Matt: And what does the parents 'higher' education have to do with children learning to count and read. Whilst there may be statistical relationships there. Simply learning the times tables and reading are something that needs to be put into perspective. What you are saying is that children from lower socio economic backgrounds are almost destined to be failed by the education system. Instead of bleating about the additional information needed in these reports to make you feel comfortable, how about offering constructive view on how we fix the system so those children are not failed by the education system (Rodgers 19/1/10).

It would seem that not everyone accepted the complementary story that the politicians told about how increasing accountability would support the aims of social justice, through 'raising standards'. Instead the two discourses were seen as being in conflict, with contributors calling for a resolution of the differences. Parents' concern for their own children influenced their understanding of how NAPLAN

affected children being or becoming disadvantaged, especially when they felt that the schooling system was not supporting their children. They drew on this understanding when they evaluated the stories told by Julia Gillard and other politicians.

CONCLUSION

The concept of disadvantage and how children became disadvantaged was a much more complicated issue for the general public than it was for the Minister. Although she did not explicitly label groups of students as being disadvantaged, by linking them to disadvantaged schools, she suggested that they were disadvantaged by association. Teachers, or their spouses, were more likely to consider parents to be the cause of disadvantage. By not teaching their children appropriate behaviours, these parents were directly responsible for other children becoming disadvantaged because they were unable to take up learning opportunities. This could be rectified by parents taking more responsibility in bringing up their children. On the other hand, parents saw schools and the education system as being responsible for the disadvantages that their children suffered in schools. This was either because the schools were unable to provide adequate support for their learning and so their children's life chances were restricted or because the publication of NAPLAN results resulted in the labelling of a whole cohort of students as being poor achievers whether this was the reality or not. Discourses around 'raising standards' and 'accountability' brought out many different conceptions of who was disadvantaged and in what ways. These had an impact on the lives of those who were considered disadvantaged and those who worked with them.

Children's possibilities for their future lives can be severely limited by the general public's acceptance that a school's NAPLAN results indicate the worth of its students as potential workers and citizens. In the same way, teachers' professional careers are discussed and dissected within the public discourse making them more or less likely to teach in particular ways, depending upon how much their social identities are marked by this discourse. The public discourse analysed here illustrated how the discursive field added value to some phenomena whilst making other phenomena invisible. In discussions about NAPLAN and My School, mathematical achievement in the tests added value to children, their schools and by implication their teachers. At the same time, ability to work as part of a team, for example, which may also be considered to be a worthy attribute for good workers and citizens, is not seen as valuable in these discussions. A discussion around raising standards in relation to team work is hard to imagine in this discourse.

Mathematical achievement and how it is measured is not a neutral activity. It is part of, contributes to, reinforces and is thinkable within the force field of social valorisation. The way that mathematics achievement is valorised provides an indication of what is 'up' and what is 'down'. Having good NAPLAN results was connected to having opportunities for a good future life. On the other hand, the

Working Group 10

linking of some students to disadvantaged schools who had poor NAPLAN results was likely to affect how teachers, students and their parents viewed the teaching and learning of mathematics. If NAPLAN is considered to be the determiner of improved life chances then, the type of mathematics assessed in these tests will be the kind valued by teachers, children and their parents in schools which are most likely to achieve poorly on these tests. They will be fobbed off with this low quality schooling whilst other schools with 'good' NAPLAN results have more opportunities to widen their focus and so provide a richer mathematics education for their students.

On the other hand, our examination of the public discourse around NAPLAN and My School suggests that within the cacophony of the discussion, there were dissenting voices. Some contributors saw as contestable the suggestion that the two discourses around 'raising standards' and 'accountability' were complementary. Their comments showed an awareness of how the process of social valorisation following from the accountability discourse contributed to some children being labelled as failures. The determination of what is 'up' and what is 'down' were not fixed for these people. They were affected by the discourses, but were not determined by them. For the parents whose children's social identities were likely to be marked because of the publication of NAPLAN results on the My School website, the process of social valorisation became obvious. Often references to being disadvantaged were located within discussions about who was responsible. Although this often referred to children, their families and their teachers, it also enabled an identification of government ministers and their policies as those who were enforcing this social valorisation of a particularly limited kind of mathematical knowledge. Thus, while the discursive field can be considered as constructing what is 'up' and what is 'down', at the same time people's awareness of it enables dissent and an unpacking of how it developed. This can open up possibilities for changes.

ACKNOWLEDGEMENT

We wish to thank Lisa Pearson who was our efficient and very tolerant research assistant for this project.

PARENT-CHILD INTERACTIONS ON PRIMARY SCHOOL-RELATED MATHEMATICS

Richard Newton and Guida de Abreu

Oxford Brookes University, UK

This paper reports some initial results and findings of a research project investigating parent and child interaction when completing primary school-style mathematics. It suggests that through using a sociocultural lens and a theoretical and analytical structure based on activity goals we can study how parents and children interact and co-construct learning and conceptual development in primary school-related mathematics. The paper also sketches out how a wider study into the milieu of parent-child interaction on primary school-related mathematics could reap interesting and insightful findings in the UK context.

Key Words: parent-child interaction, school-mathematics, co-construction, goals

INTRODUCTION

How a parent supports their child's learning impacts upon that child's attainment in primary school (Morrison, Rimm-Kauffman, & Pianta, 2003). A comprehensive review of contemporary literature on parental involvement, carried out for the UK government by Desforges (2003), showed that the quality and character of parent-child interaction plays a significant role in attainment in primary school. This is supported by large-scale statistical studies (Duckworth, 2008; Peters, Seeds, Goldstein & Coleman, 2007) and UK government policy (DfES, 2007). These suggest that in the UK, attainment at the end of primary school is more closely correlated to types and qualities of parental involvement than social class, income, maternal educational level, or the school attended. Whilst some research in the UK has focused on school- and home-mathematics practices (Abreu & Cline, 2005; Street, Baker & Tomlin, 2006), a limited amount has addressed the dynamics of primary school-related mathematics in the home contexts. In order to address this gap a research project was formed to specifically investigate parent-child interactions on primary school-related mathematics in the UK.

This paper presents a theoretical framework emerging from the study and an initial analysis of a single event of parent-child interaction on primary school-related mathematics. It sets out to begin to answer two research questions: (1) How do parents and children interact and co-construct learning on primary school-related mathematics? (2) How do parents support children's development of conceptual understanding of primary school mathematics? The paper tackles this by analysing an event of parent-child interaction. It concludes by proposing a wider study into some of the factors influencing parent-child interaction.

THEORETICAL FRAMEWORK

In this project the parent-child interaction is located in sociocultural theories of learning and development, primarily within the work of Vygotsky (1978), Leont'ev (1981), Wertsch (1985) and Saxe (1991). Such a position assumes that learning takes place on the social plane before it is reproduced within the individual. This viewpoint has been used successfully to study the social interaction between parents and children and the resultant co-construction of mathematical knowledge (Anderson & Gold, 2006; Hyde, Else-Quest, Alibali, Knuth, & Romberg, 2006; Saxe, Guberman, & Gearhart, 1987).

Vygotsky's (1978) ideas on mediation, internalization and a zone of proximal development are relevant to developing a theoretical framework to study parent-child interaction. Vygotsky rejected the idea that development was driven by any single factor, and so can not be explained by any single corresponding principle (Wertsch, 1985). The idea that psychological processes develop through 'culturally mediated' activity is at the heart of Vygotskian theory (Cole, 1996). Vygotsky (1978) was primarily preoccupied by the role of language in mediation. He saw language as facilitating social connections and cultural behaviour (Vygotsky, 1997). It is social connection, interaction and transmission of culture that allows the internalization of higher psychological functions. Internalization is not just a mental function it is the formation of a mental plane (Leont'ev, 1981). This formation occurs through cooperation and social interaction (Tharp & Gallimore, 1988). The process of internalization is critical in Vygotsky's (1978) 'general law of cultural development', which states that learning takes place on the social plane before it is reproduced within the individual. In order to ascertain learning and development Vygotsky (1978) developed the concept of the 'zone of proximal development' (ZPD). This allows us to study the difference between assisted and unassisted performance, in other words processes which are advancing or maturing but have not yet been finalised or completed. Because the ZPD is a social and contextual concept it involves some form of negotiation (McLane, 1987). This negotiation takes place between the more capable 'expert', and a less capable 'novice'. Using and interpreting theories of mediation, internalization and the ZPD to study development in cultural contexts is not new, however it is a difficult proposition.

A solution to this problem can be found by utilising elements of Activity Theory (AT) which has been used to operationalise both Vygotsky (Wertsch, 1985) and sociocultural studies in mathematical understanding (Beach, 1995). AT can be traced to the work of Leont'ev (1981). It is a complex entity and difficult to apply in its entirety. Of the many elements within AT, Leont'ev argued for a focus on goal-directed activity as a mechanism for understanding culture and cognition (Nasir, 2002). The centrality of goals to AT is expounded by Nasir and Hand (2006, p.460)

“Activity theory presupposes that all activity is goal directed. These goals, or objectives, manifest differently depending on the level of analysis; taking the activity as the

Working Group 10

fundamental unit of analysis, these objectives appear as motives. Moving to an individual or group level, motives become directly aligned with conscious goals. Although often explicit, these goals generally emerge over the course of activity”

Saxe et al. (1987) studied the relationship between numerical goals and social and cultural processes. Their basic assumption, which is adopted by this paper, is that

“...children’s numerical understandings are their goal-directed adaptations to their numerical environments, therefore, the study of number development should entail coordinated investigations of children’s emerging abilities to generate numerical goals and the shifting sociocultural organization of their numerical environments” (Saxe et al., 1987, p. 4)

This supports the idea that negotiation, interaction and goal-construction plays an important role in emergent and situated cognition. Saxe (1991) shows cognitive developments are enacted through efforts to accomplish numerical goals. He developed a framework for studying the components of these emergent goals at the microgenetic scale. Goals are emergent in the sense that they alter and shift in response to: (1) activity structures, the goals that are formed in the practice; (2) social interactions, where goals are modified and through negotiation take form; (3) artefacts/conventions; and (4) prior understandings. This is termed the four parameter model. This approach has been used in a number of research studies (Guberman & Saxe, 2000; Nasir, 2000, 2002; Saxe, 2002; Saxe and Guberman, 1998). If we accept, as Saxe does, that goals are a reflection of situated cognition, then by studying the goals of parents and children we can study co-construction of knowledge and conceptual understanding in mathematics.

METHODOLOGY

In this paper an instance of parent-child interaction is analysed using the earlier theoretical framework. The participants were a 40 year-old British female and her 10 year-old son. The dyad completed a 30-minute mathematics task which involved a number of subtractive calculations and word problems. This topic was chosen as a particular focus since professional experience, and academic research (Barmby, Bilsborough, Harries, & Higgins, 2009), suggests that children can struggle with different elements of subtractive understandings. Teaching of subtraction has evolved greatly over the past 10-15 years, which means parents may well have different experiences and mathematical representations to their children. The word problems tackled different elements in subtraction and presented different subtractive structures in order to elicit a range of conceptualisations. The task was similarly designed to allow elements of ‘expert-novice’ communication and co-construction of mathematical knowledge. Research on word problems informed the production of the task (Fuson, 1992) as did research on calculation (Anghileri, 2006). The task was designed to replicate the schoolwork parents and children regularly complete together. Whilst this is not a study of actual homework practices,

it does look at how parents and children negotiate and co-construct mathematical understanding, and begins to highlight how this interaction is shaped by social and cultural forces. The dyad was video recorded as they completed the task. This video was then transcribed and analysed qualitatively using NVivo 8.

ANALYSIS

The video recording presented a highly complex and rich corpus of data that could have been investigated from a range of directions. This analysis concentrates on the co-construction of mathematical learning evidenced by language use and behaviour. It approaches this from three tiers of complexity. These progressively narrow the focus on the analysis, but in doing so lose elements of their wider interconnectedness. This approach was both emergent, in the sense that it was informed by the data, and theoretical, in the sense that it was informed by relevant research literature.

First tier: Descriptive analysis of mathematical operations and thinking

This first tier of analysis looks at the interaction globally to begin to address the research questions of this project on parent-children co-construction of learning and understanding. In this case it interprets the utterances of the dyad in accordance with theories of goal-directed activity and mathematical principles and understandings. For example, in the following passage the dyad is trying to find the difference between 86 and 64, M refers to the mother and C to the child.

- C: Okay, so, count on from 64 to 86 because you add 6 it gets to 70 another 10 so that's 16.
- M: Sorry?
- C: 16 I think.
- M: You think 16.
- C: What do you think?
- M: 64, she's got 64 but she had 86...
- C: Yeah, Yeah.
- M: ...so I would kind of...I'd look at my 64 and I probably turn it...I...I'd add it up rather than try to take that figure away.
- C: I know that's what I just did.
- M: So that's what you've done. So if you have your 64 how many do you need on...4 to make 6?
- C: 2 [M writes down on sheet]
- M: How many from 6 to make 8?
- C: 2 [M writes down 22 on sheet]

The child has a number of different strategies available given the operation and the numbers involved. He decides to use a complementary addition and add, in steps, from 64 to 70 and 70 to 80. However he does not use a third step and add from 80 to 86. This means he reaches an answer of 16 rather than 22. He then follows a procedural objective of seeking M's confirmation of his correctness. His mother confirms the appropriateness of his strategy and that she would similarly use complementary addition. However, whilst he appears to use a mental number line to count in steps between 64 and 86, she seems to use a mental imaging of a column subtraction. This entails counting the difference between 4 and 6 (64 and 86) then writing 2, and 6 and 8 (64 and 86) writing another 2 to make the number 22. This shows that the two have a different understanding of what it means to 'add up' to 'find' a difference. This could be linked to contrasting school experiences.

Second tier: Evidence of practice-linked goals through the analysis of emergent goal construction

This second tier looks deeper to try to highlight the parameters linked to the 'emergent' goals (Saxe, 1991) formed in this cultural practice. It uses Saxe's four parameter model to study and explain the practice-linked goals constructed by the dyad. In this case instances of each parameter in the transcript were coded using a simple framework and linked to potential explanations.

The **prior understandings** that are brought to a cultural practice both enable and constrict emergent goals (Saxe, 1991). So children and parents could be expected to construct different goals since they are utilising different mathematical experiences and representations. This assertion is supported by data from the parent-child task. M had a very different primary mathematics experience to her son. This is displayed in the strategies she uses in the task and the barriers she appears to face regarding a familiarity and understanding of the mathematical methods that her son uses. Of the four parameters prior understanding is perhaps the most difficult to determine through the study of interaction alone, initiatives to address this shortcoming are discussed later.

Cultural practices, in this case the **activity structure** of the task, are defined by the motives required to complete them. The goals of one practice may be different from the goals of another. Within the interaction it is possible to see a great deal of evidence of the role that the activity setting has on practice-linked goal formation and the objectives the mother and child pursue. This is shown below in the following subtraction calculation activity. Here the dyad answered a question by following the practices ingrained within the school mathematics-related activity: reading the question, answering the question, and explaining reasoning.

M: Alright... right, let's have a look. Have we read the question?

C: Yeah. Can you solve these subtraction calculations, show your workings. 40 minus 21 equals... 20 away from 40 is 20, and take away 1 is 19.

Working Group 10

M: Well ok. Start by writing that out then, so how did you get to that? So how did you first do it? [C writes an explanation, M checks]

C: That's super... right... just pop your answer there, so you got 19.

The task gave a great deal of information about the way in which **social interaction** impacts upon goal construction. There were several cases when one participant suggested a procedure which altered the goal of the other. This usually led to a phase of negotiation around the appropriateness of the procedure. These examples showed mother and child playing out of Vygotskian roles of 'expert' and 'novice' in setting and amending practice-linked goals. The task also provided numerous examples of M explaining or modelling strategies and concepts to scaffold onto C's mathematical understandings.

The dyads' practice-linked goals constructed within the activity are also influenced by the **artefacts and conventions** enmeshed within this cultural practice. Calculations and word problems, similar to those used in the classroom, triggered a certain style of response and practice-linked goal structure (as evidenced in the above example). There was evidence that mathematical artefacts, such as algorithms for subtraction, influenced goal construction in the dyad.

Third Tier: Evidence of the negotiation of mathematical goals

This final tier delves deeper into the interaction to observe how mathematical goals are negotiated, formed and operated. Within the task the dyad appeared to operate through negotiation. There was little conflict or disagreement. There was however several instances of M prompting different mathematical goals and of C needing to reason and justify his choices. A coding framework, informed by the background literature and instances within the transcript, was used to study these negotiation processes within the social interaction.

Table 1 Codes used to study the negotiation of mathematical-linked goals

<i>Code</i>	<i>Description</i>	<i>Code</i>	<i>Description</i>
C1	Agreement with a statement	C11	Abandoning a previous answer or approach
C2	Disagreement with a statement	C12	Appearing to mathematically reason
C3	Probing understand/action	C13	Setting a new mathematical goal
C4	Prompting understanding/action	C14	Accepting the mathematical goal of the other party
C5	Confusion	C15	Rejecting the mathematical goal of the other party
C6	Checking the reasoning of the other party	C16	Abandoning their mathematical goal
C7	Suggesting an answer to a mathematical operation	C17	Suggesting a different mathematical goal
C8	Providing an explanation or model		
C9	Responding to a question or prompt		
C10	Asking the other party whether an argument is right or wrong		

Working Group 10

These codes break down the interaction into smaller components in order to view the building blocks of the co-construction of mathematical goals. From this we saw that the parent M tended to allow her child to formulate and operate his own mathematical goals, but she would intervene if she thought his reasoning was flawed or a more efficient method existed. In the following episode, which includes my reflections, we see M and C negotiating how to solve a two-step word problem: *Josh had 307 stamps. He gave 118 stamps to Katie. He lost another 43 stamps. How many stamps does Josh have now?* The problem can be solved in two different forms: $307 - 118 = 189$, $189 - 43 = 146$; or $118 + 43 = 161$, $307 - 161 = 146$. M favoured following a goal leading to the first, whilst C preferred the latter goal. Through probing and prompting, giving and answering questions and apparent reasoning we can see how one goal was accepted and another rejected.

Dialogue	Interpretation	Codes
C: How many stamps does Josh have now. So it's 307 take away 118.	<i>C recognises that the answer can be found by $307-118=x$ then $x-43=y$.</i>	C12
M: Yeah C: So basic...so then he lost 43 so... 118 add 43.	<i>C sees that he could add the two subtractive elements (118 and 43) then subtract the answer from 307.</i>	C1 C11 C12
M: I'll tell you what...what we'll do...yeah, you can add your...you could start with the sum and take the 118 from the 307 couldn't you	<i>M agrees with C but proposes $307-118=x$ then $x-43=y$ suggesting that C could break it down or (partition) prior to subtraction.</i>	C15 C4
C: Yeah. M: And you could say...could say right well we'll break that down we'll take the hundred off the 300 first and then we'll take the 18 off... C: That'd be 161 mum wouldn't it? [C points to sum on the paper?]	<i>C suggests the answer to $118+43$ and seeks confirmation.</i>	C1 C12 C15 C7 C10
M: ...and then we could add the 7 back, yeah. Or you can do it...yeah...you can do it this way, do you find it...	<i>M recognises that compensation and partitioning does not work well with these numbers. This leads her to think through C's method.</i>	C12
C: That's 161 [C points to calculation on paper] M: If he's lost 43 and he's given this amount away as well, add those together, and then take that figure off the 307.	<i>M discusses C's method and recognises that it would work.</i>	C7 C12 C16 C14 C11
C: So add those two its 161...	<i>C seeks confirmation of his answer.</i>	C7
M: Well we'll add it, we'll work it out here, write it down...write it down. Put your 118 and put your 43 underneath, do it as a sum write it as a sum like you would do at school. Yeah.	<i>M accepts C's goal and rejects her own.</i>	C1 C4 C13

Conclusion and ideas further research

In this paper we can see different mechanisms inherent within parent-child interaction, even though these can be difficult to untangle and classify. By operating from a sociocultural viewpoint in terms of study design and analysis we can attempt to answer our two research questions regarding interaction, co-construction and the development of conceptual understanding. This paper, nonetheless, only presents a single story limited to two characters. A much wider study of more parent-child dyads is needed to see if the ideas and findings from this one case are comparable to others and whether any similarities or differences exist. In addition, a focus on the interaction alone is not enough to explain the interaction. Whilst we understand a great deal about how children are taught mathematics we have little indication of parental experiences or mathematical identities. Nasir (2002) has shown how prior experience, motive and identity are important in goal construction. Her model allows the paralleling of the microgenetic study of goal-directed activity with an ontogenetic study of identity and motive. This can be incorporated by episodic interviewing (Flick, 2000) of parents, allowing a greater awareness of the milieu of the parent-child interaction and richer answers to our main research questions. Since research shows that parent-child co-construction of school-related mathematical knowledge is also influenced by factors such as the level and quality of communication between home and school (Hughes & Pollard, 2006) this should also be taken into account. This too can be accomplished through interviewing parents.

These points present a model for the next stages of this inquiry and a way forward to further study some of the elements of parental involvement which have been shown to play such a key role in attainment.

NOTES

SOCIO-CULTURAL ROOTS OF THE ATTRIBUTION PROCESS IN FAMILY MATHEMATICS EDUCATION

Javier Díez-Palomar and Sandra Torras Ortin

EMiCS – Department of Mathematics and Science Education – Universitat Autònoma de Barcelona

This paper explores the process of attribution drawing on a socio-cultural approach. Scientific literature has widely demonstrated that attribution may have a crucial impact on individuals' beliefs to learn mathematics. The process of attribution is always present within individuals' interactions. In addition, previous researches also suggest that many attributes assumed by learners may be grounded on social representations. We build on a European research study about family mathematics education. In this paper we want to give some examples to describe the kind of beliefs family members have that may impact on their own attitudes towards mathematics, as well as their children's ones. We explore how these beliefs may have a social origin.

Key words: beliefs, attitudes, social representations, mathematics, family involvement.

Mathematics is a place either for enthusiastic attitudes or negative feelings. Individuals may look at mathematics very differently according to their experience with this subject. When children ask to their parents (or other relatives) for help to do their homework of mathematics, this “previous experience” emerges and mediates parents' disposition to help them. According to previous researches, the type of memories underpinning family members' background may explain their attitudes towards mathematics. Positive reactions to this subject (the “aha!” experience of successful problem solvers) clearly have a different impact than negative experiences drawn on frustration of getting stuck on mathematical activities. However, we think that sometimes these reactions towards mathematics are not just individual responses to people' ability to solve problems and other types of activities; there is also a social (and cultural) component embedded. Individuals develop their particular identity as mathematics doers because their own ability to use them. But they also develop this identity as a consequence of the role acquired within the group. Interactions with other persons should promote either positive or negative attitudes towards mathematics depending on whether they are supportive or discouraging peers. The final result of these interactions (in terms of identity) may have a crucial influence on individuals' achievement. In fact, there is a prominent body of research suggesting that self-confidence as mathematics doers have a heavy impact on students' performances in mathematics. With this paper we aim to introduce a discussion with the scientific community about the usefulness of the attribution theory to provide some light to understand how attitudes and emotions that impact on individuals' feelings towards mathematics may be socially rooted.

THEORETICAL FRAMEWORK

Since 1970s many researchers in mathematics education had studied the impact of beliefs, attitudes and emotions on learners' performance (Bachman, 1970; Evans, 2000; Fennema & Sherman, 1976; Gómez Chacón, 2000; Hannula, 2002; House, 1975; Lester, Garofalo, & Kroll, 1989; McLeod, 1994; Zan, Brown, Evans, & Hannula, 2006). There are many researches on this field that place assumptions such as “in order to learn mathematics you need to do a number of routine mathematical tasks”, “mathematics is memorization”, or “mathematics is difficult” under the label “beliefs”. Researchers have developed many scales to study how these assumptions impact on students' mathematics learning¹. When authors talk about the idea of “confidence about learning mathematics”, there is a disagreement on whether using the term “beliefs” or “attitudes” to refer to this idea.² Although this divergence on the use of the terms, all studies proved a relation between the affective and the cognitive domains. According to Hart (1989), interactions of students and teachers in mathematics classrooms are strongly influenced by confidence and other beliefs. Bachman (1970) noticed that self-concept is a salient aspect emerging from the study of attitudes and beliefs that influences on students' performance in mathematics. This notion (self-concept) was used later on to explain adult learners' anxiety towards mathematics (Evans, 2000). This is also one of the more salient reasons underpinning the difficulties that family members should face when helping their kids with mathematics (Díez-Palomar, J., Menéndez, J.M., Civil, M., forthcoming). Anxiety explains some parents' (and other family members) reluctance to do mathematics themselves, hence they use to prefer other strategies to get involved in their children's learning, such as send them to after-school programs, to academies, or hiring personal teachers to support their children at home (Hoover-Dempsey & Sander, 1995).

According to prior researches, there is a relation between mathematics anxiety and learning. Clute (1984) found that anxious students do less well in discovery lessons than with expository teaching. Zan and his colleagues (2006) stated that anxiety inhibits cognitive processes. They affirmed that learners experiencing stressful situations within the classroom of mathematics perform worse than other students. Adult learners use to experience this feeling (Evans, 2000). According to previous researches (Díez-Palomar, 2004), anxiety and other negative attitudes may be rooted on personal past experiences. Here there is place for socio-cultural explanations. In fact, drawing on the literature review, we can find (at least) two main bodies of research: (a) the one based on individual experiences, and (b) the one grounded on social (and cultural) characteristics.

Op't Eynde and his colleagues (2006) affirm that the affect domain is primarily rooted in the social context. This is not new for the sociologists. Mead (1934), for example, developed a theory on how persons build their (individual and social) identity. Mead (1934) distinguished between I, self, and me, and progressive forms

We also take a few elements from the attribution theory to provide some light to our analysis. According to Kelley and Michela (1980), attribution explains individuals' behavior in terms of its causes. They use a schema to explain how attribution works (see figure 1).

Drawing on Kelley and Michela's (1980) schema, we suggest that a plausible explanation to understand why some family members feel confident dealing with mathematics whereas others see themselves as not good at math at all may have (at least) two different elements: (a) the content (the intrinsic difficulty of mathematics), and (b) individuals' attitudes/beliefs towards mathematics.

Regarding the second element, we already know that other's opinions have a strong impact of how a particular individual perceive him/herself, which also affects his/her attitude and behavior (Kelley & Michela, 1980; Asch, 1946). This is not new. We also know that beliefs have a crucial impact on individuals' self-concept. What we suggest is that those beliefs (or attitudes according to some authors) are socially (and culturally) rooted.

De Abreu & Gorgorió (2006) suggest that behavior and actions may be explained due to social representations. They claim that social representations are interpretative frameworks to explain social and cultural phenomena. These representations somehow are embedded on individuals' beliefs, which mediate their behavior and actions (see figure 2). Drawing on these arguments, we suggest that family members' beliefs towards mathematics are constructed based on social representations. In addition, we also suggest that the personal experiences of individuals are both rooted socio-culturally and socio-historically.

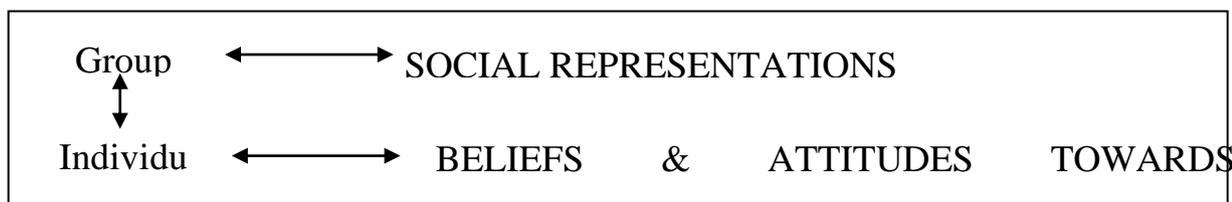

Figure 2. Relationship between beliefs & attitudes and social representations towards mathematics.

METHODOLOGY

The data used in this paper comes from a study funded by the European Commission (Grundtvig Program).⁴ This research project aims to build a European network of good practices and resources to promote family mathematics education in schools over Europe. We would provide adults with a pathway to improve their knowledge and competences in Mathematics, while promoting also the development of innovative practices in adult education to transfer them to schools all over Europe. We collected data using interviews, questionnaires and focus groups in the five countries involved in this research study. These instruments have been applied to

students, teachers and families. In this paper, we build on Spanish' data collection. We collected 355 questionnaires (n=253 students, n=96 families and n=6 teachers); and conducted 27 interviews (n=10 students, n=13 families and n=5 teachers); and 4 focus groups (n=1 students, 2=families and n=1 teachers). To analyze the data we used discourse analysis techniques (Gee, 1999) and critical communicative methodology (Gómez González & Díez Palomar, 2009; Gómez, 2006).

DISCUSSION

We organize our discussion along three cases illustrated by three different persons involved in our study. Drawing on their interviews, we discussed some salient topics to provide some light to the relationship between attitudes, beliefs, social representations and mathematics.

Case 1. Yazmín

Yazmín is a nurse assistant.⁵ She does administrative work in the hospital. She is married and she has two daughters, 12 and 7 years old. She is very demanding of her children education. She does not participate in the school family association, although she usually chats with other parents at the school front door almost every afternoon. When we asked her about her daughters, she explained that the older one is “useless for mathematics”. She described her as: “useless, useless. This [Mathematics] is the most important difficulty that she has faced ever”. Yazmín explained how her 12-years-old daughter struggles with problem solving. “When you explain to her an equation and... Of course, is the issue of reasoning, to say... well, I'm going to solve this problem... And you see her like... [making a gesture and a sound indicating embarrassment]. That's it! She had no idea what to do, she had not.” Her daughter's attitude towards mathematics was really negative. According to Yazmín, her daughter has a low self-esteem that discourages her to afford any kind of mathematical activity: “She has a very low self-esteem in the sense that she says why I am going to do that if I'm going to fail it? Then she refused to do it: she said that she was not aimed to do it [the exercise] because it will not be worth it at all.” Even teachers had a negative concept of Yazmín older daughter. When the girl was in fourth grade (elementary education), the teacher meet Yazmín to tell her that her daughter somehow had phobia against Mathematics. She always was reluctant to solve the mathematical activities.

We notice that there is a strong belief that Yazmín's daughter lacks the ability to solve mathematical problems underpinning in these comments. Drawing on our data we know that Yazmín's daughter is not confident with mathematics at all. This attitude is related to the content, but some details also suggest that there is a negative process of attribution that could be also part of the girl feelings towards Mathematics. Yazmín declares that she feels bad regarding how she has managed her older daughter education. She affirms that maybe there still are some room for doing things better: “Because you think, OK, maybe because I was working [and I had no

time] I felt stressed, so I did not do my best with her”. But, although this feeling of fault, she has strong beliefs regarding learning. She declares, “A wrong understanding of a problem always produces more troubles, of course”. She affirms that this [belief] was her biggest problem when helping her daughter with Mathematics. We may conclude that achievement somehow is related to the children context. It seems reasonable to suggest that beliefs may impact on attitudes towards mathematics, which also have some kind of influence on students’ performance.

Case 2. Carlos.

Carlos is a risk analyst graduate. He became unemployed and started to work at her wife’s business, a printing office. Now he works as a sales representative while helping her wife with the printing office. He (with his wife) has two children, a 14 years old daughter, and a 12 years old son. He is really involved in the school family association: he is the person in charge to organize the after school program. He is also an active member in his neighborhood. He participates in a range of different associations and people define him as a pro-active person who always is engaged in social life activities.

When he talks about his children’s education [in Mathematics] he is very critic. He does his best helping them with their homework. However, he has strong social representations about Mathematics. “I’m telling my children, one plus one equals two; this is Mathematics”. He has his own way to solve the mathematical activities (drawing on his memories and experience), thus he use to feel upset with teachers’ methods or strategies to solve them. “You see it either easy or difficult, because they use more steps than needed... [to solve the exercise]. He also has his own beliefs about what does it mean to learn mathematics: “you get them [Mathematics], or you don’t”; “if you get them, then you need to fully understand it”.

Carlos attitudes towards his children when helping them with Mathematics are strongly mediated by his own beliefs on the subject. He also explains how he argues with his children’s teacher about how to teach [Mathematics]. They are old mates, thus Carlos feels confidence enough to talk openly with her (the teacher) about didactics. He is very reluctant against “new” ways to teach Mathematics (more comprehensive, less mechanical), since according to him, mathematics involves “lots of practice [routine work]”. He is also very critic with his children (with adolescents in general). He claims that, “children now are in that moment like they are in a “colorful World”, they do not read well... they have their mind focused in other things, so it is difficult to focus them”.

Drawing on this data, we may suggest that parents’ involvement is really mediated by parents’ attitudes and beliefs. Carlos is a pro-active man. He is really devoted to support his children. However, his radical beliefs about Mathematics lead him to confront teachers’ methods, which may be a starting point for a conflict with his children (or his children with the teacher).

Case 3. Jordi.

Jordi is a Pharmacy graduate. He works in a Pharmaceuticals multinational company. He is married and he has two children: a 19 years old daughter and a 14 years old boy. His wife is a Nursing graduate. Both of them are members of the school family association. Both belong to a “middle class” group, and they come from well-off families. They bring their children to a religious school (catholic). They are also involved in activities for families (family involvement, teaching for families, etc.). Jordi is a person with great amounts of curiosity and he is very supportive.

He has strong beliefs around Mathematics and its teaching and learning. According to him, “I think of Mathematics that if you already have understood it when you are solving the problems, there is no need to go back... you are already in a good position. Then, you need to practice a lot with the activities, etc.”. Jordi really believe that in order to be proficient in Mathematics, there is a need of intense practice. He assumes that children need to solve series of routine activities to perform well in Mathematics assessments. This assumption suggests that somehow Jordi shares the social representation of Mathematics as a set of routine practices / methods. His belief (based in that social representation) mediates his relation with their children at home, since he asks them to practice seriously Mathematics by doing and doing exercises and using algorithms methodically.

According to him, helping children at home in some way is natural for parents, “Then, the fact that parents want to spend their time helping their children is something innate, isn’t it?” However, he believes that “not everybody can do it [help children with Mathematics] equally”. Jordi has a strong feeling on discrepancies (even inequalities) between individuals, thus some are better than others to teach Mathematics.

“...We also have extra abilities that are based on genetic issues, what “nature” has given to us, so look, you may take advantage of it or you may not, according to your [level] of understanding; but you already have it. With parents is the same... to have in mind this extra support, as a regular part of their [children] learning, maybe is discriminatory for children, because not all of them [the parents] have the same level. I’m very close to some parents of my son’s peers and, I don’t know, I’m able to imagine that for some things that I explained to my son some of them may be better than I [in explaining these concepts], but others, poor people, they will find lots of troubles to explain it or even they will not be able to do it because of their own lack of understanding themselves, or because they never studied that”.

Jordi believes profoundly that there are differences between individuals’ capacities to deal with Mathematics. According to him, parent involvement is an action that may produce streaming consequences between children. Base on that, Jordi claims that he prefers teachers to be the ones responsible for children’s learning. He thinks that teachers may have a deep understanding of the subject (Mathematics), but they also need to be able to teach it in an interesting way for children. This is another

“social representation” shared by parents and other community members, which emerges from Jordi’s arguments.

FINAL REMARKS AND FURTHER RESEARCH

Drawing on our data, we may suggest that some of the family members’ beliefs towards Mathematics are grounded on social representations (specially the ones shared with other parents). These beliefs crucially impact children’s achievements in Mathematics. Family members may project over their children their own attitudes (phobia, frustration, anxiety, lack of self-confidence) towards Mathematics (based on their past experiences). These practices could label children (as in the case of Yazmín’s daughter) and may be an exclusory fact that makes it harder for children to perform well in Mathematics. Base on our data, social context emerges as a crucial element explaining children’s achievements in Mathematics. The kind of interactions that children maintain within their everyday life could help to understand why some children always perform well in Mathematics, whereas others use to fail again and again. As previous research suggested, attitudes towards Mathematics may not be just individually based: there is room for the impact of social context. Attitudes also play a crucial role in self-concept and self-esteem, which are central aspects of the self-confidence in getting good scores in mathematical assessments. In this paper we slightly have started to analyze this kind of relationship. More research is need in order to provide more evidences and a full understanding of how these variables are related within the learning processes.

We also need more research to analyze how are “attitudes”, “beliefs”, “attribution”, and “social representations” connected to each other in the frame of family involvement practices. What type of interactions we may observe if we had the opportunity to share time with parents and children at home? An ethnographical line of research may provide more light to this question.

Finally, drawing on our data we see how some parents have beliefs about education and learning processes, which are not coherent with the findings demonstrated by the scientific community. This is the example of Jordi, who thinks that parent involvement may produce streaming, when we already know from a large body of research that it is the opposite. This is also the example of Carlos and Jordi, when they affirm that Mathematics education should be based on routine rather than other type of methods. Why do these attitudes take place, and how? What kinds of consequences have for children, and how can we manage to transfer the research findings to society? These questions also open another line for further research.

NOTES

1. The Fennema-Sherman scale (1976), the Mathematics Anxiety Rating Scale (Richardson & Suinn, 1972), the Enjoyment of Mathematics and the Value of Mathematics scale (Aiken, 1974), the Mathematics Attitude Inventory (Sandman, 1980), etc.

Working Group 10

2. While authors such as Fennema and Sherman used the term “attitude” to refer a set of feelings that individuals may have towards mathematics, such as “I like mathematics”, or “mathematics is a boring issue”, other researchers prefer the use of the term “beliefs”, such McLeod (1994). Fennema and Sherman (1976) developed the Mathematics Attitudes Scale including different sub-scales (values, beliefs, confidence in learning mathematics, math anxiety and disposition towards active problems solving). McLeod (1994) proposed a range between beliefs and emotions, with attitudes in between, assuming that “emotions” are more intensive and less stable than “beliefs”. “Attitudes” are in between these two extremes.

3. In 1946 Asch published a study about how individuals create an “image” of somebody (Asch, 1946). He chose two sets of university students. He gave them a list of personal features from an unknown person. Both list included the same adjectives (smart, handy, decisive, practical, and prudent), but one. Asch added “warm” to the first list, and “cold” to the second one. Students that received the first list described the unknown person as somebody “generous”, “kind” and “happy”. The second set of students came with adjectives such as “miserly”, “unhappy” and “unpopular”. This study suggested that identity is a result of a social construction.

4. FAMA: Family Math for Adult Learners. Number of reference: 504135-LLP-1-2009-1-ES-GRUNDTIG-GMP. This project has been funded with support from the European Commission. This publication paper reflects the views only of the author, and the Commission cannot be held responsible for any use which may be made of the information contained therein.

5. In Spain to become a nurse assistant is not required to go to the University to get the certificate. There is a vocational training course to obtain this professional accreditation.

BETWEEN SCHOOL AND COMPANY: A FIELD OF TENSION?

Toril Eskeland Rangnes

Bergen University College

This paper is based on a school/company collaboration that involves mathematics learning conversations among 8th grade pupils. It illustrates how the different goals for the use of mathematics in these fora, create a field of tension in which the pupils encounter different languages and modes of thought. Taking mathematics conversations in and out of school as a starting point, the polyphony of this field of tension is analysed and discussed on the basis of Bakhtin's ideas of dialogism. In addition I will consider how the encounter with different voices influences the pupils' positioning and strengthens their participation in making decisions.

Key words: Conversations, realistic mathematical education, pupils' positioning, polyphony.

INTRODUCTION

In the context of a more general debate in Norway on the theorisation of schools, mathematics as a subject has been criticised for its distance from mathematics in everyday life. The politicians have encouraged practical mathematics, with a focus on literacy (reading, writing and numeracy) which includes “to identify, to understand, to interpret, to create and to communicate” (Utdannings- og forskningsdepartementet, 2004, p. 33) in the Norwegian National Curriculum. Oral skills are emphasized, as well as the ability to apply problem solving and investigation on the basis of practical, everyday situations (LK06, Norwegian National Curriculum for Knowledge Promotion in Primary and Secondary Education and Training). LK06 mirrors OECD's (2006) perception of mathematical literacy as a positive and necessary skill if one is to succeed in society and participate as a democratic citizen. Cooperation outside of school (e.g. with local companies) is encouraged, in order to learn and be motivated (LK06). Although more practical approaches and outside contact are encouraged, there has been little research into the learning that takes place when pupils in lower secondary school cooperate with institutions outside school to learn mathematics.

The purpose of this paper is to examine conversations in which 8th grade pupils (ages 13–14) encounter different mathematical practices and how this influences their positioning and language usage. This is also an exploration of how conversations can close or open up possibilities for further discussion and consideration of options, as well as for critical reflection about school mathematics vs. company mathematics.

Research in this field is limited, although there are studies of conversations in which everyday discourse and school mathematics discourse meet (e.g. Rønning, 2009). There have also been studies of adults attending courses to develop numeracy associated with work and everyday life (e.g. Wedege, 2010). Essential to this paper

is that the sequences have been taken from a project with the aim of allowing secondary school pupils to learn mathematics in the context of a company they initially know little about. It was not part of the pupils' everyday life, and it is different from the school mathematics practice they knew. The teacher and the pupils engaged in developing a new practice together.

In this case study the pupils meet two kinds of practices; those of the school, governed by learning goals in mathematics as defined in the curriculum and effectuated by the teacher; and those of the building company, guided by production goals, efficiency and profitability. This creates a field of tension where participants are confronted with different goals, practices and language and where they have to cope with the challenges this entails. Johnsen-Høines (2010) describes the pupils' movement between school and company as a learning loop. This movement is not confined to location – rather, it is about how the *moving between* is present in conversations both in school and in the building company.

The pupils were told beforehand what the mathematical and social goals were. The assignment given to them by the teacher and the building company was to construct 3D models of a *rorbu*, a combined boathouse and seaside cottage, which is popular in this coastal region. Initially, the building company sent the pupils several construction drawings of different size *rorbu*. These were to provide a basis for the pupils' own construction drawings and suggestions for possible room plans. The group were to take their construction drawing to the company, and discuss their drawing with a carpenter. Back in the classroom, the pupils produced 3D models at a scale of 1:25 based on their construction drawings.

THEORETICAL FRAMEWORK

Wedegé (2006) describes the differences between working with mathematics at work and mathematics in school on the basis of the experience of her adult students. For instance, she notes that in professional life, one has to find the relevant information oneself, whereas in school, one is given problems cleansed of unnecessary information. According to Wedegé even “reality” has a different function. In professional life, reality provides opportunities to use mathematical ideas and techniques, and solutions have practical consequences; whereas in school, it serves as pretence for using mathematics, and the results usually have no practical consequences. Furthermore, the tasks in professional life are governed and structured by technology, whereas in school, the mathematical problems structure the teaching (Wedegé, 2006, p. 217).

The benefits achieved from boundary crossings between school and company settings with different cultures, is a moot point. To understand and to question one's own culture, outsidersness can be a most powerful factor, according to Bakhtin (1986, p. 7). The dialogue between cultures, does not result in merging and mixing, he says,

since “each retains to its own unity and open totality, but they are mutually enriched” (Ibid, p.7).

In Bakhtinian dialogism, the utterance is the unit of analysis. An utterance, which can be a word, a sentence, a drama or a dissertation, can never be studied in isolation, but must be seen in relation to the preceding utterance and its continuation in the utterance that follows. Utterances must, according to Bakhtin, be seen in light of time; present, past and future. They must be seen in relation to context: Social, cultural and historical (Bakhtin, 1986).

Bakhtin never explicitly defines polyphony (Morson & Emerson, 1990) but rather describes it as a space in which different opinions, understandings and linguistic settings are expressed (Bakhtin, 1981; 1986). The voices in a polyphony can be identified through choice of theme, expressivity and purpose. An utterance may contain several voices. In order to create understanding, however, an utterance has to be more than different voices; there is also a need of tension and struggle between them (Dysthe, 1999, p. 76).

A dialogue which opens up for polyphony can be contrasted with monologic talk, in which one person or group has the power to decide the topic and the mode. Polyphony opens up for different possible positions including critique and negotiation of power. This is in accordance with the perception of “power as a relational capacity of social actors to position themselves in different situations and through the use of various resources of power” (Valero, 2004, p. 15). In this case study the Bakhtinian theory of dialogue, polyphony and positioning is a tool for describing pupils’ movement between different forms of argumentation which can be positioned in a school mathematics discourse or in a company discourse.

The form of the conversation is related to how power is divided between the participants. An inquiry dialogue is considered a conversation in which there are symmetrical relationships between the participants and the participants investigate each other’s perceptions (Alrø & Skovsmose, 2002). Lindfors (1999) stresses that the object of an inquiring utterance must be an authentic wish to seek others’ help to investigate what lies beyond that which one understands. Through an inquiring attitude one also shows what one knows. To ask in order to invite others involves risk taking since one demonstrates one’s need for the other’s good will, as they must listen and interact (Ibid). However dialogue is not only about question/answer; it is about the construction of meaning and is included in a social practice (Bakhtin, 1981, p. 121).

With Lindfors’ (1999) inquiry dialogue and Alrø & Skovsmose’s (2002) inquiry co-operation model (IC-model) as a background, I will in this paper describe dialogues in which the participants demonstrate an intention to listen and contribute, as in an “inquiry dialogue”. In such a dialogue, in which awarenesses meet, there lies an opportunity for change in the participants’ awareness. (Lindfors, 1999, p. 150). In

this respect, dialogical conversations stand in contrast to monologic ones where an authority holds the truth and tries to persuade or guide other people's choices.

These perspectives give me a basis for answering the questions: *What are the characteristics of the pupils' conversations when they encounter in school and workplace? What different positions do the pupils take in the conversations as they move between different and to some degree contradictory voices?* Implicitly, this will highlight how relational power moves between the participants in conversations.

METHOD

The research project "Learning Conversation in Mathematics Practice" (LCMP) [1] of which this study is a part, cooperated with teachers in a municipality which intended to focus on the aim of carrying out practical learning in mathematics in cooperation with local enterprises. In this project student teachers were active in developing the teaching in this program. After graduating, one of these students wanted to try cooperating with an enterprise in her first year as a teacher. Her argument for doing this was that some of her pupils prefer practical work, and most of her teaching was theoretical. At the teacher's request, I was her conversation partner in the project. The teacher had the main responsibility for the design of the teaching plan and the implementation of the teaching. My role as a researcher was explained to the pupils; they were told that it was OK to communicate with me, but the teacher was in charge of the project.

The teacher and the researcher met the company carpenter for an initial clarifying conversation, in which it was made clear that it was their practical application of mathematics in the company that was of interest. The carpenter's role in the company is, among other things, to advise customers and to plan annexes and minor new buildings.

Gert Hana (researcher in LCMP) and I followed two groups with video cameras and sound recorders for seven sessions, one of which was at the company. The members of groups we followed were selected by the teacher. The groups were not based on mathematics ability; the only criteria were that the participants' were able to participate in conversations and that they had consented to take part.

In order to study both the form and the content of the conversations, the analysis has been inspired by both conversation analysis (Nielsen & Nielsen, 2005) and pragmatics (Svennevig, Sandvik & Vagle, 1995). In this paper I present three conversation sequences from one group of five pupils. In the conversations presented the active participants are two girls (Anne and Hilde), two boys (Daniel and Jonas), the teacher and the carpenter. The sequences have been selected because, according to Bakhtin's description of polyphony, they illustrate meetings between different voices based on the contextual dissimilarities represented by school and company. There is, of course, always a risk when interpreting conversations that one finds what one is looking for. To minimize this danger, possible interpretations have been

discussed in the research group that I am a member of and with the teacher. Alternate interpretations have been continually tested against each other; due to limitations of space, this material cannot be included in this paper.

CONVERSATIONS RELATED TO CHOICES OF *RORBU* MODEL

Sequence 1: Establishing the parameters

Anne was not present when the group made their sketch and needs information about the construction drawing of the *rorbu*. She asks Hilde about the plan floor and is told that there will not be two floors [2]; they will just plan the upper floor.

Anne: Won't it look like this, then, with only one floor? (Forms a one-floor structure with her hands) and not like *this*? (Then forms a two-floor structure with a slanting roof.)

Hilde: The teacher said not to make a roof. She said we could just... imagine a shoebox, she said (Forms an imaginary shoebox with her hands.)

Anne: OK. I'll imagine a shoebox. (Forms a shoebox with her hands.)

This conversation between Hilde and Anne must be seen in light of the conversation with the carpenter which they are preparing for. Anne's question reflects her experience with her family's *rorbu*. Her question, "won't it look like this with only one floor?" as she demonstrates the shape, can be seen as an argument in a discussion. Her realistic *rorbu* model with two floors and a roof becomes a counterargument to the group's artificial model with only one floor and without consideration of the slanting roof. Hilde responds by repeating the teacher's simplification: No roof, imagine a shoebox. I interpret this as a counterargument based in a school context. The choice between the two models has implications related to floor space and determines how they will proceed. Hilde refers to the teacher's utterance by saying "teacher said" or "she said", thereby implicitly giving her argument authority. The tension is articulated in Anne's utterance, which is positioned in a realistic out of school context and Hilde's utterance positioned in a school context. The utterance with reference to the teacher, the external authoritative voice, halts further discussion. Anne chooses to accept the school context.

Sequence 2: Exploring alternative solutions

Shortly after, the whole group talks with the carpenter about their construction drawing:

Cptr: What have you got?

The carpenter reads out loud the different rooms the pupils have drawn in, among them a room for computer games. The pupils have had heated arguments about whether there should be such a room in a *rorbu*. Floor use, space limitations, and special interests like computer games have been elements in the discussion. As the carpenter listens the pupils take up this discussion, speaking loudly and showing

Working Group 10

deep disagreement. The carpenter does not enter this conflict but directs his attention to the kitchen:

Cptr: You have placed the kitchen cabinets mainly on the knee wall. You can have base cabinets there, but not top cabinets.

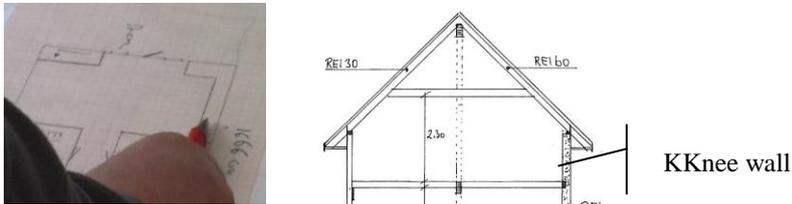

Fig 1: Carpenter points to the base cabinet on the knee wall

Daniel: [It] was a bit like that. (Points to construction drawing from company)

Anne: Yes, we looked at that. (Refers to a building plan from the company)

Cptr: The base cabinets will protrude 60 cm. (Takes his folding rule and measures 60 cm from the knee wall under the slanting roof in the room they are in.) So you can stand there doing the dishes for a while (addressed to Anne, who is standing closest to the knee wall). But not for very long. So the kitchen counter should probably be placed a bit more, so if you turned it.

Jonas: Couldn't we do it more like this, then... (He points along an inner wall.)

Cptr.: Yes, there (takes his pencil). I think I would take, put the kitchen cabinets along here (Same place as Jonas suggested where the counter is turned 90°)

The carpenter opens by asking what the pupils have to show him. This question is open and focuses on the pupils' contribution. He then looks over the plan quickly before focusing on the kitchen. This communication is both oral and written, one might say that the carpenter paraphrases the pupils' written contribution and in this way shows interest in and reinforces the pupils' contribution to the dialogue. Rather than following the pupils as they argue about who is responsible for a controversial room they have included, the carpenter zooms in on a problem he notices: The pupils have not considered the slanting roof and knee walls. This reveals his realistic approach to the model; it should be functional as if it were to be built in reality, in full scale. This supports Anne's realistic thinking. In a response to the carpenter's utterance, Daniel and Anne refer to a building plan they had been given by the company. I assume they are trying to give the company some of the responsibility for what they have done, through this reference. They defend what they have drawn and are retrospective in their positioning. The carpenter does not pick up what they say; he just goes on, communicating through a combination of words and actions. The proposed kitchen cabinet will protrude 60 cm from a knee wall. Using a folding rule, he demonstrates physically how low the ceiling will be there; a grown up will not be

able to stand upright. His expression and use of tools to demonstrate the consequences of the pupils' drawing, is polyphonic; on one hand, he instructs with the authority of a professional, concretizing to someone who is learning as in a master–apprentice relationship; on the other hand, he points out the consequences of choices in planning layout, as in a consultant–customer relationship. He indicates a possible solution: The kitchen counter could be turned. The carpenter's statements continue to be solution-oriented; he demonstrates what he would do. He uses many words to soften his statements. The kitchen counter “should probably” be placed “a little more”. When he then says they could turn it a little, Jonas is quick to suggest a concrete placement that involves turning the kitchen counter 90 degrees. The carpenter agrees with this proposal with a simple “yes” and adds “I think I would...” which suggests that others may have a different opinion. The pupils in this sequence choose to position the utterance in different ways; most of them are defensive and preoccupied with the distribution of responsibility and with explaining their choices; only Jonas chooses, like the carpenter, to look ahead towards possible solutions.

Sequence 3: Considering other perspectives

This last conversation sequence was recorded about a month after the visit to the company. In the meantime, the pupils had, among other things, practiced constructing a 90° angle using a compass and ruler, and measuring and drawing angles using a protractor.

In this sequence, Jonas and Daniel are discussing whether to cut the inner walls according to a shoebox model (wall height in real life: 1.4 m) or whether to allow for knee walls and full ceiling height, as in a realistic model.

Fig. 2: "If you have a cabinet there, right?"

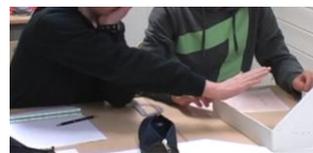

Fig. 3: "It slants"

Daniel has arguments for both the models, and uses a practical form of argumentation. In fig. 2, he points out that a cabinet will look rather odd against the inner wall in a shoebox model. He then balances this by adding that this kind of a shoebox model is easier to make. They then refer to what the teacher has told them to do, which is the shoebox model. Nevertheless, Daniel returns to the cabinet argument (fig. 3).

Daniel: But then they (inner walls) must slant, then we have to make the correct angle on all of them. That's a drag.

Jonas asks me what they should do. I tell them I don't know what teacher has said. Daniel comments: “No, well she says different things”. Teacher comes in:

Jonas: What should the inner walls be like?

Working Group 10

- Daniel: Should we make them with a slanting ceiling?
- Jonas: Should there be a slanting ceiling here or should it just go straight along?
- Daniel: That'd be a bit silly 'cause if you have a cabinet, right, it should fit with the slanting ceiling.
- Teacher: What do you want to do?
- Daniel: It will be easier if ... but a slanting ceiling is better.
- Jonas: No, it's difficult (Daniel signals his agreement through sounds and gestures)
- Teacher: Is it difficult?
- Daniel: Yeah, you have to know the angle of...
- Teacher: Yes, or the height here and here, and then it will slant automatically.

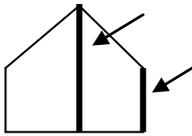

Fig. 4. Teacher points out the heights the pupils need

The boys get going at once. Their concern has been addressed.

In their conversation with the teacher, Daniel and Jonas first clarify the question they are asking, they refer to the possible choices they are facing. In so doing, they also demonstrate their insight into the problem area. They take the pupil role, asking the teacher as an authority. At the same time, Daniel is arguing against the teacher's shoebox model. In his arguments, he draws freely on the carpenter's realistic model, which problematized the location of the kitchen counter and lack of room for cabinets – the cabinet will be too tall in relation to the walls. A field of tension develops between Daniel's argumentation and the teacher's open follow-up questions, making room for polyphony. The teacher empowers the pupils when she asks them what they prefer. In her response to the pupils' problem with the angles, she gives them an alternative way to find out the slant of the walls. The teacher's statement is also polyphonous. It can be interpreted from the perspective of a practical context, in which she gives the pupils a practical solution to the immediate problem, and can also be interpreted from the perspective of a school mathematics, in which she opens for a new field of learning, with regard to the characteristics of similar triangles and the connection with trigonometry. The result of teacher's statement is that Daniel and Jonas are given a real choice as to how advanced they are going to make their model. Their voices and choices have been clarified in the field of tension between school and company.

CLOSING REMARKS

Returning to the first sequence, the conversation between Anne and Hilde appears to start as a balanced conversation between two pupils who position themselves

Working Group 10

differently. Anne has “real-world” knowledge about *rorbu* since her family owns one, and Hilde has the knowledge gained in the discussion with the group and with the teacher. The balance was altered when Hilde positioned herself in a school context and referred to an external authority, which left little room for negotiation. In the second sequence, between the pupils and the carpenter, the conversation is dominated by the carpenter, who shows genuine interest in the drawing the pupils have made. The pupils are on the carpenter’s home ground, discussing their drawing with an expert. In many ways the carpenter speaks to the pupils as he would to customers, pointing out possible solutions. However, the pupils do not have the real power a customer/buyer would have, so there is little symmetry in the conversation. I have chosen to call this interaction pattern a master/apprentice conversation. In the third sequence, the conversation between Jonas, Daniel and the teacher, I would characterize the interaction as an inquiry dialogue, in which the participants are exploring each other’s perspectives. Here, the pupils’ argumentation is given room; they are allowed the opportunity to explain their arguments and what they consider difficult.

These three sequences have different purposes and qualities. I have identified how the participants, both the pupils and the teacher, make use of voices from both school practice and “real world” in their argumentations. In this case, placement in a field of tension where the participants are confronted with different goals for the use of mathematics (Wedge, 2006), seems to open up for polyphony (Bakhtin, 1981) and make the polyphony more visible. The differences between school and company give the participants experience related to argumentation, language usage and choices. In this way, polyphony opens up for the pupils’ voices to be used and strengthened. The pupils’ participation in polyphone dialogues gives reason to believe there is potential for developing critical reflectiveness about the practice of mathematics in and outside school.

NOTES

1. This is part of my ongoing ph.d.-study in the research project Learning Conversation in Mathematics Practice (LCMP, leader: Marit Johnsen-Høines). The study is financed by the Research Council of Norway (NFR) and Bergen University College.
2. In this area a new *rorbu* always have two floors.

ETHNOMATHEMATICS IN EUROPEAN CONTEXT

Charoula Stathopoulou*, Karen François and Darlinda Moreira*****

*Univ. of Thessaly, **Free Univ. Brussels, ***Univ. Aberta UIDEF- U. Lisbon

Through a literature review we document the fact that ethnomathematics in Europe—in comparison with other places like America or Africa—are of less application. In this paper we are discussing the reasons for this late development of ethnomathematics in Europe. We explore the importance of an ethnomathematical approach to contribute and inform mathematics education of every minority and culturally different group. We intent through an ethnomathematical perspective to a mathematical education without any distinguish and which will be addressed to all students independently cultural or any other kind of differences.

Keywords: Cultural diversity, Ethnomathematics, Eurocentrism, Mathematics education.

INTRODUCTION

The research question we are focussing on is if the situation concerning ethnomathematics in a European context differs from other parts of the world, and if so why and how we can identify and explain this differences. We plead for the importance of an ethnomathematical perspective as a critical way of doing mathematics education and as an opportunity to improve mathematical education for ALL. Our analysis of the ethnomathematical perspective is mainly based on the theoretical framework of D'Ambrosio (1985, 1992) the intellectual father of ethnomathematics and Vithal & Skovsmose (1997) who analyzed the concept of ethnomathematics in a critical sense, considering that these perspectives are complementary. The research program of Ethnomathematics has been changed over the last decades. Firstly, ethnomathematics research has been associated with the mathematical practices of particular tribes or indigenous, 'primitive' peoples, as well as those of a nation and/or human race. In recent times, under the impulse of an encompassing research programme, the meaning of the concept of ethnomathematics changed and has received a much broader interpretation (François & Van Kerkhove, 2010). Looking at the description of D'Ambrosio, one can observe a rather broad meaning of the concept. D'Ambrosio speaks about Ethnomathematics as "[t]he mathematics which is practiced among identifiable cultural groups, such as national-tribal societies, labor groups, children of certain age brackets, and professional classes." (1985, p. 45) and as "[t]he arts or techniques developed by different cultures to explain, to understand, to cope with their environment" (1992, p. 1184). In his ICEM3 presentation D'Ambrosio (2006) defines ethnomathematics as "[...] a research programme in the history and philosophy of mathematics, with pedagogical implications, focusing the arts and techniques (*tics* [from *technē*]) of explaining, understanding and coping with (*mathema*) different socio-cultural environments

(*ethno*)”. Although D’Ambrosio does not restrict the application of ethnomathematics to indigenous cultures, ethnomathematics (as explicit labeled) found much more fertile ground in non-western societies. We will argue this claim by, firstly presenting the results of our literature review of both the Ethnomathematics Digital Library and the International Study Group on Ethnomathematics. From this first results on the very narrow interpretation of ethnomathematics (as explicit labelled) we will also argue that research in the field of ethnomathematics developed later in Europe and that there *seems* to be less research (or less interest) in this field. These phenomena could be explained by the concept of Eurocentrism on which we will elaborate at the end of the first part of this paper. In the second part of the paper we will investigate the notion of ethnomathematical research in a European context based on a broader perspective of the concept of ethnomathematics as related to the notion of cultural diversity. This includes the ongoing research on the relation between mathematics education and the diverse backgrounds of the students (e.g. Moreira, 2002, 2007, 2009; Stathopoulou, 2005, 2006a) and adults education which involves ethnomathematical practices (e.g. Evans, 2000; Wedege, 2010).

LITERATURE REVIEW

The method used in this explorative study is a screening of the research output of three sources: the Ethnomathematics digital library, the International Study Group on Ethnomathematics (ISGEm), and the conferences on ethnomathematics organized by ISGEm. Sources have been selected on the basis of research communities who are labelling themselves as doing research as explicit referred to as ethnomathematics research. The explorative screening of the output is based on articles and papers presented at the respective conferences. In this investigation we use the concept ethnomathematics as explicit labelling itself as ethnomathematical research. From this investigation we will argue that research in the field of ethnomathematics developed later in Europe and that there seems to be less research (or less interest) in this field. At the end of this section we will explain our findings from a sociological perspective that is dealt with in terms of Eurocentrism.

The Ethnomathematics Digital Library (EDL)

The majority of the researchers listed at the EDL at <http://www.ethnomath.org> belong to places outside Europe and very often European researchers conducted their research in places outside Europe. Our observations are highlighted in table 1. Within the European countries, the ethnomathematical research is limited and a great part of it deviates from what is considered “genuine ethnomathematical research”. Looking at the examples of Greece, Italy and Portugal almost all papers concern historical issues and thus could hardly be categorized as ethnomathematics according to the four strands of ethnomathematics proposed by Vithal & Skovsmose (1997, p. 134-135). The first strand deals with historical aspects in non-western mathematics;

Working Group 10

the second analyses the original mathematical practices of traditional cultures (mostly of indigenous peoples); the third explores the mathematics of different groups in everyday settings showing that mathematical knowledge is generated in a wide variety of contexts by both adults and children. The fourth strand focuses on the relationship between ethnomathematics and mathematics education.

Italy	7	6 historical
Greece	10	9 historical
Portugal	2	1 historical

Table 1: Overview of Ethnomathematics Digital Library

International Study Group on Ethnomathematics (ISGEem)

On the main page of the ISGEem website hyperlinks/sites are sorted according to ethnicity/geography: African mathematics, Native American mathematics, Math in Euro-American culture, Pacific Islander mathematics, African American mathematics, Latino mathematics, Middle Eastern mathematics, Asian mathematics. The research belonging to the category of Math in Euro-American culture, also hardly could be considered as ethnomathematics according the four strands mentioned above. In regard to the late development of Ethnomathematics in Europe, the situation has been changing slowly. In Portugal and Greece, e.g. several researchers have been dedicated to integrating the perspectives of Ethnomathematics in their research, e.g. Moreira, (2002); Pires (2005); Candeia (2006); (Moreira & Pires, 2006), Stathopoulou (2005; 2006a). These investigations are not included in the ISGEem website. Considering that most of it is not published in English leads us to the question of the language of publication.

Conferences of Ethnomathematics

At the 1st conference of ethnomathematics (Granada/Spain) the emphasis was on theory of ethnomathematics (e.g. Philosophy of ethnomathematics, ethnomethodology), on issues of mathematics teaching/ learning and on the connection of ethnomathematics to critical mathematics education. The main part of the research was on indigenous population while even European researchers had conducted their research out of Europe (e.g. F. Favilli's research was on Somalia). At the 2nd conference (Ouro Preto/Brazil) there was a specificity regarding the structure. The majority of the researches were presented in poster's form. Apart from it there were round tables and a few lectures. The opening lecture was Freire's contribution on Ethnomathematics, the closing concerned an overview of ethnomathematics. The other two focused on philosophy of ethnomathematics and the Eurocentrism of

mathematics. Ethnomathematics and indigenous people, ethnomathematics and rural education, ethnomathematics and its theory, ethnomathematics and teacher's qualification, ethnomathematics and its history were the focus of the round tables. At the 3rd conference (Auckland/New Zealand) the main part of the papers concerned indigenous cultures. Another part concerned theoretical issues of ethnomathematics as well as issues of more general interest. There were four papers that came from European countries; two from Greece (Stathopoulou, 2006b; Stathopoulou & Chaviaris, 2006), one from Norway (Onstad, 2006) and one from Sweden (Norén et al., 2006). At the last conference (July 2010 at Towson-Baltimore/USA), more percentage than in previous conference concerned indigenous cultures. Also issues of indigenous teachers and teachers in general were discussed. Political and methodological aspects of ethnomathematics occupied a considerable part of the presentations. There was one panel on Ethnomathematics in a European context in which the authors participated.

Eurocentrism

By ethnomathematical research and approach we referred to that literature which is deliberately labelled as ethnomathematics. Based on this narrow interpretation of ethnomathematics research we used in our literature review we can observe that studies in ethnomathematics in Europe are scarce. The outcomes of our non-exhaustive review are indicative of the progress of the ethnomathematics research in Europe. We dare an interpretation for this late development of ethnomathematics to Europe. The fact that ethnomathematics to a large extent, emerged as a contradiction to the domination of western mathematics seems to be one of the main reasons that ethnomathematics were developed later in Europe. Powell & Frankenstein (1997) suggest that ethnomathematics could contribute to the elimination of many false dichotomies such as 'practical, everyday knowledge' versus 'abstract, theoretical knowledge'. What is mostly discussed here is the fact of the domination of western mathematics and in general, the western culture that, using an evolutionist schema evaluates any other culture in comparison to itself. Greenhalgh & Megaw (1978) commenting the European interest about anything non-European, reveal that European people always tend to assimilate the various and independent art traditions of the other cultures through a diffusionist schema in the center of which there are their own experiences. Correspondingly, mathematics of other cultures are approached and evaluated in comparison to western mathematics. For a long time, western mathematics are appeared as an authoritative knowledge, as a corpus of cognition and perceptions that is preferential to others, since it is considered that are more close to the 'absolute truth'; the non-western mathematics are "measured" by the meter of western mathematics. There is no scientific perspective or any other that has not its roots to particular stories and prejudices; something that is imminent in human beings (Erickson & Murphy, 2002: 203). Concerning mathematics, Ghevarughese (1987) suggests that "there exists a widespread Eurocentric bias in the

production, dissemination and evaluation of scientific knowledge." He diagrams the "classical" Eurocentric approach as follows:

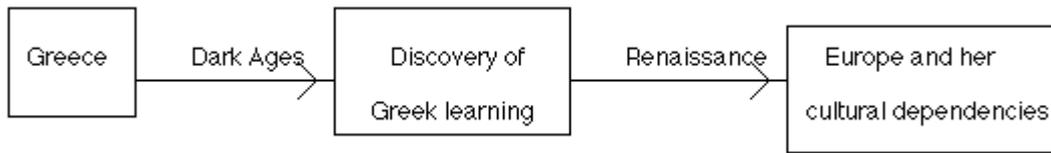

Figure 1: Eurocentric Approach on the Development of Mathematics

Ernest (2008), in this spirit, notes that many histories of mathematics, such as Eves (1953), promote a simplified Eurocentric view of its development:

Typically such accounts identify Mesopotamia and Egypt as the sites of preliminary work that provided the raw materials for mathematics. Based on this, the flame of 'real' mathematics was lit by the Ancient Greeks, kept alight by the Arabs during the Dark Ages, until when passed on like an Olympic torch, it blazed anew in modern Europe and her cultural dependencies (Ernest, 2008, p. 93).

A perception like this ignores the connection of mathematics with the corresponding culture, as well as the fact of major contributions to the corpus of academic mathematics of non-western cultures as the invention of the decimal place value system with zero in India is (Ernest, 2008). Ghevarughese (1987) claims that this Eurocentric approach served as a "comforting rationale for an imperialist/racist ideology of dominance" and has remained strong despite evidence that there was significant mathematical development in other places. This imperialistic/racist perspective of western mathematics has not only its consequences for non-western contexts. A lot of European cultures –we dare to use the plural since there is no single and unique culture in Europe- face these consequences. Although the differences in European classrooms are not so obvious, comparing with indigenous people in e.g. USA. European classrooms have to deal with a lot of students coming from minority and marginalized groups. These challenges have their impact in math classes since mathematics education is an acculturation procedure (Stathopoulou, 2006a). All groups that are marginalized and oppressed by the dominant culture and the educational system are facing more problems since their culture is contemned. Thus, teachers—teachers of mathematics— face the challenges of teaching in multiethnic and multilingual classrooms that includes students belonging to the above groups. Apart from the minority students coming from immigrants and refugees, traditional cultural groups, such as Romany students do also contribute to the formation of current classrooms. In the following part of the paper we will investigate the notion of ethnomathematical research in a European context bases on the broader perspective of the concept of ethnomathematics.

TOWARDS AN ETHNOMATHEMATICAL PERSPECTIVE

The increasing cultural diversity in Europe has been changing the landscape in the European classrooms. The debate on the concept of cultural diversity leads to the

Working Group 10

question of equity and social justice that has been pointed out as one of the main challenges in the (research) field of mathematics education. In Europe equity in mathematics education has become an important issue since basic education is mandatory and mathematical literacy has been seen as a human right. However institutional education (e.g. schools, curricula, ...) results in exclusion of a large number of students that do not succeed in schools, being most of them from cultural minority groups. Moreover student population in Europe is not only a much more cultural diverse group; their diversity has also a strong correlation with the achievements in education. The same observation has been done in the USA by Suárez-Orozco & Suárez-Orozco (2002). They observe that “today’s immigrants are a much more diverse group than ever before in terms of educational background and skills” (2002, p. 56).

