called the Highest Common Factor, is 4” in an English version. Therefore, when mathematical problems are presented in ‘complex’ English it is a source of confusion for Gaeilgeoirí in this study. Gaeilgeoirí highlighted the expectation on the behalf of lecturers/tutors that all students has learnt their mathematics through English and thus their learning needs were not catered for in the transition. Clearly, Gaeilgeoirí require assistance in the initial transition and perhaps if appropriate teaching interventions were introduced this transition process may be eased as well as improving mathematical understanding. The fact that all students interviewed are relying on rote learning in

order to pass examinations and thus are seen to ‘succeed’ at mathematics, the type of understanding being developed is not the desired and one would question if this has significant implications down the line for future mathematics learning and career development.

Mathematics Understanding – Conceptions of Mathematics

In a previous section the participants’ conceptions of mathematics were examined and it was found that the majority had a narrow perception of mathematics in that they strongly believe it only consists of ‘numbers’, ‘formulae’ and using ‘numbers to solve problems’. This perception partly stems from the mode of teaching employed at second and third level education. Didactical teaching is the norm where repetitive practice of questions is encouraged. Thus, Gaeilgeoirí are not gaining a deeper insight into the subject area as a consequence of the teaching methods they have encountered. What was surprising for the author was given the emphasis that Gaeilgeoirí placed on problems they encountered with mathematics terminology and the change in the language of learning, little saw a relationship between mathematics and language. If Gaeilgeoirí lack awareness of the influence of language on mathematics learning and understanding then this may have repercussions for their mathematical understanding. Language plays a key role in mathematics learning and understanding and awareness of this is crucial when immersed in a new language of learning. The author believes that this awareness of language as a source of difficulty may actually help the students’ mathematical understanding in the transition from Gaeilge-medium to English-medium education.

Mathematics Understanding – Language Use

During the interview Gaeilgeoirí were asked to complete a Language Use Survey (see Clarkson, 2007). This consisted of identifying what language(s) they used in answering the individual word problems on the test instrument. Gaeilgeoirí were given the option of selecting English only, English and Gaeilge, or Gaeilge Only. Gaeilgeoirí drew on their first language of learning when answering some of the mathematics word problems even though all of the problems were presented in English. Gaeilge was used primarily for thinking out a problem and conducting mental operations such as addition and multiplication of numbers as this was what they described as ‘normal’ and ‘natural’ to them. Given their complexity at times to describe their use of languages it appears to be a subconscious action and ingrained in their process skills when engaged in mathematical problem solving and understanding.

Bilingual Factors – Conceptions of Mathematics

Gaeilgeoirí’s conceptions of mathematics revolved around the belief that it consists of numbers, problem solving and using formulae. The majority saw the transition between languages as ‘relearning’ mathematical words and concepts through the new language of instruction. There was no recognition of transferring mathematical skills

from one language to another or drawing on skills developed in both languages to solve mathematical problems. This demonstrates their lack of *awareness* of the fact that they do use Gaeilge relatively often when engaged in mathematics (previous section) and therefore are drawing on both languages. Due to this lack of *awareness*, Gaeilgeoirí saw no real advantage to having two languages for learning mathematics. Perhaps if Gaeilgeoirí were more aware of the influence of language on mathematics learning this may ease the transition and improve their mathematical understanding.

Conceptions of Mathematics – Language Use

Gaeilgeoirí consider language competency in one or both languages as irrelevant to mathematics learning and understanding. They view the purpose of language as solely for reading questions, but they do not see this as an important step in solving a mathematics problem. Gaeilgeoirí failed to make a connection to language as a facilitator of understanding. They considered mathematical content solely as the source of difficulty. As a consequence this may be acting as a barrier to developing their mathematical skills and understanding.

Bilingual Factors – Language Use

There was a clear lack of understanding by Gaeilgeoirí of their use of their languages. It was only through probing that the students began to realise that they use Gaeilge, even if it was “*only just for simple things like adding and multiplying*” (Liam). They failed to see an advantage to having two languages for learning mathematics, but perceived it as occurring in one language or the other at a given time. The author strongly feels that this lack of awareness of language use and connection with mathematics learning may be acting as an obstacle to the development of Gaeilgeoirís’ mathematical understanding.

Mathematics Understanding - Bilingual Factors – Conceptions of Mathematics - Language Use

Mathematics understanding, bilingual factors, conceptions of mathematics and language use are interdependent and neither can be understood without the other. The primary aim is to develop mathematical understanding but for Gaeilgeoirí significant bilingual factors, conceptions and language use need to be taken into consideration in the development of this understanding.

IMPLICATIONS FOR THE IMPROVEMENT OF MATHEMATICS TEACHING

The focus of this investigation has been on Gaeilgeoirí in the transition from Gaeilge medium to English medium mathematics education. Clearly the teacher is going to play a significant role in facilitating this transition. The following are a number of suggestions for teachers that can be incorporated into their pedagogic practices (Anstrom, 1999), consistent with the working model developed. It is important that mathematics teachers develop innovative strategies for teaching mathematics to

Working Group 9

Gaeilgeoirí so to challenge the high ability bilingual students, while ensuring weaker bilingual students are catered for. When in the transition between language mediums, Gaeilgeoirí will be integrated with all English students. No facilitation is made for Gaeilgeoirí e.g. separate classes, extra tuition. Thus, the recommendations suggested below are good practices that may help improve mathematics teaching across the board, not just specific to catering for bilingual students. We need to improve the quality of mainstream instruction so as to make language and mathematics content comprehensible for Gaeilgeoirí, and accordingly cater for their pedagogic, cultural, linguistic and mathematical needs.

- Teachers need to ***make mathematics accessible*** to Gaeilgeoirí and this can be achieved through introducing problem solving activities. By involving Gaeilgeoirí in solving interesting, real-life problems it will encourage critical thinking, in conjunction with basic skills development and practice and accordingly change their *conceptions* of mathematics as consisting solely of numbers, formulae, etc. These real-life problems can be directly linked to Gaeilgeoirí's cultural background thus facilitating the development of *mathematics understanding* and a more student-centred *pedagogical* approach (Buchanan and Helman, 1993). Through demonstrating to Gaeilgeoirí that their prior experiences are of importance, awareness of the Gaeilge language and its importance in developing mathematical understanding will be emphasized. Moreover, the content of mathematics should not be 'dumbed' down for Gaeilgeoirí in the transition; these students have the potential to excel.
- It is important ***to teach the language of mathematics***. From the author's findings it is clear that the language of mathematics is a source of difficulty for Gaeilgeoirí in the transition. Command of the English mathematics register will play an important role in the development of Gaeilgeoirí's mathematical ability and easing the challenges encountered with *bilingual factors* when transitioning to a new language of learning. Therefore, Gaeilgeoirí will require ample opportunities to hear, speak and write mathematically. This proposition is centred on the connection between *pedagogy* and *mathematics understanding* whereby improving Gaeilgeoirí's ability to use the English mathematics register will facilitate engagement on mathematical thinking, while encouraging students to justify ideas orally and in writing (Corasaniti Dale and Cuevas, 1992).
- Mathematics teachers should ***create language supportive environments***. Planning classroom discourse that is inclusive of Gaeilgeoirí demands that teachers create mathematical environments and instructional situations that support students' linguistic and conceptual development. By integrating reading and discussion with mathematics content, it supports the development of academic language skills and encourages greater depth in the students' understanding of the mathematical topic. By adopting such strategies in the

Working Group 9

mathematics classroom it facilitate the development of Gaeilgeoirí *language use* and improve their *conceptions of mathematics*.

- Teachers should ***vary instructional methods***. By doing so they will provide Gaeilgeoirí with an opportunity to learn in different ways, through individual, small group and whole class work (Buchanan and Helman, 1993). These methods could include direct instruction, guided discovery, cooperative learning, and computer assisted learning. By varying the instructional methods it will allow for the improved *pedagogical* practices leading to a deeper *understanding* of mathematical concepts, while developing Gaeilgeoirí's *language use*.
- Finally, ***assessment should be authentic and meaningful*** (August and Pease-Alvarez, 1996). Naturally, assessment should have a specific and clear purpose. It may need to take place through the medium of English and in Gaeilge, depending on the language proficiency of the students and so as to truly reflect Gaeilgeoirí's mathematical ability and *understanding*. For Gaeilgeoirí, the test item should incorporate aspects associated with their *cultural* background and allow for *bilingual factors* that may influence their performance on the assessment. The teacher should aim to use a variety of measures such as portfolios, observations, anecdotal records, interviews, checklists, and criterion referenced tests (August and Pease-Alvarez, 1996). By employing a variety of methods it will allow for assessing Gaeilgeoirí's *mathematical understanding* of key concepts while examining their *language use* facility.

CONCLUSION

Knowledge of the difficulties that Gaeilgeoirí may experience in the transition to English-medium mathematics education in the hands of a discerning teacher can prove fruitful for easing the transition for Gaeilgeoirí. Although the findings emerging from this research are specific to the Irish context, they are important because of their applicability to other bilingual contexts. The working model presented can be employed in order to investigate other EAL learning contexts in order to improve the teaching and learning of mathematics for bilingual/multilingual students. Given the increasing number of students learning in a dominant language that is not their first language, these findings are important to mathematics education (Adler, 2001).

REVOICING IN PROCESSES OF COLLECTIVE MATHEMATICAL ARGUMENTATION AMONG STUDENTS

Núria Planas, and Laura Morera

Universitat Autònoma de Barcelona, Spain

Type your abstract here. The purpose of this paragraph is to draw attention to the style for abstracts, which is Normal, italic, and the length is up to 10 lines. In this report we draw on interactionist theories in (mathematics) education to better understand classroom processes of collective mathematical argumentation. We discuss students' uses of revoicing in different situations of mathematical learning taken from two recent micro-ethnographic studies in Barcelona and Tarragona, Spain. We document two examples that shortly illustrate two "positive" uses of revoicing in peer interaction: i) to ensure mutual understanding; and ii) to foster more explanations. We finish with comments on what is new in our research and how it needs to go in new directions to explore other uses of revoicing that appear when considering a more critical perspective in the analysis of classroom data.

INTRODUCTION

Language and discursive practices shape the concepts and processes that organize much of the everyday situations in the mathematics class. In their work, Enyedy et al. (2008) refer to revoicing as a discursive practice to promote a deeper conceptual understanding of school mathematics by positioning students in relation to one another, facilitating debate and fostering mathematical argumentation. The study we present here draws on this broad notion of revoicing to examine communication and mathematical argumentation in peer interaction. We discuss students' uses of revoicing in different situations of mathematical learning taken from two recent micro-ethnographic studies in Barcelona and Tarragona, Spain. This approach is part of our more general focus on the role of language as a social resource in the construction of collective mathematical argumentation in classroom settings.

Various works have examined teachers' uses of revoicing and interpreted this practice as an essential part of what the teacher does during the process of instruction (see Krussel, Edwards & Springer, 2004; or O'Connor & Michaels, 1996, among others). So far, there has been much more empirical literature developed on teachers' revoicing than on students' revoicing in peer interaction. Our study is a contribution to the more reduced group of works on students' revoicing, specifically for the area of mathematics education. We claim that the construction of the students' mathematical discourses is highly orchestrated by what other students say and how. Our data from small groups and pairs reinforces evidence to support the importance of knowing the students' reactions to the ways in which their peers "re-tell" their words while engaged in mathematical tasks.

Before exemplifying data on some of the uses of revoicing in students' interaction, we start with theoretical considerations on the notions of revoicing and collective mathematical argumentation. We then move on to a brief summary of our methods in the analysis of classroom data, and discuss preliminary findings centered on "positive" uses of revoicing. We finish by suggesting some of the problems regarding the exclusive interpretation of revoicing as a facilitator. Our current analysis needs further examination from a more critical perspective that also signals practices of revoicing as markers of legal talk and talkers in the mathematics class.

THEORETICAL FRAMEWORK

This section introduces how the notions of revoicing and collective mathematical argumentation are conceptualized in our work. We point to inspiring literature in the effort to establish empirical connections between these two interactional accomplishments. We claim that revoicing is an important part of the processes that lead to argumentation, although we recognize that the relationships between these two practices are problematical: revoicing may be used for different (social) purposes and may have different implications, some of them with no clear orientation towards mathematical learning.

Revoicing

An assumption of the interactionist theories in (mathematics) education (see, for instance, Voigt, 1996; or Krummheuer, 2011) is that talk among students (and between students and teachers) needs to be analyzed as discursive practices through which (mathematical) knowledge is constructed. Some examples of these discursive practices are revoicing, questioning, requesting, telling, or managing. The practice of revoicing essentially tries to repeat some or all of what has been said in a preceding turn as the basis for a shift in the interaction. This repetition can be manifested in two forms, either as a linguistically "exact" copy or as a reformulation. Despite the linguistic possibility to repeat a sentence exactly, from a social point of view and taking into account the recursivity thesis by Giddens (1979), we understand that every instance of the use of language is a potential modification of that language at the same time as it acts to reproduce it. Thus we find it more adequate to associate revoicing to conceptual reformulation rather than linguistic repetition.

O'Connor and Michaels (1996) indicate three main uses of revoicing in teachers: 1) to position students in differing alignments and allow them to (dis)claim ownership of their position; 2) to share reformulations in ways that credit students with teachers' warranted inferences; and 3) to scaffold and recast problem-solution strategies of students whose first language is not the language of teaching. These uses have been documented by these authors as having the effect to focus group discussion and scaffold conversation on the basis of what is said, when, how, with whom... However, drawing on these three uses, the work by Forman and Ansell (2001, 2002) is focused on the examination of the students' voices. These authors analyze

conversational moves in the "follow-up" part of the Initiation-Response-Feedback sequence in mathematics lessons with frequent practices of revoicing. Although there is a clear emphasis on the social dimension of the IRF sequences and obstacles to the students' voices are recognized, revoicing is primarily seen as a facilitator in the interaction.

Collective mathematical argumentation

By "collective argumentation" we mean the interactional accomplishment given by: 1) representing a task or problem alone; 2) comparing representations within a small group of peers; 3) explaining and justifying the various representations to other members of the group; 4) reaching agreement within the group; and 5) presenting the group's ideas and representations to other participants in the class to test their acceptance (see Brandt & Schütte, 2010, for a similar interpretation that expands on the idea of argumentation from an individual to a collective notion). Like Cobb (2008), we understand that situations of collective argumentation are mathematical if they are organized around specific ways in which tools and procedures are used to achieve mathematical goals. This is still a very general conceptualization of argumentation if we pay attention to the mathematics, but it becomes useful because it puts the emphasis on the processes of teaching and learning.

Sfard and Kieran (2001) have also discussed the role of the students' interaction in processes of collective mathematical argumentation. These authors interpret collective mathematical argumentations as interactive processes in the learning of how and when to participate in school mathematics discourses. They analyze the way in which students express themselves throughout their mathematical talk by means of discursive tools that help advance towards the construction of shared meanings. In particular, certain practices of revoicing in the resolution of mathematical tasks are interpreted as a social tool in the students' exploration of what counts as an accepted and "repeatable" reasoning in the mathematics classroom.

In the situated context of our work, revoicing becomes a reformulation of language to achieve new possibilities for further mathematical argumentation. The attempt is collective and entails a complex system of voices (Planas, 2011). It makes sense then to consider what it means for a student to participate in the "legal" process of constituting a culture of argumentation in the classroom. In this report, we look at the "unanimous" voice of the interaction, instead of pointing to individual voices trying to grasp what becomes necessary for them to gain membership while moving from one state of participation to another. At future stages, however, our study ventures to contribute to the much reduced group of works on the act of using revoicing socially in the delimitation of voices in the mathematics classroom.

EMPIRICAL CONTEXT

Our two research projects [1] share an interest in the qualitative analysis of narrative classroom data. Since 2005, we have been collaborating with a group of mathematics

teachers [2] to develop inquiry-oriented tasks that are to be proved as facilitators of collective mathematical argumentation in small group and pair discussion. The implementation of tasks together with the characterization of situations of collective argumentation by means of the Toulmin's scheme (2007) has provided considerable information regarding students' reasoning in peer interaction. We have recently started to analyze broader discursive practices to include language and social issues in our analysis of how students help each other through talk in their joint construction of mathematical argumentations. The integration of mathematical, language and social issues guides our current process of gaining theoretical and empirical understanding.

In the context of the group of mathematics teachers and researchers, we examine data from secondary mathematics classrooms that were first chosen to validate the implementation of tasks. Up to now, we have searched for examples of students' revoicing in two main sets of data coming from two classrooms in two schools. We have had various meetings --some with the teachers-- to comment on classroom lessons represented through video data. The meetings have been oriented by three main questions: 1) What is the evidence of revoicing in this lesson (if any)? 2) In what sense are two examples of revoicing similar/different? And 3) what are the explicit uses to which different practices of revoicing are put? In what follows, we introduce two examples of peer interaction that hold the potential to make more in depth investigations of other episodes involving a variety of practices of revoicing.

EXAMPLES OF FINDINGS

In this section, we describe processes of using revoicing as a resource. We document two types of "positive" revoicing. They are thought of as positive because they contribute to the continuity of peer interaction and mathematical argumentation. The two examples that follow illustrate two uses that prompt: i) mutual understanding, and ii) more explanations. These uses of revoicing seem to require forms of communication, argumentation, and interaction that would otherwise be difficult to achieve. Furthermore, these uses help interpret how the interaction is to be read: the degree of respect or resistance towards the students involved, with an eye to the mathematical contents or the lack there of, etc.

More generally, our examples show that mathematical learning gains "strength" when it is invoked by one student and re-invoked by other students in the context of peer interaction. Data shows different students using correct mathematical reasoning that "does nothing on its own" until it is reconstituted by others through talk. In a large variety of episodes, the argumentation is first introduced by one of the students in the small group, and then becomes an object of negotiation through conversations in which revoicing helps distribute turns among speakers. There are also episodes in which revoicing becomes a strategy to overcome occasional interruptions in some of the students' mathematical implication during the resolution of the task.

Students' use of revoicing to reinforce mutual understanding

In group discussions among three or more students, there is a "positive" use of revoicing that contributes to making one of the student's ideas available to the rest of the members in the group, and helps reinforce mutual mathematical understanding. We have several examples of episodes in which a student partially explains an argumentation, and another student in the group uses revoicing to emphasize particular aspects of that argumentation, provide additional information, and to facilitate a more adequate mathematical understanding from her/his peers.

In the example below, documented in Morera (2010), we find four students --Elba, Joan, Carles and Uriel-- trying to find out how to transform one line segment onto another by means of a rotational superposition. The students are using a dynamic geometry package to identify the right place to construct the rotation centre. Although the four students are working together in the same small group, they are working on two different computers next to each other. The distribution into two pairs --Elba and Joan, and Carles and Uriel-- leads to the development of two different initial approaches to the problem (see Figures 1 and 2, with the given line segments printed in black).

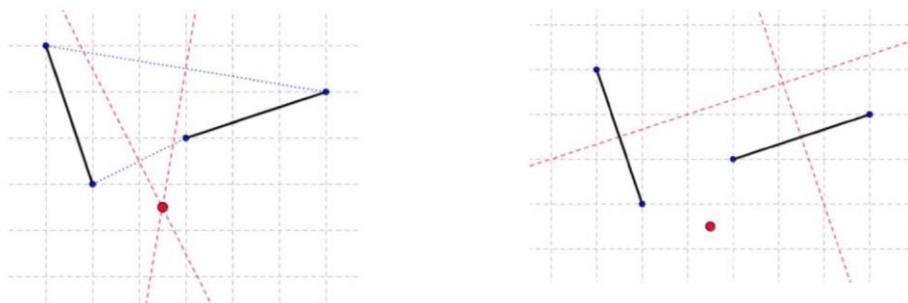

Figure 1. Elba & Joan's approach Figure 2. Carles & Uriel's approach

Two approaches to the resolution of the problem can be inferred from the transcript of the group discussion: while Elba and Joan plan to construct the segments by joining the ends and then drawing the perpendicular bisectors, Carles and Uriel draw the perpendicular bisectors from the initial line segments. There is a moment when Elba and Joan realize that Carles and Uriel are not considering the ends of the given line segments. This is the starting point of the following dialogue [3] in which the two pairs bring together their ideas:

Joan: Shall we talk about what we've been doing?

Elba: I was discussing it with Joan... Maybe, if we drew the perpendicular bisectors here, they would coincide at the same point [see the red point in Figure 1].

Uriel: It's impossible for the perpendicular bisectors to coincide over there! [see the red point in Figure 2]

Joan: [to Uriel] **If we drew the perpendicular bisectors here [3], where the two points come together, not the two line segments, they would coincide at the same point.**

Working Group 9

Carles: Ah, okay! I thought you meant this one!

Uriel: So did I!

Due to our focus on the identification of practices of revoicing in the construction of collective mathematical argumentations, we only represent the part of the transcript in which the use of a particular revoicing --with the exact repetition of a sentence in this case-- helps overcome a misunderstanding in the resolution of the problem. In the transcript above, Elba introduces a mathematical argumentation that leads to confusion as it is not clear for Carles and Uriel which line segments are for the perpendicular bisectors. Following an intervention by Uriel that confirms this confusion, Joan repeats Elba's explanation and includes a short clarification in-between --“... where the two points come together, not the two segments...”-- that helps Carles and Joan expand their understanding of the problem. The whole transcript offers more evidence of this interpretation.

This first example illustrates the collaboration among the students in the group. Joan might have completely reconstructed Elba's sentence and started with a new explanation, instead of building into his peer's explanations. More generally, this example points to the deep social dimension in the elaboration of mathematical argumentations in the classroom. Argumentation emerges in conversational contexts and is oriented toward an audience. The context and audience determine how many details and mathematical clarifications are needed to go on with reasoning, as well as to what extent certain explanations may be publicly considered as “repeatable”.

In another context, the sentence “If we drew the perpendicular bisectors here, when the two points come together, not the two segments, they would coincide at the same point”, might not represent a “good” mathematical argumentation: there is no indication as to the meaning of ‘two points coming together’, or which two line segments are being referred to. The sentence needs to be interpreted at least in relation to what has been said in previous turns, and what knowledge Elba and Joan have of their peers' reasoning. The adequacy of a mathematical argumentation in the social context of the classroom is informed by its mathematical quality, but also by the representations that the students (and the teacher) have of how mutual comprehension is facilitated.

Next, we offer a second example of collective mathematical argumentation in peer interaction with a slightly different use of revoicing that reinforces the occasions for mathematical talk, and fosters further interaction among students.

Students' use of revoicing to foster more explanations

Students need ways of talking that help them deal with lack of clarity in other students' contributions in the resolution of mathematical tasks. Some students' use of revoicing acts as an enquiry for the expansion of a point that has not been fully understood. In our research, this use tends to happen in pair work situations in which a student wants another student to clarify a mathematical position and elaborate more

Working Group 9

on a specific idea. The example below shows the collaboration between two students, Anna and Ona, to find the quantity of squares in a chessboard.

Teacher: Work in a pair and collaborate with each other, okay?

Ona: First we should reflect on the problem on our own.

Anna: Yeah, we need to know what to talk about [...]

Ona: [A few minutes later, to Anna] What are you writing here?

Anna: Just counting all the squares in an easy way.

Ona: Do you have the number?

Anna: It's one, four, nine, sixteen... they are always square numbers.

Ona: **So you're saying that they are always square numbers? ... And easy?**

Anna: Yeah. You know why? [She points to a page in her notebook with many numbers and her written resolution]. You have one big square with sixty- four small squares, that's eight times eight. Then you have four squares with forty-nine squares, you see, seven times seven [see Figure 3]. You see that?

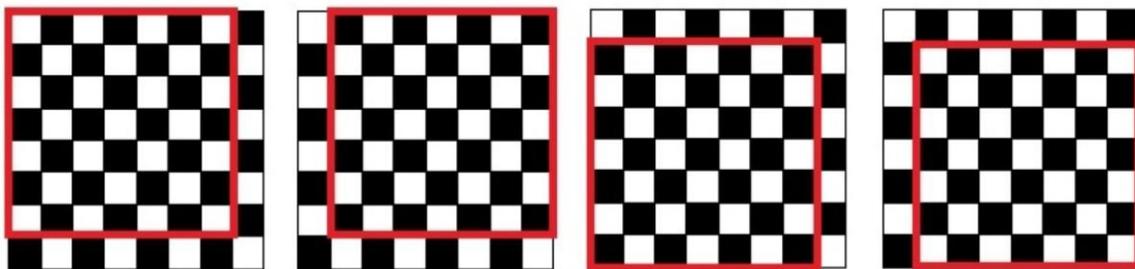

Figure 3. Anna and Ona's approach

The excerpt above illustrates a classroom situation in which two students have been working separately for a few minutes and then come together to comment on their approaches to the problem of the squares in a chessboard. Anna has developed a complete and mathematically correct written resolution for this problem, but starts explaining it to her peer in a rather synthetic way – “Just counting all the squares in an easy way.” At the end of the conversation (the entire episode is not reproduced here), Ona comes to agree that there is an “easy” way to count all the squares in a chessboard; it is improbable that this agreement has been facilitated by Anna's interventions in which she seems to expect her peer to mathematically “read” through her words. This second example is similar to the first one, in that revoicing is used by Ona as an instrument that helps provide a way of testing Anna's claims on both the mathematics and the simplicity of the resolution method.

Anna initiates her explanations as if interacting with a mathematically “ideal” peer that would share and quickly understand her reasoning. In this context of interaction, Ona's use of revoicing acts as a way of forcing attention to who the peer is and what her specific needs are to gain agency in sharing a particular mathematical argumentation. Here, the use of revoicing facilitates Ona with the role of one who

invokes a sort of participation that controls the sharing of reasoning. Anna's notebook contains a complete resolution of the problem, and by pointing to it she evokes an "ideal" reader that might feel sufficiently satisfied with the written text. Ona's reaction, with the repetition of a sentence and the emphasis on the idea of simplicity, makes it difficult to avoid further explanations and offers the possibility in practice to develop a discourse based on the resolution of the problem.

As in the first example, cooperation among students is required for the achievement of collective argumentation. Ona's use of revoicing contributes to a new conversation with the inclusion of more explicit explanations of the resolution processes that have been followed by Anna. It is necessary that Anna accepts the new basis for this conversation. When revoicing, as an instrument, is put to work it requires the involvement of all parties. Ona, Joan or any other student, on their own, do not have enough agency to convert the reformulation of sentences into an instrument with the purpose of serving collective mathematical argumentation.

Although the empirical relationship between revoicing and collective mathematical argumentation still remains unclear in our work and interpretations of the episodes need to be reinforced with complementary perspectives, we can say a few things at this time. We have chosen two examples of "positive" revoicing for this report, but we do not affirm that revoicing either expressly leads to more argumentation or more collaboration among speakers. We have data with practices of revoicing that do not turn into "more mathematics and/or more collaboration." The status of revoicing as an instrument for the sake of mathematical conversations appears linked to the social nature of this practice. In Planas and Civil (2002), some of the social issues of influence on the interpretation of discursive practices in classroom settings were already documented, with specific attention to recognition among peers. In our second episode, for instance, Ona's revoicing is effective because Anna is willing to explain her reasoning. Nevertheless, what would happen if Anna imagined her peer as an obstacle in her learning? Would she give detailed answers to her questions?

FINAL REMARKS

Together with the interest in examining relationships between revoicing and collective mathematical argumentation, a research focus on revoicing in mathematics classrooms raises many other questions. What is new in our work is the interest in the exploration of some of the critical functions that are carried out by practices of revoicing that are initially linked to "positive" uses only. Much remains to be done in this direction, and in fact, we are still at the stage of empirically illustrating "positive" uses and "generating suspicion". It is not clear whether one can critically examine revoicing in the strict context of the micro level of the small group or the whole class with no attention to the multiplicity of voices from the different and various macro levels that have an influence on how discourses are re-elaborated in classroom settings. The repetition of a sentence may serve as a strategy to foster

Working Group 9

mutual understanding and mathematical explanations, and at the same time represent messages of incorrectness, doubt, disapproval... depending on who the speakers are.

It seems unlikely that a one-dimensional view on revoicing or any other discursive practice, based on either mathematical or social issues, helps gain a better understanding of how mathematical conversations are prompted in classroom settings. On the one hand, from the joint perspective of language and mathematics, we cannot claim that all "significant" mathematical meanings are maintained the same when a sentence is reformulated, neither can we affirm that "repetitions" always stand for evidence of learning. This uncertainty points to serious methodological obstacles, especially when trying to justify processes of individual mathematical learning that are constructed in contexts of conversation with frequent practices of revoicing. On the other hand, from the joint perspective of language and social interaction, even when a sentence is repeated exactly the same, we still cannot guarantee that the context and the interpretation have not varied. The precision of the language of mathematics and the complex social discourses around it (e.g., 'who is considered as mathematically competent', 'what is expected to be included in school mathematics') makes it difficult to answer all these questions without adopting a multi-dimensional view on how everyday situations in the mathematics classroom are organized.

NOTES

1. The work is part of Projects 'Estudio sobre el desarrollo de competencias discursivas en el aula de matemáticas', EDU2009-07113, and 'Contribución al análisis y mejora de las competencias matemáticas en la enseñanza secundaria con un nuevo entorno tecnológico', EDU2008-01963, both funded by the Spanish Ministry of Science and Innovation. The two authors are members of the Research Group 'Educació i Competència Matemàtica', SGR2009-00354, recognized by the Catalan Department of Universities. The second author owns Grant BES2009-022687.
2. The Group EMAC --Catalan acronymus for Critical Mathematics Education-- is supported by Associació de Mestres de Rosa Sensat, and partially funded by Project 'Diagnosi de necessitats socials i educatives de l'aula multilingüe: aproximació des del cas de matemàtiques', ARFI-1-2009-00052, Catalan Government.
3. All dialogues have been translated from Catalan to English by the first author.
4. The bold format is used in our transcripts to mark the exact moment in which revoicing appears.

EPISTEMOLOGICAL AND SEMIOTIC ISSUES RELATED TO THE CONCEPT OF SYMMETRY

Frode Rønning

Sør-Trøndelag University College, N-7004 Trondheim, Norway

This paper emerges from a classroom study where 8 year-old pupils are engaged in activities having to do with different aspects of symmetry (reflection and rotation). The pupils' language is analysed on the basis of an epistemological analysis of the mathematical concept isometry and certain issues that might be relevant for the pupils' conceptual development are discussed. Semiotic theory focusing on the epistemological aspect of signs and symbols plays an important role in analysing the classroom episodes.

Keywords: Symmetry, epistemology, semiotics, signs and symbols

INTRODUCTION

This study is based on empirical data from a three years research and development project where two mathematics educators collaborated with the teachers at a local primary school with the intention of introducing and reflecting on new ways of approaching the teaching of mathematics. In this paper I will analyse two classroom episodes from two consecutive days involving the same pupils. Both episodes can be said to relate to the concept of symmetry, albeit in somewhat different ways. In the first episode the pupils are given tasks where it is explicitly stated that the aim is to design symmetric pictures in various ways. It is implicitly understood that what is meant is reflection symmetry. In the second episode the pupils were building three-dimensional objects and they were encouraged to talk about these objects, using mathematical terms. Part of the discussion turned out to be about what the pupils could observe when the objects were rotated. In this paper I will discuss and analyse different ways that the pupils express properties of geometrical objects that in scientific terms would be labelled symmetry properties. This discussion will relate to challenges involved in linking seemingly different mathematical experiences to one common mathematical concept, namely the concept of symmetry. More precisely I will formulate the aim of the paper in the following way: Characterise the discourse that emerges when pupils investigate various aspects of symmetry, and identify epistemological issues involved in the conceptual development process that is observed.

THEORETICAL BACKGROUND

What is symmetry?

In mathematical terms symmetry is connected to the concept of isometries. An isometry is often defined as a bijective map between two metric spaces that is distance preserving (Weisstein, 2010). In particular if both metric spaces are the

Euclidian plane and the map operates on points in the plane, two figures are called congruent “if and only if one can be transformed into the other by an isometry” (Coxeter & Greitzer, 1967, p. 80). In the plane there are four isometries; reflection, rotation, translation and glide reflection. The concept of symmetry is usually connected to invariance with respect to isometries. A bounded pattern that is invariant under certain reflections or rotations is said to have reflectional or rotational symmetry. These are the only isometries for bounded patterns but for unbounded patterns all four isometries are possible. The ideas of isometries for bounded patterns in the plane can easily be extended to 3-space.

In school geometry the term symmetry is in the early years used almost synonymously with reflection, and the work with symmetry is often supported by the use of mirrors. However, one is also supposed to work with other isometries in school. In the Norwegian National Curriculum it is written under the topic Geometry: “One studies dynamical processes like reflection, rotation and translation” (Utdanningsdirektoratet, 2006, p. 59, my translation). In light of this, and the mathematical discussion of symmetry above, it can be argued that it is desirable that pupils should develop a concept of symmetry that includes all the Euclidian isometries.

Concept development

Concept development in mathematics is in many instances a matter of making meaning out of signs. I use the term *sign* here in the sense of Peirce: “A *sign* is a thing which serves to convey knowledge of some other thing, which it is said to *stand for* or *represent*“ (Peirce, 1998, p. 13, emphasis in original). A sign could therefore be a symbol, a word (written or spoken) or a gesture. In line with Peirce, Steinbring emphasises that a sign has two functions, a semiotic function – something that stands for something else – and an epistemologic function as the sign contains knowledge about that what it stands for (Steinbring, 2005, p. 21). What the sign stands for is in Steinbring’s terms called the object or the reference context. The relation between sign and object is illustrated in Steinbring’s epistemological triangle (2005. p. 22), presented in Figure 1.

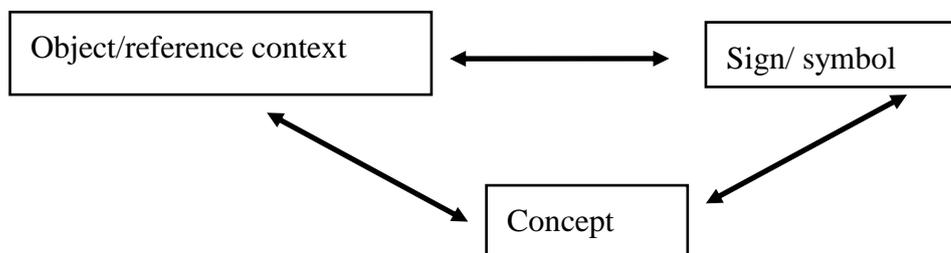

Figure 1. The epistemological triangle

This triangle is inspired by the triangle presented by Ogden and Richards (1923/1948). They write that “[b]etween the symbol and the referent there is no relevant relation other than the indirect one, which consists in its being used by someone to stand for a referent” (p. 11, emphasis in original). Using Steinbring’s terms this means that the connection between the sign and the reference context is not a priori given but it is determined by epistemological conditions of mathematical knowledge and has to be mediated through the mathematical concept. Steinbring emphasises that the system illustrated in the epistemological triangle is not a static system. It is developing, based on actions by the learner, and interaction between teacher and learner(s) (2005, pp. 22-23). Steinbring mentions (2006, p. 136) that one can think of triangles connected in a chain to illustrate concept development. This has been explicitly used by Farrugia (2007) who uses a chain of triangles (p. 1205) to analyse how the concept of multiplication develops from addition of equal groups. This linking of triangles into chains can be seen as similar to the concept *semiotic chains* that has been used e.g. by Walkerdine (1988), and also by Presmeg who describes them as chains of ‘signifier – signified’ where “[t]he new signifier stands for all that went before” (2002, p. 302). In the context of the epistemological triangle this means that the sign/symbol in one triangle can become the object/reference context for a different sign/symbol in a new triangle, and this chaining usually leads to greater abstraction.

In this paper I will develop a new way of using Steinbring’s theoretical framework where the concept development is seen not as one chain of epistemological triangles leading to greater abstraction but instead it is seen as two independently existing chains that are merged into one, which then can be developed further. I compare this to van Hiele (1986) who, in his description of levels, states that when going to higher levels of thinking “different structures can be coordinated into one new structure, so that each of the original structures can be understood as parts of it” (p. 52). I propose here a way of using Steinbring’s theory to explain a phenomenon that is similar to what van Hiele refers to as *coordinated structures* (p. 52). I will also propose a categorisation of signs depending on which of the two chains they belong to.

THE CLASSROOM SITUATION

The research was done as part of a project where two mathematics educators collaborated with the teachers on a primary school over a period of three years. We (the mathematics educators) participated in meetings with the teachers where lessons were planned and we also participated in some of the lessons, and in meetings afterwards where the lessons were discussed. Our role in the lessons varied, from being a passive observer to taking an active part in the teaching of the pupils. The episodes reported on in this paper took place towards the end of the three-year period.

Working Group 9

The first episode is taken from a lesson with 8-year-old children (3rd grade, in December) where I planned a number of different activities in which the concept *symmetry* (i.e. reflection) was central. The activities were set up on different tables in a large classroom and the pupils, working in groups of four-five, moved from one activity to the other. I followed one of the groups and video recorded their work. One teacher was supervising each activity. The second episode took place in the same class on the following day. Here the pupils worked with plastic shapes that could be built together to form 3D-objects. The pupils were allowed to use the plastic shapes freely to build whatever they wanted but I engaged in conversations with them about the objects where I tried to draw attention to geometrical concepts and start a discussion about these. The episode involves two of the girls that also were on the group I followed in episode 1. The episode developed from an utterance from one of the girls, which I found interesting and which led to a conversation where the pupils and I inquire into the properties of some of the objects that have been constructed. The conversation following the utterance that caught my interest was video recorded but not the situation leading to the utterance itself. The dialogue is analysed using the epistemological triangle as a tool to gain insight into the conceptual development of the pupils.

Episode 1

In one of the tasks in the lesson the pupils were given a large sheet of paper on which a straight line was drawn, and a selection of different plastic shapes. The task was to use the shapes to make a picture symmetric about the drawn line. Harry chooses to make his picture by placing pairs of equal shapes on each side of the given line, such that they touch the line. Eileen suggests another way of doing it by making the picture shown in Figure 2, where the shapes do not touch the line. She says “then we know that there is one like this in between”. When asked to explain what she means by this she takes another square which she places on top of the line with one half on each side (Figure 3). Then she says: “This I just take away and then I know that it is the same length between”. I interpret that she by “the same length” here refers to that the distance from the given line to the two squares is the same. Hence, she links symmetry to distance.

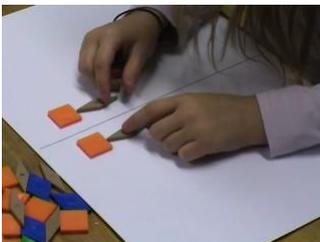

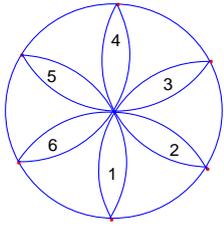

Figure 2

Figure 3

Working Group 9

Another task was based on the figure shown in Figure 4. The task was to colour the petals of this “flower” (the petals are numbered for the purpose of this paper) to get a symmetric picture.

The pupils had mirrors available, which they could use as a tool. Eileen first colours petals 1 and 4 purple. While doing that she says “It is these two, because it is the one right across.” She uses the mirror to check and she says: “If I place the mirror here, then it must be the one right across.”

Figure 4

She repeats the words “right across” several times and the result is that she colours petals 2 and 5 yellow and finally 3 and 6 blue. The result is shown in Figure 5. After having completed the pictures she places the mirror in various positions and inspects the image in the mirror. In one position she observes that “this is blue [both in the mirror and on the paper], so this is correct”. However, she is puzzled by the other colours, and remarks that “something

Figure 5

is strange”. She realises, after several attempts, that no matter how she positions the mirror, she will not see the same picture in the mirror as on the paper. She can find a position where the blue is right, and the others are not, and similarly for the yellow and the purple. Holly is sitting beside Eileen and she has made a picture based on the same principles as Eileen. Holly makes the same observation as Eileen, that there is no position for the mirror where the picture in the mirror equals the picture on the paper. Holly finds a solution by stating “these two [petals] must swap places”. While saying this she points to two petals with different colours. Eileen follows Holly’s solution and starts “recolouring” the picture (Figure 5) so that one of the yellow petals is coloured blue and one of the blue petals is coloured yellow. The areas between the petals are recoloured in a similar way.

The two tasks described here are different in terms of what is varying and what is fixed. In the first task the reflection axis is fixed and the shapes can be chosen and placed freely. In this case both Eileen and Harry choose figures equal in shape and colour, which they place on either side of the axis. Eileen also expresses something about equal distance. In the second task the underlying structure of the picture is given, only the colours can be varied. In this context Eileen first considers pairs of petals independently and colours each pair such that the petals “right across” get the same colour. When the three pairs have been coloured she is able to see the figure as a whole. Then she observes that something is not right, and by using the mirror she corrects her first solution.

Working Group 9

In these tasks the word symmetry was actively used, and with the understanding that it meant reflection, so I will argue that what I can see from this episode are various ways the concept reflection mediates between different signs and different reference contexts. A common feature in all reference contexts was the mirror which was available as a tool. Signs that can be observed for these reference contexts include “equal distance” and “right across”.

Episode 2

In this episode Eileen and Holly have built a tetrahedron and a square pyramid. I ask them to describe the difference between the two objects and Holly says, pointing to the tetrahedron: “This looks the same if I tilt it but this [the pyramid] doesn’t”. Following this I initiate a conversation with the girls about the objects they have constructed. An octahedron and an icosahedron also become part of the conversation. The conversation is centred around words like “tilting” and “spinning” and to what extent the objects look the same when these operations are performed. Eileen holds the octahedron and looks at it in various positions. Then she says: “This will be the same always. No, it won’t – not always. Now it is with the tip towards me. And if I place it like this, it is like this”. She shows with her hands where the tips point in the various positions. Later the girls compare the tetrahedron and the pyramid and Eileen says that they are “almost equal”. When asked why they are only almost equal she says that “there are four here, and here there are only three” which I interpret to mean the number of triangles meeting at a corner. Holly repeats her initial observation concerning the tetrahedron: “And this one is possible to turn around without seeing any difference”.

At this stage the conversation makes an unexpected turn when I, for the first time in this episode, introduce the word “symmetry”. The following dialogue takes place.

- Frode: How about symmetries on this one? [Referring to the pyramid]
Holly: [places her hand like a vertical plane]
Eileen: It is possible to place it there. [also showing with her hand. See Figure 6]
Holly: It is possible to place it there. It is possible to place it everywhere. If I take ... If I take it from there .. that is also possible.
Frode: Mmm. But does it, ... if I, if I turn it around like this [rotating 90 degrees], does it look the same now, for each time I rotate it?
Holly: For each time you rotate like this, yes, but not if you had rotated like this. [rotating 45 degrees. See Figure 7]

Figure 6

Figure 7

Afterwards the rotation of both the octahedron and the icosahedron is discussed and Eileen shows among other things how the octahedron can be rotated 90 degrees and she compares it to a spinning wheel.

The important observation to be made here is that the introduction of the word ‘symmetry’ immediately leads to a shift in the discourse. The girls stop talking about rotation and both of them introduce an imaginary mirror, indicated by their hands as shown in Figure 6. Shortly afterwards they go back to rotation as soon as I use that word again and their gestures adjust to this context (Figure 7).

ANALYSIS OF THE EPISODES

The most striking observation in Episode 2 is the impact that the introduction of the word *symmetry* has on the development of the conversation. When I ask about symmetries, the pupils link to the reference context *mirror*. When I later ask about *turning* and start rotating the object they immediately switch back to the discourse about rotation and give examples of possible and impossible rotations. The criteria for possible rotations that are applied are based on what can be done in order to keep the visual appearance of the object the same. Investigating the various objects the pupils physically move the objects to illustrate positions where they look the same and where they do not look the same, when seen from the same angle. The signs that are used by the pupils are *turn*, *spin*, *tilt*, *move* and I also use the word *rotate*. These signs are used to describe a reference context, which is about rotating the objects in 3D-space and identifying positions where the visual appearance is the same. In mathematical terms the pupils are distinguishing between operations that belong to the rotational symmetry group of the object and operations that do not belong to this group.

In the discourse involving the mirror, and invoked by using the sign (word) *symmetries*, the criteria for what is possible are based on where the mirror can be placed. The pupils use their hands as an imaginary mirror, place their hands in various positions, and say “it is possible to place it here, it is possible to place it there”. This can be seen as an exact parallel to what the same two pupils did with the star pattern in Episode 1 where they worked with a real mirror. In Episode 1 the

Working Group 9

mirror was placed in different positions and they judged positions as possible or impossible based on the properties of the pattern. When there were no possible positions for the mirror the pattern had to be changed.

Based on these observations I will propose a classification of the signs that are used in two groups. In the symmetry discourse the signs describe properties that the object has or has not. The object may acquire the property if suitable changes are done to it but in a given state it either has or has not the property in question. I denote the signs in this category *static signs*. In the rotation discourse the signs describe actions that can or cannot be performed on the object. I denote these signs *dynamic signs*.

Table 1 shows examples of signs from the two categories that can be found in the investigated episodes.

Static signs	Dynamic signs
There is one like this in between Same length between It is the one right across This is blue, so this is correct These two must swap places It is possible to place it there	This looks the same if I tilt it This will be the same always For each time you rotate like this But not if you had rotated like this

Table 1

DISCUSSION

The concept of isometry, containing the four operations reflection, rotation, translation and glide reflection, is constructed such that the set of isometries for a given pattern forms a *group*, hence the set should be closed under compositions (Armstrong, 1988). It is therefore possible to define the isometry concept in completely abstract terms without the need of a reference context. However, the reference context has a role as a motivation for the concept. The concept “needs this ‘reference context’ as an ‘exemplary embodiment’ of a structure or a relation” (Steinbring, 2006, p. 139). All reference contexts that are described in the episodes in this paper could have the role as “exemplary embodiments” for the concept isometry, or symmetry, as would be the term (sign) most naturally used in a school setting. However, the sign symmetry is by the pupils only connected to some of the reference contexts. The situation here is similar to what has been described by Nührenbörger and Steinbring when they observe divergent constraints between the theoretical nature of mathematical knowledge in the construction processes and the need for each individual learner to construct his/her own understanding of the mathematical knowledge (2009, p. 112). The word symmetry is in everyday language used to denote reflection. When one says that something is symmetrical it is implicitly understood that reflection symmetry is meant. When symmetry is introduced in school it is also common that the first activities that the pupils are exposed to are about reflection symmetry. This tradition was kept in the lessons

Working Group 9

reported on here, as can be seen from Episode 1. The epistemological structure that has been established through these activities could then be described by an epistemological triangle with different signs (of a static character) and different “mirror activities” as the reference contexts and the concept that mediates between sign and reference context I call *reflection*. Similarly an epistemological structure called *rotation* could be described using the dynamic signs and their corresponding reference contexts.

When symmetry is used to denote congruence transformations in general all the activities reported in the episodes have to do with symmetry, and what is presented is a variety of signs and reference contexts connected to this concept. An epistemological triangle covering these episodes could therefore be constructed in this way (Figure 8). Here I have inserted typical examples of signs that occur in the episodes.

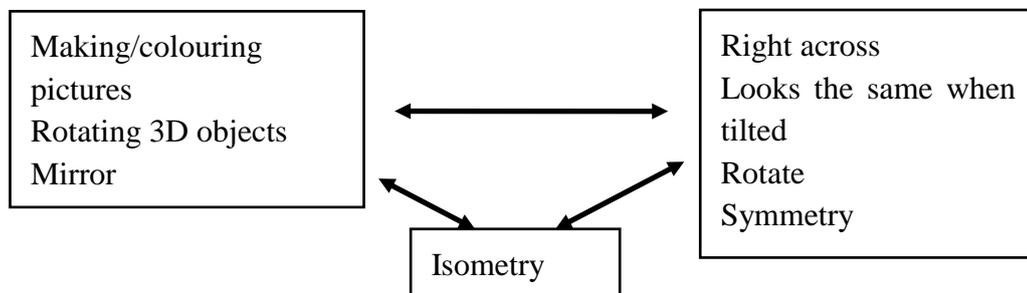

Figure 8

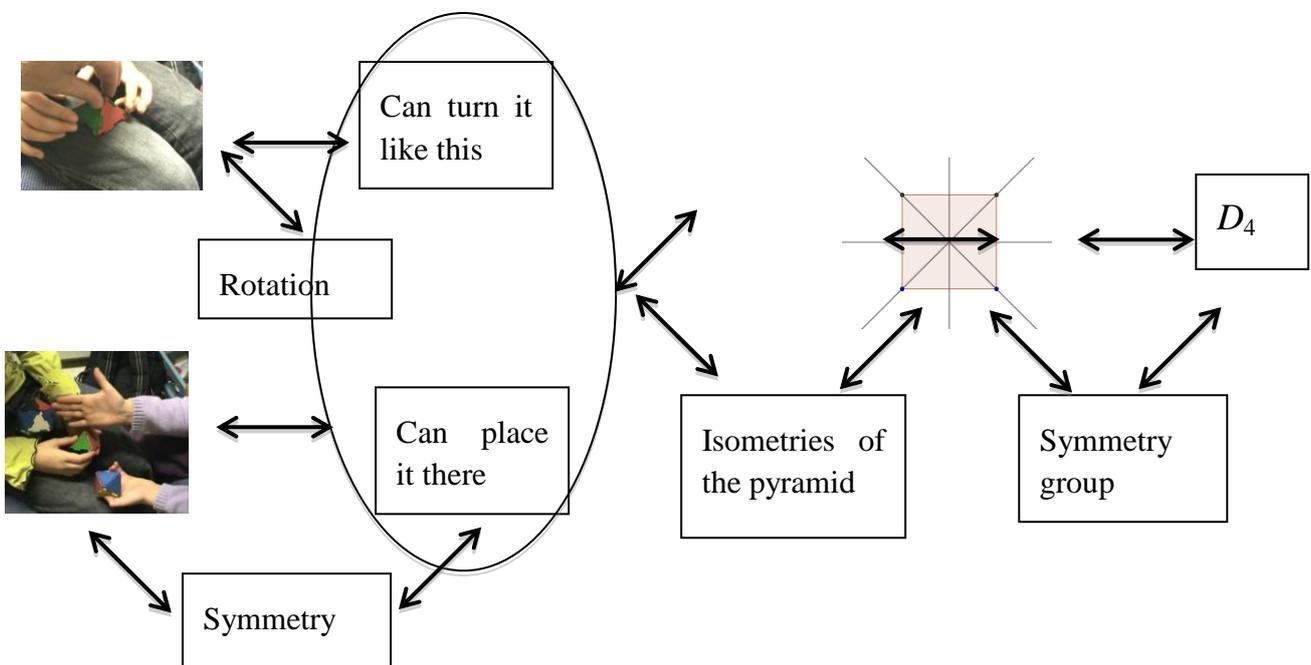

Figure 9

However, for the pupils the signs in Figure 8 belong to two different epistemological triangles, one for the static signs and one for the dynamic signs. In order to develop the general concept of isometry these epistemological triangles have to be merged into one. This triangle could further be linked to new triangles leading to further

Working Group 9

abstraction where eventually the sign D_4 (dihedral group, see e.g. Armstrong, 1988) could be a sign used for the square pyramid as a reference context, where the mediating concept is the symmetry group of the pyramid. It is important to note that there is not *one* chain leading to an abstract sign for isometry (D_4) but a branched chain where at some point two different signs have to take the role as the reference context for the same (new) sign (see Figure 9).

LANGUAGE AS A SHAPING IDENTITY TOOL: THE CASE OF IN-SERVICE GREEK TEACHERS

Konstantinos Tatsis

University of Western Macedonia, Greece

The paper presents a part of a study that focuses on the analysis of various teachers' identities. The teachers participated in an in-service training course and their narratives were used and complemented by other data to construct – from our point of view – the various identities. Characteristic examples are presented in order to show that the notion of identity as narrative can be more operational than the traditional 'beliefs and attitudes' approach, since it may overcome the obstacles related to that approach.

Keywords: identity, teacher training, narrative

INTRODUCTION

Teaching mathematics and mathematics itself can be both considered as communicational activities, which would not be made possible without language. In fact, for some researchers mathematics by itself is a language (e.g. Usiskin, 1996). However, regardless of the acceptance of that 'radical' view, it is widely accepted that the way language is used in any setting – including classrooms – may affect the establishment of a community of learners (Wenger, 1998) and shape or constitute the participants' identities (Sfard & Prusak, 2005). This last view was the trigger of the study presented here. The main aim was to relate teachers' narratives with their participation in a training course. Our interest was not theory-driven; given the large number of studies on teachers' beliefs (e.g. Chamberlin, 2010; Cooney & Shealy, 1997; Franke et al., 1998; Leder, Pehkonen & Törner, 2002), we wanted to see if the notion of identity can be more useful (i.e. operational) in teacher training and what narratives would be related to the various identities.

THEORETICAL FRAMEWORK

As mentioned earlier, the literature in teachers' and students' beliefs concerning Mathematics is vast and evolving. An important and common conclusion is that teachers' beliefs and their practice are related. It is interesting however, what Warfield, Wood and Lehman (2005) note:

... the relationship between teachers' beliefs and their instruction is not as direct as sometimes thought. Beliefs do not necessarily form a cohesive unit; it is not unusual for an individual to hold contradictory beliefs making it difficult to determine how particular beliefs influence instruction (Pajares, 1992; Pearson, 1985). (p. 442)

The idea that beliefs may not form a cohesive unit is indicative of the weaknesses of the particular approach. In our search for a theoretical and analytical tool to better

Working Group 9

understand the hows and the whys in teachers' behaviour, we realized that the concepts of belief and attitude were not operational in Blumer's (1969) sense. Sfard and Prusak (2005) claim that "the assumption that an intention (or tendency) exists in some unspecified "pure" form independently of, and prior to, a human action was a dubious base for any empirical study" (p. 15). To put it simply, some researchers assumed that beliefs are located somewhere "inside" – or "outside" – the person and they can be merely expressed by language or other non-verbal actions; this justifies the extended use of questionnaires and interviews. But what if a person holds conflicting beliefs? How can we explain the fact that although teachers are not pleased with their practice they usually resist to reforms? The notion of *identity as a narrative* may be used to overcome such obstacles and to provide us direct access to the teaching and learning process. Sfard and Prusak (2005) differentiate between:

... actual identity, consisting of stories about the actual state of affairs, and designated identity, consisting of narratives presenting a state of affairs which, for one reason or another, is expected to be the case, if not now, then in the future. (p. 18)

Consequently, by seeing learning as the way to close "the gap between actual and designated identities" (Sfard & Prusak, 2005, p. 19) we can operationalise the notion of identity, i.e. use it as a tool to explain our teachers' practices in training and eventually teaching. The way this was done in our study is shown in the next section.

CONTEXT AND METHODOLOGY

Fifty five in-service teachers (35 female and 20 male) had enrolled in the obligatory course named "Didactics of Mathematics", which is placed in the second – and last – year of their training. In order to participate in the training course they had to meet two requirements: over five years (and less than 25 years) of teaching in schools and passing a national exam. The duration of "Didactics of Mathematics" was one semester (three hours weekly). These teachers had little – if any – experience with enquiry classroom approaches (Cobb & Bauersfeld, 1995) or realistic mathematics (De Lange, 1999; Freudenthal, 1978), although most of them expressed their willingness to be informed about them.

The study was based on the assumption that teachers' identities (actual and designated) may account for their choices concerning their teaching practice.¹ The following types of data were on our disposal:

- (a) transcribed discussions and notes taken during the course,
- (b) notes made after the sessions, based on our recollection of events that occurred before, during or after the sessions,
- (c) teachers' handwritten texts taken during sessions,
- (d) teachers' texts produced as part of their assessment.

Working Group 9

We initially assumed that our main source of data would be (a) and (b), while (c) and (d) could be used complementarily. Soon we realised that (c) and especially (d) were a reliable source of teachers' designated identities, although sometimes the relation was implicit. In the present paper, however, we focus only on data (a) and (b), in order to demonstrate the flow of our research. Following Sfard and Prusak's (2005) categorisation, three types of identifying stories may be used:

${}_A A_C$ = an identifying story told by the identified person herself. This story we call A's *first-person* identity (1st P).

${}_B A_A$ = an identifying story told to the identified person. This story we call A's *second-person* identity (2nd P).

${}_B A_C$ = a story about A told by a third party to a third party. This story we call A's *third-person* identity (3rd P). (p. 17)

Our main aim was to use the above data to identify – from the researcher's point of view – the teachers' emerging identities. Our analysis was guided by the following principles:

- a) The teachers' identities came from *our* interpretations of the data at hand.
- b) No predetermined categories were used or invented for the identities, thus all titles used from now on were put *after* the analysis.
- c) The data did not come from our explicit request to the teachers to talk about themselves (or somebody else), but are selected from fragments when a person is explicitly or implicitly referring to herself or somebody else.²
- d) Since it was impossible to obtain all types of data (e.g. 1st P, 2nd P and 3rd P stories) about all participants our analysis is far from providing a 'complete' account of all identities – if such an account can ever exist.
- e) The fact that the teachers knew that they are assessed by their participation (which included many assignments and a final one that was given to them three weeks before the end of the course) is taken as a contextual element (thus, it cannot be isolated in order to study its effect).

The analytical scheme is summarised in Table 1, where (a), (b), (c) and (d) stand for the types of data mentioned before. As shown in Table 1 we were interested in actual and in designated identities. According to Sfard and Prusak (2005) "Designated identities give direction to one's actions and influence one's deeds to a great extent, sometimes in ways that escape any rationalization". (p. 18)

	Data types	Story types	Formulations
Actual Identity	(a) (b) (c) (d)	${}_A A_C$ ${}_B A_A$ ${}_B A_C$	Assertion
Designated Identity	(a) (b) (c) (d)	${}_A A_C$ ${}_B A_A$ ${}_B A_C$	Wish, commitment, obligation, necessity

Table 1: Methodological scheme

Working Group 9

For brevity reasons, we have chosen particular examples to demonstrate our analysis. These examples are not supposed to reflect by any means a ‘general trend’ among the teachers; they rather represent some of the most characteristic identities that emerged during the training course.

RESULTS OF THE STUDY – EXAMPLES OF TEACHERS’ IDENTITIES

Most teachers participated actively in the training course, which seemed a good opportunity for them to:

- a) familiarise themselves with group work and contemporary approaches in mathematics education, and
- b) express their views on (their) teaching as a complex and demanding task.

It is obvious that the teachers’ identities were highly related to their occupational demands. This is not to say that there were not any narratives related to other aspects of their lives; however, these were significantly few, appeared rarely and most of the times not during the session hours. This is totally justifiable by the context of the situation: the teachers participated in a training course provided by an instructor they had never seen before, thus they were reluctant to talk about other things than their work. Next we present some characteristic identities that we have encountered.

The politically-active teacher identity

The excerpt that follows is taken from a task that the teachers were asked to work on and comment. The task started by showing the advertisements of the three major Greek mobile telecommunication companies; their common element was the focus on the ‘population coverage’ which “is over 99%” or “touches 100%”. The focus from a teaching point of view was intended to be the use and misuse of percentages, together with the notion of limit. But once the task was presented a teacher reacted and the following discussion took place between him, another colleague and the instructor (and author of the paper). Our notes are in brackets, where we also put a code to signify the type of story told:

Teacher A: I am sorry [for the interruption], but I believe that you [the instructor and at the same time designer of the task] shouldn’t use the companies’ names in this task. [B_AA]

Instructor: Why?