Due to the shifted multicultural settings in schools and the increased variety of cultural diversity, questions and challenges in the (research) community of mathematics education has been changed. One important challenge is the background of the students; the valorization of students’ socio-cultural roots and their previous knowledge. It is important to deal with this starting position because it contributes to the future learning of the students and it contextualizes the act of learning. Indeed, the heterogeneity of the school population is expressed in various ways: language, behavior, habits, ways of enhancing the own knowledge, ways of giving meaning to school contents. In addition, when we talk about education we consider that educational processes happen within particular socio-cultural contexts, being school one of them. Indeed education is a vast process with the presence of several protagonists who use different strategies and learning technologies which are located mainly in the family, school and community (Pinxten, 1997; Moreira, 2007). Hence, an important issue for current thinking about educational inclusion is located at the epistemology of social groups. Since learning and its specific processes are socially and culturally situated, social group theory of learning and knowing emerges as essential to frame the educational content and to give meaning to social practices –being it school or communities based practices. To the extent that education conducted by the school is based on assumptions and educational processes different from those usually carried out in domestic groups –which are reflected particularly in the substantial differences between rationalities, discourses and practices– children from social groups that are more familiar with the school’s body of knowledge and artifacts have a higher probability of school success. Both the ethnographic research and theoretical/critical reflection have been showing how school achievement is related in many different ways to the cultural background of students, which withdraws or is legitimated in schooling. Furthermore, the different life histories of the students are immersed in memories, affections and knowledge that demonstrate the existence of different relationships to knowledge and how learning are processed in different ways, based as they are in their own cultural epistemologies. In this sense, one of the educational functions of schooling is seen as a way to connect and transfer discourses

Working Group 10

and practices among different social groups, being necessary to bear in mind that different types of knowledge are embedded in their own contexts, which imply the presence of cognitive processes, forms of thinking, teaching and transmitting knowledge to new generations, leading even applications, objects, problems, technologies, and particular professions (Moreira, 2009; Stathopoulou, 2002).

Research in the field of ethnomathematics –even in Europe– is clearly showing that communities are locus of mathematical knowledge much of which is yet to be considered and legitimized in schools. Acting as a strong source of criticism of how the mathematical activity of different groups has been erased or ignored by schools, ethnomathematics has been questioning the disjunctions between home based and school-based mathematical practices. Ultimately the findings from ethnomathematics show how we need to go beyond universalist and essentialist notions of mathematics and the need to build a mathematics that is based on everyday experience of mathematics, opening the door to the wealth of knowledge of various social groups. It is however necessary to think about how to interpret such perspective in the context of each particular educational setting because each one possess its own diversity and gives a meaning to it according to one experiences of the complex social fabric of present societies. Each classroom and each school imprints a particular dynamics that requires a different knowledge about the setting, the people and the culture. As Chuche points out, “in cultural construction, what comes first is the culture of the group, the local culture, the culture that joins individuals with immediate interaction with each other, and not the global culture of the larger collectivity.” (1999, p. 87). Also Pinxten (1997) reminds us that:

[A]n educational program will most probably be more efficient if it draws on the native strategies for thinking and learning than when simply implementing the western (or for that matter any other) way. (...) [T]he particular classifications and notions of a culture will in all probability constitute the best material to work within an educational setting (Pinxten, 1997, p. 135-136).

From an ethnomathematical perspective, the local references and practices have to be taken into account as a starting point of the educational process. This is, an ethnomathematical perspective that leads to an innovative reflection in educational settings and thus can change the traditional educative paradigm with its depreciation of the experiences and knowledge that students bring from their culture and daily life.

We are indeed aware of the pits and falls and the pedagogical implications of the ethnomathematical perspective. In recent years strong criticisms are made to such implications (Skovsmose & Vithal, 1997; Rowland & Carson, 2002; Adam, Barton & Allanguí, 2003; Knijnik, 2006; Duarte, 2006; Domite and Pais, 2009). These studies make aware of a counter effect by implementing ethnomathematical ideas into school curricula (e.g. social exclusion, de-substantialization of Other’s culture, essentialist approaches to culture). This observation gives rise to a central question if

the import of the concept ‘ethnomathematics’ benefits a European critical math education that is looking for social justice and math education for *all*. In the frame of this paper we can only mention this topic, knowing that deepening this issue will be the focus of further research.

CONCLUSION

In this paper we focused on the late development of ethnomathematics in Europe and the reason thereof. Based on a literature review of three sources from the ethnomathematical research community (as officially labeled) we can observe indeed a different ethnomathematical investigation in a European context. Part of the reason we explained by the concept of Eurocentrism, which includes a perspective on ethnomathematics as the study of mathematical practices of non-western cultures based on the cognitive categories of European research. This narrow interpretation of ethnomathematics gave rise to an imperialistic view on western mathematics which is not restricted to a non-western context. The European landscape changed into a multicultural society with a rich variety of diversity and even in this European context of diversity, the imperialistic perspective comes into play where school curricula do not deal with the diverse background of students. In this paper we referred to undertaken and ongoing ‘ethnomathematical’ research in a European context that focuses on this topic. More research has to be done in this area and there is a need to bring more results of this research to a broader public by translating it into the lingua franca.

DOCTORAL PROGRAMS IN MATHEMATICS EDUCATION: CURRENT STATUS AND FUTURE PATHWAYS FOR TURKEY

Behiye Ubuz¹, Erdinç Çakıroğlu², Ayhan Kürşat Erbaş¹

¹ Middle East Technical University, Department of Secondary Science and Mathematics Education

² Middle East Technical University, Department of Elementary Education

The purpose of this paper is to review the current state of doctoral programs in mathematics education in three Turkish universities. In this context, we first provide brief background information about Turkish higher education system and teacher education policies in Turkey. Then the major national initiatives towards future faculty development efforts are explained. Finally, the nature and components of mathematics education doctoral programs in Turkey is provided. In doing so, we provide information about admission procedures, requirements for coursework and dissertation, and employment opportunities for those with a doctoral degree in mathematics education.

Keywords: doctoral programs, mathematics education, higher education in Turkey

INTRODUCTION

Mathematics education in Turkey is relatively young compared to other educational areas such as educational administration and educational measurement. Undergraduate programs focusing specifically on mathematics teacher education in Turkish universities began to appear after the establishment of *Yüksek Öğretim Kurulu* (YÖK) [The Turkish Council of Higher Education] in 1981. While establishing these programs, the staff requirements were filled mostly by mathematicians, not by mathematics educators. Moreover, faculty in educational sciences has supported these programs in the pedagogical sense, without focusing much on mathematics. As Shulman (1986, 1987) and many others (e.g., Ball, Thames, & Phelps, 2008; Hill et al., 2008) have either suggested or provided evidence that simple combination of expertise in mathematics and educational sciences do not guarantee a sound base for quality instruction in mathematics. Instead, a pedagogical basis specific to mathematics needs to be established. Such a perspective calls for an audit of mathematics education programs and draw attention to the need for doctoral degrees in mathematics education for supplying quality staff for these programs.

Our goal in this paper is to describe the current state of the mathematics education doctoral programs in Turkish universities as every country is diverse and unique in its own way. For such a young field in Turkey, doctoral programs play a crucial role in the future of mathematics education. In fact, doctoral programs create contexts in which traditions of research, approaches to issues about school mathematics, and philosophical stands are produced and re-produced. In this sense, the nature of these

programs and the discourse growing in these environments will have direct and indirect impact on cultural and political issues about mathematics education in Turkey through the graduates of these programs and work produced by the people involved. On the other hand, this paper contributes to our understanding of diversity in mathematics education doctoral programs on a global level in terms of components of these programs (e.g., program activities, students, faculty and/or staff, outcomes) and the contexts they function in various countries.

In Turkey, mathematics education research on graduate level has been conducted in various programs, such as early childhood education, primary education, and the educational sciences. However, our discussion in this paper is limited to the programs offering degrees in elementary and secondary mathematics education. A better understanding of the mathematics education doctoral programs is possible when they are situated within the larger context of higher education and teacher education policies in Turkey. Thus, we will begin with a brief background of Turkish higher education system and teacher education policies. Then we describe faculty development attempts before discussing specifically the nature doctoral programs in mathematics education.

HIGHER EDUCATION SYSTEM AND MATHEMATICS TEACHER EDUCATION IN TURKEY

In Turkey, there is a unified system of higher education under the surveillance of the Council of Higher Education. Currently, in this system, there are 93 state and 38 private universities throughout Turkey (YÖK, n.d. -a). Each university consists of faculties offering undergraduate programs. Admissions to these programs are centralized and based on a nation-wide examination conducted by *Öğrenci Seçme ve Yerleştirme Merkezi* [the Student Selection and Placement Center]. Graduate programs for master's and doctoral degrees, on the other hand, are offered under the graduate schools in universities. According to the Council of Higher Education, in the 2004-2005 academic year, the total number of graduate students in Turkish universities was about 120 000 (YÖK, 2007). Of this number, 92 600 students were in master's and 27 400 in doctoral programs. No data were available for the graduate programs offering degrees specific to mathematics education.

Four year undergraduate mathematics teacher education programs were established within the faculties of education for initial training of teachers, since the establishment of the Council of Higher Education. Until 1998, mathematics teacher education programs trained teachers for both middle and high schools (grades 6 through 11). After that time, the programs were re-established so that the training of teachers for middle (grades 6 through 8) and high schools (grades 9 through 12) were separated. In fact the changes in 1998 were beyond this separation, as teacher education programs in Turkey had undergone a major reform movement. The changes include, (i) shifting the focus in teacher education to the quality of teacher, (ii) focusing more on the middle and elementary grade levels, (iii) developing

master's level programs for teacher education, (iv) focusing more on the methods of teaching relevant to specific subject matter, and (v) meeting the shortage of faculty in these programs (Simsek & Yildirim, 2001).

Although this reform movement aimed to improve teacher education programs throughout Turkey, the faculty development aspect of it had significant impact on research and graduate programs in the coming years. Increased number of faculty members in mathematics education resulted in developments in graduate programs.

FACULTY DEVELOPMENT

Although there have been some efforts to increase number of graduates having doctoral degrees, universities in Turkey still experience the problem of faculty shortage for teaching and research. There is an acute shortage of faculty members in terms of both quality and quantity in higher education institutions and the doctoral programs currently exist in the system is insufficient to supply that demand (YÖK, 2007, p. 132). In response to such shortage, bodies organizing and coordinating higher education such as the Council of Higher Education and the Ministry of National Education (MoNE) have taken certain actions to support students in graduate level studies according to Law numbers 2547 and 1416 respectively (Government of Turkey, 1981, 1929). Within this context, supporting students to study their graduate education abroad is the most important initiative for faculty development. Following this attempt, another initiative for addressing shortage of faculty members in higher education is a doctoral scholarship program for studying in Turkish universities.

Both the Council of Higher Education and the Ministry of National Education have been sending selected students abroad mostly to get their doctoral degrees in various disciplines. Every year these institutions determine the number of doctoral degrees to be pursued abroad. Candidates are selected based on their academic records, language proficiencies, and the priority of the field in that year. Candidates are also required to have an acceptance from the host university. Those students must successfully finish their studies and come back to Turkey to claim a position for which they have been sent for—a compulsory academic service. The amount of compulsory services is about two years' service for every year s/he received the scholarship. In the case of no-returns or failure to finish studies successfully, the recipients must pay back the amount received with interest (Tansel & Güngör, 2003).

Between 2003 and 2008, 300 students who were sent abroad with the MoNE scholarship returned to Turkey after completing their studies successfully. Half of these students were education majors (e.g., elementary education, social sciences education, mathematics education, and science education—including physics, chemistry, biology education) and received their degrees from the universities in the United States ($n = 106$), France ($n = 21$), and the United Kingdom ($n = 23$). Twenty-one of the education majors received their graduate degrees in mathematics

Working Group 10

education (7 from France, 6 from the United Kingdom, and 8 from the United States). The people who completed their doctoral studies abroad are currently working in Turkish universities. On the other hand, as of December 2008, 940 graduate students are studying abroad (mostly in the United States, 74.7%) with a scholarship provided by the MoNe. Hundred-and-twenty of those are in education related fields. Among them, about 23 to 27 of the graduate students are studying in the area of mathematics education.

Like the MoNe, between 1987 and 2008, a total of 3899 graduate students were sent to abroad to thirty different countries by the Council of Higher Education. In 1996, the Council of Higher Education has established a board, the Board for the Training of Academic Staff and Researchers, to coordinate this program. A great portion of the scholarship students has been sent to the United States (n = 1941) and the United Kingdom (n = 1454). A great majority of these students (n = 2485) finished their graduate education and started to serve as faculty in various Turkish universities. Among them 16 has received their doctorates in mathematics education, 7 from the United States and 9 from the United Kingdom. While 297 of the scholarship students are still in progress, the remaining students either did not finish their studies (n = 386) due to reasons such as failure and health; or did not return to Turkey (i.e., brain drain) and/or resigned from the scholarship (n = 731). The statistics about the scholarships provided by the Council of Higher Education and the Ministry of National Education were obtained from these institutions through official communication, and based on unpublished data. Some published statistics covering the years up to 2005 was provided in a report by *Türkiye Bilimler Akademisi* (TÜBA) [Turkish Academy of Sciences] (TÜBA, 2006).

The second leg of the faculty development efforts is the scholarship opportunities for seeking doctoral degrees in Turkish universities. These efforts have two legislative bases: first one is the Article 35 of the Turkish Higher Education Law No 2547 and the second one is the “Faculty Development Project.” The Article 35 of the Turkish Higher Education Law No 2547 (Government of Turkey, 1981) concerns the needs of teaching staff of the higher education institutions. According to that law, all higher education institutions, whether established or yet to be established, are responsible for educating future faculty members. Within this context, the Council of Higher Education designated more research assistantship positions to universities. In case of lack of faculty members and doctoral programs in a particular university, the assistantships in that particular university are allowed to be transferred to another university offering a doctoral program. Students who complete their doctoral studies return to their own universities to carry out compulsory service for a certain period of time.

Öğretim Üyesi Yetiştirme Programı (ÖYP) [Faculty Development Project] was initiated in 2001 with the financial support of *Devlet Planlama Teşkilatı* [State Planning Agency] in order to meet the growing need for quality faculty members in

Turkish universities. The difference of ÖYP from the above article 35 of the Higher Education Law numbered 2547 is that besides getting their salaries for the assistantship positions, graduate students are supported financially to conduct their research and to study abroad for about two semesters. Middle East Technical University (METU) was the first to offer doctoral education for ÖYP program to meet the faculty needs in other four partner universities. Until 2006, 19 other partner universities have joined the program and 562 ÖYP students were accepted for Ph.D. programs in 43 different disciplines. Currently there are eight ÖYP doctoral students studying in mathematics education at METU for different partner universities.

DOCTORAL PROGRAMS IN MATHEMATICS EDUCATION

In this part, we will explain the nature of the mathematics education doctoral programs in Turkey. In doing so, we will explain general characteristics of the program of studies - including admission procedures and various requirements-, and employment opportunities for those with a doctoral degree in mathematics education. Describing doctoral programs throughout Turkey is a challenging task for several reasons. First of all, doctoral programs in different universities have different characteristics and expectations from students. Second, the characteristics of doctoral programs are rapidly changing and new programs are being established. Finally the information about doctoral programs is available in different levels – departments, graduate schools, the Council of Higher Education– which sometimes may not be aligned with others. Despite these difficulties, we attempt to summarize general characteristics of doctoral programs by providing examples from some selected doctoral programs. More specifically, although our search in dissertation database of the Council of Higher Education has revealed that 10 universities have mathematics education doctoral programs throughout Turkey, we will only focus on the programs in three universities: Middle East Technical University (METU) in Ankara, Karadeniz Technical University (KTU) in Trabzon, and Atatürk University (AU) in Erzurum, Turkey. Considering the number of dissertations completed and their geographical regions, we consider these programs represent the diversity in mathematics education doctoral programs in Turkish universities.

The information provided in this section was obtained through the Web pages of universities and a survey sent to program chairs by e-mail to respond, which consisted of a questionnaire that included open-ended questions regarding the number of dissertations completed so far, the type of courses offered during the program, etc.

Admissions to Doctoral Programs

In Turkey, all doctoral programs are considered under Ph.D. Students can apply to a Ph.D. program after having either a bachelor's or a master's degree. Doctoral programs do not require teaching experience prior to admission. Admission to doctoral program is based on applicants' cumulative grade point average (GPA) in

Working Group 10

undergraduate and/or the masters program (if attended), their *Akademik Lisansüstü Eğitim Sınavı* (ALES) [Academic Graduate Education Exam] scores or equivalent international examination scores, such as the USA-based Graduate Record Examination, level of English language proficiency and the evaluation of other criteria required and announced by the relevant department administration, such as recommendation letters or letter of intentions. ALES is given twice a year by the *Öğrenci Seçme ve Yerleştirme Merkezi* (ÖSYM) [Student Selection and Placement Center]. This exam measures verbal reasoning and quantitative reasoning. The skills measured in verbal reasoning include the test taker's ability to analyze and evaluate written material and synthesize information obtained from it, to analyze relationships among component parts of sentences, and to recognize relationships between words and concepts. The skills measured in quantitative reasoning include the test taker's ability to understand basic concepts of arithmetic, algebra, geometry, and data analysis, to reason quantitatively, and to solve problems in a quantitative setting. Applicants' level of English proficiency is evaluated based on the result of either the university's English proficiency examination or the equivalent exams such as *Üniversitelerarası Kurul Yabancı Dil Sınavı* (ÜDS) [Interuniversity Foreign Language Examination] or Test of English as a Foreign Language (TOEFL). ÜDS is given twice a year by ÖSYM. For admission into a graduate study program, the acceptable score on these exams is determined by the recommendation of the department administration and the acceptance of the Administrative Board of the Graduate School.

Number of Faculty Members and Graduate Students

Institutions vary greatly in the number of faculty members as well as the number of graduate students. While AU has 14 faculty members in mathematics education program, METU and KTU have 7 and 4 faculty member respectively. The main reason for AÜ having more faculty members is that they offer both mathematics and mathematics education courses, which is not the case in both METU and KTU. Therefore, the program at AU employs faculty members with PhD's either in mathematics education or mathematics. While approximately half of the faculty in AU hold doctoral degrees in mathematics education, the rest have degrees in mathematics. This combination of mathematicians and mathematics educators in AU results in some doctoral students doing research in pure mathematics. For instance, only 9 out of 19 doctoral graduates in AU did their dissertation research on mathematics education (see Table 2).

Currently mathematics education doctoral programs in these three universities have 110 students in total (see Table 1). The distribution of genders of the current students and doctorates granted vary across universities. In total about half of the current doctorate and doctorate granted students were females (see Table 2). Thirty-seven of the current doctorate students have positions in the universities as research and teaching assistant. Of these 37 students, 9 are in ÖYP program and 17 are benefitting

Working Group 10

from article 35. Taking together ÖYP and Article 35, twenty-six doctoral students will return to different universities that have been assigned previously. Considering the number of dissertations completed until 2008, and the number of doctoral students currently progressing, the mathematics education will develop in the next decade in terms of the number graduates and the research. However, the rapid increase in the demand of doctoral degrees in mathematics education will eventually reach to saturation in terms of the need of faculty in the coming decades. Therefore, we believe that, it is just the time for policy makers to think about planning the supply and demand for mathematics education doctoral degrees, by considering all employing alternatives.

Universities	Faculty Members			Assistantships Status of Current Students			Dissertations Completed as of 2008
	Ph.D. earned in Turkey	Ph.D. earned abroad	Students progressing in Ph.D.	Offered by Program	ÖYP	Article 35	
	METU	2	5	52	4	9	
KTU	2	2	25	-	-	10	12
AU	13	1	33	7		1	19

Note. The numbers are as reported by the universities.

Table 1: Number of faculty members and graduate students as of early 2009

	Doctorates Granted		Doctorates in Progress	
	Female	Male	Female	Male

The Content and the Demand for Coursework

The course of studies in doctoral programs has two tracks; one for students with bachelor's degree and the other for students with a master's degree. Students who hold a masters degree must complete at least 7 courses – not being less than 21 credits in total – a doctoral qualifying examination, a dissertation proposal, and a dissertation. For those who have been accepted with a bachelor's degree, this program is comprised of a minimum of 42 credits or 14 courses, a doctoral qualifying exam, a dissertation proposal, and a dissertation. The maximum period to complete the course work is 4 semesters for students holding a master's degree, and 6 semesters for students accepted with a bachelor's degree. One credit hour for graduate courses represents an hour of lecture or two hours of laboratory work per week. Each academic year has two semesters. At the end of four or six semesters,

Working Group 10

CGPA must be at least 3 out of 4. In addition, dissertations need to be completed in four semesters. If necessary, students may use extra four semesters to complete their dissertations.

Consistent with the faculty in the program, the courses offered vary greatly in the range of mathematics, mathematics education and other topics (research courses and/or general education courses). While in KTU there are no compulsory courses, at METU some research courses such as statistics and research methods and at AU courses in science ethics and computer are compulsory. The rest of the courses are electives that are selected either by the students or by the recommendation of the supervisor. Mathematics education faculty at KTU and METU do not offer any mathematics courses, as the mathematics departments offer these courses. The official language in the universities apart from METU is Turkish. However, doctoral students at KTU are required to complete at least two courses conducted in English. All courses and dissertations at METU are conducted in English.

The Process and Nature of Doctoral Qualification Examination and Hereafter

Upon the completion of the coursework, students in each university need to take the doctoral qualifying examination. Doctoral students holding a master's degree must take this exam within their fifth semesters, and students enrolled with a bachelor's degree within the seventh semester at the latest. The doctoral qualifying examinations committee established with five members, one being the student's dissertation supervisor, are responsible to prepare and administer the qualification examinations. Committee members are required to have a doctoral degree. The doctoral qualifying examination consists of a written and oral examination to evaluate students' skills in conducting independent research and their understanding of major concepts and issues in the field.

Doctoral students conduct their dissertation research under the supervision of a faculty member whom has the position as assistant professor or above. If needed a co-supervisor may be appointed. A dissertation supervising committee consisting of three faculty members is also appointed upon successful completion of the doctoral qualifying examinations. Within six months after the qualification exam, each doctoral candidate needs to prepare and defend a dissertation proposal to a committee consisting of three members including the dissertation advisor himself/herself. Candidates are expected to prepare a doctoral dissertation demonstrating somehow an original contribution to the field of mathematics education by using appropriate methodologies.

Graduates with Mathematics Education Doctoral Degrees

The majority of doctoral graduates in mathematics education seek positions in the higher education. For example, based on our survey, we have found out that among 46 doctoral graduates of KTU, METU, and AU in mathematics education programs (see Table 1), 42 work in higher education and others are employed in test

development companies and in schools. Those employed in higher education assume a range of teaching responsibilities including teaching mathematics and/or mathematics education courses offered in the program and conduct research in the field. Considering the number of students progressing in doctoral studies (see Table 1), we assume that the graduates of doctoral programs will contribute not only to higher education, but also to other institutions, such as the Ministry of National Education, schools, or private companies in the future.

CONCLUSION

In Turkey, about 35 million people (about half of the population) is under the age of 28 (Türkiye İstatistik Kurumu [Turkish Statistics Institute], 2009). Considering that the population growth rate is about 1.013% per year, the need for education is a growing demand in Turkey. In recent years the government and the Council of Higher Education have a determined policy to increase the number of higher education institutions in Turkey. For instance, in 2006, fifteen new public universities were established throughout Turkey. Currently, 62 public universities and 5 private universities have faculties of education. With the trend of establishing new universities, there is an increasing need for faculty development. In this sense, the demand for staff is still evident for the coming few decades. Since some universities are still in the process of gathering together their staff, most of which have the potential to employ the graduates of mathematics education doctoral programs. The statistics we provided in this paper demonstrates that, in recent years, there is an increasing number of students pursuing a doctoral degree in mathematics education. However, considering the rapid increase in the number of higher education institutions, we argue that more efforts are needed to meet the need of growing faculty need. One pathway may be to find ways to enhance the possibilities for pursuing a doctoral degree in mathematics education. Another one is to explore the benefits of doing national or international collaborations in developing new programs or improving the existing ones.

While dealing with the quantity issue, another challenge for the doctoral programs in Turkey is to maintain and improve the quality. Considering the varieties in workplace of graduates, universities should try to increase the diversity in the coursework and graduate research within the mathematics education doctoral programs. In addition, doctoral programs should also try to put more efforts in offering a program of study that reflect the nature of mathematics education in variety of ways. Finally, creating a productive research community of mathematics educators that is well integrated with their international counterparts should be a major goal for the doctoral programs.

Even the Council of Higher Education has general criteria to open graduate programs in universities (YÖK, n.d. -b), the principles to guide the design and implementation of doctoral programs in mathematics education could be established to provide a number of ideas and suggestions regarding doctoral programs in mathematics

education. Besides, national conference on doctoral programs in mathematics education could be set to develop the ideas and suggestions regarding doctoral programs in mathematics education.

CONNECTING THE NOTION OF FOREGROUND IN CRITICAL MATHEMATICS EDUCATION WITH THE THEORY OF HABITUS

Tine Wedege

School of Education, Malmö University

The dialectics between individual and structure is an important issue in any sociomathematical study of students' learning conditions in mathematics education. On the basis of a conception of learning as action and intentionality as a basic element in any action, Skovsmose introduced the notion of the student's foreground as an element in critical mathematics education. The intention is to make visible learning obstacles as a political instead of an individual phenomenon based only on the student's social and cultural background. In this paper, a discussion is initiated to re-establish the significance of students' background by integrating the notion of foreground with Bourdieu's theory of habitus as systems of dispositions as principles of generating and structuring practices and representations.

Keywords: connecting theories, critical mathematics education, foreground, habitus,

INTRODUCTION

In mathematics education research, the grounding questions concern people's cognitive, affective and social relationships with mathematics. Conditions for students to learn mathematics is one of the key issues to be studied whether the focus is learning environments established in the mathematics classroom; e.g. didactical situations (Brousseau, 1986) or landscapes of learning (Alrø, Skovsmose & Valero, 2007); or the focus is students' motives for learning mathematics; e.g. motivation (Wæge, 2010) or instrumental and social rationale (Mellin-Olsen, 1987). In sociology, the grounding questions concern the connection between people and society or, from a philosophical point of view, the dialectics between individual and structure. In a sociomathematical study of learning conditions, this dialectics is an overarching theme because the societal context for teaching, learning and knowing mathematics is taken seriously into account (Wedege, 2010).

In a recent overview of the sociomathematical research field it is stated that students' positioning may cause structural disadvantage for learning mathematics:

It has long been recognised that neither education systems in general nor mathematics education in particular is neutral in terms of learners' positionings with respect to class, gender, "race", ethnicity and global position. With respect to each of these (and other) positionings, some learners are systemically, structurally disadvantaged. (Povey & Zevenbergen, 2008, p. 4)

Skovsmose (2005) has pointed out that learning obstacles are often identified in students' social and cultural background and thus, in his understanding, "individualised". Skovsmose's countermove is to introduce the notion of students'

foreground but I find it important analytically to connect people's motives for learning – or not learning – mathematics to their lived lives in order to investigate the dialectics between individual and structure. During my first reading of Skovsmose's (1994) "Towards a philosophy of critical mathematics education", I wondered why he did not have any reference to the Bourdieuan concept of habitus when the term "dispositions" and the meaning attached to this term through his definition of foreground point in the same direction: "Dispositions are grounded in the social objectivity of the individual, and simultaneously produced by the individual, partly as a consequence of the actions performed by the individual" (p.180), and the future of different social groups of students "is present in the dispositions of the students" (p. 191).

The purpose of this paper is to initiate a discussion about the possibility of integrating locally a concept of foreground in the theory of habitus. I will do this by presenting and discussing the compatibility of the notion of foreground in critical mathematics education respectively the concept of habitus in Bourdieu's sociology. As a part of this, I will try, in an analysis of a narrative interview, to link habitus and foreground of a Swedish student in vocational education.

THE NOTION OF FOREGROUND

Intentionality was the pivotal point when Skovsmose (1994) introduced the notion of foreground in his book "Towards a philosophy of mathematics education" where three notions are interconnected: learning as action, dispositions and intentions. His point of departure is that knowledge development or learning is an act and, as such, it requires indeterminism: the acting person must be in a situation where choice is possible. To be an action, an activity must be related to an intention. A person acting must have some idea about goals and reasons for obtaining them. Skovsmose sees learning as caused by the intentions of the learner, thus, he does not see enculturation and socialisation as learning. Dispositions are seen as resources for intentions: "Intentions are grounded in a landscape of pre-intentions or *dispositions*" (p. 179). As Skovsmose does not see the background (the socially constructed network of relationships and meanings which belong to the history of the person) as the only source of intentions he divides the dispositions into a "background" and a "foreground". He finds the *foreground* equally important and, in 1994, defined it as

the possibilities which the social situation makes available for the individual to perceive as his or her possibilities. (...) The foreground is that set of possibilities which the social situation reveals to the individual. (Skovsmose, 1994, p. 179)

Skovsmose stresses that the background as well as the foreground are interpreted and organised by the individual. However, at first, the foreground of a person was

defined as the opportunities in future life made available to her/him by society. In 2002⁵⁹, Skovsmose clarifies the functioning of the individual:

By “foreground” of a person I understand the opportunities, which the social, political and cultural situation provides for this person. However, not the opportunities as they might exist in any “objective” form, but the opportunities as perceived by a person. (Skovsmose, 2005, p. 6)

In this article, the notion of foreground is presented as the pivotal point in the introduction of learning obstacles as a political phenomenon. And foreground becomes the key word in one of the principles for the pedagogy of critical mathematics education. “Third, critical mathematics education must be aware of the situation of the students. (...) A way of establishing this awareness is to consider not only the background of the students but also their foreground” (Skovsmose, 2006, p. 47).

Foreground is introduced – and used – by Skovsmose (1994, 2005, 2006) as a notion not as a concept, i.e. an element of a theory. But students’ foregrounds have been investigated empirically in two doctoral thesis which have fleshed out the notion (Baber, 2007, Lange, 2009). In the publication “Inter-viewing foregrounds”, Alrø, Skovsmose and Valero (2007) have continued the work by giving a “conceptual definition” of students’ foregrounds. They stress that the concept allows linking two of the key conceptual elements of educational theory, learning and meaning, and that foreground is a concept emphasizing the socio-political nature of education and learning. It is actually the notion of dispositions – defined by Skovsmose (1994) as pre-intentions –, which disappeared from his writing (2005, 2006), that links foreground with learning. Alrø, Skovsmose and Valero (2007) point to the basic principle in the theory of learning-as-action, which presupposes the person’s readiness to find motives for engaging in action; i.e. the person’s *dispositions*:

Dispositions can be seen as the constant interplay between a person’s *background* and *foreground*. The background of a person is the person’s previous experiences given his or her involvement with the cultural and socio-political context. In contrast to some definitions of context which see background almost as an objective set of personal dispositions given by one’s positioning in different social structures, we consider background to be a dynamic construction in which the person is constantly giving meaning to previous experiences, some of which may have a structural character given by the person’s positioning in social structures. The foreground, as previously defined, is also an element in the formation of dispositions. The person is all the time finding reasons to get engaged in learning activities not only because of the permanent reinterpretation of his or her background, but also because of the constant consideration of his or her foreground. That is, the person connects previous experiences with future possible

⁵⁹ The article “Foregrounds and politics of learning obstacles” was published 2002 in a preprint: Publication no 35, Centre for research in learning mathematics, Roskilde University.

scenarios for action (pp. 7-8).

The authors see a person's dispositions as readiness to engage in intentional practice or action and they associate them selves from understanding the background as decisive. However, the awareness is present of students' positioning resulting in structural and systematic disadvantages, as well as advantages, in mathematics education. "Dispositions", which are objectively rooted but mediated by the individual, thus expressing subjectivity (Skovsmose, 1994, p. 179), is the term making it relevant to think about connecting foreground and habitus. However, the very idea of integrating foreground and habitus is based on the central place of action in both frameworks and the related critique of structural determinism.

THE THEORY OF HABITUS

"Socialization" is a key term – and concept – in sociology meaning the process of internalizing or of incorporating norms, traditions and ideologies which provides people with habits and dispositions necessary for participating within their culture and society. Like this, socialization is one of the mechanisms ensuring the reproduction of the society. In Danish and Swedish, a distinction is made between socialization as a process (socialisering) and socialization as a result (socialisation). Using the term "habitus", Bourdieu has conceptualised the result of socialization.

Many theories of socialization are based on a fundamental dichotomy: out there in society there are norms which are internalized in the individual. In Bourdieu's sociology people are most often agents in the etymological meaning of the word (Lat.: agens, agere = act). His project has consisted in combining studies of human experience with studies of the objective condition under which the same people live (Broady, 1991). Thus instead of "internalization", Bourdieu (1980) employs the term "incorporation", and the theory of habitus is incompatible with the idea of people as "bearers" of social structures and norms. In his work, according to Broady (1991) there is no direct, unmediated influence from social structures and norms to individuals. At this point, it is notable that Bourdieu's notion of socialization is consistent with the idea of social background in Critical Mathematics Education as presented above.

Habitus is the concept developed and employed by Bourdieu for a system of dispositions which allow the individual to act, think and orient her or himself in the social world. People's habitus is incorporated through the life they have lived up to the present and consists of systems of durable, transposable dispositions as principles of generating and structuring practices and representations:

The conditionings associated with a particular class of conditions of existence produce *habitus*, systems of durable and transposable *dispositions*, structured structures predisposed to function as structuring structures, that is, as principles generating and organising practices and representations which can be objectively adapted at their aim without presupposing the conscious aiming at goals and without the express mastery of

Working Group 10

the operations necessary to attain them. Objectively “regulated” and “regular” without being, by no means, the product of obeying rules they are collectively orchestrated without being the product of the organising action of a concert leader. (Bourdieu, 1980, pp. 88-89, my translation)

The term “dispositions” is only defined implicitly by Bourdieu. According to the dictionary it means “ability to”, “instinct”, “taste”, “orientation” etc., but, as it appears from the definition of habitus, it is not a case of innate, inherited or natural abilities. To make this visible, I have chosen to translate “disposition” into the Danish word “tilbøjelighed” (En.: inclination). The term “system” stands for a structured amount which constitutes a whole. Habitus (as a system of dispositions) contributes to the social world being recreated or changed from time to time when there is disagreement between the people’s habitus and the social world. The dispositions which constitute habitus are “durable” (Fr.: durables). This means that although they are tenacious, they are not permanent. Bourdieu (1994) has discussed precisely these two matters in an answer to attacks on him by critics for determinism in his theories.

There are several reasons for importing habitus as an analytical concept in mathematics education and trying to connect foreground with the habitus theory:

- The theory of habitus has to do with other than rational, conscious considerations as a basis of actions and perceptions, and it provides a theoretical starting point for criticism of the ideology of inherited abilities.
- Habitus is durable but it undergoes transformations. Dispositions point both backwards and forwards in the current situation of the individual.
- The concept of habitus aims at an action-orientation anchored in the individual and can simultaneously explain non-actions. Furthermore, habitus “allows for economy of intention” (Bourdieu, 1980, p. 97) (see Wedege, 1999).

I would claim that the notion of foreground, developed and belonging in critical mathematics education can be integrated as a theoretical element with habitus in a problematique of mathematics education. Bourdieu (1994) emphasises that the theory of habitus is not “a grand theory”, but merely a theory of action or practice. The theory has to do with why we act and think as we do. It does not answer the question of how the system of dispositions is created, and how habitus could be changed in a (pedagogical) practice⁶⁰. There is no sense in seeing habitus as the

⁶⁰ Note that at the end of the 60s the term, habitus, achieved a central place in Bourdieu's terminology, where it is presented as product in the pedagogical activity in the book “La reproduction” from 1970 about the function of the educational system in social reproduction. Here a durable formation and habitus achieve equal status (Bourdieu & Passeron, 1970, pp. 46-47). Several references in educational literature refer to this work and thus deal with habitus as a result of formal education.

result of an isolated pedagogical activity (a product of learning). But it is fruitful to employ the concept of habitus in the work of descriptive analysis about the conditions for people learning mathematics, precisely because habitus is formed through impressions and acquisition, either directly where the objective structures are experienced and leave traces, or indirectly when we are exposed to and engaged in activities that make impressions (see Wedege, 1999).

Bourdieu has not studied people's sense of doing mathematics (Fr: le sens de pratique mathématique) and, thus, he has not developed a concept of "mathematical habitus" a notion introduced by Zevenbergen in a study of implications of ability grouping in school (the middle years). Zevenbergen (2005, p. 608) proposes that when the practice of ability grouping "is enacted in mathematics classrooms it can create a learning environment that becomes internalized as a mathematical *habitus*." However, this structuralistic interpretation of habitus is neither compatible with the understanding of the dialectics between individual and structure in Critical Mathematics Education nor in the work of Bourdieu. Furthermore, Zevenbergen presents the mathematical habitus as a product of school mathematical practices alone. The data from interviews with 96 students from six schools serving upper-, middle- to working-class families were explored in terms of gender, school and year-level, not in terms of social class. Thus, I do not find that this notion of mathematical habitus resonates with the sociological theory of habitus.

LINKING BEN'S FOREGROUND FOR LEARNING MATHEMATICS WITH HIS HABITUS

As a part of an essay, one of my students, Jonas Lovén (2010) did a narrative interview with a male student at the vocational programme at higher secondary school in Sweden. The purpose of doing a mathematical life history interview was to test the analytical power of combining the concept of habitus with the notion of foreground. Carrying out the interview, Lovén followed the methodology of the narrative biographic interview as developed by the German sociologist Fritz Schütze (Andersen & Larsen, 2001). The interview with Ben, as Lovén has named the student in his essay, was taped and transcript and they have both approved my use of the transcript for further analysis. The disadvantage of this procedure is, among other things that I did not have the opportunity to follow up the interviewee's narrative. But the advantage of a young Swedish teacher student as interviewer is a reduction of the built-in asymmetry in any inquiry and hence a diminution of what Bourdieu (1993) has called symbolic violence. However, the mere fact that Lovén has a position as a future mathematics teacher and as such has been a trainee in the mathematics classroom of Ben seems to have an impact on his discourse when he – as an interviewee – answered the question about mathematics in his life, in a very favourable way.

Working Group 10

The initial question put by the interviewer is “Could you please tell about mathematics in your life? Quite simply – you may begin precisely where you want to and try to recount what comes into your mind” (l. 6-7). Ben seems to join the mathematics teacher discourse of “mathematics is everywhere”:

One uses math, yeah, every day – in principle. (I: Mmm) Yeah, where is it (Pause) Yeah, it does not work without math – nothing works. It is something you have to know and just carry on. Start in an early age. (Pause) Yeah ... (Pause). (I: Yes, precisely.) Yeah, later on it is often in the shops; these unreliable shop assistants and so on. It is fantastic being able to think and to do the sums rapidly. If they take one or two Krona from you. Not much – maybe, but (...) Quite often I am surfing on my mobile. Then it is good to calculate how much the cost is a minute if you do not have free surf. Which I do not have. Then I have to calculate a little, and eh.. you are on Facebook every day so.. So it is good to know it ... that the money does not flow away just like that. What more can one tell? Yeah a great hobby, I am playing golf (...) (l. 41-63)

And Ben continues by telling about the scoring in golf and again about not being cheated, this time by his father. Ben’s narrative takes off when he was “a little boy” just at the school start with supportive parents at home: “At that time, it was very cool. Everything was pretty simple, at the beginning. But after some years. Everything new is difficult. (Pause)” (l. 12-13). A central figure in Ben’s narrative is his grandfather, who also supported him in mathematics. He is introduced like this: “Even my grandfather [helped me]; he is a genius in mathematics. So already as a small kid I started to calculate” (l. 17-18, [my insertion]).

“Yes, OK, I ... Yeah, one has been doing mathematics for 11 or 12 years now”, Ben states (l. 32). School mathematics has been a part of his lived life over a long period and, together with the social interaction in out-of-school situations, influenced the socialization process resulting in his dispositions for doing mathematics today and tomorrow. In Ben’s biographic narrative about mathematics, two persons are important: First his grandfather, who supported him also by serving as a great example, and second Magnus, who owned a store where he had a job as a 15-years old kid. Together they did a piece of joinery:

I think that it was much fun. Then I decided to aim for joiner and to apply for this vocational school to be a joiner, but later on you circle around – you have to try everything from construction work to house painting. And I fell for the sheet metal work (...) New exciting stuff, and more great challenges and I have nothing against solving difficult problems (l. 134-139)

Ben tells that he had some difficulties with mathematics in grade 9 but the grandfather helped him and later on his uncle, who is graduate engineer and has a “sharp brain”. “Unfortunately”, Ben just passed in mathematics at the end of lower secondary:

... but I knew that I could do better and then I came here in August 2009 and started with

Working Group 10

the mathematics here. And I do not find it difficult at all because it is mostly repetition from lower secondary. (...) But when you are in the workshop it is not only $1 + 1 = 2$. As I told you before it is diameter multiplied by pi. And how many degrees you have to twist a disc wind (...) It is cool, really cool. (l. 145-150)

In Ben's narrative, the link between his habitus and his foreground for learning mathematics is visible. His lived life resulting in habitus acts as the background for the interpretation of his future life (foreground). Likewise, his experiences in the vocational school opens up for a foreground with sheet metal work. When Ben at the end of the interview is asked if he has any plans for a higher education, he refers to the fact that many of his friends have already left school:

... and mathematics above all because they think that it is damned boring. But I have nothing against it. I am doing fine. It is showing up at the test, you have to learn, it's just like that. Yes ... no, I do not care what others are thinking. It is my life. (...) I do not think that university is something for me. In fact, I have never been considering it, I think ... No ..." (l. 263-270).

In the Swedish society, the possibility of a higher education is available for Ben but this is not a part of his foreground.

INTEGRATING FOREGROUND AS A CONCEPT IN THE THEORY OF HABITUS

With this paper, I hope to initiate a discussion of possibility and potential of connecting the notion of foreground as a theoretical element in Critical Mathematics Education with the theory of habitus. I have argued for the compatibility and the connecting strategy suggested is *integrating locally*, i.e. some elements from one theoretical structure are integrated in a more elaborated theory, and the aim is theory development (see Wedege, 2010).

At first, the notion of students' foregrounds was based on anecdotic evidence (Skovsmose, 1994). Later it is given a conceptual definition based on qualitative empirical studies (Alrø, Skovsmose, Valero, 2007). Broady (1991) has argued that the key concepts in Bourdieu's sociology should be regarded as research tools or condensed research programmes. They get their full meaning when they are set in motion as tools in investigations. The notion of foreground has inspired research within Critical Mathematics Education. I claim that the concept of students' foregrounds locally integrated in the theory of habitus should be regarded as a research tool and I see the possibility of further theoretical development based on a combination of future large scale quantitative studies and qualitative studies in mathematics education.

When theories are imported from sociology, psychology, anthropology etc. into mathematics education they are adapted and reconstructed, in time. The notion of habitus has guided some studies in mathematics education (e.g. Gates, 2003;

Wedeg, 1999; Zevenbergen, 2005). I hope that local integration of foreground, which originates from the “homebrewed” theory of Critical Mathematics Education, into the theory of habitus can strengthen both concepts as research tools in mathematics education.

INTRODUCTION TO THE PAPERS OF WG 11: COMPARATIVE STUDIES IN MATHEMATICS EDUCATION

Eva Jablonka^{*} and Paul Andrews^{**}

^{*}Luleå University of Technology, Sweden, ^{**}University of Cambridge, UK

COMPARATIVE STUDIES

As we interpret “comparative” in a broad sense, including studies that document, analyse, contrast or juxtapose similarities and differences across all aspects and levels of mathematics education, some time has been devoted to discussions focussing on the identity of the group “comparative studies in mathematics education”. As comparative studies are dependant on the changing theoretical and methodological standards established in research in mathematics education in general, delineation will always be in flux. However, the view was shared that there are two “branches”, one deriving from documentation, description and analysis of classroom and school practices, and another stemming from large-scale international achievement surveys. Classifying a study as “comparative” means that the comparative method is emphasised, but comparison cannot be a goal in itself.

The papers and posters contributed to the group revealed a wide range in the aspects of mathematics education they addressed. These included teaching practices related to a particular mathematical topic, metaphors used by pre-service mathematics teachers, groups of low-achieving and high-achieving students, a teacher training course implemented in different countries, test items used in different countries, task representations in calculus textbooks, conceptions of problem-solving, theories originating from different cultural traditions, teacher education and student teaching in different countries, and the relationship between students’ self-regulation, self-efficacy and mathematical competence.

CULTURALLY SENSITIVE RESEARCH

One issue discussed throughout the sessions was how “culturally sensitive research” can be achieved in comparative studies. The notion is taken from Linda Tillman (2006), a US-based sociologist who in the context of her work describes how she sets out to understand the lives of African-American women. According to her, culturally sensitive research possesses five key characteristics. Firstly, it employs culturally congruent research methods. That is, a range of qualitative methods to “investigate and capture a holistic contextualized picture of the social, political, economic and educational factors” (p. 269) influencing participants’ experiences. Secondly, it is sensitive to the culturally specific knowledge of the researched. That is, the “researcher is committed to and accepts the responsibility for maintaining the cultural integrity of the participants and other members of the community” (p. 269). Thirdly, it seeks cultural resistance to theoretical dominance in its attempts to

Working Group 11

counter unequal power-relationships. It privileges the voice of the cultural group over more general and frequently dominant theories and, in so doing, “claims of neutrality and objectivity are questioned” (p. 270). Fourthly, it attempts culturally sensitive data interpretations in its positioning of the experiential knowledge of participants at the heart of the research. Fifthly, culturally sensitive research aims to produce culturally informed theory and practice. That is, “Researchers rely on participants’ perspectives and cultural understandings of the phenomena under study to establish connections between espoused theory and reality and then generate theory based on these... perspectives” (p. 271). In our discussions we found that not all our work would be amenable to Tillman's framework, but it helped to raise questions concerning how we undertake comparative research, whether it be a comparison of two classrooms in the same school or two different educational systems. In particular, we asked how we would be able to suspend our own culturally constructed values and expectations when we examine the classrooms of “others”.

We distinguished between form and function and noted that while insiders can recognise the function of events in a practice (culture), outsiders first of all attend to the form. One group member came up with the example of school uniforms as a form with different functions, such as covering poverty in the Philippines, and conveying an aura of discipline and learning in England. We acknowledged the value of both, the insiders’ and outsiders’ perspectives, and noted that as insiders we share blind spots due to cultural blindness.

We discussed, also, notions of “culture” and “multicultural society”. We concluded that cultural homogeneity cannot be assumed in national societies, even if there are shared political institutions. We employed the term identity rather than the term cultural affiliation, and acknowledged that individuals have multiple identities.

SPECIFIC TOPICS

The sessions were structured around possible common points of discussion thought likely to arise from the points made in the papers and poster presentations grouped together for a particular session.

The first topic concerned the development of “culturally sensitive research instruments”, as one of the contributions dealt with item performance in different cultural contexts. We acknowledged the necessity of exploring the validity of the test items imported from another culture. Also, we discussed the conditions under which such an import would make sense at all. We also discussed the labels used in research reports for outcomes related to a group. For example, the data produced in a study may be from Hungary, but if all the schools are in Budapest this label would seem too general.

More generally, the cultural bias of concepts in a research study was discussed. As an example, we used the cultural bias in answers to question about “self-concept” and “self-efficacy” and the relation between attitudes and performance that is often

Working Group 11

investigated in large-scale studies. As reported in such surveys, some Asian countries' students' show a low mathematical self-concept but high performance. This apparently inverse relation between the two constructs can be an outcome of a value attributed to unassumingness in some cultures. Consequently, such measures cannot be taken as culturally neutral.

In another session, we discussed the role of cultural traditions in theories and didactical principles. We asserted a central role to metaphors in a culture and suggested to ask whether there are structural differences in the metaphors used in different cultures. Further, the role of metaphor as fundamental to learning as well as more local metaphors in mathematics classrooms were explored, such as the use of the balance scale.

A more general issue in this context is whether we can successfully use a local home-grown theory from one culture to interpret data or ask questions in another culture. The French anthropological theory of didactics served as an example. We considered examples in which the use of theoretical frameworks linked to researchers' cultural heritage is a strength and examples where it is a limitation. Limitations could be overcome by cultural exchange between researchers, such as through the group meetings at the CERME. We found it valuable to treat theories comparatively as culturally situated.

ISSUES TO BE PURSUED FURTHER

In the course of the meetings, we identified some issues that are worth pursuing in the working group on comparative studies in mathematics education. Having noticed an extraordinary range of comparative studies, from very small to the very large, the potential of comparison should be further explored. We noticed that the purpose of comparison might not always be immediate, but it should be clearly identified in the beginning of a study in order to ensure coherence and permit planning. The issue of the overall design of comparative studies needs further attention.

We agreed that a comparison often opens our eyes to old problems of teaching and learning mathematics in classrooms, but that comparison can also assist in basic, fundamental research that opens up new issues. Generally, comparison can be seen as a tool for remaining a reflective stance in research activities. We agreed that the role and potential of comparative approaches in theory building needs to be explored further.

Although matching an appropriate question to an appropriate unit of analysis is a major problem in all research studies, we agreed that it comes out more easily in comparative studies because the sites are so different. Consequently, methodological questions related to the unit of analysis in comparative studies deserve more discussion.

Working Group 11

Further, methodological issues concerning adaptations of research instruments and translation of data and outcomes deserve more attention in comparative studies. Large-scale comparative surveys were mentioned (such as TIMSS and PISA) in a sporadic discussion about making instruments culturally more sensitive. We agreed that the goals and political influence as well as issues of validity and reliability of these studies should be discussed further.

THE CASE OF CALCULUS: COMPARATIVE LOOK AT TASK REPRESENTATION IN TEXTBOOKS

Emmanuel Adu-tutu Bofah, Markku Hannula

Department of Education, University of Helsinki, Finland

Abstract: Many mathematics teachers, across the world, rely heavily on textbooks in their day-to-day teaching. This study compared the mathematical tasks in the chapters on calculus (derivatives) in two mathematics textbooks adopted for the International Schools International Baccalaureate (IB) in Finland: a calculus textbook adopted for examination at the University of Helsinki and a Ghanaian Senior Secondary textbook. Eight classification schemes were used for the study and each mathematics task was coded into one of the categories.

Key words: Textbooks, representations, problem solving, comparative studies.

INTRODUCTION

Students' understanding of calculus concepts lays a foundation for their future study of advanced mathematics, science, and engineering. Calculus textbooks show a very definite attempt to stress the idea of meanings from the very beginning and reviewers of textbooks have made reference to the simplicity and understanding with which the subject is presented (Dragoo, 1945).

Textbooks are an important part of teaching mathematics in classrooms in Finland and Ghana as well as many other countries. It seems natural that textbooks are designed for the purpose of helping classroom teachers to organize their teaching. In this sense, school mathematics textbooks are used in varying ways and to varying degrees by teachers and schools. However, a textbook should be a tool, not a plan, but in reality many teachers rely heavily on textbooks to provide sample problems, diagrams, worked examples, and homework assignments. . The influence of mathematics textbooks upon what is taught in school mathematics has been highlighted in research into teachers' use of curriculum materials.

THE AIMS OF THE STUDY

The aim of the study was to compare the tasks in the calculus chapters (derivatives) in two Finnish mathematics textbooks for the International Schools (International Baccalaureate (IB)), an adopted calculus textbook for examination at University of Helsinki and Ghanaian Secondary School calculus textbook chapters. This study is not a country comparison but was influenced by the fact that, while existing textbook studies have been focused on content analysis (Schmidt, Mcknight, Valverte, Houg, & Wiley, 1997; Valverde, Bianchi, Wolfe, Schmidt, & Houang, 2002), less attention has been placed on the analysis of tasks presented in textbooks (Stigler, Fuson, Ham, & Myong, 1986; Zhu & Fan, 2006). There have been other studies on use and roles of mathematic textbooks (Reys, Reys, & Chávez, 2004) and textbooks and the

intended curriculum (Johansson, 2003; Chávez-López, 2003), but very few studies on secondary school advanced mathematics task representations in textbooks. This study therefore is important in that it raises the issue of textbook use again, but in previously unexamined circumstances.

During the past few decades, there has been much research on student achievement in calculus and students' understanding of calculus concepts. These studies have focused on students' understanding of concepts such as function and limit (Tall & Vinner, 1981; Vinner, 1989), calculus problem solving (Selden, Selden, Hauk, & Mason, 2000), student understanding of the derivative and integral concepts (Dragoo, 1945; Ferrini-Mundy & Gaudard, 1992; Hähkiöniemi, 2006; Tall, 1996), teaching of calculus (Dragoo, 1945), and calculus reform (Ganter, 2001). However, little research has been undertaken on the ways in which problems in calculus textbooks have been represented. The following research question was thus formulated:

33 How are mathematical tasks represented and distributed in the selected textbooks?

SIGNIFICANCE OF THE STUDY

This study will offer insights into existing textbooks' representation of calculus-related tasks, particularly from the hitherto unexamined perspective of comparing European and African textbooks.. In so doing the study will highlight the diversity of tasks presented to students located in different educational systems. To achieve these objectives the study combines Tall's (1996) spectrum of representations in functions and calculus and the coding system from Zhu and Fan (2006) to provide a common coding framework system for analysing tasks in calculus textbooks.

METHODOLOGY

Selection of textbooks

The study draws on two mathematics textbooks used in Finnish IB schools; Coad, et al. (2004), used in the Helsinki IB and abbreviated as HIBTB and Cirrito (2000), used in the Turku IB and abbreviated as TIBTB. It draws also on one calculus textbook adopted for the entrance examination at the University of Helsinki (Mendelson, 1997), abbreviated HUTB, and the national mathematics textbook used in Ghana (Eshun, et al., 1992), abbreviated as GTB. The full references to the selected textbooks are in Appendix A.

Schaum's Outline of Beginning Calculus (Mendelson, 1997) was selected for the study because it was a calculus reform textbook and was used by the University of Helsinki as a reference book for entrance examination. The IB books selected for the study were books adopted for use by two leading international schools in Finland, Turku International School and Helsinki International School. The Ghanaian

textbook is the approved ministry of education textbook. All the textbooks are intended for mathematics teaching and learning at the same secondary level. Most students using the textbooks are between the ages of 15-18 years and, calculus is introduced at that level. The decision to focus on the presentation of mathematical tasks in textbooks was based on the fact that solving textbook mathematical tasks is a typical element of the learning of the corresponding mathematical content.

In this study, only those mathematical tasks that did not have add-on solutions or answers presented were analysed. The tasks mostly appear within or immediately after the topic contents, and they often appear under such headings as: exercise, review set, investigation, past examination questions, examination style questions, self-assessment test, supplementary problems and discussion.

Data Collection and coding of problem types

In this study, we have adopted the definition of a mathematical problem from Zhu and Fan (2006) as a situation that requires a decision and /or answer, no matter if the solution is readily available or not to the potential problem solver. However, we prefer to call these exercises or tasks rather than problems. This definition suits the study and operates in textbook problem analysis. To solve the ambiguity in the terms mathematical problem, mathematical task and exercise, in this study they have been used interchangeably.

The problem classification is based on the categories described by Zhu & Fan, (2006). In addition we used Tall's (1996) spectrum of representations in functions and calculus. The following eight coding systems were used for the study.

Routine Task (RT): Is one for which solvers can follow a certain known algorithm, formula, or procedure to obtain the solution, and usually, the path to the solution is immediately evident. They involve the use of knowledge previously acquired and practiced, have a low degree of mathematical complexity and do not ask for arguments in the response. Their interpretation is straightforward and they do not require the use of different kinds of representations.

Example: Find $\frac{dM}{dt}$ if $M = t^3 - 3t^2 + 1$ (HIBTB, p.627)

Non-routine Task (NRT): Is a task that cannot be solved by merely applying a standard algorithm, formula, or procedure, which is usually readily available to problem solvers. They require the establishment of relationships or chains of reasoning, procedures, or computations and ask for a certain level of interpretation. They may include a request for justification or a simple explanation. They tend to have a closed structure and to be presented in a familiar or almost familiar context. They are mostly to introduce ideas, to deepen and extend understandings of algorithms, skills, and concepts and to motivate and challenge students.

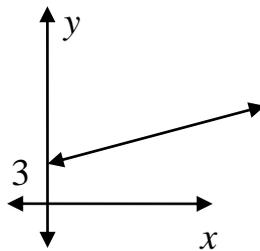

Working Group 11

Example: The tangent to the curve $y=x^3+bx$ at the point where $x=2$ passes through the point $(-1, 11)$ and $(3,-29)$. Find the values of the constant b .

(GTB, p.128)

Visual/graphic/tabular task (VT): Mostly concerned with the task of pictorialization, i.e. visualizing, graphing, and tabulation; (needs graphs or pictures to solve the task).

Example: Find the intervals where $f(x)$ is (i) increasing (ii) decreasing.

(HIBTB, p. 622)

Numerical Task (NT): Mostly concerns problems of estimating, approximating, most but not all questions demand numerical absolute answers.

Example: The radius of a circle is 5cm. Find the change in the area if the change in the radius is (a) 0.1cm (b) 0.03cm (c) 0.5cm (GHTB, p. 135).

Symbolic Task (ST): Mostly concern with tasks of manipulating, and limiting. These types of tasks mostly demand symbolic representative answers. This includes tasks that involve the use of manipulation skills in arithmetic and algebraic procedures.

Example: find, from first principles, the derivatives of $f(x)$ where $f(x)$ is:

a) $\frac{1}{x^2}$ b) $\frac{3}{x^3}$ □

(HIBTB, p. 614).

Non-Traditional Task (NTT): These are problem posing problems, project tasks, activity tasks, investigation problems and derived problems. This task normally leads students to predict, derive, and comes out with concrete understanding of a concept. It also includes activity problems linked to the CD attached to the textbook.

Example: A farmer wishes to fence off a rectangular paddock using an existing stretch of a river as one side. The total length of wiring available is 100m. Let x m and y m denote the length and width of this rectangular paddock respectively, and let A m² denote its area. Obtain an expression for y in terms of x .

Find an expression for A in terms of x , stating any restrictions on x .

Determine the dimensions which will maximize the area enclosed by this rectangle (HUTB, p. 112).

Working Group 11

Formal/Purely Mathematical Task (PT): Deduction, defining, deducing; questions which need purely calculus concepts to solve the problem. They are more complex and require a high level of interpretation and reasoning, ask for a solution that involves the coordination of several steps, and often demand a response with some written communication and argumentation. Their structure is often open or semi open and they are generally presented in less familiar situations.

Example: For each of the functions, f , given below, find the gradient of the secant joining the points $P(a, f(a))$ and $Q(a + h, f(a + h))$ and hence deduce the gradient of the tangent drawn at the point P .

$$f(x)=x, \quad (b) f(x)=x^2, \quad (c) f(x)=x^3, \quad (d) f(x)=x^4$$

Hence deduce the gradient of the tangent drawn at the point $P(a, f(a))$ for the function $f(x) = x^n$, $n \in \mathbb{N}$ (HUTB, p.125).

Calculator/PC Task (CT): It includes questions that students have been specifically instructed to use calculators or computers to solve them. These include some interactive problems on student CD's attached to the textbook. Questions are mostly linked to the textbooks own specially designed graphing packages, calculus packages and more.

Example: Use technology to help sketch the graph of $y = 4x^2 + \frac{600}{x}$ (HIBTB, p. 635).

Procedure

Utilizing the conceptual framework above, each task in the selected textbooks was examined against each of the classifications and coded into one of the categories.

Inter-rater reliability of the coding was checked between the researcher and an external scholar for 126 (10%) randomly selected tasks from each chapter according to the conceptual framework described earlier. There was an agreement on 96% of all the codings.

RESULTS AND ANALYSIS

The chapters that represented calculus and their respective percentage per textbook are depicted in table 1 below.

The total number of tasks across all the four books varied considerably. The Ghanaian textbook had the highest number of tasks. This was due to the fact that the Ghanaian textbooks give reference to one question under a different content analysis and use the same question stem to create new questions without the need to write a completely new question.

Working Group 11

In terms of task location and distribution, there were no considerable differences between the books. All tasks were located just after the content analysis with an average of three worked examples before the tasks. Table 2 shows the total number of tasks across the textbooks and their corresponding percentages.

Textbook	Chapters	%	N
HUTB	11,12,13,14,15,18,19,20	18.40	236
HIBTB	19	22.30	286
TIBTB	22,23	21.40	274
GTB	9	37.90	486
TOTAL		100	1282

Table 1: Problem Distribution Across Adopted Textbooks. N=Total number of questions in each textbook.

	RT %	NRT %	VT %	NT %	ST%	NTT%	PT%	CT%
HUTB	20.9	9.1	15.8	17.2	19.7	0	48.6	57.1
HIBTB	24.4	24	44.2	14.1	11.8	100	31.4	42.9
TIBTB	20.5	3.3	33.3	25	23.2	0	17.1	0
GTB	34.2	63.6	6.67	43.69	45.3	0	2.9	0
N	307	121	120	412	254	27	35	7

TABLE 2: Percentage Distribution of Task Across Textbook. RT=Routine task, NRT=Non-routine task, VT= Visual/Graphical/Tabular task, NT= Numerical task, ST= Symbolic task, NTT=Non-Traditional task, PT=Formal/Purely Mathematical task, CT=Calculator/PC task, N= total number of tasks in each book.

The distribution of the eight question types across the three books is depicted by the histogram in figure 1 and the line graphs in figure 2. It is obvious from figure 1 that the textbooks are different from each other, numerical tasks being typical for all the textbooks and calculator /computer aided tasks being non-existent for others. Also non-traditional tasks appear only to exist in the Helsinki IB Textbook.

Working Group 11

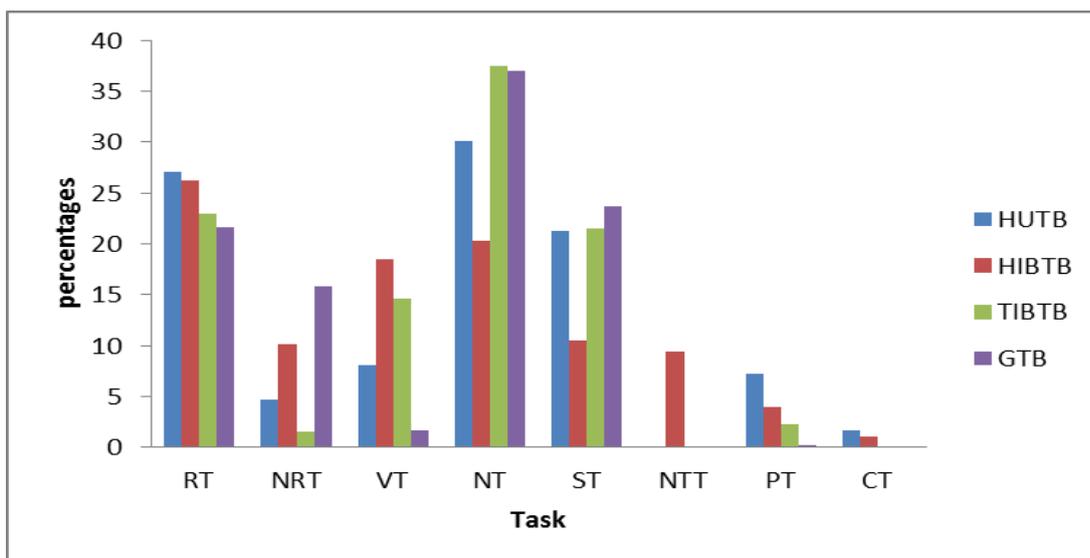

Figure 1: Percentage Distribution of Task Across Textbook

The Ghanaian Textbook has an interesting pattern in terms of task distribution. It has the highest number of a some task types and the lowest number of other task types, as shown in the zigzag line graph in figure 2. This suggests that the Ghanaian textbook has the most uneven distribution of tasks followed by the Turku IB textbook (TIBTB). Both the Turku IB Textbook and Ghanaian Textbook (GTB), have peaked and uneven graphs, reflecting a highly uneven distribution of task types.

The data also revealed that there is a uniform distribution of routine tasks. The Helsinki IB textbook has a fairly evenly distributed pattern of tasks with the exception of being the only textbook in the study that has any non-traditional tasks.

Also the line representing University of Helsinki textbook (HUTB) is relatively flat, depicting an even distribution of tasks according to the type of task.

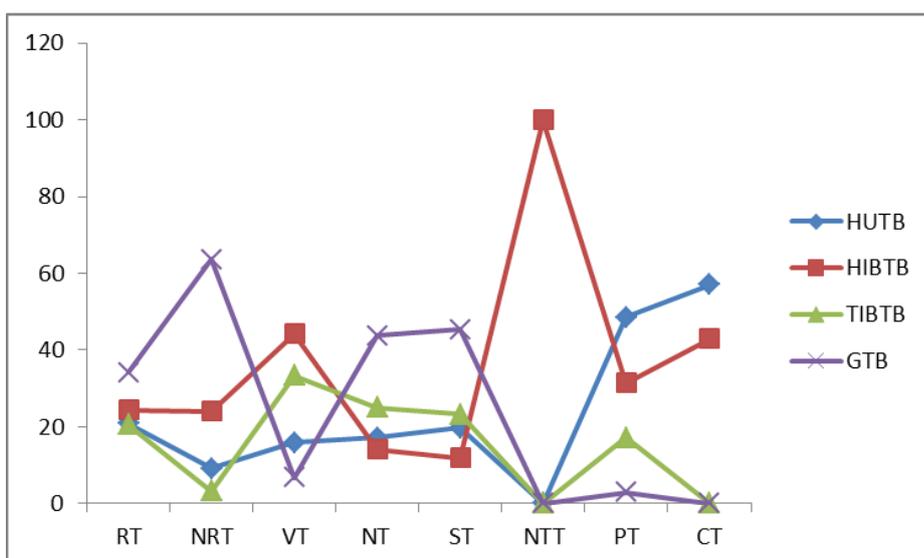

Figure 2: Percentage Distribution of Task Types Across Textbooks

Working Group 11

Numerical problems were the main focus for all the textbooks, and perhaps the textbooks give not enough attention to non-traditional, calculator problems. Students using HUTB are exposed to a more even distribution of different types of problems, than students using the other books. Students using GTB are exposed to different exercise types with respect to the other book problems but less exposed to VP, PP or non-exposure to NTP and CP.

In HIBTB all the calculator tasks were designed for students to use two specific calculator types. There were illustrations on how to use these calculators throughout the chapters. However, the students need to buy their own calculator to be able to use the book conveniently. While calculator problems in HIBTB were clearly marked, none of the tasks in HUTB was clearly marked.

Reasons for inclusion of the few calculator tasks in HIBTB and HUTB was that Finnish students are allowed to use calculators for their final examinations so the textbooks need to design some tasks that will prepare students for that challenge.

CONCLUSION

According to the study, the analysed textbooks have few non-traditional and calculator tasks although these tasks may suit present day challenges and the new reform curriculum. For instance, there is the need for textbooks to include more calculator tasks to help students adjust to present day technology use in mathematics education. As Tall, (1996, p. 318) puts it, “Calculus has broadened in its meaning from traditional symbolic techniques to a wider science of how things change, the rate at which they change, and how their growth accumulates”.

Textbooks may help students realize how useful mathematics can be in their lives, but if the link between a mathematical concept and the corresponding real life situation is not made clear, students may not be able to completely grasp the mathematical concept.

It is not clear if the students using the Ghanaian textbook are exposed to more questions than the other students and gain more problem solving skills than their Finnish counterpart. However, the researcher thinks the reason for repetitive and exploratory activities/tasks in the Ghanaian textbook is to help the lower achieving students. At the same time, there are higher-level tasks to challenge and motivate the more able ones.

Furthermore, there is the need for further studies about textbooks among or across different educational systems, by comparing the various features of the mathematical tasks and the content presentations. Such a study will be useful in furthering our knowledge of the effects textbooks have on classroom instruction and student’s mathematics achievement.

In conclusion, it appears that all the studied textbooks provide a wealthy source of problems for students to develop their ability in problem solving. As argued by Zhu

and Fan (2006), students' exposure to many problems has a substantial influence on students' learning and their achievement because tasks provide a rich learning environment in which students can have plenty of opportunities to experience problem solving.

THE TEACHING OF LINEAR EQUATIONS: COMPARING EFFECTIVE TEACHERS FROM THREE HIGH ACHIEVING EUROPEAN COUNTRIES

Paul Andrews

University of Cambridge

On various international tests of achievement Finnish, Flemish and Hungarian students have been amongst the more successful in Europe. Linear equations, a topic students traditionally find difficult, is a key topic in the transition from mathematics as inductive and concrete to deductive and abstract. This paper, by means of an analysis of video-taped lessons taught by case study teachers, one from each of Finland, Flanders and Hungary, examines comparatively how teachers defined locally as effective construct opportunities for their students to learn the mathematics of linear equations. The findings show that all three teachers acted in ways contrary to received research wisdom, exploiting the balance scale as the key metaphor for inducting students into the solution processes of algebraic equations.

INTRODUCTION

The transition from arithmetic to algebra is problematic due, not least, to ambiguities with regard to the role and meaning of symbols of mathematics in general and the equals sign in particular. On the one hand it is a command to execute an operation, reflecting *procedural* (Kieran, 1992) or *operational* (Sfard, 1995) expectations. On the other, it is as an object on which other operations may be performed, reflecting *structural* (Sfard, 1995) expectations. Related to such concerns is the distinction between arithmetical equations and algebraic equations. The former, with the unknown on one side only, are generally assumed to be susceptible to undoing (Fillooy & Rojano, 1989). However, the latter, with unknowns on both sides, cannot be solved by arithmetic-based approaches and require not only that the learners “understand that the expressions on both sides of the equals sign are of the same nature (or structure)” (Fillooy & Rojano, 1989, p. 19) but also that they are able to operate on the unknown as an entity and not a number. In this manner, arithmetic equations are procedural while algebraic equations are structural (Kieran, 1992; Boulton-Lewis, Cooper, Atweh, Pillay, Wilson & Mutch, 1997). However, many students fail to navigate this transition and are “reduced to performing meaningless operations on symbols they do not understand” (Herscovics & Linchevki, 1994, p. 60. This failure has been described as either a *cognitive gap* (Herscovics & Linchevski 1994) or a *didactic cut* (Fillooy & Rojano, 1989), although Pirie and Martin (1997) argue it is more likely to be the responsibility of inappropriate didactics than cognitive inadequacies.

Research shows that the use of different embodiments or representations can create the potential for new concepts, entities and operations to become endowed with

meaning (Filloy & Rojano, 1989). They can facilitate the link between concrete and abstract thinking by acting as analogues for the intended abstractions (English & Sharry, 1996; Warren & Cooper, 2005). With regard to equation solving, one of the most frequently used, and criticised, embodiments is the balance scale. Its advocates argue that it both helps students understand equations as entities rather than computational instructions and supports those symbolic representations that underpin algebraic formalisms (Filloy & Rojano, 1989; Warren & Cooper, 2005). Its critics argue that it cannot represent negatives in anything but a contrived way and is unfamiliar to modern students (Pirie & Martin, 1997).

Despite such criticisms several studies have examined the efficacy of the balance. Warren and Cooper (2005) found it helped children not only solve algebraic equations but also understand the equals sign as representing equivalence between entities. Vlassis (2002) found that although students understood both the conceptual and procedural role of the balance many experienced difficulties with negatives, irrespective of whether an equation was arithmetical or algebraic. Boulton-Lewis et al. (1997) found students preferred to use inverse approaches rather than the concrete representations taught them. Such examples highlight the diversity of findings with respect to the use of the balance, although their respective research designs may have contributed significantly to the findings. Warren and Cooper (2005) and Vlassis (2002) invoked the balance as a means of solving algebraic equations, while Boulton-Lewis et al. (1997) did so with arithmetic equations only.

In the following, the teaching of linear equations by three teachers, one from each of Finland, Flanders and Hungary is examined. Analyses of such teaching, located in countries typically shown to be more successful than England on various TIMSS and PISA assessments, present opportunities for an evaluation of the adaptive potential of the culturally located practices of one culture for another (Clarke, 2004). That is, such analyses have the potential to inform curriculum and teacher education development in less successful but culturally similar countries like England.