Teacher A: Because it’s like ‘pushing’ the students to buy or use a mobile phone from these companies. [B_AA]

Teacher B: But there are no other companies in Greece!

Teacher A: Yeah, but it’s still like hidden advertisement! These tasks shouldn’t be in the textbooks...

Working Group 9

Instructor: But the names [of the companies] are there because they are taken from real advertisements. I didn't want to delete the names, or put something like: "Company A" and "Company B". [AAc]

Teacher A: ... and it reminds me of some other tasks with hidden advertisements – but I don't remember now. Anyway, it's a pity that the whole educational system is working with market rules. I believe that in a while companies will take over schools. [BAc] And we [teachers] will be just their employees... I can see it coming. [AAc]

Some teachers showed their agreement with Teacher A's remarks; others said things like: "Come on, don't be so stuck with your politics!". So, he continued by saying:

Yeah, yeah... You know what? I will never agree to such kind of policies! [AAc]

Later on, during the break we had the chance to discuss a bit on his views on teaching and the current situation in Greek educational system. His main point was that teachers were trying hard to overcome their financial problems (due to their low salary) but the government does nothing to assist them. Actually, according to him every reform is to the wrong direction:

And every now and then they [the government] come up with a new big plan. And they've never been in a real classroom, [BAc] where I have to teach 25 to 30 students. [AAc] And some of them [children of immigrants who sometimes do not have the chance to attend extra Greek language courses] don't even speak Greek! [BAc] And what do I do? [AAc] Did you hear the story about that teacher who was giving extra-school Greek language lessons to children? She got herself into real trouble! [BAc] That's why we need to support each other! [AAc]

The previous transcripts are rich in the actual and designated identities involved. And actually, one can find data not only for teachers' identities, but also for the identities of the instructor and the policy maker(s). By focusing on Teacher A we can firstly locate the utterances which are directly related to his identity:

Actual identity:

- where I have to teach 25 to 30 students. [AAc] And what do I do? [AAc]

Designated identity:

- And we [teachers] will be just their employees... I can see it coming. [AAc]
- Yeah, yeah... You know what? I will never agree to such kind of policies! [AAc]
- That's why we need to support each other! [AAc]

From the above it is obvious that Teacher A's identity does not comprise of only the above short narratives, but should be enriched by his narratives about the other participants. Thus, we may conclude that this identity includes narratives about

Working Group 9

teachers who feel on the one hand helpless in their own classrooms and on the other hand threatened by the reforms who – according to them – are driven by ‘market’ criteria (e.g. of competitiveness or productivity). This usually leads them to organise themselves around politically-oriented syndicates, which are most of the times sceptical to any reform movement.

The intelligent teacher identity

There was only one teacher’s narratives related with the particular identity – we will name him Teacher C. In the second session of the course this teacher – who was always sitting alone in the first line of desks – invited me to visit his personal website. It turned out that the site was part of the Mensa members, i.e. the people whose IQ was measured within the upper 2% of the general population. Thus, the first narrative of that teacher already had a title – “Mensa member” – and some electronic content (mainly ‘artistic’ landscape pictures shot by him). During a break of the third session we talked about the site and he was eager to talk about his main interest, photography:

I hope you enjoyed it. It’s my big passion [photography]. Sometimes it takes me hours to get a proper shot. I prefer shooting landscapes. [A_AC]

During all sessions he showed great interest in all tasks, especially those that included non-standard solution paths. Usually, he was the first that completed the task; this fact irritated some of his colleagues:

Teacher D: Come on, you always finish first! Give us some time too! [B_AA]

Teacher C: I never asked you to hurry up! [A_AC]

Instructor: It’s okay, you have as much time as you need.

Teacher E: Yeah, because he is so intelligent he thinks we’re all the same! [B_AC]

Instructor: Please...

Teacher C: Come on, colleague...

At the end of the course he was one of the few who came individually to express his gratitude for the organisation and the realisation of the course and his views on teaching:

I think we should take advantage of all opportunities for training. And our teaching should not be based on the ‘average student’, but on each person’s characteristics, which make him unique. [A_AC] Something which is not easy at all. And you also have the head of the school who puts pressure on you... [A_AC] [B_AC]

Until the present moment he keeps sending informative emails about his new collections of photographs. However, it is worth mentioning that his final assignment was far from showing signs of uniqueness or originality (Tatsis, in press). The above transcripts can be categorised as follows:

Working Group 9

Actual identity:

- It's my big passion [photography]. Sometimes it takes me hours to get a proper shot. I prefer shooting landscapes. [AA_C]
- Come on, you always finish first! Give us some time too! [BA_A]
- I never asked you to hurry up! [AA_C]
- Yeah, because he is so intelligent he thinks we're all the same! [BA_C]
- And you also have the head of the school who puts pressure on you... [AA_C]

Designated identity:

- I think we should take advantage of all opportunities for training. And our teaching should not be based on the 'average student', but on each person's characteristics, which make him unique. [AA_C]

The intelligent teacher identity is comprised of two components, stories of the 1st P type and stories of the 2nd and 3rd P types. The 1st P stories talk about a teacher who has more interests than teaching (in our case photography) and seems to be aware of the fact that his abilities should not raise a barrier between him and his colleagues. Actually, he was participating in all discussions, trying – like all the rest – to express his view and eventually convince the other participants. His view on the teacher's positioning between policy makers, school authorities, parents and students was not much different than the one presented before: the teacher is most of the time helpless when s/he has to confront most classroom and out-of-classroom problems.

Other teacher identities

Other identities that have emerged include the insecure teacher identity (in two different manifestations) and the passive teacher identity (expressed as an indifference to participation).

The insecure teacher identity in the first manifestation comprised of short narratives on the teacher's inability to cope with mathematical tasks; there was no explicit attempt to justify this fact, only continuous requests for clarification concerning the tasks contained in the session. The teachers related to this identity relied highly on the instructor's expertise to evaluate their work and they rarely showed any initiative during group work. However, they seemed to be working hardly with their colleagues, always striving to deliver their work on time.

The insecure teacher identity in the second manifestation comprised of teachers' narratives on their insecurity and how it is justified on the grounds of improper mathematical background. These narratives included stories about a mathematics teacher who – in a certain moment of their school life – halted their learning of mathematics by his attitude towards teaching and towards “those who were not so good in maths” (according to a female teacher who was explaining her attitude

Working Group 9

during a whole group discussion. The teachers related to such narratives usually delivered poor assignments and always asked for more ‘loose’ assessment.

The passive teacher identity was manifested as an indifference to active and meaningful participation; in other words, those teachers were usually more interested in the deadline for the next assignment than its content. Some of them arrived late for the session or even asked to leave earlier. There was one teacher who asked to deliver an assignment in handwritten form, because she doesn’t have a PC at home and she doesn’t have time to work in the PC laboratory that was available to them (note that all teachers in the particular course had already at least one course in new technologies). Most of them were asking for extending the deadline for giving the assignment, because they were busy (although during the training course they are free from their teaching duties). Most of their narratives were focused on their difficulty in managing all factors of the Greek educational system. Some narratives were focused on particular issues, like the new textbooks:

Teacher F: Especially the 5th grade book is so hard. You know, they [the authors] have put so hard maths in it! And it’s so dense! Children don’t understand what I’m talking about! For example, once we were dealing with decimals and I had to go over and over again the same chapter... [A_AC]

Teacher G: Yeah, and the 6th grade book is also hard...

Teacher H: The previous ones were better...

CONCLUSIONS

By observing and analysing the teachers’ identities we have found some commonalities, which may be attributed to their common experiences gathered from years of teaching in the Greek schools – and from years of practice in the Greek educational system. One such commonality is the ‘resistance’ expressed by most teachers to employ any ‘novel’ approaches, which is related to an actual identity-narrative of a ‘helpless’ teacher caught between the various forces that are active in the system classroom-school-society. These narratives were complemented with narratives about policy makers (eventually personalised in the face of the ministers of education or university professors holding decision-making governmental positions). At the same time, these teachers sometimes used their teaching experience to justify their insistence on ‘traditional’ teaching approaches or to criticize the new textbooks – which proved to be one of their favourite and most provocative topics of discussion.

Concerning our methodological scheme, which was based on Sfard and Prusak’s (2005) approach, we realised that in order to efficiently describe teachers’ identities we need first, second and third person narratives, together with other elements related to their participation in a community of learners (in our case the community of the training course), e.g. their willingness to adhere to the norms established.

Working Group 9

Few teachers' narratives included elements from their out-of-school life; these were related to their hobbies or to general topics related to politics or current significant events.

Some teachers' designated identities-narratives included statements like "I hope that my (teaching) practice will be improved once I get back to school", but it was obvious that they were mostly interested in making their teaching *effective* but at the same time *easier*, i.e. without conflicts (e.g. with parents or the school principle), tensions (e.g. related to classroom management issues). This was apparent in their participation and their work, which sometimes could not move beyond what has been discussed or suggested during the session.³ This is not in line with the view that learning should pose challenges to the learner in order to stimulate his/her interest. Finally, returning to our initial aim, the notion of identity as a narrative seems more operational for the purpose of analysing teachers' participation in a learning process. The sources of these narratives can vary from verbal interactions to written assignments; the more varied the spectrum of data, the closer the researcher can get in the actual and designated identities of any participant.

NOTES

1. When we talk about teachers' practices or behaviours we refer to them as either observed by the researcher or expressed in teachers' narratives about them.
2. This is the major difference between our approach and Sfard and Prusak's (2005) approach.
3. The content of the teachers' work is not the focus of the present paper. What can be noted is that sometimes when the teachers were asked to design tasks for their classrooms they merely reproduced (by slightly changing the data) the tasks that were given to them during the sessions.

INTRODUCTION TO THE PAPERS OF WG10: DISCUSSING DIVERSITY IN MATHEMATICS EDUCATION FROM SOCIAL, CULTURAL AND POLITICAL PERSPECTIVES

Paola Valero, Sarah Crafter, Uwe Gellert, and Núria Gorgorió,
in collaboration with Alexandre Pais

SCOPE AND FOCUS

Working Group 10 discussed *research* that addresses how *diversity* influences *possibilities for practice* in mathematics education. The three elements highlighted within the group were as follows. By *diversity* we understand that students, teachers, parents and many other participants in mathematics education, as well as the contexts where mathematics education takes place, are becoming more complex and varied. Diversity might be expressed in terms such as gender, ethnicity, culture, language, social and socio-economic status, disability, qualification, life opportunities, aspirations and career possibilities, etc. Contexts are diverse in terms of the variety of sites where mathematics education takes place, and the differences in the organization and structure of practice in such contexts—schools, homes, workplaces, etc. By *possibilities of practice* we understand that, in most concrete situations of mathematics education, the multiple diversities mentioned above intersect, posing challenges to actual learning and teaching practices, as well as to their improvement. Finally, when talking about *research*, we focus our understanding on the systematic reflection, of either empirical or theoretical ways in which diversity affects possibilities of mathematics education practice.

We were particularly interested in theoretical, methodological, empirical or developmental papers focusing on the social, cultural and political challenges/issues of mathematics education. The enlarged focus of the group (in relation to previous CERMEs) meant that cultural diversity was only one of the possible focuses for the current conference. Thus our appeal was also directed towards researchers who work with sociological, anthropological, discursive, political and philosophical perspectives to read mathematics education practices. We accepted for presentation and publication fifteen papers and four posters. The array of themes, methodologies and theoretical frameworks was diverse, which allowed a rich discussion among the participants.

THE PAPERS DISCUSSED

Some of the papers attempted a reconceptualisation of some of the core notions that underpin much of the research in mathematics education, particularly in issues concerning the social, cultural and political dimensions of mathematics education. Tine Wedege articulated Ole Skovsmose's notion of foreground to Pierre Bourdieu's theory of habitus. Annica Anderson and Eva Nóren proposed to articulate the work of Pierre Bourdieu and Gert Biesta to current research in mathematics education,

Working Group 10

namely by exploring the notion of agency. Annica Andersson also took on the notion of agency to discuss an analytical framework for understanding interplays between contexts and students' agency. David Kollosche invited us to posit mathematics and its education in the social arena, where school mathematical practices can be associated with processes of alienation. Charoula Stathopoulou, Karen François and Darlinda Moreira made a critical review of the way European researchers are dealing with the insights coming from ethnomathematics. Troels Lange and Tamsin Meany, examining the discourse around national testing in Australia, showed how discourses and practices outside schools pose severe restrictions to the teaching and learning of mathematics. These papers were essays with theoretical discussions addressing central dimensions connected to the relationship between society, politics and mathematics education.

Papers involving empirical work enabled the participants to reflect about different national realities regarding the teaching and learning of mathematics in relation to cultural, social and political issues. Uwe Gellert and Hauke Straehler-Pohl, in a German context, discussed innovative ways to address issues of differential access to powerful mathematics knowledge. Núria Gorgorió and Montserrat Prat, in a Spanish context, addressed the impact of teachers' social representations on the immigrant students' learning of mathematics and their identity. Andualem Tamiru Gebremichael, Simon Goodchild and Olav Nygaard showed students' perceptions about the relevance of mathematics in Ethiopia. Behiye Ubuz discussed the current status and future pathways for doctoral programs in mathematics education in Turkey, and how these programs contribute to a diversity of views on what counts as mathematics education research in this country. Richard Barwell and Cristine Suurtamm show how, in a Canadian context, it is possible to articulate important current social concerns (in this case, climate change) with the teaching and learning of mathematics.

We also had a cluster of papers addressing the relationship between school mathematics and out-of-school mathematics. Toril Ranges explored the collaboration between school and a building company regarding mathematics learning conversations among 8th grade pupils. Javier Díez-Palomar and Sandra Torras-Ortín analysed the process of attribution regarding the relationship between school and family mathematics. Sarah Crafter and Guida de Abreu examined how teachers make sense of embedded everyday mathematics at home in relation to parents' practices. Richard Newton and Guida de Abreu, in a similar way, discussed parent and child interaction when completing primary school-style mathematics. These papers addressed the issues of transitions between different contexts of practice when a diverse set of participants meet in various sites of mathematics education. We also had four posters for presentation. Joana Latas and Darlinda Moreira described an ethnomathematical approach in a regular public Portuguese school. Petra Sevansson addressed students' foregrounds and rationales for the

learning of mathematics. Javier Díez-Palomar and Sandra Torras-Ortín described the research project FAMA, which seeks to relate family mathematics with adult education. Finally, Ana Mesquita addressed issues of parental involvement in children's mathematical achievement.

DIVERSITY AND THEORETICAL PERSPECTIVES

In order to deal with the diversity of papers, the group felt the need to recurrently discuss some core notions that underpin the research presented. Some of these notions are agency, identity, and the complex relation between the individual learner and his/her social environment. This discussion was enriched by the diversity of theories deployed by the participants in their research. Most of these frameworks come from fields such as contemporary philosophy, sociology, anthropology and cultural psychology. The group were challenged by different terminologies used by the participants in their research and an attempt was made not to unify them, but to find a common ground where different notions were enacted in a clear way. There was agreement on the idea that, rather than a fixed and unified understanding of a notion, we should highlight the differences and the common points of each one. The need for further efforts concerning the theoretical and philosophical strengthening of the core notions we use in our work was enhanced by the variety of disciplinary backgrounds represented in the group participants.

ORGANIZATION AND FUTURE

The leading team chose a different way of organizing the presentation of papers this year. Instead of having the author of the paper presenting his or her own work, we decided that the presentation of one's papers would be done by another author, who had 5 minutes to briefly present the paper and raise some initial questions to motivate the next 25 minutes of discussion. This strategy proved to be a productive way of organizing the sessions, and all participants agreed that the discussion which followed went further than if the own author had presented his or her paper. It also encouraged more in-depth reading of the papers in the group.

In the final session the group discussed its 'spirit' and role in CERME. There was consensus that this working group provides a forum for delegates to present research addressing less mainstream concerns of relevance for understanding the social, cultural and political constitution of mathematics education practices. The broader theoretical frameworks to study mathematics education practices, focusing on their political, cultural and sociological dimensions, were another trend that united the diversity of papers. Diversity was understood in the wider sense of diverse theories and methodologies, but also diversity of concerns and practices that become visible when we displace mathematics education from the classroom, the framework where we usually conceptualize it in, to a multiplicity of contexts where it is being practiced and made sense of. This way, diversity has the power to 'estrangle' us to the self-evidence of mathematics education as an established field of research.

AGENCY IN MATHEMATICS EDUCATION

Annica Andersson, Eva Norén

Aalborg University and Malmö University, Stockholm University

In this paper we elaborate on the notion of agency. We relate agency to Skovsmose's and Biesta's frameworks respectively. Both Skovsmose and Biesta are concerned with citizenship education, mathematics education and the purpose of education from a critical position. We explore if and how Skovsmose's and Biesta's frameworks respectively relate to agency.

Key words: agency, citizenship, empowerment, mathematics education

INTRODUCTION

The purpose of this paper is twofold, to widen our understanding of different approaches to the notion of agency in relation to mathematics education, and to explore the compability of Skovsmose's and Biesta's frameworks respectively in relation to agency and to each other (Wedegge, 2010). As a starting point we understand agency in a dialectic relationship to structure (Roth, 2007) and as a dynamic feature⁴² of human beings to act independently and to make choices. Sometimes the choices are conscious; however at some times we act as agents not being aware of our options (Cohen, 1994). Agency is not just individual; it is exercised within social practises. As Holland, Lachicotte, Skinner, & Cain (2003) put it: "Agency lies in the improvisations that people create in response to particular situations" (p. 279).

In this paper firstly we investigate the notion of agency in relation to earlier research addressing agency in mathematics education. We thereafter relate agency to Skovsmose's theories of critical mathematics education (1994, 2005). The third part of the paper discusses Biesta's (2009) and Biesta and Tedder's (2006) theoretical framework for understanding agency in mathematics education. In the last section of the paper we discuss how the different frameworks and agency may add to our understanding of mathematics education practices.

As we both authors use the notion of agency in our research respectively (Norén, 2010, Andersson & Valero, 2009; Andersson, 2010 forthcoming), and both Skovsmose and Biesta theoretically have inspired our different research projects we find it fruitful to explore and elaborate on the notion of agency cooperatively in this paper. One argument is that understandings of agency in Skovsmose's philosophy of critical mathematics education and in Biesta and Tedder's (2006) may enable a way to use the theories and hence a way forward in analyzing agency in discursive practices in mathematics classrooms.

⁴² Not to be seen as something situated in a person from birth

AGENCY IN MATHEMATICS EDUCATION RESEARCH

During the last years there have been increasing attentions in mathematics education research addressing the notion agency. For example Boaler (2002), Wagner (2007) and Grootenboer and Jorgensen (2010) all refer to Pickering's (1995, p. 21) metaphor *the dance of agency*. Pickering has elaborated on scientific practices and looked at science as practice and culture. To him the 'dance of agency' takes the form of a "dialectic of resistance and accommodation" (p. 22):

Within an expanded conception of scientific culture, however – one that goes beyond science-as-knowledge, to include the material, social, and temporal dimensions of science – it becomes possible to imagine that science is not just about representation. /.../ /.../. But there is quite another way of thinking about science. One can start from the idea that the world is filled not, in the first instance, with facts and observations, but with *agency*. The world, I want to say, is constantly *doing things*, things that bear upon us not as observation statements upon disembodied intellects but as forces upon material beings (p. 5f).

As people we respond to material agency such as in winds, heating or winter. Pickering goes on describing how humans as agents seem to be different from non human agency like: "the weather, television sets, or particular accelerators" (p. 15). Humans are active and intentional beings. Pickering links Foucault's elaboration on temporal emergence and the displacement of the human subject (Foucault, 1977) via the notion of agency. According to Pickering (1995) human agency has an intentional and a social structure. The 'dance of agency' manifests itself at the human end in the intertwining of free and forced moves in practice.

Boaler (2003) uses the 'dance of agency' metaphor when illustrating the importance for mathematics learners to have an empowering identity in relation to school mathematics. To know when to draw on mathematical ideas and to be able to solve mathematical problems is a critical part of the dance of agency according to Boaler. Grootenboer and Zevenbergen (2007) note that mathematics teachers have to engage in a 'dance of agency' when to decide to encourage students' own agency as mathematicians or rearrange to the requirements of standard procedures or forms of representation. Wagner (2007) investigated students' voice in utterances, he wanted to discuss with the students who had agency in the discourse and who had control in the classroom communication. Grootenboer and Jorgensen (2010) combine the work of Boaler (2003) and the work of Burton (2001) to illustrate how teachers work together to solve mathematical problems. Teachers' sense of agency allowed them to expand their sense of learning and achievement through the solving of mathematical tasks, relying on the members of the group, their individuals' knowing, and the collective knowing of the group. Powell (2004) uses the notion of agency and motivation to avoid deterministic theories and to resist deficiency explanations of African-American students' failure in mathematics in the US. Powell's research study among 24 sixth graders gave "evidence of the mathematical achievement of

students of colour as a byproduct of their engagement of their agency” (p.10). Powell found that the students initiated investigations, reasoned and progressed in building foundational understanding of certain mathematical ideas. He continues saying that understanding agency “is particularly important since both failure and success can be located within the same set of social, economic, and school conditions that usually are described as only producing failure” (p. 6).

The last example we present comes from a Danish context, where Lange (2010) in his study on 10-year old children concludes that children seem to be suspended between two conflicting experiences: from the practical and creative school subjects and the school subjects, like mathematics, not so creative but important for their future. In the practical and creative school subjects students experience they have more space for agency than in mathematics classrooms⁴³.

From this we infer that the research mentioned above seem to draw on differently theoretical standpoints such as socio cultural ones (research referring to Pickering’s ‘dance of agency’ and Lange) and critical theories (Powell).

SKOVSMOSE’S PHILOSOPHY OF CRITICAL MATHEMATICS EDUCATION

In this part of the paper we explore the notion of agency in relation to Skovsmose’s work on critical mathematics education.

Towards a philosophy of critical mathematics education, including agency

Skovsmose developed his philosophy of critical mathematics education based on the Frankfurter school. The influence of Habermas and the philosophy of Critical Theory can be traced in his work “Towards a philosophy of critical mathematics education” (1994).

Critical Theory has changed its emphases since its beginning with the Frankfurter school. Today it has included contributions from structuralism, feminism and lately postmodernism and post colonialism (Popkewitz, 1999). The different perspectives have various assumptions regarding definition of power and the self. One influence of post modernity is from Foucault and his conception of power as productive and positive, not repressive and negative. Power is then conceptualised as working in two directions and not as a one-way surveillance technique of power. The late Foucault (1980, 1982) saw discourse as a medium through which power relations produced speaking objects – in our view this relates to the concept of agency even though Foucault did not discuss agency, but related to human beings as agents

Critical mathematics education emphasizes social justice issues and students empowerment through mathematics education. In Skovsmose’s work, (1994), a basic

⁴³ Though we don’t perceive mathematics as non creative, Lange relates to what students told him

assumption is that implicit as well as explicit functions of mathematics education are of importance for society and democracy (see also Skovsmose, 1998; Skovsmose & Valero, 2001). According to a thesis of mathematics as a formatting power Skovsmose finds mathematics as “an essential instrument when technological authority is exercised. Mathematics is part of technological empowerment” (1998, p. 201). When he spoke about the formatting power of mathematics Skovsmose says it was a way to try to address the relationship between mathematical knowledge and power (2005). Skovsmose also articulates that mathematics education serves as a gatekeeper, to who will get and who will not get access to the information and communication structures in society (1994, 1998, and 2005). He concludes saying that the learner is a member of society and mathematics can be a source for decision-making and action makes mathematics education a critical feature in society.

When conceptualising Critical Theory “as an interdisciplinary attempt to raise awareness of problematic socio-political states of affairs” (Skovsmose 2005, p. 130) Skovsmose relates to post-modernism. He also relates to Foucault and his description of technologies of the social, the connections between power and knowledge, and to discourse. To Skovsmose it seems obvious that knowledge can be expressed in ways of acting.

Is agency part of Skovsmose’s writings?

Certain forms of acting and communicating in the mathematics classroom may support the development of citizenship. According to Skovsmose (1998) citizenship is about to face the “output” from authorities, but also to provide an “input” to authority. Education for citizenship “also presupposes participation” (p. 199). Skovsmose states that “mathematics education could play an important role in developing critical citizenship” (2005, p. 132). To Skovsmose “empowerment” seems to refer to a person in an informal meaning; as to have the capacity to speak for oneself. We believe this reasoning of Skovsmose applies to the notion of agency in terms of students’ capacity to act independently and to make personal choices in a situation. Intentionality and action presupposes agency.

Skovsmose (1994) does not use the concept agency explicitly, in his writings it is an evasive concept that conceals behind expressions as empowerment, intentionality, action and choice. He writes:

Actions cannot be described in mechanical or in biological terms; and if a person’s behaviour can in fact be described in such a way, then behaviour is not a part of his or her actions. It is not a personal action to breathe or to let one’s hair grow. This I see as the first essential condition for performing an act: indeterminism must exist, or, the acting person must be in a situation where choice is possible. The person acting must have some idea about goals and reasons for obtaining them (p. 176).

Skovsmose writes that it does not make sense to talk about human action when a person is forced to do something or when a person is doing something out of a habit

Working Group 10

or as a reflex, like when combing your hair. To be called action a person's intentions must be present in what is done. "Intentions are examples of intentionality directed towards action" (p. 177). But a person may not always be aware of her/his intentions. Intentions are grounded in a "landscape of pre-intentions or *dispositions*" (p. 178). Skovsmose divides dispositions in background and foreground. Background belongs to the history of a person, and foreground to the possibilities a certain social situation makes available for the person to perceive as her/his possibilities. The dispositions of a person reveals when a person comes to action. Skovsmose sees learning as caused by the intentions of the learner and learning has to be performed by the learner:

Students will enter school with ideas, hopes and expectations. Intentions are inherent within every human being. /.../. But the demands of the situation in school too often result in *broken* or *ignored intentions*. When students' intentions are ignored, it seems impossible for students to perform actions, which could fulfil negotiated intentions (p. 187).

Skovsmose (2005) articulates that possible structures behind social events may be much more complex than those explanatory principles which are conceptualised within contemporary sociology. He writes:

Social practices, or collective actions, can appear to be so complex that no 'acting subjects' (a person, a group of persons, an institution, a government, an organisation) can be identified. The very existence of an acting subject may appear impossible. Such actions I will refer to as *happenings*. A happening is certainly not a natural phenomenon and it cannot be explained within a framework borrowed from the natural science. Happenings are social constructions and achievements, which pack together a density of contingencies. In a happening, the involved persons are doing something, but it seems out of control as of what this could imply (p. 135f).

As an example of a happening he addresses Woodstock, the music festival. Persons taking part in a happening may not be aware of their role in it, and they may not have any control. In a happening there is no defined acting subject and a happening cannot be explained as a sum of human actions. But, we inquire, if agency is looked upon as a result of social practices, can a happening then be explained in the terms of agency?

There is a possibility to see happenings and intentions as intersecting. When intersecting the notions converge close to the notion of agency; as the capacity of human beings to act independently and to make choices of their own, though they not always may be aware of it, and as a result of social practices, as stated in the beginning of this paper.

Another way of understanding Skovsmose and the notion of agency is when Skovsmose suggest students and teachers to work within an investigative landscape, in contrast to the exercise paradigm. Skovsmose writes that working within the

investigative paradigm provides recourses for working with investigations as a learning milieu. He finishes his article with the following sentence:

My only hope is that finding a route among the different milieus of learning may offer new resources for making the students both acting and reflecting and in this way providing mathematics education with a critical dimension (2001, p. 131).

We conclude that Skovsmose within a critical paradigm concerns democratic aspects of mathematics education, part of that is the intentions of students and their role as acting and reflecting subjects in mathematics classrooms. To us the notion of agency seems to work well with Skovsmose's critical mathematics education.

BIESTA'S PHILOSOPHY OF (MATHEMATICS) EDUCATION

In this part of the paper we explore the notion of agency in Biesta's (2009) and Biesta's & Tedder's (2006) writings. Biesta's (2006) philosophy of education is influenced by philosophers such as Dewey and Derrida.

Biesta (2009) discusses the purposes of education against a background of, what he understand as "the new language of learning"(p.6), that is e.g. the rise of theories emphasising teachers more facilitating role in relation to the active role students' play in their construction of knowledge, the shift of responsibility for education turning education "from a right into a duty" (p.5). He concretizes his reasoning with examples from citizenship education and mathematics education and we find these examples interesting to emphasis in relation to Skovsmose's writings and the concept of agency.

Biesta's (2009) way of understanding the purpose of education as such he describes with the qualification, the socialisation and the subjectification functions. The qualification purpose provides students with skills and knowledge required for particular professions, further studies or more general as an introduction to modern culture. Biesta argues that the qualification function is obviously a major function of schooling. The socialisation function has to do with the purposes to "become members of and part of particular social, cultural and political 'orders'" (ibid p.40). Biesta elaborates this purpose further:

But even if socialisation is not the explicit aim of educational programs and practices, it will still function in this way as, for example, has been shown by research on the hidden curriculum. Through its socializing function education inserts individuals into existing ways of doing and being and, through this, plays an important role in the continuation of culture and tradition – both with regard to its desirable and its undesirable aspects. (ibid p. 40)

The last purpose of education Biesta refers to is the subjectification process. Biesta writes that education has an impact on the processes of becoming a subject. In education newcomers do not only get inserted into existing orders, they also get to know how to become independent of such orders. The subjectification process,

Working Group 10

understood as a process of becoming thus relates to a way of independence and being agentic. An example of the subjectification process is Biesta's reasoning about a citizenship education taking political agency seriously:

Political knowledge and understanding (qualification) can be an important element for the development of political ways of being and doing (subjectification), just as a strong focus on socialisation into a particular citizenship order can actually lead to resistance which, in itself, can be taken as a sign of subjectification (p. 42).

We agree with Biesta when he concludes that whether all education actually contributes to subjectification of students is debatable. However, any education worthy of its name should contribute to processes of subjectification that allow those educated to become more autonomous and independent in their thinking and acting; thus becoming agentic in our understanding of agency. He continues discussing the subjectification function in mathematics education as raising possibilities for students becoming a person who "through the power or mathematical reasoning is able to gain a more autonomous or considered position towards tradition and common sense" (p.43). To us the last quote seems to be an argument for agency as a notion relating to Biesta's philosophy. Biesta exemplifies his arguments with e.g. exploring moral possibilities of mathematics, e.g. dealing with division in relation to sharing – suggestions we think connects very well with Skovsmose's theory about critical mathematics education.

Agency in Biesta and Tedder's writings

Biesta and Tedder (2006) put forward two key ideas for understanding agency, theoretically mainly building on the work by Emirbayer & Mische (1998). The first idea is that agency "should not be understood as a capacity, and particular not an individual's capacity, but should always be understood in transactional terms, that is, as a quality of the engagement of actors with temporal-relational contexts of action" (p.18). They refer to an ecological understanding of agency, "i.e. an understanding that always encompasses actors-in-transaction-with-context, actors acting by-means-of an-environment rather than simply *in* an environment" (ibid p. 18). The second key idea is that agency should not be understood as a possession of the individual, rather that something that is achieved" (ibid p. 18) in relation to the particular context. They continue: "the idea of achieving agency makes it possible to understand why individual can be agentic in one situation but not in another. It moves the explanation away, in other words from the individual and locates it firmly in the transaction (ibid p.19).

Concluding, Biesta suggests that we engage in a discussion about the purposes of education, where he sees the notions of qualification, subjectification and socialisation as important and interrelating components. His examples from citizenship education and mathematics education highlight possibilities for further discussion within these areas. As we understand agency in Biesta's and Tedder's

words as achieved in relation to/transaction with time and context, narrow in the focus, from the larger purpose of education to the individual within education. We see it as one way to further elaborate on relations and intersections between the individual, society and mathematics education.

CONCLUSIONS

What we intended is to widen our understanding of different approaches to the notion of agency in relation to mathematics education, and to investigate the notion of agency in relation to Skovsmose's and Biesta's writings respectively. We find that Skovsmose, Biesta, and Biesta and Tedder have established cores grounded on basic democratic concerns, citizenship and empowerment. Though Skovsmose's writings are explicitly addressing mathematics education Biesta and Tedder's are not. In line with Skovsmose we believe that certain forms of communication in the mathematics classroom may support the development of citizenship. We think the "certain form of communication" may enhance students' space for agency, and vice versa, students' agency may support the "certain form of communication".

Biesta and Tedder are implicitly concerned with agency when discussing subjectivity and the individual becoming agentic. We find Skovsmose's and Biesta's frameworks compatible to some extent (Wedegé, 2010) but we need to explore this further. One reason for that is that the framework of Skovsmose is grounded in his many writings since a long time back, Biesta and Tedder's work is not.

In mathematics education research, agency can be used both as a tool for locating certain forms of communication in the mathematics classroom and for locating students' activity and intentions in the communication. An example is when students' agency change directions of teachers' already planned lessons. Also the empowerment of learners as individuals and as citizens in today's society can be discussed when relating to agency. The notion of agency can add to our understanding of mathematics education practices.

As learners' intentions and their role as acting and reflecting subjects in mathematics classrooms can be discussed when relating to agency some questions arise. The questions are concerned with whether agency is something a learner can attain or achieve? Is agency already there? Can mathematics education enhance agency?

INTERPLAYS BETWEEN CONTEXT AND STUDENTS' ACHIEVEMENT OF AGENCY.

Annica Andersson

Aalborg University, Denmark, and Malmö University, Sweden

The purpose with this paper is to explore, within a socio-cultural theoretical landscape, an analytical framework for understanding interplays between contexts and students' achievement of agency in mathematics education. However, it became apparent that account also had to be taken for relationships between students' identities and their achievement of agency as they impact, together on the students' decisions to participate in mathematics education and hence in their learning of mathematics. A case study from an upper secondary critical mathematics innovation setting provides an empirical example of how the analytical framework was used.

Keywords: critical mathematics education, agency, identity, context, student.

INTRODUCTION

The students in focus of this research are a group of the increasing number of upper-secondary students who either just dislike mathematics, or who objectify (Sfard, 2008) themselves as e.g. "math-haters", or remedial students who are present in classrooms but not obviously participating in the learning activities. The students referred to are not students with specific learning difficulties in mathematics, the concerns are for students who in a mainstream way take compulsory mathematics classes but whose well-being "diminishes when they are asked to engage with mathematics learning" (Clarkson, Seah & Bishop, 2010, p.1), whose attitudes to mathematics has fallen as they progressed through school (Beswick, Watson & Brown, 2006) and who have not experienced feelings of inclusiveness in mathematics education (Solomon, 2009). My concern is for these students who have not had the opportunity to experience a prior mathematics education that made sense to them.

For the empirical part of my Ph.D.-study a critical mathematics innovation was arranged for Swedish upper secondary social science students' first compulsory mathematics course. The pedagogy was deeply inspired by concerns raised in critical mathematics education (Skovsmose, 2005) and connected mathematics to society as intended within the domain of sociomathematics (Wedegge, 2010). The innovation was a serious attempt to consider possibilities for a pedagogy acknowledging concerns in critical mathematics education although within the frames of national curriculum and assessment qualities. A focus on individual's voices in this study provided a way to understand students' shifts in participation and changes in identities during this particular mathematics course. The purpose of this paper is to present the analytical framework which assisted explaining the interplays between contexts and students' achievement of agency. Under consideration are different

levels of context that impacted on the classroom work; the socio-political school context (Valero, 2002), the situation contexts within the classrooms and the task contexts expressed in e.g. textbooks exercises and through the developed pedagogical projects (Wedge, 1999). My underlying expectation in this paper is to open up for critique and scrutiny of the analytical framework.

This paper is built on two assumptions. First, mathematics learning can be a good thing and may contribute to empowerment and emancipation, even if that not always seems to be the case today (D'Ambrosio, 2007; Skovsmose, 2005). Second, there is a strong belief that students' expect and enjoy to be able to make decisions on their personal learning, that they want to have their ideas valued, and that they enjoy being treated as responsible young adults.

THE THEORETICAL FRAMEWORK

The theoretical framework that guided the Ph.D.-study was grounded within a contemporary social-cultural perspective. Learning was thus viewed as a social activity, implying that learning processes "are constituted in the encounter between contextualised, historically grounded human beings and their activity in particular settings and spaces that are socially structured" (Valero, 2004, p.10). Learning in a social-cultural perspective is not just about getting to know, learning is also about becoming someone (Radford, 2008), thus a movement between present and designated identities (Sfard & Prusak, 2005; Solomon, 2009). This view of learning provided a lens for understanding relationships between contexts, identities and students' achievement of agency in mathematics education at particular historical times during the course. The coming section is divided into three parts. First, theoretical concerns raised in critical mathematics education are presented. Second, an analytical framework for understanding agency is put forward and third, relationships between achievement of agency, context, identity change and learning are discussed.

Theoretical concerns raised in critical mathematics education

The developed pedagogy was deep inspired by critical mathematics education theory. Critical mathematics education is not to be understood as a special way of teaching or branch of mathematics education, on the contrary it is raised by concerns that need to be accounted for with reference to the particular context where the education takes place (Skovsmose, 2005). Concerns raised by Skovsmose addresses issues as how mathematics education can be stratifying and legitimising inclusion and exclusion. While Skovsmose writes about students' inclusion and exclusion in a wider socio-political context, Solomon (2009) engages in questions about inclusion and exclusion within mathematics classrooms. She points to reasons for students' identities of exclusion to be "a product of their particular educational histories and the ways in which they have responded to the ascribed or designated identities carried in repeated discursive positioning." (Solomon, 2009, p. 137)

Working Group 10

Critical mathematics education is also concerned with the nature of the competencies supported in mathematics education, as e.g. if learning mathematics can support empowerment. Students' development of competencies as mathemacy (Skovsmose, 2005), or mathematical literacy (Solomon, 2009) in a way that supports critical citizenship can be seen as empowering as expressed by Ernest (2002, p. 1-2):

Social empowerment through mathematics concerns the ability to use mathematics to better one's life chances in study and work and to participate more fully in society through critical mathematical citizenship. Thus it involves the gaining of power over a broader social domain, including the worlds of work, life and social affairs.

Critical mathematics education also raises concerns and awareness of the students' whole situation. They have different foregrounds, understood as those opportunities that the social, political and cultural situation provides for the individual and backgrounds in relation to mathematics (Skovsmose, 2005). Regarding the students' intentions to participate in mathematics education, understanding participating and learning as action, Skovsmose (ibid, p. 20) continues:

Intentions of a person refer not only to his or her background, but also to the way he or she experience possibilities. Intentions express expectations, aspirations and hopes.

Indeed, critical mathematics education raises concerns about inclusion and exclusion, considers the competences that are learnt and take students intentionality seriously in mathematics education. That is why a critical mathematics innovation became the context, the background setting, for the empirical part of my Ph.D. thesis and thus the mathematics education context for the students referred to in this study.

Agency

Learning is a social constructed activity and requires an agent, a committed human being who makes the decision to engage herself in the activity of learning (Valero & Stentoft, 2010). Human agency denotes the faculty to act deliberately according to one's personal will and by that make free choices (Johnson, 2000). A person's agency can be understood as initiating ideas, agreeing with others, to elaborate and critique, and questioning or disagreeing with others (Gresalfi et al, 2009, p. 53). There is an obvious dialectic relationship between agency and structures (e.g. Holland et al. 1998). Concerns about agency in education research relates, from the socio-cultural theoretical perspective, to the empirical conditions of agency as when and in what way agency is possible (Biesta & Tedder, 2006). Building mainly on Emirbayer and Mische's work (1998), Biesta and Tedder put forward two key ideas for understanding agency. They first suggest that agency should be understood in an ecological way, i.e. strongly connected to context and second, they implicate that agency should be seen as achieved and not as an individual's capacity:

... agency should not be understood as a possession of the individual, but rather as something that is *achieved* in and through the engagement with a particular temporal-

Working Group 10

relational situation. The idea of *achieving agency* makes it possible to understand why individuals can be agentic in one situation but not in another. It moves the explanation away, in other words, from the individual and locates it firmly in the transaction (which also implies that the achievement in one situation does not mean that it will necessarily be achieved in other situations as well). (Biesta & Tedder, 2006, p.18-19)

Agency is thus not about *how* we act in particular situations; the agentic dimension “lies in the ways in which we have control over the ways in which we respond to the situation” (p. 20-21). Within a socio-cultural theoretical framework, regarding learning as a social activity, a definition of agency in line with Biesta and Tedder’s ecological understanding of agency fits particular well.

Biesta and Tedder (ibid) argue that a dimension of agency can be understood as ways in which actors bring their past experiences and future orientations to bear on the present situation, resonating with Skovsmose’s (2005) understanding of students’ backgrounds and foregrounds as reasons for students’ intentions for engaging in mathematics learning. Another aspect Biesta and Tedder (2006) address relates to “the extent to which people are able to distance themselves from their agentic orientations, i.e. make such orientations the object of reflection and imagination” (p. 21). This way of reasoning resonates with the definition of identity as the reified, endorsed and significant narratives told about a person as suggested by Sfard and Prusak (2005) and thus firmly connects the concept of achieving agency with changes of identity. This connection will be elaborated further in the next section.

Identity-agency dialectic relationship

The relationship between achieving agency and changes of identity needs to be elaborated further as there are other aspects of importance to emphasise. One aspect relates to objectification processes (Sfard, 2008). As a student, being objectified, labelled from experiences in the past, possibly has an impact on how the student act and behave in the future. The labels originate in what Sfard recognise as objectification processes, initiated by our way of transplanting words from one discourse to another. Sfard identifies *metaphors of object* as a special figurative expression with “roots in our tendency for picturing the perceptually inaccessible world of human thinking in the image of material reality” (p. 42). These metaphors can obviously be useful or potentially harmful depending on whose actions is objectified and in what way they are objectified in the mathematics education language discourse.

By comparison, another way of understanding the identity-agency relationship is through Boaler and Greeno’s (2000) discussions of students’ experiences of agency with reference to the notion of *figured worlds* (Holland et al, 1998), that is “places where agents come together to construct joint meanings and activities” (p. 173). Agency is here conceived in terms of authorship and as a prime aspect of identity. A mathematics classroom may be thought of as a socially and culturally constructed

figured world. Boaler and Greeno's (2000) research showed that the figured worlds of many mathematics classrooms are unusually narrow and ritualistic, leading able students to reject the discipline at a sensitive stage of their identity development: "traditional pedagogies and procedural views of mathematics combine to produce environments in which most students must surrender agency and thought in order to follow predetermined routines" (ibid, p. 171) and thus lead to exclusion in the way Solomon (2009) addresses the problem. Boaler and Greeno argue that capable students discard mathematics as the views of mathematic education run counter to the students developing identification as responsible, thinking agents. They argue that students do not just learn mathematics in school classrooms, they also learn to be and thus they move between the present and designated identities as described by Sfard and Prusak (2005). Boaler and Greeno's results suggest that many students find the narrowly defined roles they are required to play within mathematics education incompatible with their developing identities.

A CASE STUDY

In this section four 'critical moments' from Sandra's⁴⁴ course trajectory will exemplify how the analytical framework was used. The information was collected with ethnographic methods throughout my participation in two social science students' mathematics classes. In Sandra's case, the data consisted of several spontaneous conversations (Kvale & Brinkman, 2009) and written documents as classroom blog comments, evaluation sheets, logbooks and my field notes. The data was primarily coded in line with Sfard and Prusak's (2005) suggested analytical framework defining identities as reified, endorsed and significant narratives. In this way, the analysed stories were the stories that were significant for the students themselves at those times they were told. To clarify *why* these particular narratives were told/written at specific historical times, all narratives were arranged in chronological order on a timeline that became a 'storyline', one 'storyline' for each student. Events and incidents at the school and the teacher's assessments comments and test results were added on the 'storylines'. At last, students' comments referring to individual or group action as e.g. "I decided to..." or "we went to the bank", or "fucked algebra today" finalised the 'storylines'. In these 'storylines', clusters, which were labelled 'critical moments', emerged in different ways and numbers for different students however with family resemblances. The 'critical moments' illumined changes in the students' narrations of themselves and how the transactions with contexts impacted on the students' identities through changes in their expressed narratives at particular historical times.

In this paper four 'critical moments' from Sandra's mathematics course trajectory provided a frame within which to consider interplays between agency and context.

⁴⁴ All names are pseudonyms. The data was analysed in Swedish and here translated by the author.

Working Group 10

They were, in chronological order: 1) Sandra's narratives told in the transition phase between lower secondary and upper secondary schools 2) Sandra's narratives during the project '*Making your dreams come true*' 3) Sandra's narratives during a teaching sequence organised with textbook work and 4) Sandra's narratives after the larger cross-subject project '*Ecological footprints*'. I refer to Andersson (2010) for an in-depth description of the development of the teaching sequences and the projects within their societal-, and school contextual background.

First 'critical moment'. Sandra initially shared with me that she had always disliked mathematics because she had "mathematics anxiety". This label was Sandra's way of objectifying herself (Sfard, 2008) and causing her "not wanting to spend more time with mathematics than was absolutely needed". That is the reason for why she did not want me to interview her, which would, as she said, "result in more mathematics related time". However, I was very welcome to read her blog comments, evaluation sheets and logbook and to talk with her in the classroom.

Sandra told me she desperately wanted to pass the mathematics course, as it was required for her future university studies. Foregrounding herself as a university student became her intentionality for attending and passing the mathematics courses that were required by society. The socio-political context constrained Sandra's achievement of agency; she could not decide to not participate, as her designated identity was to become an university student. Within the situation context, objectifying herself with the label 'having math-anxiety' seemed to impact on her decisions on how to act within the classroom (e.g. spending a minimum of time with mathematics). Sandra's agentic orientation might be characterised as iterative at this time; she effected action consistent with schemas derived from prior personal experiences.

Second 'critical moment'. This moment occurred during a two-week project where the students got high possibilities for deciding on task contexts, personal time and work distribution. Sandra evaluated her project work in the following way:

We distributed the time well, I think. [...] The group worked well. We were good at different things, and helped each other. I am proud of the work I have done as I felt I could contribute a lot in the beginning when we talked about borrowing money and interest rates. To plan time and content self got me to feel it was related to me. I think mathematics has been a little more fun than usual. [...] I feel the project has been meaningful and to look at mathematics from different angles (vända och vrida på matematiken) was positive. But I would have liked more time for explanations from the teacher, as mathematics is difficult for me. (Sandra, evaluation sheet, 10-2009)

During this project Sandra achieved agency in relation to task context and situation context. Her personal influence on content, time and work distribution impacted on her decisions to engage in the classroom activities in a different way than she

Working Group 10

intended at the course start. In addition she experienced feelings as ‘a little fun’ and mathematics as ‘meaningful’. At this time Sandra took a projective action for learning differently to the initially intended and got rewarded with feelings as “being proud” of her work. However, even if she was proud of her work and actually passed this sequence with distinction (teacher, results sheet), the last sentence indicated that being objectified with ‘mathematics anxiety’ still implied her wishing for extra help and support from her teacher.

Third ‘critical moment’. In the middle of the semester the students were expected to work with textbook algebra exercises during two separate weeks. In contrast to the second critical moment, during these weeks Sandra only made two blog comments. Sandra’s first entry emphasised Sandra’s worries and feelings of stress for not passing a coming test: *I am currently worried about the test. I have received help with things I need help with. Stress. Stress. (Sandra, blog, 10-2009).*

In class she repeatedly asked the teacher about what would happen if she did not pass the test, and she asked for advice on exercises that was ‘extra smart to calculate’ when preparing for the test (Annica, field notes). She worried, and her achievement of agency was restricted to do what was required for just passing the test she was so anxious about. Not passing the test would impact on her designated identity. At this time her label ‘mathematics anxiety’ could be interpreted as ‘test anxiety’, however she never used this word herself.

Her second blog comment during this period was: *Quiet, concentrated and do my best (Sandra, blog, 11-2009)*

Sandra’s positive experience of the prior project appeared to have vanished. The tensions between task contexts, restricted to advised exercises in algebra, “something I don’t understand why I have to learn” (Sandra, classroom conversation), the situation context with expected quiet individual textbook work and her foreground to become a university student were obvious in her actions. Her “math anxiety”, resulting in her imagining herself not passing and thus not becoming what she wanted, became problematic and restricted her achievement of agency at this particular time.

Fourth ‘critical moment’. At this time a larger cross-subject project commenced themed “Students’ Ecological footprints on earth”. At that time Sandra’s logbook was rich with comments regarding hers and her work-friend’s collaborative work. This excerpt exemplifies her reflections on her mathematics learning during the project:

During the project I have learnt about different diagrams. E.g. I did not know about histograms before the project. I think it has been really interesting with manipulated diagrams and results – now I will be more observant when reading newspapers etc!

What surprised me most though was how important role mathematics plays when talking about environmental issues. With support of mathematics we can get people to react and

Working Group 10

stop. [...] I am so interested in environmental questions and did actually not believe that maths could be important when presenting different standpoints.

I have probably learnt more now than if I had only calculated tasks in the book. Now I could get use of the knowledge in the project and that made me motivated and happy! I show my knowledge best through oral presentations because there you can show all the facts and talk instead of just writing a test. To have a purpose with the calculations motivated me a lot. (Sandra, logbook, conclusions).

The teacher assessed her with the highest grade, implicating she presented her statistical investigation with correct mathematical language using appropriate concepts and terminology, that she had chosen appropriate diagrams and arithmetic mean values and could argue for her choices, and that she reflected on possible sources of error and how these could have been prevented. Sandra was convinced that she had not been able to account for these criteria on a written mathematics test. However orally she clearly in a correct and convincing way presented her results and answered questions in front of an audience of 50 students, two teachers and one researcher (Annica, fieldnotes).

Sandra's actions voiced as e.g. "I will be more observant...", "I have learnt more than..." and "I could get use for..." evidently expressed her achieved agency and the relationship between her present identity as a responsible and thinking agent, achieved agency and her learning of mathematics at this particular time. Her expressed narratives, oriented both to the past, future and present is an important factor for actual agency according to Biesta and Tedder (2006). Her learning is expressed both in relation to the subject mathematics and the power of mathematics in society. There seems to be an indication of a changing agentic orientation in this particular situation context; e.g. her 'mathematics anxiety' identity is not expressed at all at this point.

Concluding remarks regarding Sandra's achievement of agency

Sandra's change of identities expressed different qualities of her achieved agency that impacted on her classroom engagement and her learning of and accountancies for mathematics. The implications of this case suggest that Sandra's possibilities for achieving agency is an important component for her learning of mathematics, her accountancy of mathematics and in the end – even for her marks. Maybe Sandra's stories indicate that possibilities for achieving agency are an important feature when constructing mathematics learning environments.

CONCLUDING REMARKS

The purpose of this theoretical paper was to present the analytical framework which explained the interplays between different contexts and students' achievement of agency in this particular setting. The analytical framework put forward by Biesta and Tedder (2006) understanding agency as achieved in-transaction-with-context at

Working Group 10

particular historical times opened up possibilities to consider Sandra's different narratives and actions in the figured world of a particular mathematics classroom. I want to stress that it was Sandra's personally told or written stories that counted as her identities within this analytical framework. Hence, what she considered significant for her to tell at different times became the data in this research. To clarify *why* these particular narratives were told/written at specific historical times the framework suggested by Biesta and Tedder (2006) was combined with Sfard and Prusak's (2005) operational definition of identities and Skovsmose's (2005) concept of intentionality understanding learning as action. This was done in parallel with considering the relationships between achieved agency and different contexts. Analysing Sandra's achievement of agency in relation to the obvious task-context could have given information on how this student achieved agency when conducting project work, compared with mathematics textbook work. However, by also taking the wider socio-political context and class-room situation context into consideration gave a deeper understanding of Sandra's achievement and indicated why she acted, or achieved agency in some situations but not in others. Further elaboration of this framework might open up possibilities to recognise students as agents of their learning of mathematics in mathematics education research.

CLIMATE CHANGE AND MATHEMATICS EDUCATION: MAKING THE INVISIBLE VISIBLE

Richard Barwell & Christine Suurtamm

University of Ottawa, Canada

Mathematics is crucial for describing, predicting and communicating climate change. In this paper, we use the perspective of critical mathematics education to examine how mathematics is constructed in reporting climate change. We focus particularly on accounts of mathematical modelling. Our discussion is illustrated by reference to two texts: a newspaper report and a policy document. We argue that mathematics, human mathematical activity and the role of human activity in causing climate change are all largely invisible in such texts. Mathematics education has an important role to play in making the invisible visible.

Keywords: climate change, critical mathematics education, mathematical modelling

Climate change is perhaps the most urgent challenge facing human society. There is little doubt that climate change is a human-induced phenomenon with potentially disastrous consequences over the next century and beyond (IPCC, 2008). Human understanding of climate change, both collective and individual, is almost entirely mediated by mathematics: without mathematics we would have little sense of how the climate is changing and no idea how it might change in the future. Given the urgency, the scale of the challenge and the importance of mathematics it is surprising to observe that mathematics educators appear to have paid little attention to climate change in their work. One purpose of this paper is to argue that this situation needs to change. Mathematics educators have an important role to play.

Climate change is now reported, discussed and debated in a wide variety of genres, including scientific papers, newspaper reports, television reports and documentaries, policy documents, treaties, websites and blogs. We are interested in how the mathematics of climate change is represented within these different genres. An understanding of the representation of mathematics in these various kinds of text will enable us to identify what mathematics is relevant, how it is relevant and to consider ways of enhancing public understanding of climate change, whether through schooling or other means. Our discussion is informed by critical mathematics education, as we set out below. To focus this paper, moreover, we restrict our attention to the role of mathematical modelling in reporting and understanding climate change. To illustrate our discussion, we examine two examples of publicly available texts concerning climate change: a newspaper report and a policy document. We argue that, despite its centrality, the role of mathematics is largely invisible in public discussion of climate change, such as in these two texts.

MATHEMATICS, MODELLING AND CLIMATE CHANGE

Mathematics is implicated in three aspects of climate science: description, prediction and communication (Barwell, 2010). The description of climate change largely involves measurement (of temperature, rainfall, sea level etc.) and the statistical analysis of these data. The prediction of climate change involves more advanced mathematics, such as mathematical modelling, non-linear systems and stochastic processes (McKenzie, 2007, pp. 22-23). The communication of climate change involves the production and consumption of information about climate change in the form of written texts, graphs, charts, diagrams etc. Clearly these three dimensions of the mathematics of climate change are inter-related. The interpretations made by consumers of the communication of climate change are influenced by these consumers' understanding of the mathematics of description and prediction. [1]

In this paper, we focus in particular on the role of mathematical modelling in predicting climate change. Earth climate models have been developed over many years, are highly complex and draw on expertise in many different domains of research. Weaver (2008) summarises how they work as follows:

A climate model starts with a set of equations governing the dynamics of the climate system and translates those equations into a model grid that represents the Earth. Each of the subcomponents (ocean, atmosphere, land surface, cryosphere) interacts and exchanges heat, moisture, and momentum. The resulting system is then driven by specified radiative forcings, including energy from the sun and emissions of human produced greenhouse gases (p. 183).

To evaluate the model, certain starting conditions are specified and it is then run until an equilibrium is reached. The equilibrium state is then compared with recorded data of the Earth's climate with the aim that the model corresponds reasonably well with observed conditions. This process takes several weeks of 24-hr computer processing (Weaver, 2008, p. 189). An example of the atmosphere component of a climate model is shown in Figure 1:

$$\begin{aligned} \partial u + u \rightarrow \cdot \nabla u + 2\Omega \times u &= -1\nabla p + gk + F + \mathfrak{J}(u) \\ \partial \rho + \nabla \cdot (\rho u) &= 0 \\ p &= \rho RT; \rho = f(T, q) \\ \partial T + u \cdot \nabla T &= SW \\ \leftrightarrow & \\ + LW & \\ \leftrightarrow +SH + LH + \mathfrak{J}(T) & \\ SW = f(\text{clouds, aerosols} \dots) & \\ LW = f(T, q, \text{CO}_2, \text{GHG} \dots) & \\ \partial q + u \cdot \nabla q &= \text{Evap} - \text{Condensation} + \mathfrak{J}(q) \end{aligned}$$

Figure 1: Atmosphere - Equations of a typical climate model (McKenzie, 2007, p. 13)

Working Group 10

The models are refined until a satisfactory fit is obtained. Predictions can be generated by modifying the conditions to represent, for example, an increasing concentration of greenhouse gases in the atmosphere (Weaver, 2008).

Interest in mathematical modelling in mathematics education has been growing over the past two decades in different parts of the world (e.g. Niss, Blum, & Galbraith, 2007; Suurtamm & Roulet, 2007). One reason for this greater interest is the advances in technology that help to facilitate the creation of models by students. Mathematical modelling helps students to see the relevance of mathematics in investigating and making sense of the world, so that mathematics is not experienced as a static domain with little connection to students' lives. In particular, mathematical modelling uses real data to investigate a wide variety of issues. The discussion document for the ICMI – Study 14 on applications and modelling, describes the modelling process:

The starting point is normally a certain situation in the real world. Simplifying it, structuring it and making it more precise - according to the problem solver's knowledge and interests - leads to the formulation of a problem and to a real model of the situation. [...] If appropriate, real data are collected in order to provide more information about the situation at one's disposal. If possible and adequate, this real model - still a part of the real world in our sense - is mathematised, that is the objects, data, relations and conditions involved in it are translated into mathematics, resulting in a mathematical model of the original situation. Now mathematical methods come into play, and are used to derive mathematical results. These have to be re-translated into the real world, that is interpreted in relation to the original situation. At the same time the problem solver validates the model by checking whether the problem solution obtained by interpreting the mathematical results is appropriate and reasonable for his or her purposes. [...] At the end, the obtained solution of the original real world problem is stated and communicated (Blum, 2002, p. 152-153).

In mathematical modelling, then, students are able to reach outside the realm of mathematics and to engage in something "real in the world" and to move back and forth between mathematics and the world as a way to understand both the world and mathematics (Pollack, 2007). The iterative comparison between the model and the phenomenon requires the creator of the model to reflect on how well their model represents the actual situation, to make clear the assumptions in creating the model and to evaluate its reliability as a predictive model. Jablonka (2010) reiterates that "explicating the underlying assumptions and exploring alternative forms" (p. 95) of models is an important part of the modelling process. Mathematical modelling goes beyond simply fitting a curve to a set of data points drawn from an experiment (Galbraith, 2007).

This general account of the modelling process fits well with Weaver's summary of climate change modelling. Both accounts use the term 'translating,' for example, to describe the relationship between observed data and model outcomes. Similarly,

climate models undergo an iterative process of evaluation and refinement in relation to observed data about the climate (Weaver, 2008, pp. 188-198).

CRITICAL MATHEMATICS EDUCATION

Skovsmose (1994) makes the important point that our technological society relies heavily on mathematics. Computers in particular rely on algorithms and models that are fundamentally mathematical in nature. While the role of mathematics is often rather invisible, it plays a key role in shaping society and leads to tangible social effects. Key aspects of our everyday lives, such as banking, insurance, medicine, transportation or shopping are shaped by often hidden mathematical models and procedures. As an example, he discusses how a mathematical model of airline ticket sales includes a degree of overbooking, as a result of which, on some occasions some passengers are unable to fly since there are insufficient seats on their flight (Skovsmose, 2001). He uses this example to illustrate the way that mathematics is a powerful predictive tool, but also to show that this tool has limitations and real social effects, such as some people not being able to fly. These limitations are unavoidable, since mathematics formalises a situation, effectively creating a particular mathematical interpretation, which in turn develops a social reality of its own: “mathematical models become guidelines for our design of our world and, therefore, they become not only descriptive but also prescriptive,” (Skovsmose, 1994, p. 55). These mathematical models are not necessarily good or bad; airline ticket sales models contribute to convenience and in some cases to cheaper fares. But the model does change the nature of pricing and of air travel itself. In other words the traditional principle of: ‘Do not sell any more tickets than there are seats’ becomes substituted with the much more complex principle that includes maximizing revenues and quantifying customer dissatisfaction (Skovsmose, 2006, p. 39). Hence the decisions based on complex mathematical models developed by experts are inaccessible or invisible to citizens (Skovsmose, 2006; Jablonka, 2010). This invisibility results in a society that often accepts the output of experts and feels disempowered to examine or question the conclusions of these experts or to enter into any kind of discussion or debate.