METHOD

This paper draws on data from the EU-funded, Mathematics Education Traditions of Europe (METE) project. Based at Cambridge, England, the project, which ran from 2003-2005, examined aspects of mathematics teaching in Flanders⁶¹, England, Finland, Hungary and Spain. This paper draws on analyses of video recordings of sequences of lessons taught by teachers defined locally as competent in the manner of the Learner's Perspective Study (Clarke, 2006). Thus, while it is not possible to

⁶¹ From the perspective of the METE study, Flanders, the autonomous Dutch-speaking community of Belgium, is construed as a country. This distinction is well known in the literature with, for example, Flanders being reported as a different educational system from Wallonia, the French-speaking community of Belgium.

Working Group 11

comment on the attainment of project students, it would be reasonable to assume that project teachers would be as successful as any of their national peers. Four sequences of five lessons were filmed on the same topic in each country during the academic year 2003-2004. One of the topics was linear equations, chosen because of its importance in the transition from arithmetic to algebra. Videographers focused on the teacher whenever they were speaking. Teachers wore radio-microphones while a static microphone was placed strategically to capture as much student talk as possible. For each sequence, according to agreed project procedures, the first two lessons were transcribed and translated by English speaking colleagues working in the project universities. The translations, which were verified by Finnish-, Hungarian- and Dutch-speaking graduate students, enabled the creation of subtitles to facilitate a foreigner's (my) viewing and comprehension of the lessons.

It is important to acknowledge that although data were collected by local academics familiar with the teachers' contexts, the analyses presented here represent one cultural outsider's attempts to understand how participants enact their roles in culturally diverse classrooms. In such circumstances, where researchers are cultural outsiders, there is a danger of inaccurate reporting due to incomplete understanding of the cultural issues underpinning participants' beliefs and actions (Liamputtong, 2010). Such concerns invoke a need for culturally sensitive research (Tillman, 2002, p.6), whereby researchers accept and maintain the "cultural integrity of the participants and other members of the community" by privileging the voice of the cultural group over more general and frequently dominant theories. Moreover, culturally sensitive research aims to produce culturally informed theory by drawing on participants' culturally located perspectives on the phenomena under scrutiny. The manner in which data were collected, involving academics based at the partner universities and local teachers well known to them, was managed with appropriate regard to cultural sensitivity, as were the analyses described below.

All videos, with and without subtitles, were viewed by me several times and a narrative for each lesson constructed in which participants' actions and utterances were recorded in as much detail, and with as little interpretation, as possible. Where they were available, narratives were developed alongside transcripts in such a way that sections of dialogue were annotated with additional details relating to participants' actions. Where transcripts were unavailable, the narrative comprised my attempt to describe what was seen. All narratives ran to several pages of prose. These narratives were read against repeated viewings and increasingly refined. Eventually, having viewed and reviewed every lesson several times, a tentative understanding emerged with respect to the key elements of each teacher's conceptualisation and presentation of linear equations. Throughout this process, and conscious of the need to achieve culturally sensitive analyses, one was conscious of the need to avoid evaluation of teachers' actions alongside the desire, in accordance with conventional

case study practice, to provide as thick a description of events as possible. The following reflects these ambitions.

RESULTS

The teachers were between 29 and 33 years of age with between six and eight years' teaching experience. Each was a graduate of the project partner university and was known locally to have a commitment to both continuing professional development and school-based teacher education mentoring. All three teachers, two women, Pauline in Flanders and Emese in Hungary and one man, Sami in Finland, worked in unremarkable schools in provincial cities that were homes to the partner universities.

The analyses indicated that all three sequences comprised four phases that I have come to call, definition, activation, exposition and consolidation phases. In general, the definition phase introduced students to the notion of an equation and, either implicitly or explicitly, presented a definition. The activation phase alerted students to or revisited intuitive procedures for solving arithmetic equations. The exposition phase, through an initial presentation of an algebraic equation, exposed the inadequacies of intuitive approaches and warranted the introduction of the balance. Lastly, the consolidation phase enabled students to exploit their newly acquired skills. In the following each phases is discussed against, due to space limitations, a selection of the available evidence.

The definition phase

Lasting up to one lesson, this phase saw Sami in Finland, Emese in Hungary and Pauline in Flanders introducing and defining the topic.

Finland

The first Finnish lesson found Sami writing on the board that an equation was “two expressions denoted as being of equal magnitude”. He then wrote six “sentences”, as he called them, on the board: 5 , $x - 1$, $x = 3$, $5 + 3 = 7$, $3x - 1 = 4$, $x^2 = 8$, before asking students to decide which were equations and which were not. Through constant reference to the definition, the “sentences” were categorised. Those accepted as equations were then discussed from the perspective of truth and a classification emerged that equations could be conditionally true, always true or always false.

Hungary

Emese exploited several open sentences to revisit the role of the basic set in determining a statement's validity. This was followed by a discussion through which an equation was defined as comprising two expressions connected by an equals sign. She asserted, through her questioning, that equations may or may not contain variables or unknowns depending on circumstances and that they were always true, sometimes true or never true. Finally she operationalised her definition through an

Working Group 11

exercise in which three open sentences, $5 - \square = 8$, $5 - \square > 6$ and $\square \cdot 2 = 7$, were solved in relation to the basic set $-3 \leq \square \leq 3$.

Flanders

Pauline posed a problem involving characters from the cartoon series, the Simpsons: if Bart, Lisa and Maggie, are 7, 5 and 0 years old respectively and their mother, Marj, is 34, in how many years would the sum of the children's ages equal their mother's? She drew a two-rowed table before completing, collaboratively, the first three columns. Individual completion of the remaining columns was followed by a discussion leading to the solution of 11 years. Pauline then discursively introduced the unknown and the equation, $34 + x = 12 + 3x$, appeared, after which she sketched the straight line graph for each row in the table to highlight the intersection.

Summarising, Sami and Emese presented explicit definitions, although Sami's, which was presented both orally and in writing, involved no student input. His definition and the tripartite classification were operationalised collectively by means of his six sentences, while Emese's definition was discursively derived and operationalised. Her use of inequalities provided a more general entry to equation solving and facilitated an awareness of the three categorisations. Pauline exploited a *realistically*-derived equation to define, implicitly, both equation and equation solving. The latter was achieved with reference to both the table and graphs. She made no allusion to equation types.

The activation phase

This second, activational, phase saw all three teachers, as preparation for their main presentations, activate material covered earlier in their students' careers to both contextualise and facilitate the material that followed.

Finland

Sami began his second lesson by asking for a conditional equation. One student suggested $x + 5 = 2$, with a second offering -3 as a solution. Sami then introduced $x/8 + 1 = 4$ and invited mental solutions. After a minute, despite a student offering a correct solution, he demonstrated a *covering up* method and, through closed questions and his board sponge, confirmed 24 as the solution.

Hungary

Emese began by posing oral problems like, "Kala is twice as old as her sister; the sum of their ages is 24, how old are they?" Each was solved individually before solutions were shared. Next, the class was split into four groups with each given a superficially different word problem for translating into an equation. One group's problem was: "Some friends went on a trip. The first day they covered just 2km. The second day they covered 2/10 of the remaining journey. If they covered 6km on the second day, how long was their journey?" After several minutes the group representative explained how its equation had been derived and wrote $0,2 \cdot (x - 2) = 6$

Working Group 11

on the board. Lastly, a volunteer, exploiting a *thinking backwards* strategy, obtained a solution of 32, which Emese checked against the text of each problem.

Flanders

Pauline modelled, through discussion, several sketches and an introduction to the balance, an analytical solution to $x + 7 = 9$, which was then summarised symbolically before $x - 2 = 10$, $3x = 8$ and $x/3=7$ were managed in the same way. This was followed by her summarising the relationship between each of her four exemplars and their respective formalisations. For example, in relation to $x+7=9$ she wrote $a = b \Rightarrow a + c = b + c$. The lesson ended with her setting a homework whereby solutions to equations like $x - 3 = 10$, $200 - x = 20$ were placed in a crossword grid. The following lesson answers were shared with particular attention being paid to $3/2x = 30$ and how division by $3/2$ was equivalent to multiplying by its inverse.

Summarising, Sami invited his students to solve intuitively two equations with the unknown on one side and used the latter to introduce the cover up method that he never again mentioned. Emese exploited various word problems; initially to revisit the processes of *undoing* and latterly to derive arithmetic equations from *realistic* contexts and solve them with a thinking backwards strategy. Pauline privileged an explicit revision of arithmetical structures and their role in the solution of less straightforward equations. In so doing, she made an explicit reference to the balance.

The exposition phase

All three teachers began their formal exposition by presenting their students with an algebraic equation, seemingly in the knowledge that intuitive methods would fail.

Finland

Sami wrote $5x + 3 = 2x - 8$ and invited solutions. Once it became clear that this was too difficult, spoke of balance scales and how the same operation applied to both sides would retain the balance. Throughout he used outstretched arms to demonstrate the effect of different actions on the scales while commenting that “an equation is like scales... in principle, if you have it in balance, the equation is true”. Returning to the equation, he asked what could be subtracted from both sides of the equation. Someone suggested x and Sami, without comment, wrote $4x + 3 = x - 8$. Another volunteer suggested subtracting $2x$, at which point Sami wrote, with little student input:

$$\begin{array}{r|l} 5x + 3 = 2x - 8 & -2x \\ 3x + 3 = -8 & -3 \\ 3x = -11 & \end{array}$$

After some student uncertainty with regard to the next step, Sami, having asserted that they should divide by three as division is the opposite of multiplication, led the class to the solution $x = -11/3$. Lastly, individual seatwork was set from a text book.

Hungary

Emese began her second lesson with a word problem, “On two consecutive days the same weight of potatoes was delivered to the school's kitchen. On the first day 3 large bags and 2 bags of 10kg were delivered. On the second day 2 large bags and 7 bags of 10kg were delivered. If the weight of each large bag was the same, what weight of potatoes was in the large bag?” Soon a volunteer wrote $3x + 20 = 2x + 70$. Then, having established that intuitive strategies were now insufficient, Emese drew a picture of a scale balance with the various bags represented on both sides. Drawing on a student's suggestion Emese erased two small bags from each side, leaving a representation of $3x = 2x + 50$. Next she erased two large bags from each side to show one large bag balancing 5 small. Then, in response to her request, students volunteered sufficient for her to write alongside her drawings:

$$\begin{array}{rcl} 3x + 20 = 2x + 70 & | & -20 \\ 3x = 2x + 50 & | & -2x \\ x = 50 \text{ kg} & & \end{array}$$

Finally, Emese reminded her class of the importance of checking and did so.

Flanders

Midway through her second lesson, Pauline wrote $6(x - 5) - 8 = x - 3$ on the board and began a formal treatment in which the algebra, including actions, was written on the left side of the board and justificatory annotations on the right. Throughout the process, which lasted more than twenty minutes, Pauline questioned continuously. Space prevents a detailed account, although what follows represents a fragment of what was written.

$$6(x - 5) - 8 = x - 3 \quad (1) \text{ Eliminate brackets}$$

At this point, Pauline drew from her students notions of associativity and commutativity before settling on distributivity as the warrant for what she was about to do.

$$6x - 30 - 8 = x - 3 \quad (2) \text{ Calculate if possible}$$

$$6x - 38 = x - 3$$

Eventually, after obtaining a solution and discussing its uniqueness, Pauline undertook a check.

Summarising, all three teachers presented equations with the unknown on both sides with, it seemed, the intention of creating contexts in which intuitive approaches could not be exploited. All three teachers invoked the balance as an underlying principle although the extent to which it was sustained varied. Sami, having introduced the balance, made little use of it during his rather directed exposition. Moreover, despite an implicit acceptance of his first student's subtraction of x , his

subsequent actions indicated that he had a clear view as to what was acceptable. His solution was annotated conventionally although he invited no student input into its introduction. Emese exploited a realistic word problem to warrant the construction of her equation. She sustained the balance throughout her presentation, made explicit the relationship between her sketches and the symbolic representation and questioned her students constantly. Pauline offered the most complex of equations, deliberately provoking a frisson of excitement in her students. Her solution process, which was driven by many questions, was very formal and invoked a number of concepts studied earlier to highlight inter-topic and structural links. Both Sami and Pauline operated in exclusively mathematical worlds although it was Pauline and Emese who included checks at the conclusions of their expositions.

The consolidation phase

The fourth phase, lasting two or three lessons, provided various opportunities for students to consolidate earlier learning and further develop both conceptual and procedural equations-related understanding. All three teachers set increasingly complex exercises, all involving algebraic equations incorporating brackets and both negative and fractional coefficients. Sami and Pauline located all their exercises within mathematics-only worlds while Emese integrated *realistic* word problems. Sami and Emese derived additional insights from the tasks set, while Sami introduced the *change the side change the sign* rule and, essentially, prescribed a preferred approach. Emese invited multiple solution strategies, discussed notions of efficiency and elegance, and constantly solutions. Pauline included a test. The manner in which tasks were completed and solution shared varied with Sami and Pauline sharing solutions after several problems had been completed while Emese always shared solutions after each problem had been solved individually.

DISCUSSION

All three sequences shared common structural - definition, activation, expositions and consolidation - characteristics. Such similarity is unsurprising as comparative studies that adopt broad and inclusive variables tend to find similarity rather than difference; as in LeTendre, Baker, Akiba, Goesling & Wiseman's (2001) analysis of teachers' self reported use of core instructional practices that included, for example, seatwork and whole class instruction. In other words, such broad categories tend to be inclusive and reflect patterns of instruction commonly found across cultures.

However, within these macro-level similarities were important similarities and differences. With respect to similarities, all three teachers offered definitions, either explicitly or implicitly, which were operationalised through problems and exercises. All three, having activated students' knowledge and skills, provoked analytical solution methods by posing an algebraic equation that could not be solved by intuitive methods. All, as is discussed below, based their expositions on the balance, and all three offered extensive opportunities for consolidation that incorporated

expectations of students' managing brackets and different forms of coefficient alongside particular privileged additional insights.

In respect of differences, several issues of interest emerged. Despite similarities with respect to the balance, the manner of its introduction and maintenance varied greatly. Pauline offered only a scant allusion; Sami enacted bodily its characteristics but made no further reference once the first expository example had been solved. Emese, through bodily enactment and sketches, made explicit the link between the embodied and symbolic forms of equation, a link sustained through several examples. Interestingly, and confounding Pirie and Martin's (1997) scepticism, not only did all students appear familiar with the balance but also, once introduced, negatives. The examples and exercises exploited by Sami were located entirely within a world of mathematics. Pauline, having kick-started the topic with a single word problem, behaved similarly. Interestingly, while the tasks set by Sami and Pauline were generally complex, task difficulty was so teacher-managed that students experienced few teacher-independent opportunities to engage with non-routine problems. In this respect, the data suggest that both teachers had been slower than systemically desired to incorporate problem solving into their repertoires, whether in Flanders (Verschaffel, De Corte & Borghart, 1997) or Finland (Pehkonen, 2009). Emese, on the other hand, exploited both mathematical and word problems throughout and, in accordance with earlier studies, provided her students with constant opportunities to mathematise and solve text problems (Andrews, 2003). With regard to classroom norms, Emese engaged her students in collective activity focused on students' awareness and acquisition of diversity of mathematical thinking. Pauline had clear objectives that were explicitly addressed by means of extensive but tightly focused bouts of public questioning. Sami, having operationalised his definition, exploited extensive bouts of teacher telling, interspersed with exercises, from which students were expected to infer meaning. In conclusion, although space prevents a detailed summary, such teacher behaviours, whether similar to or different from those found elsewhere, are likely to reflect characteristic patterns indicative of a national mathematics teaching script.

EXPLORATORY DATA ANALYSIS OF A EUROPEAN TEACHER TRAINING COURSE ON MODELLING

Richard Cabassut* & Jean-Paul Villette**

*University of Strasbourg, France, LDAR, Paris 7 University

**University of Strasbourg, France

The European project LEMA experimented a teacher training course on modelling in four different countries. We present here an exploratory analysis to evaluate the effect of the training course. From the teachers' answers to a questionnaire on beliefs before the beginning of the training course, the teachers are split in different clusters. With the answers to the questionnaire after the training course, we observe how in every cluster the answers change. We will show how the national groups can be taken into account. Then we will point to questions and challenges related to comparative studies.

THE EVALUATION OF A TEACHER TRAINING COURSE

The LEMA project context and the focus of the paper

The project LEMA [1] has from 2006 to 2009 developed a teacher training course on mathematical modelling. This project was not a research project trying to answer a research question but has tried to evaluate the training course. The course was implemented in some partnership countries. Before attending the course the teachers have answered a questionnaire. This questionnaire deals with their biography, with their interest in modelling, with their beliefs about mathematics, and with their beliefs about their ability to teach modelling. The same questionnaire had to be answered at the end of the attended training course. The aim of this paper is not to present the teacher training course, which does not mean that this presentation would not be interesting. A description of the LEMA project is made in (Cabassut & Mousoulides, 2009) and a description of the questionnaire is made in (Maaß & Gurlitt, 2009). The aim of this paper is not to discuss the relevancy of this questionnaire, which does not mean that this discussion is not of interest. A discussion on qualitative and quantitative methods in comparative research is made in (Cabassut, 2007). An example of qualitative evaluation of the teacher training course is offered in (Cabassut & Mousoulides, 2009) and in (Schmidt, 2009). The main aim of this paper is to present an exploratory analysis of the data, produced by the answers to the questionnaires, in order to help to answer the questions: How to evaluate the LEMA teacher training course? How to integrate in this evaluation the comparative approach between countries? A secondary aim is to present a comparative method of analysis of data from different countries in order to contribute to the debate on comparative methods. Let us consider the theoretical framework related to this exploratory analysis.

The theoretical frameworks

Different theoretical frameworks are used in this paper. For the study of modelling we use the theoretical framework of PISA, based on the mathematisation cycle inspired by the works of (Blum, 1996) and described in (Cabassut & Mousoulides, 2009). The questionnaire takes into consideration works of Grigutsch, Raatz and Törner (1998) on teachers' beliefs in school mathematics, of Bandura (1997) on teachers' self efficacy and of Kaiser (2006) on knowledge and beliefs on modelling: the theoretical framework of the questionnaire is well described in (Maaß & Gurlitt, 2009). We describe with more detail the theoretical framework related to the main object of this paper: the exploratory data analysis. We propose to present this method of analysis because first we did not find so many studies in mathematical education using exploratory data analysis and secondly this data analysis looks as fitting with a comparative approach as illustrated later.

The exploratory data analysis was developed in (Tukey, 1977) in order to analyse data, and to formulate hypotheses based on this analysis. These hypotheses could be confirmed with a confirmatory analysis. In the case of exploratory analysis, descriptive statistics is used to observe the data without preconceptions and without formulating hypotheses in advance. In our example, the data are composed of a whole population of 83 teachers and their answers to a questionnaire. The descriptive statistics on the whole population will allow an inductive approach to describe the population and to formulate hypotheses on the structure of the population depending on the results of the exploratory data analysis. It is possible to try to evaluate assumptions made on the population.

On the contrary, confirmatory analysis uses inferential statistics to test, in a deductive approach, the hypotheses formulated in advance. Confirmatory analysis works on a sample of a population, using hypothesis tests and confidence interval estimation. The assumptions have to be accepted and are not testable: only the hypotheses are tested. Confirmatory data analysis is used in the LEMA project as reported in (Maaß & Gurlitt, 2009). In this confirmatory analysis two teachers' groups are compared: the intervention group did attend the teacher training course and the control group did not. The data analysis tests the research question: Has the intervention group outperformed the control group over time (by comparing the responses to the questionnaire before the training course and after the training course)? Means and standard deviations are used to summarize the answers to the different parts of the questionnaire (questions on beliefs, self-efficacy and pedagogical content knowledge) for the intervention group and for the control group. A two-factorial analysis of variance is used (factor intervention/control group and factor pre/post test). An F-test is used to test the hypotheses. Let us present now the methodology used in our exploratory data analysis.

Methodology

The population studied is composed of 83 teachers. The questionnaire is composed of questions (variables) with multiple-choice qualitative answers and questions with quantitative answers. All quantitative variables are reconditioned in two intervals by using the median to separate the classes. We split now the variables in three parts: the biographical variables are the questions related to the teachers' biography (country, age, gender, type of school ...) that do not change between the pre and the post questionnaires; the active variables are the questions of the pre-questionnaire, except the biographical variables; the variables of the post-questionnaire are considered as illustrative variables.

We begin with a multiple correspondence analysis (MCA) on the active variables (36 variables with a two choices answer, which means 2^{36} possibilities). Then we apply a hierarchical ascendant classification (HAC or cluster analysis) by using the distances measured on the first coordinates between teachers on the teachers' first coordinates on the factorial axes determined by the MCA. SPAD software is used. There is a cluster of three teachers who have too many no answers. We decide not to take these three teachers into consideration for the cluster analysis. After the cluster analysis each of these three teachers joins his nearest cluster. In this new cluster analysis there is a one teacher cluster. We repeat the precedent procedure and we get eventually 79 teachers offering with the active variables a cluster analysis with four clusters [2].

For every cluster we consider the **splitting active variables**. A splitting active variable is an answer for which the percentage of the answer in the cluster is very different than in the whole population. In the next paragraph, every cluster will be described through these splitting variables. In the post-test, the answers to the same questions are considered as illustrative-supplementary variables. Those for which the percentages are very different in the cluster than in the population are split by clusters. The biographical variables (gender, type of school, nationality, level of studies ...) are also split by clusters. Let us describe the clusters.

TEACHERS ' BELIEFS BEFORE THE TRAINING COURSE

To describe the whole population, we observe a variety of positions about beliefs and self confidence: a majority can agree for some items, or disagree for other ones or being divided between agreement, disagreement or neutrality. To describe every cluster we look at the difference in the percentage of an answer between the studied cluster and the whole population.

First cluster

The first cluster contains 13 teachers with the following splitting answers, much more answered than in the whole population. They agree strongly that every student can create or recreate parts of mathematics; that there is usually more than one way

Working Group 11

to solve mathematical tasks and problems at school; that students with the right age are able to solve the proposed modelling task and that this task does not take too much lesson time; and that if students get to grips with mathematical problems they can often discover something new (connections, rules and terms). They disagree strongly that to solve a mathematical task at school, one has to know the one and only correct procedure or you are lost; that school mathematics is the memorizing and application of definitions, formulas, mathematical facts and procedures; and that school mathematics is a collection of procedures and rules which determine precisely how a task is solved. The teachers look less confident than the whole population for all the items, and specially to give effective verbal feedback to groups and individual students to assist them with modelling, or to support students in developing competencies in arguing related to modelling tasks.

The teachers of this cluster look positive at the teaching of modelling, expressing a need to support students in modelling and having an open-minded view on school mathematics beliefs, with mostly strong positions on these points (strongly agree or disagree).

Second cluster

The second cluster contains 31 teachers with the following splitting answers, much more answered than in the whole population. Most of the teachers feel less confident than the whole population for all the items to teach modelling, and specially they feel less confident to be able to design modelling lessons that help students overcome difficulties in all modelling steps (e.g. problems in validating); to use students' mistakes to facilitate their learning in modelling; to effectively assess students' progress as they work on modelling tasks; to adapt tasks and situations in text books to provide realistic open problems; and to design their own modelling tasks. In this cluster the teachers look less confident to teach modelling.

Third cluster

The third cluster contains 14 teachers with the following splitting answers, much more answered than in the whole population. They agree strongly that school mathematics is the memorizing and application of definitions, formulas, mathematical facts and procedures. They strongly disagree that school mathematics is useful in helping individuals to become critically aware citizens; that it is possible for students to discover and try out many things in school mathematics; and that school mathematics helps to understand phenomena from various areas of our society. Much more than in the whole population, they are neutral to agree that mathematics is of general and fundamental use to society, and that there is usually more than one way to solve mathematical tasks and problems at school or that school mathematics helps to solve daily tasks and problems. About self confidence, there is a variation depending on the items, sometimes they are less confident than the whole population, sometimes more confident, without strong difference. The teachers of

this cluster look conservative on school mathematics and are less open to application of school mathematics in life.

Fourth cluster

The fourth cluster contains 21 teachers. For all the items of self confidence, these teachers are much more confident than the whole population, and specially to design modelling lessons that help students overcome difficulties in all modelling steps (e.g. problems in validating); to design their own modelling tasks; to effectively assess students' progress as they work on modelling tasks: to develop detailed criteria (related to the modelling process) for assessing and grading students' solutions to modelling tasks; to use students' mistakes to facilitate their learning in modelling; to support students in developing competencies in arguing related to modelling tasks; and to give effective verbal feedback to groups and individual students to assist them with modelling. They strongly agree to use the modelling approach in their future teaching. The teachers of this cluster look very self-confident to teach modelling.

TEACHERS' BELIEFS AFTER THE TRAINING COURSE

We observe that for the answers to self-confidence variables the average and median are increasing after the training course, which looks quite normal.

For the variables on beliefs about mathematics there are small variations with some exceptions. Teachers agree much more that school mathematics is useful in helping individuals to become critically aware citizens. Maybe the training has offered examples or situations to illustrate this possibility. There is also a big increase in the probability to use a type of modelling task in teaching, or to disagree that the students will not be able to solve a given modelling task.

To analyse the change in every cluster, we look after the training course what are now the answers with the biggest differences between the percentage of the answer in the cluster and the percentage of the answer in the whole population.

First cluster

More than in the whole population the teachers strongly disagree that school mathematics is the memorizing and application of definitions, formulas, mathematical facts and procedures. They strongly agree that every student can create or recreate parts of mathematics and that there is usually more than one way to solve mathematical tasks and problems at school. They disagree that central aspects of school mathematics are flawless formalism and formal logic. For these split variables the difference with the whole population is smaller than it was before the training with the splitting variables. All these changes are positive to teach modelling.

Similarly, before the training course, for all items of the self-confidence variables, the teachers were less confident than in the whole population. After the training we observe that the level of confidence has increased in the population and in the cluster

Working Group 11

and there are no more strong differences with the whole population for the self-confidence variables. More precisely, for the two items where the self-confidence was splitting before the training course, after the training course we have a change of the confidence. Before the training course a majority of the cluster had a degree of confidence under the median of the whole population for both items. It is the contrary after the training course, even if the median of the whole population has increased after the training course.

More generally after the training course, the difference between this cluster and the whole population is weaker.

Second cluster

Much more than in the whole population, the teachers are neutral to think central aspects of school mathematics are flawless formalism and formal logic, disagree that doing mathematics at school involves innovative thinking and new ideas, and agree that there is usually more than one way to solve mathematical tasks and problems at school. These split differences are difficult to interpret because the differences observed are reduced. The case is particularly true for the confidence items. The teachers of the cluster keep less confident than in the whole population, even if the level of confidence has increased in the population and in the cluster. But there is no more big difference.

After the training course, in this cluster, there are not so much split answers and the differences are considerably reduced.

Third cluster

More than in the whole population the teachers disagree that every student can create or recreate parts of mathematic; that school mathematics helps to understand phenomena from various areas of our society; and that it is possible for students to discover and try out many things in school mathematics. For these three variables we observe after the training course a decrease of strongly disagreement and an increase of disagreement. The differences with the whole population are reduced in comparison with the splitting differences before the training course. The splitting variables of strong disagreement and agreement, present before the training course, are no more present as split variables after the training course. Even if the teachers of the cluster keep some conservative beliefs as illustrated above, their position is more moderated and less splitting than before the training course.

Fourth cluster

For all items of self-confidence the average has increased in the cluster and in the whole population. The median for all items has increased in the whole population. In the cluster for all items the majority of the answers keep in the interval over the median. Even if this percentage has decreased, for every item teachers are more confident in the cluster than in the whole population, and specially to develop

detailed criteria (related to the modelling process) for assessing and grading students' solutions to modelling tasks; to adapt tasks and situations in text books to provide realistic open problems; to support students in developing competencies in arguing related to modelling tasks; and to effectively assess students' progress as they work on modelling tasks and to select appropriate tasks suitable for a modelling approach to teaching. The teachers of this cluster keep more confident than the whole population even if the difference is reduced.

BIOGRAPHICAL VARIABLES AND CLUSTERS

We can observe now how the biographical answers (gender, age, country...) are split in the clusters. We use the same method as for the answers after the training. We look what are the biggest differences between the percentage of the answer in the cluster and the percentage of the biographical answer in the whole population.

We will try to interpret the relation between biography and clusters. But it is clear that you can find the same age or the same country or the same type of school split in different clusters. It means that we want to break the idea to define a cluster with the biography answer. A biography answer, for example a given country like France, can be an explanation factor but neither a necessary factor, neither a sufficient factor to belong to a cluster, it means to fill the profile of a cluster.

First cluster

Younger teachers and French teachers are more numerous in this cluster than in the whole population. On the contrary Hungarian teachers, secondary school teachers, older teachers, teachers with a high number of years as teacher are less numerous.

The teachers of this cluster look positive to teach modelling, expressing a need to support students in modelling and having an open-minded view on school mathematics beliefs, with mostly strong positions on these points (strongly agree or disagree). Young teachers could be more sensible to open-minded beliefs because their teacher education was more focused on didactics and pedagogy than older teacher education. In France problem-solving plays a main role in mathematics teaching focused on mathematical content. The French teachers of the training course were from primary school where every day life problems are very important in the official syllabus (Cabassut & Wagner, 2009). Hungarian teachers are less present maybe because their school system is more traditional (Vancso & Ambrus, 2009). Secondary school teachers are also less present maybe because they are more focused on mathematical content than on modelling activities.

Second cluster

Secondary school teachers, German teachers, and older teachers are more numerous in this cluster than in the whole population. On the contrary primary school teachers, and younger teachers are less numerous.

Working Group 11

The teachers of this cluster look less confident to teach modelling, and moderately open-minded to modelling. The secondary school teachers are maybe more focused on mathematical content than primary school teachers and have a pressure to achieve their syllabus. German teachers have seen a big change in their curriculum in 2009 where modelling becomes a leading idea (Garcia, Wake, & Maaß, 2007). This official change could make them open to modelling but less confident because it is a new idea in the curriculum. Older teachers could also feel uncomfortable to change their teaching if modelling corresponds to a new teaching.

Third cluster

Older teachers, teachers with a high number of years as teacher, Hungarian teachers, teachers who have studied mathematics at university level, and secondary school teachers are more numerous in this cluster than in the whole population. On the contrary German and Spanish teachers, teachers with a low number of years as teacher, and younger teachers are less numerous.

The teachers of this cluster look very conservative on school mathematics and are less open to application of school mathematics in life. Older teachers with long experience could have a more conservative behaviour than young and less experienced teachers. Hungary has a traditional and theoretical mathematics teaching that can explain this position (Vancso & Ambrus, 2009).

Fourth cluster

Younger teachers, Spanish teachers, and primary school teachers are more numerous in this cluster than in the whole population. On the contrary older teachers, teachers with a high number of years as teacher, German teachers, and secondary school teachers are less numerous.

The teachers of this cluster look very self-confident to teach modelling. Younger teachers or teachers from Spain are maybe more confident (Garcia et al., 2007). Primary school teachers, being used to multi-subject activities, are more confident to teach modelling. We have explained in the second cluster why German teachers, older teachers or secondary school teachers could be less confident to teach modelling. With the fourth cluster we observe that young teachers or primary school teachers seem to be more open to modelling.

DISCUSSION

Teachers can be split in different groups depending on their mathematical beliefs (conservative or open minded) and on the degree of confidence to teach modelling. The main difference after the training course is the increase of the level of confidence. The consequence is that the level of confidence is no more a split variable for the two first clusters. It keeps to be a split variable for the fourth cluster gathering teachers much more confident than the whole population.

Working Group 11

After the training course, the variables on the beliefs about mathematics are no more strongly split variables: the training course seems to homogenize and to moderate the beliefs. The training course has effectively taken into consideration advantages and disadvantages, difficulties and interests, needs and potentialities of the teaching of modelling. The third cluster keeps on characterising the teachers by conservative points of view on mathematics teaching, even if they look more moderate after the training course. It means that a big change in the beliefs seems difficult to be achieved as expressed in (Maaß & Gurlitt, 2009). If one of the aims of a future course is to change the teachers' beliefs, the course will have to focus on this aim.

We have offered this example of comparative study to contribute to the discussion on comparative studies in mathematics education. We do not know why the exploratory data analysis is not so popular in mathematical education in comparison with other fields. A reason could be related to the fact that mathematical education is more controlled by mathematicians than other fields of knowledge. For a mathematician confirmatory data analysis uses a deductive approach and inferential statistics while exploratory analysis uses an inductive approach and descriptive statistics. In the exploratory analysis, clusters enable to zoom in the whole population by aggregating individuals through their answers and not through their biographical values. They enable to build types of teachers to whom targeted training can be addressed.

In some international comparative studies, a descriptor aggregates the answers of a country in order to compare it with other countries, ranking the countries with the value of the descriptor. For example, the performance of Germany at PISA 2000 shows that Bavaria is significantly above the OECD average and Brandenburg is significantly below. Considering the German performance is a zoom-out where the difference between Bavaria and Brandenburg is not taken in consideration, this zoom-out leads to identify for every country a coherent body of practices. The hit is to define the best country - Finland for example in PISA 2000 - and to propose this country as a model for the others.

The aim of the example developed in this study is to show that other ways are possible. The diversity of the practices in a country shows that the country contributes to different clusters and that teachers from different countries can be gathered in the same cluster. The information got from a zoom-in can be as much interesting as that from a zoom-out. The challenge is to develop the comparisons among different countries taking into account the diversity of the practices and of the beliefs inside every country.

NOTES

1. LEMA means "Learning and Education in and through Modelling and Applications". This project is funded by the European Union and is described on the project site: www.lemma-project.org
2. The data analysis (MCA and HCA) is made for the statistical part under the control of J.-P. Villette, and for the didactical interpretation of the clusters under the control of R. Cabassut.

COMPARISON OF ITEM PERFORMANCE IN A NORWEGIAN STUDY USING U.S. DEVELOPED MATHEMATICAL KNOWLEDGE FOR TEACHING MEASURES

Arne Jakobsen, Janne Fauskanger, Reidar Mosvold and Raymond Bjuland

University of Stavanger [1]

In the Learning Mathematics for Teaching (LMT) project, measures were developed in order to gauge growth in teachers' mathematical knowledge for teaching (MKT) and to learn if and how such knowledge contributes to students' achievement. This paper documents the results from using adapted U.S. developed measures in a pilot study involving 142 Norwegian teachers. Psychometric analyses were performed on the Norwegian measures, and for some item parameters, we find strong correlation to the item performance characteristics found in the U.S.

INTRODUCTION

The study of mathematics teachers' knowledge and practice has been an active field of research for several decades (Ponte & Chapman, 2006). Inspired by Shulman's (1986) work, a group of researchers at the University of Michigan have developed a theory of "mathematical knowledge for teaching" (MKT). Part of this research included development of items used to measure teachers' MKT and to understand the effect such knowledge has on student achievement. It is also used to study and to compare outcomes of professional development of teachers and to improve teacher education. Research shows that teachers with high MKT score can be positively associated with increased learning by their pupils (Hill, Rowan, & Ball, 2005) and with the mathematical quality of instruction (Hill, Blunk, Charalambous, Lewis, Phelps, Sleep, et al., 2008). While some researchers claim that teaching is a cultural activity (Stigler & Hiebert, 1999), little is known to what extent this also applies to the MKT construct.

The measures under investigation were created on the basis of qualitative studies of mathematics teaching in U.S. classrooms and designed to reflect U.S. teachers' knowledge about the content taught as well as pedagogical content knowledge (Ball, Thames, & Phelps, 2008). Although the items were never made for use outside of the U.S., there have been several attempts to adapt and apply the MKT measures in other countries (e.g. Delaney, Ball, Hill, Schilling, & Zopf, 2008; Mosvold, Fauskanger, Jakobsen, & Melhus, 2009; Ng, 2009). The challenges of adapting and validating these items for use in Norway relate to issues of translation (Mosvold et al., 2009) as well as issues concerning teachers' experiences and reflections after having worked individually on the measures (in Norway, see Fauskanger & Mosvold, 2010; Bjuland, Mosvold, & Fauskanger, in progress). As part of this ongoing research, we want to see how the U.S. developed MKT measures perform in Norway and compare with performance in the U.S. This is important if one wants to rely on research and

development of MKT theory done in other countries. In this paper, we discuss how the items performed in a pilot study involving 142 primary and lower secondary school teachers in Norway. Our results are compared to results obtained in the U.S. (Hill, 2007). We focus on psychometric properties of the items by addressing the following research question:

Do the U.S. developed mathematical knowledge for teaching items perform in the same manner in Norway?

THEORETICAL BACKGROUND

In recent years, effective professional teacher development has been studied extensively (e.g. Garet, Porter, Desimone, Birman, & Yoon, 2001). According to these authors, however, literature in this field provides little direct evidence of positive outcomes for the participating teachers and their students. Some promising work has been carried out by researchers at the University of Michigan. Their analyses of teachers' MKT demonstrate that teachers' MKT made a difference in teachers' mathematical quality of instruction (Hill et al., 2008) and in pupil's achievement in mathematics (Hill et al. , 2005).

Theoretically, the MKT construct follows Shulman's (1986) work and the categorization of the various components of teacher knowledge that has evolved from Shulman's original proposal. The work done at the University of Michigan resulted in the model of MKT presented in Figure 1, a model still under development.

The MKT items were developed based on studies of videos from classroom practice, and the domains have been identified both in the U.S. (Ball et al., 2008) and in Norway, where Drageset (2009) has verified the existence of the constructs specialized content knowledge (SCK) and common content knowledge (CCK).

Although the items focus on important tasks of teaching (e.g. presenting mathematical ideas), which are supposed to be of a universal nature (Ball et al., 2008) they may not perform as intended in other countries (e.g. Delaney et al., 2008). This indicates that the translation and adaptation of the MKT measures into a different language (and culture) is not straightforward and requires careful scrutiny and different methodological approaches in order to be successful (e.g. Mosvold et al., 2009).

Investigating what in-service mathematics teachers know is uncommon in Norway, and according to Lysne (2006), assessment in education is a controversial issue in many western countries. In addition, the multiple-choice format is seldom used in Norway, but this seems to be changing (Sirnes, 2005). Reutzel and his colleagues (in press) claim that the measurement of practicing teachers' knowledge is not widely accepted, and other assessments than written are highlighted (Baxter & Lederman, 1999).

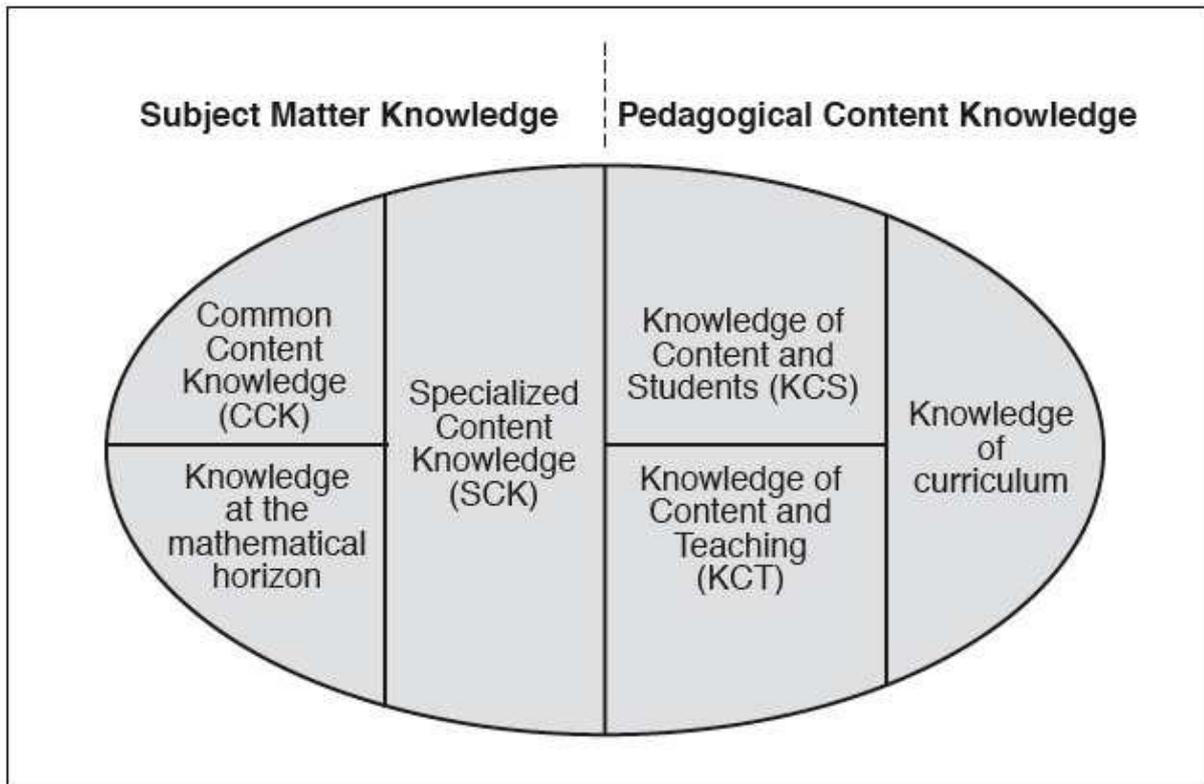

Figure 1: Domains of Mathematical Knowledge for Teaching (Ball et al., 2008, p. 403. The domains are defined and discussed in the same reference).

We recognize that no assessment is perfect, and all measurement instruments have their advantages as well as disadvantages. The MKT is no exception (e.g. Kane, 2007; Schoenfeld, 2007). It is clear from the writings of Hill and her colleagues (Hill, Sleep, Lewis, & Ball, 2007) that the goal is to move the debate on assessment of teachers from a debate of argument and opinion to one of professional responsibility and evidence. These authors claim that there is a need for assessment instruments that are designed to “*investigate* what teachers know, and to associate that knowledge with their professional training and their instructional effectiveness” (ibid. p. 112). From this perspective, it is important to develop different approaches to measure teachers’ MKT. The measures in focus in this paper represent one such attempt.

Schilling and Hill (2007) describe their work on validating the MKT measures, and even when building on their work, we need to be aware of the fact that researchers believe that more efforts need to be made concerning the work of validation (Schoenfeld, 2007) in general and more specific the use of psychometric models as the IRT (e.g. Kane, 2007).

METHODS

Efforts have been made to translate and adapt the 2004 elementary form A (MSP_A04, see LMT 2010) of the MKT items into Norwegian (Mosvold et al., 2009). After the translation phase, a pilot study was organized in order to add to the

process of validating the translation and adaptation of the MKT items. The overall aim of the study was to investigate whether and how the MKT measures could be used in a Norwegian context (Fauskanger & Mosvold, 2010). The study includes a quantitative part where 142 teachers' MKT were measured and a qualitative part where a selection of teachers were interviewed in five focus groups. In this paper, we analyze data from the quantitative data only, using item response theory (IRT) models as an approach.

The form that was used consisted of two parts. Part 1 included a total of 61 items (30 item stems). Part 2 consisted of some questions related to the teachers' gender, teaching experience and background education in mathematics. Part 1 is the focus of attention here. Figure 2 illustrates the nature of the items. This example asks teachers to respond to a mathematical task situated in a teaching context.

11. Students in Mr. Hayes' class have been working on putting decimals in order. Three students — Andy, Clara, and Keisha — presented 1.1, 12, 48, 102, 31.3, .676 as decimals ordered from least to greatest. What error are these students making? (Mark ONE answer.)

- a) They are ignoring place value.
- b) They are ignoring the decimal point.
- c) They are guessing.
- d) They have forgotten their numbers between 0 and 1.
- e) They are making all of the above errors.

Figure 2: Example from the set of released items (Ball & Hill, 2008).

Item Response Theory (IRT) models

Since MKT is not directly observable, the MKT items are meant to relate to the construct and can be viewed as one possible operationalization of the construct. Many measurement models could serve as a link to the observed latent world, and item response theory (IRT) is one such model (Edwards, 2009). The LMT project used IRT models to learn more about item performance characteristics, and in order to compare item performance in Norway and the U.S., we have followed the same approach.

A basic idea in IRT is that an observed item response is a function of person properties and item properties (Edwards, 2009). We have used two IRT models in the analysis of our data. A two-parameter model was used first, making it possible to identify items with high slope and item difficulty. The higher the slope is, the more variability in items responses is attributable to differences in the underlying construct. Item difficulty indicates the point on the ability axis where an individual would have a 50% chance of endorsing a particular item. Item difficulty is reported

in standard deviation units, and 0 is the average teacher ability. Items with negative difficulty indicate easier items, whereas items with positive difficulty indicate more difficult items.

Edwards (2009) found that adequate IRT parameter recovery is possible from as few as 200 respondents. However, a general rule is that the bigger the sample size is, the better the estimates get. The quality of the data also determines the number needed for adequate parameter recovery. Since the number of respondents in our sample is lower than 200 ($n=142$), we also compared the results coming from a one-parameter model. Missing data is not used in parameter estimation in both models.

In addition to the psychometric analysis, we also present the test information curve and the reliability of the assessment. The test information curve shows how much information items provide for the individual teacher along the ability axis.

RESULTS

In this section, the psychometric analyses are presented and discussed in order to determine if the U.S. developed measures perform well in Norway. We have used the program BILOG-MG (Zimowski, Muraki, Mislevy, & Bock, 2003) for the estimation and testing of item response theory (IRT) models.

Difficulty	< -2	[-2,-1>	[-1, 0>	[0, 1>	[1, 2>	> 2
Norway	9	14	22	9	5	2
U.S	5	19	20	12	2	3

Table 1: Numbers of items within different ability intervals in Norway and U.S.

In order to study item performance characteristics in Norway, we first looked at the output from BILOG-MG using a two parameter IRT model. We used the same item names as in the original U.S. form. Data coming from the Norwegian sample show that one item has a negative point-biserial correlation of -0.116 (Item 17c). This indicates that respondents who answered other items correctly would most likely give the wrong answer to this item, which again indicates that the item is not working well in Norway and should be removed. The average difficulty for the Norwegian items was -0.649, and standard deviation 1.267 (average standard error 0.152), where as in the U.S. the average item difficulty was -0.573, i.e. slightly higher. In both countries the scale used consists of a distribution of items of difficulty across the ability spectrum (see Table 1).

Figure 3 displays a scatter plot of the Norwegian item difficulties relative to item difficulties found in the U.S. study (LMT 2004). The correlation between the relative item difficulties is relatively strong (0.804 and p -value < 0.0005). Similar strong

Working Group 11

correlation is also reported in an Indonesian study where two MKT geometry measures were adapted and used (Ng, 2009).

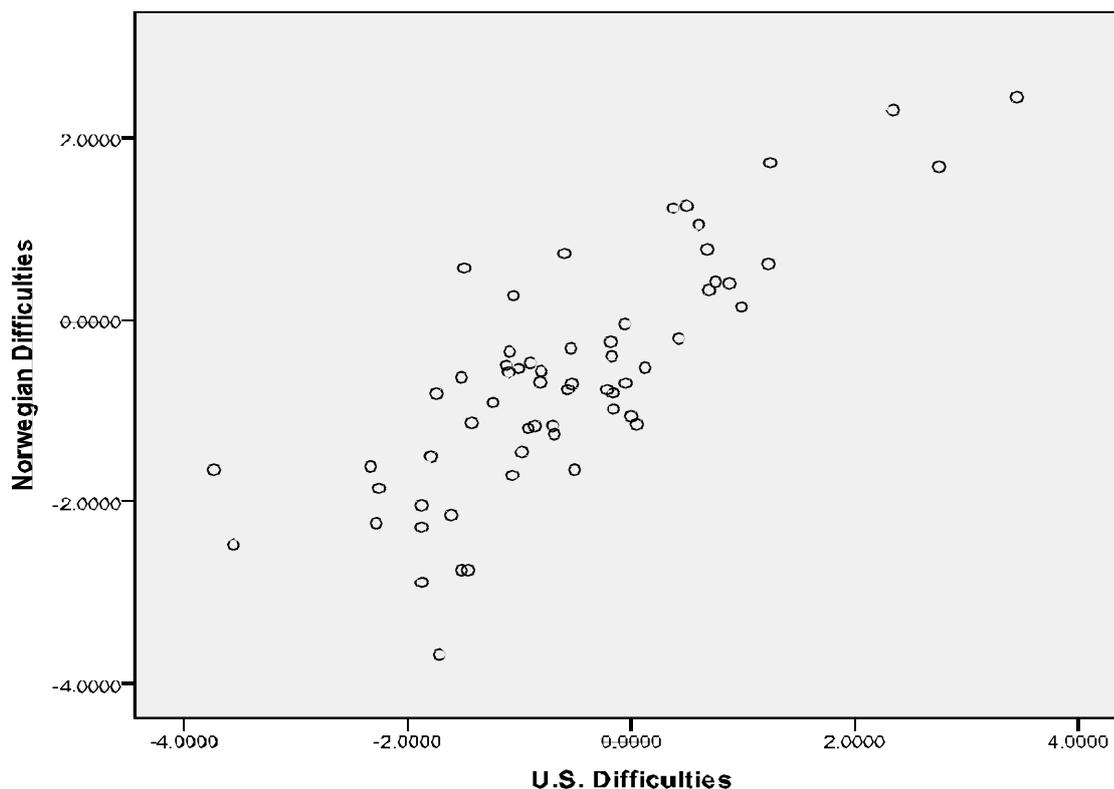

Figure 3: Scatter plot of the relative difficulties of items in the Norwegian adapted form and the U.S. version of the same form, using a two-parameter model.

The average Norwegian item slope was 0.688 with standard deviation 0.287 (average standard error 0.152), while the average item slope found in the U.S. was 0.533. We found the correlation between U.S. slopes and the Norwegian slopes to be rather low (0.375). This can be explained by the low sample size.

Items with slopes lower than 0.5 are normally considered as problematic because they do not discriminate between teachers with high mathematical knowledge for teaching and those with lower mathematical knowledge for teaching. We find that the majority of the items have slopes higher than 0.5, both for items in the adapted form used in Norway (51 out of 61 items) and for the original U.S. form (41 out of 61 items). In both countries, only two items had slopes below 0.3.

Each item also has its own information function that is calculated from the item's parameters, and the peak of the function is a value of the item difficulty. The item slope determines how peaked the test information curve is, and the higher the slope value is, that item will provide more information around this difficulty level. To understand how our test is functioning as a whole, the items information's function can be combined into a test information function. The test information curve shows how the test measures teachers across the ability levels.

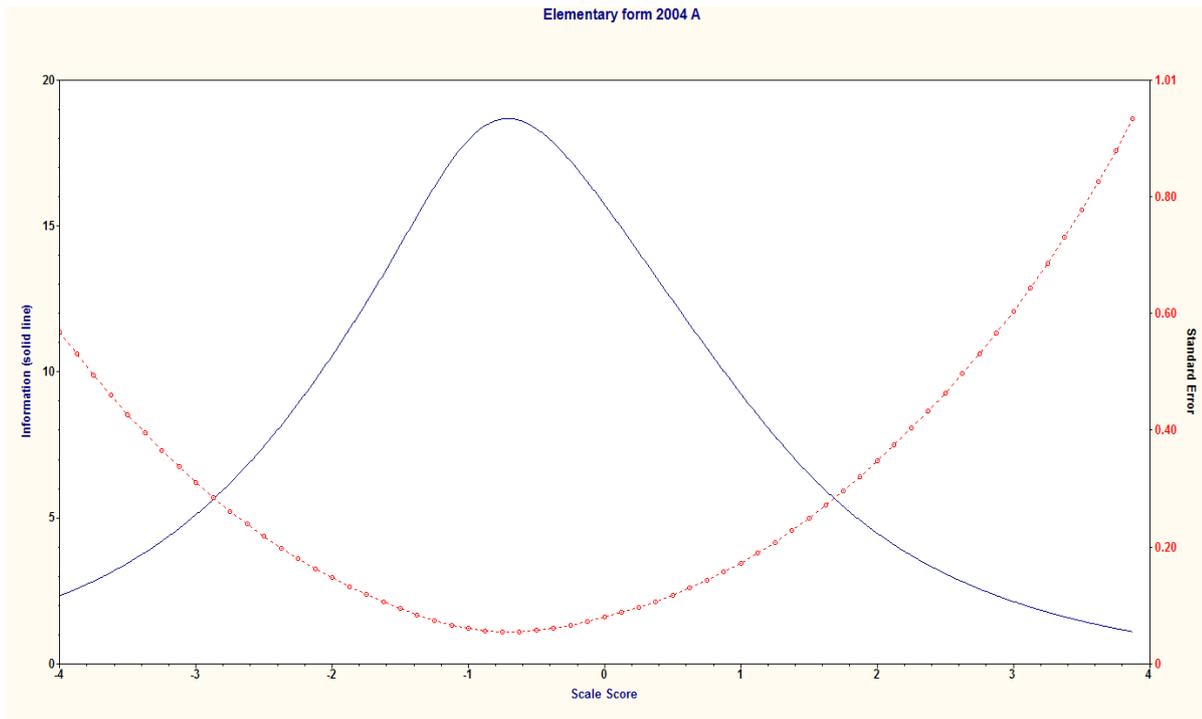

Figure 4: Test information function (solid line) and standard error (dotted line) curves for the Elementary 2004 A form.

In Figure 4 we have plotted the test information function for the adapted Norwegian form. 0 is the mean teacher's ability score. The peak of the test information function is at -0.75, and this test measures best individuals between -2.5 and 2 standard deviations from the mean ability level. The corresponding standard error for this range is below 0.3, which is under a third of a standard deviation. Reliability for the two-parameter IRT model was 0.9145, higher than what was found in the U.S. study.

Due to the relatively small number of respondents in Norway, a one-parameter IRT analysis was also performed. However, since the U.S. item characteristics are coming from a two-parameter model, we will not compare item characteristics coming from two different models (and for slopes it is meaningless). We observed that the correlation between the U.S. difficulty and the Norwegian difficulty was less strong using a one-parameter model (0.775 compared to 0.804). For the one-parameter model the reliability index of the test was 0.899, and maximum information for -0.8750.

CONCLUSIONS

During the translation of the items and in focus group interviews with teachers, we became worried if the measures would function in Norway. Several teachers expressed concern about some of the items, finding them difficult and hard to answer. Some teachers had expected a test with questions similar to what can be found in a textbook for their own students, and being challenged with the

Working Group 11

understanding of e.g. nonstandard student solutions in a test situation was frustrating (Bjuland, Mosvold, & Fauskanger, in progress). In our analysis of the data, we find that the scale was composed with items with difficulties over a broad ability range (from -3.683 to 2.443) in the same manner as in the original U.S. scale (from -3.734 to 3.454). We also find that there is a strong correlation between the item property characteristics found in Norway and in the U.S. The reliability index is high (0.9145), and from only looking at the item property characteristics, we argue that the adapted measures are working well in Norway and that the measure performs as intended. The scale is performing well for an individual with the ability between -2.5 and 2 standard deviations from the mean ability level. However, this study has several limitations. First, the sample size is low, making the use of a two-parameter model questionable. Second, our study only examines the content knowledge domain, and we would therefore like to do further studies involving the knowledge of content and students (KCS) and the knowledge of content and teaching (KCT) domains. Third, we also believe that observations in classrooms need to be done in order to investigate if the mathematical quality of instructions is linked to MKT measures in the same way as found in the U.S. For items with difference in item performance, we are also looking into the content of the items trying to see if for instance cultural differences can explain this difference.

NOTES

BELGIAN AND TURKISH PRE-SERVICE PRIMARY SCHOOL MATHEMATICS TEACHERS' METAPHORICAL THINKING ABOUT MATHEMATICS

Çiğdem Kiliç

Mersin University, Education Faculty

The aim of this study was to examine Turkish and Belgian pre-service primary school mathematics teachers' perceptions of mathematics. 42 Belgian and 41 Turkish mathematics teacher students participated in the study. They were asked to indicate their metaphors about mathematics and explain the reason. The results of the study revealed that Belgian pre-service teachers tended to use action metaphors while Turkish pre-service teachers tended to use emotion metaphors for explaining mathematics. It is concluded that cultural factors and the teacher education system are the likely causes of such different metaphors.

Key words: teacher education, pre-service primary school mathematics teacher, metaphor, comparative studies in mathematics education

INTRODUCTION AND THEORETICAL FRAMEWORK

Beliefs are an interesting and powerful research object. In order to develop effective teacher training, the belief systems of pre-service teachers need investigating and metaphor, in this respect, is an important tool (Reeder, Utley and Cassel, 2009; Schinck et al., 2008). As indicated by Presmeg (1998), metaphor is derived from the Greek, *metaphora*, meaning to 'transfer' or 'carry over' and is an implicit form of analogy. According to Leavy, McSorley and Bote (2007),

Metaphors have a coherence and internal consistency, which provide insights into ideas that are not explicit or consciously held. They can also be evocative, stimulating both self and others to tease out connections which might not be made use of by direct questions (p.1220).

Metaphor, long thought to be just a figure of speech, has recently been shown to be a central process in everyday thought. Metaphor is not a mere embellishment it is the basic means by which abstract thought is made possible (Lakoff and Nunez, 2000). Reasoning with metaphor is considered a fundamental way of human thinking and communication, as can be seen in our everyday use of abstract concepts (English, 1997). Metaphors have many advantages for educators and learners. Metaphors link abstract ideas to concrete images, thus evoking an experiential connection. Metaphoric thought supports embodied knowing and is not merely a communication or visualization device (Sterenberg, 2008). Metaphor is seen as a strategy for explicating peoples' views about a phenomenon (Sterenberg, 2008). It is a research tool (Reeder, Utley and Cassel 2009) showing relationships and focusing on similarities.

Metaphors are explicit explorations of personal views of mathematics and understanding new images of mathematics can contribute to the explication of teachers' views of mathematics (Sterenberg, 2008). If our conceptual systems and thought processes are largely metaphorical (Lakoff & Johnson, 2003) analyzing peoples' metaphorical thinking is a good way to understand what happens in their mind. We understand metaphor as finding a mapping between the target domain, that is, the topic of metaphor, and the source domain (English, 1997).

Metaphor-related educational research has been undertaken on specific content like mathematics (Sterenberg, 2008; Schinck et al., 2008), more broadly on teaching and learning (Saban, Kocbeker and Saban, 2007; Mahlios and Maxson, 1998; Leavy, McSorley and Bote, 2007) and in juxtaposition, the teaching and learning of mathematics (Reeder, Utley and Cassel, 2009). Research on use of metaphors to describe images of mathematics shows diversity. For example, Lim (1999) categorized mathematics as a journey, a skill and a game or a puzzle. Sterenberg (2008) categorized the metaphors produced by pre-service teachers into mathematics as a battle, a mountain, a bridge and a language. Noyes (2006) explored pre-service mathematics teachers' beliefs about mathematics and the teaching and learning of mathematics. Among participants' metaphoric descriptions of mathematics were found four metaphors like structure, journey, language and toolkit. In the study of Reeder, Utley and Cassel (2009) production, journey and growth were identified as pre-service teachers' metaphors about mathematics teaching and learning.

The aim of this study was to examine Belgian and Turkish pre-service primary school mathematics teachers' beliefs about mathematics. The beliefs of participants were revealed using metaphorical expressions. There were two main questions in the study;

- 1) What kind of metaphors are used by Belgian and Turkish participants?
- 2) Are there any differences between two countries' participants' metaphors for mathematics?

METHOD

Participants

The participants of the study were 42 Belgian and 41 Turkish pre-service primary school mathematics teachers. All participants were enrolled in mathematics method and basic mathematics courses and were able to articulate effectively their metaphorical thinking about mathematics. In Belgium a primary school mathematics teacher trainee program is three years, in Turkey it is four. Demographically, all participants were aged between 20 and 22.

Data Collection

Data were collected during university sessions. Metaphor was explained to participants before they were presented with a written form, “*Mathematics is like... Because...*” Participants were then invited to write their images of mathematics and their justification for them. The data were collected during an Erasmus Staff Mobility project in March 2010 in Belgium and at the beginning of April in Turkey.

Data Analysis

Students’ written metaphoric expressions were read, listed, organised, coded and labelled according to their common characteristics. One colleague also helped the researcher with data analysis. The colleague and researcher coded metaphors separately. First, all metaphors were listed and similar metaphors were combined. Listed metaphors were reorganized. All metaphors were coded and similar coded were combined. Coded metaphors were labelled (if, for example, a metaphor had been coded as human or plant it would have been characterised more generally as animate and so forth). In this manner, metaphors were categorized in four different clusters based on the patterns that emerged as animate, inanimate, emotion and action (see in Figure 1). Inter-rater reliability was calculated and found to be 98%. When a repeated metaphor was found, a (+) sign was written beside it to show its frequency.

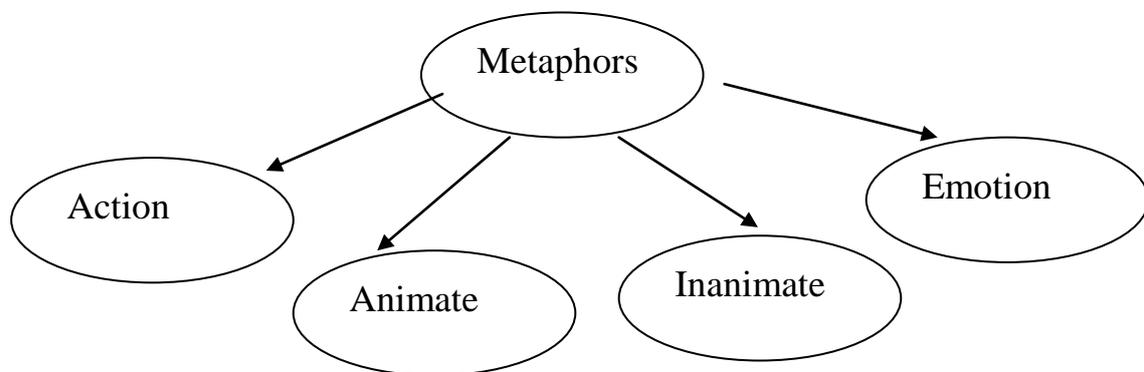

Figure 1: Metaphors that emerged in the study

RESULTS

In the study animate, inanimate, action and emotion are the main metaphorical themes, although in all categories there were sub-categories. In Table 1 can be seen the metaphors produced by participants for mathematics, while in Table 2 sub-categories and frequency of metaphors are given.

Working Group 11

Table 1: Metaphors for mathematics produced by participants

Turkish	Belgian
A star in sky that you know the name	A toy
Reality itself	Building a house
Depression	A ghost
A woman	The roots of a planet
A ladder that you never reach summit	A tree +++
A puzzle +++	A puzzle ++++++++
A life ++++	Learning how to drive
An ocean+++++	A volleyball
A cyclic chain	A computer
A buckle	A chain
Dividing Turkish bagel equally	A circle
A infinite road	A spoon
Returning earth	A summer
A game	A pyramid ++
A matryoshka baby	A maze
Universe +++	A game
Knowing everything	An infinity
A pencil	A fairy tale
A maze	Climbing a mountain ++
A wardrobe	A flower ++
A jinn Ali figure	An air
A chocolate	Gardening
Erupted corn	Playing the piano
Lifblood	Riding a bicycle
Growing a human	Running a marathon
A kite	A magic box ++
An eye	The world
A ball of yarn	Playing an instrument
An artist painting	A house

Table 2: Frequency of metaphors for mathematics produced by participants

Country	Animate		Inanimate		Emotion		Action	
	Human	Plant	Thing	Place	Abstract	Concrete	Action	Game
Belgium	-	5	5	2	5	3	8	11
Turkey	2	-	8	-	5	14	6	5

Working Group 11

As seen from the figures of Table 2 sub-categories of emotion- and action-related metaphors were used by both two groups. Some differences can be seen among the animate and inanimate categories.

Animate

In the animate category human and plant sub-categories were used. Human metaphors were used by Turkish and plant metaphors by Belgian participants. Some examples and participants' reasons are given in Table 3.

Table 3: Participants' animate metaphors for mathematics

Animate	Country	Mathematics is like....	Because...
Human	Turkey	an eye.	when you look you see the original.
		a woman.	to understand mathematics look like to understand a woman, in fact you can't understand both of them easily.
Plant	Belgium	a flower.	mathematics needs to grow. A flower needs water to grow. We need mathematics (questions, exercises) to grow. Also the children need to grow, so we give them water (theory, exercise).
		a tree.	you start with a base. No knowledge, when you start, but the longer you study math, the more you discover.

Inanimate

In this category place and object sub-categories were used by Belgian and Turkish participants. Although Belgian participants used object and place metaphors, Turkish participants used only object metaphors for expressing mathematics. Some examples can be seen in Table 4.

Table 4: Participants' inanimate metaphors for mathematics

Inanimate	Country	Mathematics is like....	Because...
	Belgium	a computer.	you really have to learn to use it and when you understand how it works, you can use it to do a huge amount of things.
		a pyramid.	in primary school you learn the principles of maths those are the fundamentals of math. When one brick placed wrong, the pyramid will fall

Working Group 11

Object			down. After a time you will have build a pyramid.
	<i>Turkey</i>	a wardrobe.	every topic of mathematics is clothes and mathematics looks like a wardrobe which contains all of them.
		a chocolate.	what you feel while occupying mathematics looks like the taste of chocolate while you are eating it.
Place	<i>Belgium</i>	a house.	first of all you learn the fundamentals and later you learn difficult things.
		the world.	you have all kinds of people. In mathematics there are so many parts, you can't learn them all.

Emotion

In the emotion category abstract and concrete sub-categories were found. Both groups used this metaphor for explaining mathematics. In Table 5 some examples from participants are given.

Table 5: Participants' emotion metaphors for mathematics

Emotion	Country	Mathematics is like....	Because...
Abstract	<i>Belgium</i>	air.	mathematics is everywhere, you can find it in the nature, in stars...
		a circle.	everything is constructing.
	<i>Turkey</i>	a ladder that you never reach its summit.	the more you climb up stairs, the more you meet new stairs. You never reach its summit.
		a depression.	when you think you solve the problem, you meet new problem. After a while you confront a more difficult problem.
Concrete	<i>Belgium</i>	a magic box.	you always get surprised when you work with it.
		the roots of a plant.	there are many ways to reach solution a problem.
	<i>Turkey</i>	a star in the sky that you know the name.	you know only the things that you probe, identify. You don't know the things that you never gain, set forth.
		an ocean.	there is no border of mathematics. The more you put out to sea, the more you can lose your way. In it, there are a lots of wind and wave.

Action

In this category action and game sub-categories were found. Some examples from participants' produced metaphors are given in Table 6.

Table 6: Participants' action metaphors for mathematics

Action	Country	Mathematics is like...	Because...
Action	Belgium	playing an instrument.	there is a lot to learn about and one small mistake can get the entire exercise wrong.
		building a house.	first you need to have a good fundamentals, bricks to build, a roof and so on, later on you can give the house your own style.
	Turkey	painting an artist.	a painter paint freely, mathematics also is the same. It is a kind of information network.
		dividing a Turkish bagel equally.	in mathematics there is an equity, an order and an aesthetic.
Game	Belgium	a game.	you play with numbers. There are certain rules you have to follow.
		a puzzle.	you have to put together all the pieces before you really understand the whole picture.
	Turkey	a game.	there are definite rules of game and so is mathematics.
		a puzzle.	in mathematics you feel you are in dilemma and try to find the exit.

DISCUSSION AND CONCLUSION

Participants produced animate, inanimate, emotion and action metaphors for mathematics with, in every category, sub-categories. Analyses of participants' metaphors for mathematics indicated that Turkish and Belgian participants had different images of mathematics; a finding likely to have several causes. A number of writers argue that different views of mathematics, as reflected in the metaphors presented, are linked to interpretations of how mathematics is played out in their own lives, both within and outside of school (Schinck et al., 2008; Noyes, 2004; Soto-Andrade, 2007). Indeed, as indicated by Stigler and Hiebert (1999), in Noyes (2004),

Working Group 11

the way mathematics duplicates the text through which is taught varies according to location, both geographical and cultural, at international and national levels. When the reasons indicated by participants were scrutinized it can be concluded that differences in Belgian and Turkish pre-service primary school mathematics teachers' metaphoric expressions may stem from participants' cultural background, individual experiences about mathematics within and outside of their school and also educational system.

Saban, Kocbeker and Saban (2007) emphasized that metaphors are selective. When asked to complete the statement *Mathematics is like... Because...* their participants' metaphoric expressions about mathematics were different from each other. In this study, however, some similar metaphors were used by Belgian and Turkish pre-service primary school mathematics teachers. This was seen in the game sub-category with words like *puzzle, maze and game*. Both Turkish and Belgian students exploited puzzle metaphors to reflect their thoughts about mathematics. In similar vein, the metaphorical categories of emotion and action were used predominantly by participants from both countries. That can be explained by the characteristics of mathematics itself. Participants explained the abstract nature of mathematics by using both abstract and concrete phenomena. As indicated in the study of Lakoff and Nunez (2000) one of the principal results in cognitive science is that abstract concepts are typically understood, via metaphor, in terms of more concrete concepts.

Comparing different countries' pre-service mathematics teachers' metaphorical mathematics-related expressions may help us to understand the extent to which such devices are culturally located. The evidence above suggests that the more we use metaphor analysis as a research and evaluation tool, the more we will understand the belief and thought systems of people.

PROBLEM SOLVING AND OPEN PROBLEMS IN TEACHERS' TRAINING IN THE FRENCH AND MEXICAN MODES

Alain Kuzniak*, Bernard Parzysz*, Manuel Santos-Trigo** , Laurent Vivier*

* Laboratoire de Didactique André Revuz, Paris-Diderot University, France

** Center for Research and Advanced Studies, Cinvestav-Mexico

Mathematics education may differ in traditions and theoretical approaches throughout countries, but it is generally acknowledged that problems and tasks play an important role in learning. Two research teams, one in Mexico and the other in France, decided to work together in giving mathematics teachers in both countries the same task to solve during a training session. This paper summarizes the results of this study. It shows that in the two countries the reference to different theoretical frameworks results in putting emphasis on different but complementary aspects of teaching.

INTRODUCTION

In different countries, mathematics teachers' education and research programs in mathematics education exhibit differences both in principles and ways to implement them. There are also different research traditions or paradigms to frame mathematics education projects, but all of them recognize that mathematical problems or tasks play an important role in fostering the development of teachers' and students' mathematical knowledge. Contrasting different systems and approaches, in this study French and Mexican, may be of interest to identify features, common goals, and differences associated with their traditions in education. Our research interest is to analyze and document both the processes put into play by pre-service teachers while working directly with problems and later the way they use these problems in their teaching practices.

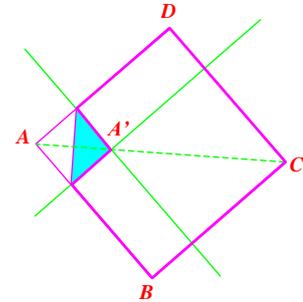

Specifically, the purpose of our common project is to investigate ways in which pre-service and in-service teachers work on a series of problems in order to prepare, organize, schedule and implement their lesson plans. Moreover, the development of technologies in class is quickly changing teaching practices and it appears necessary to take it into account. During their interaction with the tasks, pre-service teachers were encouraged to use computational tools.