Recognizing that mathematics is powerful yet invisible suggests that mathematics education needs to equip the citizens of our society with a critical awareness of the role of mathematics and its effects. In developing a critical approach to mathematics education, Skovsmose (1994) identifies three forms of knowing: mathematical knowing, technological knowing and reflective knowing. He emphasises that the distinctions are analytical, rather than empirically distinguishable (Skovsmose, 1994, p. 115). Mathematical knowing is concerned with formal mathematics: the kind of ‘within’ mathematics procedures and thinking with which mathematicians work. Technological knowing is about the application of mathematics – knowing both how to construct a tool and how to use it. Mathematical modelling is one such tool. Knowing how to construct a model requires more than a familiarity with, for

example, different types of equations. It requires an understanding of how to construct particular equations to model a situation as well as an understanding of how to use the model (Skovsmose, 1994, pp. 98-99). Clearly there are overlaps between mathematical and technological knowing. They each give meaning to the other.

Reflective knowing builds on mathematical and technological knowing and augments that knowledge with critical awareness of the broader effects of mathematics and of its social or ethical consequences. The value of reflective knowing in mathematics is the awareness it provides of the way mathematics works to shape our lives in different ways (its 'formatting power', Skovsmose, 1994). Reflective knowing is one of the bases for critical mathematics education, the project of which is the empowerment of critical citizens (Skovsmose, 2006). Students can use mathematics as a tool for critical investigation as they draw on all three forms. Thus, students make mathematical sense of the world, while maintaining a critical, reflective orientation towards these mathematisations and the insights they bring.

The connections between mathematical modelling in mathematics education and critical mathematics education are clear. In a critical mathematics education situation, Skovsmose (1994) highlights the following 'tasks' of reflective knowing:

to make explicit the preconditions of a modelling process which become hidden when mathematical language gives it a neutral cover. (p. 106)

to address problems and uncertainties connected with transitions between the different types of language game involved in the mathematical modelling process. (p. 111)

to identify the formatting power of mathematics. (p. 114)

This reflective knowing is very similar to the processes suggested by Blum in his description of mathematical modelling: both suggest making explicit and visible the assumptions and limitations that are inherent in the creation of the model. Jablonka (2010) suggests that genuine examples of mathematical models can provide a source for understanding and assessing the use of mathematics within different areas of society. Several researchers provide examples of engaging students in mathematical modelling of social justice issues such as racial profiling (Gutstein, 2006) or issues of equity (Makar & Confrey, 2007). Such work shows how students' interest in mathematics can be enhanced through engaging in mathematical modelling of issues that concern them. At the same, students become more aware of the issues they are exploring. Such work helps students to develop a critical stance that helps them to understand, evaluate, and respond to technological and social issues (Jablonka, 2010). We believe that this approach is applicable to the issue of climate change.

CRITICAL MATHEMATICS EDUCATION AND CLIMATE CHANGE

Climate change models open a space for technological imagination and hypothetical reasoning which allows society to make predictions about events in the future. The

mathematical modelling of climate change is used to justify certain actions, for example concerning the development of renewable energy sources or the construction of sea defences, despite the invisibility of the mathematics (see Skovsmose, 2006). This situation is apparent in the communication of climate change. In our initial survey of articles on climate change we have observed that while scientific principles are often referred to and explained, explicit reference to the role of mathematics is much less common. To illustrate and discuss this invisibility, we refer to two examples of texts about climate change: the first is a newspaper report; the second is a government policy document.

Climate predictions in the news

In August 2010, a report headlined ‘Climate scientists forecast more heat, fires and floods’ appeared in Canada’s Globe and Mail newspaper. [2] The article is typical of the proliferation of news reports about climate change, often prompted by extreme weather events. Here are three extracts:

Floods, fires, melting ice and feverish heat: From smoke-choked Moscow to water-soaked Pakistan and the High Arctic, the planet seems to be having a midsummer breakdown. It’s not just a portent of things to come, scientists say, but a sign of troubling climate change already under way. [...]

The UN’s network of climate scientists – the Intergovernmental Panel on Climate Change – has long predicted that rising global temperatures would produce more frequent and intense heat waves, and more intense rainfalls. In its latest assessment, in 2007, the Nobel Prize-winning panel went beyond that. It said these trends “have already been observed,” in an increase in heat waves since 1950, for example. [...]

The WMO [World Meteorological Organization] did point out, however, that this summer’s events fit the international scientists’ projections of “more frequent and more intense extreme weather events due to global warming.”

The report refers to several events from the preceding weeks: the heatwave and fires affecting Moscow, floods in North West China and a huge ice island that had recently calved from a Greenland glacier. The main thrust of the report is that these events ‘fit patterns predicted by climate scientists’. In the latter part of the report, these three events are linked to specific predictions from the IPCC’s latest synthesis report.

Despite the relatively detailed nature of the report, none of the three dimensions of knowing proposed by Skovsmose (1994) are particularly apparent. The report involves only a minimal level of mathematical knowing, mostly through the statistics that are quoted (e.g. “Moscow temperatures topping 37.8 degrees for the first time”) and the use of rather vague comparisons like ‘more’ or ‘increase’. Only very general references are made to the process of modelling (i.e. technological knowing), such as, for example: *modellers of climate systems are “very keen” to develop*

supercomputer modelling that would enable more detailed linking of cause and effect as a warming world shifts jet streams and other atmospheric currents.

Models are constructed as simply being ‘developed’ by ‘modellers’. In terms of reflective knowing, the report does not explain how the IPCC’s predictions were made, how trends are established or how projections are arrived at. The construction of climate models involves human actors making assumptions (Jablonka, 2010) but this aspect of the process is not apparent. Predictions and trends are attributed to ‘scientists,’ ‘climate scientists’ or ‘climatologists’ but their role is rather unclear. Similarly, the role of technology is apparent but only in general terms, through references to ‘supercomputers’. Such references tend to give a gloss of reliability and obscure the role of the modeller in constructing the model: both mathematics and the human nature of mathematics are largely invisible. Interestingly, the human role in climate change is also not apparent. The article makes no explicit reference to specific human actions that have been identified as contributing to climate change. There is a discussion of cause and effect, but it concerns the question of whether climate change ‘causes’ extreme events like heat waves.

Climate change in public policy

In June 2009, the UK Government published ‘Adapting to climate change: UK Climate Projections,’ a document setting out likely effects of climate change on the UK, discussing various options for ‘mitigation and adaptation’ and summarising policy and action at various levels of regional and national government. In the opening part of the chapter that presents the UK Climate Projections, there is a paragraph of explanation of climate models:

Climate models are computer simulations of the way the Earth’s climate works. Beginning with the laws of physics, they represent the characteristics of air, ocean water, ice, and crucially, heat around the Earth. They model chemical, biological and physical processes in the atmosphere, oceans and on land. Ever more sophisticated models and increasing computer power enable climate scientists to understand our climate better and study a range of possible future climates. Model results are checked in part by simulating past and present climate observations and seeing how well they perform. All of the models used in UKCP09 are internationally recognised and peer reviewed. These climate model results, together with observations of climate change, form the basis of the overwhelming consensus there now is in the scientific community and international bodies (including the Intergovernmental Panel on Climate Change – IPCC) that the world’s climate is changing quickly and that this is mainly as a result of our actions.

The challenge now, and one which the UK Climate Projections will help us meet, is to use this enhanced sophistication and the variety of models to provide us with a more detailed picture of the nature and probability of various possible outcomes.

Working Group 10

This will inform practical decisions, helping our society to deal with the risks from climate change. (DEFRA, 2009, p. 3)

As with the newspaper report (and somewhat ironically), this explicit discussion of mathematical modelling does not involve much mathematics. The quote makes only passing reference to any kind of mathematics (e.g. probability). The ‘technological knowing’ dimension is confined to a rather general account of the modelling process. While this account conforms to a certain extent with the process as understood in mathematics education (Blum, 2002), it emphasises the ‘laws of physics’ and ‘chemical, biological and physical processes’ rather than mathematical processes. In terms of reflective knowing, the human role in constructing the models, making assumptions and evaluating and applying the models is largely absent. They are computer simulations rather than human mathematical creations. Indeed in some parts of the texts, the models themselves have agency: they ‘provide us with a more detailed picture.’ Humans act only secondarily through ‘peer review’, for example. Unlike the newspaper report, there is some reference to human activity as a cause of climate change, but only in very general terms. Indeed, throughout the document, human or organisational activity is discussed mostly in terms of mitigation of climate change (e.g. constructing flood defences) rather than as contributors to the problem. The description of modelling, moreover, does not explicitly include human activity in its summary of what is modelled.

CONCLUSION

Our discussion of these two texts illustrates the idea that mathematics and human mathematical activity are largely invisible in the reporting of climate change. Furthermore, the role of human activity in causing climate change also seems to be heavily obscured. These observations are consistent with claims in the critical mathematics education literature that mathematisation results in dehumanisation (e.g. Jablonka, 2010; Ernest, 2010). Clearly there is a role for mathematics education to make the invisible visible. Making mathematics visible, however, risks contributing to this dehumanization particularly in relation to the human role in climate change. This is not to say that mathematics should be left invisible, but that a mathematics that includes reflective knowing is necessary. Consumers of reports about climate change need to be aware of the assumptions and the iterative process of working with models and their various variables. As Jablonka (2010) suggests:

‘model-oriented reflection’ helps at evaluating whether a mathematical model is likely to fulfil the specific purpose for which it is constructed. Explicating the underlying assumptions and exploring alternatives forms an important part of this activity. (p. 95)

The emergence of human agency as a key issue in our examination of these texts is related to critiques of discourses of ‘the environment’ in contemporary society. In particular, such discourses construct humans as distinct from the environment, over

Working Group 10

which they exercise control and can exploit and manipulate to better their own (i.e. human) welfare, rather than as just one part of an ecosystem (see, for example, Bowers, 2001). The mathematical treatment of climate change risks perpetuating this discourse through its quantification of human activity: once the situation is mathematised, human actions are replaced by variables in an equation. Mathematics, in its quantifying mathematical ‘mesh’ (Ernest, 2010), seems to filter out human activity. Mathematics helps us to become invisible.

Our discussion of these texts is *not* intended to shed doubt on the claims that are made about climate change. Rather, we argue that the full modelling process needs to be more visible, since particularly the assumptions that are made mathematise climate processes and human behaviour. Such a task is not straightforward: one might not expect a newspaper report to explain in any detail the nature of the mathematical models involved. The question arises, therefore, of where the consumers of such texts may learn about such things. Moreover, not everyone can be expected to work with the mathematical model equations shown in figure 1. Nevertheless, a more widespread public understanding of the role of mathematics in our understanding of climate change would allow for a more informed discussion of the issues and a stronger and more effective societal response. Mathematics educators have an important role to play in responding to these issues, whether through schooling or broader forms of public education. Climate change is a serious threat to our ways of life. Mathematics education can play its part in addressing this threat. We would like to see more research, more teaching and more action on climate change and mathematics education.

NOTES

1. The nature and effect of this influence is an empirical question that remains to be investigated.
2. ‘Climate scientists forecast more heat, fires and floods’ by Charles J. Hanley of the Associated Press, published in the *Globe and Mail* on 12 August, 2010. The report can be viewed at <http://www.theglobeandmail.com/news/world/climate-scientists-forecast-more-heat-fires-and-floods/article1671364/actions.jsp>.

TEACHERS DISCUSSIONS ABOUT PARENTAL USE OF IMPLICIT AND EXPLICIT MATHEMATICS IN THE HOME

Sarah Crafter & Guida de Abreu⁴⁵

University of Northampton & Oxford Brookes University

Embedding everyday mathematics in home learning is considered by educationalists as one of the best mediators for learning. There is also evidence that everyday mathematics, such as cooking or the use of board games, is not used as a resource for learning by all parents. This paper examines how teachers make sense of embedded everyday mathematics at home in relation to parents' practices. The theoretical concepts of Boundary Crossing and Implicit/Explicit practice will form the basis for this paper. Data comes from interviews with eight teachers who work in culturally diverse school settings. The analysis focuses on teachers' narratives about the complexities of shared boundary crossing and home constraints which make everyday mathematics learning problematic⁴⁶.

Key words: everyday mathematics, teachers, boundary crossing, implicit/explicit

EVERYDAY MATHEMATICS

Embedding everyday mathematics into learning in the home has been considered beneficial in both academic circles (see Young-Loveridge, 1989) and educational policy within the UK (The Williams Report, 2008). We argue, like Street, Baker, and Tomlin (2008) that embedding everyday mathematics at home is a complex business as it involves more than the inclusion of mathematics activities and procedures. Numeracy practices are enabled or constrained by sociocultural contexts, values and representations (Gorgorió & Abreu, 2009), social and institutional relations (Street, Baker, & Tomlin, 2008) and personal histories (O'Toole & Abreu, 2005). In culturally diverse home and school settings the use of mathematical practices and the resources parents draw on to make sense of their children's learning can be contradictory and complex (Crafter, 2009). This paper asks, what are teachers understandings of parents home mathematics practices? This paper uses two theoretical constructs to attempt to understand how teachers makes sense of embedded home mathematics learning – 1. Boundary Crossing and 2. Implicit/explicit numeracy practices.

BOUNDARY CROSSING AND IMPLICIT/EXPLICIT LEARNING

Until recently, both traditional and sociocultural traditions in cognition have focused on learning progression within particular communities. The situated cognition tradition for example, centred on movement from periphery to full legitimate participation in a particular community (Lave & Wenger, 1999). Developmental psychological research investigating the interplay between culture and cognition has looked at the change of mathematical practices over time (Saxe & Esmonde, 2005). Movement of knowledge between or across communities has been of interest for some time, first in the form of transfer which suggested that knowledge used in one context is utilised in another (Thorndike & Woodworth, 1901). While this idea has been taken up in areas like mainstream cognitive psychology, it has been widely recognised that knowledge, including mathematical knowledge, is culturally situated to particular contexts (Abreu, 1995; Nasir, 2008).

The change of focus from the concept of transfer to transition proved much more helpful for those of us interested in studying the cultural nature of mathematical knowledge. Transitions could come in different forms – some transitions are consequential, because not only can they be a struggle, but also they have the potential to alter ‘one’s sense of self’ (Beach, 1999, pp. 114). In other words, they usually have an impact on the individual and the social context that they inhabit. The type of transition that a child makes between home and school is called a ‘collateral transition’ where, historically speaking, activities are taking place simultaneously. The child is in a continuous process of moving between these two major communities of practice and therefore the construction of meaning is ongoing for all the key players of those communities.

More recently, attention has (re)focused on the notion of boundary crossing. It is still not clear to us what distinguishes the forms of transition mentioned by Beach (1999) from boundary crossing. Perhaps it is that boundary crossing encompasses more than strategic knowledge to include symbolic resources and representations (Zittoun, 2010). For Wenger (1998) boundary crossing, seems to emphasise the practices themselves as units of analysis whilst for the purpose of this paper, the representation of the practice takes centre stage. However, Wenger’s (1998) conceptualisation of boundary crossing is useful in that it addresses the continuities and discontinuities to the forms of practice which are enacted when moving between one community and another.

Some forms of mathematics knowledge have greater power and status than others (Nasir, 2008). Some practices are deemed more worthy than others (e.g. board games are valued mathematics practices by the school while dress making and carpentry largely go unnoticed – see González, Andrade, & Civil, 2001). The mathematical value of dress-making might not be recognised by school (the more powerful community). When certain practices are reified they are imbued with greater status than others. Boundary crossing from a cognitive perspective connotes a

Working Group 10

shared knowledge (Akkerman, et al., 2007) but we question where this shared knowledge begins and ends.

Using the notion of implicit/explicit practices may provide a useful mechanism for looking at the boundaries of mathematical practice across the communities of home and school. Tomlin, Baker and Street (2002) explore in their research those practices which are more visible or explicit, and are recognised by all concerned as improving mathematical skills. However, some mathematical practices are viewed as less salient, or are more implicit, because they often go unrecognised as contributing to the mastery of mathematical skills. There are a number of crossovers between schooled mathematics and out-of-school mathematics practices such as working on number bonds, times tables, dates, measuring, money and playground games. Other practices such as homework and shop bought textbooks also transcend both contexts. Out-of-school mathematical practices like laying the table, counting stairs, setting the video and producing calculations from looking at car number plates reveal how varied numeracy learning can be. These examples further highlight how much the uses of home mathematical practices are reliant on the social characteristics of engaging in numeracy.

This has led to some questions - what is constrained or facilitated in the boundary crossing? What forms of mathematical knowledge (implicit/explicit) make it possible to address the continuities or discontinuities across communities? This paper explores how teachers talk about tensions and expectations on home mathematics learning across the boundaries of home and school when thinking about parents' practices.

THE EMPIRICAL STUDY

To examine teachers' representations of parents uses of everyday numeracy practices we draw selectively on findings from interviews with eight teachers who participated in a wider ethnographic study exploring home and school mathematics learning. The teachers taught children from two different primary schools situated in the same town, known as school A and school B (all catering for pupils aged between 5-11 years). In school A the proportion of ethnic minority pupils could be described as 'culturally mixed' and school B was mainly white school. At the point of data collection pupils, parents and teachers were sampled from the highest and lowest achievement groups in the year. The exception being Richard's class in school B (see table) which had a policy of mixing different achieving children.

School	Teacher	Year Group	Achievement Group
School A	Catherine	Ages 6/7 years	High
School A	Jane	Ages 6/7 years	Low
School A	Anna	Ages 10/11 years	High

Working Group 10

School A	Mary	Ages 10/11 years	Low
School B	Richard	Ages 6/7 years	Mixed
School B	Chris	Ages 10/11 years	Low
School B	Susan	Ages 10/11 years	High

The empirical data we use in this paper to illustrate our thinking was collected using the episodic interview and analysed using an episodic analytic technique (Flick, 2000). Selections of questions which are pertinent to the data explored in this paper are:

In your view, how important is it that parents are involved in their children's school learning? Could you tell me about a situation around that?

Do you think that practical [mathematics] work is more beneficial at home than the more traditional academic work, can you describe how you feel about it?

SHARED BOUNDARY CROSSING

Everyday mathematics which forms that grey area between implicit and explicit mathematical practices was a central feature of the teacher narratives in this study. In a previous paper we argued that there are some home mathematical activities which are obviously explicit – homework, mimicked school-like activities like shop-bought books (O'Toole & Abreu, 2003), etc... This first quote from Jane highlights what she perceives as some of the discontinuities between her own perspective/practices and those of some parents. She has been shown a vignette from another teacher who argues strongly in favour of everyday embedded mathematical activity as a learning tool. There is not space to put the whole vignette but it provides a general idea:

I have a real antipathy towards homework for children on this age. I would much rather that the parents were helping the children in general ways, to learn. For example, if they wanted their maths to improve, I'd much rather see them taking their children shopping and talking to the children about, 'oh, you know, these apples are £1.50 and kilo, you know, how many do you think we're going to get', and just bringing mathematics into their everyday life. I tend, I do find in this school, and I don't know whether it's a generalisation, you know, or whether its true everywhere, but the parents tend to want a sheet of sums,

She responds:

Jane: I agree with her that maths should relate to the everyday life, I don't dispute that. And again, there's a big difference, and it's been studied with my own

Working Group 10

son – stairs, count them as you go up and as you come down, pre-school thing. There are parents who don't believe unless you have a sheet, because they remember their own homework but what they're remembering is high school homework. Unless you've got a sheet folded in half, sums down there and sums down there.

This was not necessarily an opinion shared by her colleagues. Just to give you a flavour of variation around the boundaries of implicit/explicit mathematics practices another teacher says:

Susan: ... I think a lot of parents just do what she's saying automatically, and kids these days will, you know 'just whip round the corner shop and get me a loaf of bread and a pint of milk and make sure you get the right change' and they can, I think they're far more streetwise these days than they've ever been, so they're getting that kind of experience. We laugh about the traveller kids who are not necessarily that good at maths but if you give them a money problem and they've got it like that, because they've got the experience of actually going out and spending money and dealing tangibly with coins.

Her mention of the traveller community and "kids these days" is interesting in that it shows recognition for both the cultural situatedness of everyday mathematics but also alludes to the historical aspect of boundary crossing which will be addressed more deeply in a moment. Jane raises an aspect of the implicit/explicit dilemma of mathematical practice which was a feature of most teacher narratives – laying the foundation of number in pre-school.

Foundation laying

From the interviews with these teachers it would seem that implicit mathematical practices are most valued when children are young, prior to coming to school. As such, parents are ideally expected to lay the foundations of their child's learning in the first five years of life. The expectation though, is that this is a 'natural' activity that is implicitly embedded in everyday practice. This foundation then sets the child up for the boundary crossing into school. Catherine is responding to the quote from the teacher about everyday mathematics mentioned already:

Catherine: I mean the idea is that parents give them support. I find that most of the parents do give them support but I think this what she's talking about here, about real life maths, like going shopping, then I think hopefully the parents are doing that anyway as well. And have been doing that ever since they were, I mean that's what makes these children better mathematicians, better at anything. That from day one when they were tiny babies you start counting their fingers and counting their toes, and doing things like that. The parents either do that naturally or they don't. They don't teach them to do it. And the

Working Group 10

ones that started with the baby counting its toes will be at the shop saying ‘well, you tell me what the change might be’ ...It has an impact on how they come into school, and what they can do when come into school. I mean, some come into school really quite numerate and literate really. Knowing lots of nursery rhymes and all these sort of things. And other children come to school knowing absolutely nothing. And they’re not necessarily less intelligent at the end of the day, but just have not had five years of education, or whatever, that their parents would have given them.

Work from the ‘funds of knowledge’ research suggests that parents do not always “naturally” undertake mathematical practices valued by the school (see Gonzalez, Moll, & Amanti, 2005 in the US or Andrews & Yew, 2006 in the UK). Wenger (1998) talks about boundary peripheries – the trajectory where a newcomer to a community becomes a full member of that community with time and experience with the practice. In a school setting it is almost impossible for a parent to become a full member of the community because their connection through a third person (the child) keeps them on the periphery. The direction of knowledge is assumed to go from school to home, not the other way (Gonzalez, Moll, & Amanti, 2005). Yet in the case of foundation laying, parents are expected to develop the right kind of knowledge prior to their child arriving in the school community:

Mary: Children really from year dot should be learning how to speak, and if it isn’t -you know, your phone number, your door number, numbers all around you, I think that helps a lot. And then they’re not frightened of it and don’t look at it and think ‘ah, it’s totally scary’.

Foundation laying was in some cases recognised as a historical activity within the home community:

Catherine: I think its one of these things, you know, if your dad is really good at maths or your mums really good at maths it will show through in the child.

Sociocultural theories and Communities of Practice recognise the importance of mutually engaging histories by members of communities or societies. Parents own mathematical past experiences are recognised as having an influence on their current mathematical endeavours (O’Toole & Abreu, 2005).

Resisted boundaries

Some parents whose knowledge in one community is enough that it can carry to another community may resist institutional boundaries placed on them. Parents who are themselves teachers have full participatory knowledge in one context which crosses the boundary to another. Anna discusses her resistance to some mathematical practices sent home from school, which she subsequently reconstructs:

Anna: though my son is only five, during the Easter holidays and half holiday, this list came; he has this maths booklet at home, which I

Working Group 10

must admit we very rarely look at. And there was this list saying do page fourteen, fifteen, sixteen, you know, about ten different pages. And I looked at that and I thought, and I did look them up and see what areas it was and then I thought no, he's not doing that we're not going to sit and he doesn't have to write it or anything or take it back to school. But I just thought I'm not going to slog through this during his holidays, but I thought we could spend our time much more valuably. And so we did, he had 50p during the holiday and we took him to the shop 'right ok, you can buy yourself a treat', 'how much have I got mum?' 'well you've got 50p there' and it was about his change or whatever. And then another time we were cleaning out the car and it was all the money that we found underneath the seat.

As a teacher Anna's insider knowledge allows her greater freedom in terms of the boundary crossing between home and school with her own children. Her expert knowledge means she can be resistant to formal mathematical practices sent from school to home. With explicit knowledge this is less complex than implicit knowledge which is largely culturally and experientially driven.

HOME CREATES CONSTRAINTS

Teachers were very conscious of the constraints to mathematical practice in the home. Some of those constraints came about because of boundary crossing with other extracurricular activities such as swimming clubs, sport activities, Mosque or dance. Some of the teachers spoke of the other difficulties in explicitly embedding everyday mathematical activities in the home. Catherine narrates the difficulties in sending practical work home for children to do:

Catherine: Do you think that practical work is more beneficial at home than the more traditional academic work?

Catherine: So what would you put in that, as practical work?

Interviewer: Um, what's been mentioned to me before are things like measuring, going in and weighing tins, rather than your sheet of sums

Catherine: Which you can end up with a lot of problems giving homework like that, because they can come back and say 'well, I haven't got a tape measure at home or I haven't got a ruler or I have no scales in the kitchen

Interviewer: So it excludes some of the children

Catherine: It does, definitely. I mean you'd be surprised what they say. I gave them some colouring, well it was a homework which said 'colour all these squares blue' or whatever, and I had a child who

Working Group 10

said ‘but I’ve got no colours at home’, so I had to give her some. But you can’t give them scales, and you can’t give them tape measure, rulers. I mean, even, um, when we did some measuring a couple of weeks ago and one girl in my group came back and said ‘well I couldn’t do my measuring because my sister took her ruler to school’ so we did it in school with her instead. But the point is, they can’t all...we even get the trouble with clocks, some children don’t even have clocks at home. They’ll have plenty of videos and microwaves and things, with digital time on them, but they will not have an analogue clock in the house.

We have argued elsewhere that the resources parents use to understand their child’s mathematics learning can be in symbolic form, such as the representations of child development (Crafter, 2009). Resources in the form of artifacts also have the potential to reify participation between two Communities of Practice (Wenger, 1998). In relation to boundary crossing, Wenger (1998) discusses how artifacts (such as colouring pencils or clocks) help organise the interconnections between communities. As Catherine points out, culturally diverse settings can create disconnections which arguably can increase the gap between children who do, and do not engage in implicit mathematical practices at home.

Anna spoke of another form of constraint on children’s home and school mathematics learning

Interviewer: Why do you think some children do better in their mathematics than other children? Can you tell me about it?

Anna: Quite possibly the attitude of their household to mathematics. If you have parents who always say ‘oh, I was no good at maths at school, oh I found it difficult, oh not maths, don’t ask me’ I think it tends to show the children that there is something hard about it. Whereas, I actually think that with a positive attitude most children actually enjoy maths. But I suppose it’s with any subject you know, some children will find learning numeracy more difficult, but then you’ll find other children who find reading more difficult but they’re very good at numerical problems.

Chris alludes to a similar issue to that raised by Anna.

Interviewer: Do you think there are any aspects of the home background, which may affect their mathematics? Can you describe anything?

Christ: Again, I think attitudes towards numeracy in general. Again, there doesn’t seem to be any shame about not being able to do maths and it’s either joked about, whereas you’d never joke about not

being able to read, or write. I think that's probably the biggest issue to get over, that it's not ok, not to be able to do maths.

SOME CONCLUDING THOUGHTS

This paper has attempted to make sense of teachers' understandings of parents' everyday mathematics in the home through the theoretical lens of boundary crossing and implicit/explicit mathematical practices. Understanding episodes where implicit/explicit use of mathematics has crossed boundaries seems to be important. Grossen (2010) talks about the ways in which a piece of text in one 'sphere of experience' is incorporated in the social and cultural experience in another 'sphere of experience'. Can we focus on mathematical practice in a similar way? If so, we could perhaps help avoid the tendency that teachers and schools have to 'impose upon' the home the 'right kind' of mathematical practice. Teachers' lack of knowledge about the diversity of home mathematics encourages notions like 'foundation laying' which are imbued with notions of 'naturalness.' Foundation laying obviously works well but it is also narrow in its scope in that only certain practices are included in that. While teachers know that parents' mathematical insecurities can pass on to their children there appears to be very little 'mathematical identity' work which goes on in practice. One might imagine that this is largely because a) they are not trained to address the psychology of identity and b) there is little time and space in the delivery of the curriculum to do so.

STUDENTS PERCEPTIONS ABOUT THE RELEVANCE OF MATHEMATICS IN AN ETHIOPIAN PREPARATORY SCHOOL

Andualem Tamiru Gebremichael, Simon Goodchild and Olav Nygaard

University of Agder, Norway

This paper presents results from a pilot study into students' perceptions of the relevance of mathematics. Cultural historical activity theory is used as an analytical perspective. Data are collected through interviews supported by classroom observation. Convenience and purposive sampling were used to select the school and students. Findings indicate that students perceive that only basic mathematics is used in their everyday activities whereas the mathematics they are learning at the moment: has an indirect relevance through other subjects or used by professionals; has use in their future studies; has an exchange value in the market place of joining the university and getting job; and in mathematics they experience a sense of identity, empowerment, spirituality, and trust in the curriculum and their teacher.

Key words: context, preparatory school, perception, relevance

INTRODUCTION

The students in this study are preparing for higher learning institutions (hence the school designation 'preparatory'). The first author's experience as a mathematics teacher has revealed that there are many who consider mathematics as an academic exercise rather than a social activity; he has observed that even some teachers are challenged when they encounter real-life problems that could be solved using mathematics. He has observed that students pay attention to what they perceive as relevant to them. The textbook rarely includes practical problems; for example, the topic limit, which is said by teachers to be difficult for students to understand, consists of 177 exercises and 62 examples, of which there is only one practical exercise. Literature indicates that mathematics with real world connections makes learning mathematics more effective (e.g. Mason & Spence cited in Even & Tirosh, 2008, Goldin, 2008) and that the perception of students about mathematics is important for success (e.g. Even & Tirosh, 2008, Mulat and Arcavi, 2009). Motivation – "the inclination to do certain things and avoid doing some others" – is an important construct that affects performance in mathematics (Hannula 2006, p. 165). According to Roth and Lee (2007) identity, motivation and emotion are integral to the activity of learning. They contend that emotion as well as identity – the sense that the individual has about who she/he is with respect to others and with respect to the activity of learning – are central in the student's motivation to engage.

A key term in this study is perception, which means, "a result of perceiving" where to perceive means "to attain awareness or understanding of ... to regard as being such" ('Dictionary and Thesaurus – Merriam Webster', n.d.). Our study seeks to expose the students' understanding of the relevance of mathematics she/he is

learning. Thus, the term that fits the purpose here is perception. Mulat and Arcavi (2009) also studied the perception of high achieving students about what fosters “their mathematics and academic trajectory” (p. 77). In their study ‘perception’ referred to the students’ understanding of the factors that enable or constrain learning and achievement of mathematics. The purpose of this paper is to report a characterization of Ethiopian students’ perception of the relevance of mathematics with respect to their learning goals as well as about the relevance of mathematics to their society and real life situation, which we believe exposes the perception in a peculiar context and contribute to the improvement of learning mathematics in Ethiopia. The principal research question addressed in this paper is ‘what are Ethiopian students’ perceptions of the relevance of mathematics and how are they characterized’. The paper is structured in such a way that the theoretical perspective and methodology are discussed first, followed by the analysis, presented in eight themes that emerged through the analytic process.

THEORETICAL PERSPECTIVE

The theoretical perspective that guides this study is cultural historical activity theory (CHAT), which is one strand of sociocultural theory that has evolved from the work of Vygotsky (Roth & Lee, 2007). Sociocultural theory is about people’s active involvement in cultural practices and the inherently social nature of mental processes (Cobb, 2007; Lerman, 1996). Proponents of sociocultural theory contend that there are many things that will remain obscure if the focus is only on the individual (Lerman, 1996; Wundt, in Cole & Engstrom, 1993). A basic tenet of cultural historical activity theory is that knowledge appropriation is a social process and learning doesn’t take place in the mind only but distributed in the activity system, which is mediated by cultural tools such as language, with human activity as the unit of analysis (Lerman, 1996). Central to CHAT is the notion of agency, that people can choose their goals for action and this object oriented action is mediated by cultural tools, community, rules and division of labour (Roth & Lee, 2007). Engström’s expanded mediational triangle (Cole & Engström, 1993) can describe the situation, which models the individual’s activity within which perception is mediated by the tools, rules, division of labour, and the community, as well as contradictions that might exist among and/or within them (Roth & Lee 2007).

The students have been involved in the activity of learning mathematics long before they were enrolled in preparatory schools. In this activity which has a historical dimension independent of the individual student, i.e. it has no definite beginning nor an end, with the ultimate motivation of survival of the society and the individual in the society (Roth & Lee, 2007), students are involved in a variety of activity systems, for instance, the school and the local community. The school rules enforce the curriculum and exams, and the textbooks are mediating artefacts. The teachers are supposed to follow the textbook strictly, and they take it to the classroom with them and give class work and home work from it. The medium of instruction is English

language which the student uses at school only. The experience of the first author indicates that whereas the students were all learning in English and interacting with each other in Amharic, they had different mother tongues. These students are living in an impoverished economic circumstances. Teachers are less paid than other professions as a result of which teaching is considered to be of less social value. On the contrary, the teacher is generally perceived as the authority when it comes to knowledge, and in Ethiopia it is popularly said, “The teacher is the father of knowledge”. The students’ perceptions are mediated by these elements. It is in such a framework that such behaviours could be interpreted (Roth & Lee, 2007).

METHOD AND METHODOLOGICAL REFLECTIONS

The study is situated in the interpretivist paradigm. The intention is to understand students’ perceptions. The research question and the theoretical framework lead to the development of a qualitative research methodology because perceptions are behaviours that “can only be understood within [their] environment, which needs to be explored and explained” (Burton, 2002, p. 8), and it allows the investigation of the situation from the perspective of the participants. It is a case study design recognising that the knowledge gained is influenced by the peculiar culture of the context. The data are collected through interview of students from one chosen school which has its own peculiar features although ‘typical’ of Ethiopian preparatory schools. Since the purpose is to see the relevance of mathematics through students’ eyes the appropriate way to do it was holding an interview because it enables one to hear their own account. Particularly focus group discussion was used where students were provided discussion points to expose their opinions, and probe with further questions to enrich the responses. This was intended to create a situation where the students feel secure among their own classmates, and probe each other as well as to engage with more informants in the time available. Classroom observation supported probing during the interviews and exposing features of the mathematics classroom. The first author had taught for more than three years in the selected school and there are former colleagues who helped the selection of students. The topics and students’ experiences might vary across gender, streams, grade levels, and achievement level. The department head selected 4 classes – 2 from social science and 2 from natural science (i.e. one from each of 11th and 12th grades) – where the mathematics teachers were homeroom teachers (the teachers having first line of responsibility for the students in a class) because they have better experience of the students and their academic standing. Then each teacher selected 3 female and 3 male students who were identified as low, medium, and high achievers. A total of 24 students were selected. Students of same sex from the same class were interviewed in the same group which was intended to create a situation where the students felt more comfortable and the relative freedom to express their ideas and probe each other. Themes emerged from the analytic process, and each theme is analysed using CHAT as a framework for identifying key features.

DATA ANALYSIS

In this section the data analysis is presented as a descriptive account of students' perceptions of relevance, under eight themes which are 'grounded' in the analysis.

Mathematics is relevant because it is used in every day activity

The students are engaged in the activity of learning mathematics and they are also participating in the day to day activities of the society. Some students perceive that mathematics is relevant to every day activity Azenegash says, "how far I am coming from home. ... Those who work in the Edir [1] should know mathematics". Her perception is mediated by the artefact (the road) and the community in the local activity. Their mathematical knowledge is valued by their community. Ruth says, "When my mother wants to calculate something she calls me to do it for her; if she was educated she could have done it herself [2]". Her perception is mediated by her role in the local activity – she is involved in the budgeting of the family's expenditure. However, Ibrahim perceives that the knowledge being used in every day activity is that which they learnt at primary school because the society is "not a developed society" but he mentions that, "the ball should be spherical so that it can roll". His perception is mediated by the local community and the cultural artefacts. On the other hand, Beza mentions an example where an outcome of the school activity was used as a tool at the workplace, "population size, proportion, death rate, average, etc. are useful in society. ... My father works for the statistics authority". Her perception is mediated by the local community, through her father. Fisiha works in a wood work shop with his brother. He says, "For example, in my job, I measure, I should read the number; in order to cut accurately you should learn number". His role in the activity of the local community mediates his perception.

Mathematics is relevant because it is used in other subjects

Some students perceive that mathematics is relevant to other subjects they are learning, Mekia says, "mathematics is useful for physics. ... In chemistry we have mathematics". Beza gives a specific example. She says, "Log, we learnt, is applied in bacterial growth; so it is used in biology". Habtu provides another example, "physics involves number e.g. vector", but he comments that "those [they] are learning now are rarely used". Their perceptions are mediated by the school curriculum. Debesh sees two distinct mathematics. He says:

There is calculation in Geography, Business; not the [subject] mathematics but the calculation in these subjects is useful. ... I think there are subjects which are related to mathematics. Those subjects have societal values. Thus, your knowledge of mathematics will help you for dealing with those subjects.

His perception is mediated by the local community and the school rules. Fikru says, "In 7th or 8th our teacher said 'mathematics is the king of all subjects'. ... it has use in chemistry; rector scale in geography; it is related with all other subjects". His

perception of relevance is mediated by the school community and rules. On the other hand, Meseret's perception of relevance is associated with her stream. She says, "We are social, we don't use much calculation... Other subjects are to be learnt by heart; I take break with mathematics". Her perception is mediated by the other subjects, the school rules and the school community.

Mathematics is relevant because it is useful in an unknown future

The students are preparing for university studies. Hence their perception of the relevance of mathematics is mediated by their future goal. Habtu says, "I want to study astronomy and my brother told me that in addition to mathematics, physics is the base". The local community mediates his perception of relevance. Yirdaw says:

What we are learning now, I don't see its application. ... But in offices I think they use it. ... We are in the process of development. It is useful for what will learn in the future, I think. So, we must learn it.

His perception is mediated by the local community as he perceives that it is being used in the work place. On the other hand, some students explain the future based on their experience of the interdependence of the current activities of learning, Abebe says:

I don't know the detail about astronomy and how much mathematical capacity it requires. Since mathematic is important in our every day activities, it would be the same at that level. I think it would be important.

Whereas Meseret considers a specific case and projects it to the future. She says, "[mathematics] is a mother tongue. ... In economics there is slope. We learnt it in 7th or 8th. We didn't know then that it has this use". Hayal who wants to study Medicine or Chemistry remarks its relation with science "Science without mathematics? I don't believe that". Whereas, Makida says, "In books we don't see where to apply [it]. [It] has relation with other subjects and we apply it on them... at tertiary level". Thus, the other subjects, the school rules and the tools at school mediate their perceptions.

Mathematics is relevant because it gives an identity

Students form their identity in relation to mathematics. Debesh wants to "study Banking and Insurance because it has mathematics" and he "like[s] mathematics ... it is not difficult for [him]". He perceives himself as someone who can do mathematics well, and this sense of identity is a motivational factor towards making a decision about what he has to study in the future. Essayas, on the other hand, perceives himself as someone who does not want to deal with mathematics; he says, "I want to study law because my brother told me that it doesn't involve mathematics ... economics, but [it] has mathematics; so I don't like". His perception of relevance is mediated by the local community, and the emotion towards mathematics. His decisions about the future are mediated by his identity and emotion. These students are learning in English which they only use at school. The students' perceptions

Working Group 10

might be related to this nature of mathematics. Debesh says, “I like all but word problems are tricky. Use difficult words ... or they are difficult to understand”. In addition to the mathematical concepts, he is facing difficulty in understanding the English words embedded in the mathematics problems. Abebe says,

I like word problems, because it involves critical thinking and analysing ... it has to be related to our society, things that we know and experience in our lives. Not in some other society; the names when related to our situation then we do it with interest. When it talks about some world we don't know – names and places we don't feel that we have any concern about it – then it is done while we didn't understand the use

His identity is a motivation to his being engaged in learning mathematics. The students' perceptions of relevance to their identity might also be understood in a dialectical relationship between the individual and the collective. Ruth says, “Most social science students don't like mathematics. Only few students work hard. Thus our teacher always advises us”. She is high achieving and in other discussions as well she refers to the whole of students and the social science when locating herself in the mathematics classroom. There could also be a shift in students' perceptions. Beza says, “When I saw that I scored B in mathematics in 10th I didn't expect and I believed that I can perform well”. Her perception changed because of her score. The school rules which insist on examination success in learning and the examination score used as a tool to evaluate learning mediated her perception. It is noted here that Beza's perception is related to her motivation to study mathematics. The student's role as a mathematics learner also mediates perception of relevance, Azenegash says:

... But now I departed from my friends. ... They are in another school [3] now. ...there were clever students [who] explain to us. We used to discuss while walking home. ...I don't score in it and when I miss something I don't get back to see it again.

The change in Azenegash's activity system had an impact in her learning of mathematics. She used to pay attention to her surroundings with respect to mathematical meaning, and relevance of mathematics she mentioned before was about distance from home to school. She had formed an identity as a member of that group which shifted when she departed. Her identity with respect to that group was a motivational factor for her engaging in mathematics, which later changed as a result of the change in her identity.

Mathematics is relevant because it empowers one to make informal decisions

Some perceive that mathematics and the other subjects are there for them to expose their talents. Erikihun says:

I want to study language or philosophy. ... I am doing well in language. ... Mathematics and most of the subjects we are learning now might not be related to what we learn in the future. But, they help us to identify/know our interest and direct us to the future. We used to learn music; it is not important but if you have the interest then you will know. Some of us may end up in a field that doesn't involve mathematics at all but others may need it.

Working Group 10

He perceives that the other subjects are competing with mathematics for students' choice or attention. Since he made other choices of social science, he perceives that he doesn't need mathematics, but learns it because others in his group need it. His perception is mediated by the other subjects, the school rules and community. We also see that his perception of relevance is a motivational factor, and negative one in relation to mathematics. Other students perceive that mathematics is there to broaden their mental capacity, Netsanet says,

In sequence, we use formulas. But before we use formulas, there are items which we do simply by observation, by looking at it attentively. That helps you to think and analyse; it broadens your mental capacity.

Her perception is mediated by the school rules. Her perception of relevance about the mathematics she is learning seems to motivate her to work on mathematics.

Mathematics is relevant because the student trusts the curriculum

There is a sense of trust in the curriculum. Asad perceives that they learn mathematics because "[they] should learn it". Ruth trusts the curriculum because "the teacher tells [them]" and her perception is mediated by the school community. Azenegash says:

[The teacher] is our eye. ... If it were not relevant we wouldn't have been taught ... my teacher was telling me, now I realized that it was right: 'when you are walking, it is the shortest distance to travel on the straight path'. He did it for himself.

The teacher is the origin of perception for trusting the curriculum, and the division of labour in the school activity also mediates her perception. She didn't see how the teacher did it and her role was to listen. She puts trust in the teacher that what is taught would have meaning in her life to come. On the other hand, Debesh says, "We don't see. But, the teacher tells us; for example, log in earthquake measuring, in chemistry, though the concepts are difficult for us". In one of my classroom observations in Debesh's class (a social science 11th grade classroom) the teacher was providing an example about earthquake and pH value in a lesson about logarithmic function. The mathematics teachers have natural science background, which might influence their practices in implementing the school curriculum and they use the same textbook for both streams, which mediates students' perceptions of relevance.

Mathematics is relevant because it has exchange value

These students are supposed to score a qualifying grade to be admitted to the university, and Ethiopia is a poor country in which success in education and securing a job relates to sustaining the life of the individual as well as parents. Beza says, "We used to hear that 10th is the turning point for life. ... [Studying] any social science would be ok [to be a hostess]. ... Mathematics is compulsory". She is sure that success in mathematics is the gate keeper to joining the university and to achieving

Working Group 10

the goal of securing a job – becoming a hostess. This perception of relevance she attaches to mathematics motivates her engaging in mathematics. The division of labour in the local community also mediates students' perceptions. For example Ruth says, "Earlier I wanted to study law but it is 5 years. [I] study economics ... then I can help my parents. ... If I don't have the basis in mathematics I can't do [economics]". Thus, she learns mathematics to sell it at the marketplace of learning economics so as to get job at the end which enables her to sustain her family and study law which she really likes to study. The division of labour – her responsibility to help her parents – mediates her perception of relevance. Her perception of relevance is a motivational factor for being engaged in mathematics. The tools in the school activity mediate Yirdaw's perception in his endeavour to become "a private accountant". He says, "Mathematics books from abroad are better at applications than domestic ones. ... I prefer the [latter] for success in exams. But, for my interest I prefer the [former]". Here we see that this perception is a development which resulted from the contradictions between the mediating artefacts and the school rules. Ahadu wants to "become a [medical] doctor", and he thinks that "whether one becomes a medical doctor or something else learning mathematics is part of the process". His perception is mediated by his future goal. Emotion also mediates students' perceptions. Alewi says, "I am not interested in it but it is required ... I liked polynomial at the beginning. ... when I scored poor at the first test, I turned my back to it again". The contradiction between her emotion – that she liked it at the beginning – and the school rule – that she should succeed in exam – led her to change her perception of relevance, and consequently, dropping it as irrelevant.

Mathematics is relevant because it gives a fresh perspective of life

Some students give spiritual meaning to the mathematical concepts they are learning. Hayal says:

I brought the idea of limit to my life and interpreted it as, there is time when life ends; all the things that bother me together with my life in this world, come to an end, and begin the new life in heaven.

She is looking at her life as function of time whose limit at a certain time gives the static life – life after death which her society believes in. Her perception is mediated by the rule in the local activity – the religious teachings. In the same interview group, another student, Makida says:

Similar to what is mentioned by Hayal, when I learnt sequence, I learnt that things are in order they don't occur/happen randomly. It is as the saying goes 'there is time set for something' [Solomon's saying from the Bible]. For example, we can't say 1 then 5; in life also we can't walk immediately after we were born; it goes in steps. Things in life are ordered or they happen sequentially. This is what we learn indirectly.

Since the school curriculum did not provide direct applications the school rule mediated these perceptions of relevance.

CONCLUSION

The participant students perceive that mathematics in general is relevant to their real life situation. But, they perceive that the mathematics dominantly in use is that which they learnt at primary school and some concepts they are learning at the current stage have got some uses in other subjects or workplaces. This relates to their access to material and technology which might involve application of higher mathematical concepts. They perceive that the mathematics they are learning has use in some unknown future which is mediated by their future goals; and others do not see any relevance to their future studies. They see it as a means of access to the university and getting a job, which relates to the economic context of Ethiopia as well as the responsibility of the students to support their family/parents. Some put trust on the curriculum and the teacher, who is thought to be a big authority. They exhibit identity related to mathematics which sometimes changes, resulting in change in motivation. At times we see the students struggling with the contradictions between the languages at home and in school (textbooks and lessons are in English which students begin to experience as of lower secondary). The students face difficulty in understanding word problems, which are the only ways practical problems are meant to be experienced by this students. In some cases the students make informal decisions about the use of mathematics. Others attach a spiritual meaning which relates to the peculiar features of Ethiopian society: the belief in life after death which is static, and use of sayings from the Holy Book. This indicates that being situated in a mathematics classroom where the textbook, and hence the lessons, rarely present practical problems (and not in their mother tongue), the students need to produce their own contexts in order to understand the mathematical concepts they are learning. It is the gate keeper to their access to the university, hence to the better life they aspire for themselves and their parents. It becomes apparent that students are under enormous pressure to succeed in mathematics. The students exhibited motivation to engage in mathematics when they perceived that it is relevant to them in some way. Addressing the question, whether there is any relationship between the different categories of students included in the sample and different characterizations of perceptions discussed above is left to the next stage of the project.

NOTES

1. EDIR is social institution in the Ethiopian culture where members gather to discuss about issues related to social problems. They contribute money every month, and on the death of a member or siblings, they arrange a mourning ceremony including the funeral which lasts for three days. Members earn money as compensation on the death of a member or siblings. It is led by an elected board members consisting of chairman and a secretary. In some cases there are EDIRs for women only.
2. It is a common phenomenon in Ethiopia that mothers didn't go to school. Some might have gone to the traditional school (called Kes Timihit literary means Priest School) where they learn the Geez alphabet (an old language now used in the Ethiopian Orthodox Church only and Amharic uses the same alphabet) and Ethiopian numerals which range from 1 to 1000 only, after 1000 it is elph (which means infinity).
3. In the Ethiopian education system students are enrolled to preparatory schools if they qualify in a national exam at the completion of 10th grade. Then, they will be assigned to the preparatory schools where they

learn for two years and take another national exam which screens those who will be eligible for university studies.

DIFFERENTIAL ACCESS TO VERTICAL DISCOURSE – MANAGING DIVERSITY IN A SECONDARY MATHEMATICS CLASSROOM

Uwe Gellert & Hauke Straehler-Pohl

Department for Educational Studies and Psychology

Freie Universität Berlin, Germany

Crucial to the reading of our paper is the assumption that students enter school with diverse experiences with language and diverse experiences with construing meanings through language. We will argue that teacher-student interaction in secondary mathematics classrooms often is realised to the effect that only for those students, who have already been introduced to the linguistic qualities of academic or institutionalised discourse, further access to it is provided in schooling. Central to our argument are the notions of vertical/horizontal discourse, of contextualised/decontextualised language and of grammatical metaphor. We discuss these concepts before illustrating their power by an analysis of a transcript on the introduction to algebra in a sixth grade mathematics classroom. The focus of the analysis is on the strategies by which the teacher manages to cope with the diversity of students' sociolinguistic orientations to meaning.

Key words: teacher-student interaction, language, vertical discourse, access, algebra

CHARACTERIZING VERTICAL DISCOURSE

As has often been said, schooling acts as a mediator of two major societal functions. Schooling provides access to particular discourses and hence to particular forms of knowledge while, at the same time, regulating this access and hence socialising its students into differing positions of power. In this context, some groups of students have been described as privileged and others as marginalised – although in many cases the marginalised build the majority. In research in mathematics education, the issue of privilege and marginalisation has been discussed in terms of social class (e.g., Cooper & Dunne, 2000), race (e.g., D. Martin, 2010), and migration (e.g., Gorgorio, Planas & Vilella, 2002). For many students, these conditions coincide and their marginalisation is exacerbated by an interaction of migration, race and social class issues. In many situations it is difficult to adequately express the complexity and diversity of marginalisation. Thus our focus is on the commonalities and, as we will argue, on the theoretical core of privilege and marginalisation: the differential access to a particularly powerful discourse – vertical discourse.

The particularities of the discourses of power to which students are differentially introduced in school have been described differently, though mostly in form of dichotomies. We will briefly reconsider the most relevant concepts for our analysis that have been constructed in Sociolinguistics and Systemic Functional Linguistics

(SFL). For further concepts of other academic disciplines, that we consider relevant, but that we are not actively applying in this paper, see Cummins (1996) and Koch and Oesterreicher (1985). All concepts taken together, serve as the theoretical grounds for the subsequent analysis of an interactional mechanism that regulates the differential access to powerful mathematics provided by instructional practice:

As a sociologist of education, Bernstein (1999) is concerned with the differences between horizontal and vertical discourse, where the concepts of discourse and knowledge are closely interrelated. Horizontal discourse “is likely to be oral, local, context dependent and specific, tacit, multi-layered, and contradictory across but not within contexts. However [...] the crucial feature is that is it [sic] segmentally organized” (p. 159). Knowledge and strategies of the horizontal discourse have the aim to maximise encounters with persons and with habitats. Vertical discourse, in contrast, “takes the form of a coherent, explicit, and systematically principled structure, hierarchically organized as in the sciences, or it takes the form of a series of specialised languages with specialised modes of interrogation and specialised criteria for the production and circulation of texts, as in the social sciences and humanities” (p. 159). The contemporary dominant ideology of the life-long learner, making use of knowledge in differing contexts, is privileging vertical forms of knowledge and hence privileging those with access to vertical discourses. But how can access to vertical discourse be provided? On what kind of students’ resources can access to vertical discourse be based? It is a core problématique of pedagogy to recontextualise horizontal discourse in school as a means to make institutional, vertical discourse more accessible for all.

Hasan (2001) draws on Bernstein’s distinction of horizontal and vertical discourse. For Hasan, horizontal and vertical discourses differ mainly in their relation to contexts. She sees the natural condition of human discourse as being contextualised language, concise a language with a close connection to the material situational setting of the interactants. Decontextualised language in contrast has a loosened or even detached connection to the material setting. However, it is decontextualised language, which is connected to positions of power: “what is remarkably pervasive today is the kind of language use that is known as context independent, disembedded or decontextualised, especially in the sorts of societies spawned by the so-called progressive Western world. [...] After all, among other things, decontextualised language is the voice par excellence of official ideology” (Hasan, 2001, pp. 48-49). The distinction between contextualised and decontextualised language is organised along the terms of actual and virtual reference. Actual references have the potential of being physically sensed by the interactants. These references may be immediate as well as displaced in time or space, however they need to be potentially sens-ible. Virtual references lack this potential. They are “non-material and removed from situational realities, they simply cannot be directly and physically experienced: they are intellig-ible, not sens-ible” (p. 54). For participation in horizontal discourses,

contextualised language may well be a totally sufficient base. However, in the vertical discourse knowledge is not structured through the sens-ible context, but through the internal logic of a specialised practice. It is obvious that this internal logic is only intelleg-ible and far beyond material situational realities. In the case of academic mathematics, it is evident, that we deal with a highly intelleg-ible discourse, far from being sens-ible. No matter how much contemporary school-mathematics is organised around sens-ible actual experiences, its end is the vertical discourse of virtual ideas: “the mastery of disembodied language will consist in feeling at home with reality that is not sensuously mediated” (p. 57). Hence, the orientation towards decontextualised language is a crucial condition for participation in the mathematics classroom.

As Bernstein and Hasan, J.R. Martin (2007) sees horizontal discourse as the original and intuitive mode of discourse. However through the perspective of SFL his concerns include the lexico-grammatical qualities of discourse, that is the make-up of utterances. He describes horizontal discourse as characterised by a harmony of the semantic and the lexico-grammatical stratum (see Fig. 1): Taking the sentence “I love my mummy and my mummy loves me.”, semantics and grammar are in complete harmony: participants (mummy, I, me) are described by (pro)nouns, processes by verbs (love(s)), and logical relations by conjunctions (and). Presumably, someone with a more elaborated use of language would rather express the same feelings in a sentence like: “My mother and I have a good relationship.” Now semantics and grammar have created a tension: the noun “relationship” is not expressing a participant, but a process (loving each other). Moreover, it gains further meaning, as through social everyday discourse different kinds of qualities implicitly got attached to it. Martin calls this tension of the semantic and lexico-grammatical stratum *grammatical metaphor*. However, although being more elaborated, the sentence quoted above remains part of horizontal discourse. Applying Hasan’s perspective, the orientation to meaning is still contextualised. As we will argue, the key to vertical discourse lies in grammatical metaphor acting on decontextualised language, or as Martin puts it, in “abstractions acting on abstracts” (p.54).

As can be seen in Figure 2, the major characteristic of grammatical metaphor is a tendency to express all kinds of semantic categories in nouns, a process Martin calls *thingification*. From a multisemiotic perspective, O’Halloran (1999, p. 382) concludes: “The analysis of mathematical pedagogical discourse indicates that nominalization and extended nominal group structures are a feature of mathematical discourse.” Martin (2007), summarising extensive research on both scientific and human-scientific texts, claims: “if no grammatical metaphor, then no verticality” (p. 54). Concerning the social ramifications of grammatical metaphor, Martin holds, “from a functional linguistic perspective, access to vertical discourse is bound up with control of grammatical metaphor, which in western societies students are expected to master in secondary school. Failure to access this recourse entails

exclusion from [academic] knowledge structures. Here lies the social semiotic nub of institutionalized learning, educational failure and the distribution of knowledge in our expiring world” (p. 55).

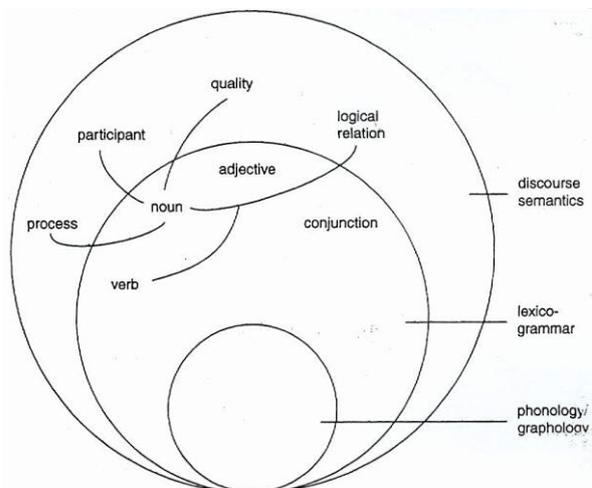

Fig. 2 Grammatical metaphor as stratal tension semantics

NEGOTIATING MEANING: A MECHANISM OF APPEASEMENT

Our issue is interaction in the mathematics classroom. We focus on the interactive mechanism by which one teacher deals with the diversity of his students in terms of their access to mathematics related vertical knowledge. As we will see, the concepts of (de)contextualised language and grammatical metaphor provide powerful tools for analysing the amplification of differential access to the vertical discourse. For a detailed description of the empirical research, see Knipping et al. (2008).

The setting is a 6th grade mathematics class in Nova Scotia, Canada. It is the very first lesson after the summer holidays, in which the teacher and the students engage in teacher-student interaction. The 6th grade is the beginning of secondary schooling in that region, thus no hierarchy of achievement has yet been established among students. It is a rural area and the social background of students is quite diverse.

Fig. 3 Mathematics task

Fig. 4 T-table at the whiteboard

The students are sitting at group tables. At home they have solved the task displayed in Fig. 3. Our analysis starts in the moment when a student is filling her solution into a T-table provided by the teacher at the whiteboard (see Fig. 4). We split the following ten minutes of classroom interaction into six episodes, which we consider as functionally distinct for the interactional mechanism. We shall demonstrate each episode and its relevance for the negotiating of meaning in that classroom.

Episode 1: Introducing the context (10:32-12:38)

In the first episode Alicia is filling the missing numbers in the T-table at the whiteboard. Her classmates are encouraged by the teacher to help her out. Regarding the use of language, the whole episode is characterised by harmony of semantic and lexical strata, hence no grammatical metaphor is employed. Further, there is an extensive presence of physical resources (e.g. the teacher invites his students to refer to the T-tables they have in their textbooks). The language is contextualised and the discourse tends to be horizontal. The function of this episode may be best described as a smooth introduction into the emerging discourse, emphasizing the affective security necessary for the students to actively participate.

Episode 2: Common negotiation of orientation (12:38 – 13:45)

10 12:38 T Is there anybody from her group, as well as Alicia, who can tell us how those numbers fit in the way they do? What did you do?