In the present contribution, we will focus on the initial step of the project in which a common problem was used as a teachers' training tool in both systems of education. Our main interest was to see the implementation in contexts in which "solving a problem" has not necessarily the same meaning. Introduced by Polya (1945), problem solving constitutes the traditional framework for teachers' training in Mexico. In France, the traditional framework for teachers' training relies much more on Brousseau's Theory of Didactical Situations (Brousseau, 1998).

Working Group 11

Taking into account the differences in the referent frameworks in France and in Mexico, we chose the following mathematical problem in both countries for teachers' training to compare how it was used. Other problems were discussed, but not chosen by the French team because of the difficulty to use them in secondary teaching.

The task: A square piece of paper $ABCD$ with side l , has a white front side and a blue back side. Corner A is folded over point A' on diagonal AC . Where should point A' be located on this diagonal (or: how far is A' from the folding line) in order to have the total visible area half blue and half white? (Based on Carlson & Bloom, 2005, p.71).

For each country, we expose briefly the main features of the theoretical framework used and describe and analyze teachers' training scenarios based on this problem. We start with teachers' training in Mexico City, then with teachers' training in Blois (France). Furthermore we analyze the main elements of the comparison.

TEACHERS' TRAINING SESSIONS IN MEXICO

Problem solving

Mathematical problem solving perspectives have framed and oriented the development of multiple research programs and supported curriculum proposals in mathematics education in the last four decades (Schoenfeld, 1985, NCTM, 2000). In general, a problem-solving route to learn mathematics relies on an inquiry or inquisitive approach to deal with mathematical ideas or problems (Santos-Trigo, 2007); however, there are multiple factors around its identity and practical applications. "The patterns that form a problem-solving identity are complex, involving varied motivational patterns, affective reactions and cognitive and social engagement in different circumstances both within a given task and across tasks" (Lesh & Zawojewski, 2007, p. 776).

In teachers' education, it is important to address issues regarding the nature of problems, the rationale for using them, and the goals that are intended to be achieved during the problem solving sessions. Similarly, it is also important to elaborate on ways to organize and develop the problem solving sessions to be held with pre-service teachers. For that, it is important to discuss the dynamic of the problem solving scenarios in which teachers and students will work on the problems.

The context

The problem was given on a sheet of paper to a group of 14 pre-service teachers. Afterwards, they were asked to read and make sense of the problem individually, and later they worked on the problem in pairs. Then, each pair had the opportunity to present their approaches to the problems to the others. At this stage, all the

Working Group 11

participants and the instructor could ask for concept explanation or clarification. At the end of the session, the instructor encouraged the participants to contrast the different models used to solve the problems. In general terms, the sessions' dynamics fostered the participants' inquiring approach to the problems. For example, when the participants introduced an idea or a problem representation, the instructor questioned them and encouraged them to reflect on their ideas and other related concepts. Similarly, when the participants ran out of ideas the instructor either oriented the discussion (through questions) or asked other participants for suggestions to be considered. The aim was to encourage all the participants to formulate and then go deeper into the questions. In this perspective, the organization of the sessions is consistent with the activities recommended by Mason and Johnston-Wilder (2006) to have students participate during problem-solving discussions. In particular, the authors identify four ways to organize students' participation in developing and discussing their mathematical knowledge:

Individual work allows learners to review, consolidate, and develop their facility, as well as to reconstruct for themselves.

Work in *pairs* allows learners to try out ideas on each other before offering them to a wider group; it also provides an opportunity for learners to consider something that has happened or been said, and to generate more ideas about this [the problem] than an individual is likely to produce when working alone.

Work in *small groups* allows a multitude of ideas to be generated, and also allows a large task to be split up amongst several people; with discipline, small groups can provide a forum for discussing ideas, modifying conjectures, and coming to a consensus with supporting reasons and justifications.

Collective and *plenary* work allows everyone to hear about novel ideas and approaches, and to see teachers or peers displaying their mathematical thinking (p. 52, italics in the original).

It is important to mention that the pre-service teachers were taking a problem-solving course when they worked on the task. The aim of this course was to use different computational tools in problem solving activities. The participants worked on the task during two sessions (2 hours each) held at the end of the semester. The goal of this report is not to analyze individual approaches to the task but to focus on characterizing mathematical behaviors exhibited by the group of participants as a whole. The solution process is structured into episodes which distinguish key principles associated with the finding of solutions (Santos-Trigo & Camacho; 2009).

First Episode: An overarching inquisitive principle

The core aspect in this approach is to conceptualize and examine the contents of the problem (definition, theorem, etc.) in terms of questions or dilemmas that need to be explored. An overarching principle that permeates the entire problem solving process is that teachers and students should transform the problem statement into a set of

meaningful questions to be examined. Thus, the questions addressed by the group included: What are the relevant properties of a square? What does it mean to fold a vertex over to a point on the diagonal? And also questions to examine properties of the involved figures: What properties does the folding line hold? What figures are formed in blue and white colors? What happens to both areas when point A' is close to point A or close to point C ? What type of triangle is formed (blue region) when point A is reflected with respect to the folding line to determine A' ? How can we calculate the areas of the blue and white regions? In general, the participants observed that for different positions of point A' (*i.e.* when A' is moved along the diagonal) the area of one region increases while the other decreases. Then, they agreed that there would be a position for point A' where both areas were equal. At this stage, two main approaches to solve the task appeared: one focusing on representing the task algebraically and the other relying on constructing a dynamic model of the problem.

Second Episode: An exploration principle

The figure provided in the problem statement (some labels were added) was used by some participants to represent the triangle area as $x^2/2$ and the other as l^2-x^2 , which led them to solve the equation $l^2-x^2 = x^2/2$ in order to find the position of point A' .

The dynamic approach carried out by some participants required thinking of the problem in terms of mathematical properties and software commands. This approach allowed them to visualize and quantify the area variation of both regions as a result of moving a point on the diagonal.

During the plenary discussion, the participants acknowledged that the two approaches complement each other because they gave them an opportunity for examining the task from various perspectives. While the algebraic method gives a general solution to the problem, the dynamic approach offers not only the possibility of exploring visually the area variation of both regions; but also to graphically interpret the solution achieved algebraically (intersection point of curves).

Third Episode: The principle of extension and generalization

The participants asked whether the methods used to compare the area variations of the square could be extended to the case of a rectangle. They recognized that in the process of solving a problem or understanding a mathematical concept or idea it is always important to reflect on the scope of the solution or applications of that concept. In this context, the method used to explore the square case dynamically was adjusted to deal with the rectangle case.

Fourth Episode: Reflection Principle

Participants generally recognized that a problem solving approach for learning mathematics involves the construction of mathematical representations of concepts, situations or problems, in order to find and explore mathematical relations. In this

process, any mathematical statement (problem, definition, statement, content) is conceptualized as a starting point for teachers, students, or problem solvers in general to search for different ways of solving and extending a problem. In this perspective, the use of technological tools offered the participants the opportunity to explore some parameters of the task from varied angles and as a consequence, they could relate different ways of reasoning about the problem. For example, the construction of a dynamic model requires from the problem solver a functional approach without defining explicitly a function which is necessary with an algebraic approach. However, both models complement each other in terms of making sense, visualizing, and generalizing a set of relations emerging during the solution process.

Conclusion

In this approach, teachers tend to guide their practices through problem solving principles that lead them to search and explore diverse ways to solve the task. This particular process takes a long time for the participants to get appropriated and exhibited in their regular practices. However, they clearly recognized it as powerful approach to develop a deep comprehension of mathematical concepts and solving problems. Thus, the emphasis in teachers' education is to conceptualize the problem solving process as an opportunity for them to look for various ways to approach the tasks and to search for relations that emerge as a result of using different tools.

TWO TEACHERS' TRAINING SESSIONS IN FRANCE

Problem situation, open problem and research narrative

The notion of "problem situation" appeared in France in the 1980s in Brousseau's TDS, which is based on a socio-constructivist conception of learning. A problem situation is a learning situation aiming at fostering the acquisition of a new knowledge by the students. Its setting up implies identifying previously erroneous or weak conceptions among the students by analysing their errors. On this basis the teacher conceives of and sets up a situation presenting some specific features, namely: 1) be relevant for the cognitive objective aimed at; 2) have a meaning for the student; 3) allow him/her to begin the search for a solution; 4) be rich (in terms of mathematical and heuristic contents); 5) be possibly formulated within several conceptual "frames" (Douady, 1986).

The notion of "open problem" was introduced at about the same time (Arsac *et al.*, 1988, Arsac & Mante, 2007). In comparison with the problem situation, the aim of an open problem is methodological rather than cognitive. The students are induced to implement processes of a scientific type, *i.e.* experimenting, formulate conjectures, test them and validate them. The problem must belong to a conceptual domain in which students are somewhat familiar with, the wording (statement) has to be short and induce neither a solution nor a solving method.

Working Group 11

The French official curricula for junior high school (BOEN 2008) integrated recently – though without naming them – open problem and problem situation, which refer to two complementary sides of mathematical work:

- in the case of an open problem the question is to find a genuine, personal solution, with one's own means, the general solution being out of reach;
- in the case of a problem situation the question is, starting from a specific problem, to elaborate a more general knowledge (concept, process...) which is intended to be institutionalised, socially acknowledged and mastered by all.

The notion of “research narrative”, which is explicitly linked with those of open problem and problem situation, appeared in France some twenty years ago (Bonafé *et al.*, 2002). It involves asking the student to write an account of the thought processes he/she has undertaken in order to solve a given problem, pointing out his/her ideas, successes, failures, etc. The features of the problem are the same as for an open problem, but it has often several questions and the student must be able to start a research, test his/her results and validate them. And, if possible, different solutions need to be considered.

Implementation in high school teachers' training in Blois

Sessions on the folded square problem were organized with two groups of pre-service teachers: a “standard group” included 18 trainees in their first year of professional training and a “special group” included 6 trainees who had not been appointed to a permanent post at the end of the normal training year.

Besides this different context, the tasks given to the standard and special groups are quite the same. A material bi-colored square folded along its diagonal is used to explain the problem. The trainees have to compare both areas using different tools: software, spreadsheet, calculator, paper and pencil. They were asked to write a research narrative of their exploration and solution of the problem with the specific tool used and then to prepare a classroom session for their own students, to make explicit their mathematical aims and the material they would use with their students.

The standard group

The described session is a 3 hour lecture, part of a course focused on theoretical issues aiming at initiating the trainees to Brousseau's theory and the pedagogical use of open problems. They were also initiated to pedagogical uses of Dynamic Geometry Software (DGS) and spreadsheet. They generally mastered very well DGS but not spreadsheet, which is not a common tool for mathematics students at university. No particular mathematical framework was privileged and students had to use some specific artefacts to solve the problem. The 18 trainees were split into 5 teams: 2 teams worked with *Geogebra*, 1 team with a spreadsheet, 1 team with a hand-held calculator and 1 team with paper and pencil. When they had completed

Working Group 11

work, all the teams presented it to the others. After the presentations, they were asked to prepare a classroom session for their secondary students.

Team with DGS. The task is very open and dependent on knowledge about the software. Normally, the problem must be handled a bit more in the geometric frame than with other tools. Students had indeed a very good knowledge of the software and they immediately solved the problem by linking it to the curriculum for grade 9. We can follow the methods from the narratives:

- Drawing the folded square, linked with the area of both parts. The dragging point is point A' on the diagonal.
- Drawing two curves in a Cartesian system (one representing the area of the blue triangle and the other the area of the white hexagon). The link between the point and the area is made by using the *track* mode (not *locus*). The intersection point is reached by approximation.

Both teams indicated the objective of exploring the problem as an example of modelling. They retained that modelling and experimental approach in official documents must rely on the computer. These teams wanted to support students by giving them a rich environment favouring an exploration of the problem. They gave the same problem with the same instruction as that received during the course (for them the use of digital tools is not a problem for the high school students). In a second stage, they intended to work on the difference between exact and approximate values: the exact value controls the different results depending on the square size.

Team with calculator. The team focused on an approximate resolution of the equation of two curves and followed this method: free hand drawing modelling the situation, where x is a side of the right angle in the folded triangle; observation that it is impossible to find an exact geometrical construction of the point equalling the two areas (hence they decided to approximate the result with a calculator); plotting curves representing the areas in a particular case; approximating the result with a table of values and using the calculator zoom; solving algebraically a quadratic equation to get the exact value.

This team's objectives were using the calculator and writing out equations. They therefore used the activity to improve their students' knowledge of calculator. They retained the instrument for the course, using it to work graphically on the variation of two functions and the intersection points of curves.

Team with spreadsheet. This team started the research with a bi-colour paper and modelling. Students chose the height of the blue triangle ($AA'/2$) as a variable. After discussion, they agreed to make the values vary on a range equivalent to the diagonal. Then they used a spreadsheet to increment the variable with a given step

Working Group 11

and calculated the areas of the blue triangle and white hexagon, and their ratio. An approximate value was reached when this ratio was 1.

To determine objectives for the class, members of the team discussed sharply and did not agree, some wishing to continue with the spreadsheet, others finding no interest in this activity with the spreadsheet.

Team paper-and-pencil. This team changed its name into Paper-and-Brain Team. They immediately solved the problem by using two general equations.

Only junior high school teachers participated in this team (grades 7 and 8) and they concluded that the activity was too difficult for their students. They made a proposal for grade 10 students based on the resolution of a quadratic equation. They remained in a paper-and-pencil environment and did not plan to use software (the institutional pressure for using technologies is weaker on junior than on senior high school teachers). They spent time writing instructions for the students with no reference to an actual folding.

The special group

Each trainee received by mail an envelope containing a square sheet of paper and the task they had to perform. The trainees were isolated from each other and the exchanges took place only during the two sessions. They had to undertake a research of the different possible solving strategies, choosing two environments (paper and pencil; calculator; DGS; spreadsheet) and to write a research narrative. They also had to write a complete course for one of their secondary classes and really teach this course. They had to write down their work and present it to the group (the first session was mainly devoted to mathematical research and the second to the lesson).

All trainees used a paper-and-pencil environment, which is not surprising. Calculator was only used by one trainee (approximate values were obtained with *GeoGebra* by visual adjustment of the areas, sometimes with the *slider* tool, in order to get better values); spreadsheets were not used at all. All trainees used the *GeoGebra* software for modelling the folding; no other dynamic geometry software was used.

Only the two trainees who taught in senior high school used the software for solving the problem by considering intersections of function graphs. It seems that the syllabus plays a great role for these two trainees, since the senior high school curriculum emphasises functions and graphs. This link between teacher's research and topics he teaches at school also appeared with a grade 8 teacher who focused his research on geometrical proofs, which are of great importance at grade 8.

Unsurprisingly, the tasks given to their students confirm this last point, since teachers care a lot about the subjects they have to teach. In spite of this obvious fact, a detail has to be mentioned: only the two senior high school teachers proposed a comparison of the areas to their students; all of the others changed the question into

Working Group 11

“when are the areas equal?”. It is a fact that the comparison of functions by means of graphic strategies is an important subject at grade 10.

Conclusion

In both French groups, the grade, or the teaching institution, in which a teacher teaches seems to influence not only the transposition of the problem for the students, but also his/her research when he/she solves a problem for himself. And this could be observed whether trainees knew that they had to set up a course for their students (special group) or not (standard group).

The software chosen in the special group was still *GeoGebra*, one could think that there was in fact no choice of the software. This is linked with software currently used: the standard group is richer for DGS and especially *GeoGebra*. We explain this in this way: *GeoGebra* is a free software, both a dynamic and analytic geometry software which can even replace a calculator, and for that reason the training and school institutions possibly put the stress on it. But this does not explain why spreadsheet was left aside (maybe because of a lack of teachers' competences?).

We also noted the importance of the artefact used during the session on the trainees' school planning: they stayed very close to the experience they lived during the training. This argues for repeating this kind of training sessions but changing the tools used by the teams.

COMPARISON OF FRENCH AND MEXICAN SESSIONS

There are a lot of similarities between teachers' training in France and Mexico. Obviously, we can first mention structural organization similarities: number of trainees in a course, duration of sessions, trainees teaching in a real class. There are also some pedagogical organization similarities, such as sharing courses into individual work, work by groups (even by pairs) and plenary sessions. These similarities show that the way to plan teachers' training is quite equivalent from a pedagogical point of view.

The emphasis on the use of new technologies is another similarity. Obviously it relies on didactics and the interest for teaching mathematics, but we could also see an external pressure of society and more specifically curriculum demands. Nevertheless, spreadsheet seems to be left out in France which is not possible in Mexico because of the problem solving framework which demands to explore all solving possibilities.

The main difference is clearly the role of real secondary classes. In France it appears that the level at which the trainees teach has a great influence on their behaviours and, in teachers' training, teaching at secondary level is one of the main aims (virtually for the standard group and really for the special group). In Mexico, real classes seem to be out of the training since there is no reference to them in problem solving sessions. Obviously this is not the case because one of the aims of the Mexican problem solving sessions is that teachers would be able to do the same

activities with their students. But this is not explicitly worked, contrary to French teachers' training.

Another difference could be related to the difference in didactic frameworks reference. In France the trainees' work began with a material square whereas in Mexico the situation was modelled under the form of a geometrical diagram.

CONCLUSION

These examples from two different countries with different cultures and traditions about mathematics education show that in each of them the stress is put on different points: In Mexico solving strategies and associated scenarios or episodes, in France the influence of tools and implementation of the problem situation in a classroom. Both aspects are important for the training of mathematics teachers: On the one hand they must be prepared to understand, assess and support any solution proposed by their students, and on the other side they need to identify the contribution of the situation to the students' knowledge and consider how to bring it into play in a real class. We believe that the development of such cross studies can have an influence on the training of pre- and in-service teachers and finally help them to develop a more holistic view of teaching.

WHAT KINDS OF TEACHING IN DIFFERENT TYPES OF CLASSES?

Céline Maréchal

Equipe DiMaGe, Université de Genève

In our research we examine the forms of teaching found in three structurally different primary classrooms in Geneva (“ordinary” classes, specialized classes, and schools with classes dealing with children with personality and learning difficulties). The aim is to determine whether the ecology of the didactics in those three types of classes obstructs, even prevents, the achievement of certain didactical goals, in our case, the introduction of addition.

Key-words: teaching practices, mathematic organizations (MO) and didactic organizations (DO), conditions and constraints

INTRODUCTION

In this paper, the comparative aspect on which we focus deals with groups of students, which share specific characteristics in primary school. We distinguish “ordinary” classes, specialized classes, and schools with classes dealing with children with personality and learning difficulties. One of the main aspects of the study is to determine if the teaching is dependent on the type of class structure. Indeed, we hypothesise that the institutional conditions and constraints particular to each of those three types of classes will have an impact in terms of didactical and mathematical organizations. “It is in the classroom that we can best discover those conditions and constraints that make up the specific ecosystem in which the teacher has to handle knowledge” (Chevallard, 1989, p.62). In this research we are interested in the case of the introduction of addition in first year of primary school in Geneva.

BACKGROUND

Our investigation takes place in a primary school in Geneva where there is a policy of structural differentiation, which is defined by Doudin and Lafortune (2006) as the creation of various types of classes within the same school system. Each type is supposed to accommodate a certain profile of pupil defined principally by his school qualification, level and/or problem behaviour in class. In this research, we observed three “ordinary” classes (OC), three specialized classes (SC) and three classes with children with difficulties with personality and learning (TC).

One particularity of the French-speaking Swiss context is that there is a single common official set of pedagogical material for mathematics teaching, including text-books and files for students and a book for teachers with didactical commentaries. However, teachers in special education do not have to use those official documents, while it is more or less compulsory in “ordinary” ones. We also know that teachers in special education usually have more liberties than in

“ordinary” education, which will necessary influence their practice. For example, they are neither obliged to follow the official curriculum nor to evaluate their pupils, through the official tests designed for “ordinary” classes.

METHODOLOGY AND CONSTRUCTION OF A TYPOLOGY OF TASKS

For our research, we have collected scenarios from our 9 classes during a school year. We compared the time of effective teaching of addition during one year, the frequency of use of official documents and we analyzed the types of tasks and register of ostensive involved. These various elements allowed us to bring out the mathematic organizations and didactic organizations in each type of institutions (at the *regional*^[1] level). From those, we were able to define the MO and DO typical for each type of institution.

To analyze each activity about addition proposed by teachers to their pupils during one year, we needed to construct a typology of tasks. This allowed us to categorized all the activities according to the types of tasks implied.

Our research focuses on teaching practices. This is why we use the ATD – the anthropological theory of the didactic (Chevallard, 1992) – to analyze praxeologies, which are available in one particular type of classes. Therefore, we consider those three types of classes as three different *institutions* that offer us the possibility of systemic analyses. A “praxeology” is the basic unit into which one can analyze human action at large. In our research we started by a categorization of mathematical praxeologies. This offers tools to analyze institutional practices instead of one single person practice. Any praxeology defines itself by the following quadruplet: $[T/\tau/\theta/\Theta]$. This grouping defines a system of types of task (T) to carry out with a technique (τ) that must be validated by a technology (θ), which requires a theoretical justification (Θ). The first block $[T/\tau]$ defines a know-how which is a matter for the practice (praxis) while the second block $[\theta/\Theta]$ is from a reasoned speech (logos). To study teacher’s work, the ATD proposes two interdependent components which are mathematical organizations (MO) and didactic organizations (DO). It allows us to examine teachers’ work by means of two questions “what does he teach?” and “how does he teach it?” As mentioned by Chevallard, the analysis of these two components cannot be independently undertaken because of their co-determination.

The tools offered by this theory allow us to bring out the mathematical and didactical organizations set up by the teachers. We thus are interested in the block "praxis", defined by Chevallard, that focuses on the types of tasks and associated techniques . For this purpose we introduce a typology of tasks with two levels of specification that we explain below.

The numerical calculus

At first, we look at the numerical calculus involved in each activity proposed to pupils. In an on-line addition of type $a + b = c$, we distinguish three different

possibilities to code the activity: 1) a and b are given and c is to be found; 2) a (resp. b) and c are given and b (resp. a) are to be found; 3) Only c is given and some or all possibilities for a and b are to be found (additive decomposition). We also differentiate with the symbol (+) and (-) whether the activity involves an addition or a subtraction^[2].

Below we present the coding of the various possibilities we distinguished for the analysis of the activities proposed in the classes:

1° Mathematic : (numerical calculus)		
T ₁	(+) $a + b = \dots$	(-) $a - b = \dots$
T ₂	(+) $a + \dots = c$	(-) $a - \dots = c$
T ₃	(+) $\dots + \dots = c$	(-) $\dots - \dots = c$

Figure 6 : First level of specification: numerical calculus

The registers of ostensive

Then, we added a second level of specification. Indeed, our first categories did not allow us to differentiate the coding of certain activities collected, which were however very different. We used the registers of ostensive introduced by Bosch and Chevallard (1999). Ostensive objects are defined as handleable objects which have a handleable reality by the subject. Non ostensive objects, on the contrary, are neither "seen", nor "perceived", nor "heard". They need ostensive objects to appear. For example, the notion of addition (non ostensive), needs ostensive objects (such as the manipulation of tokens or codes of type $a + b = c$) to emerge.

We distinguished six different registers of ostensive, that we present in figure 2 below:

3° Registers of ostensive (Bosch & Chevallard, 1999)

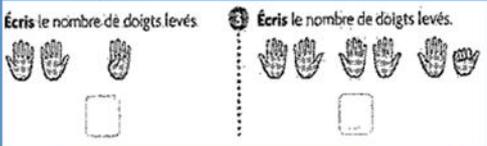

<p>1 – effective body movements</p> <p style="text-align: center;">Jeu impliquant des manipulations</p> <p>3a- figurative body movements</p>  <p>4a – written formalism</p> <p>4b- oral formalism</p> <table border="1" style="width: 100%; text-align: center;"> <tr> <td colspan="2"><u>Calculs</u></td> </tr> <tr> <td>$1 + 3 = 4$</td> <td>$3 = 1 + 4$</td> </tr> <tr> <td>$3 + 3 = 6$</td> <td>$4 = 2 + 2$</td> </tr> </table>	<u>Calculs</u>		$1 + 3 = 4$	$3 = 1 + 4$	$3 + 3 = 6$	$4 = 2 + 2$	<p>2-graph</p> <p>Écris le nombre de doigts levés</p>  <p>3b- written problems</p> <p>3c- orals problems</p> <p>Pierre a 2 bananes. Il en achète encore 5. Combien en a-t-il?</p>
<u>Calculs</u>							
$1 + 3 = 4$	$3 = 1 + 4$						
$3 + 3 = 6$	$4 = 2 + 2$						

Figure 2: Third level of specification: registers of ostensive

The first register of ostensive corresponds to a task which involves an effective situation involving pupils. This task allows a material validation by manipulation (counting collections of concrete objects representing quantities). In the second register of ostensive, the task represents a fictitious situation where the manipulation is no longer possible, but the result can be reached by counting collections of figurative objects. The register of ostensive 3a represents, through a pictorial representation, a fictitious situation, yet the manipulation is not possible any more. The pupils have to reconstruct mentally the operations to be made, but the image facilitates this organization. The registers of ostensive 3b and 3c correspond to written and oral problems where a fictitious situation is described through writing or oral speech. The pupils have to reconstruct mentally the operations to be made, but there is no image anymore to facilitate the understanding of the described situation. Finally, in the registers of ostensive 4a and 4b, there is no longer any reference situation, this is purely formal, only written or oral numerical operations are conveyed.

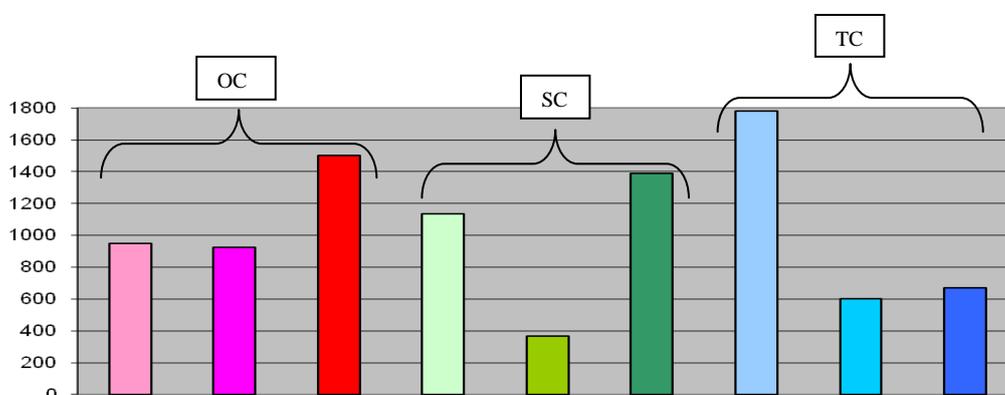

This second level of categorization informs us about a hierarchy in possible techniques to solve the types of tasks proposed previously in figure 1. We present, below, the analyses we developed on the basis of this typology of tasks.

INVESTIGATION

For the nine scenarios of teaching, we established a set of data corresponding to the time of effective teaching about addition during one year (DO), the frequency of use of official documents proposed in Geneva (DO) and an analysis of the types of tasks (MO) and register of ostensive involved during one year of teaching (DO). Those different data bring to light the mathematical and didactic organizations set up about the teaching of addition by the nine teachers.

Time of effective teaching addition

We begin with the graph below which indicates for every class the time (in minutes) that was assigned to the teaching of addition during the year.

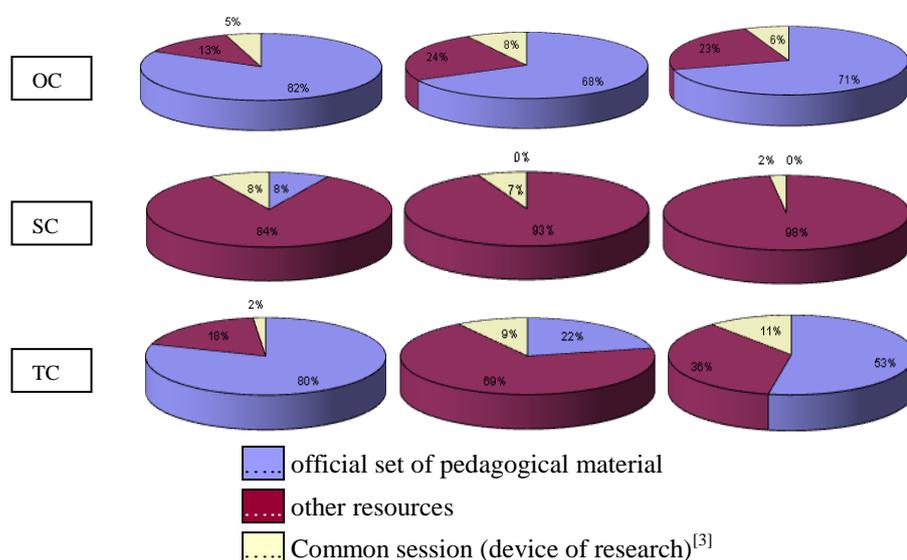

Graph 1: Time (in minutes) which was assigned to the teaching of addition during one year in the 9 classes

Working Group 11

First of all, we notice a clear disparity within the nine classes. However, the values are more homogeneous in the OCs. This fact can be related to the strong constraint of the program, which constrains teachers in the ordinary classes. In the case of the SCs, one of the teachers dedicated a particularly low time to the teaching of addition. In fact, this teacher has chosen to interrupt her teaching concerning addition in the course of the year. Indeed, she considered this notion too complex for the only pupil of the class for whom the introduction of addition was appropriate. Even if this case is extreme, it shows that the teachers of the SCs are not forced, unlike the teachers in the “ordinary” classes, to follow the official program. Concerning the two other classes, the values indicate a slight overinvestment with respect to “addition” compared to the OCs’ average. This seems to be due to the importance of the numerical domain in the specialized context, as several research works have already indicated (Conne, 2003, Cherel & Giroux, 2002). For the three classes of the TC’s institution, we notice two very low values and a very high value (in fact the highest of all 9), in a class, where the teacher has chosen to teach almost only addition in mathematics over the whole year. In the two other classes, the teachers teach all mathematical modules during the year and consequently devote a more restricted time to work on addition.

Frequency of use of official set of pedagogical material

The following graphs represent the use of the official pedagogical material by the teachers of the three types of institutions OC, SC and TC:

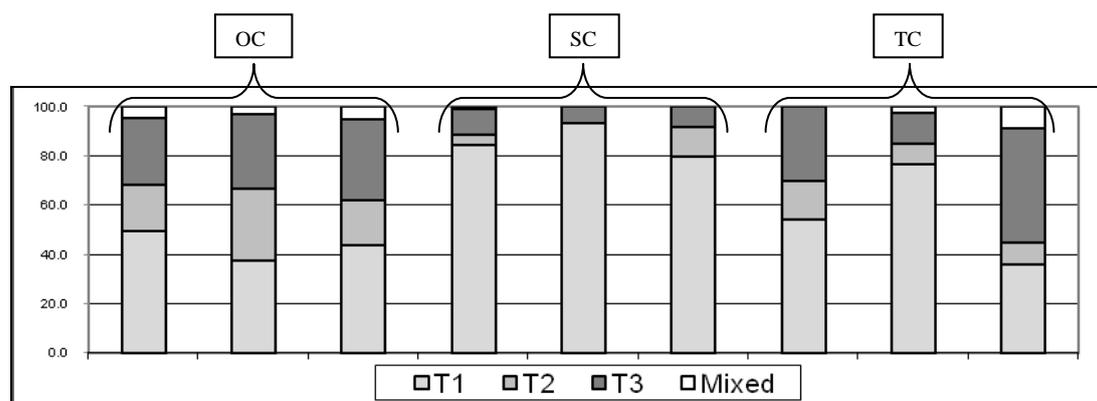

Graph 2: Use of the official pedagogical material by the teachers of the three types of institutions OC, SC and TC

In the three OCs, we notice homogeneous scenarios with a net tendency for teachers to use extensively the official pedagogical materials. This fact is not surprising considering the strong constraint that represent those documents. On the contrary,

teachers of the three SCs use little, if at all, the official material. In fact, these teachers do not even employ replacement textbooks, but dig into a reserve of activities that they accumulated over the years. Therefore they are more involved in the process of didactical transposition (Chevallard, 1991) through a necessary adaptation of the knowledge to the specificities of their pupils. This work is normally executed by the *noosphere* and thus demands a reflection on the contents of an upper level.

Analysis of types of tasks

Let us look in what follows the distribution of the types of tasks T1, T2 and T3 during the year of our observations in each of the nine classes:

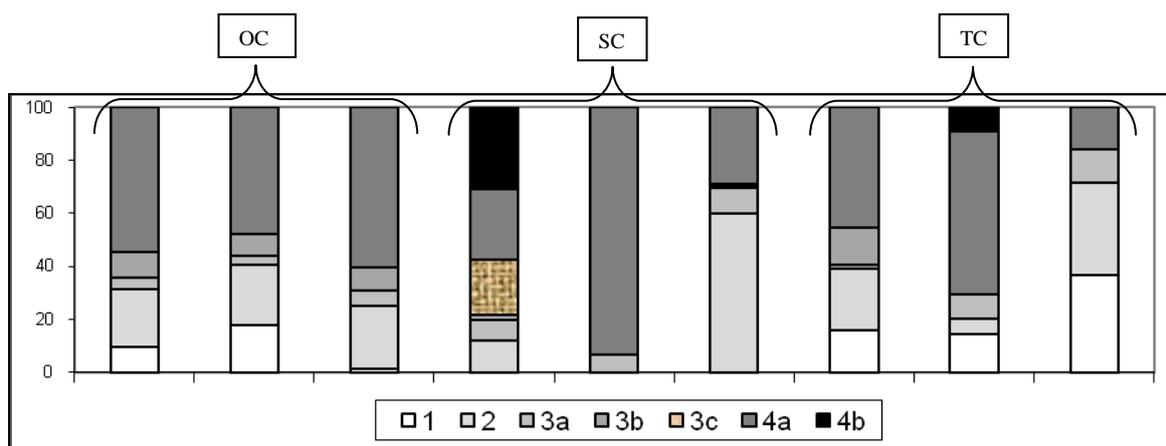

Graph 2 : Distribution (in percentages) of the types of tasks T1+, T2+ and T3+ during one year^[4]

This graph shows homogeneity within ordinary classes. We note a distribution more or less balanced by the three types of tasks, with however a majority of activities of type T1, then T3 and T2. In the specialized classes, homogeneity is also noticed. However, there is, in the three classes, a substantial overinvestment in type T1 tasks to the detriment of the two other. This result is certainly due, among other factors, to the fact that teachers do not use the official material or any other textbook, and implies a "thoughtful" progression of the content of teaching. On the other hand, for the TCs' institution, no homogeneity is noticed between the three classes. The first one gets closer to the functioning of the "ordinary" classes, the second to the specialized classes and the last one has a functioning rather original. It is the only class, where type T3 tasks are the most represented.

Analysis of registers of ostensive

Finally, let us look at the distribution of the registers of ostensive during the year of our observations of the nine classes (graph 3):

Graph 3 : Distribution (in percentages) of the registers of ostensive during one year

Again this graph indicates homogeneity within the OCs that we can attribute to the use of the official pedagogical material by the teachers and to the strong constraint of the program. A certain variety of registers of ostensive is represented in these three classes with, however, a majority of activities involving the register of ostensive 4a. The techniques of calculation, even counting, are thus facilitated, even if this is contrary to the fact that at the end of the primary school such strategies of “enumeration” should be overcome. In the specialized classes a "certain" homogeneity is noticed, because the three teachers chose to introduce a large number of "formalized" activities and the register of ostensive 1 (allowing the counting of collections of concrete objects) is absent. In the TCs, we notice again three different scenarios, representative of a large heterogeneity in these places. The first class has results close to the OCs' and the second close to the SCs' .

CONCLUSION

Our various analyses quickly presented above show that the different constraints, which weigh on the three types of institutions are not the same and engender the activation of different praxeologies. The teachers of the "ordinary" classes are confronted with strong constraints such as the use of the official pedagogical material and the "strict" follow-up of the proposed program. This results in relatively homogeneous MO and DO in this institution, with a large variety of different types of tasks relative to addition and also a variety of registers of ostensive.

In specialized classes, the constraints are numerous^[5] and come along, according to the classes, with more "local" constraints such as the behavior disorders of pupils or school heterogeneousness of the classes. The activated praxeologies are thus more or less homogeneous with, in particular, a massive accent on activities "formalizing" and implying essentially the type of tasks T1. This practice seems to be the result of the fact that teachers do not use reference textbooks. So teachers propose activities "valued" by numerous actors of the school, even the more general society, and

Working Group 11

overinvest the numerical domain (of which “addition” is part) at the expense of the geometrical domain or of measure. Furthermore, the fact that specialized classes are located in the same building as “ordinary” classes occasion a certain connection to the “ordinary norm” and “pressure of reinstatement” of pupils in the “ordinary” network, which influences the choices of MO and DO. In this case, we can notice a preference for the type of tasks T1 and registers of ostensive 4a, with a lot of “formalized” activities. In the interview we had with the teachers, one of the three specialized teachers discussed proposing a large number of “formal” activities to his pupils to prepare them for a possible reinstatement in the “ordinary” circuit.

The fact that the TC obtained heterogeneous results can be explained by the large autonomy of the teachers in this institution. They can focus on more “local” constraints to activate their praxeologies, which results in more varied cases.

Our study showed that the differences in teaching in “ordinaries” classes, specialized classes, and schools with classes dealing with children with troubles in personality and learning can be to a certain point explained by the differences in the constraints that weigh on these 3 types of institutions. Our work helped at explaining this fact and sorted out the different effects.

The activated praxeologies thus depend on the conditions and on the institutional constraints, which weigh on the teachers of every type of institutions. It stands out from this research work that the didactic ecology in the SCs’ institution may not be optimal and may give rise to scenarios of repetitive and impoverished teaching, which do not coincide with the initial intention to introduce addition. So, the teachers who are due to have a more active role in the process of didactic transposition are not equipped didactically to adapt their practice. On the other hand, the teachers of the TC’s institution have a larger space of freedom that explains why they can focus on the more particular context of their class (local constraints).

NOTES

1. Concerning more particularly the study of the OM, several levels are distinguished in the TAD (*punctual, local, regional and global*). The regional organization corresponds to a whole sector of the mathematics, as for example the notion of arithmetic operation represented by the sign + or - (Chevallard, 2002).

2. In our whole research, we also took into account if the unknown was a (initial value) or b (Vergnaud, 1981). However, we do not present these results in this article, because they bring few significant elements.

3. Session which we do not discuss in this article.

4. We do not consider the subtractive types of tasks. Indeed, during the first introductory year of addition, no subtractive activity is proposed in the official pedagogical material. However, we noticed that only the classes of the special education (SC and TC) proposed subtractions during the year of our collection of data.

5. For a more detailed analysis of the constraints appropriate for every studied type of institutions, refer to Maréchal (2010).

COMPARING THE CONSTRUCTION OF MATHEMATICAL KNOWLEDGE BETWEEN LOW-ACHIEVING AND HIGH-ACHIEVING STUDENTS – A CASE STUDY

Ingolf Schäfer*, Alexandra Winkler**

*Georg-August-University of Goettingen, **University of Bremen

The case study reported in this paper investigates whether there is a difference in the way high-achieving and low-achieving students construct mathematical knowledge and, if there is, how it might look. Furthermore, it investigates possible differences in metacognitive actions between these groups. For this, we study how pairs of high-achieving and pairs of low-achieving students deal with a problem-solving task about the divisibility of sums, using the theory of abstraction in context and a category scheme for metacognitive activities. This paper is part of a larger ongoing project that compares knowledge construction of high-achieving and low-achieving students using different tasks.

INTRODUCTION

When it comes to understanding why some students are low-achieving in mathematics there are many different approaches to the problem, including a focus on basic arithmetical difficulties often discussed in the context of dyscalculia (cf. Moser Opitz, 2007, for an overview), emotional aspects like, in the extreme case, math anxiety (Ashcraft & Moore, 2009) or motivational aspects like self-esteem (Pendlington, 2006). Research also indicates metacognitive actions to be very influential in mathematics achievement (Cohors-Fresenborg et al., 2010; Wang, Haertel & Walberg, 1993). Other factors like social class or cultural background play an important role, too (Cooper & Dunne, 2000).

We restrict ourselves to looking at the process of knowledge construction while separately taking metacognitive actions into account as a complementary view. This approach is done because it is an open question whether there are structural differences in the way low-achievers and high-achievers construct mathematical knowledge and if there are whether this is mainly due to differences in metacognition as indicated in (Cohors-Fresenborg et al., 2010).

THEORETICAL BACKGROUND

Abstraction in Context

The theory of abstraction in context (Hershkowitz, Schwarz, & Dreyfus, 2001; Dreyfus, Hershkowitz, & Schwarz, 2001), rooted within activity theory, is a model for the process of knowledge construction that has been applied to low-achieving students (Schäfer, 2009) and processes of knowledge construction that were only partially correct (Ron, Dreyfus, & Hershkowitz, 2006). In these studies the main

benefit over other theories concerning epistemic processes is that the epistemic actions defined below are observable actions – usually verbal – that allow insight into the internal process of abstraction.

Defining abstraction as “an activity of vertically reorganising previously constructed mathematical knowledge into a new structure”, Dreyfus et al. (2001) propose that the process of abstraction consists of three phases. In the first phase a *need for a new construct* arises, followed by a sequence of epistemic actions in an actual *construction* phase. Finally there can be a phase of *consolidation* of the construct.

In the construction phase three epistemic actions can be found. *Recognising* existing mathematical structures, *building-with* those structures, e.g., combining recognised artefacts to justify a particular claim, and *constructing* a new structure. These epistemic actions are nested, i.e., constructing incorporates building-with and recognising actions, and building-with incorporates recognising actions.

Layers of relation to objects

One of the directions in which activity theory has been developed is given by Oerter’s (1982) theory of action, which we will use to refine the three epistemic actions. Oerter uses the notion of action as the foundation of this theory and postulates that any interplay between individual and environment is only possible through actions. These actions, whether they are mental actions or physical actions, are always done with respect to some object, which may be physical or mental. An individual’s relationship to objects may only be changed by performing actions.

Oerter describes three different layers of relation to an object, which we summarise briefly in the following table.

Layer	Description
Singular	Object is only existent in the course of the action
Contextual	Object is discernible, but only inside a specific context of use
Formal	The formal structure of the object without its use

Table 1: Oerter’s Layers of Relations to Objects (Oerter, 1982, p. 114)

The singular layer is defined as the layer where subject and object cannot be distinguished by actions. Oerter gives the example of a child that uses a stick as a “sword” in playing knights. If the object “sword” is not existent anymore when the child has finished playing, then the object is only existent in the course of the action. If this playing knights is repeated more often and done with other children, the “sword” will exist beyond the actual situation, but still inside the contextual layer of play. The reader should be warned that the notion of contextual layer refers to similar situations and is different from the context in the sense of abstraction in a context which includes personal history or the classroom setting for example. Thus, we

always state explicitly which notion of context is meant in the following. The abstract layer is the equivalence class of all object uses which means that only the abstract formal structure of the object is left, e.g. the mathematical definition of a triangle is located here. For further details on Oerter's framework and the interplay with the theory of abstraction in context we refer to the considerations in (Schäfer, 2009).

Metacognition

The concept of metacognition, introduced by Flavell (1976), refers to the knowledge, active monitoring and controlling by the individual of her or his cognitive activities. As is shown by Schneider and Artelt's (2010) recent overview of research in mathematics education and psychology on metacognition, the concept has developed much since then. We follow the approach of the Osnabrück school (Cohors-Fresenborg et al., 2010; Cohors-Fresenborg & Kaune, 2007) and study the concrete metacognitive actions of participants in mathematics learning processes. They see metacognitive actions as a triple with the components *planning*, *monitoring* and *reflecting*. Planning refers to actions like organising or anticipating, monitoring includes regulating, verifying and checking, and reflecting comprises evaluating, assessing and judging. Cohors-Fresenborg and Kaune (2007) suggest the additional component of discursive actions for the analysis, but we restrict ourselves to the three principal components. Based on these components Cohors-Fresenborg and Kaune (2007) empirically developed a categorisation scheme for metacognitive and discourse actions. Although this scheme was developed for classroom situations in which algebraic questions are discussed on the basis of a discursive classroom culture, it is applicable to our situation as well, since the metacognitive actions themselves should not differ as long as the setting gives room for discourse.

We choose this framework for our metacognitive analysis, because it relies on an action perspective that is very fitting with Oerter's approach to express everything in terms of actions.

On the interplay of metacognition and abstraction in context

It is not our aim to have a unified theory of abstraction in context with epistemic and metacognitive actions, because some metacognitive actions can be part of the epistemic actions and the need. We would rather see our approach as looking at the same problem with different lenses in order to contrast and compare the findings with different theoretical perspectives (Prediger, Bikner-Ahsbahr & Arzarello, 2008).

Working environment: Divisibility of sums

The main task described below is concerned with the question whether, in a set of k natural numbers, there can always be found n numbers, such that their sum is divisible by n . This kind of question has been used in problem solving tasks for some

time now, e.g. it was the problem of the week no. 80 from Harvard Physics Department (2004), which also contains a general solution with proof.

Depending on the numbers n and k the solutions of the problem can be very different. We restrict to the two cases which we used. Case 1 is $k=13$ and $n=4$, which was given to the low-achievers, case 2 for the high-achievers was $k=17$ and $n=5$. Bardy (2007, p. 72-91) used the same problem for a case study [1] on gifted students in primary school.

In both cases the fundamental insight required is that it does not matter which concrete number is given in the set of k numbers, but only the remainders matter. After restricting to the remainders each case is solved by arguing how many numbers there have to be in each remainder class. A priori we expect to find the constructs “residue class” and “Dirichlet’s box principle”.

It may seem that case 1 is more complicated because recognising the different remainder classes seems more obvious with respect to five, but that does not take into account the effort of handling an additional number in the subset. On the other hand in case 2 the combinatorics for the residue classes are more complicated and involve a case-by-case analysis.

The notions “low-achieving” and “high-achieving”

The school system in Bremen comprises the Gymnasium and two forms of secondary school (Realschule and Hauptschule). Each type has its own curricula, final exams, lessons per week and years to exam. While 15-year old students in the Gymnasium perform above the international average in tests like PISA 2003, the students in the Hauptschule perform below average (with over 50% at risk). The difference in performance between Hauptschule and Gymnasium students is equivalent to a difference in 3-4 grades on the average (PISA Konsortium Deutschland, 2005).

For our purpose we state that those children in Hauptschule are low-achieving whose achievement in school is significantly below their peers and who have been identified by school tests as in need of additional support in mathematics. On the other hand, we state that students in Gymnasium who achieve significantly better in mathematics than their peers and who successfully take part in mathematics problem solving competitions are high-achieving.

RESEARCH QUESTIONS

We are interested in answering the following questions:

1. Are there different patterns in the use of epistemic actions between high-achievers and low-achievers?
2. Are there different patterns in the use of metacognitive actions between high-achievers and low-achievers?

METHODOLOGY AND DESIGN

The students are presented the task on paper in form of a dialog between two children. One fictional child named Kathy says she had found out about an interesting problem in a riddle magazine and goes on (translation of German original for the low-achievers; the high-achievers had the same text with the parameters 5 and 17 and the different example sequence (22, 7, 2, 4, 6, 6, 9, 18, 6, 12, 17, 6, 11, 6, 20, 5, 16)).

Kathy: You take 13 natural numbers, e.g., 7, 2, 4, 5, 5, 9, 14, 5, 10, 1, 5, 11, 3.

Lars: Ok, I understood. And what is so interesting about them?

Kathy: Within those 13 numbers you can always find 4 numbers, whose sum is divisible by 4!

Task:

- 1. Verify Kathy's claim in her example. Find as many subsequences as possible of 4 numbers whose sum is divisible by 4.*
- 2. Is it really always true what Kathy claims?*

The students are asked to discuss these problems with each other and write down a solution. They are given no additional information or help, with the exception of certain prompts from a field manual that should be given to the low-achieving students at certain times to ensure that they recognise certain phenomena, e.g., one of the authors might ask the students to explicitly compare two subsequences they found in order to help them recognise the fact that it is possible to replace a number with another representative of the same equivalence class without contravening divisibility. The task was mainly chosen because it does not depend on special knowledge other than basic arithmetic skills (other tasks are planned in future). No such prompts are provided for the high-achievers. The whole process is then videotaped and transcribed. The data is analysed in two separate turns: Each utterance in the transcript is coded according to the coding guidelines for the metacognitive actions as described in Cohors-Fresenborg & Kaune (2007). Separately, the analysis according to the RBC-model was done in a sequence analysis using an interpretative approach to the text utilising the theory of speech acts (cf. Bikner-Ahsbabs, 2008).

FINDINGS

Our case study was conducted with 2 pairs of high-achieving grade 6 students in Gymnasium and 2 pairs of low-achieving grade 9 students in Hauptschule meeting the definition. The difference in grades is supposed to roughly compensate for the difference between the school types as explained above. Due to space limitations we can only give a short summary here.

The case of Alice and Betty

Alice and Betty [2] are in the low-achievers group. They look for subsequences for question 1 more or less by trial and error and do not make much use of additional structure besides using the sum of the subsequences for ordering and comparing, which they talk about explicitly but use rarely. After a prompt by the interviewer they realize that certain numbers belong to the same remainder class, but it seems that they do not come to a more concrete understanding of the concept. Other than stating that they would need to find other examples, since one example is no proof and guessing that the product of the numbers in the subsequence might be involved, they do not come to arguments for question 2.

The case of Carl and Dan

Carl and Dan are also in the low-achievers group. For question 1 they struggle with the formulation of the task where Carl initially understands “subsequences of four numbers” as “four subsequences of four numbers”, which is clarified by Dan and the interviewer, but 30 minutes later Dan shows the same misunderstanding. Due to a prompt by the interviewer (“in a subsequence a 5 can be replaced by 1 without changing the divisibility of the sum”) they are able to use the concept of remainder class and Dan even finds the general definition of equivalence. Although they make some considerations on the divisibility of even and odd numbers, they do not achieve a proof by themselves.

The case of Eric and Fred

Eric and Fred are high-achievers. They work separately for most of the time while still informing each other about their respective findings and apply some strategies in finding examples including Eric doing a systematic case-by-case testing for subsequences of length 4, which he stops at some point. Fred tries to assemble a counter example and realises that it is possible to restrict the numbers from 1 till 9 for the sequence. Eric builds on this and introduces remainder classes. This restriction, in combination with Fred’s combinatorial considerations on the way to construct a counter example, leads to the proof given above in the mathematical considerations.

The case of Greg and Hank

Greg and Hank are high-achieving students. In answering question one they use many different strategies to find subsequences, most prominently a replacement strategy where they start with a given subsequence and replace numbers in it such that the sum remains a multiple of 5. They explicitly call these “rules” and give example subsequences with rules to modify them. Working with those rules they find the concept of remainder classes, writing down the first ten elements of each class. Restricting to the representatives 1 to 5 they give the proof outlined in the mathematical considerations.

Similarities and differences in the RBC-model

For all groups we notice many instances of recognising and building-with actions, but constructing mainly occurs among the high-achievers. Regarding the quantity of epistemic actions we note that the high-achievers perform a greater number of such actions in a fixed time span than the low-achievers. But one should keep in mind that although we tried to compensate by using smaller numbers in the task for the low-achievers, they spend much time on arithmetical actions, mainly adding the numbers, leaving less time for epistemic actions. Most of the epistemic actions happen at the situational or contextual layer in all groups and we could reconstruct three common contexts in the sense of Oerter's theory of action among the groups:

1. *Arithmetics*, in which the sums of the subsequences are calculated and some important properties can be recognised, for instance the invariance of the divisibility under replacement of a number by another representative of the same remainder class.
2. *Combinatorics*, in which possible subsequences are explored, e.g., how many pairs of numbers sum up to 12, or how many numbers have to be at least in each remainder class.
3. *Understanding of the task*. Some recognition actions are about what the task is and what it is not, i.e., how many subsequences must be found, how to deal with duplicate numbers etc. Since these actions are on-going for a longer period of time (a couple of minutes) and in all the groups, we consider them contextual rather than situational.

The low-achievers spend most of their time on situational epistemic actions or epistemic actions on the contextual layer regarding arithmetics or understanding the task and show very little formal actions, the high-achievers show more formal actions and also are less occupied with the arithmetical contextual layer.

We want to focus on a specific example of epistemic action which illustrates the difference between low-achievers and high-achievers. At some point the students in every group have found a subsequence of n identical numbers, but this does not lead to the same kind of epistemic actions. When confronted with the specific case of the number six while dealing with question 1, Greg and Hank immediately contextually recognise that this is n times six, i.e., multiplication and thus, divisible by n . Later when they deal with question 2 they recognise this case on the formal layer.

Hank: So, if you got five of one [number], you can divide it by five in any case.

Eric and Fred deal with the example of 6, 6, 6, 6, 6 in no special way in question 1. They just treat it as an example like the others, but in dealing with question two, they recognize on the formal layer that five times an identical number is divisible by five. For the low-achievers this piece of knowledge has probably not previously been constructed in a way that they could recognise it. In the case of Carl and Dan, they

construct multiple examples of sequences of identical numbers and Dan calculates the sum of four of them to check, whether they are divisible by four. This means that they are building-with the idea that the sum of four identical numbers is divisible by four contextually and seem to be unable to recognise the structure. Alice and Betty do not find the example of 5, 5, 5, 5 in working on the first question. When they work on the second question they follow a prompt by the interviewer to look at sequences containing only the numbers 1 to 4 first. Betty suggests to look at sequences containing only one number, for example the number 1.

Alice: Yes, then I can take – then – I can take four times one. Yes, four.

Then they try four times two and four times three by calculating the sum and checking whether it is a multiple of four. In the case of four times four she says

Alice: ... and four times four is – works anyway.

which may indicate that she has recognised some structure here. But as the episode shows, they do not recognise on the formal layer, but rather recognise divisibility of each result in the first three examples in the contextual layer.

There is also a difference between high-achievers and low-achievers regarding falsely recognising a mathematical property. This happens for all groups, but the difference is in the way it evolves: In the case of the high-achievers they drop those ideas when they find a counterexample, the low-achievers are usually willing to keep them for at least another counterexample.

In summary, we uncover several differences regarding Oerter's layers between the groups, e.g., the high-achievers may "easily" recognise a formal property, while low-achievers have to built-with it contextually. We do not find a more systematic pattern in our cases.

Similarities and differences in the metacognitive actions

All four groups use many different metacognitive actions in all of the three components, but there are differences in the use of certain subcategories. No actions occur in the subcategories related to different representations, which is due to the fact that all groups solely used the representation by numbers. Note, that the letter and the number in curly brackets refer to the metacognitive actions in the scheme of Cohors-Fresenborg and Kaune (2007).

Regarding the planning component there are few differences between the two groups, but in the monitoring and reflecting component, we see differences. The high-achievers reflect on the notions used {R1} and change their point of view numerous times {R4}, the low achievers do not reflect on the notions and change the point of view only in one case. But even for those metacognitive actions that are common to both groups there are differences in quality and use. Those differences can be described by three themes, which we illustrate by means of specific examples.

Working Group 11

One of the themes is the *broadness of the content* to which the metacognitive strategies are applied. For example in the monitoring of deficits in understanding or planning {M5, M6}, the low-achievers only apply this to each other's direct actions and utterances or in understanding the questions.

Dan: What does she claim then? [regarding Kathy in question 1]

In contrast, the high-achievers also monitor with regard to the purpose of certain steps or intermediate results.

Eric: What do we get out of it, when we know how many groups there are?

The second theme concerns *the interplay of metacognitive actions*. All groups actively search for divisible subsequences and monitor their actions with respect to the goals {M7}, but the low-achievers mainly utilise calculating monitoring strategies for this {M1}, while the high-achievers plan in advance {P2, P3}, e.g., Eric fixes three numbers, states possible numbers to be added in general and controls which of these numbers are occurring in the example and thus allowed.

The last theme relates to differences in the *perseverance of metacognitive actions*. While high-achievers and low-achievers alike monitor their actions with respect to content and goals {M7}, the low-achievers seem unable to maintain the level of monitoring all the time, e.g., both groups of low-achievers at first calculate the total sum of a sequence of 13 identical numbers, when working on question 2, instead of calculating the sum of only 4 numbers. The high-achievers also study the example of sequences where each number is identical, but correctly use only partial sums.

In summary, our cases indicate a difference between the groups with regard to metacognition, but more about the quality than about simple occurrences.

SUMMARY AND OUTLOOK

The above analysis indicates that it is worthwhile comparing the processes of knowledge construction between low-achievers and high-achievers. In the cases studied there seem to be great differences already in the recognising actions, which then in turn affect the possibility of building-with and constructing due to the nested nature of the epistemic actions. The role of contextual actions and the different themes in using metacognitive actions also seem to be influential. But, as was mentioned above, the arithmetical side of the problem was considerably more time-consuming and therefore probably harder for the low-achievers. Since this may account for some of the differences between the groups regarding the process of knowledge construction, we are in the middle of performing two additional tasks – one related to graph theory and another to geometry – with the students to see how much is related to these arithmetical problems.

NOTES

1. The question and the transcript itself is not part in the book. We thank Peter Bardy for sharing them with us.
2. The names of the participating children have been replaced by arbitrary chosen names.

CONCEPTUAL METAPHORS AND “GRUNDVORSTELLUNGEN”: A CASE OF CONVERGENCE?

Jorge Soto-Andrade^{62,*} and Pamela Reyes-Santander^{1,°}

* University of Chile, ° Universität Augsburg.

We compare the Metaphor Approach to mathematics teaching and learning and the Basic Ideas (“Grundvorstellungen”) approach of the German school of didactics of mathematics. We find close connections as well as some differences: “Grundvorstellungen” tend to be more “top-down” from the student’s viewpoint than metaphors, which operate in a more “bottom-up” and “poietic” (concept generating) ways.

Keywords: Metaphor, Basic Ideas, Grundvorstellungen, fractions, stochastic thinking.

INTRODUCTION

In this paper we compare two theoretical approaches to the didactics of mathematics, which have evolved independently, in different periods of time, although they address the same didactical problems in closely related ways. They could be described as the “Basic Ideas Approach” and the “Metaphor Approach”. Here “Basic Ideas” (even better, “Basic Notions”) is an approximate English rendering of the German “Grundvorstellungen” (vom Hofe, 1998), which alludes to the basic ways we imagine or represent something rather abstract to ourselves. “Metaphor” means in fact “Conceptual Metaphor” in the sense of Lakoff and Núñez (2000).

Although metaphors can be traced back to Aristotle’s Poietic, the cognitive and didactical role of (conceptual) metaphors in mathematics has been only recently and progressively recognized (English, 1997; Lakoff & Núñez, 2000; Presmeg, 1997; Sfard, 1997; Soto-Andrade, 2006, 2007). On the other hand, the origin of the “Grundvorstellungen” approach, developed by the German school of didactics of mathematics over more than two centuries - see vom Hofe (1995, 1998) for a detailed account - as a means of grasping and making sense of abstract mathematical concepts, may be traced back to Euler, who already in 1766 interpreted negative numbers as debts, pointing out that “to take away a debt amounts to make a gift” (v. Hofe, 1995, p. 19). German didacticians, however, do not mention metaphors and researchers working on the metaphor approach have completely ignored the “Grundvorstellungen approach”, perhaps because “Metapher” in everyday German is typically understood as a rhetorical device and contributions of the German school, mostly written in German, were scarcely known outside Germany, until vom Hofe’s paper on the generation of basic ideas and individual images (vom Hofe, 1998).

⁶² Supported by PBCT- CONICYT, Project CIE-05 and FONDEF Project D06i1023.

In what follows, after reviewing the main ingredients of the metaphor and ‘Grundvorstellungen’ approaches, we argue that conceptual metaphors, in the sense of Lakoff and Núñez (2000), play essentially the same cognitive role as “Grundvorstellungen” in vom Hofe (1995, 1998), although their didactic implementation may differ. We support our claim by comparing concrete examples of both approaches, taken from the literature and from our own teaching experience. We further discuss the ‘poietic role’ of both Metaphors and “Grundvorstellungen”.

THEORETICAL FRAMEWORK

In what follows, we adhere mainly to the theoretical framework laid by Presmeg (1997), Sfard (1997) and Lakoff & Núñez (2000) for metaphors, Breidenbach (1967), Oehl (1967), Griesel (1971), vom Hofe (1995, 1998, 2003) and Prediger (2008) for Grundvorstellungen.

Nature and Role of Metaphor

Metaphors are not just rhetorical devices, but powerful cognitive tools that help us to build or grasp new concepts, as well as solving problems in efficient and friendly ways (Lakoff & Núñez, 2000; Soto-Andrade, 2006, 2007). In the literature, often “metaphor” means “representation”, “analogy”, “model”, “image”, etc., but we intend here to be more precise, as in the diagram in Fig. 1, where metaphors “go up”, representations “go down” and analogies, “go horizontally” both ways.

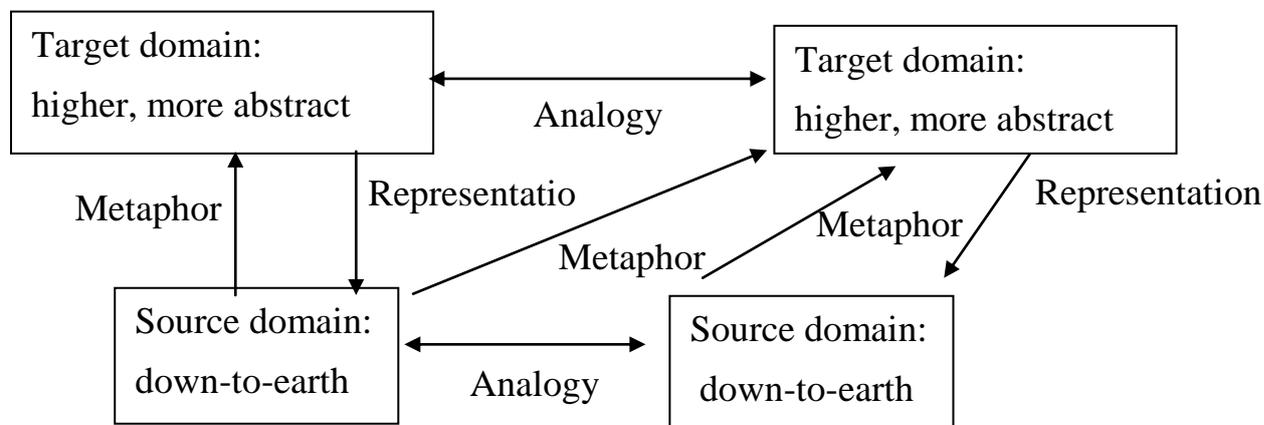

Figure 1. A spatial metaphor for metaphors, representations and analogies.

Here analogy means “simile” (an explicit comparison between two different things), symmetric in nature, and it is not an umbrella concept embracing metaphors, representations, similes, etc. So our viewpoint is closer to Sfard’s (1997) than to Presmeg’s (1997).

Example: Metaphors for multiplication

Most primary teachers are well acquainted with the “area metaphor” for the product, but somewhat less with the “grafting metaphor” (Soto-Andrade, 2006), illustrated below in Fig. 2, where both metaphors help us to visualize that $2 \times 3 = 3 \times 2$.

Fig. 2. Two metaphors for the commutativity of multiplication.

In the first, commutativity is perceived simply as invariance of area under rotation in one fourth of a turn. So you “see” that $2 \times 3 = 3 \times 2$, without counting and knowing that it is 6. In the second, commutativity is less obvious: you need to be familiar with trees for this metaphor to become a “met-before” in the sense of Tall (2005). Notice that these tree diagrams, drawn upside down, also suggest an ‘hydraulic metaphor’, which helps us to understand multiplication of fractions: A litre of water will drain evenly, by gravity, from the tree root, through the pipes, splitting into two and then into three in the left tree. So $1/6$ appears not only as $1/3$ of $1/2$ but also as $1/2$ of $1/3$.

This illustrates the importance of having metaphors of various scopes for the same mathematical object and of being able to transit between them. Indeed, from the grafting metaphor for multiplication we may transit to a deeper metaphor for multiplication: “*multiplying is concatenating*”. Fig. 3 below suggests commutativity if you look at the resulting diagonal arrow, but not so if you consider the concatenated pathways, which are different (The mathematical notion of category emerges here!). If we concatenate now triple arrows (which could be realized as triple threads or braids) we end up with “products” which depend on the order of concatenation (see Fig. 4).

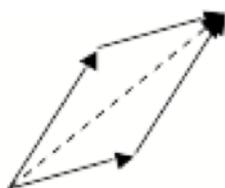

Fig. 3. Concatenation metaphor for multiplication (1 arrow)

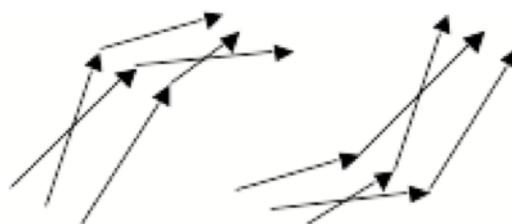

Fig. 4. Concatenation metaphor for multiplication (3 braided arrows).

Finally, note the connection with 2×3 and 3×2 : if we concatenate an enlargement of ratio 2 with one of ratio 3, we get one of ratio 6, and the other way around.

Metaphors in mathematics education

Mathematicians have been aware for a long time of the key role of analogies and metaphors to achieve understanding and insight (Sfard, 1994). Indeed, Euler himself

may be seen as a forerunner of this approach, when he suggests considering negative numbers as debts (Euler, 1802, p. 12). Thom, the creator of Catastrophe Theory, besides complaining that since the advent of positivism analogy is considered as a remnant of magical thinking to be condemned absolutely and at present is thought to be just a figure of rhetoric (Thom, 1994), uses even animistic metaphors: “On tue la topologie de la variété en l’appliquant sur l’axe réel, mais la topologie résiste, elle ‘crie’, et ses cris se manifestent par l’existence de points critiques” (Thom, 2002).

After Euler, the use of metaphors in mathematics education proper began rather late and heterogeneously. They were employed first mainly by mathematicians turning to didactics, like Dienes (1960) or Tall (2005), among others. It may be argued that when Dienes and Bruner (Dienes, 1960; Bruner & Kenney, 1964) posited that abstract concepts and processes may be apprehended by manipulating various embodiments, they were in fact using various metaphors for the same concept, as in “factorizing is assembling a puzzle” and “factorizing is balancing a family of weights against a single weight in a balance beam with hooks” (Bruner & Kenney, 1964).

In general, educational promotion of metaphors has been intermittent, with mixed results. In the U.K. the systematic use of the number line metaphor as a “key classroom resource” promoted by the National Numeracy Strategy since 1999 for primary school, was clearly not a success (Doritou & Gray, 2007). Apparently not enough attention was paid to preparing the soil first, where metaphors may grow. In Chile, the explicit use of metaphors, like the hydraulic one, was exemplified in textbooks distributed by the Ministry of Education to public primary and secondary schools during 2000-2008. However, their exploitation in the classroom remained limited, because most teachers had the feeling that to rely on metaphors is not serious, while mathematics is indeed serious stuff (Soto-Andrade, 2006, 2007, 2010). However, recent hard evidence of the positive didactical impact of the prescriptive use of metaphors in Chile is reported in Araya et al. (2010). An example of a non prescriptive use of metaphors, being tested at present in Chile, Germany and France: “the emergent metaphor approach”, is commented below (Brownie’s random walk).

Basic Ideas or “Grundvorstellungen” (vom Hofe, 1995, 1998)

Since the beginning of the 19th century, German didacticists, influenced by Pestalozzi (vom Hofe, 1998), were acutely sensitive to the importance that students imagine, visualize and represent to themselves abstract mathematical concepts and processes in some concrete way, to be able to make sense of them and so gain real understanding. This approach involved the generation of “Anschauungen”, i. e. visual mental models for mathematical objects, albeit in a rather passive and merely associative way, until Kühnel (1916) emphasized the role of individual activity and insight in the learning of mathematics. He developed a course of mathematical instruction for primary schools where the generation of “Stellvertretervorstellungen” (representative notions), mediating between the world of abstract mathematical thinking and the world of “real life” played a key role. Later, Breidenbach (1957)

Working Group 11

initiated didactical analyses of mathematical subject matter, creating the influential German school of “Stoffdidaktik” (“Stoff” = mathematical “stuff” or content), that produced teaching units for introducing different mathematical content and supporting the generation of suitable “Grundvorstellungen”. Oehl (1962), introducing the term “Grundvorstellungen” systematically, integrated the previous approaches into a coherent theory, that was later extended to the secondary school level by Griesel (1971) and others. “Grundvorstellungen” remained however used in a *prescriptive* way, as normative categories to train students to learn with understanding, until vom Hofe (1995, 1998) investigated their *descriptive* aspect, as idiosyncratic notions students actually develop, eventually inadequate from the teacher’s viewpoint. They involve (vom Hofe, 1998):

- Gv1. The constitution of meaning of mathematical concepts based on familiar context and experiences (as in metaphor = metbefore);
- Gv2. Generation of visual representations making operative thinking possible;
- Gv3. Ability to apply mathematical concepts to real life contexts.

Vom Hofe (1992) distinguishes moreover between *primary* and *secondary* “Grundvorstellungen”. The former are mainly psycho-motoric in nature, involving manipulation of concrete objects or acting in the world and entailing activation of the concrete or enactive representation mode in the sense of Bruner (Bruner, 1996; Bruner & Kenney, 1965). The latter take foothold on iconic or pictorial objects instead, like the number line, the Cartesian plane, graphs, and so on. They all correspond to metaphors, but with different kinds of source domains: concrete, iconic, abstract...

Example 1: “Grundvorstellungen” and metaphors for multiplication of natural numbers (Prediger, 2008; vom Hofe, 2003)

Prediger (2008) lists the following “Grundvorstellungen”:

- GM1. Iterated addition (3×5 as $5 + 5 + 5$)
- GM2. Area of a rectangle (3×5 as the area of a 3 times 5 rectangle).
- GM3. Multiplicative comparison (3×5 as 3 times as much as 5)
- GM4. Enlargement (3×5 as a 3-fold enlargement of 5)
- GM5. Combinatorial (3×5 as number of ways to combine 3 shorts and 5 shirts)

and points out that only GM2, GM3 and GM4 carry over to fractions and that on the other hand, the “*portion of - Grundvorstellung*” ($1/3 \times 1/2$ means $1/3$ of $1/2$) for fractions does not come from the natural number case. These “discontinuities” and the required conceptual change highlight epistemological obstacles (Prediger, 2008).

In the metaphor approach however, instead of considering the combinatorial and the “portion of – Grundvorstellungen” as totally unrelated, recalling that “to multiply is to concatenate” students might look upon the trees in Fig. 2 (drawn upside down) as trees of ducts and visualize *simultaneously* multiplication of natural numbers (product = the number of ducts in the last generation) and multiplication of fractions

(product = portion of 1 litre poured at the root that will drain down to each end of the tree). In this way the “concatenation metaphor” in some sense bridges the gap between GM4 and GM5 for natural numbers and the “portion of - Grundvorstellung” for fractions, suggesting that the relation between the former and the latter is in fact one of duality...