In (10) the teacher, for the first time, goes beyond discussing particular numbers and by his elicitation indicates that there is a pattern, a principle structuring the T-table. He does that by using the conjunction “how”. The semantic and grammatical strata are still in harmony, though at the same time a first insertion of decontextualised language can be observed: “How” is accompanied by a (semantic) metaphor “fit in the way they do”. Here, “Fit in” does not mean a potentially sensible way of fitting. It refers metaphorically to the above-mentioned structuring principle. However, this question is followed by an alternative one: “What did you do?” This refers back to previous actions and illustrates the ambivalence of the word “how”, as the students may either describe their experience or their reasoning. Hence, the teacher provides two different discourses within one utterance: a vertical discourse of reasoning and a horizontal discourse of experience. At this time, no preference can be observed: both discourses appear legitimate.

In the following, a dialogue evolves between the teacher and Mike. Mike seems to have identified the discourse as a discourse of reasoning and explains his considerations, using the conjunctions “because” and “so”. The teacher in reaction always links Mike’s answers back to the particular numbers on the board and hence seems anxious about keeping the discourse overt for horizontal discourse and contextualised language. In summary, this episode is characterised by its tendency to verticality through a smooth and partial introduction to decontextualised language remaining, at the same time, open for contextualised meanings. It is remarkable that

Mike is the propulsive force in the negotiation and, further, that he is the only student taking part in it.

Episode 3: Practice of a vertical discourse (13:45-14:30)

After having – under apparent leadership of Mike – negotiated the orientation towards a more decontextualised language and a more vertical discourse of reasoning, the teacher now comes to the core of vertical discourse: He introduces the term of “relationship”.

27 13:45 T I have a question. This can come, the answer may come from any group. You may look at the T-table here or you may look at the one you've created in your notebook. Can anybody figure out or tell me the relationship between the left side of this T-table and the right side of the T-table.

28 (Mike is the only student who raises his hand.)

29 14:14 T OK.

30 M The difference between the numbers, there's a difference of two on each number.

31 T A difference of two. How do you mean difference?

32 M There is, one is two higher.

33 14:28 T So in other words, this one is two higher.

By this he is making use of a grammatical metaphor. Semantically, “relationship” is not a participant. In contrast, it rather expresses qualities, a process and logical relation. Hence, there is a tension of the semantic and the grammatical stratum; qualities, process and logic relation are *thingified*. Accordingly, to successfully understand the teacher's elicitation one has to decode both grammar and context. The discourse has reached verticality in its linguistic orientation and the term “relationship” entails the mathematical core of the talk. What students can learn here is the fact that T-tables materialise relationships, as the teacher quotes later on (48, episode 6). As expressed by Martin (2007), the core of vertical discourse goes along with the use of grammatical metaphor. But again – as in episode 2 – it is only Mike who is able to recognise and realise this orientation. As by “difference” he autonomously employs a grammatical metaphor, he seems comfortable with its use. All other students remain silent, hence are not yet actively participating in the vertical discourse.

Episode 4: Re-linking to the horizontal discourse

In line 31 the teacher starts coming back to a more harmonic use of semantics and grammar. There, he is demanding to express logic relations by the use of the conjunction “how”. In line 32 and 33 Mike and the teacher are stepwise coming back to the visible and particular T-table, thus orienting towards contextualised language

and horizontal discourse. The function of this short episode may well be assumed as making the discourse more accessible to all.

Episode 5: A second try of common negotiation of orientation

35 **T** I have a question. How do you go from this number to this one? Remember you said that we added down or you folks added down. How do we get from this side if you were looking at these numbers and if you say they sort of, they sort of seem to match up in a way? How do we get from this side to this side? Karsten, can you figure it out?

In some way, this elicitation resembles utterance 10 in episode 2. The teacher is reconstituting the harmony of semantics and grammar. His tool for asking for logical relation again is the conjunction “how”. This is accompanied through processes (go, added, get, etc.) which are expressed through verbs. But as the “how” is clearly related to processes, it - this time - is not ambivalent (compare to episode 2). He is really asking for “How do you go from this number to this one?” instead of “why”. Hence the use of language is more contextualised, more bound to the experiences, the students have made in their work. However, he is not entirely coming back to a contextualised discourse, but still offering a decontextualised alternative, asking for how “they sort of seem to match up in a way”, which is equivalent to “how those numbers fit in the way they do?” (10). While marking horizontal discourse as legitimate, there remains an implicit tendency towards the vertical decontextualised discourse. But again, he is offering alternatives and accordingly giving apparent control to the students over which discourse they like to refer to. The function of this episode can be regarded as another strive for a common negotiation of orientation. However, this strive remains unsuccessful and the teacher goes on to revise his strategy.

Episode 6: Apparent unification of horizontal and vertical discourse

37 **T** Is there anybody else or is there anybody else who can see anything else here that goes from here to here as far as relationship? How do we compare this number with this number?
(*T waits two seconds.*)

Similar to Episodes 2 and 5 the teacher is offering two alternative questions differing in their degree of verticality. Apparently, the teacher still follows his strategy of negotiation. However, a more detailed look at the first and more vertical of the two questions indicates a modification of the strategy. He is firstly asking for a process expressed in a verb (goes) and then links it in some unhandy way to the grammatical metaphor of relationship. The use of “as far as” implies that there is something beyond the demanded process which is not expressible in a way that students can access. The difference to line (10) and (35) is in the direction towards which the discourse is oriented. While in line (10) and (35) the aim could be expressed as

drilling the seeds for the orientation towards the decontextualised vertical discourse, the aim now is to re-establish the students' feeling of comfort, neglecting the relevance of participating in vertical discourse. The following four and a half minutes of the discussion confirm this view. The teacher is limiting teacher-student-interaction on arithmetical questions as:

53 **T** Wayne, are you with us son? What's ten minus two buddy?

54 **W** Eight.

The focus is on the affective outputs of the discussion rather than on the content. There are several examples of the teacher's strategy of re-establishing the students' comfort in the discussion. An analysis of one of these examples may provide a good insight in the function of this strategy.

48 **T** Because guess what, a lot of T-tables work in a pattern something like this where you can fill in a little tiny equation. If you understand that with this one you'll understand most of what happens in most of the rest of the T-tables. See this little equation here? It gets a little bit harder but they work basically the same way.

The teacher highlights the exemplarity of the T-table and outlines the relevance of the discussion in the vertical discourse. In addition with his behaviour of eliciting simple arithmetic results and positively evaluating the answers, he is establishing a straight logical chain from filling out spaces in this particular T-table to understanding algebraic structures in T-tables in general, that is, a (false) progression in verticality: If you are able to answer "ten minus two buddy?", then you "understand that with this one" and "you'll understand most of what happens in most of the rest of the T-tables." His use of the notion "little tiny equation" is illustrative for this strategy of appeasement: Through the qualities of "little" and "tiny" the term "equation" shall lose the scare of an academic grammatical metaphor.

50 **T** Now all of a sudden you are into real simple arithmetic. You did this ages ago so guess what? We made the math look a little bit hard, now we're trying to make it look easy.

Of course, the teacher does not have the power to tear down the boundaries between horizontal and vertical discourse. Arithmetic serves as a tool in algebra, but factually it will remain a different discourse. Hence, the teacher is only able to mask the boundaries and consequently to render them invisible for the students.

DISCUSSION

The analysis illustrates how our chosen theoretical framework allowed us to identify an interactional mechanism, which bares the potential of amplifying the students diversity resulting from their differential linguistic socialisation in early childhood and

Working Group 10

primary school. Bernstein, Hasan and Martin all make us aware that this differential socialisation is closely connected to the issue of privilege and marginalisation. The ongoing research indicates that the mechanism observed is not a singular phenomenon.

The interactive mechanism the teacher is using to negotiate mathematical meaning on two different discursive levels effects a differential provision of access to valued forms of mathematical knowledge. As Martin (2007) and O'Halloran (1999) have argued, without grammatical metaphor and decontextualised language there is no vertical school mathematics discourse. Those students who are already prepared for decoding and using grammatical metaphor experience opportunities to further access the legitimate discourse of secondary school mathematics. Those who are only used to horizontal discourse are not challenged by new forms of knowledge. There is no attempt to make the different orientations to meaning visible. Instead of generating linguistic conflicts, the teacher establishes horizontal discourse as legitimate and blurs the boundaries between horizontal and vertical discourse. Hence, the teacher appeases rather than challenges those students who most need an explicit introduction into vertical discourse.

Atweh, Bleicher and Cooper (1998) report on the differences of register of two mathematics teachers working in schools with disparate student population. Where students are expected to aspire future university studies the teacher challenges them constantly with decontextualised language. In contrast, in a working class suburb the focus of the mathematics teaching was to develop skills useful in a consumer society, resulting in a more intuitive and less systematic use of language. Here again, we see how the teacher's perception of low educational ambitions and aspirations limits the students' access to valued forms of mathematical knowledge.

However, these teachers work with either positively pre-selected or socially marginalised groups of students. Their discursive practices are characterised by a high degree of internal consistency: either aiming at vertical *or* at horizontal discourse. The interactive mechanism of negotiating meaning on two different discursive levels *within one classroom* seems to be particularly important in unstreamed and inclusive school systems as student heterogeneity with respect to orientation to meaning is greater. In inclusive school systems, all students *potentially* access vertical discourse. In our illustrative case, however, interactional mechanisms translate student diversity into disparities of achievement. *Actually*, through appeasement, the characteristics of vertical discourse remain masked for the non-privileged.

MATHEMATICS TEACHERS' SOCIAL REPRESENTATIONS AND IDENTITIES MADE AVAILABLE TO IMMIGRANT STUDENTS⁴⁷

Núria Gorgorió & Montserrat Prat⁴⁸

Universitat Autònoma de Barcelona, Catalonia (Spain)

Immigrant students in mainstream schools join in social practices that are already structured by social representations. Representations have a crucial impact on how immigrant schoolchildren construct their learning experiences and the ways in which they make sense of themselves as learners. Immigrant students' transition processes are co-constructed with other social actors. In the school context, the teacher is a key person in helping them on creating new meanings, constructing new knowledge and establishing new relationships. Mathematics teachers' social representations, however consciously or not, mediate not only the actual content immigrant students may learn but also the identities they develop.

Keywords: immigrant students, transitions, mathematical identities, social representations

IMMIGRANT STUDENTS CONSTRUCTING MATHEMATICAL IDENTITIES

Immigrant students' learning mathematics as a transition process

Immigrant students' processes of learning mathematics in mainstream schools may be understood as transition processes. Being an immigrant student in a "foreign" mathematics classroom implies a new context of mathematical practice, different relationships with people and knowledge, and different understandings of the actions and interactions that take place.

According to Zittoun (2007), transitions involve changes in the social, material or symbolic spheres of experience of the person and imply processes of relocation in all of them. These changes in position convey new expectations and new possibilities but also constraints on action and losses. Transitions also imply reconstruction of identities and require new forms of knowledge and skills and bring the need to engage in meaning-making to confer sense to what happens to the person. Zittoun establishes that 'in youth, learning difficulties are often linked to the fact that the person feels his/her identity put at stake or cannot find a personal sense in the learning situation' (op. cit., p. 196).

⁴⁷ The research presented here has been partially supported by a private foundation –Fundació LaCaixa & ACUP (RecerCaixa 2010) – and the Spanish Science and Innovation Ministry of (DGI-EDU2010-15373)

⁴⁸ Both authors are members of the EMiCS group –Mathematics Education in its Sociocultural Contexts–(2009 SGR 00590) granted by the Direcció General de Recerca of the Catalan Government.

We argue that transition processes require transactions of meaning between people and across contexts and are therefore limited and shaped by social representations about the role and achievements of the person as part of a group to which s/he belongs or identifies with. Transition processes are co-constructed with other social actors. In the classroom the teacher is a key person in establishing new meanings and constructing new knowledge, but also in making available to his or her students certain mathematical identities.

Transitions originate in changing contexts of social practice, changes in persons, or changes in the relations between persons and objects (Zittoun, 2007). Transitions require processes of adjustment to new life circumstances and involve multiple changes in frames of reference and meanings, and in relations with people. These changes require people to modify routines and interpretations, explore new possibilities, and develop new ways of acting and interacting. Social representations, as a means of constructing reality, have a special impact on the transition processes of immigrant students, in particular on their processes of learning mathematics and the construction of mathematical identities.

Mathematical identity

The limited extension of this paper does not even allow for a short account of the work done in mathematics education in relationship to mathematical identity. For an initial definition, we want to note that Martin (2007) establishes that mathematics identity (as he calls it) encompasses the dispositions and deeply held beliefs that individuals develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics to change the conditions of their lives. A mathematics identity involves a person's self understandings as well as how s/he is constructed by others in the context of doing mathematics. Therefore, a mathematics identity is expressed in narrative form as a negotiated self, a negotiation between our own assertions and the external ascriptions of others. Mathematical identities are always under construction.

For the purposes of this paper, by the students' "mathematical identity" we mean the academic identity that they develop as mathematics learners and users. Mathematical identities include how students view their own aptitude for mathematics and how they see themselves as users of mathematical knowledge both in school and beyond. Students develop their mathematical identity through their participation in mathematical activities, their interpretation of their own classroom experience, their expectations about future (mathematics) education and about their uses of mathematics both in school and outside. Students' mathematical identities are dynamic rather than static, and are bound up in other social or cultural identities they may develop.

Mathematics lessons are patterned activities organized with reference both to social norms and values and to mathematical concepts and rules. Therefore, students'

mathematical identities also include their sense of affiliation with the mathematical practices in their particular classroom and their identification with the norms and values regulating it. The development of mathematical identities is shaped by students' social positions in the mathematics classroom, their construction of mathematical knowledge, and how students understand their experiences as mathematics learners.

Students' mathematical identities are constantly being reconstructed in relation to students' perceptions of themselves as mathematics learners and how they are seen by significant others involved in mathematical activities. How students see themselves as mathematics learners, however, is as important as how they are defined by others, especially their mathematics teachers.

Cobb and Hodge (2002) established that the gatekeeping role that mathematics plays in students' access to educational opportunities includes the difficulties that students experience in reconciling their views of themselves and who they want to become with the identities that they are invited to construct in the mathematics classroom.

Identities in transitions

Immigrant students' transitions have the potential to change the ways in which they interpret themselves and their roles both in school and outside. The ways in which they experience and have experienced their learning of mathematics in the different contexts and how they interpret these experiences impact on their practices and in the identities they develop. The identities they develop as mathematics learners have also to do with their sense of affiliation with the mathematical practices in the classroom they attend, their identification with the norms and values regulating it and their possibilities to participate in the mathematical practices.

According to Abreu and Cline (2003) there are three complementary processes of identity development: a) identifying the other – how the individual understands the social identities of “others” that are dominant in the context of specific practices; b) being identified – how the individual understands the identity extended to them by “others”; and c) self-identification – how the individual internalizes and takes positionings in relation to identities that had previously existed in the social sphere. These three complementary processes are not fixed but evolve through the interaction between the person and the sociocultural world. Identities are constantly reconstructed by engaging in a practice and belonging to a group, but also by wanting to engage in real or imagined practices and belong to real or imagined worlds.

Crafter and Abreu (2010) reveal how processes of self-identification, identification of others, and identification by other significant people play a crucial role in transitions and that such processes are linked with social representations. Self-identification coexists with identification extended by others and one process is a reaction to the other. “Being identified” is a process whereby individuals understand

the identity extended to them by others. According to these authors, it is not uncommon that “others”’ identification of oneself is based on dominant representations, which can be seen as part of the social context of practices.

Our focus is on immigrant students’ identity development in relationship with school mathematics. We are interested in identities associated with learning mathematics as part of a transition process and on how this development is influenced by social representations of immigrant children as mathematics learners held by their mathematics teachers.

IDENTITIES MADE AVAILABLE TO IMMIGRANT STUDENTS

Social representations and identity construction

The purpose of Moscovici’s theory of social representation is to explain a process whereby individuals and groups can manage to construct a stable and predictable world out of the diversity of persons, attitudes and social phenomena (Moscovici, 1984). This diversity is organized through social representations that carry previously constructed meanings concerning the past, and make these meanings available for new applications.

Social representation theory offers a way of understanding the social construction of reality that takes into account both the cognitive and the social dimensions of this construction (Ibáñez Gracia, 1988). Identifying the representations surrounding social phenomena is an approach that allows us to understand how persons both construct and are constructed by social reality through processes of communication and interaction. Social representation theory is particularly useful for understanding phenomena related to the teaching and learning of mathematics in classrooms in which immigrant pupils are present (Abreu & Elbers, 2005; Gorgorió & Abreu, 2009).

Among the functions of social representations Abric (1994) includes the following: a) knowledge of reality through an integration of information into a common frame of reference that is consistent in the values, social norms and practices of the group; b) definition of identity and group belonging, and identification and positioning in relation to other groups; c) guidance for forms of action and social practices through definition of the purpose of a given situation, production of expectations and anticipations, and definition of what is normative and counter-normative; and d) justification of opinions and actions in regard to people and objects and, on a more general level, the maintenance of social differentiation.

The learner in transition belongs at the same time to different groups and participates in different practices. As in Duveen (2001), in the account of identity development we consider a fundamental idea that the individual in transition enters a social practice that is already structured by social representations of the specific community. In particular, teachers’ representations about immigrant children as

mathematics learners will result in actions, discourses, and relationships that make available certain identities to immigrant students. This occurs in a context, the school, where power is not homogeneously distributed.

However, identities are not only constituted by labels that people place on themselves and others. Identity is about how people become who they are and how they come to understand themselves (Urrieta, 2007). It is about how they come to figure who they are, through the worlds they participate in and through how they relate to others within and outside these worlds.

In the following two sections, we illustrate how mathematics teachers, however consciously or not, make available certain mathematical identities to their immigrant students through the actual practices they promote in their classrooms. Through the opportunities they offer to their students, teachers contribute to shaping how immigrant students become who they are as mathematics learners, and how they come to make sense of themselves. For that purpose, we will draw selectively from two different ongoing studies.

Marta and Ronnie

Marta and Ronnie provide us with our first example. Ronnie is one of the participants in an ongoing study aimed at understanding the transition processes of immigrant students learning mathematics in Catalan schools (see Costanzi, Gorgorió, & Prat, in press, for more details). To date we have interviewed 33 Ecuadorian students in compulsory secondary school. In one of these schools, we have worked with 15 boys and girls, Ronnie among them. We have also worked with their mathematics teachers, and we have recorded several interviews with Marta, Ronnie's teacher.

Marta's representations about mathematics being a universal school subject and learning depending solely on cognitive abilities, led her to attribute to her students low achiever identities. During the different interviews, she told us repeatedly that she did not consider her students' place of origin to be relevant information for her teaching of mathematics. In fact, one third of the students in her class were immigrant, and she could not tell us how many of them were from Ecuador. She insisted that to her all students are equal. However, when asked, it was clear that she had a prevailing view of students from Ecuador as "working below grade level", a fact that had important consequences for her immigrant students' chances to participate in mathematics tasks with a high level of requirement.

Marta: There's no room for activities that are challenging, mathematically speaking. They're too weak; we can only do exercises if our goal is to get the students to pass. We can't do problems.

In fact, during classroom observations, we never saw any problem solving situation, and during the interviews, her students confirmed this absence.

Working Group 10

However, Marta's students told us that she was a good and caring teacher. Ronnie is one of them. At age 16, Ronnie was in the third year of the four years of compulsory secondary education, one year behind where he should be. He told us that "*when I got here I couldn't talk*", by which we understand that he means he could not speak Catalan, the language of instruction in Catalonia. He also told us that "*since I was not up to grade level in mathematics because I came from Ecuador I was placed in a class a year behind*" where he should have been according to his age.

Now, he speaks Catalan well and says that he wants to go to university, although he understands that it will require hard work. Despite this, although he still has one more year of compulsory education and two of baccalaureate to complete, he also believes that he will not have access to the university system because of his being weak at mathematics.

Ronnie: since I'm not good enough at math, I won't be able to pass the entrance exam to go to university.

Ronnie is one of the cases that show how a student has limited possibilities as a mathematics learner because of what is offered to him as school mathematics. It also illustrates that he has accepted the identities made available to him, to the point that his narrative could be that of his mathematics teacher instead of that of a student who wants to succeed.

Carles' and his students

The other example, that of Carles' lessons, comes from Prat (2009). Carles is the mathematics teacher of a group in the second year of compulsory education, with students aged around 13. We have observed the development of the mathematics lessons during several weeks and interviewed the teacher, and the students have answered an open questionnaire about the social organization of the mathematics lessons.

During our first meeting, when Carles was asked about his students in class in order to organize the viedorecording of the lessons, he referred to those having learning difficulties or attitudinal problems. He only talked about the good ones if they had a behaviour that made them "*too obvious*". When asked about the three immigrant students in his class, he told us:

Carles: (...) the three of them follow the lessons with no problem, they are good students. Other years, I've had some immigrant students that were not so ...

From all the conversations we have had with him, it seems clear to us that he is ready to give opportunities to all his students, regardless of their place of birth. He commits to complete the prescribed curriculum each year and scaffolding learning is to him the basic strategy of mathematics teaching. From the very first interview he expresses that to him the person is more important than the mathematics content he is teaching.

Working Group 10

Carles: When we teach, we are facing people that have to learn something, each one with their own ways of being and doing, (...) the basic issue is that they are human beings. (...) the most important thing is to educate them, even before teaching them mathematics.

Next, we want to share with the reader some moments in Carles' lessons. We want to insist that, once again, our interpretation is based not only on the short vignettes that we are presenting now, but on a whole process of analysis of an ample set of data.

In one of the sessions we observed, Carles' students were solving problems. The students were facing the blackboard and the teacher was the one leading the task. They were solving the following problem:

In a rectangle, the length is 3cm longer than the height. The area is 80cm^2 . Determine its dimensions.

Carles: (to all the students) What's the area in a rectangle?

10 (JR): (not asked individually) Length times height

Carles: (to 10(JR)) Before answering, you have to be asked.

We want to note that Carles had described 10(JR) as "*a bright student that likes to be paid attention too much*".

Later on, when using the formulae to solve the problem, 10(JR) prompts, without being asked:

10(JR): when one of the solutions is negative, we cannot use it as a solution, since lengths cannot be negative.

Nobody is paying attention to 10(JR) except the teacher that tells him that his thinking is correct. Then, the teacher explains it to the rest of the group. As observers, we noticed that the time for the lesson was running short, and Carles wanted a right answer to finish the problem before all left.

In fact, we observed a repeated pattern in the interaction between Carles and 10(JR). When the teacher wanted an efficient answer, he would ask him or allow him to prompt his answer. However, he would not accept his non-invited contributions, even when they were right and useful, unless he was short of time. It was like on the one hand, he wanted to teach him that there were norms on how to contribute. However, on the other hand, by asking him when efficiency was needed, he was pointing him out as an able student.

From the interaction with another student we recorded the following:

Carles: (to all the students) It's always important to clearly establish the "x". If you know what "x" means here, raise your hands.

Working Group 10

Carles: (several hands are raised) 16(DM), tell us.

16(DM): the length.

Carles had described 16(DM) as a student whose “*attitude... well, it has to improve, right? But, well, he is starting.*” From classroom observation and our conversations with the teacher, we understand that the teacher’s intention was to have the student involved in the lessons’ development. However, the pattern we observed was that he only asked him simple questions, like the one above. This was pointing the student out as one that was less able than average and that could only be asked about simple facts. This is especially obvious in the vignette, when he pretends the question to be an important one.

Later on, during the same lesson, he gave them a list of equations to be solved. He told them that if anyone has a doubt s/he had “*to stand up and come to ask me*”. Once they were finished, and before correcting them, he gave them the solutions of the equations and asked “*who got all the answers right? Raise your hands!*” In other occasions he asked them to raise their hands when they had the exercise or the problem wrong. This was a pattern that repeated itself throughout the time, to the point that the students described it as a natural part of the lesson.

According to his explanations about how he organized the lessons, the teacher’s intention was to follow both each student individually and the whole group. However, requiring them to go and ask him when they had any doubt or raise their hands whether they have the answers right or wrong, was also a way to distinguish those who do well from those that do not.

DISCUSSION

Immigrant students’ transitions imply processes of identity reconstruction that could afford as well as constrain. How students see themselves as mathematics learners is as important as how they are defined by others, especially their mathematics teachers. Grades are an obvious mechanism through which students come to figure out how good they are thought to be at mathematics. Explicit praise or criticism is also a way to let students know whether they are doing what they are expected and how much they are expected to do. However, there are more subtle ways through which teachers extend identities to their students.

In Ronnie’ and Marta’s case, we have seen how identities were made available to students, as a group, through everyday classroom practices, by leading them to construct a very restricted kind of mathematical knowledge, a fact that suggested constraints in their possibilities for their academic future. How could they become good at mathematics, or how could they think they were, or would be good, at school mathematics if they were offered no mathematical challenge? Marta, with an honest intention to make them feel that they succeeded at the tasks she offered them, she

Working Group 10

only proposed routine exercises, reinforcing her *a priori* image of them as low achievers.

Through Carles' case, we have seen how identities were extended to individual students, individually, through an honest effort to follow each student's progress. We have seen how, in everyday classroom practices, the way the teacher orchestrated participation in the classroom, and his pursuit of scaffolding learning provided evidence to all of who needed help and who succeeded without it. This way, in the actual developing of classroom practice, students could make sense of themselves as good or bad in mathematics.

Our work is still a work in progress. In this paper, we have neither discussed how acceptance or rejection of the attributed identities take place, nor how students position themselves in relationship to normative identities in class. There are many other questions still open, such as what is the role played by agency and power in the realisation or contestation of social representations, or how students negotiate with themselves and others the different identities they construct through their participation in different practices.

We have illustrated how social representations play a role in the attribution of identities through the mathematical tasks that the students are offered to participate in, and through the interactions that take place between teacher and students. It could be asked whether there is a way for teachers not to attribute identities to their students. We are convinced that the answer to this question is no. In the same way that we all have representations of the world around us, when relating to others we all identify them, while being identified by them and take positions in relationship to them.

At the beginning of the paper, we said that we would present our argument to show how mathematics teachers' social representations, *however consciously or not*, mediate what the students learn and the identities they develop. The crucial issue here is the awareness of this mediation. As mathematics teachers it is our responsibility to engage in reflexive practices to critically examine our social representations and how they impact on the identities we make available to our students.

SOCIAL FUNCTIONS OF SCHOOL MATHEMATICS

David Kollosche

Universität Potsdam, Germany

In this essay, I explore the question which social functions school mathematics might hold. After presenting a criticism of prescriptive functions, the function of imparting mathematical knowledge and its boundaries are presented. A discussion of logic thinking, of alienation in modern societies, and of the functions of school mathematics in technocratic societies in general is presented that broadens the understanding of which social functions school mathematics might hold, leaving many open questions to explore.

RAISING THE QUESTION

Mathematics education is compulsory for all children in modern societies. What should be learnt and why it should be learnt are central questions of mathematics education research worldwide. Answers to these questions may vary in many aspects, but most mathematics education researchers agree on one point: routine calculations are over-represented and mathematics lessons should be more mind-challenging. Depending on perspective, »mind-challenging« may include focusing on creativity, problem solving, proofs and argumentations, applications and modelling, historical and social issues of mathematics, and so on; but, no matter the perspective, most suggest alternatives to routine calculations.⁴⁹

The questions *why to teach* and *what to teach* are explicitly addressed throughout the mathematics education literature and in national standards documents. Heinrich Winter's (1995) essay "Mathematikunterricht und Allgemeinbildung"⁵⁰ and Hans-Werner Heymann's thesis (1996) *Allgemeinbildung und Mathematik*⁵¹ are the most popular German examples of the first; the *Principles and Standards for School Mathematics* (2000) – published by the National Council of Teachers of Mathematics in the USA – and the *Bildungsstandards im Fach Mathematik* (2004) –

⁴⁹ This paper will not discuss the corresponding concepts and show in what way they criticise too much routine calculations. For the purpose of this paper, it suffices to see that mathematics lessons comprehend routine calculations and that alternative concepts, in advocating different activities, are therefore directed against routine calculations. However, this is not to mean that mathematic educators or even mathematic teachers condemn routine calculations altogether.

⁵⁰ *Allgemeinbildung*, literally translated meaning *general education*, is a highly influential concept in German pedagogy without any conceptual equivalent in the English speaking world.

⁵¹ Available to English readers as Heymann (2003) *Why Teach Mathematics? A Focus on General Education*.

published by the German Standing Conference of the Ministers of Education and Cultural Affairs and influenced by Heymann's work – are exemplars of the later.

Addressing what should be done implies that what is being done is not satisfactory. Winter and Heymann certainly belong to those who criticise too much calculating. But while the prescriptive concepts of Winter and Heymann suggest what should be done, they are unable to explain what is being done. Therefore, I ask: Is there any sense in having children master the masses of routine calculations, which we – the community of mathematics education researchers – might regard as being over-represented? Are there any reasons for the contemporary state of school mathematics? Can these explain why the abovementioned »mind-challenging« alternatives are not implemented on a large scale? And would not the answers to these questions strongly influence our ideas of what school mathematics should be like?

Pointing to tradition does not help here. Tradition may show us how the situation came to be, but it does not explain why some things changed while others have not. Therefore, I propose to address the issue in a broader context. Identifying school mathematics as an organ in our interacting, organic society, I raise the question: What are the social functions of school mathematics?

DISCUSSING NAÏVE ANSWERS

Curricular research offers a division between *material education*, i. e. mainly imparting knowledge, on the one hand and *formal education* on the other hand. My thesis is that the role of imparting mathematical knowledge is over-estimated and that further functions must be analysed to develop a comprehensive understanding of school mathematics.

A first approach to these functions might be a sceptical discussion of the concept of *competences* which curricular standards often use. These competences may already point to social functions of school mathematics, but starting with them creates problems. First, it is yet unclear how (or if) the demanded competences are indeed learned by children – especially when curricular concepts are used as tools for curricular reforms as is the case in the *Bildungsstandards im Fach Mathematik* –, and how (or if) these competences are indeed used outside school. Second, the focus on these competences might mask other functions of school mathematics that could be more central. Therefore, I suggest a different approach: After a discussion of the boundaries of imparting mathematical knowledge, I will elaborate on insightful connections between mathematical education on the one hand and Aristotelian logic, alienation and technocracy on the other hand. These are the points my studies concentrated on so far. In each case we can ask: What is the social impact of these and how does mathematical education contribute to them?

MATHEMATICAL KNOWLEDGE AND ITS BOUNDARIES

A function of school mathematics could be to have children impart certain mathematical knowledge in order to master certain situations that arise in society. Central questions are: What are these situations? What knowledge suits them? Is this knowledge indeed acquired in school?

A first set of situations that can be mastered mathematically is located in *private life*. Popular examples are cooking, shopping and trading, investments, or painting walls. A second set could consist of situations from *work life* that are not mathematics-intensive. Assuming that the mathematical knowledge required to master these situations is acquired in school mathematics, we nevertheless have to admit that the better part of school mathematics used in these situations has been taught after 7 or 8 years of school. For most people, quadratic, exponential, and trigonometric functions are not tools needed in mastering everyday situations in private or work life; neither are linear equation systems, calculus, conditional probability, and so forth. Heymann (2003, p. 104) argues:

In their private and professional everyday lives, adults who are not involved in mathematics-intensive careers make use of relatively little mathematics. Everything beyond the content of what is normally taught up to 7th grade (computing percentages, computing interest rates, rule of three) is practically insignificant in later life.⁵²

After comparing several studies exploring the uses of mathematics in private and work life, Heymann outlines the mathematical concepts that are frequently used (2003, pp. 88-89):

Arithmetic: counting; mastery of basic arithmetical operations ('in one's head' or with paper and pencil, depending on the complexity); calculating with quantities, knowledge of the most important units of measurement, making simple measurements (primarily of time and distance); calculating fractions with simple denominators in unambiguous contexts; calculating decimal fractions; computing averages (arithmetic mean); computing percentages; computing interest rates; using the rule of three; completing arithmetical operations with a pocket calculator; basic skills in estimating and making rough calculations.

Geometry: familiarity with elementary regular figures (circle, rectangle, square, etc.) and objects, as well as with elementary geometrical relationships and properties (perpendicularity, parallelism); ability to interpret and draw simple graphic representations of quantities and their relationships (charts, diagrams, maps) and the relationships between given points using Cartesian coordinate systems.

⁵² Heymann's thesis was followed by a vivid public discussion when the German red-top newspaper *Bild* (1995), disregarding the context of Heymann's work, printing the title »Professor: Too Much Maths is Nonsense« and stated, that »The mathematics adults need has been learned after 7 years of school.«

Working Group 10

Mathematics certainly *is* used to master situations in private and work life, and this mathematics *is* being taught in school. Here, I must make two points, however. First, only until the seventh year of school, imparting mathematical knowledge can be regarded as a social function for people in non-mathematical jobs. Second, it is yet unclear whether the mathematical knowledge used in private and work life is indeed learned in school.

It is at least doubtful whether the mathematical knowledge used in private and work life is indeed learned in school. In her influential publication *Cognition in practice*, Jean Lave (1988) presents studies of the everyday use of mathematics in private and work life conducted in Liberia and the USA. She doubts whether »schooling is a font of transferable abilities« (p. xiii) and develops her thesis that mathematical knowledge needed to master situations in private and work life is learned »in practice« rather than in school. More recent studies, for example studies on the numeracy of nurses in the UK (see Coben, 2010, p. 14), support Lave's thesis. Heymann shares this view (2003, p. 98):

A number of factors indicate that specific vocational mathematical qualifications tend to be learned more implicitly on the job and that thus the persons involved often remain unaware of them.

The thoughts presented above leave only a relatively small group of people engaged in mathematics-intensive professions, for whom higher mathematical qualification in school might be useful. Interpreted from a social perspective, it is possible that a function of school mathematics is to prepare as many children as possible for mathematics-intensive professions. It then would be reasonable to teach all children mathematics beyond their seventh year of school, attempting to maximise the number of children entering mathematics-intensive professions.

ENCULTURATION BEYOND KNOWLEDGE

Imparting mathematical knowledge is not as dominant a social function of school mathematics as might be expected. A critical examination of the sets of competences that curricular standards want children to learn in school mathematics suggests that competences such as »solving problems«, »modelling«, »using formal aspects of mathematics« or even »thinking logically« point at the nature of our engagement with the world, of our thinking. Our worldviews and the nature of our thinking depend on the society (or culture) in which we learned thinking and perceiving the world. This learning process can be called *enculturation*⁵³.

⁵³ »Enculturation« as a terminology, derives from cultural studies. Sociologists prefer to speak about »socialisation« while educators often prefer »education«, although the latter has a strong intentional meaning.

Working Group 10

Imparting mathematical knowledge is a part of enculturation, as it enables and encourages people to perceive and approach the world in a certain way, namely mathematically. Unfortunately, there is little literature on enculturation in school mathematics, though the work of, e.g., Roland Fischer, Alan Bishop and Ole Skovsmose is well acknowledged. However, Fischer's work (e. g. 2006) is very fragmentary and does not draw a comprehensive picture. Bishop's (1988) chapters on the »Values of Mathematical Culture« and on »Mathematical Culture and the Child« are highly important for my issue, but I do not want to discuss them in this paper. Skovsmose's work (2005) raises inspiring questions about the social functions of school mathematics, but he does not come to convincing answers.

Further related work are the analyses (and criticism) of »rationalism« and the role of mathematics in modern society in the work of Max Weber (1921/2008), as well as Max Horkheimer and Theodor W. Adorno (1944/1997), the sociologic analysis of mathematicians in practice by Bettina Heintz (2000) and the critical study concerning the legitimacy of modern mathematics by Philipp Ullmann (2008). Horkheimer and Adorno analyse and criticise how the ideas of Enlightenment shape our thinking and organise our society. Ullmann's work is strongly based on that of Horkheimer and Adorno but lays more emphasis on mathematics and its applications in society. Heintz' studies come to the conclusion that the modern mathematician is characterised by his will to avoid contradictions and that he therefore chooses a method that is intended to avoid contradictions, namely the logical proof. However, her work hardly draws attention to the social and educational implications of her results.

I do not want to discuss or present this literature in any more detail. Instead, I present my current, ever-evolving thinking of further social functions of school mathematics.

HIERARCHY AND LOGIC

The first thought I offer reaches back into the depths of history on human culture, specifically, to the development of hierarchical thinking. Roland Fischer (2006, pp. 133–141), building on the work of the Austrian philosopher Gerhard Schwarz (2007), describes *hierarchy* as a certain system of relationships between people of a certain community. In the history of human culture, the genesis of hierarchies can be observed wherever a community transitioned from a nomadic "tribe" to a fixed "state". The organising principle for tribes was based on kinship, setting a limit to the growth of a community. So, on the one hand, social growth and the development of states were only possible where hierarchies were established. On the other hand, the idea of organising communities hierarchically could only spread because the developing state communities were successful.

Working Group 10

Living in a society that is ordered hierarchically is a powerful everyday experience: People learn that for every (but some) person(s) there is a person who decides what to do and what not to do; that actions are either allowed or forbidden; and that everyone is held responsible for his obedience or disobedience, neglecting the situation that led to her or his actions.

Living in such a society leaves its marks not only on the principles of our everyday actions but also on the principles of our everyday thinking. The idea of hierarchy became an element of thinking, of perceiving the world. For example, today we consider it normal to think of a husky as a dog, of a dog as a mammal, and so on. In fact, the biological classification is totally hierarchical.

In ancient Greece, scholars became aware of the principles of the thinking invoked by hierarchies. The *logic* of Aristotle is a description and analysis of this *logical thinking*. He postulates, for example, that every statement is either *true* or *false*. This may mean: allowed or forbidden in thinking. Furthermore, for every (but some) statement(s) we have statements on the basis of which we can decide whether the first statement is true or false. Eventually, the truth or falsity of a statement depends on the system of logic only, neglecting any (e. g. everyday life) connotations the statement may have.

While logic thinking was already a topic of ancient Greece philosophy, it was not until the beginning of modernity that logical thinking became conventionalised as the only “right” thinking with mathematics as its purest manifestation. René Descartes, the French mathematician and philosopher, may be considered the founder of this modern rationalism. In his *Rules for the direction of the mind*, he states, that »arithmetic and geometry alone are free of any error of falsity or uncertainty«⁵⁴ (1629/1959, pp. 8–9) and

that those who seek the right way to truth must not engage with any matter that does not allow them to obtain a certainty comparable to that of arithmetic and geometric proofs.

This kind of thinking features a worldview that relies on antagonisms, causalities, and pre-determined, static concepts. It has certainly helped mankind to increase its understanding and possibilities of handling the world, but at the same time, it has shaped our thinking and perceiving the world in a certain way, leaving black spots and possibly discrediting those who think differently.

Logical thinking is not without alternative; it is not the only way of making sense. This alternative becomes clear when we look at non-Western societies (see Bishop 1988 for examples) or acknowledge that people had indeed thought in tribal communities before hierarchies and logic thinking evolved. The relentless division

⁵⁴ Translated into English from the German translation of the Latin original *Regulae ad directionem ingenii* from 1629 by D. K.

into true or false has even been criticised from within mathematics. For instance, at the beginning of the twentieth century, the Dutch mathematician L. E. J. Brouwer (1918) began to create mathematics without the assumption that every statement must be either true or false.⁵⁵

Connecting my aforementioned (somewhat oversimplified) analysis of logic to school mathematics, we might ask: Is logical thinking represented here, *more* than in any other school subjects, maybe even *only* here? Does school mathematics prepare children to think and act in a logically thinking and acting society? Extending the connection more critically, we might ask: What worldview do we create by teaching the dominance of logical thinking? And eventually, what does it mean for children who develop alternatives to “our” logic?

MODERNITY AND ALIENATION

At the verge to modernity, industrialisation made everyday life change dramatically. The medieval man (or woman) was a peasant or a craftsman, subsisting on what he produced. Although committed to kin, church, and state, he was the sovereign of his everyday life, making nearly every decision, especially the economic ones, on his own. This personal freedom was lost when more and more people began working in factories, where they had to perform prescribed repetitious work at a prescribed time of the day without causing any problems that might interfere with the production of the factory.

But it would be short sighted to assign the qualities of obedience, punctuality, and reliability in doing repetitious work to the factory worker of early industrialism alone. Contemporary work life requires the same qualities, and the modern employee must be enculturated to think, feel and act accordingly. The essence of this performance, which can be named *alienation*⁵⁶, is that a person must not act according to his actual feelings and wishes. Alienation is necessary for cooperative work where the work of many depends on the cooperation and reliability of the individual.

Primary and middle schools that emerged at the time of industrialisation took over a function of enculturation, preparing children to endure the alienation necessary for factory work. School mathematics was included from the very beginning and might have a particular role in the process of alienation so typical for the modern man and woman: Do the command-like masses of mathematics exercises drill obedience (cf. Skovsmose 2005)? Does the lack of individualisation in the mathematics classroom – in the process of teaching as well as in the nature of the answers expected from

⁵⁵ In Brouwer’s logic, statements can be neither true nor false. But still, they cannot be both true and false.

⁵⁶ Alienation here is understood in a slightly broader sense than in Marxian terms.

children – represent the factory’s disregard for individual concerns? And to return to the beginning of this essay: Do routine mathematics calculations serve a social function, e. g., developing the ability and willingness to perform repetitious routine tasks whose broader sense might not be understood and/or favoured?

MODERN GOVERNMENT AND TECHNOCRACY

Modern government⁵⁷ has often been interpreted under the term *technocracy*. Technocrats (i.e., scientific specialists of a certain domain) name and determine the urgent questions of our time, planning work, health systems, education, economy, and so forth. Considering the aforementioned discussion, we may register that technocracy features a certain way of thinking; that is, logical thinking, and requires that people perform in a predictable, alienated fashion. Specifically, a technocracy requires people who follow rules which are not set up by themselves but by experts. (i. e., the technocrats).

Technocratic decision-making depends a lot on mathematics. Mathematical models are used to describe, prescribe, and predict technical, economical, and social matters. For example, medical studies claim that the effect of a new medication is twice as high as the old, the 2% increase of the GDP shows that the economy is doing well, or income taxes must be raised because the costs of the health system exceed the budget by 2 billion Euros. We accept these decisions, although we do not fully understand the justifications used.

But technocracy is nothing *imposed* on people; it is *lived* by people. Technocracy requires people to trust in it and it requires technocrats. Concerning the issue of trust, we might ask: How do people come to trust in mathematical justifications? Do people consider mathematics especially trustworthy?⁵⁸ And if so, do they develop this trustworthy attitude in school mathematics?

Concerning the issue of technocrats, another function of school mathematics can be identified. School mathematics might not only practice logical thinking, it might also select those children able to thinking logically, allocating the special few to technocrat positions in society. Ole Skovsmose (2005), in his book *Travelling Trough Education: Uncertainty, Mathematics, Responsibility*, raises the corresponding questions (p. 11):

Could it be that mathematics education in fact acts as one of the pillars of the technological society by preparing well that minority of students who are to become ‘technicians’, quite independent of the fact that a majority of students are left behind?

⁵⁷ »Government« here means any form of decision-making that other people depend on, not only in the executive of a state.

⁵⁸ Here, I omit an excessive, yet illuminating, discussion about the certainty and legitimacy of mathematics (cf. Skovsmose, 2005; Ullmann, 2008).

Working Group 10

Could it be that mathematics education operates as an efficient social apparatus for selection, precisely by leaving behind a large group of students as not being ‘suitable’ for any further and expensive technological education?

FINAL THOUGHTS

In this essay, I have argued that school mathematics might have the social function of *identifying*, *selecting*, and *allocating* children, as well as preparing children for the contemporary predominant society in terms of

- developing children’s *mathematical knowledge*,
- shaping children’s *thinking* towards a form we may call logical, and
- shaping children’s *feeling* towards a form that supports technocracy and living in a society that requires alienation.

As the works cited suggest (e. g., Skovsmose, 2005), many of these points have been discussed in the literature. These discussions are limited and often isolated, and fail to draw a cohesive picture of the social functions of school mathematics. Moreover, the discussions are highly evaluative, especially when it comes to people who suffer from mathematics education and are interpreted as being suppressed by a reign of technocrats. Although our own feelings and ideals *are* important, I am afraid that a perspective that places emphasis on the ethics of mathematics education might silence possible explanations that are necessary for a comprehensive understanding of the social functions of school mathematics.

Moreover, in this essay, I raise more questions rather than provide answers. The purpose of the essay, however, was to only mark the trajectory of my research project. My project aims not only to determine probable answers to the questions raised but also to develop a cohesive understanding of the social functions of school mathematics. This project requires not only further research on the functions discussed but also the development of deeper understandings of the intellectual concepts on the basis of which functions of school mathematics might be discussed.

BECOMING DISADVANTAGED: PUBLIC DISCOURSE AROUND NATIONAL TESTING

Troels Lange and Tamsin Meaney

Charles Sturt University

The importance of mathematics or its alter ego 'numeracy' has been cemented in the mind of the public with the instigation of national, high-stakes testing in Australia. The discourse around these tests illustrates how the process of social valorisation operates. Using press releases, online news articles and online public comments, we show how politicians, parents, teachers and the general public discuss ideas about disadvantage in relation to national testing of numeracy. In these discussions, deficit language labelled some children as being less likely to perform well because of their backgrounds. In contrast, poor results for individual schools were seen as contributing to the wider community labelling their students as disadvantaged.

Keywords: public discourse, disadvantage, social valorisation, national high-stakes testing

NATIONAL TESTING, MATHEMATICS AND DISADVANTAGE

In a broader research program, in which we investigated the public discourse around the *National Assessment Program – Literacy and Numeracy* [NAPLAN], the theme of disadvantage was prominent. In this paper, we concentrate on Australians' conceptions of disadvantage as being complex and sometimes contradictory.

For some time, mathematics has been considered a gate-keeping subject in relation to people's opportunities to take up further study and work opportunities (Davis, 1996; Quintos & Civil, 2008). In Australia, national testing has solidified this role for numeracy; with literacy the only other subjects being tested and therefore considered valuable in judging the ability of a school to deliver education to students (Donnelly, 2009). The NAPLAN website describes the background of the tests in this way:

The content of each test is informed by the National Statements of Learning in English and Mathematics which underpin state and territory learning frameworks. Test questions cover aspects of literacy (Reading, Writing, Spelling, Grammar and Punctuation) and numeracy. Questions are either multiple-choice or require a short written response (Australian Curriculum, Assessment and Reporting Authority [ACARA], 2010b).

The tests determine whether Australian students reached minimal standards at Years 3, 5, 7 and 9 (ACARA, 2010a). Four months after the children sit the tests, parents and caregivers are sent a report about their child's performance against the standards and in relationship to other children. In early 2010, the Federal Labor Government opened a website, called *My School*, which compared different schools' results on the NAPLAN tests, thus very quickly making them high stakes (Lingard, 2010).

Working Group 10

The reasons given for requiring students to complete these tests are similar to those in other English-speaking countries and are linked to ‘raising standards’, particularly for students from disadvantaged backgrounds (Donnelly, 2009). As Lingard (2010) stated, this reasoning “has become a globalized educational policy discourse” (p. 131). Researchers, such as Hursh (2008), have linked this discourse of raising standards for students under-achieving at school to neoliberal beliefs about the need to hold schools accountable and privatise them, along with other institutions. The results of tests purportedly allow individuals to make choices so they can maximise the benefit of schooling in an education market. Thus, a discourse of accountability of teachers, schools and education systems runs in tandem with one about raising standard for at risk students (Lingard, 2010). As suggested by Gutiérrez and Dixon-Román (2011) little has been done to reconcile the two discourses:

[A]lthough many use “the achievement gap” as an important call for school accountability around needed resources and additional support for marginalized students, (e.g., Education Trust, 2005), such discourse has done little more than replace “the culture of poverty” in the latest of deficit frameworks. That is, while equity issues are becoming more mainstream in the mathematics education community, theoretical framings continue to reflect equality rather than justice, static identities of teachers and students rather than multiple, fluid, or contradictory ones (Gutiérrez, 2007; 2002; Martin, 2009) and schooling rather than education (p. 21).

The consequence of these types of discourses saturating educational debates is that the discursive field pervading mathematics teaching and learning becomes highly charged. Inherently, a discursive field attributes value to some phenomena whilst depriving others of value or visibility. The result is that the discursive field facilitates only some views becoming acceptable. Summarising their findings from several studies, Abreu and Cline (2005) described this process as social valorisation:

We have evidence from previous studies that the social valorisation of practices is a key element in a person’s representation of these practices. Studies with Brazilian schoolchildren (Abreu, 1995) and with British schoolchildren (Abreu & Cline, 1998) showed that they had developed an understanding of how specific forms of mathematical knowledge were socially marked and that this enabled them to construct categories, to compare them and to relate these to given social identities (Abreu & Cline, 2003). (p. 699).

As gravitational and magnetic fields define directions in the physical world, a discursive field assigns what is ‘up’ and ‘down’, ‘south’ and ‘north’, ‘along’ and ‘against’ thus constituting what could be termed a force field of social valorisation. The force field affects the saying, doings and relatings (Kemmis & Grootenboer, 2008) of students, teachers and the general public, and it shapes backgrounds and foregrounds of students and their dispositions to engage in learning mathematics (Alrø, Skovsmose, & Valero, 2009; Skovsmose, 2005). The force field of this discursive world is inescapable to its ‘inhabitants’ in the same sense that we cannot

escape the gravitational field. It does not mean that people cannot talk or think in ways not aligned with the valorisations of the discursive field; rather, it is more appropriate to consider them as always being affected by it. The discursive field, in which ‘raising standards for those at risk’ and ‘accountability’ are included, pervades public discussions about NAPLAN and My School. Whilst participants are constrained by this force field, they also contribute to its perpetuation by their acceptance that children can be judged as potential workers and contributors to society as a result of their mathematical achievement on NAPLAN.

In this paper, we explore how ‘disadvantaged’ is used within public discourse and how it is compared and contrasted with discourses around accountability and raising standards. The use of ‘disadvantaged’, with its meaning of something or someone being less privileged, presents an opportunity to examine how status is added to certain types of mathematical achievement. Being disadvantaged or attending a disadvantaged school impacts on the social identity of students, their teachers and their parents. Measuring and broadcasting the mathematical achievement of students provides a focus in discussing what it means to be disadvantaged. Through an examination of data from publicly available news items about NAPLAN and My School, we show there are differences in how being disadvantaged is conceived. In some situations, it appears that children’s backgrounds contribute to them being considered disadvantaged. At other times, it is the process of valorisation through the labelling of some schools as failures which results in their students being considered disadvantaged.

METHODOLOGY

The data set consisted of five interview transcripts and four media releases from the Department of Education, Employment and Workplace Relations (DEEWR), and 19 online news articles, five of which included public comments. This data set captures the views of the Minister for Education at the time, Julia Gillard, and also how this information was received by journalists, academics, the teacher union, the association of school principals and members of the general public who contributed publicly to the discussions. Wherever possible we took news articles from national sources such as the *Australian Broadcasting Corporation* (ABC), the online journal *Inside Story* or the newspaper *The Australian*. However, at times articles from the Brisbane-based *The Courier Mail* and the Adelaide-based *The Advertiser* were used because they included online comments from the public. There was over 230 pages worth of data.

The data were collected between September 2008 and March 2010. Although the first NAPLAN tests were conducted in May 2008, we chose to start from September 2008, when parents were about to receive information about their children’s achievements for the first time. Our cut-off date in March 2010 meant that most of the discussion was captured about the release of the school results for NAPLAN on

the My School website, but avoided discussion of the controversial 2010 NAPLAN tests. Although not all the public discourse was documented, the data set has sufficient breadth to reflect the variety of views of people involved in these discussions at this time.

Initially, both authors and a research assistant combed through the data, developing classifications and categories with an open mind, and finally identifying eight themes. In this paper, we report on the theme concerned with disadvantage. To this end, the data were re-examined for discussion dealing with or referring to disadvantage. We choose to focus on this theme because we felt that the complexity of the ideas about disadvantage that were discussed illustrated how a discursive field operated. In discussing disadvantage, people appeared to be aware of the process of social valorisation and as a consequence often tried to divert responsibility from themselves for disadvantaging others in the system. At times, the government's system of high stakes testing was blamed for contributing to the disadvantaging process.

As all documentation was publicly available, the names used by contributors, including those used to comment on online news articles, are provided in the quotes below. We have also left the spelling and grammar as they were in the contributions.

WHO IS DISADVANTAGED AND IN WHAT WAYS?

In the data set, being disadvantaged was presented in several ways. Sometimes the term 'disadvantage' was used, whilst at other times, it was implied by suggesting that some children had less opportunity for learning or fewer life chances. The backgrounds of some groups of children meant that they were expected to do poorly in the NAPLAN tests. As a result, they or the schools that they attended were likely to be described as disadvantaged. Some children were positioned in the discourse as disadvantaging other students' learning because of their disruptive behaviour. Finally and in contrast, being disadvantaged was discussed in relationship to how the results of the tests meant that certain schools were labelled as failures, with the children who attended them gaining the same label. Thus, there was no consistency in descriptions of the cause of the disadvantage and the effect of the disadvantaging process.

The Minister of Education consistently identified students who were most likely to do poorly on the NAPLAN tests as those who came from disadvantaged backgrounds. Their enrolment at a school contributed to the school being known as disadvantaged. The label of disadvantaged schools has a long history in Australia. In the 1980s, schools became disadvantaged when they fulfilled a number of criteria such as enrolling students from low socio-economic areas. These schools received extra funding. Testing students did not contribute to this identification of disadvantaged schools and so funding was not tied to improving test results. The first quote seems to hark back to these earlier beliefs about disadvantaged schools.

Working Group 10

Julia Gillard: The National Assessment Program will help us identify schools that aren't reaching the kind of standards that we want kids to get to. And there are other things that can tell us about disadvantage in schools—number of Indigenous children enrolled, for example; number of children with disabilities (DEEWR 10/9/08).

Julia Gillard: But it remains of great concern that the data shows that Indigenous student achievement is significantly lower than non-Indigenous students in all areas tested and all jurisdictions (DEEWR 19/12/08).

Julia Gillard: It's about lifting standards for every child in every school and making a huge difference for those kids most at risk of being left behind, who are our kids from our poorer households in this country (DEEWR 10/11/09).

For Julia Gillard the two discourses of 'raising standards' and 'accountability' seemed to be complementary. 'Raising standards' presupposed identification of schools with sub-standard results, in order to hold them accountable for those results, and also initially to provide money so they could improve those results. However, in presenting a case that NAPLAN would support all children to gain appropriate outcomes in literacy and numeracy, the Minister contributed to a deficit discourse. Indigenous students, students with disabilities and those from poor homes contributed to schools being disadvantaged. Simultaneously, it was predicted these students' backgrounds would lead to them performing poorly on NAPLAN. By having inappropriate backgrounds, students were to blame for their poor performance whilst at the same time it was up to schools to overcome these backgrounds. If they did not do so then they also were to blame. The inconsistencies and circularity in these arguments are not acknowledged, nor problematised.

There were few comments by the general public in the data set, which identified specific groups or schools as disadvantaged. One of these is the following comment on the ABC website to a story on teachers voting to boycott the NAPLAN tests.

Joker: And what do you purpose teachers do in indigenous communities in which you are lucky if the kids show up to school for 2 days a week???

Stop thinking about your own immediate area and start thinking about the whole of Australia.

I don't agree with this site [My School] at all. It gives an inaccurate reflection. How can you possibly compare the education standards of a remote community to say a private school in inner Melbourne where each student has a laptop and a remote community is lucky to have a reliable computer????? (Rodgers 28/1/10)

In this comment, the disadvantages faced by Indigenous students were not discussed. Instead, the writer seemed to suggest that it was the schools in Indigenous communities, which were disadvantaged because irregularly-attending students were unlikely to perform well on tests. At the same time, there was an awareness of how

Working Group 10

My School contributed to value being awarded to some schools which may already have been privileged. The responsibility for this disadvantaging of the school seemed to be shared between the children and the system which made such rankings.

On the other hand, teachers and their spouses were much more likely to see disadvantaged students as those who were disrupted by their badly behaving peers. The parents of misbehaving children were often positioned as being responsible for the poor behaviour and thus for other students becoming disadvantaged.

Johnny Unimpressed of Adelaide: My wife gets constant abuse from parents for handing out detentions to kids who misbehave, abuse, distract and bully other students, or they simply write notes to the school making up stories about why their precious angel can't do the detention (Kenny 11/11/09).

Skip of Brissy: Parents need to be more accountable and make thier little darlings work. I came from a tough up bringing and the wrong side of the rails. My parents valued education and I have done reasonably well. Comparing schools makes no sense when it is the same trashy kids at each. My wife is a teacher, you wont turn Chaff into Bread, no hope. If parents had to do more, then educational standards would improve over night. The fault may well be two way, but with out proper and useful parental support then I am afraid we will continue to dumb down (Kenny 11/11/09).

For some time, it has been known that teachers commonly blamed factors within the child or the family if the child failed to learn at school (Hempenstall, 2009) and the comments by teachers in the public discussions, like those of their spouses above, were often of this ilk.

Parents often felt that some students were disadvantaged at school. However, they were most likely to mention children with disabilities or who were labelled gifted and talented. As exemplified below, they felt that these children were disadvantaged because their legitimate needs were not met within the schooling system. Although there was some teacher blame in these comments, parents were more likely to blame the system because of under-resourcing. As described by Gutiérrez and Dixon-Román (2011), these types of comments are connected to an accountability discourse around making schools or education system provide for marginalised students.

Bullfrog: Whilst there are some sociological advantages in classes of mixed ability, unless the resourcing model is vastly changed, the current set up disadvantages non-normal learning kids, both the less capable, and more capable (Woodley 17/11/09).

Bernard Wood of Modbury: Many kids I've met with ASD [autism spectrum disorders] don't meet the requirement for a special class but they can not handle mainstream and unfortunately mainstream teachers are not experts in teaching these children and they get suspended [temporarily barred from school] etc. therefore the kids suffer (Kenny 11/11/09).

Working Group 10

Adelaide: The Victorian Affiliated Network of Gifted Support Groups estimates that 75 per cent of gifted students are underachievers and as many as 40 per cent leave school before the end of year 12. Dr McGuigan reported research showing that some 15 per cent of children of high intellectual potential drop out of school before completing year 12 (Kenny 11/11/09).

If NAPLAN or My School were mentioned in parents' comments about their disadvantaged children, then it was generally to dismiss them. Some commentators connected the government's discourse to one about accountability and unlikely to contribute to a more just society. In the few comments of this kind, the two kinds of discourse tended to be juxtaposed as contrasting, rather than complementary as had been the case in Julia Gillard's comments.

Sjames: Another example of a government harrasing poorly funded and undersupported schools, teachers, children and their communities. The Labour Govt has inherited its 'wisdoms' from the hyper-rationalism of the Liberals - its all about accounting (Woodley, 17/11/2009)

Nevertheless, NAPLAN and My School could not be ignored. Perceptions of a school as being disadvantaged were recognised as having a long-term impact on children's life chances.

Dan: I have pretty much no choice where my kids go to school given the zoning rules, so to me all this does is perpetuate and exacerbate the discrimination my very young children are already subject to. That is, because of where they live, they have to go to a fairly low performing school. Because of that, they will be considered to be low performing students whether or not they are. Because of that they may have more difficulty finding a job and because of that, they may not be able to afford to live in a wealthier suburb and send their kids to a private school either.....and so on (Woodley 17/11/09).