Example 2: Grundvorstellungen and metaphors for stochastic thinking

In a prescriptive way, Malle & Malle (2003), consider the following “Grundvorstellungen” for the probability of an event:

GP1. A measure of the likelihood that the event occurs.

GP2. The relative portion of favourable outcomes to the event, within the set of all possible outcomes of the corresponding experiment.

GP3. The relative frequency of the event in a series of repetitions of the experiment.

GP4. The subjective confidence in the occurrence of the event.

In a descriptive way, Wollring (1994) has investigated the emergence of animistic “Vorstellungen” in elementary school students, finding that they strongly determine their stochastic thinking. Most animistic notions, with no experimental support, concern the “will” and “consciousness” of coins or dice, the possibility of mentally influencing them and the fact that “the world is fair”.

Borovcnik (1984), who adheres, like vom Hofe (1998), to the “didactical triangle” (theory, reality, subject) where “Grundvorstellungen” live as a didactical construct, besides rehabilitating descriptive statistics as a didactically and mathematically interesting domain, points out that following the “spiral principle” one may develop at each successive level of teaching of descriptive statistics, adequate “Grundvorstellungen” for stochastic concepts. So this provides contexts where students can “mathematize” and “translate” problematic situations into mathematical models, besides developing their critical thinking in real applications, recognizing subjectivity and arbitrariness in model construction.

On the other hand, it has been shown that Bayesian “false-positive problems” in bio-medical test interpretation (“How likely is it that I am infected, if my viral test was positive?") may be solved by 6th graders, with the help of pedestrian metaphors, which allow them to calculate with natural (absolute) frequencies as in Zhu & Gigerenzer (2006) instead of fractions or percentages that confuse even experienced physicians.

RESEARCH QUESTIONS AND HYPOTHESES

We have reviewed two independently developed theoretical perspectives concerning mathematics teaching and learning, the ‘Grundvorstellungen’ approach and the metaphor approach, both aiming at achieving a meaningful teaching-learning process, as an antidote to rote, mechanical learning, without understanding.

Working Group 11

Given the high degree of influence that the former has had in German didactics and the increasing didactical attention the latter is now receiving, we would like to compare them, in terms of their theoretical cognitive and didactical background, as well as their classroom implementation with students and in-service teachers. In particular we would like to find out how they address the problematic of facilitating meaningful learning and *construction* (“*poiesis*”) of concepts by the students themselves.

Our first research hypothesis is that metaphors as well as “Grundvorstellungen” are key and necessary ingredients in a meaningful teaching-learning process that usually entails a switch between cognitive modes.

Our second hypothesis is that in almost every didactic case we could look upon “Grundvorstellungen” as metaphors and vice versa, without modifying the operational sense of the didactics, although in some cases metaphors may have a clearer poietic “bottom-up” role than “Grundvorstellungen”, which tend to be more prescriptive and “top-down” in their classroom implementation.

We intend to gather evidence in favour of these hypotheses from didactical experiments reported in the literature or coming from our own teaching experience or research. To this end, we comment below some compared examples from the viewpoint of “Grundvorstellungen” and metaphors.

COMPARED DIDACTICAL EXAMPLES

Example 1: Which fraction is bigger?

Using the “Grundvorstellungen approach”, Padberg (2009) points out that 6th graders have trouble in comparing fractions because of a lack of instruction in suitable “Grundvorstellungen”. They apply mechanically the standard method of calculating a common denominator, instead of flexibly using different strategies adapted to the fractions involved. He gives paradigmatic examples in context, of fractions to compare, and suggests to take advantage of the “sharing Vorstellung”, prompting the students to draw “ratio tables” to arrive at equating either the numerators or the denominators of the involved fractions. A typical example is the exercise where 5 children share evenly 3 pizzas and 8 children share other 5 identical pizzas, and it is asked in which group does each child get more pizza.

Metaphorically, one can proceed in an analogous way with the help of the metaphor “fractions are portions”, but also tackle some more unfriendly comparisons like that of $15/25$ and $16/26$ (loc. cit., exercise 2.b, p. 61) or say, $17/153$ and $18/154$, with the help of a different metaphor. To this end, the students could be challenged to recall other metaphors for fractions, adequate to look at the unfriendly $17/153$ and $18/154$, that allow for an easier denominator manipulation. They might recall the “ratio (or proportion) metaphor”. In our case, this could mean a big bag with 153 apples, 17 of which turn out to be rotten. How do we “move” to a bag with 154 apples, 18 of

which are rotten? Just adding one rotten apple to the previous bag! The “proportion” of rotten apples clearly increases! So, a shift to a more suitable metaphor enables the students to compare some unfriendly fractions in a transparent way, without even calculating.

Example 2: Brownie’s walk (Soto-Andrade, 2006, 2007, 2010)

We claim that random walks provide a meaningful and friendly way to introduce students to stochastic thinking. We comment here on a baby avatar of Brownian motion (a natural example of randomness).

Brownie is a puppy that escapes randomly from home, when she smells the shampoo her master intends to give her. At each street corner she chooses equally likely any of the 4 cardinal direction and runs nonstop a whole block until the next corner. Exhausted, after 4 blocks, say, she lies at some corner. Her master would like to know where to look for Brownie and also to estimate how far she will end up from home...

This problem may be tackled in several ways:

1. Using descriptive statistics in a meaningful way (cf. Borovcnik, 1984 and “Grundvorstellung” 3 after Wollring), i.e. simulating, to begin with.
2. Applying Malle & Malle’s GP2 prescriptive “Grundvorstellung” above.
3. With an “ideal simulation” metaphor or “Vorstellung”: if we unleash a pack of 4^4 Brownies from home, say, they will split evenly among the 4 cardinal directions, and so on... The *pedestrian metaphor* (Soto-Andrade, 2006) may so be rediscovered!

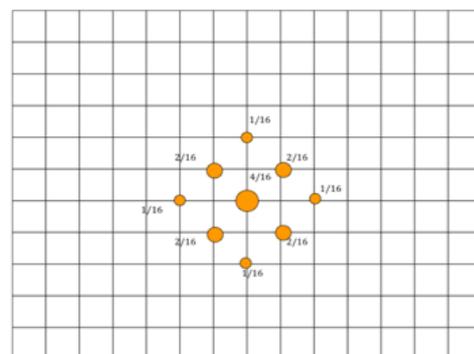

Fig. 4. Brownie’s splitting (2 blocks).

4. In the metaphor approach, students would be also prompted to see Brownie’s random walk in a more concrete way. The *splitting metaphor* may then emerge, which sees Brownie, at each corner, splitting into 4 pieces, and so on... Or the gentler and less scary *hydraulic metaphor*, where the streets of the city become pipes and Brownie becomes a litre of fruit juice that flows equitably at each junction of pipes. This metaphor may be easily visualized or even performed with students sharing a litre of fruit juice (see figure 4).

Note that in the metaphor approach the students are not given a “Grundvorstellung” for probability before they address the problem. On the contrary, they are prompted to tackle the problem “bare handed” first and eventually look for a friendly metaphor for the *concrete random walk* they want to study (e.g. “Brownie splits”). When trying to give pertinent answers to the questions asked, “poietic metaphors” may emerge that enable them to construct the abstract probability concept, like “probabilities of finding Brownie at a given corner are pieces of Brownie”.

DISCUSSION

Although Metaphors and “Grundvorstellungen” play essentially the same didactical role, aiming at giving concrete and familiar meaning to abstract concepts, we have seen that their typical ways of implementation may differ to some extent. Metaphors appear more radical and blunt, playing a poietic, bottom-up, role. “Grundvorstellungen” on the other hand, are more often used to represent in the “real world” pre-existing mathematical concepts, than to construct them; they tend to be used in a more prescriptive and top-down way, although we also have examples of descriptive research on idiosyncratic animistic metaphors in probability (Wollring, 1996). A systematic classification of “Grundvorstellungen” has been undertaken (vom Hofe, 2003; Blum & vom Hofe, 2003) and exercises for their visualization for a vast array of mathematical concepts have been proposed (Weber, 2007), but no examples of a poietic role of “Grundvorstellungen” seem to have been reported.

On the other hand, the typical contemporary metaphor approach is somewhat more optimistic, à la Dienes (1960), regarding as possible and trainable the spontaneous and autonomous emergence of suitable metaphors when students have the opportunity of tackling a problem, or a didactical situation à la Brousseau (1960), with their own means. Moreover, further research in this direction is suggested by the fact that this approach may be more naturally integrated with Brousseau’s theory of didactical situations (loc. cit.) than the more top-down “Grundvorstellungen” approach.

INTRODUCTION TO THE PAPERS OF WG12: HISTORY IN MATHEMATICS EDUCATION

Uffe Thomas Jankvist, Snezana Lawrence, Constantinos Tzanakis, Jan van Maanen

THE BRIEF HISTORY OF THE HISTORY GROUP

The idea to have a group focussing on the *empirical side of history in mathematics education* was coined by Abraham Arcavi and Uffe Thomas Jankvist at CERME-5 in Cyprus, 2007. The proposal was made to ERME and a first call for papers was written in 2008 by A. Arcavi, U. T. Jankvist, C. Tzanakis and J. van Maanen (the latter two former chairs of HPM, the ICMI affiliated study group on the relations between History and Pedagogy of Mathematics). Fulvia Furinghetti (also former chair of HPM) chaired the group at CERME-6 in Lyon, 2009; she did so with the help of co-chairs Tzanakis, van Maanen, Jankvist, and Jean-Luc Dorier. In Lyon, 13 papers and 1 poster were presented. For CERME-8 in Rzeszów, the group had 13 papers and 5 posters. During its brief time of existence the history group has come to embrace not only the research on history *in* mathematics education, but also research on history *of* mathematics education in relation to (present) educational practices. This, together with the always relevant issue of quality versus inclusiveness at CERMEs, led to many thoughts on the actual structuring of the working group sessions. We discuss this below after presenting themes and papers.

WG12'S MAIN THEMES AS GIVEN IN THE CALL FOR PAPERS

1.	Theoretical, conceptual and/or methodological frameworks for including history in mathematics education;
2.	Relationships between (frameworks for and empirical studies on) history in mathematics education and theories and frameworks in other parts of mathematics education
3.	The role of history of mathematics at primary, secondary, and tertiary level, both from the cognitive and affective points of view
4.	The role of history of mathematics in pre- and in-service teacher education, from cognitive, pedagogical, and/or affective points of view
5.	Possible parallelism between the historical development and the cognitive development of mathematical ideas
6.	Ways of integrating original sources in classrooms, and their educational effects, preferably with conclusions based on classroom experiments
7.	Surveys on the existing uses of history in curricula, textbooks, and/or classrooms in primary, secondary, and tertiary levels
8.	Design and/or assessment of teaching/learning materials on the history of mathematics
9.	Relevance of the history of mathematical practices in the research of mathematics education

Working Group 12

PAPERS AND POSTERS PRESENTED IN WG12

Authors	Contribution	Main Themes

STRUCTURE AND OUTCOMES OF THE WORKING GROUP SESSIONS

The sessions of WG12 were organized so that every session began with two short presentations of papers. These presentations were followed by group work or reports from group work. The group work was structured according to four general topics (A, B, C, and D – listed below) and the participants discussed these topics in two smaller subgroups, the compositions of which varied according to the topics.

Topic A: Research questions and relevance of research

For the first sessions the two subgroups, say α and β , were made so that subgroup α consisted of the less experienced researchers in the field of history in mathematics education, who, based on the papers and posters of the WG, would discuss topic A under the guidance of a more experienced researcher and ‘subgroup manager’ (van

Working Group 12

Maanen). Examples of questions that subgroup α discussed are: *Why is your research relevant (and do you have literature references to underpin the relevance)? Do you have clearly stated research questions? How will your research questions guide you in your research – and in the choices you have to make? Is your research theory-driven or problem-driven – and how is this reflected in your research questions?* In the initial group work phase, the participants of subgroup α were asked to briefly present their work and research questions if they had these formulated. This turned out to be a good, fast and efficient way of getting the ‘younger researchers’, and in particular the poster presenters, engaged in the WG discussions from the very beginning. Several participants decided to reconsider their research aim(s), formulate questions, refine formulations of existing questions, or expand their research perspectives. Also, the discussion of theory-driven versus problem-driven research led to discussions of the role of theory in (empirical) research, etc. O’Reilly presented the report from subgroup α .

Topic B: Use of HPM theory and mathematics education theory

Subgroup β , consisting of the more experienced researchers in the field, discussed topic B – use of HPM theory and mathematics education theory – based on questions such as: *What should the use of theory be in our subfield? What may we make use of from both mathematics education theory and history of mathematics theory? To what extent do we need HPM theories – and how may theses be shaped?* For a selection of the WG-papers, subgroup β discussed the influence of various other fields, e.g. history, history of mathematics, history of science, education and pedagogy, mathematics education, science education as well as philosophy and epistemology of mathematics and science. The following key-issues were identified as important, or crucial for the domain of history in mathematics education: *the need for developing theoretical constructs that provide some order in the wide spectrum of research and implementations done so far; to somehow check the efficiency of introducing a historical dimension, not least to convince the target population (teachers, math educators, curriculum designers, etc.); and to develop appropriate conditions for designing, realizing, and evaluating our research, including for instance the availability of useful resources, ‘worked-out’ material ready for ‘direct’ use, ‘history friendly’ teachers to cooperate in research as well as ‘history friendly’ authorities/curricula/ official regulations.* C. Tzanakis ‘managed’ and reported.

Topic C: Methods, data, and analysis

For topics C and D two subgroups were again made: subgroup γ consisting of researchers in the area of history of mathematics education and subgroup δ of researchers in history in mathematics education. The subgroups discussed topics C and D in turn. Examples of questions to be considered for theme C are: *What methods do you use to answer your research questions and how are these connected to your theoretical framework? What kinds of data do you gather (or have access to) and why these? How do you analyze your data and how is your analysis connected to*

Working Group 12

method and theory? Could you come to the same or similar conclusions using different methods, collecting different data, or analyzing those using different theoretical constructs? Regarding data subgroup γ discussed, for example, the occasional scarceness of historical sources, which can make methods of ‘triangulation’ more or less impossible. Among many other things, subgroup δ discussed the different methods related to quantitative and qualitative research, and the possibilities of combining such methods in the same study. K. Bjarnadóttir was the ‘subgroup manager’ for subgroup γ , and J. Krüger gave the report. T. Kjeldsen was ‘manager’ for subgroup δ and the report was delivered by M. Alpaslan and P. Ransom.

Topic D: Validity, reliability, and generality of research results

Examples of questions for topic D are: *How valid are your results? On what grounds must the validity be ‘measured’? How reliable are your results? How is this connected to method and theory (e.g. quantitative/qualitative; explain/predict)? Are your results generalizable and if so, then in what way?* For topic D, subgroup γ in particular, had to consider implications for mathematical practices of today. Also, subgroup γ spent a long time discussing the problems related to defining reliability and validity for qualitative research. Following similar discussions, embracing also reproducibility and driving forces for empirical research, subgroup δ ended up discussing a variety of research questions that was deemed essential for the present status of the field of using history in mathematics education. And a plan was made for constructing a list of such ‘burning’ questions and publishing it once done.

EVALUATION AND ASPECTS TO CONSIDER FOR THE NEXT WG

It was decided that for the next CERME the poster proposals will be sent to everyone in the group before the meeting and that the posters will be displayed *during* the sessions. Also, the chairs consider it important to maintain and even strengthen the connections between the CERME history group and the HPM group. One of the main things that were brought forth when evaluating WG12 was the friendly, inclusive and productive atmosphere, where everybody talked to and interacted with everybody. One participant expressed it like this:

A week ago I was completely scared, because I didn't know how the CERME work was done, and I didn't know how everyone in the WG would react to my work and my opinions (if I had enough courage to express them). Today I have in my memory the best conference I ever attended: a fantastic working group that made me desire for more opportunities to work with everyone.

USES OF HISTORY IN MATHEMATICS EDUCATION: DEVELOPMENT OF LEARNING STRATEGIES AND HISTORICAL AWARENESS

Tinne Hoff Kjeldsen

IMFUFA, Department of Science, Systems and Models, Roskilde University

The purpose of the paper is to present a theoretical framework for a systematic analysis and discussion of uses of history for teaching and learning mathematics, hereby proposing a didactical transposition of history from the academic research subject to history in mathematics education. The use of the theoretical framework is exemplified by an analysis of a project work on the history of Ancient Egyptian mathematics taught in a class of Danish upper secondary school students (10th grade), illustrating how uses of past mathematics can aid development of students' learning strategies and historical awareness.

INTRODUCTION

The purpose of the present paper is to develop a theoretical framework for a systematic analysis and discussion of uses of history for teaching and learning of mathematics with respect to how history benefits students' learning of mathematics, and develops students' historical awareness. Several recent papers have discussed whether these two aims pose a dilemma between genuine history and relevant mathematics for teachers who want to use or integrate history in their classrooms (Freid, 2001; Jankvist and Kjeldsen, forthcoming; Kjeldsen, forthcoming; Kjeldsen and Blomhøj, forthcoming). While these discussions have focused on transforming views of mathematics and mathematics education, their conception of history has been taken to be more or less synonymous with a traditional professional historians' approach to history – at least in the methodological approaches and the criteria for a genuine approach to history. However, perhaps we also need to broaden our view of history as well if we want history to play a more significant role for teaching and learning mathematics. In the present paper such a broadened view of history is outlined, and its implications for history in mathematics education are discussed. The aim is to develop an adequate theoretical framework for integrating history of mathematics in mathematics education that can be used to analyze specific implementations and to provide a tool for orienting the design of future implementations of the history of mathematics in mathematics education. The main focus of the paper is theoretical, but it also contains an empirical section that illustrates the theory in a carefully designed and implemented case study.¹

First of all, some historiographical reflections and a position are presented. Secondly, uses of history are discussed to present a framework in which their uses for the teaching and learning of mathematics can be systematically analyzed with respect to purposes and didactical values. This discussion is based on the Danish historian

Bernard Eric Jensen's (2010) approach to history. Thirdly, the framework is adapted to mathematics education. Lastly, to connect the discussion with the practice of teaching, a project work on mathematics in Ancient Egypt is analyzed. The project work was designed by a mathematics teacher working at a Danish Gymnasium (upper secondary level) during a professional development course in "problem based project work in, with and about mathematics". The teacher implemented the project work in his own teaching practice in a class of first year Danish high school students (age 16-17) and documented his experimental teaching in a written report. His report will be analyzed to illustrate how uses of past mathematics can aid development of students' learning strategies and historical awareness, thereby substantiating some of the points raised in the present paper. The paper ends with some concluding remarks.

HISTORIOGRAPHICAL REFLECTIONS

Mathematical knowledge is produced and used by humans; hence we can think of such activities as integrated elements of historical-social reality and of human life. We can perceive mathematical activities as creations of history as well as acts that create a history of mathematics. The development of mathematics and changes within our perceptions, views, and treatments of mathematics can to a certain extent be understood as realisations (intended as well as unintended) of goals set by people. If we want to understand historical-social processes in the development of mathematics as products of human activities, we must pay attention to intentions and thoughts of the actors, as well as their understanding of the subject matter and the context in which they performed and made their choices.

At a first sight it might seem that while such an approach can be used to study the history of sociological aspects of mathematics, such as the development of its profession in different countries and/or places or the history of mathematical journals, it cannot be used to study the history of the subject-matter of mathematics due to the universal character of mathematics. But if the development of mathematics is studied from its practice, where the historian focuses on concrete practices of mathematics, acknowledging that, despite its universal character, mathematical knowledge is produced by mathematicians, who live, interact and communicate in concrete social settings, the history of mathematical ideas, concepts and theories can also be pursued within such a framework.

Such a position is in accordance with recent trends in the history of mathematics that have emerged as reactions towards the well-known critic of the widely used anachronistic (whiggish) approach to history of mathematics and the methodological debate of internalism versus externalism (Epple, 2000), (Kjeldsen et al. 2004), and *Science in Context*, 2004, 17(1/2). Within the last decades many studies in the history of mathematics focus on the practice of mathematics within social, intellectual, and cultural contexts of mathematical activities. Here professional

historians of mathematics have a critical approach to source material they analyze in order to understand its significance in its proper historical context.

USES OF PAST EPISODES

It is not the main purpose of general mathematics education to educate and train professional historians of mathematics, and in most cases mathematics teachers will not be professional historians. In some countries development of students' historical awareness is part of the curriculum, but that is not always the case, and if it is it only plays a minor part. With this in mind it seems too restrictive to require that the history of mathematics taught within mathematics education should be presented as traditional academic history. A didactical transposition is needed, just as is the case with school mathematics, which is also not identical with the discipline of (academic) mathematics. In the following, Jensen's (2010) broader view of history will be introduced along with several pairs of concepts that can be useful for a nuanced analysis and discussion of the role of past mathematical episodes for the learning and teaching of mathematics.

Jensen (2010) sees the academic research subject *history*, as professional historians think and work with it, as just one of many approaches to history. According to him, history is employed every time a person or a group of people is interested in something from the past, and uses their knowledge about it for some purpose. People use history for many different purposes and in many different connections, and consequently there are major differences between a lay person's and a professional historian's use of history. Recent investigations (Rosenzweig and Thelen, 1998) have shown that lay persons' and professional historians' conceptions of history differ in various respects and on several levels. Lay-history has a reputation of being naïve viewed from the academic discipline of history, while on the other hand lay historians view academic history as lifeless and remote from the real world. For professional historians it is important to place past episodes and artefacts in their historical contexts. Their historical awareness is conceived of as an interpretation of the past whereas lay persons view history more as a source of memoirs.

Jensen distinguishes between pragmatic and scholarly approaches to history. In a pragmatic approach the study of the past is guided by the idea that we can learn from history. The "usefulness" of history is an underlying perspective or principle in a pragmatic approach to history. The idea is that through history we can gain knowledge about our world of today, that history can teach us better ways to live our lives. In a pragmatic approach to history, past events are studied from a utility perspective. Jensen (2010, p. 51) contrasts a pragmatic approach to history with a scholarly approach, where historians retain a critical distance to past events and emphasize differences between past and present. In the professional, academic discipline of history both traditions can be found, but since the mid 19th century the scholarly approach to history has been more and more dominant.

Observer history and actor history are another pair of concepts through which we can discuss and understand uses of past events and sources. Jensen (2010, p. 41) talks about uses of the past from an actor perspective, if we use history to orient ourselves and act in a present context. He calls this an intervening use of history. If the past is viewed retrospectively with a purpose to enlighten instead of a purpose to act or intervene he talks about uses of past from an observer perspective.²

Finally, the so-called "living history" use of history is a way of using the past to help participants develop historical awareness and learning strategies. In Denmark living history takes place at some museum centres and at some yearly events. One such centre is The Medieval Centre. On their homepage (<http://www.middelaldercentret.dk/Engelsk/welcome.html>) they state that the centre: "is an experimental museum where you can experience life in a reconstructed late 14th century market town: Daily life, knights tournaments, trebuchets, canons, ships, markets, ... and a lot more...". According to Jensen (2010, p. 145) living history appeals to so many not only because the participants actively take part in the events, but also because they use other types of learning strategies where the focus can be, for example, to develop the skills of past craftsmen.

WHAT IS THE CONNECTION TO MATHEMATICS EDUCATION?

These concepts of, approaches to, and thinking about history and uses of past episodes and artefacts present a framework for a refined discussion and systematic analysis of how past episodes and sources can be/are used in the integration of history for the teaching and learning of mathematics. They open up a variety of approaches to history and uses of the past for teachers who want history to play a role for teaching and learning mathematics. Which approach to choose depends on the intended learning. For example, Kjeldsen and Blomhøj (forthcoming) argue, based on Sfard's (2008) theory of thinking as communicating, that history presents itself as the obvious tool for developing students' proper meta-discursive rules, because meta-discursive rules are contingent and as such can be studied at the object level of history discourse. This presupposes a scholarly approach to history. The idea is to use past mathematical activities and sources with the intention of creating learning and teaching situations where students can experience what Sfard calls commognitive conflicts. Hence, the past is used with the purpose of intervening, and therefore the scholarly approach to history is from an actor perspective.

Kjeldsen (forthcoming) discusses the role of history for the teaching and learning of mathematics with reference to a competence based understanding of mathematics education (Niss, 2004). Here the development of students' mathematical competence is the main purpose of mathematics education along with the development of some second order competencies, including historical overview and awareness. For the development of historical overview and awareness, a scholarly approach from an

observer perspective can be chosen. For development of specific mathematical competencies, a pragmatic approach from an actor perspective might be considered.

AN IN-SERVICE COURSE ON PROJECT WORK

The focus of the paper is on theoretical issues, but to illustrate the theory, a project work that was developed and implemented during an in-service course for upper secondary teachers in Denmark will be analysed. In this discussion the “living history” approach will be examined to see how it might be adapted as a way for mathematics teachers to use past episodes and sources to develop students’ learning strategies and historical awareness.

The theme for the project work was Egyptian mathematics. It was developed and tested in a classroom of students (10th graders) in the Danish upper secondary school in 2004 as part of an in-service course for mathematics. The in-service course was developed in response to a reform that was to be implemented in 2005.

Compared with more traditional ways of teaching mathematics the reform challenged the teachers in several ways: (1) Many were not used to teach either the history of mathematics or mathematical modelling, both of which having more prominent positions in the new curriculum than they had in the former curriculum; (2) they were required to bring mathematics into play in interdisciplinary projects in cooperation with other subjects, from science, from the humanities, and from the social sciences; and (3) they had to design, organise and carry out project work in their mathematics teaching. The goal was to create an in-service course where theories in didactics and pedagogy interacted with development of the participants’ own teaching practice in ways that also related to inquiry-based teaching and learning. On this basis the objective of the in-service course was to support teachers in their development as teachers, implementation in their own classes, evaluation of the project work, and documentation through a written report of a project-based and problem-oriented course in the history of mathematics or in mathematical modelling. The core element of the in-service course was the development of the teachers’ experimental practice with history of mathematics or mathematical modelling and problem-oriented project work.

The in-service course began with a three day seminar where the teachers were introduced to the history of mathematics, mathematical modelling, didactical theories, and problem oriented project work. The teachers worked in small groups developing a project-organised course in either history of mathematics or mathematical modelling of their own choice consisting of approximately 10 lessons of 45 minutes each. They decided on (1) the objectives for their own professional development, (2) their objectives for students’ learning, (3) how to “set the scene” for their own students’ project work, and (4) how to evaluate the students’ learning.

A few weeks after the seminar a first draft of the design for the project work and the materials that should be given to the students were distributed to all participants in

the in-service course. All teachers tried out their project work in their classroom. During that period there was a one day seminar to support the teachers in the documentation of their results and reflections on their experimental teaching. It all ended with a 2-day seminar, where the teachers' written reports were discussed extensively. The final reports are published on the internet together with the handout materials for the students for other teachers to use (<http://magenta.ruc.dk/nsm/uddannelser/gymnasielaerer/>).

I will not go into further detail on how we define problem-oriented project work (interested readers are referred to Blomhøj and Kjeldsen, 2006), but only emphasize that the problem that students are going to work on should function as the “guiding star” for their work. In the ideal case every decision made in the project work should be justified by its contribution to the solution of the problem. This is crucial, since engaging in decisions provides opportunities for students to work independently, to gain control, and to direct the project. In order for this to happen, though, the teacher needs to set a scene for the project work, that is to formulate the task for the work, the conditions for the working process, the time constraints, and the requirements for the end product, for example a written report or a power point presentation fulfilling some specific requirements. In this way it is possible for the teacher to have some control while at the same time to leave room for the students to take responsibility and make decisions.

The in-service course is still offered with the modification that we focus only on mathematical modelling. Therefore we only have one history project to present, but since its function here is to serve as a concrete illustration of the theoretical framework developed above, and not as documentation from an empirical experiment it can be used to characterize the suggested methodology.

EGYPTIAN MATHEMATICS: A PROJECT WORK IN A 10TH GRADE

The project on Egyptian mathematics was developed and implemented in a classroom of 1. year students (10th grade, age 16) in a Danish upper secondary school in the fall term. The project work was meant to be interdisciplinary, with history about Ancient Egypt in combination with their mathematics. The mathematics teacher had no experience with project-organised teaching in mathematics, which was his focus for his own professional development. His objectives for the students' learning were to:

- a) enhance the students' competence to work in teams
- b) enhance the students' independent learning
- c) enhance the students' oral presentation skills
- d) have the students gain experiences with power point

Working Group 12

- e) have the students appreciate that mathematics has been different from what it is today
- f) develop the students' awareness that mathematical results have evolved, that mathematics is not static, which is contrary to the way it is often presented
- g) develop the students' awareness that mathematics develops in an interplay with culture and society. (Wulff, 2004, p. 2-3; my translation)

The objectives fall into two parts that cover all three of the above listed challenges of the reform: the first four address competence in independent study, the development for which problem-oriented project work is an excellent pedagogical tool, whereas the last three concern the history of mathematics requirements of the new mathematics curriculum. Note that a)-c) and e)-g) are elaborated versions of some of the ICMI Study *whys*, see Fauvel and van Maanen (2000, pp. 205, 207, 211-212).

The teacher orchestrated the students' project work in three stages:

- (1) The first stage was an introduction to Egyptian mathematics using a text from the students' textbook (Carstensen and Frandsen, 2002), where the teacher introduced the Egyptians' method of multiplication by repeated doubling, their number symbols, and their way of formulating problems (two lessons).
- (2) The introduction was followed by eight lessons during which the students worked in teams of four, guided by a description of
 - i) the problem formulation, which was given by the teacher (see below);
 - ii) the learning objectives; iii) the product; iv) the topics for the teams.

The teams worked independently. The teacher took the role of a consultant who could be called in for advice. When that happened he focused on posing questions and challenging the teams instead of providing answers. The problem formulation for all teams was: How and why did the Egyptians calculate? Each team worked with a chapter from a textbook on Egyptian mathematics (Frandsen, 1996), seven chapters all together treating their numerals, their methods for arithmetical operations, the $2/n$ -table, bread and beer (Pesu) exercises, equations and geometry. To have a whole textbook on an episode from the history of mathematics in Danish is a rare circumstance, and one of the reasons why Egypt was chosen for this project work.

- (3) Each team had to present its results for the rest of the class in an oral presentation supported by a power point presentation. This took up four lessons.

The first set of learning objectives deal with issues of enhancing students' independent study skills. In his evaluation the teacher emphasized in particular that the students acquired the mathematical knowledge of the Egyptians by themselves (in contrast to ordinary teaching where he explained everything), that they "cracked the code" themselves, and that they were conscious about it. Regarding item e) and f)

Working Group 12

of the second set of learning objectives, the teacher wrote: “they were all about gaining insights into current mathematics precisely by studying the mathematics of another time” (Wulff, 2004, p. 3), from which we can infer that the teacher used a pragmatic approach to history. He used past episodes of mathematics from a utility perspective. This also becomes clear from his description of a discussion that took place between him and the students during the introduction: “Already during the first module [the first two lessons] came the classical question, why are we going to learn this? And we had a good talk about the intended learning issues e), f), and g), during which the class apparently accepted that historical mathematics, besides being interesting as such, could contribute to a more nuanced view on current mathematics.” (Wulff, 2004, p. 5). Regarding the learning objective of realizing that mathematics has evolved over time, the teacher was rather critical, explaining that this aspect was not really complied with, since a comparison of Egyptian and modern mathematics only shows that mathematics has changed; it does not give insights into the actual process of change. Regarding the last item g) of the second part of the learning objectives, the teacher wrote in his evaluation: “here is where the subject of history can be involved. From a general knowledge about Ancient Egypt and its society, students can discuss how society and culture have been driving forces for the mathematics of that time. At the same time the historians’ method of source criticism is an essential tool for interpreting ambiguous and defective papyri” (Wulff, 2004, p. 4). In contrast to items e) and f) the teacher here takes a scholarly approach to history. The teacher used the past from an observer perspective in both approaches.

The students’ work with the sources and exercises in the textbook on Egyptian mathematics to answer the “How” part of the problem formulation can be considered a “living history” approach. They put themselves in the place of Ancient Egyptians, trying to understand and learn how they calculated, how they dealt with geometry, how they proposed mathematical problems, and so forth. The teacher reported the following situation he observed in the classroom: “Many students wondered about how “stupid” the Egyptians were. Why did they only use unit fractions? Why should a number be expressed as a sum of different unit fractions? On the other hand their methods were very difficult to understand; that is rather advanced, so in that respect they weren’t stupid at all. I think that many of the students realized that current mathematics is not “just” like today, but is a result of a long development, during which many things have been simplified.” (Wulff, 2004, p. 7). This shows a development of historical awareness among the students. That the students’ learning strategies were developed through this kind of “living history” approach can be inferred from the following observation made by the teacher: “This [that mathematics had made progress] became especially obvious when the students constantly rewrote the Egyptian notation to current notation with x ’s, formulas, etc. After they had finished an Egyptian calculation they would say: ‘but that just corresponds to ...’ followed by a solution of an equation in our way. It was very inspiring to see how students, who normally were a bit alienated towards x ’s and

equations now had taken those to themselves as their own, and all of a sudden perceived equations as an easy way to solve problems. The students became aware that modern notation makes the calculations much easier than they would have been otherwise” (Wulff, 2004, p. 7).

As mentioned above the teacher found that item g) in the list of learning objectives, which was supposed to link the development of mathematics with a scholarly approach to history, was not realized. The “why” part of the problem formulation was designed especially towards this goal. The mathematics teacher had hoped that the students would have been able to experience concrete examples of how needs of society sometimes act as driving forces for the development of mathematical ideas. This is a very ambitious goal, and since the history teacher focused more on religion and dynasties, the mathematics teacher felt that the students did not get opportunities to gain real insights into why mathematics was developed in interaction with the needs of society and culture. A less ambitious teacher would probably evaluate this part differently, pointing towards the fact that was explained above, that the students gained genuine historical knowledge about Egyptian mathematics situated in the proper historical context. Finally, the teacher concluded that the students afterwards showed signs of possessing a more mature and reflective approach to mathematics than they had before. Unfortunately, the teacher did not document this with observations from the classroom.

CONCLUDING REMARKS

The purpose of the paper was to present a theoretical framework for a systematic analysis of the uses of history for teaching and learning mathematics in order to propose a didactical transposition of history from the academic research subject to history in mathematics education. The analysis of the teacher’s report on the project work on Ancient Egyptian mathematics with respect to the described framework of different uses of past episodes shows that in this project, history was used in different ways to provide a very rich teaching and learning environment. The teacher used different approaches to history and used past episodes from various perspectives for different purposes, thereby creating learning situations that developed students’ historical awareness and mathematical learning strategies at the same time. History was used in ways in which students gained genuine historical insights, developed learning strategies, and enhanced their mathematical problem solving skills even though they worked on mathematics that might not be part of the core curriculum.

NOTES

¹ I would like to thank Costantinos Tzanakis for helpful comments on an earlier version of this paper.

² A fourth pair of concepts is identity neutral vs. identity concrete history writing, which will not be used in this paper.

CLASSIFYING THE ARGUMENTS & METHODOLOGICAL SCHEMES FOR INTEGRATING HISTORY IN MATHEMATICS EDUCATION

Constantinos Tzanakis

Yannis Thomaidis

Department of Education, University of
Crete, Rethymnon 74100, Greece

Regional Administration of Education,
Central Macedonia, Thessaloniki, Greece

tzanakis@edc.uoc.gr

gthom54@gmail.com

The ICMI Study volume “History in Mathematics Education”, published in 2000, includes a comprehensive list of arguments for integrating history in Mathematics Education (ME) and methodological schemes of how this can be accomplished. Recently Jankvist distinguished between using “history-as-a-goal” and using “history-as-a-tool” to classify the above arguments. Independently, Grattan-Guinness distinguished between “history” and “heritage” in the hope that –among other things- this will help to understand better which history is expected to be helpful and meaningful in ME. We attempt to connect these two conceptual “dipoles”, aiming to provide in this way a finer and deeper classification of the arguments and methodological schemes for integrating history in ME that will serve as an appropriate theoretical framework.

Keywords: *History, Heritage, History–as–a-tool, History–as–a-goal, complementary*

RATIONALE AND BASIC IDEAS

In the last decades, there is a worldwide growing interest in integrating the history of mathematics (HM) in mathematics education (ME). Several attempts have been made, education material has been produced, empirical research has been conducted, methodological schemes have been invented & implemented and arguments for this integration have been put forward to refute possible objections and/or to enhance the interest of the ME community in this direction. For a long time, there were no coherent theoretical ideas and framework to place, see and compare all these activities. A serious attempt in this direction is the comprehensive ICMI Study volume (Fauvel & van Maanen 2000). In particular, it presents a comprehensive list of the arguments for integrating the HM in ME (the whys)¹ and the general ways of how to accomplish this task (the hows)¹, in the sense that the whys correspond to tasks that one attempts to accomplish and the hows correspond to methodological approaches one could follow.

Since then, further important work followed, however:

Jankvist (2009a, b, c, d) has reconsidered the whys and the hows. He made the distinction between two broad ways to introduce the HM in ME, namely in his terminology,

- *History as a tool* emphasising *inner issues* in Mathematics (*in-issues*), and
- *History as a goal* emphasising *meta-perspective issues* in Mathematics (*meta-issues*)

and attempted to classify the *whys* using this distinction (Jankvist 2009a §§2.3, 8.1, 8.5; 2009b §1.1; 2009c §§2, 3), which constitutes the first **conceptual dipole**, in the context of the present paper².

Moreover, he attempted to classify the *hows* according to his 3-fold distinction of possible implementations: *illumination approaches*, *modules approaches* and *history-based approaches* and to connect them to the above conceptual dipole (Jankvist 2009a §§2.4, 2.6, 2009c §§6, 9).

Independently, Grattan-Guinness (2004a, b) introduced in a more general context the distinction between “*history*” and “*heritage*”, to interpret mathematical activities and their products, in an effort to clarify existing conflicts and tensions between a mathematician’s and a historian’s approach to mathematical knowledge. Grattan-Guinness (2004b) gives several examples by contrasting the general characteristics of the two concepts. This is our second **conceptual dipole**. It could be an important tool to revisit the issue of “which history is appropriate to ME?” (see e.g. Barbin 1997).

As we will argue, within each *dipole*, the two “*poles*” are **complementary**³ to each other, in the sense that they are **mutually exclusive** for a **simultaneous** use, but none of them, taken alone, can lead to a sufficiently wide and deep enough understanding of what (a specific piece of) mathematics is; instead **both are necessary** to understand mathematics as a cultural endeavour & human intellectual activity, either didactically or/and epistemologically. We stress at this point that “mutually exclusive” should not be understood in its strictly **logical** sense, but rather in Bohr’s broader sense⁴. Here, “complementarity” has to do with the fact that within each dipole, each pole focus on a particular aspect of what mathematics and its development are, but none of these emphases is sufficient for that if taken alone and an extreme version of each one of them leaves no space for the others.

The key idea and aim of this paper is to **classify** the ICMI Study *whys* and *hows* in a **finer** way, by projecting them onto the 2X2 grid formed by the two dipoles, thus getting “... a clear[er] idea about **why** history should be used in a given situation; i.e. what *whys* the use of history should fulfill...” and which are suitable options of *hows* (Jankvist 2009c p.256). Connecting the two dipoles in this way may contribute to clarify their relevance to ME and provide a finer conceptual framework to integrate HM into ME. However, this **2-dimensional classification** is **tentative**, possibly subject to modifications, as **specific** realizations & examples of the *whys* and the *hows* are examined how they fit into it.

The paper is structured as follows: A concise description of each *dipole* is given in the next section, with reference to distinctions similar to the *History-Heritage* dipole found in Fauvel & van Maanen 2000. The next two sections give a concise list of the ICMI Study *whys* and *hows* (together with Jankvist's 3-fold implementations), followed by the **classification tables** with brief reference to indicative examples that support this classifications, or reveal some possibly controversial aspects of them. Some final remarks are given in the last section. Due to space limitations, only the general ideas are presented, with specific applications to illustrate their use given in another paper (Thomaidis & Tzanakis, to appear).

THE TWO CONCEPTUAL DIPOLES

Jankvist introduced two broad ways (or purposes, as he calls them) in which HM could be helpful and relevant to ME: *History-as-a-tool* and *History-as-a-goal*, which are intimately connected with issues within mathematics (what he calls *inner issues*) and with issues that concern mathematics itself (what he calls *meta issues*). In his own words,

“History-as-a-tool concerns the use of history as an assisting means, or an aid, in the learning [or teaching] of mathematics... in this sense, history may be an aid both...”⁵ “as a motivational or affective tool, and... as a cognitive tool...”⁶ “[It] concerns... inner issues, or in-issues, of mathematics [that is] issues related to mathematical concepts, theories, disciplines, methods, etc.— the internal mathematics”⁷.

On the other hand,

“*History-as-a-goal* does not serve the primary purpose of being an aid, but rather that of being an *aim* in itself... posing and suggesting answers to questions about the evolution and development of mathematics,... about the inner and outer driving forces of this evolution, or the cultural and societal aspects of mathematics and its history” (Jankvist 2009b §1.1). In other words, “[It] concerns ... learning something about the meta-aspects or *meta-issues* of mathematics ... [that is] issues involving looking at the entire discipline of mathematics from a meta perspective level” (Jankvist 2009c, pp239-240)⁸.

This description makes clear that these two ways in which HM becomes relevant to ME are mutually exclusive, in the sense that the emphasis put on each are clearly different and to a large extent mutually incompatible. Nevertheless, it should be remarked that although “history-as-a-goal ‘in itself’ does not refer to teaching history of mathematics *per se*, but using history to surface meta-aspects of the discipline ... in specific teaching situations, [it] may have the positive side effect of offering to students insight into mathematical in-issues of a specific history” (Jankvist 2009d, p.8). Conversely, using “history-as-a-tool” to teach and learn a specific mathematical subject may stimulate reflections of a meta-perspective nature extrapolated from the particular subject considered; that is, we may have a kind of *anchoring* of *meta-issues* into the *in-issues* that constitute the study of the subject (see Jankvist 2009b, §§5.3, 5.4, 6.1, 6.3 for more details and examples of this idea). These are important interrelations, stressing the indispensability of both the “history-as-a-tool” and the “history-as-a-goal” ways, which

thus constitute what we called earlier a coherent *conceptual dipole*.

Quite independently, having in mind both historians and educators of mathematics, Grattan-Guinness introduced the distinction between *History* and *Heritage*. More specifically:

The History (Hi) of a particular mathematical subject N refers to "... the development of N during a particular period: its launch and early forms, its impact [in the immediately following years and decades], and applications in and/or outside mathematics. It addresses the question 'What happened in the past?' by offering descriptions. Maybe some kinds of explanation will also be attempted to answer the companion question 'Why did it happen?'"⁹. "[It] should also address the dual questions 'what did not happen in the past?' and 'why not?'; false starts, missed opportunities ..., sleepers, and repeats are noted and maybe explained. The (near-)absence of later notions from N is registered, as well as their eventual arrival; differences between N and seemingly similar more modern notions are likely to be emphasized"¹⁰.

On the other hand,

The *Heritage* (*He*) of a particular mathematical subject N refers "...to the impact of N upon later work, both at the time and afterward, especially the **forms** which it may take, or be **embodied**, in later contexts. Some modern form of N is usually the main focus, with attention paid to the course of its development. Here the mathematical relationships will be noted, but historical ones... will hold much less interest. [It] addresses the question '*how did we get here?*' and often the answer reads like 'the royal road to me.' The modern notions are inserted into N when appropriate, and thereby N is unveiled... *similarities* between N and its more modern notions are likely to be emphasized; the present is *photocopied* onto the past" (Grattan-Guinness, 2004a, p.165). Although, Grattan-Guinness is mainly concerned with the implications of this distinction on the way past mathematics should be approached, he clearly indicates its relevance to ME (Grattan-Guinness 2004b, §1.6). He argues that ME can profit equally well from both Hi and He, urging for further exploration in this context, a fact that has not passed unnoticed (Siu 2006, p.273, Rogers 2009 pp.120-121, Schubring 2008, p.5). He also gives a detailed list of the differences between these two conceptions (Grattan-Guinness 2004b, §1.3), showing their **incompatibility**, summarized as follows:

"The distinction between history and heritage is often sensed by people who study some mathematics of the past, and feel that there are fundamentally different ways of doing so. Hence the disagreements can arise; one man's reading is another man's anachronism, and his reading is the first one's irrelevance. The discords often exhibit the differences between the approaches to history usually adopted by historians and those often taken by mathematicians." (Grattan-Guinness 2004b, p.8).

On the other hand, however, their **indispensability** in understanding the development of mathematics is clearly emphasized:

"The claim put forward here is that both history and heritage are legitimate ways of handling the mathematics of the past; but muddling the two together, or

asserting that one is subordinate to the other, is not.” (I. Grattan-Guinness 2004b, p.8)

Thus, the above quotations show that the two concepts are complementary in the sense of the first section, constituting the two poles of a coherent conceptual dipole.

As far as HM in ME is concerned, the distinction between History and Heritage is related to the rationale underlying the distinction between pairs of methodological approaches put forward in the past, like explicit & implicit use of history, direct & indirect genetic approach, forward & backward heuristics (Fauvel & van Maanen 2000, §7.3.2 and references therein), e.g.:

When “... HM is explicitly integrated, mathematical discoveries are presented in all their aspects. Different teaching sequences can be arranged according to the main historical events, in an effort to show the evolution and the stages in the progress of mathematics by describing a certain historical period ... [When] ... HM enters implicitly, history suggests a teaching [approach], in which use may be made of concepts, methods and notations, that appeared later than the subject under consideration, keeping always in mind the general didactic aim, namely to understand mathematics in its modern form. ... [It] does not necessarily respect the order by which the historical events appeared; rather, one looks at the historical development from the current stage of concept formation and logical structuring of the subject ... they have a dual character...and both may be used.... in complementary ways ... in an explicit integration of the HM, the emphasis is on a rough, but ... more or less accurate mapping of the path network that appeared historically and led to the modern form of the subject; in an implicit integration [of the HM], the emphasis is on the redesigning, shortcutting and signalling this path network”¹¹ (Fauvel & van Maanen 2000, p.210; our emphasis).

Hence, Grattan-Guinness distinction is potentially of great relevance to ME (as he himself points out; see also Rogers 2009), serving - among other things - to contribute towards answering the recurrent question “Why history and which history is appropriate to be used for educational purposes?” (Barbin 1997).

A CONCISE LIST OF THE *WHYS & HOWS*

In this section we present concisely the list of the whys & hows according to the ICMI Study volume (Fauvel & van Maanen 2000, §§7.2, 7.3) and Jankvist (2009c, §6) that will be used in the next section.

The “ICMI Study whys”

The following are the areas in which the teaching and learning of mathematics can profit from integrating the HM in the educational process.

A. The learning of Mathematics

1. Historical development vs. polished mathematics: To uncover/unveil concepts, methods, theories etc.

2. History as a re-source: To motivate, to raise the interest, to engage the learner by linking present knowledge and learning process to knowledge and problems in the past.

3. History as a bridge between mathematics and other disciplines/domains: From where and how did a great part of mathematics emerged? To bring in new aspects, subjects and methods.

4. The more general educational value of history: To develop personal growth and skills, not necessarily connected to mathematics.

B. *The nature of mathematics and mathematical activity*

1. *Content*: To get insights into concepts, conjectures & proofs, by looking from a different viewpoint; to appreciate “failure” as part of mathematics in the making; to make visible the evolutionary nature of meta-concepts.

2. *Form*: To compare old and modern; to motivate learning by stressing clarity, conciseness and logical completeness.

C. *The didactical background of teachers*

1. *Identifying motivations*: To see the rationale behind the introduction of new knowledge and progress.

2. *Awareness of difficulties & obstacles*: To become aware of possible didactical difficulties and analogies between the classroom & the historical evolution.

3. *Getting involved and/or becoming aware of the creative process of “doing mathematics”*: To tackle problems in historical context; to enrich mathematical literacy; to appreciate the nature of mathematics.

4. *Enriching the didactical repertoire*: To increase the ability to explain, approach, understand specific pieces of mathematics and on mathematics.

5. *Deciphering and understanding idiosyncratic and/or non-conventional approaches to mathematics*: To learn how to work on known mathematics in a different (old) context; hence to increase sensitivity and tolerance towards non-conventional, or “wrong” mathematics.

D. *The affective predisposition towards mathematics*

1. *Understanding mathematics as a human endeavour*: To show and/or understand explicitly evolutionary steps.

2. *Persisting with ideas, attempting lines of inquiry, posing questions*: To look in detail at similar examples in the past.

3. *Not getting discouraged by failures, mistakes, uncertainties, misunderstandings*: To look in detail at similar examples in the past.

E. *The appreciation of mathematics as a cultural endeavour*

Working Group 12

1. *To appreciate that mathematics evolves under the influence of factors intrinsic to it:* To identify and appreciate the role of internal factors.
2. *To appreciate that mathematics evolves under the influence of factors extrinsic to it:* To identify and appreciate the role of external factors.
3. *To appreciate that mathematics form part of local cultures:* To understand a specific piece of mathematics through approaches belonging to different cultures.

The “ICMI Study *hows*”

Below is a similar account of the *hows* for integrating HM in ME according to the ICMI Study volume, followed by that of Jankvist.

1. *Learning **history** by providing **direct historical information***

Isolated factual information; historical snippets; separate historical sections; whole books and courses on history etc.

2. *Learning **mathematical topics** by following a teaching **approach inspired by history***

Teaching modules inspired by history; worksheets based on original sources; historical-genetic approach; modernised reconstructions of a piece of mathematics etc.

3. *Developing*

*Awareness of the intrinsic nature of mathematical activity (**intrinsic awareness**) and*

(i) The role of general conceptual frameworks

(ii) The evolutionary nature of all aspects of mathematics

(iii) The importance of the mathematical activity itself (doubts, paradoxes, contradictions, heuristics, intuitions, dead ends etc);

*Awareness of the extrinsic nature of mathematical activity (**extrinsic awareness**)*

(i) Relations to philosophy, arts and social sciences

(ii) The influence of the social and cultural contexts

(iii) Mathematics as part of (local) culture and product of different civilizations and traditions

(iv) Influence on ME through ME history.

“Jankvist’s *hows*”

1. ***Illumination approaches:*** Teaching and learning of mathematics, in the classroom or the textbooks used, is supplemented by historical information of varying size and emphasis.

2. ***Modules approaches:*** Instructional units devoted to history, and often based on the detailed study of specific cases. History appears more or less directly.

3. *History-based approaches*: Directly inspired by, or based on the HM. Not dealing with studying the HM directly, but rather indirectly; the historical development not necessarily discussed in the open, but, often sets the agenda for the order and way in which mathematical topics are presented.

Both types of *hows* correspond to possible implementations of the HM into ME, of a different character, however; the ICMI Study *hows* focus on different emphases, whereas, Jankvist's focus strictly on the adopted methodologies. Both are useful in the present context and will be further considered later. Their possible interrelations is an interesting issue needing further study, not to be done here.

THE 2-D CLASSIFICATION OF THE *WHYS* & *HOWS*

By taking into account the presentation of the conceptual dipoles above (in connection with the details provided in the corresponding references therein), a 2X2 table results, composed by the distinct elements of each dipole. Then, according to the description provided in the preceding section, each of the *whys* and *hows* can be placed in at least one cell, depending on how sharply and clearly it has been described in the corresponding references (Fauvel & van Maanen 2000, §§7.2, 7.3; Jankvist 2009c, §6).

	<i>History</i>	<i>Heritage</i>
<i>History as a goal (emphasis on meta-issues)</i> ¹²	C.2, C.3(?); E.1, E.2, E.3	A.3; B.1, B.2; D.1
<i>History as a tool (emphasis on inner-issues)</i> [12]	A.3; C.1, C.3, C.4, C.5; D.2, D.3	A.1, A.2; B.1, B.2(?); C.2, C.3; E.3

Table 1: The classification of the ICMI *whys*

In this way, classification scheme results, in which the two conceptual dipoles act as a “magnifying lens”, either requesting a more complete description of each *why* and *how*, or/and providing a clearer orientation of the way each *why* and *how* could be implemented. This is explained below by means of some examples.

Items appearing more than once are marked in green and those placed with reserve appear in red and an interrogation mark¹³. This suggests that the *whys* are not **irreducible** with respect to the two classification dipoles, but consist of **simpler** elements; hence, they should be further analysed and more sharply described. For instance, C.3 is a good example in this respect: It appears in three cells. According to the preceding section, it concerns the involvement and/or acquisition of awareness of the *creative process of “doing mathematics”*, by (i) tackling problems in historical context; (ii) enriching mathematical literacy; (iii) appreciating the nature of mathematics. Clearly, (i) is related to the *History – History as a tool* cell and (ii) to the *Heritage – History as a tool* cell (one is being involved into doing mathematics in historical context and in so doing improves his mathematical literacy, thus becoming more aware of what this intellectual activity has been through the ages). However, (iii) cannot be classified without ambiguity. Although it should be placed in the *History as a goal* row, this can be

accomplished by looking either at a subject's *History*, or *Heritage*. This argument needs further clarification. Moreover, A.4 is not easy to be placed in the table; it is necessary to be analysed further. In view of such examples¹⁴, we think that most of the ICMI *whys* could be further sharpened, so that they are decomposed into “irreducible” arguments, in the sense that they fall into only one cell of Table 1. But this remains to be shown and further work is needed (hence the tentative character of this and the other tables, mentioned in before). Similar comments hold for the other items as well. In this way, a **finer** classification of the *whys* becomes possible, to the extent that the classification dipoles have been determined as sharply as possible, of course. Clearly, this presupposes the detailed study of the *whys* and each *conceptual dipole* in the context of specific examples (cf. Tzanakis & Thomaidis, to appear). In addition, this and the following tables can be considered in relation to the **target population** to whom they are addressed; mathematics teachers; curriculum designers, producers of didactical material; mathematics teachers’ trainers and advisors. That is, they can be useful to specify which entries are better suited to whom.

	<i>History</i>	<i>Heritage</i>
<i>History as a goal (emphasis on meta-issues)</i> [12]	Direct historical information Intrinsic awareness (ii) Extrinsic awareness (ii)	Direct historical information Extrinsic awareness (i) (iii) (iv)
<i>History as a tool (emphasis on inner-issues)</i> [12]	Intrinsic awareness (i) (iii) Learning mathematical topics (explicit use of history)	Learning mathematical topics (implicit use of history)

Table 2: The classification of the ICMI *hows*

The labels (i) to (iv) in this table refer to the corresponding items in §3.2.3 and provide another example of the “irreducibility” idea mentioned above; the development of mathematical awareness has been described rather clearly in the ICMI Study volume, which allows for an unambiguous classification of its various aspects. The same holds for learning mathematical topics by following an approach inspired by history, either explicitly, or implicitly (cf. the last paragraph of the second section on the distinction between “explicit” and “implicit” use of history). However, this is not so for learning history by providing direct historical information, which is only briefly described.

	<i>History</i>	<i>Heritage</i>
<i>History as a goal (emphasis on meta-issues)</i> [12]	<i>Modules approaches</i>	<i>Illumination approaches</i> <i>History-based approaches(?)</i>
<i>History as a tool (emphasis on inner-issues)</i> [12]	<i>Illumination approaches</i> <i>Modules approaches</i>	<i>History-based approaches</i>

Table 3: The classification of Jankvist’s *hows*

Working Group 12

The table above suggests that Jankvist's *hows* constitute an interesting and promising identification of broad categories of approaches, which can be analysed into more sharply described approaches. We think that this is already apparent in the description given in Jankvist 2009c, §6.

CONCLUDING REMARKS

Due to space limitations, the paper is theoretical, with no illustrations of the classification schemes by means of specific examples. This is absolutely necessary, in order to check the validity of these classifications more thoroughly and to show how they can be useful in actual implementations (an example is given in Tzanakis & Thomaidis, to appear). This is a promising line of inquiry and expect that analysing specific examples in this context, the arguments for and approaches of integrating HM into ME will be sharpened and the importance and possible interrelation of the conceptual dipoles described here will be better revealed and understood. Finally, proceeding along the same lines, the **objections** against using HM in ME (e.g. as they appear in Fauvel & van Maanen 2000, §7.2, Siu 2006, §2) can be classified, as well.

NOTES

1. In Jankvist's (2009a) terminology.
2. We use the term "dipole", instead of a more directly interpretable one, like "pair", to emphasize the deep interconnections between the two concepts, which reflects better their complementary character described below.
3. The term "complementary" is used in a way close to that introduced by N. Bohr to describe the microphysical reality and subsequently was raised to a general conceptual tool to understand reality (see Bohr 1934, 1958).
4. E.g. Understanding biological systems requires a holistic view, whereas, understanding their biochemical processes needs a reductionist approach: Both are indispensable for a sufficiently wide and deep understanding of life phenomena, but it is impossible to put **absolute** emphasis on the one, without "destroying the other (Bohr 1958, chs.2 &3).
5. Jankvist 2009b §1.1.
6. Jankvist 2009d, p8.
7. Jankvist 2009c, p240.
8. E.g. "How does mathematics evolve in time and space? What forces and mechanisms cause the evolution of mathematics? How does the evolution of mathematics interact with society and culture? Can mathematics become obsolete?" (Jankvist 2009d, p.8).
9. Grattan-Guinness, 2004b, p.7.
10. Grattan-Guinness, 2004a, p.164.
11. Careful reading of these quotations, reveals the co-existence of the two poles of each of the dipoles (History, Heritage) & (History-as-a-tool, History-as-a-goal)
12. Relating *History-as-a-goal* and *History-as-a-tool* with *Inner-issues* and *Meta-issues*, respectively is done keeping in mind the possibility of cross-interrelations mentioned in the third section!
13. This convention is applied to all tables in this paper.
14. Others could be similarly analyzed, but lack of space does not allow for that.

THE DEVELOPMENT OF ATTITUDES AND BELIEFS QUESTIONNAIRE TOWARDS USING HISTORY OF MATHEMATICS IN MATHEMATICS EDUCATION

Mustafa Alpaslan, Mine Isiksal, Cigdem Haser

Middle East Technical University, Turkey

This study intends developing a valid and reliable instrument in order to determine pre-service mathematics teachers' attitudes and beliefs towards using history of mathematics in school mathematics courses. The data were collected at the beginning of the fall semester of 2010-2011 academic year from 237 teacher candidates in Turkey via Attitudes and Beliefs towards the Use of History of Mathematics in Mathematics Education (ABHME) Questionnaire developed by the researchers. The reliability coefficient of the ABHME was calculated as .91 and explanatory factor analysis revealed three factors: positive attitudes and beliefs towards the use of history in mathematics education, negative attitudes and beliefs towards the use of history in mathematics education, and self-efficacy beliefs towards the use of history in mathematics education.

INTRODUCTION AND THEORETICAL FRAMEWORK

The origins of the attitudes and beliefs of teachers about teaching probably endure their school years as a student (Kagan, 1992). This idea stands on the 'apprenticeship of observation' which basically means that teachers develop ideas about their profession when they were students (Lortie, 1975). In addition to these opinions, it may be claimed that pre-service training programs have a leading role in the shaping of the attitudes and beliefs at issue. Among several elements constituting the education given in undergraduate programs, history of mathematics should take place for better professionally developed future mathematics teachers. In the literature, quantitative measurement instruments for accessing beliefs and attitudes toward using history in mathematics education are somewhat limited. Some of the existing relevant instruments are on some specific issues about the use under consideration. There are also instruments comprising few items which do not seem to be comprehensive enough to see the whole picture. Developing a versatile instrument measuring attitudes and beliefs of pre-service mathematics teachers towards the historical approach is crucial, because they are going to undertake today's teachers' educational missions in the future. Thus, this study aims to develop a valid and reliable instrument for investigating elementary mathematics teacher candidates' attitudes and beliefs towards the use of history of mathematics in mathematics education. With this purpose, the research question for this study could be stated as follows:

- What could be the underlying constructs of Attitudes and Beliefs towards the Use of History of Mathematics in Mathematics Education Questionnaire?

Working Group 12

The idea of using history in the learning and teaching of mathematics is not new; as it has been discussed since the beginning of the 20th century (Fried, 2001). An historical approach enriches mathematics teachers' repertoire with its different usages (e.g., Mitchell, 1997; Tzanakis & Arcavi, 2000). It supplies meaningful examples of mathematical algorithms and methods, and offers semantic representations which enable students to see mathematical concepts from unusual perspectives (Furinghetti, 2007). It also supports the preparation of a classroom environment where students discuss the past of mathematics and mathematics as a discipline (Jankvist, 2010). Jankvist (2009) separated the reasons proposed in the literature in favour of using the historical approach into two main categories: seeing history of mathematics as a teaching tool, and seeing it as a goal in itself.

Leder and Forgasz (2002) introduced that the concepts of attitude and belief were defined by different researchers in many times, and there are not common definitions of these. To achieve this study's goal, the concept of belief was considered in respect of Törner's study (as cited in Goldin, Rösken, & Törner, 2009). From his perspective, beliefs are strongly related to affective aspects which include attitudes as an element. According to Philipp (2007), individuals' true-false dichotomies constitute their beliefs. It can be inferred that mathematics teachers' beliefs about a teaching method amount to their thinking about different components, applications and some other aspects of that method as true or false. In this study, historical approach in mathematics education corresponds to this teaching method. Philipp (2007) also stated that these ideas and dispositions of individuals are clarified by their behaviours. In other words, behaviours are reflections of individuals' emotions, actions and thoughts called as attitudes. It is possible that mathematics teachers' attitudes towards an instructional method reveal themselves as emotions, feelings, actions, and thoughts about that method. Thompson (1992) expressed that beliefs are sensed less densely, but more cognitively than attitudes. In her opinion, beliefs are structured more strongly than attitudes, so they are less changeable. It can be expected that individuals' expressions of their beliefs are more direct and certain than their expressions about the attitudes they have. With reference to Leder and Forgasz (2002), these kind of affective matters comprise the learning of mathematics as well as cognitive ones. In this sense, the teaching of mathematics could be influenced by affective domain because of that instructors also keep some thoughts, feelings, and emotions to the education which they give. Their beliefs and attitudes towards a teaching method are believed to determine the degree of benefiting from that method, and this will naturally have effects on the quality of instruction that they give.

The inclusion of the history of mathematics in pre-service mathematics teacher training programs has been supported by mathematicians, mathematics educators and mathematics historians (Schubring, 2000). There are many studies on this matter in which pre-service teachers participated. Sullivan (2000) found that a positive change

is possible in prospective secondary mathematics teachers' attitudes towards the integration of history in mathematics education. In the context of Turkey, it was shown that prospective mathematics teachers' had high positive attitudes towards the historical approach (Oprukçu-Gönülateş, 2004). There are also studies regarding historical materials' usage. Fraser and Koop (1978) determined that in-service teachers liked historical materials, a play and an article, and find them appropriate for mathematics teaching. However, they brought up some concerns about considerable time required, and stated that they would not use such materials in their teaching.

The elementary mathematics curriculum in Turkey draws attention to the importance of using history of mathematics (Ministry of National Education [MNE], 2009). It emphasizes that students must have an idea about the historical evolution of mathematics; its role on many scientific fields, its status and value in the development of human thoughts. It suggests carrying out mathematics projects on several domains of mathematics in which history of mathematics plays a part. In spite of the fact that history of mathematics has such a crucial place in the mathematics education, there are few studies conducted about it. Among these, it is necessary to consider the work of Oprukçu-Gönülateş (2004) as background to this study. She examined pre-service mathematics teachers' views about the integration of history of mathematics in mathematics courses and determined that they agreed on the benefits of the integration for getting high motivation in mathematics classes. They thought that it was more appropriate for motivational purposes than for conceptual development.

METHOD

Participants

The data of the study were collected from 237 pre-service elementary mathematics teacher candidates (including 45 freshmen, 52 sophomores, 96 juniors, and 44 seniors) purposefully sampled at the beginning of the fall semester of the academic year 2010-2011. The participants, who were 53 males and 184 females, have been attending elementary mathematics teacher education program in one of the large state universities in Ankara, Turkey.

Measuring Instrument

The measuring instrument developed for this study is a questionnaire entitled "Attitudes and Beliefs towards the Use of History of Mathematics in Mathematics Education (ABHME) Questionnaire". The ABHME consisted of two parts: the first is related to the demographic information such as gender, and grade level; and the second part consisted of 35 Likert type (where 5 corresponds to "strongly agree" and 1 to "strongly disagree") items (including 13 negative and 22 positive expressions).

Working Group 12

Those items were developed in order to measure pre-service teachers' attitudes and beliefs towards the use of history in the teaching of mathematics.

In the very beginning of the instrument's development process, an item pool of 220 items for the actual questionnaire was formed following a comprehensive review of the literature on the related field, and examining the existing instruments relevant to attitudes and beliefs towards the historical approach in mathematics education (e.g. Clark, 2006; Fraser & Koop, 1978; Oprukçu-Gönülateş, 2004; Percival 1999, 2004; Sullivan, 2000). During this process necessary permissions were taken from the authors mentioned above. For ensuring the content validity of the instrument, three experts from elementary mathematics education field, and one expert in elementary science education field were consulted. Necessary corrections (like combining and deleting items) were made on the items and number of the items was reduced to 40 after this process. The pilot study was performed with these 40 items which were related to teacher candidates' attitudes and beliefs towards the usability of the historical approach, its effects on the comprehension of the disciplinary structure of mathematics and the understanding of mathematical concepts, its contributions to their professional development, and their efficacy about using the history of mathematics in their own teaching. The questionnaire items were written by using statements in which the teacher candidates can choose the most appropriate response to their feelings, thoughts, and also possible actions which they would do towards the mentioned sub dimensions (such as the usability of the history in mathematics teaching, and the historical approach's contributions to their professional development) about the history use in mathematics education. The developed instrument's items which shelter strong expressions are closer to beliefs, and the items that contain less strong expressions are closer to attitudes. These were determined in accordance with Thompson's (1992) detachment approach among the two concepts as mentioned before. During this test item writing process, the difference between the concepts of attitudes and beliefs were not considered, rather these two very close concepts were dealt in the frame of the affective factors influencing the teaching and learning of mathematics as Leder and Forgasz suggested (2002). Thus, any item discrimination according to the concepts of attitude and belief was not expected to appear at the beginning of the instrument's development process as it was not the intention of this study.

For investigating the instrument's validity and reliability, a software program named PASW Statistics 18 was used. Before the validity and reliability analyses, hot deck imputation was used to fill the missing values in the raw scores. The construct validity of the instrument was gained by factor analysis which intends to reduce great variable (item) sets to smaller component groups (Pallant, 2007). Exploratory factor analysis technique with the principal components factor extraction approach was utilized to clarify the dimensions of the instrument. Varimax rotation was selected to analyse each of the factors appeared, and minimum factor loading for an item to be

placed in a component was selected as .3. Before the factor analysis was performed, negative items were recoded.

In Pallant's (2007) opinion, the number of factors can be limited if researchers think that a particular number is best describing the variables' interrelationships. Thus, the number of factors was limited to three for this study. After the factor analysis was conducted, the suitability of the data for this factor analysis was controlled by checking the assumptions, which are sample size, factorability of the correlation matrix, linearity, and outliers among cases, as Pallant (2007) offers. The underlying reason for designating the sample size is that it should be at least five times of the number of the items in the instrument. In other words, five cases are enough for each item in the questionnaire (Tabachnick & Fidell, 2007). In this study, the instrument formed of 40 items was applied to 237 participants, so this sampling is adequate in number. The factorability of the correlation matrix (strength of the relationship among items) was assessed by examining the correlation matrix, Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy, and Bartlett's test of Sphericity. The correlation matrix clarified some correlations of $r=.3$ or greater among many item (variable) pairs, Bartlett's test of Sphericity was found significant (Chi-Square $\chi^2=3447.582$; $p=.000$), and the KMO value was calculated as .871. These are indicators of that the data were appropriate for factor analysis (Tabachnick & Fidell, 2007). It would not be a problem that the linearity assumption was not checked because the sample size was high enough (Pallant, 2007). The data were screened for outliers, but none could be found. After the assumptions were checked and it was understood that there was no problem with conducting the factor analysis, the values concerning the factors were analysed. Moreover, factor loadings of the items were examined with the help of the rotated component matrix in order to make a decision about each component's items and determine whether any item should be taken out of the instrument or not. The values regarding the factors can be seen in Table 1 below:

Factor	Initial Eigenvalues		
	Total	% of Variance	Cumulative %
1	9.893	24.733	24.733
2	2.893	7.234	31.967
3	2.466	6.166	38.133

Table 1: The values related to the factors (components)

It can be inferred from the table that the three factors explain a total of 38.133 per cent of variance. Moreover, the three envisaged components before the factor analysis have appeared with 4 items (Factor 3) or more. With respect to Pallant's view (2007), at least three items loading on each component are sufficient. Furthermore, an item's maximum factor loading to a component should be at least .1 greater than its factor loading to the other components (Büyüköztürk, 2002). When

Working Group 12

the maximum factor loadings for each item were examined, it was seen that the maximum factor loading of the item ‘38’ was .155 to the second factor. Because of that an item’s factor loading to a component was selected as at least .3 previously, the item 38 was extricated from the instrument. There are also 5 items whose largest factor loading to a component was not .1 greater than its factor loading to other components. Therefore, they were removed from the instrument, as well. The reliability was ensured by calculating Cronbach Alpha coefficient as .905. This value indicates very good internal consistency reliability for the instrument (George & Mallery, 2001).

After the problematic items were removed from the questionnaire, the same statistical process was conducted for analysing validity and reliability again. It was seen that the three factors of the finalized questionnaire (35 items composing of 3 factors) explained a total of 39.711 per cent of the variance, Bartlett’s test of Sphericity was found significant again (Chi-Square $\chi^2=2870.341$; $p=.000$), and the KMO value was calculated as .875 this time. The Cronbach Alpha coefficient was .902, which addressed a high reliability. When the contents of the items placed in each component were examined by considering the field of history in mathematics education and some instrument development studies about social sciences (e.g., Cantürk-Günhan & Başer, 2007; Turan & Demirel, 2009), a meaningful pattern was established among the components. In respect of this pattern, the factors were defined. The first component is “Positive Attitudes and Beliefs towards the Use of History in Mathematics Education” including positive items of the instrument. The second factor is “Negative Attitudes and Beliefs towards the Use of History in Mathematics Education” corresponding to the negative items. The third and last factor is “Self-efficacy Beliefs towards the Use of History in Mathematics Education” corresponding to items about an individual’s self-efficacy, which is criticism on his/her own proficiency about overcoming tasks specified beforehand (Bandura, 1997). The items related to attitudes and beliefs were not separated by these underlying factors of the instrument as the researchers expected before. Three sample items from each of these factors can be seen in Table 2 below:

Item	Name of the Factor
Learning the history of mathematics enriches teacher candidates’ professional repertoire.	Positive ABHME
Pre-service teachers must be given courses about how to use the history of mathematics in mathematics education.	
The history of mathematics makes students to notice that mathematics is a universal product.	
It is <u>difficult</u> to integrate history in mathematics education.	Negative ABHME
Using the history in mathematics education causes students to <u>lose their enthusiasm</u> for mathematics.	

Working Group 12

Including history in mathematics education <u>hinders</u> mathematics teaching.	Self-efficacy Beliefs towards the Use of History of Mathematics in Mathematics Education (SBHME)
I <u>do not</u> have an idea about how to use historical materials.	
I <u>do not</u> know how to integrate history in mathematics teaching process.	
I <u>do not</u> have enough information about the historical evolutions of the concepts which I will teach in the future.	

Table 2: Sample items from each of the factors

RESULTS AND DISCUSSION

The aim of this study was to construct a valid and reliable instrument measuring pre-service elementary mathematics teachers' attitudes and beliefs towards the use of history of mathematics in mathematics education. The conducted factor analysis eliminated some of the items (1, 2, 29, 37, and 38) and terminated the number of the items as 35. It also showed that 22 items were gathered under the component 'Positive ABHME', 9 items were collected under the component 'Negative ABHME', and 4 items formed 'SBHME' component. When the possible underlying reasons of the separation of these components are thought, it can be said that a difference existed between in favour of and opposed to the attitudes and beliefs of the teacher candidates towards the expressed mathematics teaching approach, and the pre-service teachers have a perception about to what degree they are able to use and/or integrate history in mathematics education. Moreover, the instrument was found to have very good reliability ($\alpha=.9$), which is an indication of high internal consistency among the items. The validity and reliability of it is open to being ensured by other researchers via following the similar procedure mentioned in the method section of this paper.

To bring in such an instrument to the literature is believed to inspire the researchers interested in this field for producing studies regarding the attitudes and beliefs towards the use of the history of mathematics for the teaching of mathematics either with pre-service elementary or secondary mathematics teachers. If it is adopted (e.g. by deleting and adding some items, changing some of the items' words written particularly for teacher candidates) properly, it can also be used with in-service mathematics teachers since the contents of the items are focused on teaching mathematics with its history. In order to advance the investigations of this field, the researchers may benefit from the instrument as an attachment of an experimental study concerned with the use of history in mathematics education in order to reveal potential effects of interventions on the attitudes and beliefs towards the teaching approach in question. Survey research also can be conducted with the scale in order to form an opinion about the attitudes and beliefs towards the historical approach usage of both pre-service and in-service teachers. Moreover, future studies will make

some important contributions to the research conducted in the field of using history of mathematics in the teaching and learning of mathematics, and take attention of those concerned with mathematics education to this approach some more. Additionally, the results gained via using the instrument by future research projects would have valuable implications for teacher educators, education policy makers and curriculum developers in designing curricula for mathematics education at different levels.

IMPLEMENTING ‘MODERN MATH’ IN ICELAND – INFORMING PARENTS AND THE PUBLIC

Kristín Bjarnadóttir

University of Iceland – School of Education

‘Modern math’ was implemented in Icelandic schools at all levels in the 1960s. It was introduced to parents at meetings and by media articles, interviews and a television programme in 17 episodes. It is argued that the information was presented by unrealistic convictions of the value of the ‘modern math’ programme, that the timing of the presentations was sub-optimal, and that more information was needed when the programme had reached the majority of primary-level.

INTRODUCTION

In the 1950s questions arose in many countries about mathematics teaching. In November 1959, the OEEC (later OECD) arranged a meeting on reform of school mathematics in Royaumont, France (OEEC, 1961), whereby reform ideas turned into an international movement. The dominant idea was that the theory of sets, uniting the various branches of mathematics, be the basis for school mathematics. This reform movement is commonly referred to as ‘modern mathematics’.

The ‘modern math’ movement hit Iceland at a standstill state (Bjarnadóttir, 2006). The Education Act of 1946 ensured compulsory schooling of all children aged 7–15 and equal access to higher education, while the legislator failed to ensure university access for primary teachers. There was a serious shortage of secondary school mathematics teachers (OECD, 1961, p. 158; Bjarnadóttir, 2007, 184–192, 238–239). Research revealed that mathematics and science syllabi for 13–15 year old pupils, who had only eight month schooling a year, were behind those in the other Nordic countries (Björnsson, 1966). Primary level mathematics textbooks created in the 1920s were still in use. Textbooks were then, as now, produced by a state enterprise, which was in a serious financial crisis at that time.

A reason often mentioned for implementing the ‘modern math’ was the fear to lag behind other countries in a progress towards modern society, e.g. in England:

... topics as the algebra of sets or relations might be taught with a profit ... lower down the school ... In other countries they are learning how to do this, and unless we learn too we shall be left behind (*Mathematics Teaching*, 1958; Cooper, 1985, p. 76)

This view was reflected in Iceland: ‘... we have to protect our honour and interests in the cultural competition of today’ (Sigtryggsson, 1964, p. 146), and in Brazil: ‘The teaching of mathematics had to be modern, such as Brazil wanted and expected to be’ (Búriago, 2008).

The implementation of ‘modern math’ in other countries has been examined, e.g. in Denmark, Norway and England (Høystrup, 1979; Gjone, 1983; Cooper, 1985). This

Working Group 12

study is an extension of a larger study on the implementation of modern math in Iceland (Bjarnadóttir, 2007), focussing on its publicity, such as information offered to Teachers, parents and the public.

Questions to be explored are: What went wrong in the implementation of the ‘modern math’? Was the timing of the publicity process wrong, or was the ‘modern math’ a cause too weak to defend?

The questions are of interest, not only to understand the past, but also for the present. Much time, effort and resources are devoted to centrally organized curriculum development for the relatively small market in Iceland, with about 4000 children in a year cohort. How should the limited means be allocated? There are issues regarding the quality of content and material, and the publicity to teachers, parents and providers of funds. The study might offer some hints of relevance.

THE RESEARCH METHOD

The research method is historical; searching information in newspapers, journals, leaflets, archive documents, and by personal communication in emails and telephone interviews. The interviewees are a sample of convenience. In a small society as in Iceland, it is relatively easy to contact persons, who are likely to provide relevant information, through family, colleagues and acquaintances. Widespread newspapers have been digitalized so access to printed discussion is relatively easy. The sources found may therefore reflect enthusiasm and subsequent regrets rather convincingly.

‘MODERN MATH’ IN ICELAND

After the Royaumont meeting, the Nordic countries – Denmark, Finland, Norway and Sweden – established cooperation on school mathematics reform, each appointing four persons to a Nordic committee for modernizing mathematics teaching, *Nordiska kommittén for modernisering af matematikundervisningen* (NKMM) (Gjone, 1983, II, p. 78). Information from the NKMM was transmitted to Iceland through personal contacts. Mathematics professor Svend Bundgaard, the main advocate for ‘modern math’ in Denmark, was a friend of Guðmundur Arnlaugsson, associate professor and high school mathematics teacher, educated in Copenhagen; and Agnete Bundgaard, primary teacher and the author of a ‘modern math’ textbook series for primary level on behalf of the NKMM, was Svend’s sister.

Arnlaugsson became a leader of those concerned about mathematics education. His activities were in several steps: In 1964 he asked to be appointed as consultant in mathematics teaching at the Ministry of Education in a half-time position, to continue until 1966 (Minister Gylfi Þ. Gíslason, personal communication, Jan. 10, 2002). He organized week-long in-service courses for teachers on the ‘modern math’ from 1965. In 1966 he published a textbook, *Numbers and Sets*, (Arnlaugsson, 1966) on introduction to numbers and set theory. The book was intended for college bound students preparing for a national entrance examination into high schools and was

Working Group 12

tested in 1966–1968. Finally, Arnlaugsson suggested the textbooks by Agnete Bundgaard to be translated and tested in seven groups in two primary schools in Reykjavík during 1966–1967.

The primary school project was planned with regular meetings of the two project leaders and the teachers, and with meetings to inform parents. In spring 1967 the project was presented to headmasters of primary schools in Reykjavík, who became enthusiastic with the majority wishing to adopt it in their schools. By the time the series was chosen, only the first year-course had been finalized in Danish, the second year-course been tested for two years and the third was being tested for the first time (K. Gíslason, 1978) so it was not known how the project would proceed.

The latter part of the series turned out to be highly theoretical (Høyrup, p. 59). The commutative and associative laws, Roman numerals and place-value notation to the base five, prime numbers, permutation of three digits and the transverse sum together with its relation to the nine times table were introduced in the third grade. Set theory with pairing, subsets, intersection and union, more place-value systems and geometry in a set-theoretical framework were added in fourth grade. Last but not least, there were algorithms that were different from those Icelanders were accustomed to, especially the multiplication algorithm (Bundgaard, 1967–1972).

PUBLIC INTRODUCTION TO THE ‘MODERN MATH’

The first presentation of the ‘modern math’ to the public was characterized by optimism. Articles were written and a television programme was made to introduce the modern ideas, to parents in particular. Later sources indicate concerns.

An interview with one of the project leaders, K. Sigtryggsson, was published in *Foreldrablaðið / Parents’ Journal* in 1967. Only the teaching methods were being changed, not the content, he said, while some topics were introduced earlier than before. Mechanical working methods had been overly emphasized at the expense of discussions of basic mathematical concepts, training of logical thinking and accuracy in presentation. Finally, children were to have no homework (Stefánsson, 1967).

Later that same year, 86 teachers attended a course to prepare for teaching the new syllabus to the majority of first grade pupils in Reykjavík (NN1, 1968, p. 95). The leaders did not have capacity to keep in contact with all the teachers and arrange information to parents. The television programme that autumn must have been expected to reach a greater number of parents than possible otherwise.

By April 1968, around 200 secondary school pupils gathered outside the parliament building with protest banners, claiming ‘Down with obsolete textbooks’, ‘Better teaching methods’, ‘We are not parrots’, ‘No dry-book learning’ and ‘Youth today is the public tomorrow’. The protest was peaceful and Minister of Education, Gylfi Þ. Gíslason, invited members of the group to his office and discussed with them for most of the day. Benedikt Gröndal, Member of Parliament, spokesman of the

Working Group 12

minister, recited this event in a semi-yearly general political radio discussion, admitting that much was needed in the school system, while listing what had been achieved in modernizing it. ‘Modern math’ was taught widely, and the public television had brought information to parents. Televised teaching was a topic of the near future (Gröndal, 1968). The government thus used the televised teaching to indicate its constructive reactions to criticism of a longstanding standstill state.

In 1970 a newspaper, *Morgunblaðið*, published an interview with the textbook author Agnete Bundgaard and her colleague, Karen Plum, who had visited Iceland to give a course to 65 teachers (NN2, 1970). By then the ‘modern math’ material was used in 141 classes in the first four grades in primary schools. Bundgaard stated that the main emphasis was on promoting the pupils’ understanding of the nature of their tasks and on training them in using their own logical faculties. The ‘modern math’ had been introduced in many countries and had influenced the way of teaching mathematics. The experience of other nations suggested that its concepts and symbols would be of great use in training pupils in clear thinking and communication. The ‘modern math’, Agnete Bundgaard said,

is as a new language, totally different from the mathematics the parents of modern school-children learnt themselves. Many parents have a hard time in accepting being unable to know exactly what their children are working on at school and assist them. But it can have very bad consequences for the child if its parents are trying to help, more willing than able to guide the child. This can lead only to confusion. Therefore it has been decided to not to assign homework to the children and even not allow them to bring their books home. However, in order to increase parents’ understanding of what their children are working on, special books have been published, admittedly not available in Icelandic, where the new mathematics is explained. It should pacify the parents until the moment, when the children have reached enough understanding of the project to be able to explain to their parents what is happening there (NN2, 1970, pp. 23–24).

Plum added that the ‘modern math’ had caused dispute in many places, and that

many years will pass until its advantages can be proven statistically, since all comparison is difficult. But surely the ‘modern math’ teaches children to think logically and ... logical thinking will always be necessary ... children ... like the ‘modern math’ and they show more interest than do children at the same age, who learn by the old methods ... (Ibid.)

This period was characterized by great confidence in experts and the mistrust to parents in the case of school mathematics was not unique. Parents were asked to refrain from teaching their children to read as this would be taken care of by experts in schools, and parents were e.g. not allowed to visit their hospitalized children. The request that parents did not interfere with school assignments was thus not unique.

THE TELEVISION PROGRAMME

To promote the compulsory school ‘modern math’ project, Arnlaugsson gave a series of seventeen episodes in a television programme on school mathematics during October 1967–January 1968. Each episode lasted about 15–18 minutes. It was sent out during prime time at 20:50 after the foreign news report each Tuesday.

Copies of the programme do not exist anymore. All remarks on it are therefore from memory. There was a tradition of adult education in foreign languages on the public radio so mathematics on television was a natural analogue. In this second year of domestic television broadcasting, over 92% of 10–14 year old children in Reykjavík and Vestmannaeyjar reported in a sociological survey that their homes had a television set, while the broadcasting had not reached further than the south and south-west area of Iceland (Broddason, personal communication, Aug. 23, 2010).

The author of this paper had no TV-set and could only watch a few episodes of the series, but with great interest, as a student mathematics teacher. Most owners of TV-sets at that time and parents or teachers of school children are now past seventy and they and their then adolescent children are the few likely to remember the content. Among them are Vilhjálmur Bjarnason (personal communication, Aug. 28, 2010), Jón I. Magnússon (Sept. 2, 2010), Guðný H. Gunnarsdóttir (Sept. 3, 2010) and Jónína V. Kristinsdóttir (March 4, 2011) who agree, as this author does, that the content was closely connected to Arnlaugsson’s textbook, *Numbers and Sets*; that is

introduction to numbers, their divisibility, prime numbers and prime factoring, and number notation in place-value systems to various bases, such as 6, 8 or 2. The binary system received special attention with respect to the new computer technology. Definitions of set operations, open sentences, implications, negations, introduction to Boolean algebra, etc., followed (Arnlaugsson, 1966).

Figure 1. G. Arnlaugsson on the TV-programme.

The programme was well reviewed in the newspapers. The picture in Fig. 1 was attached to the television programme schedule in one of the newspapers along with the remark that Arnlaugsson’s programme had been very well received and many had expressed that they had learnt quite a lot from it. A special TV-leaflet introducing the programme remarked twice (NN3, 1967) that the episodes were excellent, Arnlaugsson was a born TV-celebrity and the explanations were clear.

Magnússon, then 14 years old, now mathematics professor, and Bjarnason, 15 years, now lecturer in economics, remember that they watched the programme closely, as did their fathers, both teachers, but their mothers did not. The programme had without doubt a good influence on a group preparing for an entrance examination into high school, using Arnlaugsson’s text on experimental basis. The group included Bjarnason, who remarked that he liked the base-two algorithms and the

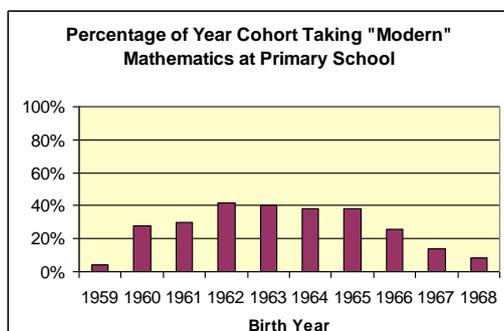

Boolean algebra, and the implications were a revelation to him. His classmate, J. V. Kristinsdóttir, now lecturer in mathematics education, noted that their teacher had discussed topics from the programme, and she, J. I. Magnússon and G. H. Gunnarsdóttir, also lecturer in mathematics education, remember also that their elder siblings, then in high school, watched the programme attentively. In general, the programme had a good reputation in their homes, theoretical as it was.

Much later Professor Magnússon (1996) wrote in memory of Arnlaugsson on behalf of the Icelandic Mathematical Society: “His programs on the television about ... ‘modern math’ are ... unforgettable, and many people were as glued to the TV-set when they were programmed”.

Different opinions were also voiced. The reporter of the foreign news report (A., personal communication, September 19, 2010), remembers a feeling of inferiority being unable to assist his children with this new math, and the managing director of the broadcasting service (G., personal communication Sept. 23, 2010), said that the series did not appeal to him, and he preferred the old math.

REACTIONS TO THE ‘MODERN MATH’

By the time of Bundgaard and Plum’s visit, authorities had realized that things were going wrong; the mathematics teaching experiments in the primary schools had become far too extensive, too difficult to run with respect to guidance to teachers, and even in a few cases close to being disastrous (R. Bjarnadóttir, personal communication, Sept. 16, 2003). A School Research Department, SRD, of the Ministry of Education had been established. It laid down a certain procedure for adopting school reforms; i.e., to set goals, write national curricula, and from there compose learning material on an experimental basis. In the crisis that had emerged, the department decided in 1971 to skip the goal-setting and curricular-writing steps, and go directly ahead to create a new set of home-made mathematics textbooks (Ísaksson, personal communication, March 10, 2003). In their final editions, sets were hardly mentioned. Enthusiasm for the ‘modern math’ at primary level had passed its peak in Iceland before 1972.

The cohort born in 1965, entering first primary grade in 1972, was the last large cohort to use the Bundgaard material. After that authorities began gradually to withdraw it, while the new state-made material was introduced after careful testing, keeping in mind the difficulties of the rapid implementation of the ‘modern math’.

Figure 2: Percentage of year cohort studying Bundgaard material up through grade 6.

Working Group 12

H. Lárusson, a mathematics consultant at the Ministry of Education knew of the problems but attempted to defend the ‘modern math’, while he himself was writing a series as a continuation of the Bundgaard material. He wrote in the teacher journal:

Among parents, teachers and others ... there have been many discussions on a new syllabus in mathematics ... People have had very different views on this new syllabus ... There has been no general publicity of the syllabus as a whole, nor of its goals, and this may partly cause the criticism which has emerged. This innovation became far more widespread far quicker than was planned ... (Lárusson, 1972, p. 9).

In 1973, Lárusson was on record stating that set-theoretical concepts were overly emphasized instead of being used to complement traditional methods. This had reduced pupils’ number skills, which was detrimental to their later studies in secondary schools and at work. Alterations made were expected to contribute to pupils’ broader perspectives and deeper understanding of mathematics at all levels and spheres of mathematics. Abroad, people were making extensive experiments on the content and presentation of textbooks with special consideration to those who have difficulty studying mathematics (Bjarnadóttir, 2007, p. 299).

An evening school for adults, Námsflokkar Reykjavíkur, reacted to parents’ need for support and offered them a course in the ‘new math’ (Árnadóttir, 1975).

AFTERMATH

The adventure of the ‘new math’ lingered in people’s memory for a long time. Educational matters were brought up in parliament in December 1988. Eiður Guðnason, M.P., recalled that many reforms had gone wrong. The ‘modern math’ had been a serious mistake; whole cohorts knew little mathematics and could not do mental arithmetic (Guðnason, 1988). A governmental report on the development of education policy in European environment, dated in 2010, claimed that the ‘modern math’ of the 1960s and 1970s failed (Menntamálaráðuneytið, 2010, p. 46).

Minister of Education, Gylfi Þ. Gíslason, stayed in office during 1956–1971. He had to cope with the great increase in student population of the post-war baby boom and the rebellious currents in the late 1960s. In a personal communication (G. Gíslason, Jan. 10, 2002) he expressed a great confidence in Arnlaugsson as a school leader, but also doubts about his role in introducing the ‘modern math’. A confidential source told a story of another minister of the same government, E. Jónsson, an engineer and a renowned mathematics student during World War I, who had expressed a doubt that he would be able to solve an O-level examination equivalent of the 1970s, when the ‘modern math’ had been implemented.

Only recently a retired primary teacher in his eighties remarked: “It is always the same problem in this country. We took up this material when the Danes themselves had discarded it.” (S. Jólsson, personal communication, Nov. 27, 2010).

DISCUSSION

Working Group 12

What went wrong in the implementation of the ‘modern math? The problem was not in adapting something discarded by other nations, as Icelanders often fear in their linguistic and geographical isolation. On the contrary, the Bundgaard material had only been finalized for the first grade and its continuation for grades 4–6 had not even been created. The books for the first two grades were not too complicated, while the hardcore mathematics emerged in the third grade. One may clearly conclude that the consequential decision was not well grounded.

Was any serious harm done? The ‘modern math’ with its unfamiliar algorithms was an intellectual surprise to a nation that was homogeneous, educationally as well as ethnically. Everyone knew the same algorithms. If anyone had seen any different approach abroad it was much scarcer than at present times. Some pupils may not have learnt any algorithms, but pocket calculators were coming soon.

Clearly, an effort was made to publicise the ‘modern math’ in the media as a part of a modernizing process, in a ‘cultural competition’. The publicity, such as the television programme in 1967–1968, may therefore have created too great expectations. It may not have been well timed either. Arnlaugsson’s TV programme fascinated some of the 15-year old students, chosen to study his textbook on an experimental basis, while preparing for entrance examination into the upper secondary level. For parents of primary school children it might have been more appropriate in 1969–1970, when place-value notation to different bases, prime numbers etc. were introduced to the first large cohort, or the year after, when the concepts of set theory were implemented. And finally, Arnlaugsson was an academic, a professional mathematician, famous for his radio talk shows on the widely practiced game of chess, but his mathematics may have failed to reach common people.

The interview with Bundgaard and Plum had doubtlessly the aim to inform parents and the public, in 1970 when the majority of primary school children were studying their material. However, remarks that information in a foreign language was ‘to pacify the parents’ witness a lack of sense of the situation and respect for the parents, as well as the decision not to let the pupils bring their textbooks home as it ‘can have very bad consequences for the child if its parents are trying to help, more by being willing than able to guide the child’. That, and remarks that ‘the ‘modern math’ teaches children to think logically’ to a higher degree than earlier, and that parents should wait ‘until the moment, when the children have reached enough understanding of the project to be able to explain to their parents’ witness unrealistic convictions of the value of the programme. The ‘modern math’ was indeed a difficult cause to defend.

However, the ‘modern math’ programme at least inspired Prof. Magnússon and eventually led him to undertake the serious studies of mathematics. This was also the case with V. Bjarnason, G. H. Gunnarsdóttir and J. V. Kristinsdóttir who were in their teens in 1967. All of them have had a role in the field of mathematics,

mathematically related subjects or mathematics education in Iceland. In a small country, each individual weighs in this respect.

The leaders of the project experienced that they were not able to guide all the teachers involved in the curriculum reform. Many teachers gave up, reverted to the old syllabus and there is no doubt that a bad reputation has followed the ‘new math’ reform ever since. However, isolating one factor of a large study, the publicity process, as is done in this paper, can lead to oversimplification. The project may be credited for that many teachers experienced that there was more school mathematics, useful to children, than the four operations in whole numbers and fractions, as presented in the traditional national syllabus. The reform offered those teachers the training they missed by the 1946 legislation when the legislator failed to open a route for them to higher education.

A group of teachers began to create new material in the favourable climate of SDR, supported by all governments for over a decade. This environment made it possible to replace the difficult syllabus in minimal time, in contrast to decades of previous stagnated syllabus. This second reform was initiated only five year after the implementation of the Bundgaard material. The lesson was learnt to avoid too great enthusiasm for hastily chosen novelties. Resources were made available to recruit teachers to test it and implement it slowly and properly.

Now, forty years after the eventful period of the late 1960s, a new state-made syllabus has replaced the one of the 1970s. It has not been universally well received. Resources have not been allocated to test the material before distributing it to whole cohorts. Many teachers have protested indirectly by photocopying old material. In the 1960s, centralized week-long courses for teachers were organized, while presently they are offered half-day meetings, if their schools choose to allocate funds for specific subjects rather than general topics, such as class discipline. The lessons learnt from the ‘modern math’ of the 1970s have gradually faded away, while its deficiencies contribute more to its reputation than its merits.

VOICES FROM THE FIELD: INCORPORATING HISTORY OF MATHEMATICS IN TEACHING

Kathleen M. Clark

The Florida State University

Using the voices of teachers in the field, this paper describes how and what historical content secondary and post-secondary teachers decided to use in their teaching. For the small exploratory study, I analyzed survey results in which teachers reported their use of history as anecdote, biography, or interesting problems during the 2008 – 2009 academic year. Of the 32 episodes reported, 20 involved “history as anecdote”; nine episodes were characterized as a use of “history as biography”; and 15 included the use of “history as interesting problems” (with each episode having the possibility of being coded as a use of each or some subset of the three). The “history as interesting problems” episodes are provided in some detail and I end with a discussion on directions for future research.

SITUATING THE STUDY

In the field of mathematics education we know little about how teachers obtain historical knowledge and subsequently implement that knowledge in teaching. Experts agree with the claim, “teachers can profit from studying the history of mathematics” (Bruckheimer & Arcavi, 2000, p. 135) yet corresponding research is difficult to find, especially in the United States. More recently, Jankvist (2009; 2010) provided two purposes for using history of mathematics in teaching: (1) history as a tool, in which history of mathematics is an assisting means for teaching and learning mathematics, and (2) history as a goal, where students are taught about the historical development of mathematics, its interplay with other practice areas, and societal and cultural influences on mathematics and the other way around.

Jankvist (2009; 2010) observed that too much rhetorical and theoretical literature exists that describes the affordances that history of mathematics can lend to both classroom teachers and their pupils. Furthermore, he stated that, “despite history in math education being an old topic only relatively few empirical studies have been made” (Jankvist, 2010). While Jankvist makes the point regarding the lack of empirical studies that examine history as a tool or history as a goal in mathematics teaching and learning from a global perspective, the lack of empirical research on these same notions is even more extreme when examined within the context of the United States.

A CURRENT PERSPECTIVE

My view regarding the direction of studying the incorporation of history of mathematics in teaching is that we must begin with teachers “friendly” to the idea.

Working Group 12

To that end, the exploratory study discussed in this paper begins with teachers who possess some general knowledge of how the history of mathematics may be used in teaching, including the knowledge of appropriate resources. Furthermore, they expressed positive results (either for themselves or with students) from initial efforts to use history of mathematics in teaching.

The primary goal of the study was to survey a purposeful sample of secondary and post-secondary teachers and collect their reported planned and actual use of history of mathematics in teaching. The research questions were:

What historical content (e.g., anecdotal, biographical, mathematical) do teachers incorporate in their teaching?

What obstacles do teachers report, from either their own or from the student perspective, as a result of incorporating history of mathematics in teaching?

What benefits do teachers observe, from either their own or from the student perspective, as a result of incorporating history of mathematics in teaching?

RATIONALE

Incorporating history of mathematics in teaching is problematic for several reasons. For example, obtaining knowledge of the historical development of school mathematics topics requires guidance (e.g., selecting appropriate and reliable resources) and time to read, study, and adapt historical content for use with students. These reasons are accompanied by the typical obstacles that teachers report; the primary of these is having instructional time to use history in teaching mathematics. Although beyond the scope of this paper, considerations of time obstacles often accompany teachers' views that drawing upon history of mathematics when teaching is something extra and any inclusion of history of mathematics is often viewed as supplemental to the mathematics curriculum. Consequently, this primary obstacle discourages teachers to use history as an instructional tool or history as a viable goal for instruction.

We know little about how teachers obtain historical knowledge and consequently implement such knowledge in teaching. Fauvel (1991) observed that:

making use of history...is hard for teachers – who have usually learned little or no mathematical history during their training, let alone received training on how to use history with their pupils. (p. 4)

Other experts agree with Bruckheimer & Arcavi's (2000) claim that there is something to be gained by teachers who use history of mathematics in teaching and that if we seek to humanize mathematics instruction for students "we must do it through the teachers" (Avital, 1995, p. 3).

PARTICIPANTS

I considered the dearth of empirical studies on incorporating history of mathematics in teaching within the United States as a justification for conducting an exploratory study of teachers who indicated their interest to incorporate history of mathematics in their instructional practice. To identify my purposeful sample, I sent a survey to 26 teachers at the end of an online course, *Using History in the Teaching of Mathematics* [1]. Fourteen of the 26 teachers responded to the survey, of which 12 responded favorably to the final question, “Would you be interested in participating in a research effort designed by Dr. Clark, regarding the use of historical content in teaching mathematics?” Finally, six of the 12 teachers agreed to participate in the study beginning in August 2008. These teachers received a two-page summary of the study, including goals of the study and the approximate time commitment for completing monthly surveys. Additionally, each teacher received a copy of the survey questions so that they could use the document format to compile their responses for the Survey Monkey™ monthly survey. The monthly survey included prompts such as:

- Describe your plans for incorporating history of mathematics in teaching, including dates of instruction, the course title, the mathematical topic, and what you included in your instruction.
- Describe any obstacles that you experienced when implementing your instructional plans for including history in teaching mathematics.
- Describe any obstacles that you feel your students experienced as a result of incorporating the history of mathematics in teaching.
- Identify the benefits (to you, the teacher) that you experienced as a result of studying, planning for, and incorporating the history of mathematics in your teaching.
- Identify the benefits that you feel your students experienced as a result of your inclusion of the history of mathematics.
- Classify the overarching historical perspective from which you approached each inclusion of the history of mathematics as: history as anecdote; history as biography; history as interesting problems; or, a combination of two or more of these.
- Provide the bibliographic information for the resources that you accessed for planning and implementing the history of mathematics in teaching.
- Indicate whether you created handouts to be used with students (or that were actually used with students) or used handouts from other sources.

The six teachers (only pseudonyms are used here) were teaching in three different states. Evan, Judy, Jeannette, and Suzanne were teaching in the same state in the

Working Group 12

southeastern United States; Maxine was teaching in a state in the Midwestern US; and Libby was teaching in the southeastern US. As an unfunded, exploratory study, the online survey was the most viable data collection method. Although I am fully aware of the problematic nature of self-report data, my original plan was to use the “Voices from the Field” monthly survey responses to describe what teachers in a variety of teaching contexts were able to accomplish, given their self-professed goals of wanting to infuse their teaching with history of mathematics. Table 1 presents the six teacher participants, their teaching assignment in 2008 – 2009, and an excerpt from their response to the question, “Do you plan on using history of mathematics in teaching in future? If so, please describe an example or two.”, from a final summary assignment during the *Using History in the Teaching of Mathematics* course.

Participant	Teaching assignment	Do you plan to use history of mathematics in the future?
Maxine	Developmental mathematics courses (community college level)	“I would like to refine the “restoration and opposition” approach so that students in the skilled trades have more facility in solving equations for a certain variable.”
Evan	Middle grades mathematics (advanced/honors level)	“Over time, I will work to integrate more history of mathematics in my teaching. More than anything, learning about mathematics history has shown me how important it is for my students to know why mathematical concepts exist.”
Judy	High school mathematics (advanced level)	“Definitely. I know I will use lessons from [the <i>Historical Modules</i>] in every class that I teach next year.”
Suzanne	Middle grades mathematics (all levels)	“I will use the history of mathematics in my future lessons. I will use the modifications I made to the ‘determining the angle of the sun with shadows’ activity this school year. Next year, I’d like to use my module add-on lesson ‘From the Earth to the Sun’.”
Libby	High school mathematics (geometry)	“I absolutely will incorporate many historical aspects into the subjects that I teach in the future. For example, if I am teaching Algebra 1, I would certainly include the activities from the negative numbers module that we studied.”
Jeannette	High school mathematics (geometry)	“Yes, I am planning on using some of the logarithms activities with my students when I get to that section. I will be looking through the modules again over the summer to decide which ones I would like to include next year.”

Table 1: Teacher participant data

DATA COLLECTION

Participants were asked to complete the “Voices from the Field” survey approximately every six weeks, or six times during the 2008 – 2009 school year. Table 2 documents each participant’s survey completion, as well as comments on issues that a participant may have experienced during data collection. Comments are provided when participants were unable to complete each of the six surveys.

Participant	Surveys completed	Comments
Maxine	Surveys 1 – 6	
Evan	Survey 2; Survey 6	Did not complete surveys when no use of history to report
Judy	Survey 1; Survey 2; Survey 6	Unable to continue with plans to incorporate history of mathematics during high-stakes test “season”
Suzanne	Survey 1; Survey 2; Survey 4	Obstacles resulting from administration intervention
Libby	Survey 1; Survey 3	Unable to continue due to graduate school and new course planning
Jeannette	Survey 1; Survey 2; Survey 3; Survey 4	Discontinued plans to incorporate history of mathematics due to high-stakes test “season”

Table 2: Documentation of participant survey completion

RESULTS

For the purposes of this paper, I only address the first research question (What historical content (e.g., anecdotal, biographical, mathematical) do teachers incorporate in their teaching?). As indicated in their response to a final summary assignment during the *Using History in the Teaching of Mathematics* course, each teacher did indeed incorporate history of mathematics in their teaching. This was not completely unexpected given the positive-toward-the-power-of-using-history disposition each participant shared while taking the *Using History* course and their subsequent expression of interest to participate in the study.

Examination of the survey responses revealed that the teachers, some of whom in spite of experiencing significant obstacles, developed particular preferences for incorporating history of mathematics when teaching. As one way to describe such preferences I used the terms, “history as anecdote”, “history as biography”, and “history as interesting problems”, which were adapted from the reasons for using history in the teaching of undergraduate mathematics suggested by Siu (1997). Siu identified four such strategies (“ABCDs”):

- A is for Anecdotes;
- B is for Broad Outline;
- C is for Content; and

Working Group 12

- D is for Development of Mathematical Ideas. (p. 144)

The modifications I developed, based upon my experience with teachers seeking to incorporate history of mathematics at the secondary level, are:

<u>Siu's strategy</u>	<u>Modification for the "Voices from the Field" study</u>
A is for Anecdote	history as anecdote
B is for Broad Outline	(none represented)
{mostly aligned with "A"}	history as biography
C is for Content	history as interesting problems
D is for Development	(none represented)

Question 10 of the survey requested that teachers classify the overarching historical perspective from which they approached each inclusion of the history of mathematics in their teaching. The question, which asked teachers to identify their "goals of using history in teaching", was developed prior to publication of Jankvist's (2009) identification of purposes, "history as a tool" and "history as a goal". With the view of these purposes, I could argue that each episode reported by the teachers in this study represents an example of "history as a tool". I would further argue, however, that elements of "history as a goal" are reflected in both teachers' descriptions of what they included in their teaching, as well as in the comments that they offered about their work in this regard. My purpose in this paper is to not so much delineate types of use of history of mathematics in teaching; instead I aim to highlight ways in which teachers are able to, and to suggest directions for future empirical work.

History as...

Teachers reported that they included history of mathematics in their teaching in 32 teaching episodes, with content ranging from Grade 7 mathematics (pupils aged 12 to 13) to community college developmental mathematics (mathematics course work at the secondary level, taken after secondary school in colleges preparing students for college-level work). "History as anecdote" was identified as the overarching perspective for their use of history in 20 of the 32 episodes. "History as interesting problems" was identified in 15 episodes and "history as biography" was reported in only nine of the 32 episodes (note that any episode had the possibility of being coded as a use of each or some subset of the three types of use of history). The prevalence of use of historical anecdotes in teaching mathematics is not surprising. Sharing anecdotes can situate a new topic – both for students and teachers, can aid in humanizing mathematics, and often require the least amount of preparation and time commitment during teaching [2].

The result with significant promise, however, is that teachers chose to plan an instructional episode in which students would work with historical problems in 15 of the 32 episodes. This is significant for two reasons: a "history as interesting

Working Group 12

problems” perspective engages students in mathematical content and this engagement allows students to investigate alternative solution methods. The 15 “history as interesting problems” episodes are described in Table 3.

Participant	Course/topic	Historical content	Participant comments
Maxine	Basic Math	Numerals in ancient number systems	Students were apprehensive about doing something new; student confusion and discomfort
Maxine	Intro to Algebra	Al-Khwarizmi’s method of completing the square	Students needed more time to understand these sorts of problems
Maxine	Intro to Algebra	Solving right triangle problems from historical documents	Students demonstrated interest and engagement, in particular because of relevance of material to students’ lives
Maxine	Intro to Algebra	Solving linear equations using Euler’s method for transforming equations	A student question prompted the teacher to introduce operations with integers using ancient Chinese methods; student exclaimed, “Wow! You should tell the whole class!”
Maxine	Intro to Algebra	Solving quadratic equations using the methods of al-Khwarizmi	Students were able to see that such problems are “mathematical ideas that people have struggled with over centuries”.
Maxine	Intro to Algebra	Theorem of Pythagoras; solving right triangles	Integration of history feels “natural” after doing so for several semesters
Maxine	Intro to Algebra	Chinese method for integer addition	Using the Chinese method reduced misunderstanding and subsequent re-teaching
Maxine	Intro to Algebra	Solving equations (Maclaurin’s transformations)	Students indicated that they really “get it”
Judy	Honors Geometry	Proofs of the Theorem of Pythagoras	Students enjoyed working on the problems, though they question themselves when working on atypical problems
Judy	Honors Geometry	Solving right triangle (historical) problems	Working with history is rewarding if students “get it”
Libby	Geometry	Research on tangrams; construction of	Learning about the background contributes to the experience; includes logic skills and spatial

Working Group 12

Participant	Course/topic	Historical content examples	Participant comments
Jeannette	Geometry	Goldbach's conjecture	Historical information helps her to understand the material better
Jeannette	Geometry	Gauss' number theory	Students benefit from "knowing the people behind the math"; makes it more real for students
Jeannette	Geometry	Discussion of the Declaration of Independence	Reading is a big obstacle for the students
Jeannette	Algebra 2	Babylonian guess-and-check method for solving equations	Students get to see another side of mathematics; historical problems promote critical thinking skills

Table 3: History as interesting problems (by teacher participant)

Maxine's and Jeannette's "history as interesting problems" use was the most prevalent of the six teacher participants. Maxine identified actual problems she used with her students in eight of the nine teaching episodes she reported in the survey responses. In many ways, Maxine may have experienced the time obstacle more extensively than other teacher participants. Although she did not have to deal with the pressure of a high-stakes assessment of her students at the end of the year, she did have to adhere to a very full curriculum, for courses that met only two or three days per week for one semester. She mentioned that her students did not always have sufficient time to work on the mathematical ideas within the historical problems, yet she consistently incorporated them in her teaching.

Jeannette did have concerns about the high-stakes assessment and because of it she abandoned her plans to incorporate history of mathematics at the end of the school year. Judy experienced the same issue, however she did resume her plans for using history after the conclusion of the assessments. The remaining three teachers did not incorporate historical problems as frequently (Libby) or at all (Evan and Suzanne). This may be due to the level of courses they taught (Evan and Suzanne taught middle grades mathematics; Libby taught regular geometry). Follow-on interviews – along with classroom observations – may provide information to better understand this phenomenon.

DISCUSSION

The episodic account presented here is encouraging, but many questions arise. Certainly it is encouraging that after participating in a one-semester history course (e.g., *Using History in the Teaching of Mathematics*), teachers felt empowered and able to incorporate history of mathematics into their instructional plans. This may be attributed to a variety of reasons, including the participants' predisposition to use history of mathematics or the availability of classroom activities with which they had

Working Group 12

prior experience (e.g., access to collections of classroom materials, including *Historical Modules for the Teaching and Learning of Mathematics* (Katz & Michalowicz, 2005)). Yet the ways in which a teacher develops his or her mathematical knowledge for teaching still requires high-quality, empirical study. In particular, it is necessary to examine ways in which history of mathematics contributes to mathematical knowledge for teaching, aids in improving “students’ problem-solving skills, lays a foundation for better understanding, helps students make mathematical connections, and highlights the interaction between mathematics and society” (Karaduman, 2010).

The current study contributes in two ways. First, analyzing the use of history of mathematics employed by teachers, along with the obstacles and benefits that they observe provides a foundation from which to plan future research. For example, when and for what topics is it more beneficial to incorporate “history as interesting problems”? And, what is the value-added effect of “history as anecdote”? Second, this study contributes to the current conversation and framework-building surrounding “history as...”, as suggested by the tool I used to analyze teachers’ use of history and the approaches of Jankvist’s (2009; 2010) two purposes of using history of mathematics in teaching. Developing a framework can only result from research that proceeds with a purpose. In this case, our purpose should be focused on moving away from the rhetoric that has survived for several decades, and on moving towards implementing a research agenda that seeks to address the questions regarding the use of history of mathematics in teaching.

NOTES

¹. The course was required in an online Masters of Science in Mathematics Education program at a large university in the southeastern US. Admission to the program required students to be classroom teachers (mathematics, grades 5 – 12).

². This is not to say that anecdotes are always used for an instructive purpose and without appropriate resources can be wildly inaccurate. See for example, Montelle and Clark (2009).

DESIGNING TEACHING MODULES ON THE HISTORY, APPLICATION, AND PHILOSOPHY OF MATHEMATICS

Uffe Thomas Jankvist

University of Southern Denmark [1]

Firstly the paper raises the question of designing teaching modules focusing on elements of the history, application, and philosophy of mathematics for use within the Danish upper secondary mathematics program. The design relates to the Danish KOM-project's competence-based framework and may be seen as a way to put its three types of overview and judgment into practice. The design question is answered by a description of a specific module. Secondly the paper poses a research question of the ways in which the design of such modules may create a basis for students' development of overview and judgment. Finally the paper discusses theoretical constructs from general mathematics education research that may assist in answering this second question based on in-progress classroom implementations.

THE DANISH KOM-PROJECT

The Danish KOM-project [2] defines *mathematical competence* as “a well-informed readiness to act appropriately in situations involving a certain type of mathematical challenge” (Niss & Jensen, 2002, p. 43). Depending on the mathematical challenge in question, different types of mathematical competencies are called for. The KOM-project identifies eight more or less self-explanatory mathematical competencies (each referred to as a *competency*) that students are to come to possess during their mathematical training and which together span the above mentioned overall and general mathematical *competence*. These competencies are divided into two groups:

- I. the ability to ask and answer questions in and with mathematics, and
- II. the ability to deal with mathematical language and tools.

From an overall point of view, the ability to cope with and in mathematics can be said to consist of exactly these two capacities, each of which contains a set of four specific competencies. The four specific competencies which make up the first capacity (I) are: (1) mathematical thinking competency, (2) problem solving competency, (3) modeling competency, and (4) reasoning competency. The four competencies regarding mathematical language and tools (II) are: (5) representation competency, (6) symbols and formalisms competency, (7) communication competency, and (8) aids and tools competency.

Besides these eight ‘first order’ competencies, the KOM-project also mentions three ‘second order’ competencies, referred to as the three types of *overview and judgment*:

- OJ1: the actual application of mathematics in other subject and practice areas;

Working Group 12

- OJ2: the historical evolution of mathematics, internally as well as in a societal context;
- OJ3: the nature of mathematics as a subject.

Where mathematical (first order) competencies “consist in having knowledge about, understanding, being able to practice, apply, and commit oneself to mathematics and mathematical activities in a profusion of connections in which mathematics plays a part or can play a part”, or in other words a kind of “insightful readiness to act expedient in situations which hold a certain kind of mathematical challenges”, the three types of overview and judgment are “‘active insights’ concerning the character of mathematics and its role in society”. Niss & Jensen state that “these insights equip those who possess them with a set of viewpoints, which provide overview and judgment about the connection of mathematics to circumstances and allotting in nature, society, and culture” (Niss & Jensen, 2002, pp. 43, 66).

OJ1 concerns actual application of mathematics to extra-mathematical purposes within areas of everyday life, society, or other scientific disciplines. The application is brought about through the creation and utilization of mathematical models. As opposed to the so-called modeling competency, which deals with active modeling skills, this type of overview and judgment is of a more broad and generalized form, almost of a sociological or science-philosophical nature. OJ2 should not be confused with knowledge of the history of mathematics viewed as an independent topic. The focus is on the actual fact that mathematics has developed in culturally and socially determined environments, and is subject to the motivations and mechanisms which are responsible for this development. On the other hand, the KOM-project says, it is obvious that if overview and judgment regarding this development is to have any weight or *solidness*, it must rest on concrete examples from the history of mathematics. The third type of overview and judgment (OJ3) concerns the fact that mathematics as a subject area and academic discipline has its own characteristics, as well as the characteristics themselves. Some of these, mathematics has in common with other subject areas, while others of them are unique. This type of overview and judgment includes several elements of more modern *philosophy of mathematics* (OJ3), and for that reason I shall also refer to it as such. For similar reasons the other two types shall also be referred to as *history of mathematics* (OJ2) and *applications of mathematics* (OJ1).

INTERRELATIONS BETWEEN OJS AND COMPETENCIES

Although being of different ‘order’ the eight mathematical competencies and the three types of overview and judgment are related. Niss & Jensen (2002) list the interrelations which are illustrated on figure 1.

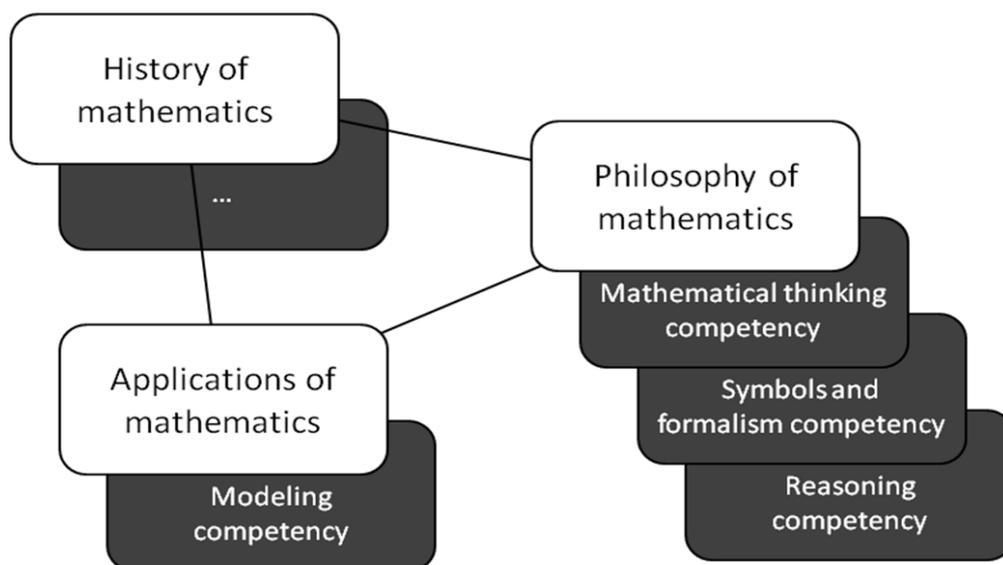

Figure 1: Interrelations between the OJs and the mathematical competencies.

Niss & Jensen state that a well-developed modeling competency on the one hand will contribute to a concrete entrenchment and consolidation in terms of OJ1, but on the other hand that such not automatically is a result of having a well-developed modeling competency. For OJ3 Niss & Jensen (2002, p. 69) state that if one were to point to competencies which in particular contribute to “the creation of a basis for overview and judgment when it comes to the *particular* traits of mathematics, then it must be the mathematical thinking, reasoning, and symbol and formalism competencies.” As evident from figure 1, OJ2 cannot in the same way as the two other OJs be said to have a set of corresponding competencies (although one may speak of a ‘mathematical historical competency’ as part of the overall mathematical *competence*). However, the KOM-report also makes clear that to be properly entrenched, the three types of overview and judgment need to rest on a foundation of the eight competencies. Or in other words: “to have overview and judgment regarding mathematics, it is insufficient merely to have heard (stories) of mathematical application, historical development, and its particular nature” (Niss & Jensen, 2002, p. 70).

MOTIVATION AND A QUESTION OF DESIGN

The three types of overview and judgment play a role in the new Danish mathematics program for upper secondary school, i.e. the students have to develop these ‘second order’ competencies to some extent. Besides the fact that this can happen as part of 1/3 of the curriculum, which is free for the teachers and schools to choose themselves, neither the KOM-project nor the regulations for mathematics at upper secondary level say much about how it is to take place in practice. In a previous study [3] I considered this for the case of history (OJ2), although choosing historical cases related to actual applications of mathematics as well (OJ1) (Jankvist, 2009c). Thus, one question for this study is:

Working Group 12

- How to design teaching modules that take into account all three types of overview and judgment – in unison – with upper secondary level as the target group?

A ‘GUIDED READING’ OF ORIGINAL SOURCES

The main idea of the design is to have the students read and work with one original source for each of the three types of overview and judgment, all of them adhering to a common mathematical theme and/or topic. I shall illustrate this by describing a concrete module. The three texts (in Danish translation) included in the teaching material for this module are:

- Leonhard Euler, 1736: *Solutio problematis ad geometriam situs pertinentis*
- Edsger W. Dijkstra, 1959: *A Note on Two Problems in Connexion with Graphs*
- David Hilbert, 1900: *Mathematische Probleme – Vortrag, gehalten auf dem internationalen Mathematiker-Kongreß zu Paris 1900* (the introduction only).

The overall theme for these are ‘mathematical problems’, which was what Hilbert addressed in general terms in the introduction of his lecture from 1900. To make Hilbert’s general observations a bit more concrete, the students are first to read the two other texts, each of which addresses a mathematical problem. Euler’s paper from 1736 is on the Königsberg bridge problem: how to take a stroll through Königsberg crossing each of its seven bridges once and only once – and today the paper is considered the beginning of mathematical graph theory. Two centuries later, with the dawn of the computer era, graph theory (and discrete mathematics in general) found new applications. Dijkstra’s algorithm from 1959 solves the problem of finding shortest path in a connected and weighted graph, and today it finds its use in almost every Internet application that has to do with shortest distance, fastest distance or lowest cost. Furthermore Dijkstra also discusses a method for finding minimum spanning trees, a problem relevant for minimizing the amount of expensive copper wire to be used in the building of computers at the time, but also highly relevant today.

Because original sources often are difficult to access, the presentation of these are supplied with explanatory comments and tasks along the way, one purpose of these also being to bring the students up to date with modern notation, definitions, and terminology. Thus, the presentation may be considered a so-called ‘guided reading’ of the sources, very much inspired by the format developed by David Pengelley, Jerry Lodder, Janet Barnett and others related to the group at NMSU who consider the use of original sources in the classroom [4].

Practically no mathematical requirements are needed beforehand on the students’ behalf to study the text of Euler, and many of those needed for the Dijkstra text are introduced along with the Euler text. This was a major reason for choosing exactly these two texts, taking into account that the 1/3 free curriculum allowed such topics.

MATHEMATICAL COMPETENCIES LAYING THE GROUND FOR OJS

The way of trying to create a basis for the students' development of overview and judgment is by focusing on and having the students work with the mathematical content of the original sources by Euler and Dijkstra in such a way that their work will require a development of the mathematical competencies related to the different types of overview and judgment (see figure 1). To illustrate this I shall show three exercises from the teaching material, which each focus on the development of one of the three mathematical competencies related to the type of overview and judgment on the philosophy of mathematics (OJ1), i.e. the mathematical thinking competency, the symbols and formalism competency, and the reasoning competency.

The students' way into the first original text is by looking at Euler's diagram of landmasses and rivers in Königsberg (figure 2, middle) and then verify that this is in fact an accurate representation of (or model for) the Königsberg bridge problem by comparing with a picture of the town (figure 2, left). Afterwards the students are told that in modern graph theory, landmasses are represented by vertices (or nodes) and links between them by edges. Students are asked to transform Euler's diagram into such a modern graph individually and then compare their own representation to the students next to them, this illustrating that graph representations are not unique. The idea is to have the students adapt more and more schematic representations of the Königsberg bridge problem until arriving at something looking like figure 2 (right), gradually increasing the level of abstractness.

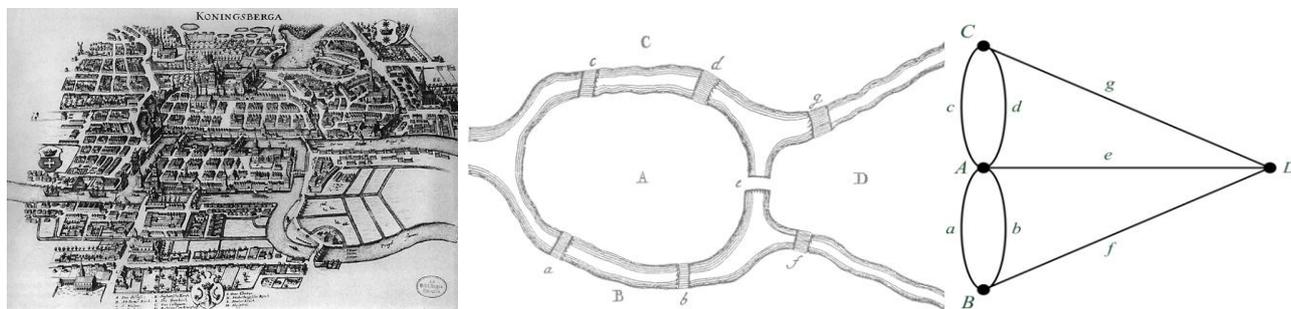

Figure 2: Left: A picture of Königsberg with its 7 bridges from 1652. Middle: Euler's 1736 simplification of Königsberg's bridges. Right: A modern graph representation.

Once being familiar with the modern representation of a graph, the students are introduced to the problem of representing *multiple edges*, such as for example the two edges between vertices A and B in the Königsberg graph. These cannot be represented by only their pair, (A,B) , since this causes ambiguity (which also is why Euler named them a and b , respectively). To illustrate a formal and general way of dealing with this to the students, they were provided with the following modern definition: A graph G is a set of vertices $V(G)$ and a set of edges $E(G)$ together with a function ψ , which for every edge $e \in E(G)$ assigns a pair, called $\psi(e)$, of vertices from $V(G)$. As a way of having the students develop their symbols and formalism competency, which also includes being able to go back and forth between ordinary

language and a language of symbols, they are asked to write up the sets $V(\mathbf{G})$ and $E(\mathbf{G})$ for the Königsberg graph and the seven function values of $\psi(e)$. On the one hand, the idea of this is to enable them to perceive the definition of a graph as a triplet $\mathbf{G}=\{V(\mathbf{G}), E(\mathbf{G}), \psi_{\mathbf{G}}\}$, and on the other hand to have them realize how the above definition in a general fashion resolves the problem of ambiguity when two vertices in a graph have multiple edges.

As Euler himself in his text introduces various constructs, the students are introduced to the somewhat equivalent modern terminology in the intermediate commentaries, e.g. *route*, *path*, *Euler path* (open and closed), *subgraph*, *degree* of a vertex as well as a few small theorems which Euler explicitly or implicitly uses, such as for example the *handshake theorem* [5]. At the end of his paper, Euler states his three main results (Euler, 1741, pp. 138-139; Fleischner, 1990, p. II.19, numbering is mine):

- [i.] *If there are more than two regions with an odd number of bridges leading to them, it can be declared with certainty that such a walk is impossible.*
- [ii.] *If, however, there are only two regions with an odd number of bridges leading to them, a walk is possible provided the walk starts in one of these two regions.*
- [iii.] *If, finally, there is no region at all with an odd number of bridges leading to it, a walk in the desired manner is possible and can begin in any region.*

The students are first asked to formulate these three results using the modern terminology and notation they have been introduced to. Next they are provided with a modern definition of a *connected graph*, i.e. that there exists a route between every pair of vertices, a property Euler does not state explicitly. Using this property, the three results may be reformulated as (e.g. Jankvist, 2010b, pp 17-21):

- i. *If a connected graph \mathbf{G} has more than two vertices of uneven degree, then it does not contain an Euler path.*
- ii. *Let \mathbf{G} be a connected graph, then \mathbf{G} contains an (open) Euler path if and only if \mathbf{G} contains exactly two vertices of uneven degree.*
- iii. *Let \mathbf{G} be a connected graph, then \mathbf{G} contains a (closed) Euler path if and only if all vertices of \mathbf{G} have even degree.*

Most of Euler's efforts goes into proving his first result (i), and regarding the third (iii), which today is considered the main theorem of the paper, he only proves it in one direction. To develop the students' reasoning competency as well as to introduce them to the notion of if-and-only-if theorems, they are to consider result i as being of the form $\mathbf{P} : \mathbf{A} \Rightarrow \mathbf{B}$, and then identify \mathbf{P} , \mathbf{A} , and \mathbf{B} . After having the students prove that $\mathbf{A} \Rightarrow \mathbf{B} \equiv \neg\mathbf{A} \Leftarrow \neg\mathbf{B}$ (by means of a truth table), they are asked to write up $\neg\mathbf{B} \Rightarrow \neg\mathbf{A}$ for result i, i.e. formulating the contrapositive of this theorem, which states that *if \mathbf{G} is connected and has an Euler path (open or closed), then \mathbf{G} has two or less vertices of uneven degree*. Since Euler has shown, in his own context of course, that a graph will always contain an even number of vertices with uneven degree, we may

distinguish between two different cases: when G has exactly two vertices of uneven degree and when it has none, i.e. when all vertices have even degree. These cases correspond to the \Rightarrow -direction in results ii and iii, respectively. Thus, by looking at Euler's original text again, the students would be able to deduce that the missing parts of the proofs are the \Leftarrow -directions for results ii and iii. For result iii this is ascribed to Carl Hierholzer (published posthumous in 1873), and the students are shown this proof. The students are then asked to prove the \Rightarrow -direction for iii and both ways for result ii using modern terminology.

To illustrate a task that is thought to develop the students' mathematical thinking competency, we move into the context of finding minimum spanning trees and shortest paths in connected, weighted graphs as discussed in the paper by Dijkstra. As an introduction to this paper, the students are provided with definitions of a *weighted graph*, a *tree*, and a *spanning tree*: *A connected graph T without any subgraphs that are circuits is called a tree, and a tree that for some graph G contains all vertices of $V(G)$ is called a spanning tree.* In one task the students are asked to look at the Königsberg graph (figure 2, right) and find the number of different spanning trees that can be constructed from this and then explain their method for finding the answer. (Try it yourself to see the systematic approach required, when not using a formula [6].)

After the students having worked through the Dijkstra text, the commentaries to this, accompanying examples, and a modern proof of the shortest path algorithm's correctness (Dijkstra gives none), the students get to the third text by Hilbert and following this the three so-called *essay assignments*.

THREE ESSAY ASSIGNMENTS INVOLVING THE THREE OJS

In my previous study [3] I found that having groups of students prepare small essays was a good way of bringing them to work with the history of mathematics. So the same approach is taken to bring in the two other types of overview and judgment. The module includes three essay assignments and I shall address elements of them in turn.

The first essay is on *mathematical problems*, linking the three texts by Euler, Dijkstra, and Hilbert together. Paraphrasing Hilbert roughly, he talks about that often some mathematical development is spurred on by a problem in the extra-mathematical world. Then it is drawn into mathematics and rephrased so that it is hardly recognizable anymore and embedded in a much more general context. Years later, when this has grown into a mathematical discipline, what often happens is that it may then again be used to solve some new extra-mathematical problem. This is of course the case for graph theory, spurred on by the Königsberg bridge problem, which Euler generalized so that the answer to the original problem falls out as a small corollary to his more general results. Two centuries later when we have a much clearer idea about the discipline of graph theory, Dijkstra solves the extra-

Working Group 12

mathematical problem of shortest path (and also considers minimum spanning trees) in this graph theoretical context. For the students to realize this, they are asked to identify the criteria that Hilbert proposes for a good mathematical problem and see to what degree the problems treated by Euler and Dijkstra fulfill these, and then relate these cases to Hilbert's comments on the development of mathematics in general.

The second essay is on *mathematical proofs* and first deals with different kinds of proofs and proof techniques as well as the use and need for new signs and symbols (both arithmetical and graphical) in the development of new mathematics (concepts, definitions, etc.), something that Hilbert also addresses. The students are asked to discuss this with relation to Hilbert's text and try to draw connections to the two cases, in particular the advantages Dijkstra had in 1959 with a fully developed graph theoretical and conceptual apparatus at his disposal as compared to Euler who had to start from scratch in 1736. In the end, this essay moves into Hilbert's actual discussion of proofs and their role in solving mathematical problems as well as the role of rigor in mathematical proofs. On the overall, the idea of this is to spur some reflections on the students' behalf regarding the epistemological development of the notion of proof.

The third essay is about *mathematics' status as a (scientific) discipline*, in its own right and in comparison to other disciplines, e.g. physics. Based on their readings of Hilbert, and the two texts by Euler and Dijkstra, the students are asked to try to point out some characteristics of mathematical problems, methods, and ways of thinking as well as to say something about the types of results mathematics delivers and what they may possibly be used for. They are invited to discuss this by comparing mathematics to other academic disciplines. Then they are asked to identify what Hilbert says about the differences and connections between mathematics and other disciplines, and then discuss to what extent they agree or disagree.

RESEARCH QUESTION AND EXPERIMENTAL SETUP

This brings us to the actual research question of this study in progress:

- In what ways may the design of the modules create a basis for students' development of overview and judgment – and perhaps even help in ensuring such development?

The approach to trying to provide an answer to this question is an empirical one. The described module together with a second one, which is in preparation, will be implemented in an upper secondary class in their first (age 16-17) and second year of high school [7]. The set up of the implementation is that student groups to the largest degree possible read and work with the material themselves, i.e. they read at home and in class they work on the related tasks, proofs, etc. in their respective groups. The teacher circles the class and provides help in the form of regulatory input and feedback when needed. In this way an attempt is made to keep the voice and discourse of the teacher to a minimum, in order to be able to assess the design discourse of the module and its material. The students also do their essay

assignments in groups and they do group hand-ins of these as well. Two sets of selected mathematical tasks from the material are however to be handed in to the teacher individually.

The experimental setup includes before, in between, and after individual questionnaires and interviews with the students and teacher following a model developed in Jankvist (2009b). One of the student groups, referred to as the focus group, is video filmed by myself during the implementations of both modules. Together with questionnaires, interviews, the hand-in essays and mathematical tasks, the video recordings provide the opportunity to do methodological triangulation between data sources in order to address the research question.

THOUGHTS ON THEORETICAL CONSTRUCTS FOR ANALYSIS

The theoretical constructs to be used in the analysis of the data in particular include the discursive and commognitive approach of Sfard (2008) and the adaption and/or application of this to research on use of history in mathematics education (Jankvist, 2009b; Kjeldsen & Blomhøj, in press). More precisely, it may be argued that the students' discussions (and reflections) follow various different discourses: historical, cultural, sociological, philosophical, epistemological, psychological, etc. and of course mathematical. By comparing the discourses present in the students' discussions – and essays and interviews – it should be possible to say something about the connections and dependencies of these with the discourses present in the teaching material, which mainly center around an historical/cultural for OJ1, an applicational/sociological for OJ2, and a philosophical/epistemological one for OJ3.

Following the recommendations of the KOM-report, one important feature of the materials for these modules is that the treatment of overview and judgment related aspects build on and are rooted in the actual mathematics related to these. Another way of saying this is that the treatment of the meta-issues is *anchored* in the related mathematical in-issues (Jankvist, 2009a, 2009b). Therefore an important aspect of the assessment and evaluation of the modules – as well as the answering of the research question – is to see if this built-in anchoring somehow transfers to the student discussions. This may be done by searching for instances in the data where meta-issue discourses related to the OJs build upon in-issue discourses or episodes where the (historical and/or modern) mathematical in-issues are used by the students to substantiate or deepen the meta-issue reflections (Jankvist, 2009b, In Press).

NOTES

1. This study is financed by a postdoctoral grant from the Danish Agency for Science, Technology and Innovation.
2. KOM is a Danish abbreviation for 'competencies and mathematics learning'. The report from the KOM-project has not yet appeared in English, so all quotes are my own translations from Danish.
3. The study of my PhD (Jankvist, 2009b) has, among other places, been reported in Jankvist (2009a, 2009b, 2010a).

Working Group 12

4. Links are: http://www.math.nmsu.edu/hist_projects/ and <http://www.cs.nmsu.edu/historical-projects/> (Retrieved on November 29, 2010).
5. These terms and theorems are explained in most textbooks dealing with graph theory..
6. The number can be calculated using the so-called (Kirchhoff-Trent) *Matrix-Gerüst-Satz*. Deleting the i 'th row and column of this matrix and taking the determinant of the one dimension smaller matrix reveals it – in our case it is 21.
7. The first module was implemented in Spring of 2010, but data have not yet been analyzed. The next module, which will be on Boolean algebra and Shannon's use of it in circuit design, will be implemented in the Spring of 2011.

USES OF HISTORY IN MATHEMATICS EDUCATION: DEVELOPMENT OF LEARNING STRATEGIES AND HISTORICAL AWARENESS

Tinne Hoff Kjeldsen

IMFUFA, Department of Science, Systems and Models, Roskilde University

The purpose of the paper is to present a theoretical framework for a systematic analysis and discussion of uses of history for teaching and learning mathematics, hereby proposing a didactical transposition of history from the academic research subject to history in mathematics education. The use of the theoretical framework is exemplified by an analysis of a project work on the history of Ancient Egyptian mathematics taught in a class of Danish upper secondary school students (10th grade), illustrating how uses of past mathematics can aid development of students' learning strategies and historical awareness.

1. INTRODUCTION

The purpose of the present paper is to develop a theoretical framework for a systematic analysis and discussion of uses of history for teaching and learning of mathematics with respect to how history benefits students' learning of mathematics, and develops students' historical awareness. Several recent papers have discussed whether these two aims pose a dilemma between genuine history and relevant mathematics for teachers who want to use or integrate history in their classrooms (Freid, 2001; Jankvist and Kjeldsen, forthcoming; Kjeldsen, forthcoming; Kjeldsen and Blomhøj, forthcoming). While these discussions have focused on transforming views of mathematics and mathematics education, their conception of history has been taken to be more or less synonymous with a traditional professional historians' approach to history – at least in the methodological approaches and the criteria for a genuine approach to history. However, perhaps we also need to broaden our view of history as well if we want history to play a more significant role for teaching and learning mathematics. In the present paper such a broadened view of history is outlined, and its implications for history in mathematics education are discussed. The aim is to develop an adequate theoretical framework for integrating history of mathematics in mathematics education that can be used to analyze specific implementations and to provide a tool for orienting the design of future implementations of the history of mathematics in mathematics education. The main focus of the paper is theoretical, but it also contains an empirical section that illustrates the theory in a carefully designed and implemented case study.¹

First of all, some historiographical reflections and a position are presented. Secondly, uses of history are discussed to present a framework in which their uses for the teaching and learning of mathematics can be systematically analyzed with respect to purposes and didactical values. This discussion is based on the Danish historian

Bernard Eric Jensen's (2010) approach to history. Thirdly, the framework is adapted to mathematics education. Lastly, to connect the discussion with the practice of teaching, a project work on mathematics in Ancient Egypt is analyzed. The project work was designed by a mathematics teacher working at a Danish Gymnasium (upper secondary level) during a professional development course in "problem based project work in, with and about mathematics". The teacher implemented the project work in his own teaching practice in a class of first year Danish high school students (age 16-17) and documented his experimental teaching in a written report. His report will be analyzed to illustrate how uses of past mathematics can aid development of students' learning strategies and historical awareness, thereby substantiating some of the points raised in the present paper. The paper ends with some concluding remarks.

2. HISTORIOGRAPHICAL REFLECTIONS

Mathematical knowledge is produced and used by humans; hence we can think of such activities as integrated elements of historical-social reality and of human life. We can perceive mathematical activities as creations of history as well as acts that create a history of mathematics. The development of mathematics and changes within our perceptions, views, and treatments of mathematics can to a certain extent be understood as realisations (intended as well as unintended) of goals set by people. If we want to understand historical-social processes in the development of mathematics as products of human activities, we must pay attention to intentions and thoughts of the actors, as well as their understanding of the subject matter and the context in which they performed and made their choices.

At a first sight it might seem that while such an approach can be used to study the history of sociological aspects of mathematics, such as the development of its profession in different countries and/or places or the history of mathematical journals, it cannot be used to study the history of the subject-matter of mathematics due to the universal character of mathematics. But if the development of mathematics is studied from its practice, where the historian focuses on concrete practices of mathematics, acknowledging that, despite its universal character, mathematical knowledge is produced by mathematicians, who live, interact and communicate in concrete social settings, the history of mathematical ideas, concepts and theories can also be pursued within such a framework.

Such a position is in accordance with recent trends in the history of mathematics that have emerged as reactions towards the well-known critic of the widely used anachronistic (whiggish) approach to history of mathematics and the methodological debate of internalism versus externalism (Epple, 2000), (Kjeldsen et al. 2004), and *Science in Context*, 2004, 17(1/2). Within the last decades many studies in the history of mathematics focus on the practice of mathematics within social, intellectual, and cultural contexts of mathematical activities. Here professional

historians of mathematics have a critical approach to source material they analyze in order to understand its significance in its proper historical context.

3. USES OF PAST EPISODES

It is not the main purpose of general mathematics education to educate and train professional historians of mathematics, and in most cases mathematics teachers will not be professional historians. In some countries development of students' historical awareness is part of the curriculum, but that is not always the case, and if it is it only plays a minor part. With this in mind it seems too restrictive to require that the history of mathematics taught within mathematics education should be presented as traditional academic history. A didactical transposition is needed, just as is the case with school mathematics, which is also not identical with the discipline of (academic) mathematics. In the following, Jensen's (2010) broader view of history will be introduced along with several pairs of concepts that can be useful for a nuanced analysis and discussion of the role of past mathematical episodes for the learning and teaching of mathematics.

Jensen (2010) sees the academic research subject *history*, as professional historians think and work with it, as just one of many approaches to history. According to him, history is employed every time a person or a group of people is interested in something from the past, and uses their knowledge about it for some purpose. People use history for many different purposes and in many different connections, and consequently there are major differences between a lay person's and a professional historian's use of history. Recent investigations (Rosenzweig and Thelen, 1998) have shown that lay persons' and professional historians' conceptions of history differ in various respects and on several levels. Lay-history has a reputation of being naïve viewed from the academic discipline of history, while on the other hand lay historians view academic history as lifeless and remote from the real world. For professional historians it is important to place past episodes and artefacts in their historical contexts. Their historical awareness is conceived of as an interpretation of the past whereas lay persons view history more as a source of memoirs.

Jensen distinguishes between pragmatic and scholarly approaches to history. In a pragmatic approach the study of the past is guided by the idea that we can learn from history. The "usefulness" of history is an underlying perspective or principle in a pragmatic approach to history. The idea is that through history we can gain knowledge about our world of today, that history can teach us better ways to live our lives. In a pragmatic approach to history, past events are studied from a utility perspective. Jensen (2010, p. 51) contrasts a pragmatic approach to history with a scholarly approach, where historians retain a critical distance to past events and emphasize differences between past and present. In the professional, academic discipline of history both traditions can be found, but since the mid 19th century the scholarly approach to history has been more and more dominant.

Observer history and actor history are another pair of concepts through which we can discuss and understand uses of past events and sources. Jensen (2010, p. 41) talks about uses of the past from an actor perspective, if we use history to orient ourselves and act in a present context. He calls this an intervening use of history. If the past is viewed retrospectively with a purpose to enlighten instead of a purpose to act or intervene he talks about uses of past from an observer perspective.²

Finally, the so-called "living history" use of history is a way of using the past to help participants develop historical awareness and learning strategies. In Denmark living history takes place at some museum centres and at some yearly events. One such centre is The Medieval Centre. On their homepage (<http://www.middelaldercentret.dk/Engelsk/welcome.html>) they state that the centre: "is an experimental museum where you can experience life in a reconstructed late 14th century market town: Daily life, knights tournaments, trebuchets, canons, ships, markets, ... and a lot more...". According to Jensen (2010, p. 145) living history appeals to so many not only because the participants actively take part in the events, but also because they use other types of learning strategies where the focus can be, for example, to develop the skills of past craftsmen.

4. WHAT IS THE CONNECTION TO MATHEMATICS EDUCATION?

These concepts of, approaches to, and thinking about history and uses of past episodes and artefacts present a framework for a refined discussion and systematic analysis of how past episodes and sources can be/are used in the integration of history for the teaching and learning of mathematics. They open up a variety of approaches to history and uses of the past for teachers who want history to play a role for teaching and learning mathematics. Which approach to choose depends on the intended learning. For example, Kjeldsen and Blomhøj (forthcoming) argue, based on Sfard's (2008) theory of thinking as communicating, that history presents itself as the obvious tool for developing students' proper meta-discursive rules, because meta-discursive rules are contingent and as such can be studied at the object level of history discourse. This presupposes a scholarly approach to history. The idea is to use past mathematical activities and sources with the intention of creating learning and teaching situations where students can experience what Sfard calls commognitive conflicts. Hence, the past is used with the purpose of intervening, and therefore the scholarly approach to history is from an actor perspective.

Kjeldsen (forthcoming) discusses the role of history for the teaching and learning of mathematics with reference to a competence based understanding of mathematics education (Niss, 2004). Here the development of students' mathematical competence is the main purpose of mathematics education along with the development of some second order competencies, including historical overview and awareness. For the development of historical overview and awareness, a scholarly approach from an

observer perspective can be chosen. For development of specific mathematical competencies, a pragmatic approach from an actor perspective might be considered.

5. AN IN-SERVICE COURSE ON PROJECT WORK

The focus of the paper is on theoretical issues, but to illustrate the theory, a project work that was developed and implemented during an in-service course for upper secondary teachers in Denmark will be analysed. In this discussion the “living history” approach will be examined to see how it might be adapted as a way for mathematics teachers to use past episodes and sources to develop students’ learning strategies and historical awareness.

The theme for the project work was Egyptian mathematics. It was developed and tested in a classroom of students (10th graders) in the Danish upper secondary school in 2004 as part of an in-service course for mathematics. The in-service course was developed in response to a reform that was to be implemented in 2005.

Compared with more traditional ways of teaching mathematics the reform challenged the teachers in several ways: (1) Many were not used to teach either the history of mathematics or mathematical modelling, both of which having more prominent positions in the new curriculum than they had in the former curriculum; (2) they were required to bring mathematics into play in interdisciplinary projects in cooperation with other subjects, from science, from the humanities, and from the social sciences; and (3) they had to design, organise and carry out project work in their mathematics teaching. The goal was to create an in-service course where theories in didactics and pedagogy interacted with development of the participants’ own teaching practice in ways that also related to inquiry-based teaching and learning. On this basis the objective of the in-service course was to support teachers in their development as teachers, implementation in their own classes, evaluation of the project work, and documentation through a written report of a project-based and problem-oriented course in the history of mathematics or in mathematical modelling. The core element of the in-service course was the development of the teachers’ experimental practice with history of mathematics or mathematical modelling and problem-oriented project work.

The in-service course began with a three day seminar where the teachers were introduced to the history of mathematics, mathematical modelling, didactical theories, and problem oriented project work. The teachers worked in small groups developing a project-organised course in either history of mathematics or mathematical modelling of their own choice consisting of approximately 10 lessons of 45 minutes each. They decided on (1) the objectives for their own professional development, (2) their objectives for students’ learning, (3) how to “set the scene” for their own students’ project work, and (4) how to evaluate the students’ learning.

A few weeks after the seminar a first draft of the design for the project work and the materials that should be given to the students were distributed to all participants in

the in-service course. All teachers tried out their project work in their classroom. During that period there was a one day seminar to support the teachers in the documentation of their results and reflections on their experimental teaching. It all ended with a 2-day seminar, where the teachers' written reports were discussed extensively. The final reports are published on the internet together with the handout materials for the students for other teachers to use (<http://magenta.ruc.dk/nsm/uddannelser/gymnasielaerer/>).

I will not go into further detail on how we define problem-oriented project work (interested readers are referred to Blomhøj and Kjeldsen, 2006), but only emphasize that the problem that students are going to work on should function as the “guiding star” for their work. In the ideal case every decision made in the project work should be justified by its contribution to the solution of the problem. This is crucial, since engaging in decisions provides opportunities for students to work independently, to gain control, and to direct the project. In order for this to happen, though, the teacher needs to set a scene for the project work, that is to formulate the task for the work, the conditions for the working process, the time constraints, and the requirements for the end product, for example a written report or a power point presentation fulfilling some specific requirements. In this way it is possible for the teacher to have some control while at the same time to leave room for the students to take responsibility and make decisions.

The in-service course is still offered with the modification that we focus only on mathematical modelling. Therefore we only have one history project to present, but since its function here is to serve as a concrete illustration of the theoretical framework developed above, and not as documentation from an empirical experiment it can be used to characterize the suggested methodology.

6. EGYPTIAN MATHEMATICS: A PROJECT WORK IN A 10TH GRADE

The project on Egyptian mathematics was developed and implemented in a classroom of 1. year students (10th grade, age 16) in a Danish upper secondary school in the fall term. The project work was meant to be interdisciplinary, with history about Ancient Egypt in combination with their mathematics. The mathematics teacher had no experience with project-organised teaching in mathematics, which was his focus for his own professional development. His objectives for the students' learning were to:

- h) enhance the students' competence to work in teams
- i) enhance the students' independent learning
- j) enhance the students' oral presentation skills
- k) have the students gain experiences with power point

Working Group 12

- l) have the students appreciate that mathematics has been different from what it is today
- m) develop the students' awareness that mathematical results have evolved, that mathematics is not static, which is contrary to the way it is often presented
- n) develop the students' awareness that mathematics develops in an interplay with culture and society. (Wulff, 2004, p. 2-3; my translation)

The objectives fall into two parts that cover all three of the above listed challenges of the reform: the first four address competence in independent study, the development for which problem-oriented project work is an excellent pedagogical tool, whereas the last three concern the history of mathematics requirements of the new mathematics curriculum. Note that a)-c) and e)-g) are elaborated versions of some of the ICMI Study *whys*, see Fauvel and van Maanen (2000, pp. 205, 207, 211-212).

The teacher orchestrated the students' project work in three stages:

- (3) The first stage was an introduction to Egyptian mathematics using a text from the students' textbook (Carstensen and Frandsen, 2002), where the teacher introduced the Egyptians' method of multiplication by repeated doubling, their number symbols, and their way of formulating problems (two lessons).
- (4) The introduction was followed by eight lessons during which the students worked in teams of four, guided by a description of
 - i) the problem formulation, which was given by the teacher (see below);
 - ii) the learning objectives; iii) the product; iv) the topics for the teams.

The teams worked independently. The teacher took the role of a consultant who could be called in for advice. When that happened he focused on posing questions and challenging the teams instead of providing answers. The problem formulation for all teams was: How and why did the Egyptians calculate? Each team worked with a chapter from a textbook on Egyptian mathematics (Frandsen, 1996), seven chapters all together treating their numerals, their methods for arithmetical operations, the $2/n$ -table, bread and beer (Pesu) exercises, equations and geometry. To have a whole textbook on an episode from the history of mathematics in Danish is a rare circumstance, and one of the reasons why Egypt was chosen for this project work.

- (3) Each team had to present its results for the rest of the class in an oral presentation supported by a power point presentation. This took up four lessons.

The first set of learning objectives deal with issues of enhancing students' independent study skills. In his evaluation the teacher emphasized in particular that the students acquired the mathematical knowledge of the Egyptians by themselves (in contrast to ordinary teaching where he explained everything), that they "cracked the code" themselves, and that they were conscious about it. Regarding item e) and f)

Working Group 12

of the second set of learning objectives, the teacher wrote: “they were all about gaining insights into current mathematics precisely by studying the mathematics of another time” (Wulff, 2004, p. 3), from which we can infer that the teacher used a pragmatic approach to history. He used past episodes of mathematics from a utility perspective. This also becomes clear from his description of a discussion that took place between him and the students during the introduction: “Already during the first module [the first two lessons] came the classical question, why are we going to learn this? And we had a good talk about the intended learning issues e), f), and g), during which the class apparently accepted that historical mathematics, besides being interesting as such, could contribute to a more nuanced view on current mathematics.” (Wulff, 2004, p. 5). Regarding the learning objective of realizing that mathematics has evolved over time, the teacher was rather critical, explaining that this aspect was not really complied with, since a comparison of Egyptian and modern mathematics only shows that mathematics has changed; it does not give insights into the actual process of change. Regarding the last item g) of the second part of the learning objectives, the teacher wrote in his evaluation: “here is where the subject of history can be involved. From a general knowledge about Ancient Egypt and its society, students can discuss how society and culture have been driving forces for the mathematics of that time. At the same time the historians’ method of source criticism is an essential tool for interpreting ambiguous and defective papyri” (Wulff, 2004, p. 4). In contrast to items e) and f) the teacher here takes a scholarly approach to history. The teacher used the past from an observer perspective in both approaches.

The students’ work with the sources and exercises in the textbook on Egyptian mathematics to answer the “How” part of the problem formulation can be considered a “living history” approach. They put themselves in the place of Ancient Egyptians, trying to understand and learn how they calculated, how they dealt with geometry, how they proposed mathematical problems, and so forth. The teacher reported the following situation he observed in the classroom: “Many students wondered about how “stupid” the Egyptians were. Why did they only use unit fractions? Why should a number be expressed as a sum of different unit fractions? On the other hand their methods were very difficult to understand; that is rather advanced, so in that respect they weren’t stupid at all. I think that many of the students realized that current mathematics is not “just” like today, but is a result of a long development, during which many things have been simplified.” (Wulff, 2004, p. 7). This shows a development of historical awareness among the students. That the students’ learning strategies were developed through this kind of “living history” approach can be inferred from the following observation made by the teacher: “This [that mathematics had made progress] became especially obvious when the students constantly rewrote the Egyptian notation to current notation with x ’s, formulas, etc. After they had finished an Egyptian calculation they would say: ‘but that just corresponds to ...’ followed by a solution of an equation in our way. It was very inspiring to see how students, who normally were a bit alienated towards x ’s and

equations now had taken those to themselves as their own, and all of a sudden perceived equations as an easy way to solve problems. The students became aware that modern notation makes the calculations much easier than they would have been otherwise” (Wulff, 2004, p. 7).

As mentioned above the teacher found that item g) in the list of learning objectives, which was supposed to link the development of mathematics with a scholarly approach to history, was not realized. The “why” part of the problem formulation was designed especially towards this goal. The mathematics teacher had hoped that the students would have been able to experience concrete examples of how needs of society sometimes act as driving forces for the development of mathematical ideas. This is a very ambitious goal, and since the history teacher focused more on religion and dynasties, the mathematics teacher felt that the students did not get opportunities to gain real insights into why mathematics was developed in interaction with the needs of society and culture. A less ambitious teacher would probably evaluate this part differently, pointing towards the fact that was explained above, that the students gained genuine historical knowledge about Egyptian mathematics situated in the proper historical context. Finally, the teacher concluded that the students afterwards showed signs of possessing a more mature and reflective approach to mathematics than they had before. Unfortunately, the teacher did not document this with observations from the classroom.

7. CONCLUDING REMARKS

The purpose of the paper was to present a theoretical framework for a systematic analysis of the uses of history for teaching and learning mathematics in order to propose a didactical transposition of history from the academic research subject to history in mathematics education. The analysis of the teacher’s report on the project work on Ancient Egyptian mathematics with respect to the described framework of different uses of past episodes shows that in this project, history was used in different ways to provide a very rich teaching and learning environment. The teacher used different approaches to history and used past episodes from various perspectives for different purposes, thereby creating learning situations that developed students’ historical awareness and mathematical learning strategies at the same time. History was used in ways in which students gained genuine historical insights, developed learning strategies, and enhanced their mathematical problem solving skills even though they worked on mathematics that might not be part of the core curriculum.

NOTES

¹ I would like to thank Costantinos Tzanakis for helpful comments on an earlier version of this paper.

² A fourth pair of concepts is identity neutral vs. identity concrete history writing, which will not be used in this paper.

ESTABLISHING THE 'METER' AS CITIZENS OF FRENCH NATIONAL ASSEMBLY DURING THE FRENCH REVOLUTION

Panayota Kotarinou, Charoula Stathopoulou, Anna Chronaki

University of Thessaly

This paper discusses how a group of adolescent students has been engaged in a cross-curriculum project focusing on making explicit the historical background of establishing the 'meter' as a commonly used unit. The project was organised around a role-playing debate imagined to have taken place at the time of French Revolution. The potential of this particular project can be recognized at varied interrelated levels; a) in its effectiveness in students' knowledge in Mathematics and Physics and in changing stereotypic images of Mathematic, and b) in supporting student's creative and critical thinking in the realm of their involvement in social problems within a specific economic and historical context. Moreover we consider that students, in their involvement in this project, have the potential for cultivating communicative abilities and a stronger sense of citizenship.

INTRODUCTION: HISTORY OF MATHEMATICS AND EXPERIENTIAL LEARNING

The integration of the history of mathematics in teaching can support, enrich and ameliorate mathematics education processes as far as mathematical learning is concerned. Besides to mathematical learning, the development of beliefs (and positive attitudes) concerning the nature of mathematics and mathematical activity, as well as the recognition of Mathematics as a human cultural product can be encouraged through the history of the subject.

Tzanaki and Arcavi (2000, pp.203) refer to five main areas in which mathematics teaching may be supported, enriched and improved through integrating the history of mathematics into the educational process: a) the learning of mathematics b) the development of views on the nature of mathematics and mathematical activity c) the didactical background of teachers and their pedagogical repertoire d) the affective predisposition towards mathematics and e) the appreciation of mathematics as a cultural-human endeavour. According to Jankvist (2009), the arguments for using history are of two different kinds: those that refer to history-as-a-tool for assisting the actual learning and teaching mathematics and those that refer to history as-as-a-goal in itself which focus on the developmental and evolutionary aspects of mathematics as a discipline. Based on a review of the literature, one could point out that the historical approach in mathematics teaching, amongst other things, focused towards:

1. Disputing the mathematics myth as a sterile, static and insular science, projecting mathematics as humanitarian science whose development depends on social, historical and philosophical factors (Ernest, 1998).

Working Group 12

2. Highlighting the interaction between Mathematics and society, revealing the ways, the norms and practices of various cultures, which influence Mathematics and vice versa how Mathematics influences the ways in which people operate, and think about, the world (Wilson, 2000).
3. Exemplifying and making explicit the genesis and origins of some ideas and procedures (Furinghetti, 98)
4. Supporting the learner to appreciate that heuristic processes, conjectures, doubts, mistakes insufficient claims and proofs, and impasses, all make constitutive pieces of Mathematics creation, and hence an inextricable piece of what Mathematics is (Tzanakis, 2009: pp. 20).
5. Stressing the close and two-way interrelation of mathematics and physics, through their historical evolution (Tzanakis & Thomaidis, 2000; Tzanakis, 2000)
6. Showing the interdisciplinary nature of mathematics – its relevance to every aspect of human life— (Ernest 1998).
7. Integrating elements of different curricular subjects, through the interdisciplinary projects in which History of Mathematics plays an important role (Furinghetti, 97; Furinghetti, 98; Kotarinou & Stathopoulou, 2009)
8. Providing us with ways to introduce students to the beauty, utility and abstraction of Mathematics (Wilson, 2000)
9. Supporting the introduction of notions and methods, the necessity of which we find difficult to explain to the students.
10. Providing students with the opportunity to ascertain that famous mathematicians not only followed the similar way of thinking, but had done the same mistakes as students (Furinghetti, 2003). [1]

History of mathematics can also contribute towards experiential learning. Experiential learning theory defines learning as "the process whereby knowledge is created through the transformation of experience. Knowledge results from the combination of grasping and transforming experience"(Kolb 1984, p. 41, in Kolb et al, 2000). Experiential learning permits student learning in an effortless, constant and permanent way through the 'real' experience and in participating in activities that concerns him and that he finds interesting. Some ways of experiential learning through the history of mathematics, are: enactment of theatrical plays (Fraser & Koop, 1981) dramatization of different themes from History of Mathematics (Hitchcock, 1998; 1999; 2000; Lawrence 2000; Prosperini, 1999) story-telling from History of Mathematics (Selby, 2009; Schiro, 2004), educational programmes inspired from history of Mathematics in Museums, archaeological or historical places, role-playing (Perl and Christner, 1982; Hallenberg, 1995), debates (Furinghetti, 97), historical debates based in a mathematical issue (Bartolini, Bassi & Mariotti, 1999a,1999b; Katz, 1997)

In this paper we shall provide a review of our research which aimed to explore the use of Drama in Education and specifically the role-playing debate with a theme from the history of mathematics: 1) in helping students realize the relationship of mathematics and science in a socio-cultural-historical context; and 2) in assisting students to understand the mathematical and/or scientific notions of a selected historical case. For this reason an interdisciplinary project has been conducted about the processes of establishing the ‘meter’ as a commonly used unit during the French Revolution. Among other activities a role-playing debate was carried out, which was a simulation of the confrontation in the French National Assembly during the French Revolution and was concerned with the choice of a unified unit of length measurement.

DEBATE AND ROLE-PLAYING: THEIR CONNECTION WITH HISTORY OF MATHEMATICS

Drama in Education is a highly structured pedagogical activity that utilises exercises and techniques of dramatic art, in which the emphasis is on the procedure and not on the final product (Alkistis, 2000). It constitutes an experiential approach to teaching and aims at collaborative, active learning through experience while giving the child the opportunity to develop acceptance, understanding, creativity, curiosity, the ability to express themselves, self-consciousness, and skills in team work (Wagner, 1999). Among other techniques of Drama in Education is Role playing. Role playing is a technique in which students adopt a particular character putting themselves in the same position as him, trying to think what would that imaginary character have said, thought or felt (Neelands 1998).

As has been noted through bibliography, this technique is often supplemented with the use of debate. The use of debate in teaching can facilitate knowledge acquisition as well as the development of critical thinking (Huber, 2005; Snider 2006). Furthermore, participation in activities of this type familiarizes children with the holistic handling of issues, makes them able to justify their point of view, practices their mental flexibility and alertness, and enhances their ability of self-criticism and their conciliatoriness. At the same time they are given the opportunity to exercise their mind by producing and communicating ideas. Debates about mathematical discoveries can help students understand that old paradigms of thought were successful because the theories worked in the context of the old world, not because people of that day were ignorant (Snider, 2006 pp.230). Debates can also enable teachers to bring the historical contexts of mathematical theory to real life.

More specific, the role playing debate that simulates historical events, can revive the historical context within which a science theory (or technique) was developed (Snider 2006). Role-playing emphasizes the dimension of Science as “process” and as “social institution” makes Science education more effective (Alkistis, 2005). In addition, through the research required for the debate, students have the opportunity

to get to know the historical and social context within which a certain scientific theory emerged and generally comprehend that science, society and culture are interrelated.

METHODOLOGY

The project was carried out in the 2nd State Lyceum of Ilion in Greece, in a low social and economical area of Athens, during school year 2007-8, with two classes of 11th grade [2] students (with 22 and 23 students) in order for them to approach through experiential learning an historical event concerning the establishing of the meter [3] as a unified unit of measurement. This project aimed to discuss notions in Mathematics and Physics and the connection of the two disciplines, the change of stereotypic images of Mathematics by the students, the students training in argumentation skills, the students development in creative and critical thought and the students cultivation of communicative abilities and of a stronger sense of citizenship.

We chose the model of collaborative teaching practice which was based on the reiterative cycle of planning - researching - sharing resources - teaching collaboratively - and finally assessing the outcomes of a lesson (Lawrence, 2008).

THE INTERDISCIPLINARY PROJECT

Historical events: By the end of the 18th century the diversity of weights and measures in France was held responsible for great problems in economical dealings as well as the exploitation of people by feudal lords. Embezzlement, fraud, injustice, arbitrariness were ascribed to the diversity of about 2.000 different units of measurement in all France. Things were made worse because majority of the population was illiterate and thus incapable of making conversions amongst different measuring units. Due to the aforementioned reasons standardization of measuring units was one of people's basic demands. The establishment of new units consisted a political decision. From the first year, the French National Assembly voted the uniformity measurement units and sought new ones. In 1790, the French National Assembly accepted the definition of the meter as the length of pendulum that has a period of 2 sec at latitude of 45°, and asked the Academy of Science to propose the base of the metric system. The Academy responded to this request and recommended a decimal system of measurement. In 1791 a committee of the French Academy of Science—Lagrange, Laplace, Condorcet, Borda and Monge—suggested that the new definition for a meter be equal to 1/ 10 millionth part of the quadrant of the terrestrial meridian between Dunkirk and Barcelona and this was accepted by the National Assembly. The unit was given the name “meter” in 1793.

Placing the drama project in practice: ‘sensitive pendulum or heavy earth?’

During this project, a role-playing debate was organized, which was a simulation of the confrontation in the French National Assembly. This particular debate entitled “The sensitive pendulum or the heavy earth?” was carried out twice with 11th grade

Working Group 12

students of two different classes. One class had previous experience with activities in the use of Drama techniques, in contrast with the other class in which the students had had no similar experience. A class that wasn't involved in the project attended each debate. This confrontation concerned the choice of a length measurement unit, through the two aforementioned different approaches. The topic of the debate was selected to show students the confrontation, the protagonists and the historical context within which the unit 'meter' was introduced to help them comprehend that scientific theories are result of both intellectual and social interaction.

Preparing the 'debate' seven teaching hours was required over a period of three weeks. In history-class, a PowerPoint presentation concerning the establishment of the meter, helped students to realize the problems stemming from the use of many different units of measurement. Extracts from a documentary film about the French Revolution introduced them in the ambience existing before and during the first two years of the French Revolution. During the subsequent discussion, pupils started pondering why the choice of weighs and measures by feudal lords was a privilege for them. They finally found out that the change of size of the unit of volume resulted into an increase of taxes. The role of scientific unions concerning their decisions not only in scientific subjects but in social and political ones has been discussed.

During the language-class, the teacher helped students translate and understand texts concerning the origin and life, as well as the ethical and political role of scientists and other historical issues emerging in this revolutionary period.

The students were divided into 6 groups and had to locate their arguments for preparing a 'debate', reading extracts from Denis Guedj's book "*Le metre du monde*". Each group chose a representative to take part in the debate. The teachers in charge were present all the time to support the teams in their work. The students' ability to argue about the choice of the pendulum is directly correlated with their comprehension of its governing laws. Therefore, the students were taught in physics-class the pendulum principles and were also familiarized with the notion of pendulum isochronisms phenomenon. In the debate, for a suitable atmosphere to be created, simple settings and costumes have been used. In order to find out the way the members of the Assembly were dressed and how they spoke, the children watched David's famous painting 'The Oath of the Tennis Court' and dramatized scenes from a documentary with Robespierre speaking in French Assembly.

In the debate all students adopted the role of a responsible citizen, member of the French Constituent Assembly, who had to take decisions about crucial matters, in this specific historical context. Certain students played the role of historical figures as Talleyrand, Bailly, Prieur, Condorcet, Borda. Prieur spoke in favor of establishing new units; Borda presented the proposition of the French Scientific Academy, while Talleyrand spoke in favor of the pendulum and Condorcet in favor of the meridian. Some students, as members of the Assembly spoke either for the pendulum or for the meridian. During the debate students participated vividly either acclaiming or

disapproving the speakers. Before reading the real decision of the French Assembly, all of them- in roles of citizen members of the assembly- voted in favor of the meridian as the most appropriate unit of measurement, without knowing the real decision of the French Assembly.

PRELIMINARY DISCUSSION

The project has been evaluated through the analysis of students' answers to a questionnaire and of particular episodes of the process as they were captured by means of videotaping the debate performance. The reason for distributing a questionnaire was primarily to identify whether the project had any impact on students' knowledge concerning the measuring units. The majority of students, even a month after the debate, answered correctly to questions involving the establishment of the meter (27 from the 45 students answered correctly about the meridian definition of the meter) and the laws of pendulum (28 students answered correctly that the period of swing of a simple gravity pendulum depends on its length and the local strength of gravity and that it is independent of the mass of the bob, while 17 gave wrong answers or didn't answer at all). The students emphasized that this activity engendered the development of critical thought, the familiarization of a more rounded approach, active participation and cooperation with each other. More importantly that what they learned they emphasized the way in which they learned: they pointed out that they all took part, worked together, took the initiative and felt enthusiastic. Furthermore they liked the seriousness with which the debate was carried out; the good organization and the role-play which made them believe that they really took part in the French National Assembly.

Analysis of the videotaped debate performance

A preliminary analysis of the videotaped debate performance permitted us to stress a number of episodes related to processes of knowledge construction and values building such as; discussion of mathematics and physics, training their skills in argument, and gaining a sense of becoming responsible citizens. Each of these are briefly analysed below.

Discussion about mathematics and Physics notions: Students have discussed about arbitrary and conventional measures, connecting the conventional unit of length measurement with justice. From their arguments in the debate we concluded that students had understood the laws of simple pendulum as they referred - in their argumentation - to the dependence of the period of pendulum on π and on g - the acceleration to the gravity [4].

Training in argumentation skills: Both sides had to prepare strong arguments to support the definition of the meter. The team in favor of the pendulum used the argument that pendulum was a rational solution, simple, cheap in construction and easy and functional in use. The second team claimed that the definition of the meter

Working Group 12

as a part of a meridian was a global solution, not easy and cheap but yet an accurate and reliable one, as not depending on numbers that in real life can't be calculated with accuracy.

Quotes from student-in- role of Talleyrand argumentation in favour of the pendulum

...Laws of pendulum are dictated by Newton laws and because we are now in a rationalism era we believe that this is one of the best solutions...Laws of pendulum are very simple. Its movement depends only on the length of the rope and the geographical area. The weigh that you see in the end of the rope doesn't play any role (He explains the pendulum laws pointing out on a pendulum in movement). We can then define as unit of measurement the meter, equal with the length of pendulum which does this movement forward and backward in 2 seconds. It's something very simple, it can be realised in front of people, it's very economical and easy...

Quotes from student-in- role of Condorcet argumentation in favour of the meridian

...You have mentioned that we live know in an era that we must be rationalists. Can the measurement that you have proposed, be a product of rational and realistic thought? You have mentioned some other factors to which I will now refer. More precisely you have referred to the acceleration of gravity and to the number π , the well-known 3,14.... I want to remind you that all these numbers have infinite digits ... Is it possible that the meter that we will use in all our life, for all the time from now and then, for all next generations, will not be an exact number? Is it allowed such a thing? How is it possible for the meter to be approximated in such a way? As citizen Talleyrand correctly mentioned before, the acceleration of gravity changes from place to place. Is this not enough for us to reject it? Will France have a different acceleration of gravity, Spain another one, and Russia too? Will we have then a different meter for every different place in the earth? How is it possible for us to accept it?

Fostering the sense of citizenship: Through the whole procedure, the value of public (and responsive) dialogue has been brought out. During the introduction of the debate, the necessity of innovation 'in order for the people stop being victims' has been underlined. Also, the exploitation of people by feudal lords though the use of arbitrary units of measurement has also been emphasized by the students. The need to release from king's units has been emphasized, as they were local and also being defined in an arbitrary way. Students correlated the common meter with human rights while both teams have argued that the 'meter' had to be defined in a way that can be understood by every citizen.

...I would like to agree with Condorcet aspect, as pendulum is a phenomenon, which is encountered with a lot of formulas and notions that any person in France isn't obliged to know. So, how is it possible for any simple tradesman or farmer to measure the period as it was mentioned before? How are they obliged to know the oscillation?

Working Group 12

...Pendulum is based in a physical phenomenon. Everyone of us can use it simply, as many times he wants, quickly and with precision, something that is quite impossible with the method of meridian.

SOME CONCLUDING REMARKS

The experiential dimension of learning, considered as a fundamental component in alternative approaches of teaching, is absent or has a decreasing role in traditional teaching. In the aforementioned project we have seen students involving in an experiential way –with role playing- in a more complicated process than a traditional lesson and we have seen them cultivate multiple aspects of their selves and their creativity. Apart from the students their facing different subjects in the same activity, they saw another image of Mathematics. Contrary to a conventional lesson which emphasises solving of formal problems, -often de-contextualised - students faced a non direct mathematical problem but a problem with mathematical notions. The social conditions determining the context have appeared to also determine decisions, while the scientists' social responsibility, as people who play active roles in society, came into the fore. According to Ernest (2008) the adoption of mathematics as a cultural construction, as much from a historical perspective as from the perspective that examines knowledge in relationship to the context, can endow a human element to school mathematics once more. We believe that with all the aforementioned activities this aspect of mathematics came to the forefront. With the role-playing the central role of historical and social context and ways mathematics could be utilized in was brought to light and students were able to experience this dimension of mathematics, not only mentally but emotionally and physically. We think that there is a need to reconsider research related to ways in which Drama in Education techniques can contribute to an experiential learning of history of mathematics and mathematics in general.

NOTES

1. We consider that the first seven from the aforementioned benefits -for integrating the history of mathematics into the educational process - are the most relevant for the study presented in the present paper.
2. The necessary knowledge for the project -the 'simple pendulum' and 'the French Revolution'- is included in the 11th grade Physics and History curriculum.
3. The 11th grade Euclidean geometry curriculum includes the notion of a straight line segment measurement. In the school book there is a reference of the arbitrariness of the measurement unit. This reference gave us the opportunity for the project concerning the establishment of the meter.
4. $T=2\pi(1/g)^{1/2}$, T=The period of a simple pendulum, l = length of the pendulum

LESSONS FROM EARLY 17TH CENTURY FOR CURRENT MATHEMATICS CURRICULUM DESIGN

Jenneke Krüger

SLO (Netherlands Institute for Curriculum Development), Enschede, Netherlands

The Dutch Engineering School at Leiden University (Duytsche Mathematique) is the first example in the Netherlands of a professional training for engineers and surveyors, connected to a university. The Instruction (the formal curriculum) was provided by Simon Stevin in 1600. A manuscript from 1622, 'Mathematische Wercken', presumably lecture notes by Frans van Schooten the Elder, is clearly based on the Instruction. Stevin and Van Schooten designed an up-to-date curriculum, which seems to have been successful for about 65 years. Some reasons for its success and decline are still meaningful for curriculum design in mathematics education today.

RESEARCH

The motivation for this research originates in the heated discussions before and during recent revision of the Dutch national study programmes for mathematics at secondary level. The upheaval was at least partly caused by differences of opinion on which topics to include and to which depth. Attempts to influence the content based on personal points of view were noticeable. An obvious question, also prompted by the recent interest in links between history and mathematics education, is whether and how history can provide inspiration and reference material for those involved in the design and evaluation of mathematics curricula. The case presented in this paper forms part of a research for a PhD thesis on the history of mathematics education.

The main research question is

Which are the factors and actors that influence to a high degree the content of mathematics curricula?

The following questions structure the research more specifically.

- Which motivations and whose ideals are influential on the content of the formal curriculum?
- Which factors and which people determine the interpretation of the formal curriculum and its implementation?
- Which factors and which people are important for successful implementation of a curriculum?

Method

Analysis and comparison of three cases, considering influences on the formal curriculum and the relative success of each of them, will result in a preliminary list

Working Group 12

of conditions, which are important for successful curriculum design and development. Comparison of these conditions with recent curriculum design and development in mathematics education should result in a list of criteria which are decisive for successful mathematics curricula today.

The three cases in Dutch history of mathematics education, in the seventeenth, eighteenth and nineteenth century are described as follows.

1. The *Duytsche Mathematique*, established as a school for Engineers at Leiden University in 1600 shows the first known example in the Netherlands of a formal curriculum. It was especially successful from 1600 - ca 1665.

2. In the second part of the eighteenth century, the three Foundations of Renswoude offered professional education to talented poor orphans. Mathematics was the main subject for all pupils at least during the first two years of their education. The focus of my research in this second case is the Foundation in Utrecht, operational from 1761. and still existing today.

3. In the second part of the nineteenth century, in 1863, the Dutch national government established the *Hogere Burgerschool* (HBS), a secondary school for children of citizens who would not enter university, but who were to take up higher positions in society or enter the Polytechnic Institute in Delft, the present Technical University of Delft.

In this paper some aspects of the first case, the *Duytsche Mathematique* are presented.

THE DUTCH REPUBLIC

On 23 January 1579, four provinces in the Low Countries signed the Union of Utrecht, a treaty to establish a military league to fight the Spanish armies. During 1579 and 1580, more provinces and towns signed the treaty, which is considered the foundation of the Dutch Republic (the Seven United Provinces). The States General, established in The Hague, formed the government of the Republic, and the 'stadtholders', elected by their provinces, became powerful political leaders. In 1584, the leader of the rebellion, Prince William I of Orange, was assassinated in Delft, and the following year his son Prince Maurits of Orange, aged 18, became stadtholder of Holland and Zeeland. From 1590, Maurits was commander of the army of the States and successful in (re)capturing a number of fortified towns. He was interested in mathematics and its applications and was well aware of the importance of the application of mathematics to modern warfare.

From about 1590, the economic situation improved considerably: trade and navigation increased, and some towns grew to four or five times their earlier size during the early years of the seventeenth century. The political and economic situation led to a high demand for qualified surveyors and engineers, who were able to design and build modern fortifications, but who also could map the country or had

other surveying skills. Town expansions were necessary to house the fast growing population, though during the first part of the seventeenth century this was secondary to fortification (Maanen, 1987; Struik, 1981). Surveyors and engineers, both military and civil, needed mathematical knowledge and skills.

Italian architects and engineers became very influential in the Netherlands: in the first half of the sixteenth century, Italian advisors were responsible for improving the defensive walls of towns. Their ideas also became widely known through publications of Italian mathematicians such as Tartaglia, Marcaurelio de Pasino, Castriotto, Serlio, and others like Daniel Speckle and Simon Stevin (Maanen, 1987; Metin, 2007). In the *Stercktebouwing* (1594) Stevin described a system of fortification based on the Italian system with polygons as plan, and pentagonal bastions. Any engineer who applied this system had to have knowledge of geometry and trigonometry. Surveyors and engineers should also be able to measure land and determine area, subdivide land into proportional parts, produce maps, determine the height of towers, the width of water, or the volume of dykes, both on accessible and inaccessible land (Gulik-Gulikers 2005). The use of a reliable trigonometric table could improve the results of surveying techniques considerably. The extensive calculations that were necessary could be simplified using decimal fractions, which were not yet commonly used by mathematical practitioners (Struik, 1995). This is also apparent in publications and manuscripts from that time, see Sems and Dou 1600; Ceulen 1615; Marolois 1628 and manuscripts BPL 1351; BPL 1970; BPL 2084. Stevin did much to promote the use of decimal fractions in *De Thiende* (1585).

Thus in order to meet the demands of the developing nation there was a great need for good mathematical education. In the Dutch Republic there was no centralized educational system. Schools were the responsibility of town councils, and in addition there were private schools or private teachers. There was no standard curriculum, nor any form of quality control (Krüger, 2010).

THE DUTCH ENGINEERING SCHOOL AT LEIDEN UNIVERSITY (1600–1679)

In 1600 a school for military engineers was attached to the University of Leiden at the request of Prince Maurits, with a separate programme, devised by Simon Stevin and taught in Dutch instead of Latin: *Duytsche Mathematique* (Dutch Mathematics) or Engineering School. The School taught both surveying and fortification. Thus, practical mathematics of high quality became available to those who did not have access to university education. Both Maurits and Stevin, but also Rudolf Snel, professor of mathematics at Leiden and at least one of the curators, Jan de Groot, valued a combination of theory and practice and thought mathematics very relevant to engineering.

The intended programme by Simon Stevin is known as the *Instruction*¹. In this early example of a formal curriculum, Stevin unambiguously connected content and

Working Group 12

working methods with the purpose of the School: training of engineers for the Dutch army.

The audiores will be trained to serve the country as engineers as quickly as possible. To this end they shall learn arithmetic or counting, and surveying, but of both only so much as is necessary for a common engineer. Those who have come this far are allowed to study more in depth if they wish to do so. This is the general outline, specifications are the following.

The *Instruction* of Stevin specified in more detail what the content of the programme should be.

Arithmetic, including the four operations in whole numbers, rational numbers, and decimal numbers; also the rule of three in those three types of numbers
Surveying on paper, that is calculating area with the use of decimal numbers
Measuring a circle, parts of a circle and area, ... subdividing rectilinear figures and curvilinear figures into several parts, such as triangles or other figures, checking calculations
Measurements on paper of dykes and learning how many 'schachten' or feet the works contain
Fieldwork, learning how to use proper tools
Mapping on paper what is measured in the field and the reverse, from a map setting out stakes in the field
Fortification, learning the names of the parts from wooden or earth models, making maps of towns, drawing the perimeters of forts or towns with four, five, or more bastions and staking them out in the field

Table 1: Main items of *Instruction* by Simon Stevin

The first known interpretation of the *Instruction* is a manuscript from 1622, *Mathematische Wercken* (*Mathematical Works*) by Frans van Schooten (the elder), who taught Duytsche Mathematique from 1611 to 1645 (Maanen, 1987). *Mathematische Wercken* is a set of lecture notes that presumably served as background for teaching. The manuscript gives insight into the level of mathematics taught and an indication of the didactical methods used at the time at Duytsche Mathematique.

Frans Van Schooten (1582 - 1645) assisted Ludolf van Ceulen, professor from 1600 - 1610 and continued teaching after Van Ceulen had died, though without a regular salary. He also worked as a surveyor and engineer for the army. In the archives of the University for the Period 1611 to 1614 there are references to payments made to him and to the provision of four wooden instruments for the teaching of mathematics (LdnUL Arch. Cur. 42). There are also requests from his students for him to be made

van Ceulen's successor. He finally was appointed professor in 1615 (LdnUL Arch. Cur. 42).

MATHEMATISCHE WERCKEN: AN INTERPRETATION OF THE INSTRUCTION

Fig. 1: Measuring the distance between two mountain tops A and B, from a base CD. *Mathematische Wercken*, f 83^r

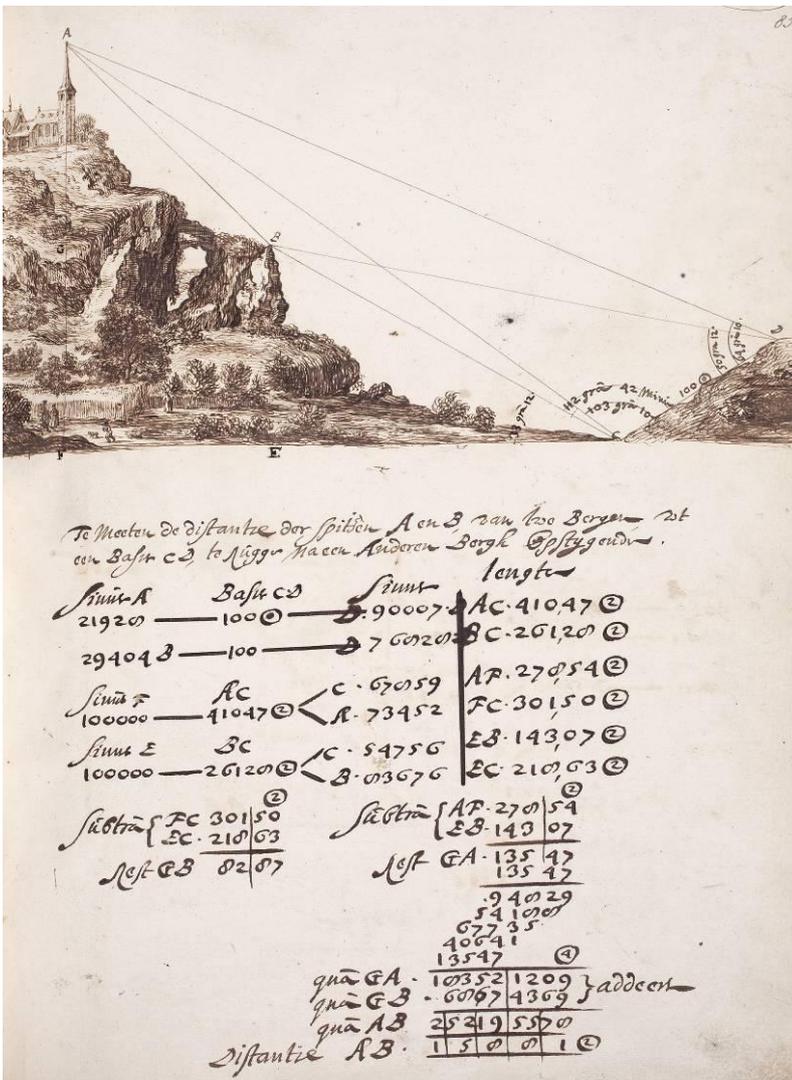

Figure 1 shows one of the exercises from the second half of the manuscript (measuring heights). Looking at the solution presented, there are quite some steps to be thought of and performed by the students in order to get to the required solution. Some virtual points are included (F, E and G). The sine rule is applied repeatedly, in the form of the rule of three. Pythagoras' Theorem occurs once. Van Schooten used an effective notation for decimal numbers, which was not at all common at that time.

When comparing the main content of *Mathematische Wercken* by Van Schooten (table 2) with the *Instruction* by Simon Stevin (table 1) it is obvious that Van Schooten took the *Instruction* as guidance. Both started with arithmetic,

including the use of decimal notation. Stevin, but clearly also Van Schooten, saw the importance of using decimals, e.g. to diminish the length of calculations. Algebraic equations, conic sections, and similar subjects which were at the time important in mathematical research were considered of less use to surveyors and engineers, thus they were not included in the programme. But Van Schooten also omitted subjects which were presumably for his students not necessary, such as the four operations in whole numbers, which were mentioned in the *Instruction*. He added subjects which were helpful to an engineer or surveyor (extraction of square and cube roots, use of trigonometric tables).

Arithmetic: extraction of roots, decimal numbers, calculation of area
Geometry: definitions and axioms, propositions from Euclid, constructions, transformations
The practice of surveying: preparation, measuring distances in accessible land, and calculations
Use of trigonometric tables, measuring in inaccessible lands, making maps, measuring heights (or depths), also measurements without use of tables
Solids: calculations on all kind of shapes and materials, calculating content
Fortification: definitions, plans of fortifications, bastions, calculations

Table 2: Main content of *Mathematische Wercken* by Frans van Schooten

The students who came to the lectures of the *Duytsche Mathematique* were of different background: they might know only the basics of arithmetic or they might be surveyors who wished to improve their knowledge and skills, or craftsmen like carpenters and bricklayers, or university students who wished to study engineering. Van Schooten started with the explanation of square and cube roots, and the explanation of the decimal number system used in surveying, both subjects were linked to geometry (see Figure 2). The manuscript as a whole shows some striking features from the point of view of teaching methods. Strong coherence, elaborate use of visualisation and relevant contexts alternating with rigorous training in mathematical skills without contexts suggest an author who had a good knowledge of the relevant mathematics, who had thought about teaching methods and enjoyed teaching.

Examples of coherence are: consistent use of decimal notation whenever relevant; the use of nearly every element of the part on fundamental geometry (definitions, propositions of Euclid, constructions and transformations of figures) in the part on surveying techniques, in the calculations in three dimensions and in fortification and the repeated use of three main techniques in the notes on surveying (rule of three with sine, fig. 3, the tangent and rule of three with similarity, fig. 4). Throughout the manuscript, illustrations are used with every exercise and every definition, axiom and proposition. The illustrations are always very neatly executed and if necessary labelled with capitals, to facilitate understanding.

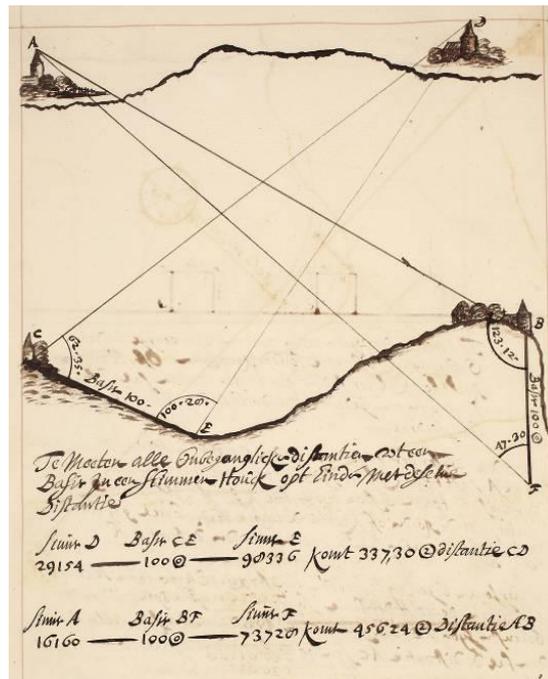

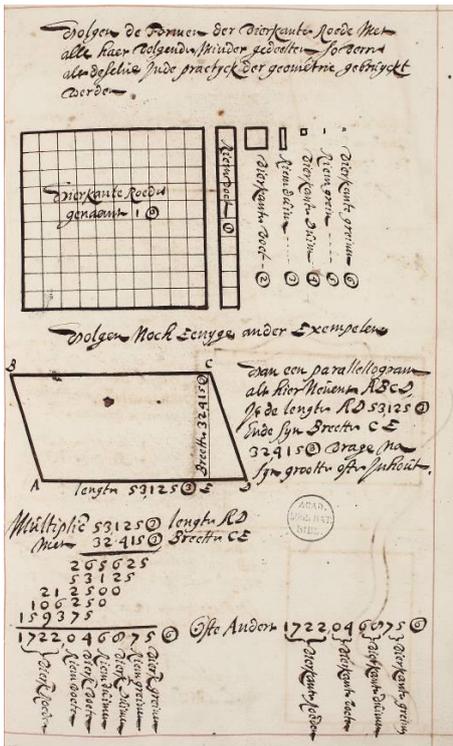

Fig. 2: decimals in surveying, f 45^r Fig. 3: rule of three with sine, f 57^v

Some of the illustrations are of a much higher artistic quality than one usually sees in such texts (see Figure 1). Illustrations may represent a context, combined with the mathematical translation of the problem, for example in the part on surveying (Figures 3 -5). They are also used to facilitate understanding of a new concept (fig. 2).

When van Schooten’s lecture notes are compared with publications on the same subjects (Ceulen, 1615; Marolois, 1628; Sems and Dou, 1600; Stevin, 1594; Stevin, 1605) it is clear that none of these authors treated all these topics in one book. Furthermore the books have far more text and less visualisation, for obvious reasons. In his treatment of Euclid, van Schooten is more academic than Sems and Dou in their *Practijck des Lantmetens*. Because of his use of decimal fractions, his calculations are shorter than those of van Ceulen or Marolois. The latter did not use trigonometric tables either. Manuscripts from the seventeenth century on these subjects by other authors are less coherent in the treatment of the subject, the illustrations are of lesser quality, the use of decimal notation is either absent or occasional (Author A?, 1658; Author A? & Cardinael, 17th century; Kechelius, 1655).

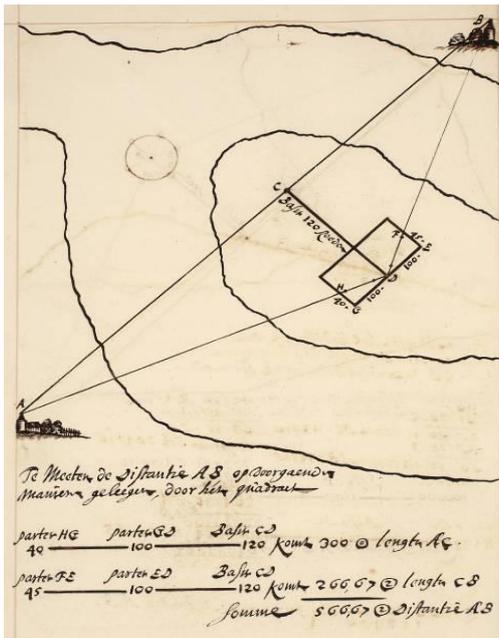

Fig. 4: similarity, f 58^v

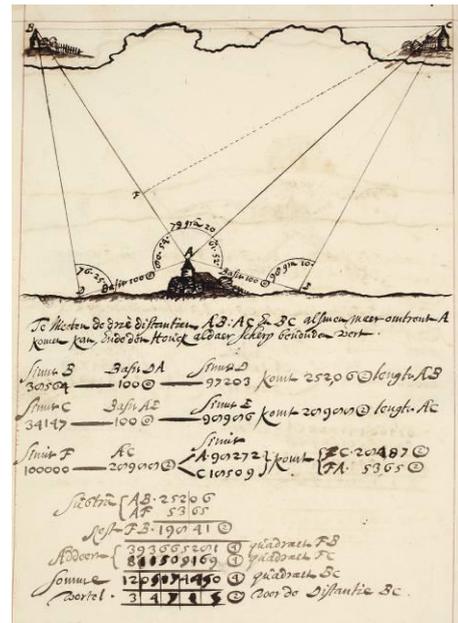

Fig. 5: combination of techniques, f61^v

The Duytsche Mathematique at Leiden University was successful until about 1668: as is evident from number and background of students (Du Rieu, 1875; Witkam, 1967), repeated mentioning as an example worthwhile to follow and reputation of professors (Krüger, 2010). From about 1668 it went into fairly rapid decline. It was closed in 1679 and resurrected a few years later, but never again became as successful as during the early seventeenth century.

DISCUSSION AND (PRELIMINARY) CONCLUSIONS

Some factors and actors which influenced the success and decline of this programme are discussed in the remaining part of this paper.

The Engineering School was established in 1600 at the request of an at the time very influential person, prince Maurits, who himself had studied at Leiden University and personally knew the curators. Around 1679 there were no influential people who would take an interest in the Duytsche Mathematique.

The curriculum had a clear aim and was devised by a respected mathematician and engineer, Simon Stevin, who worked for and with Maurits. The content of the curriculum may be considered optimal as opposed to maximal, both in the formal curriculum and in the interpretation of 1622; modern techniques such as up-to-date trigonometric tables and decimal notation, were used if relevant for the aim of the programme. However the mathematical content and structure of the programme hardly changed during sixty years, and so gradually the programme became outdated.

There was a population of prospective students and there were ample employment opportunities for those who had studied Duytsche Mathematique. However during the seventeenth century more institutes offered courses in mathematics for engineers in Dutch language, also during the seventeenth century engineers only got temporary

Working Group 12

contracts with the army, which may have diminished the attractiveness of the profession.

Teachers were capable and respected mathematicians and often also professional surveyors. However, the successor of Frans van Schooten, his son, Frans the Younger, was a respected mathematician, but he was not a professional engineer and as far as we know did not show much interest in this profession.

The teaching methods, level of accuracy and contexts were aimed at the requirements of the future professions of students; there was a good combination of theory, practice and fieldwork. After 1645 there is no mention of practical work.

The differences with present-day mathematics education are obvious, but from this case it seems likely that at least some aspects still are important today, both for curriculum design and for mathematics education.

- Agreement on and explicit formulation of realistic aims of a new mathematics curriculum before deciding on the content might well provide a better framework for the whole process of development, provided the formulated aims are kept in view during the process of curriculum design, as was the case with the lecture notes Frans van Schooten wrote around 1622.

More opportunity for teachers to design part of their own curriculum, with strong emphasis on quality, might well improve the teaching of mathematics. Structural links between professionals who use mathematics in their work and schools could help to improve both the teaching of mathematics and motivation of students.

- Even the best curriculum has to change with new developments in society and in technology, or risk becoming outdated.

NOTES

1. This document and others concerning the Duytsche Mathematique are kept in the archives of the library of the University of Leiden (Arch. Cur. 20, 42); most of them are published in Molhuysen 1913 and later volumes.

HOW MUCH MEANING CAN WE CONSTRUCT AROUND GEOMETRIC CONSTRUCTIONS?

Snezana Lawrence and Peter Ransom

Bath Spa University, England

This paper describes a way in which the mathematical heritage can be used to identify potentially 'rich' tasks undertaken by student teachers to deconstruct, and subsequently better understand, the meaning of mathematical concepts they already know and are expected to teach. It is based on a small-scale project undertaken in the South West of England and which is proposed as a pilot for a larger project to map the curriculum against such topics. The project has been generously supported by the National Centre for Excellence in the Teaching of Mathematics (NCETM)¹.

Of course, mathematics involves deductivity. Working with the slide rule and the protractor is no mathematics, measuring areas and volumes is no mathematics. But accepting a deduction is no mathematics either, unless you adhere to the interpretation of mathematics as a ready made subject.

Hans Freudenthal, *Geometry between the Devil and the Deep Sea*, 416.

THE CURRICULUM CHANGES AND THE CULTURAL HERITAGE

Within the past few years a great number of changes have been initiated in the mathematics education in Great Britain². The first of the most dramatic two of those changes was certainly the introduction of the new curriculum which was brought in as the old government prepared to leave the scene and the new was preparing to step in³.

One of the most important things for schools to get right is being identified now to be mathematics education⁴. But is it mathematics that we as a society are interested in, or the results of the PISA study⁵, the content of the curriculum, the pedagogy, the level of difficulty of our qualifications, or the power of teachers in classrooms?⁶ We will argue in this paper that none of the above gives satisfactory answers to the better teaching and learning of mathematics, and that the disengagement of teachers from the actual mathematical content is the most important reason for disengagement of our students⁷. We will also argue that this is so because the teachers are not inducted in any way in the mathematical culture which they are supposed to transfer and transform through their own practice, either by 'doing maths' or by inducting their own students into that practice. It is our fear that whatever curriculum we have the same will be valid in this regard: when the student teachers engage in doing maths, they follow the 'heritage' path and are rarely aware of the origin of concepts and therefore their meaning. This paper will argue that the awareness of mathematical

cultural heritage, and a set of skills in identifying such heritage, is a necessary component in any preparatory teacher education. This process we identify also as a possible way into introducing the students to the history of mathematics which brings out all the well known benefits to their subsequent practice. (Grattan-Guinness, 2004).

THE RESEARCH IMPETUS

Grattan-Guinness (2004, 174) describes the type of mathematics education ‘very much guided by heritage.’ But this heritage he identifies thus as one which brings out the ‘...reactions of students – including myself, as I still vividly recall – are often distaste and bewilderment; not particularly that mathematics is very hard to understand and even to learn but mainly that it turns up in “perfect” dried-out forms, so that if there are any mistakes, then necessarily the student made them.’

In this way described, the heritage in secondary school is the tradition of learning Euclid by rote, or in more recent times, following algorithmic learning and teaching of famous examples such as completing the square or the theorem of Pythagoras without the historical accuracy evident in teaching, or the real understanding reported by students. Although not entirely the same, this reminds us also of the Freudenthal’s anti-didactical inversion: in fact we are dealing here with taking the ‘mathematical activities of others... as a starting point for instruction’ (Gravemeijer & Terwel, 2000, 780).

We argue however, that the heritage, and its dried-out mathematics which does not engage students, has a role to play in teacher training if only as a way of exploring a culture of mathematics and a possible initiation route into the historical study of mathematical concepts. In other words, we should use the ‘heritage’ approach of the ready-made mathematics of the prescribed curriculum(s) to identify the concepts which may be rich in their potential to search for ‘meaning’, so that dealing with concepts and doing mathematical problems or exercises which use them, becomes a meaningful activity. The use of curriculum in such a way provides a comfort zone for teachers to structure their exploration in a sustainable way, through gradual learning process rather than sweeping enthusiasm which ends up with not having enough time to engage with the ‘new’ material through research and reading, and subsequently can end as a project never to be completed⁸.

In order to use ‘heritage’ in this way we propose that answers to the questions:

- Why do we call this (concept/process/tool) by this name?
- What does it mean and/or how does it work?

must be possible to answer. For example, Euclidean tool or construction, and a Pythagoras’ theorem would be starting points for an investigation of such type in which heritage would be used to explore the history and gain the meaning about a

mathematical concept.

How else can teachers themselves impart the ‘meaning’ of concepts they are dealing with onto their pupils? This may seem like an obvious fact, but the research presented here will show that imparting the all elusive ‘meaning’ is not a part of everyday practice, and that teachers in education are prone to unquestionably take concepts in a heritage-like, ready-made mathematics way. Should every teacher be aware of why we call certain constructions ‘Euclidean’ (In fact how many teachers actually do so?) and why a certain way of solving equations is done through the method of ‘completing the square’? How can a teacher use these concepts with the secondary age pupils in a meaningful way without herself/himself really being sure what they mean? Not knowing these simple facts by teachers approaches the near-total disengagement with a mathematical culture that the teachers are trying to somehow in turn engage their students with. It may not then come as a surprise to hear that the perception that many young people in Britain have of mathematics is that it is “boring and irrelevant” as a consequence (Smith, 2004, 2).

FROM EXPERIENCE TO EXPERIMENT

While exploring the possible ways in which mathematics ‘subject knowledge’ can be revitalised through the Initial Teacher Education course for Secondary and Middle Years Mathematics Students, we came across the barrier of students wanting to engage with simple exercises and working things out for themselves. Doing mathematics is different to teaching mathematics, but can mathematical concepts be re-examined for the purposes of education without doing the mathematics one already ‘knows’? This was another of the questions that puzzled us as we tried to understand both the wide-spread lack of knowledge about the origin of certain concepts that we teach at secondary level, and the lack of questioning from prospective teachers as they train to use these in their craft, and in their (what it seemed) ultimate goal of covering the prescribed curriculum. In fact, should we be asking the questions: ‘Do they actually care?’ and ‘Does it make a difference to their teaching and students’ learning?’ However those questions are beyond the research of this paper.

Watson (2008, 7) documents the way that we have in fact structured our curriculum through examinations in the recent past:

Questions involving application of theorems can be avoided in UK national tests at 16+ and students still be awarded the highest grades. Theorems and proof of any kind, let alone geometrical contexts, do not play a part in higher school examinations.

The lack of questioning of the premises upon which we should build some mathematical understanding by new graduates in this context does not then seem puzzling. The difference between doing mathematics (seen in all its diverse cultural interactions, a mode of intellectual enquiry but also a mode of intellectual

Working Group 12

communication), and doing the ‘school’ mathematics, is described by Watson (2008, 2) in the same paper:

Learners... have a different experience to those taught with a more abstract view, but solving realistic and everyday problems need not lead them to understand the role of mathematics beyond providing ad hoc methods for real problem-solving, or as a service subject which holds tools for moving forward in other domains.

How it is possible that such practice is embedded in the system of education becomes apparent when at the start of such practice it is evident, as will be shown, that the enquiry stops at the gate of the curriculum temple.

The project described here was a pilot project to deal only with the single issue of Euclidean constructions. The question was ‘How much do teacher students understand what a Euclidean construction is and how could they employ such understanding to teach the topic from the curriculum?’ The aim was to:

- find the level of understanding of Euclidean constructions and their historical origins;
- engage the student teachers in exploring the possibilities to do mathematics but also to think about how they would teach it;
- find the ways in which this process could be modelled for other topics from the curriculum.

The pilot will serve as a basis to plan a larger project to examine the issues of

- overcoming the disengagement of teacher students from the meaning of mathematical concepts through
 - doing mathematics first through a heritage-like way
 - identifying the ‘heritage’ elements of mathematics thus ‘done’
 - going onto the exploration of the history of the concept (with all subsequent benefits, but primarily: aiming to understand the way of mathematical thinking associated with the concept, and aiming to systematize the interconnectedness with other mathematical discoveries and concepts)
- devising a system to identify the topics from the curriculum which can be rich to offer such explorations by the teachers in training and
- attempting to define ‘how’ and ‘how much’ history of mathematics should and could be incorporated into the teacher education.

This paper therefore does not give a full and/or comprehensive list of answers to the question of how and why to introduce the teachers in education and training to the history of mathematics. But it does trace a project which shows the increased engagement and motivation giving teachers the confidence to use the syllabus in a

Working Group 12

creative way and to explore the concepts they are meant to teach, which would otherwise be made into an empty list to be ticked off as they go into the lessons. It also evidences the students' increased capability to search for cultural and historical roots and construct the meaning around mathematics they are teaching.

The results of the experiment

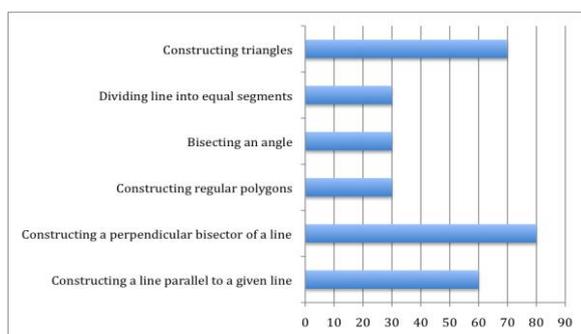

The study concentrated on analysing a group of students at a university in South West England. They were all mathematics specialists: 24 who enrolled on a postgraduate course leading to the Postgraduate Certificate in Education (PGCE) preparing them to teach at secondary level (11-18 year olds) and 12 students preparing to teach in middle-schools (8-14 year olds), but all working on the mathematics related pedagogy for 11-14 year olds.

The students were given a task to complete on geometrical constructions. They needed to:

- research the requirements of the curriculum regarding geometrical constructions
- find as many constructions as possible, appropriate for the curriculum levels and execute them themselves
- devise a learning activity for their prospective pupils.

The first problem that teacher students encountered was the material from which to source their own, and then their students', learning. While many school textbooks deal with geometrical constructions, they do so in a haphazard way without sufficient explanation as regards to the context in which these arise, or were conceived, and often do not provide any underlying conceptual understanding. The history of the concepts is often entirely disregarded, even though one of the most widely available textbooks insists on mentioning 'Euclidean constructions'⁹. This has been identified by authors in other countries as well, such as in recent study of Nicol and Crespo (2006).

At the end of the task, the students were asked to say what constructions they learnt and were able to execute without resource to repeated instruction. The percentages of students being able to complete various constructions are given in table below.

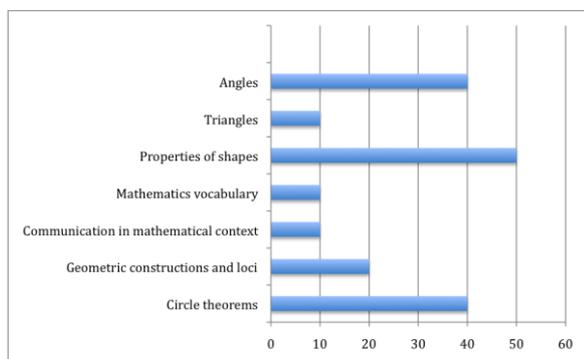

However, of more interest was the subsequent students plotting of the constructions against the curriculum for 11-14 olds; the students were asked to say how many topics from the curriculum they could teach (partially or in full) through geometrical constructions. Percentages of student teachers who believed they could

teach topics listed are given below.

Working Group 12

In this survey, some interesting results came through:

- 70% of students originally said they could construct triangles, but only 10% declared they could see how geometric construction of the triangles would be relevant to the curriculum topic

- Furthermore, only 20% of students were able to identify or recognise that you could teach geometric constructions and loci (a topic in the curriculum) by actually doing geometric constructions.

When students were asked in a whole-group discussion to make sense of these two

answers, they further clarified:

- They could not see how constructions of triangles aided the conceptualisation of various properties of triangles and/or geometrical reasoning related to this topic
- Whilst they recognised that the geometric constructions and loci were part of the curriculum, they believed this to be an ad-hoc and not important part of actually ‘doing’ mathematics on one hand, and on the other, that engaging with constructions was not going to cover the curriculum topic in its entirety.

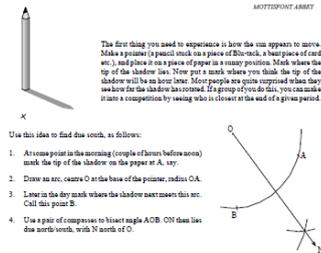

In our opinion the application of geometrical constructions is important to school students. Many texts and exercises consist of the pure geometrical constructions first, before looking at applications of these constructions. Even then the applications are thinly disguised (e.g. boat sailing between two rocks). Our work with 13/14 year old students suggests that by putting constructions into a larger piece of practical work (usually a 2½ hour single session, though this can be spread over three single lessons) more is appreciated of the use of such constructions and there is then time to explain more of the geometrical proof of why the construction works. One example used in the classroom (and shown here) is on how to find true north/south using a vertical pointer. Other examples can be found at Ransom (2004, 22-26) and the student teachers involved in this research project worked through these examples. It was interesting watching them work through the materials since their first reactions to drawing a perpendicular from a point was to use a protractor, just as school students tend to do. This does, however, allow the point to be made that all measurement is approximate (to varying degrees of accuracy), yet the construction method is theoretically accurate. This concept of accuracy does not appear to be important to many.

Deconstruction and discussion

Without doubt the most important part of the experiment was the further deconstruction of the students' learning process, which they used to improve the design of their learning task. Van Maanen (1992, 223) has claimed that the use of constructions begins only when these are to be designed:

Clearly the crucial point is to find out which construction steps are needed to solve the problem (the analysis stage). When these steps have been discovered the proof of the correctness of the construction (the synthesis stage) is usually easy.

Through this analysis, and subsequent synthesis of the Euclidean constructions, the students first made the discovery that geometry and measurement are not necessarily the same; this led some students to delve further into the history of measures as well as measuring devices on the one hand, and constructions and mathematical instruments on the other.

The first thing you need to experience is how the sun appears to move. Make a pointer (pencil) mark the piece of filter (stick, a bar of wood etc.), and place it on a piece of paper in a sunny position. Mark where the tip of the shadow lies. Now put a mark where you think the tip of the shadow will be an hour later. How people are often surprised when they see how far the shadow has moved. If a group of you do this, you can make a game a competition by seeing who is closest at the end of a given period.

Use this idea to find the north, as follows:

1. At some point in the morning (roughly 1 hour before noon) mark the tip of the shadow on the paper as 'A', say.
2. Draw an arc, centre 'O' at the base of the pointer, radius 'OA'.
3. Later in the day mark where the shadow meets this arc. Call this point 'B'.
4. Use a pair of compasses to bisect angle AOB. ON this line the north-south, with 'N' north of 'O'.

If you have already made a sundial then you can use the direction you have just found to align the gnomon along this line, making sure that the gnomon points to the north. Then you can use the dial to find the time by reading the time indicated by the shadow, making the necessary adjustments for longitude, the time of year, and any daylight saving alterations that operate in the country in which it is to be used.

Whilst the students discussed the two technical meanings of the 'construction' – the construction of the theorem and the construction in a form of a drawing (Martin, 1998, 3), the issues of the 'Euclidean' tools arose (as defined by Martin, 1998, 6, and Holme, 2002, 48). It was this crucial piece of 'meaning', of the difference between the measurement and the theorising through construction with Euclidean tools that led students to a better understanding of the way that

Greek mathematics dealt with magnitudes as tools for understanding the relationships and building upon those which have already been established. At this point in the discussion the student teachers began to be truly engaged in an intellectually active way and see mathematics as a possible way of sharing that intellectual dialogue with their prospective students.

At the beginning of the experiment exactly 50% of the students had never heard of Euclid and 100% didn't know what Euclidean constructions were, although they were happy to include mentioning of both Euclid and his constructions and tools in the learning tasks they devised for their pupils. At the end however, **90%** described that **their main motive for using Euclidean constructions would in future be in order to engage the students in geometrical reasoning and proof.**

CONCLUSIONS

While small in scope, this experiment showed that the practical way of engaging student teachers through:

- the process of doing (albeit some simple) mathematics;
- discussing the historical context and hence dissecting the meaning attributed to some concepts (Euclidean tools);

Working Group 12

- the learning about a topic they are attempting to teach, and a vision of how to transfer that engagement in their classrooms.

It has been noticed, and Gulikers (2001, 224) gives supporting evidence, that there is ‘...growing interest among teachers in the history of mathematics. ...results of two questionnaire surveys... reveal that teachers are interested in the history of mathematics, but at the same time, are not well resourced to actually use such material in their own teaching’. While we agree with this, this small study and the long term engagement with teacher groups from around England¹⁰ also gives cause to believe that

- teachers do not have the **full motivation** and don’t actually see the history as a necessary part of mathematics learning;
- they have not experienced those **crucial insights** that would make the history of mathematics ‘necessary’ to the process of understanding and engaging with a mathematical concept either for themselves or for their pupils.

At the end of the experiment, 75% of student teachers declared the desire to engage more with the history of mathematics and 83% declared that they could see how to do it¹¹. So, while it is worthwhile discussing the need to introduce the history of mathematics into mathematics instruction, **the student teachers need to have the experience of how this is useful in their own practice**. They are often bogged down with many daily pressing issues, such as pupil motivation, behaviour management, getting the hang of the mathematics curriculum, understanding the levels which are appropriate for the classes they teach both in terms of age and ability, and finding enough preparation time whilst learning how to plan effective lessons. Only after they have understood a crucial piece of mathematics that they have ‘inherited’ and thus practiced for many years (not very well if we are to judge by the results of the first questionnaire) without questioning, do they begin to see the potential of the history of mathematics. The learning of mathematics includes various other activities that support learning other than doing mathematics. Freudenthal identified those as ‘organising a subject matter... from reality which has to be organised according to mathematical patterns if problems from reality have to be solved. It can also be a mathematical matter, new or old results, of your own or others, which have to be organised according to new ideas, to be better understood, in a broader context, or by an axiomatic approach’ (Freudenthal, 1971). Others, like Lakatos for example, focused on the problem-solving as a way of reconstruction of a pure research mathematical discourse (Lakatos, 1976)¹². Both of these are valid ways of learning mathematics, but for those who already ‘know’ and whose path to teaching is littered with ready-made mathematics modules and heritage-style pictures of good mathematics like some dusty and beautiful picture of a remote landscape in an old frame, the way of rediscovery can simply be to engage with a question of when did we identify a concept as a concept, why do we call it as we do and what does that mean. Only then does the mathematics history become part of the

Working Group 12

mathematics education culture, and the pleasure becomes the cultural one¹³. And that is just for teachers, the kids will follow.

IDENTITY OF MATHEMATICS EDUCATORS. THE PORTUGUESE CASE (1981 - 1990)

José Manuel Matos¹

New University of Lisbon

A historical case study centred on the Portuguese community of mathematics educators intending to understand how its identity was shaped from 1981 to 1990 is presented. Keywords: history of mathematics education; professional identity

The notion that mathematics education may consist of a world-wide *community* is expressed in the title of the book *Mathematics Education as a research domain: a search for identity* that publishes materials presented at the Study Conference “What is research in mathematics education and what are its results” organized by ICMI in 1994. In the summary, the editors, Anna Sierpinska and Jeremy Kilpatrick, conclude:

In spite of all the differences that divide mathematics education researchers (in terms of theoretical approaches, views on relations between theory and practice, philosophies of mathematics, etc.), they still constitute a community, and it is necessary to search for what constitutes its identity. (1997, Vol. 1, p. ix)

Understanding how such community came about and consequently how such *identity* is shaped, is then a necessary endeavour. An early reflection about the nature of such identity and its diversity can be found in the discussion about a *Theory of Mathematics Education* (Steiner et al., 1984) that took place in ICME 5. Later, Alan Bishop (1992) distinguished three traditions of research according to the goal of enquiry, the role of evidence, and the role of theory. The study of specific traditions — essentially those nationally bounded — has also been the object of analysis² centred on paradigms, methods, and results.

But the study of *research* alone does not suffice to understand the *identity* of this community. Claude Dubar (1991) defines identity as the “result simultaneously stable and provisional, individual and collective, subjective and objective, biographic and structural, of the several processes of socialization that, jointly, construct individuals and define institutions” (p. 113) and it is formed through the articulation of two heterogeneous processes, the *identity for others* involving social expectations and acts of attribution, *self-identity* based on self-perspective and acts of belongingness.

By using a historical case study approach, this paper aims at understanding how the *self-identity* of the community of mathematics educators was shaped in Portugal. At the centre of this analysis is the meaning attributed to the term *mathematics educator*. I chose to designate as *mathematics educators* those concerned with the research of problems relating to teaching and learning mathematics. Today most share common practices (teacher education and research, for example), communicate through institutionalized forums, and have professional ties to universities or

colleges. In the Portuguese context, however (and certainly in other countries), boundaries are fuzzy and some primary or secondary teachers engage in research activities. That was not the case in the early 1980s where we can hardly speak of professionals focusing on research in mathematics education in Portugal. This paper will study the actual *emergence* of the community of mathematics educators out of a community of teachers of mathematics. The time frame starts in 1981 — when the first discussions in a democratic context about the state of mathematics teaching and learning occurred — and ends in 1990 — coinciding with the adoption of new curricula. Data collection was centred on articles, books, official documents, and gray literature. Content analysis studied this *corpus* as historical documents (Certeau, 1975) focusing on evidence for the representations and the practices of the participants (Julia, 1995).

EARLY 1980s, DISCOMFORT WITH MATHEMATICS PROGRAMMES

The Portuguese educational system experiences tensions and changes during the 1970s. On the one hand, there is a steady growth in the number of students that is not accompanied by a proportional growth of schools or teachers. On the other hand, there is a shift on the purposes of the system. The separation between schools for students aimed at the universities and professional schools gradually moved from 4th grade to 6th grade (in 1968), and after 1976 gradually disappeared. Significant changes in some curricula, and especially in school management, occurred as a consequence of the democratic revolution of 1974. The seventies were a period characterized by overpopulated schools, lack of certified teachers, of textbooks, and other materials, and unstable school management and curricula.

At that time, mathematics curricula embodied the Modern Mathematics approach. The ideas of this movement were firstly published in Portugal in 1957, experimented through the 1960s, and adopted in the following decade. Teachers with the responsibility of training other teachers enthusiastically embraced the reform because they saw it as a perspective adequately merging psychological and mathematical approaches (Matos, 2009). However, by the 1970s (and well into the 1980s), a majority of teachers of mathematics were not certified, nor had enough mathematics background. The ways in which the reform changed the daily life of mathematics classrooms has not been researched, but there are studies about its effectiveness suggesting widespread learning difficulties (Matos, 2010).

In the late 1970s documents show discomfort among young teachers of mathematics, some teaching in teacher education courses, but most of them still following courses at universities, about the state of mathematics teaching and learning. Small group discussions over curricular and mathematical issues (Pólya's *How to solve it*, for example) were conducted and in 1981 the participants presented papers at the first professional meeting about teaching and learning of mathematics organized under the new democratic regime, started a newsletter *Inflexão* [*Inflection*], and actively

Working Group 12

engaged in a series of meetings planned by the Portuguese Society of Mathematicians to discuss the programmes of upper secondary school. By the end of these meetings, a coherent set of perspectives about mathematics teaching and learning emerged (“Os programas em debate”, 1982). Reacting against what was perceived as “a critical situation”, Modern Mathematics programmes were condemned because they rendered mathematics hermetic, formalized, with a great emphasis on symbols, and foreign to reality and applications. Programmes should change to integrate

- a strong component making use of problems, i. e., great relevance to the role of problems as a means to develop an investigative and discovery spirit (...);

- a strong focus on the practical side [of mathematics], by using calculators (...) [and] computers;

- a special attention to the applications of mathematics and to its relationships to other disciplines, [adopting] a marked interdisciplinary sense;

in sum, an increased relevance to the formative aspect. (“Os programas em debate”, 1982, p. 20)

These three dimensions (problems, technology, and applications) that departed from the official curricular options at the time will integrate the backbone of the idealized mathematics curriculum proposed by the document.

The document approved in 1981, also discusses curriculum development. Criticising previous practice of writing programmes in closed commissions appointed by the Ministry of Education, new curricula, the document stated, should be developed by a Commission composed of elements indicated by the Universities, Secondary Schools, Portuguese Society of Mathematicians, and lastly, the Ministry of Education. This “parliamentary” approach to curricular development, almost marginalizing the governmental body, shows that this emerging community is also seeking the ownership of (or reclaiming its expertise over) specific knowledge dimensions, thereby exerting pressure on other social bodies as a means to acquire power.

In 1982, several papers centred on curricular perspectives were presented at a national meeting. From the distance of time, and by today’s standards, one cannot help to notice their exploratory nature, hardly supported by relevant literature, rudimentary methodologies, and with scant conclusions. But it is also clearly apparent their voluntarism, their strong ties to the life of schools, and the firm desire to change a situation perceived as professionally frustrating.

In brief, during this period, there is a small loose network of young teachers of mathematics and assistant professors, almost all of them still acquiring their scientific or professional certification or their doctorates. Exchanges among the members occurred at small informal gatherings. At the end of the period a newsletter

appeared. Their practice included not only the common practice of mathematics teachers in the country, but also interventions outside regular classes (math clubs), and interventions at meetings requiring changes in mathematics curricula, implicitly seeking public recognition of their expertise on the subject. Many of the members had also intervention in other dimensions of social life (teachers' unions, for example). Their theory was straightforward: school success will come from problem solving, technology and applications of mathematics; school failure should be attributed to repetition, widespread formalization, and premature abstraction, the last two been interpreted as the hallmark of Modern Mathematics.

THE CONSTITUTION OF A COMMUNITY (1982 – 1986)

During the year 1981, Joseph Hooten, Jr., from the Department of Mathematics Education of the University of Georgia, USA, was a visiting professor at the University of Lisbon³. Through seminars, visits, small group discussions, and informal conversations, for almost a year he disseminated a coherent perspective about the problems of teaching and learning mathematics.

The concept of *connected history* (Gruzinski, 2003), developed by cultural historians, has been used to understand how communities elaborate their representations and practices in connection with other communities. Going beyond both a mirror perspective — in which one culture tries to emulate another —, and a power perspective —interpreting cultural influences as either acts of emulation or resistance —, the influence of one culture by another is seen as acts of *hybridism* (*métissage*) in which external appropriations are not seen as mere imitations (or distortions) from the original, but as producers of a new originality. In this model, a key role on the circulation of ideas and practices has been attributed to *mediators*, persons that travel among societies and cultures. Posing as mediator, Joe Hooten brought firstly a new pedagogical model. Portuguese Modern Mathematics curricula, inspired essentially on ideas from France and Belgium, were confronted by a distinct perspective centred on problem solving, laboratories, the value of applications of mathematics, and of the use of manipulative materials. Joe Hooten also brought an appreciation for empirical research as a means to consolidate educational knowledge.

One tangible product of this influence is the translation of the book *Agenda for action: recommendations for school mathematics of the 1980s* (NCTM, 1980) that circulated before 1985. Its first proposal, that problem solving be the focus of school mathematics in the 1980s became one of the key elements of a pedagogic alternative of the Portuguese group. In the USA, this emphasis can be seen as a response to the middle 70s “back-to-the-basis” approach thereby valuing problem solving’s allowance for more significant mathematics involving higher-level reasoning, not limited to the memorization of facts and algorithms. In Portugal, however, problem solving was also valued because of its non-abstract and non-formal qualities, which was seen as permitting an alternative to the Modern Mathematics curricula.

Working Group 12

By the end of 1986, the small group of young teachers, having completed their graduation and post-graduation, incorporated the first Portuguese association of teachers of mathematics (in 1986), with annual national meetings (since 1985) with a growing participation of teachers, and publishing a journal (since 1987). Three other small non-disjoint groups of teachers integrated this movement. The first was an active group of teachers responsible for in-service teacher education at grades 5th and 6th. The second were teachers and mathematicians based in Coimbra and promoters of the national Olympiads of mathematics. A third was composed of teachers for schools aiming at forming primary teachers that, as a group, underwent a graduate programme on mathematics education³ in the University of Boston, thus reinforcing the USA ties and becoming mediators themselves.

All these groups and mediators enlarged the practices of the community and shaped their representations as can be observed in the first national meeting of teachers of mathematics (*ProfMat*) that occurred in 1985 in Lisbon. The proceedings were published in a newly founded journal *ProfMat, Revista teórica e de investigação sobre o ensino da matemática* [*ProfMat, Theoretic and research journal about mathematics teaching*] that, as other scientific journals, had its Editor and Editorial Board⁵. The value attributed to research is expressed in its name, its purpose and is the focus of the first editorial:

[The journal's] purpose is to provide for a broad exchange of perspectives related to the formulation of research problems, methodologies for collecting and analysing data, theoretical foundations, evaluation, and syntheses of results. ("Editorial", p. 3)

The journal includes 11 papers, mostly reporting investigations produced for the completion of graduate studies at American universities. These works show a very distinct style from the ones of the early 80s. Now, there is a clear emphasis on structured empirical research on issues concerning mathematics education, including the definition of a problem, a review of literature, data analysis, and conclusions.

The proceedings also include three texts on computers, calculators, problem solving (originally in English), manipulative materials, and mathematical clubs. The three plenary lectures, given by leading mathematicians, were all devoted to the issue of mathematics and computers.

In 1985, the term "educação matemática" (mathematics education) is used for the first time on the cover of a book presenting a chronology of mathematics teaching (Matos, 1985), and is also included in the name of one the discussion groups at the first ProfMat (on "Theory of Mathematics Education"). In 1986 it is used again on the cover of the second issue of the journal that published the proceedings of the second national meeting. In this issue, the journal itself had a slight change in name replacing "mathematics teaching" for "mathematics education" and the term is discussed in the plenary of the second congress (Ponte, 1986). The consolidation of this denomination in 1985/86, and consequently of the identification of the members

Working Group 12

of the community as *mathematics educators*, also suggests the consolidation of the community. It also indicates the departure from other denominations, namely *didactique des mathématiques*.

The foundation of the first Portuguese association of teachers of mathematics (APM) at the second national meeting in 1986 marks the appearance of a national professional organization, specifically concerned with the problems of teaching and learning mathematics and the publication of a new bi-monthly journal *Educação e Matemática*. It also results, internally in the consolidation of the community's membership — a mathematics educator *must* be a member of APM —, and in its external legitimation.

The dominant perspective on the community can be obtained through the first editorial of this second journal, written by Paulo Abrantes (1987). There he complains about the “crisis” in mathematics teaching in recent years and endorses its responsibility to the Modern Mathematics approach, which is “very removed from students' concrete reality, with considerable importance been given to mathematical structures and their properties.” (p. 3)

He proposes initiatives that may promote change: out-of-class activities centred on applications, problem solving (math week, conferences, problem competitions, and Olympiads), or the use of computers. He notes the importance of initial teacher education and teachers' meetings. He finishes by stressing the importance of active methodologies, of considering the active and social dimensions into the broad objectives of education, the importance of out-of-school contexts, the new technologies, problem solving, applications of mathematics, and interdisciplinarity.

In summary, by the end of 1986 the community is grouped under the national association for teachers of mathematics that includes virtually all small groups of innovators interested in teaching and learning of mathematics. Almost all of its leading members are now certified teachers, many are working at universities in teacher education programmes, and have some practice in conducting research in the field. There is a functional and complex network and exchanges among their members can occur through national (or regional) meetings, or through the association's journal. For some, a regular presence in international meetings diversified sources for the circulation of ideas. The practice of some members continues to be similar to the common practice of teachers of mathematics, including organizing math clubs. Their theory has become more sophisticated. Research is now seen as a fundamental option to legitimize innovation and knowledge building. But problem solving, technology, and applications of mathematics, together with the importance of the use of manipulative materials continues to be equated with success; repetition, widespread formalization, and premature abstraction, still prevalent in school curricula, continue to be seen as promoting failure.

CONSOLIDATING IDEAS AND REPRESENTATIONS (1986 — 1990)

The volumes from the first two years of the teachers' association's journal (1986-7) contain many articles presenting problems, or about problem solving, others relating to applications of mathematics, some discussing the use of technology, or manipulative materials. But, there are almost no accounts of actual interventions in classrooms. The same can be observed as we look at the first books published by the community. Apparently, most of the applications of the theory (valuing problem solving, applications, technology, and manipulative materials) can only be seen outside real classes — in math clubs, for example — in environments that do not confront the national curricula.

In May 1987, intending to adapt the educational system to a democratic society, the Ministry of Education initiated a public discussion of new curricula. The preliminary document raised widespread concerns in the community, as, apparently, it favoured a “back-to-bases” approach. As a reaction, APM convened a meeting for the elaboration of an alternative perspective.

“For four days, morning to night, 25 teachers and researchers discussed some of the essential problems to the renewal of mathematics for basic and secondary grades. (...) The following texts are the product of this work and constitute documents that support an enlarged debate among all members of the Association and, in general, among teachers of mathematics.” (APM, 1988, p. 3)

As a consequence, a collective book was produced (*Renovação do currículo de Matemática* [Renewal of mathematics curriculum], 1988), known as the *Milfontes document*, containing a coherent perspective on learning and teaching mathematics that was also published by the National Commission for the reform. But, perhaps the impact of this document outside the community can be ascertained by the interview given by the responsible for the coordination of the new programmes to the journal of the Association and published shortly after. In this interview, Brigitte Tudichum, overseeing curricula from all areas, agrees on the importance of problem solving, technology, and communication in mathematics teaching (Tudichum & Nunes, 1989). “Mathematics must appear and be explored through problems” (p. 24) she states. The success obtained by this social intervention was new to the Association and reinforced its status. Moreover, the ideas of the *Milfontes paper* prompted some participants in the seminar to test its proposals empirically through a three-year curricular development project in grades 7th through 9th, Project Mat789 (Abrantes, Leal, Teixeira & Veloso, 1997).

As representations of successful mathematics teaching and learning became more reflective, newly masters' courses on education promoted the development of applied research. In fact, from 1987 teaching experiments centred on the four axes for innovation — technology, problem solving, and in a smaller degree, applications and

manipulatives — were conducted. Moreover, specific research groups appeared, on teacher education, problem solving, and learning.

In brief, the community is now composed of a very large group of teachers and APM is seen nationally as a reference as far as innovation is concerned. There are several working groups in the Association, the annual national conferences experience a growing participation, and throughout the country there is a multitude of regional meetings. At the same time, a differentiation within the community starts to show because, so far, researchers identity can hardly be distinguished from the teachers of mathematics. The emergence of graduate programmes in mathematics education located in Portuguese universities is going to change the representations and the practices of a small number of members and, at the same time, endows them with power over the others. In this period, especially after the publication of the *Milfontes paper*, practice became the application of theory for some members. Theory itself became much more elaborated.

CONCLUSION

This case study of the emergence of identity in the community of mathematics educators in Portugal has shown how the community itself started from a loose group of beginning teachers, essentially located around Lisbon that gradually incorporated other teachers. It also showed how this community gradually differentiated into a large majority of teachers and a minority of teachers “that teach teachers”.

Identity itself was characterized as an enumeration of practices and theories followed by the community. As for the practices, this study has shown that curricular innovation was an intention from the early beginnings but either the lack of knowledge of adequate comparable practices, or the centralized structure of Portuguese curricula, did not allow for much in-class innovation. Early pedagogical practice is therefore displaced to the outside of the classroom. Only later, essentially after 1987, with new curricula in sight and the generalization of graduate studies, some experiments were performed.

In the beginning, another particular kind of practice emerged, essentially around problem solving. Documents from that time include problems, challenges for solving problems, and examples of the nesting of problems. In some schools teachers prompted students to solve problems in out-of-class activities. Apparently, it was as if the community needed to construct a perspective about what constitutes mathematics distinct from university teachings, which was dominated by Bourbakian approaches.

We have also seen how theories have evolved. From a naïve perspective on mathematics education problems, and with the help of mediators, more elaborate representations emerged, with a strong influence from USA’s perspectives. Later, and prompted by external solicitations (a curricular reform), a coherent perspective was collectively elaborated (the *Milfontes* document). The modes and values of

Working Group 12

educational research became appreciated, as the empirical scientist tradition (following Bishop's classification) was appropriated.

As we have seen, in the beginning, mathematics educators (today seen as researchers on teaching and learning mathematics) in Portugal were undistinguished from innovative teachers of school mathematics. Differently from other countries where the community was initially composed of trained mathematicians, for example, virtually all the early members began their careers as teachers in secondary schools, and only later a differentiation started to emerge. It may be the case that such origin explains the existence of a strong national association of teachers of mathematics, the numerous presence of school teachers in research meetings (usually from one half to two thirds), the late constitution of an association of researchers in mathematics education, and the affiliation of the Portuguese research journal, *Quadrante*, to the Association of Teachers of Mathematics.

NOTES

1. This paper was supported by the Project "A Matemática Moderna nas escolas do Brasil e de Portugal: Estudos históricos comparativos" financed by FCT (Portugal) and CAPES (Brazil).
2. For example, Artigue and Douady (1986) discussed the specificity of French research, Arzarello and Bartolini Bussi (1997) examined the Italian tradition, and in Portugal an overview of research on the field was analysed (Ponte, Matos, & Abrantes, 1998).
3. He was supported by a Fulbright grant to work with science education professor Odete Valente.
4. This programme was part of a larger project financed by the World Bank to provide new founded schools for forming primary teachers with teaching staff in all areas. It involved Boston University and the Université de Bordeaux.
5. Domingos Fernandes together with João Ponte and José Matos constituted the Editorial Board.

In 1772 the teaching of Mathematics in Portugal, at a higher level, was transformed with the creation of a Faculty of Mathematics in the University of Coimbra. The newly reformed Portuguese University was ruled by Statutes. In the words of Francisco Gomes Teixeira, these Statutes are a “remarkable dissertation about the teaching of sciences, exquisite both in deepness and form and a monument to healthy pedagogy and high philosophy, written in vernacular and elegant language, where all justifications are clearly explained and justified”¹. In our article we will analyze some parts of these Statutes, aiming to recover a 250 years old mathematical curriculum in what represents lessons to be used in present mathematics education.

Keywords: Portuguese teaching of Mathematics; Eighteenth century; Statutes; University of Coimbra.

INTRODUCTION

The university teaching of Mathematics in Portugal suffered a deep reformation in 1772 when the Faculty of Mathematics at University of Coimbra was created. As far as we investigated, it was the first time, in the world, that one University recognized such a high standard of importance to Mathematics that it created a whole Faculty to teach Mathematics (several/different courses for different degrees) to all students of the University (‘Do curso Mathematico’, 1772, p. 141).

As all the other Faculties reformed or created by this reform, the Faculty of Mathematics was ruled by Statutes, written and published under the guidance of king D. José. Those Statutes are undoubtedly a pedagogical document that might be used as an example for those who are responsible for teaching Mathematics nowadays. This work aims to study a 250 years old mathematical curriculum with the objective to retrieve the teachings of this document to the current mathematics teaching and curriculum development in mathematics.

THE CREATION OF THE FACULTY OF MATHEMATICS AT UNIVERSITY OF COIMBRA

Mathematics was supposed to be taught in Portugal at least since 1559 at the University of Coimbra (Queiró, 1993, p. 4), even though sometimes there was no lecturer available for this course. Mathematics was also taught by the Jesuits who

were installed in Portugal since their very beginnings. Ruling the University of Évora, as well as many other schools/colleges, Jesuits in Portugal became clearly interested in teaching Mathematics and lecturers/teachers were always available.

In the beginning of the eighteenth century Portuguese mathematicians started to publish books on recent mathematics, as *Theorica verdadeira das marés* by Jacob de Castro Sarmiento or *Logica racional, geometrica e analytica* by Manuel de Azevedo Fortes (Queiró, 1993, p. 11).

By 1750, D. José reached the Portuguese throne and called Sebastião José de Carvalho e Melo, later known as Marquês de Pombal, to be his Secretary for Foreign Affairs. Six years later Marquês de Pombal becomes Minister of the Kingdom with larger powers to rule. His powers were in particular used to reform the school system in Portugal, expelling the Jesuits (by 1759) and implementing reforms from the very elementary level to the university level (Teixeira, 1934/2010, p. 223 – 232).

Marquês de Pombal went to Coimbra to formally open in 1772 the newly reformed University. Under this reform the five faculties (Theology, Law, Medicine, Philosophy and Mathematics) included two new ones (Philosophy and Mathematics). The creation of the Faculty of Mathematics was justified right at the beginning of the Statutes:

Mathematics has such an indisputable perfection among all natural knowledge, as well as in the luminous accuracy of its method, and in the sublime and admirable speculation of its doctrines; that it deserves the name of sciences not only in rigor but with property; but it is also the one which has singularly believed in the Man's strength, skills and sagacity. For that reason it is extremely necessary, also for security and improvement of other Faculties, that this science has at the University an adequate establishment of its place, occupied in the General System of Human Knowledge; being clear, that if that same University was dismissed of the Mathematics lights, as it unfortunately was in the past two centuries, it would not be more than a chaos, similar to the Universe, if deprived from the brightness of the Sun. ('Do Curso Mathematico', 1772, p. 141, the translation from Portuguese and the underlines is ours but the punctuation is the original)

THE STATUTES OF THE FACULTY OF MATHEMATICS

The Author and his Inspiration

José Monteiro da Rocha (1734 – 1819) was the author of the Statutes for the Faculty of Mathematics. He was born on June 25th, 1734, in small town in the north of Portugal called Canavezes (Amarante). It is also known that in his youth Monteiro da Rocha went to Brazil to study with the Jesuits. By 1752, he was teaching in the Jesuit's "Colégio da Baía". When Marquês de Pombal expelled the Jesuits from Portugal, in 1759, Monteiro da Rocha left the Society of Jesus (Fernandes & Figueiredo, 2006).

Having been a member of the Society of Jesus, Monteiro da Rocha wrote the Statutes naturally influenced by the Jesuit pedagogy. Indeed, at a first glance, the organization of the Faculty Statutes seems very much alike the organization of *Ratio Studiorum*, the pedagogical code for the Jesuits published in 1599, but a comparative study between these two documents remains to be done.

The importance of the studies of Mathematics

We have seen previously the general justification given by Monteiro da Rocha in the Statutes for giving to Mathematics a higher place within the University. But he continues saying that:

[Mathematics] not only goes through a road of lights, from the first Axioms, to the most sublime and recondite Theorems; but it also illuminates the understanding in the study of other Courses: showing them the most perfect example on how to treat a subject according to order, precision, strength, closed chains and even joining some truths to others: inspiring the pleasure and the necessary discernment to distinguish the solid from the frivolous, the real from the apparent; the Demonstration from the Paralogism: and giving them an accuracy, according to the Geometric Spirit; rare and precious quality, without which they cannot go on neither make any progress in the knowledge of Mankind. ('Do Curso Mathematico', 1772, p. 141-142)

The justifications of every single statement are clear, complete and rigorous in all the analyzed documents in the Statutes.

These Statutes also include applications of Mathematics, showing that this science is not only a theoretical one but also a practical: regulation of time; geography; cartography; tactics for army; architecture and engineering are some of the subjects that may be found in the Statutes.

Mathematicians: a “special career”

The goal for teaching Mathematics at the University was to create professional Mathematicians. The career of "Mathematician" and the research on Mathematics were encouraged, as stated in the Statutes ('Do Curso Mathematico', 1772, p. 148-150), by counting the years spent in the Faculty of Mathematics as years spent in war campaigns for the allocation of social benefits, such as social status. Having a degree in Mathematics would, in particular, grant advantages in getting a place in the Army. Furthermore, those who were Doctors in Mathematics would officially be in advantage when applying for jobs.

Awards, called "*Partidos*", were to be given to students with exceptional classifications. These awards would stimulate students to study and encourage them for following a scientific carrier ('Do Curso Mathematico', 1772, p. 216-218).

On the other hand, sanctions were imposed on those who did not recognize the benefits of studying mathematics, for example to those who, when offering jobs, did not give priority to holders of a degree in Mathematics as well as to the students that

did not perform well on the tasks of the courses ('Do Curso Mathematico', 1772, p. 202).

THE DEGREE OF MATHEMATICS

The degree of Mathematics was composed by four courses distributed in 4 years: *Geometry* in the 1st year; *Algebra* in the 2nd year; *Phoronomy*² in the 3rd year and *Astronomy* in the last. There also existed a course in *Design and Architecture* (Civil and Military), for students who showed interest in these courses.

The lessons of the four years of the degree took place every day of the week, with the duration of one and a half hours, according to the years (the students attending 1st and 2nd year had classes in the morning while the students in 3rd and 4th years in the afternoon).

The lessons were divided into two different parts. In the first one, the students were asked about the previous lesson and were allowed to ask the lecturer to explain their doubts. The second part of the lesson was for lecturing without interruption from the students and, in this case, the lecturer was advised to follow the "inventor's path", this is, following the historical development of the subjects. The students should then go home to study the lesson and wait for the following day for further clarification of the subject (Do Curso Mathematico', 1772, p. 200-201).

The lessons of Geometry

The first course in the degree was Geometry and it was taken not only by the mathematics students but also by every other student from all the other faculties. The subject of study was elements of Arithmetic, Geometry and Trigonometry.

The beginning of the course included, each year, the prolegomena where the lecturer would present the subject, its division and generalities such as the method, the utility and the excellence of Mathematics. The lecturer would also present an abstract on the History of Mathematics, including Greek and Christian ages as well as Descartes. This prolegomena aimed to motivate students for Mathematics ('Do Curso Mathematico', 1772, p. 169).

The prolegomena was followed by Arithmetic: the importance of symbols and Arabic notation; the notion of number, unity and the fundamental idea of numeration; the learning of the four fundamental operations and their justification; the quadratic and the cubic numbers; the root extractions; proportions; both arithmetic and geometric progressions; rules of three and false position; logarithms.

Subsequently, Geometry was taught, which was considered vital for the development of mathematical reasoning.

This science [Geometry] requires all possible attentions because it is the basis for the lessons of the following years: and because in that science there must be the use of judgment to feel the evidence of the mathematical reasoning; to search for accuracy and

Working Group 12

Geometrical rigor of the Demonstrations; and to think methodically in every subject. ('Do Curso Mathematico', 1772, p. 172)

Here, the lecturer would once again start with history (of Geometry) followed by notions, definitions and fundamental principles, the relationship between theory and practice and finally the stereometry and its application to measurement of tunnels, piles and ships.

In the last part of the course trigonometry was to be studied: preliminary notions, construction of tables for *sines* and *cosines*, use of those tables and analysis of triangles using trigonometry.

The lessons on Algebra

Algebra was the 2nd year course because it was understood as being more abstract and containing principles that were more difficult than Arithmetic and Geometry. As a result, the lecturer was due to use all his capacity for making his students understand such an important science.

The lecturer should engage himself with care in the complete and profound instruction of his students in this sublime and important Science, from which it depends the large progress, that can and should be done during the frequency of the degree of Mathematics: because it is the place, where all the spirit of invention, so necessary to this science, is formed; and it is the instrument to everything that can be discovered about quantity. ('Do Curso Mathematico', 1772, p. 175)

The study of Algebra started with a historical abstract and the presentation of the three principal items: to express any and every circumstance, conditions and relationships of quantities in algebraic language; to know how to combine the conditions with each other and to do all operations on them to reach the intended purpose; finally to explain the result of algebraic manipulations.

Then, students would learn literal calculus (the fundamental operations on magnitudes simple, complex, fractional, rational and irrational), equations (general and particular properties, method of preparation and transformation), fundamental rules of analyses, conic sections, differential calculus (definitions, differentiation rules and general theory of curves) and integral calculus (fundamental rules and applications).

One of the most important aspects in Algebra should be its connection with Geometry. To relate these two sciences, the lecturer, after presenting the literal calculus and equations, should present to his students the use of the rules in solving geometrical problems (determined and undetermined) and should practice those exercises until students achieve skill and sagacity. The same should be done for differential and integral calculus ('Do Curso Mathematico', 1772, p. 177-182).

The lessons of Phoronomy

In the lessons of Phoronomy, in the 3rd year, the physics of bodies, fluids, light and sound were studied.

The aim to study physics in the Faculty of Mathematics was to give a profound knowledge of the science of movement. The students were meant to attend lectures during the second year, lessons on experimental physics in the Faculty of Philosophy where they were to learn about the physical phenomena. Then, in the lessons of Phoronomy, the lecturer should provide justifications to those phenomena using chains of mathematical reasoning, given by the methods of calculus and geometry. The lecturer was preparing the students to go beyond the obvious, analyzing and generalizing the studied principles ('Do Curso Mathematico', 1772, p. 182-184).

The lessons of Phoronomy started with the study of the physics of bodies, the statics, mechanics, dynamics and ballistics. Following these, the students were to study the physics of fluids: hydraulics, hydrostatics and hydrodynamics. The physics of light contained optics, dioptrics, catoptrics and perspective. Finally, in acoustics, students were to analyze a small number of phenomena such as the vibrations of chords, using the Mathematical calculus.

Although, Architecture was not clearly seen as part of Mathematics, students could also study it in form of mechanical problems.

The lessons of Astronomy

The lessons of Astronomy started, as usual, with a historical abstract: beginning with the Astronomy to Hipparchus, going through Ptolemy, Albategnius, Kepler and Newton. The historical abstract, along with the presentation of the subject and method, aimed to introduce students to the course with pleasure and motivation ('Do Curso Mathematico', 1772, p. 189-190).

The lessons would then continue with a preliminary treatise on spherical trigonometry followed by three different aspects of Astronomy: the knowledge of phenomena deduced by observation; the proof of the physical reasons for the observed phenomena; the establishment, in consequence of these reasons, of rules to determine the studied phenomena at any given time.

The fixed stars, the planetary movements and the eclipses of satellites were also studied. In the last part of the lessons the Chronology and the Calendar were considered without reference to its historical development.

The study of Astronomy was not only theoretical but also practical. An Astronomical Observatory was built and furnished with the best instruments available at the time, so that the students could have practical sessions and be instructed in the observation of astronomical phenomena.

The lessons of Design and Architecture

In the Design and Architecture course, students were able to learn metaphysics of the design (skill, style, accuracy and expression), Civil Architecture, Military Architecture and maps.

As referred previously, these lessons were not compulsory but the students were advised to attend to it during their 3rd or 4th years.

The Exercises

During the Mathematics degree the students had to make several exercises. Oral, practical and written exercises were proposed daily, weekly and monthly.

The oral exercises aimed to prove the understanding and demonstration of the contents. All students were asked to explain some proposition or a theorem, and those who demonstrated a difficulty in this, would benefit from the help of others, designated as their tutors. This was definitely a proof of real cooperative education ('Do Curso Mathematico', 1772, p. 198-202).

However, the exercises were also practical, since Mathematics was applicable to different uses in daily life ('Do Curso Mathematico', 1772, p. 202).

Written exercises were problems requiring that students meditate about what they had learnt, combining subjects and developing new concepts. Students were encouraged to deliver their solutions as fast as they could, since the lecturer would only receive 5 or 6 good solutions. Those solutions were then published as a method to stimulate students' further learning. There were also monthly exercises, which required some discussion, presented by every student in a brief dissertation. Again, those exercises were used to prepare students for research ('Do Curso Mathematico', 1772, p. 204-205).

THE TEXTBOOKS

The textbooks for which the lecturers should follow their lessons were also considered in the Statutes. Although there was no fixed textbook, at the end of each academic year, the Congregation of Mathematics³ should choose proper textbooks for the following year, since mathematics was considered to be a science in constant development. Nevertheless, the chosen textbooks were deemed to have to accomplish some conditions:

[The Congregation] should always consider that the Treatises, that have to be explained, are concise and elementary; and contain the most effective and sublime methods that are known; so, those who gain their degree following them, will be entitled to understand without obstacles the deeper scripts that exist in these sciences. ('Do Curso Mathematico', 1772, p. 164)

A case was also considered where no adequate textbook existed for a specific course. In that instance, the lecturer should write his own treatise in order to facilitate the

Working Group 12

students' study and to contribute to development and research of Mathematics as well as those sciences that depend on Mathematics. For those treatises that were chosen, no oral commentary was allowed except for the lecturer who, when necessary, had to present all the demonstrations to his students.

The choice of textbooks was therefore a task for the Congregation, but there is one textbook mentioned explicitly in the Statutes: Euclid's *Elements*. The geometrical books of Euclid's *Elements* (from 1st to 6th) had already been translated into Portuguese, in 1756 by João Ângelo Brunelli, and so this was used for Geometry lessons. The choice of this textbook is also clearly justified in the Statutes:

In it [the Geometry textbook] it is required that not only each geometrical truth is rigorously demonstrated; but also that all together these form a stable, sequenced and continuous chain of matters; there should not exist any lonely proposition; but all interacting with each other. And with these advantages there is no other author to the present date who wrote, with such perfection, as Euclid did in his *Elements*, for the reasons of which the lecturer will follow the lessons. ('Do Curso Mathematico', 1772, p. 164)

Together with Euclid's *Elements* the Statutes also mentioned Proclus' *Commentary on Euclid*, noting that the lecturer should follow it in order to explain to the students the metaphysics of Geometry.

By the time that the Faculty was created, *Elementos de Arithmetica* and *Elementos de trigonometria plana* by Bezout were also chosen for Geometry (along with Euclid's *Elements*). *Elementos de Analisi Mathematica* by Bezout were chosen for Algebra. *Tratado de Mecânica* by Marie, *Tratado de Hidrodinamica* by Bossut and *Optica* by La Caille were the three textbooks for Phoronomy, while *Astronomia* by Lalande was chosen for the 4th year of the degree (Freire, 1872, p. 38).

The privileged choice of French authors for the Faculty of Mathematics did not seem casual since Portugal and France had maintained very good relationship in relation to concerns in education and the general development of sciences. Indeed, from the very beginnings of Portugal, we can find Portuguese Mathematicians as well as other scientists attending the prestigious French Universities as students, such is the case of Manuel de Azevedo Fortes or José Soares de Barros e Vasconcelos. Admirably, the cited textbooks were immediately translated into Portuguese facilitating this way the study of these mathematical subjects.

FINAL REMARKS

The creation of the Faculty of Mathematics at University of Coimbra by 1772 and the principles defended by the Statutes that ruled it conduct to a change in the study and teaching of Mathematics in Portugal. This huge reform of the teaching of Mathematics leads to the development of the teaching of mathematics at other levels. Furthermore, in the Academies which prepared the Portuguese army (Brazil

Working Group 12

included) Mathematics was a central subject and many students graduated in the Faculty became lecturers at these Academies.

The foundation of an Academy of Sciences in Lisbon, by 1779/1780, also fomented the study of Mathematics, particularly by one of its founding and most influential partners: Monteiro da Rocha, himself.

Nowadays, in Portugal, as well as in many other countries, the mathematics curriculum follows closely the *Principles and Standards for School Mathematics* published by the National Council of Teachers of Mathematics (NCTM).

These “new” standards for teaching mathematics present, in our opinion, the same structure and the same ideals already presented in the Statutes for the Faculty of Mathematics of University of Coimbra, almost 250 years ago, namely: rigour in teaching a science such as Mathematics; the importance of the study of Mathematics for everyday life; the importance of the History of Mathematics for the contextualization of the content taught and for increasing student motivation; the importance of a systematic and continuous study by students to a better understanding of the content; the cooperative education that allows students to help each other in pursuit of success; the careful choice of textbooks suitable for students and enabling them to acquire mathematical knowledge consistently; and, in addition, the constant appeal to promote excellence and encourage effort in students’ work.

In Portugal, together with this “perfect” historical example, we might/should also speak of the possible cultural advantages of referring/following such an important curriculum in Mathematics.

Simultaneously, teachers and others responsible for the development of mathematics curriculum worldwide might also use these Portuguese Statutes both as a tool in their work, look at the examples of teachings presented in this document in daily classes, and as a reference to reflect upon Principles and Standards of nowadays. In fact, we are in this matter sharing Herodotus’ opinion that by knowing the past we can better understand the present and steadily prepare the future.

NOTES

1. As cited in Estrada & Ralha, 2008, p. 733.
2. Phronomy was the name given, in the 18th century, to the physics of the movement.
3. The Congregation of Mathematics was a governing body, chaired by the University Rector and formed by all lecturers of the Faculty of Mathematics, with the aim of making the Statutes to be accomplished.

USING STUDENTS' JOURNALS TO EXPLORE THEIR AFFECTIVE ENGAGEMENT IN A MODULE ON THE HISTORY OF MATHEMATICS

Maurice O'Reilly

CASTeL, St Patrick's College Drumcondra, Dublin 9, Ireland

The author taught a module on the History of Mathematics to a class of nine second and third year students taking a three-year BA in Humanities. Students were required to keep a learning journal for the duration of the module. This paper considers extracts from students' journals that can reasonably be identified as coming from their respective 'participant' persona (Liljedahl, 2007). These extracts have been classified in an effort to gain insight into the affective domain of these students' engagement with the module. Questions of sustainability, contingency and authenticity arise.

Key words: journaling, affective domain, history of mathematics, persona

INTRODUCTION

It can take a while for a mathematician to gain confidence to offer a module in the history of his subject. In my own case, eleven years! My first serious question arose about spring 1997, while teaching algebra to computing students at Dundalk Institute of Technology, between Dublin and Belfast. It was this: The civilisation of Baghdad had a flourishing mathematical community in the late 8th century (CE). At that time there was a vibrant civilisation in Ireland. What, if any, mathematical activity existed in the latter? I still have not answered this question, yet I know more about it than I did in 1997 (O'Reilly, 2009). I offered a module on the history of mathematics for the first time in the spring semester of 2008. The second time was two years later. In the intervening period, I had the good fortune to attend the HPM satellite meeting at ICME-11 in Monterrey, Mexico. Fourteen months later, Jan van Maanen presented a paper in Dublin (van Maanen, 2009) which stopped me in my tracks. It alerted me to the deeply intricate interactions between History of Mathematics, Mathematics and Mathematics Education, and, in particular, it propelled me to begin to use original sources.

Glaubitz (2010) suggests that using original sources in teaching is a demanding activity, yet the rewards can be very significant. He mentions, *inter alia*, how such sources sharpen students' awareness of representation and provide material for debate on what matters. Indeed, their very strangeness can give rise to useful 'anchor points' for teaching. His appraisal of the use of original sources in the mathematics education is positioned in a landscape of hermeneutics. Kiernan (2010) also acknowledges the challenge to the instructor in designing a History of Mathematics module and, in particular, when the use of original material is considered. These authors echo the work of Jahnke (2002) who recognized the study of original sources

as the most ambitious, yet most rewarding, way to integrate history into teaching mathematics.

Janqvist (2009, 2010) distinguishes between two models of using History of Mathematics in Mathematics Education, one where history is used as a ‘tool’, the other where it is the ‘goal’ of the endeavour. In the planning and implementation of the latter model, ‘meta-issues’ will arise including: how students’ ‘virginal beliefs’ are modified during a history course; how to anchor comments, arguments and discussion; the need to orientate questions in a variety of registers (e.g. historical, sociological or philosophical). He calls for more research in the HPM community to relate HPM to Mathematics Education research. One can expect a healthy symbiosis! Fried (2010) raises a call to arms (or is it peace?):

The tension between the aims of history of mathematics and the other aims in mathematics education must be confronted if one wishes to embrace the history of mathematics not as a tool but as an inquiry important in its own right.

He makes the case for Mathematics Education to be ‘justified’ not just on the basis of utility, but also of culture. This issue was discussed by OReilly (2000), albeit in relation to Mathematics.

This paper considers issues arising from personal experience of offering a one-semester undergraduate module on the history of mathematics in a two-subject BA programme, with mathematics as one of those subjects. An effort is made to situate this experience in a broader setting. Part of this setting is informed by the author’s collaborative work on mathematical identity and narrative (Eaton & OReilly, 2009), although an explicit link to this work is not made here. Instead, students’ learning journals are used as primary data; these are set in a framework modifying that of Liljedahl (2007). The question addressed is: how can evidence from students’ journals be harnessed to explore their affective engagement with mathematics and its history?

OVERVIEW OF MODULE DELIVERY

The module under discussion was a required mathematics module taken by second and third year BA students in the second semester (late January to mid-May) of the 2009-2010 academic year. It was spread over a period of fourteen weeks (excluding a two-week Easter vacation period) and involved 44 contact hours nearly a quarter of which took place in a computer laboratory. Seven second-year and two third-year students took the module. Typically few BA students choose mathematics.

The stated learning outcomes of the module were that students should be able to:

1. Outline in very general terms the timeline of the development of mathematics
2. Describe significant historical periods when key changes in mathematical thought occurred and new areas emerged

Working Group 12

3. Summarise some important contributions of prominent mathematicians
4. Explain how topics arising in school mathematics developed historically
5. Discuss important examples of cultural factors influencing the development of mathematics
6. Discuss the technical details of specific mathematical problems pertinent to 2-5, above
7. Situate points 2-5, above, in a broader historical context

In retrospect, examining these through the lens of Jankvist's 'tools' and 'goals', it seems appropriate to conceive learning outcomes 1, 2 and 5 as focusing on *the developmental and evolutionary aspects of mathematics as a discipline* (Janqvist, 2009) and hence on 'history as a goal'. On the other hand, learning outcomes 3, 4 and 6 are concerned more with 'history as a tool', that is with *how students learn mathematics*. Outcome 7 serves both of these purposes.

The module was anchored around reading Derbyshire's *Unknown Quantity* (2006). This book was chosen because it is accessible (and affordable!); moreover it covers a broad canvass of the history of algebra as well as touching on aspects of geometry. Anyone acquainted with the book will know that it is not without shortcomings. Some serious reviewers (Grabiner, 2006; Katz, 2006; Segal, 2008) will consider this an understatement, yet the defects are, for the most part, in the detail or in Derbyshire's sometimes arbitrary preferences in his emphasis and his irksomely gratuitous remarks. This author has found the book a helpful bridge for undergraduate students between mathematics and its history. Its shortcomings were compensated for by using additional reliable sources (e.g. Bos 1980; Cardano, 1545; Kwārizmī, 1831; Leibniz, 1675/1920) to expose students to original material in some detail; moreover the book's defects led to interesting discussion on meta-issues relating to the module.

Most of the module dwelt on the history of algebra (from its origins to the solution of polynomial equations to the emergence of abstract algebraic structures) with a three-week insertion of the history of the calculus (with emphasis on Leibniz' contribution). Both the computer algebra system, Maple, and the dynamic geometry system, GeoGebra, were used to support students' exploration of the mathematical detail of the material under consideration (e.g. Kwārizmī's classification and solution of quadratic equations and Leibniz' transmutation rule, following the actual historical conceptions closely). A variety of web (e.g. O'Connor & Robertson, 2010; Lee 2007) and library resources was recommended. Thus there was a significant diversity of register amongst the resources presented to students.

Now let us turn to the focus of this paper, the students' learning journals. As part of assessment for the module, students were required to keep a learning journal (LJ). Students were directed as follows:

Working Group 12

You should bear three things in mind as you prepare your LJ:

1. It should indicate your engagement with the [module].
2. It should include reflection on this engagement.
3. You should see it as useful for [module] revision when preparing for the final exam.

For 1, you are recommended to include a summary (in your own words) of the main topics/themes encountered, covering both mathematical concepts and historical notes. You should complement each summary by indicating the key technical details of relevant problems.

For 2, you might wish to comment on how you encountered each topic/theme: what you found surprising; what you found easy or hard; to what extent GeoGebra or Maple helped you with your understanding; how your personal understanding of a particular topic/theme has been influenced by studying its historical evolution.

Clearly these directions were not prescriptive, thus allowing each student considerable leeway in choosing how to articulate her/his own learning. All nine students show significant engagement in the module. However some chose to focus exclusively on summarizing mathematical and historical detail (valuable for module revision and exam preparation), rather than reflect on their engagement and reveal aspects of the affective domain.

DATA FROM STUDENTS' LEARNING JOURNALS

Students' personas

Liljedahl (2007) considers three personas, *narrator*, *mathematician* and *participant*, that students use in journaling. His goal is to achieve authenticity in representing the processes in which students engage in tackling mathematical problems.

The *narrator* moves the story along. ... The *mathematician* is the persona that provides the reasoning and the rational underpinnings for why the mathematics behind the whole process is not only valid but also worthy of discussion. Finally, the *participant* speaks in the voice of a real-time evolving present. This persona reveals the emotions and thoughts that are occurring ... as he is experiencing the phenomenon. (p. 663)

Let us adapt these personas to the purpose of the title of this paper. The *narrator* chronicles the progression of the module. The *mathematician* documents the mathematical detail (both conceptual and technical). The *historian*, a new persona necessary in this context, documents the historical detail (narrative, timeline, context, etc.). The *participant* reveals what is actually happening for the student as the module progresses. For our purpose, we focus exclusively on the participant persona, for it is precisely this persona who reveals a student's affective engagement in the module. It is important to point out that personas, by their nature, overlap to some extent, and so we choose (as outlined below) to consider a rather broad expression of

Working Group 12

the participant persona including situations when this persona draws on the substance of mathematics or history, but with an affective lens.

Of the nine students taking the module, only five of them expressed their participant persona significantly in their journals. There were 161 such expressions amongst these five: Michael (13), Olivia (33), Rachel (37), Seán (30) and Tara (48).

Classification of data in the affective domain

In classifying these 161 instances, nine codes were identified:

- Expressions of *interest* (33)
- Expressions of *enjoyment* (17)
- Expressions of *surprise* (29)
- *Anticipating* (looking forward) (10)
- *Recalling* (linking to already known facts) (5)
- *Reflecting* (articulating general insight) (34)
- *Understanding* (articulating specific insight) (25)
- Identifying what is *easy/hard* (39)
- Identifying what is *helpful* (36)

The distinctions between the first three of these are not always clear-cut. Typically ‘interest’ refers to a fairly neutral expression, ‘enjoyment’ indicates something stronger, while ‘surprise’ identifies situations where a student has shown a significant change of attitude or deepening of insight.

In the context of the data, it makes sense to refine Liljedahl’s participant persona into five sub-personas:

- The *maths participant* who expressed evolution of mathematical understanding (95)
- The *history participant* who expressed evolution of historical understanding (32)
- The *inner participant* who expressed a strong personal conviction indicating attitudinal change (15)
- The *outer participant* who expressed a considered judgement about the world outside (13)
- The *spectator* – the other participant who articulated the affective domain without evidence of particular understanding, conviction or judgement (27)

The frequency of each code and sub-persona is indicated in brackets. Of course the sum of the frequencies, in each case, exceeds 161. The general approach to classification here is well-established grounded theory adapted to the context and scale of the data. Here, the maths participant is to be found where the mathematician

Working Group 12

and participant personas overlap; likewise the history participant is located where the historian and the participant meet. The intention is that this refinement of the participant persona will bring out more clearly distinctions within the affective domain as students reflect on mathematics and its history. The use of the nine codes appears to be of much less significance. In the presentation of data and discussion which follow, we will focus on the personas.

PRESENTATION OF DATA

Let us read the words of each persona (identifying the student by pseudonym and indicating the codes in each case). First, the *maths participant* relating how he feels and thinks about making progress with his understanding of mathematics:

Question 2 [Let $x = t$ be a root of the cubic $x^3 = cx+d$. Find the other two roots in terms of c , d and t .] was one of the questions I struggled with but when it was explained on the board, the ease with which $x = t$ was found to be a solution of $x^3 = cx+d$ was eye opening. It certainly made me feel it could be accomplished easily. (Michael; surprise, easy/hard.)

This was called Leibniz' transmutation. It is developed through the use of the characteristic triangle and yields a transformation of the quadrature of another curve, related to the original curve through a process of taking tangents. I found this lesson useful for developing the idea of how Leibniz developed the transmutation. (Michael; helpful.)

The *outer participant* joins in with the *maths participant* as they make a judgement about the presenter's behaviour yet in the context of mathematical reflection:

In today's lecture we watched Donny Lee from Singapore, work on Leibniz and his formula for π , on You Tube. He links the famous formula ... to Leibniz transmutation rule. He does this with great enthusiasm, so much so that when watching it for the first time I believe he got 'carried away' to a certain extent which resulted in me being completely lost. However when I watched it for a second time I think I learned and understood a little more. I hope this will continue to happen. (Rachel; reflecting, understanding.)

Now we hear the *maths* and *history participants* together as they place mathematical development within an historical narrative:

For the essay I picked the history of notation as I thought it covers so much time that it would help me learn more about the development of Maths. I enjoyed doing it as I was interested in the development [through] the ages and what different people at different times [did]. But I found it very hard to condense such a massive topic. I could have [written] pages and pages. I also [tried] my best to bring in some [GeoGebra] and Maple. (Tara; interest, enjoyment.)

Next the *history participant* alone, reflecting on how the historical discipline helped her understanding:

Working Group 12

From keeping the Journal and constructing the time line, I know if I had to write a bit about all of the above, I could. I found this really [helpful]. (Tara; helpful.)

The *history* and *inner participants* join forces showing a powerful transformation in perspective, articulated unambiguously:

Since researching my essay on women mathematicians my attitude towards mathematics has been altered. Although of course these male mathematicians achieved great things during the 16th & 17th century, I can't help but think about women such as Sophie Germain and Maria Agnesi. These women had to fight so much harder than their male counterparts to achieve [and] succeed in this area. They did not receive the same respect or education that they should have been entitled to. (Olivia; surprise, reflecting.)

Now we hear the voice of the *inner participant* alone, clearly asserting his own learning style and suggesting a personal strategy on how to gain even more insight:

Felt in a much better mood about the maths since last class and was raring to go. As a result, dove in today head first into analysing the diagrams given on 23/2 (yesterday) and using the graphs and seeing Geogebra in action helped me visualise. From today's [two] classes I have concluded that I am in fact a very visual learner rather than theoretical [and] algebra side of things. All I need to do now is to make stronger links between them! (somehow) ☺ (Seán; anticipating, reflecting.)

Here is the strong voice of the *outer participant* in the presence of the *history participant*, critical of Derbyshire's treatment of the narrative of early algebra:

I feel that Derbyshire presents a biased attitude towards Al-Khwarizmi's achievements and the Arabic way of thinking in general. He has a very negative opinion of Al-Khwarizmi's way of thinking. In fact, I feel that he has an extremely condescending attitude towards this great Arabic mathematician. On the other however Derbyshire appears to believe that the Hellenic way of thinking is much superior to the Arabic way. He praises Diophantus throughout. (Olivia; reflecting.)

Finally an example of the *spectator*, expressing interest in the preoccupation of the Arabic mathematician with Islamic law:

We learn that the Islamic law of inheritance played an extremely important role behind the development of algebra. I find it extremely interesting that Al-Khwarizmi devoted a chapter in his book 'al-jabr' to the solution to the Islamic law of inheritance using algebra. (Rachel; interest, reflecting.)

DISCUSSION AND CONCLUSIONS

Here the cohort of students is small – only nine – and the cohort of those who engaged in the affective domain a mere five. Yet it is remarkable how rich the data is and how varied the style of its expression. The classification by code and by (sub-) persona provides a structure underpinning an intricate interaction between different aspects of students' learning processes in the affective domain and the implementation of diverse teaching approaches.

Working Group 12

The voices of these participants, and, in particular, that of the *inner participant*, resonate with recent work of Rosas Mendoza and Pardo Mota (2010). These authors report on how students engage in a very personal way with mathematical ideas when working with original sources, such as Newton's *Principia*. Two of the extracts given above (the second and last) demonstrate significant engagement with original sources. There is strong evidence, especially in the voice of the *history participant*, of a humanistic understanding of the development of mathematics (Liu, 2010), and that sustained collective effort with mathematics bears fruitful results. All participants, and especially the *maths participant*, displayed evidence of 'working with doubt' and of the 'struggling mathematician' which/who draws a parallel between the learning of mathematics and the development of mathematics by its first inventors (van Maanen, 2010). We see here that working with an historical lens invigorates learning.

The module described here drew from a variety of sources: YouTube, 'popular' mathematics, fundamental invention (Lee, 2007; Derbyshire, 2006; Leibniz 1675/1920); it evoked diverse affective (and other) engagement from students as evidenced by the personas and sub-personas described above. Liljedahl (2007) suggests that students work with more mathematical awareness when they tune in explicitly on personas while journaling. Such 'specific focus' places demands on students. To what extent are such demands reasonable? It seems that the use of journals is particularly fruitful when used in the context of history of mathematics. Moreover, it is helpful to refine the participant persona as described in this paper since such refinement helps distinguish aspects of students' affective engagement with mathematics and its history. There are, of course, practical questions when we seek to implement such a framework in the teaching situation. How might students tune in to their personas and sub-personas, even when not journaling? How can this work be sustained, be implemented efficiently, be deepened? How can its contingency be nurtured, its authenticity assured?

A CROSS-CURRICULAR APPROACH USING HISTORY IN THE MATHEMATICS CLASSROOM WITH STUDENTS AGED 11-16

Peter Ransom

Bath Spa University

Over the past decade I have developed many lessons that use history in the mathematics classroom. These lessons are cross-curricular using events from history to enthuse students in their learning of mathematics. They show that the mathematics used today had, and continues to have, applications to everyday life. As well as being classroom lessons these episodes form mathematics masterclasses done on Saturday mornings around the UK incorporating Texas Instruments handheld technology. The lessons use old and new technology to provide students with an insight into how they are made and used. Recent developments with the STEM (science, technology, engineering and mathematics) initiative in the UK mean these lessons are even more relevant. The two newest episodes are described here.

THE RESEARCH IMPETUS

I incorporate events from history into mathematics lessons because I find it very interesting to see the practical applications of mathematics set into the period when it was used. My research questions are qualitative and are concerned with whether students find it interesting and if it helps improve their attitudes to mathematics. I chose to write about these two episodes since they have been developed over the past year and are both very rich in mathematical history. The Galileo episode emerges from an anecdotal point of view incorporating cross-curricular work with science, the Brunel one uses examples from his original calculation books.

Using Jankvist and Grattan-Guinness previous works (Jankvist 2009, Grattan-Guinness 2004), Tzanakis & Thomaidis (2011) classify the arguments and methodological schemes for integrating history in mathematics education and my episodes fit into the two-way table mainly as *History-as-a-tool* and *Heritage* though there are overlaps into the *History-as-a-tool* and *History* cell (*op.cit.* section 4, Table 1). The overriding concept in my work is *History-as-a-tool*.

The reliability of this research in the sense of reproducibility by someone else is impossible to quantify, since teachers use such episodes in different ways with different students and probably not in costume! Every session I do with students is different according to local conditions and the knowledge students bring to the sessions, so results will vary.

THE EVOLUTION OF THE EPISODES

Back in the 1990s I was introduced to the Royal Institution mathematics masterclasses for gifted and talented 13/14 year old students. These took place (and still do) on Saturday mornings and last for 2½ hours. They are organised by local

Working Group 12

groups of interested teachers and generally take place at prestigious places covering schools within travelling distance. They put on a programme of 4 to 8 sessions (though most places do 6) inviting staff at local schools to nominate a couple of students who would benefit from these masterclasses. Members of staff are also invited to attend and without these volunteers the sessions would be difficult to run since they attract between 30 and 60 students each session. These volunteers help when students are involved in the tasks since the sessions involve a lot of interactivity. The topics offered vary considerably and cover a wide range of mathematical topics. As the years progressed I felt that there was plenty of material that was suitable for general classroom work and so by developing the masterclasses I do in my own classroom I was able to trial the work with a wide variety of ages and abilities.

In my opinion the work should have relevance to the students, so I always try to include material that covers mathematics primarily and history secondly. However science, engineering and geography also play significant parts and all these are brought together to provide a holistic coherent scenario in which to develop the mathematics. Technology changes daily and in preparing our students for the future we need to use the technology of today as well as that of yesterday so that students become digital natives rather than digital immigrants. In my school and masterclasses I use handheld technology by Texas Instruments since that is what I had in school and it fits the work remarkably well, being portable and wireless.

Sometimes the opportunities arise by chance: a suitable anniversary, an interest or an opportunity can be the spur to spending many hours pursuing threads which gets sewn into a rich tapestry of mathematics. The STEM (science, technology, engineering and mathematics) initiative in the UK is aimed at developing an interest in those subjects since they have shown a drop in numbers at degree level over the years. The STEM programme aims to rationalise and improve the provision of support for students. It puts into practice the recommendations of the STEM Programme Report that was published in October 2006. This report focused on how best to support STEM through school, post-16 education and university and how to streamline the current numerous STEM initiatives and implement them more effectively in every school, college and learning provider. The Government wants to increase students' STEM skills in order to provide employers with the skills they need in their workforce help to maintain the UK's global competitiveness and make the UK a world-leader in science-based research and development. The proposals in the STEM Programme Report build on the Government's strategies for developing a strong supply of scientists, engineers, technologists and mathematicians. By tackling these areas with scenarios that show how they were dealt with in the past I believe it gives students enthusiasm for mathematics and provides them with a rich background of general knowledge. The episodes I mention here are the two latest

Working Group 12

ones that have been trialled with teachers and students in the classroom and then improved after feedback from them and my peers in the last year.

GALILEO AND PENDULA

This was the basis of two one-hour classroom lessons with 15 low-achieving 14 year olds. I wanted to introduce some wireless handheld technology (TI-nspires) so that the class could develop their IT skills, so we set up an experiment that involved just string and a mass to act as a pendulum. The students were asked to work in pairs since there was a need for one to record data and the other to time the pendulum swinging. After logging on to the wireless system in the classroom, all students were sent a file to the nspire handhelds. This consisted of a page about Galileo and a bit about his work with pendula, but not the result he found. The advantage to the student (and teacher) is that the work they are doing is relayed wirelessly to the interactive white board and refreshed every 30 seconds so the teacher can see how the students are progressing with the work. There is also the added advantage that any student's work can be made to fill the board, so misconceptions can be identified and corrected at an early stage, or good work can be brought to the notice of the whole class with the student presenting their work.

The materials provided in the room included rulers, string, sticky tape, a few stopwatches and some small bits of metal with holes in that can be used as the pendulum's mass. They then worked in pairs to measure the time taken for 10 oscillations of a pendulum (using a stopwatch or their iPhone!) and recorded the time and length of the pendulum, after having discussed what factors they thought affected the time of a swing.

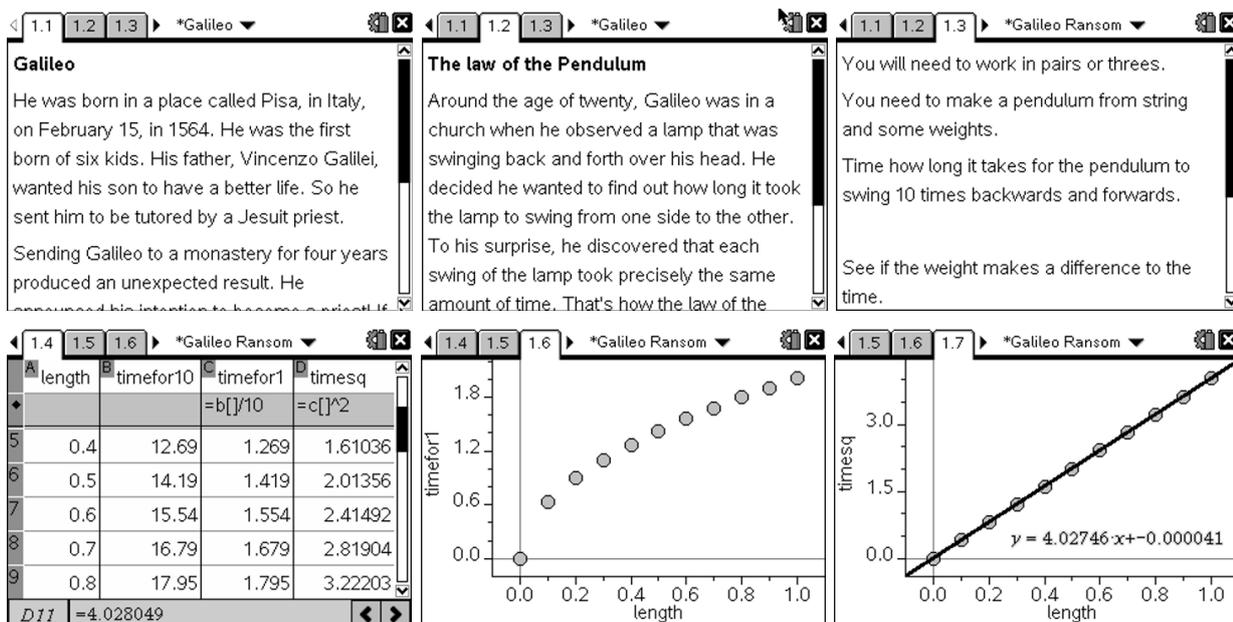

Fig 1: Screenshots from the pendulum experiment and analysis

Working Group 12

They recorded the data collected in a spreadsheet page, using that to calculate the time of one swing. They then used a statistics page to show the data from the spreadsheet. With the low attainers in this class we stopped at that point though higher attainers can experiment with changing the variables on the axes until they find a straight line. Built in menus allow the student to find the equation of the straight line that links the length of the pendulum with the square of the time, then by considering the gradient an approximation for the value of acceleration due to gravity can be found.

Previously I thought this activity was too difficult to do without the technology since the low attainers did not have the graphing skills necessary and this would have frustrated their learning. Using the technology removed this blockage and allowed them to realise that there was a connection between the length of the pendulum and the time taken for a single oscillation.

The other benefits to this class' learning included the following: working cooperatively; developing their creative skills and recording the lengths in metres when they tended to use centimetres to measure. Watching them talk to each other about how and where to put the pendulum was fascinating. Some students attached the string to the doorframe, some to the backs of chairs which they put on the table so they could work with a pendulum length of about one metre. Others tried small lengths of less than 0.2 metres, but soon realised that there were some timing difficulties.

This STEM based activity links the science of pendula with the mathematics and involves students thinking for themselves about making working pendula. This episode was repeated with 90 15 year old students in a large hall at a London comprehensive school in November 2010. It was less successful than in the classroom due to other mathematical activities taking place at the same time meaning that the whole group could not be engaged in discussion about the findings. Feedback from students in the final stages was positive however – they enjoyed working on group activities more than working as individuals since they had learnt from each other and the new technology had not impeded their learning. (Sometimes it is the teacher who fears that technology they do not understand will interfere with their students' learning, but this is rarely the case.) They mentioned that they saw a reason why they had been taught gradient in the past because it now referred to a physical problem.

Did the historical aspect make a difference? I have no evidence to say 'yes' or 'no' at this point since no question was directed at this aspect. However the experiment lesson was preceded by one, where I asked the students to prepare a PowerPoint presentation about Galileo, his life and his mathematical works. This exceeded my expectations since the students were totally engrossed in the work, demonstrating their ability to use the Internet to obtain facts and create impressive files. (This links

Working Group 12

in with the History side of the two-way table mentioned in Tzanakis & Thomaidis (2011).)

When trialling new work with my students I never know what will happen, but with over 30 years' experience of the 11-18 year classroom I think I can judge reasonably well what will be accepted. In the plenary at the end of a session students are asked about what they learnt and it is only the comments that students offer at the end of the lesson that give me an insight into whether these lessons are successful or not. Comments such as 'I learnt loads today about Galileo and some maths'; 'It was good working in pairs' encourage me to continue with such lessons adapting them for different classes. Comments such as 'It was too hard'; 'We didn't have a stopwatch' means I make amendments to the work and try again with another class. This episode survived and will be developed further over the next year.

BRUNEL: BUILDING BRIDGES

Isambard Kingdom Brunel (1806-1859) was an engineer who designed and built many things thought impossible in his day. His Clifton suspension bridge still spans the Avon gorge near Bristol. Much has been done in the UK to encourage teachers and students to work with this image (and others) using dynamic geometry software to find the equation of the bridge's curve.

Your investigation

Use a chain and supports to allow a chain to hang freely.
Stick a paper ruler along the horizontal support.
Use a ruler to measure the vertical distance of the chain from the horizontal support at intervals from where the paper tape starts.
Enter your data into a [spreadsheet](#) page on the [nspire](#).
Use a graph page to show a scatterplot of the data and see if you can find the equation of the chain.

Fig 2: Isambard Kingdom Brunel yesterday and today and the student investigation

Fig 3: The chain and framework

Working Group 12

I decided to make this a more practical activity by investigating the shape of the curve caused by a suspended chain (see above). Initially the work was trialled with prospective teachers at Bath Spa University, then with actual teachers at the Brunel Museum in Rotherhithe, London. The work with 14/15-year-old students was on a large scale with 90 of them in a school hall. The equipment used was a chain (1 metre long) and framework I have previously used in another activity. It is possible to use a cereal box with the front panel cut away to suspend the chain.

They also work in a more practical sense by suspending chains on a framework and measuring the horizontal and vertical distances from an origin. This data they put into a spreadsheet page on a TI-nspire handheld then try to find the equation of best fit using either a graph or statistics page. This helps develop their measuring, algebraic and IT skills.

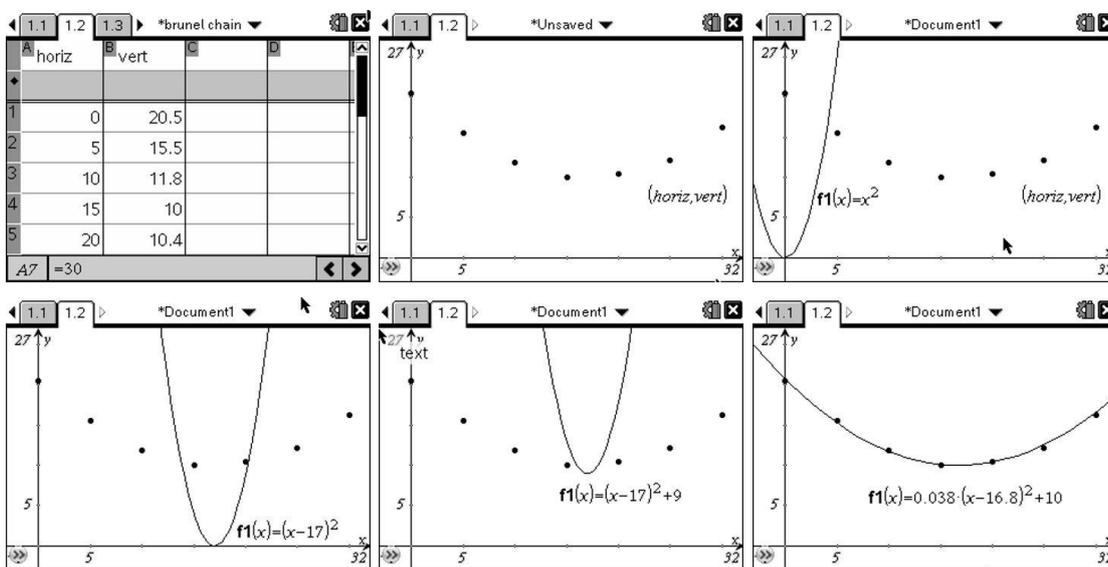

Fig 4: Screenshots of the data and successive transformations of $y = x^2$

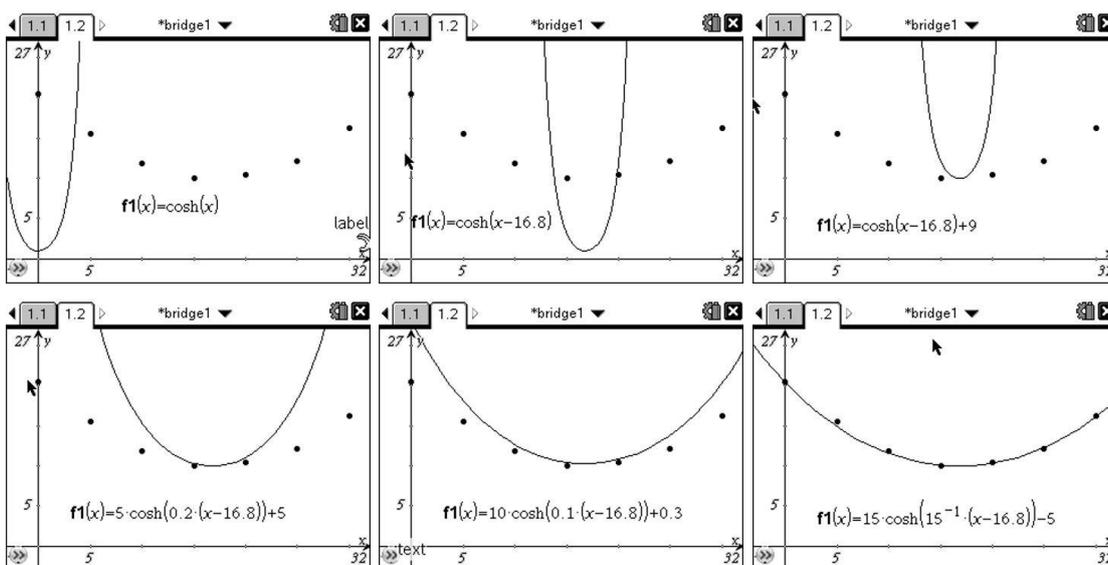

Fig 5: Screenshots of transformations of $y = \cosh x$

Working Group 12

Teachers and students appreciated the practical approach and felt that it strengthened their understanding of transformations. The work with the hyperbolic trigonometric function was not mentioned to students under-16 since that is not part of their syllabus, but the link between the transformations of the quadratic and $\cosh x$ was appreciated by the teachers, though that aspect has yet to be trialled in the classroom.

It is possible to visit the Brunel collection at Bristol University and I have acquired photocopies of Brunel's actual calculation books (see illustrations below). Some of the mathematics he used is appropriate in today's classroom and worksheets have been developed that have been trialled in various situations.

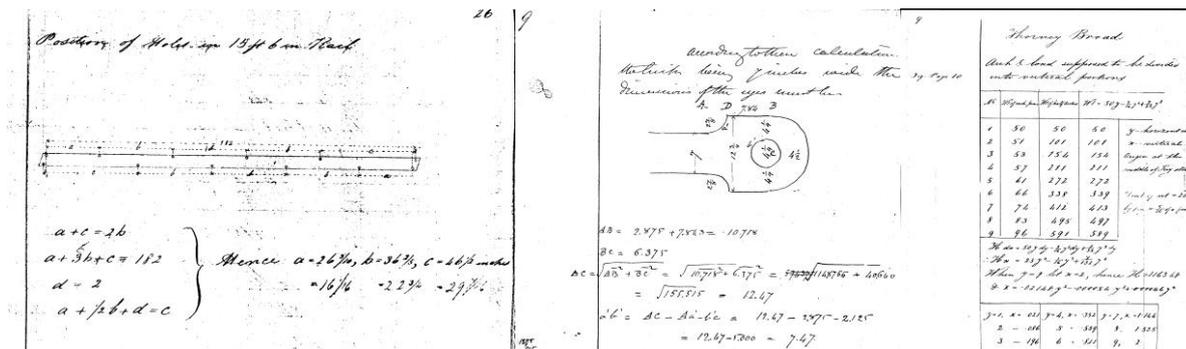

Fig 6: Brunel's use of simultaneous equations, Pythagoras and calculus

Students are asked to check Brunel's solution to the simultaneous equations above, comment on the results and look at the proportion of the two sets of answers. These are used in calculating the regular distances between holes in a metal rod. One student found this work fascinating commenting that it was very interesting to see how simultaneous equations were used in real life.

Students under 16 work with the Pythagoras manuscript, those who have experience of calculus also work with the Thorney Broad sheet. I cover up some of the terms and solutions and students have to work these out themselves.

Fig 7: Brunel's box of mathematical instruments

Proportional dividers, seen here at the bottom of the box (Isambard Kingdom Brunel's initials, IKB, are engraved on them) are used to enlarge diagrams with given scale factors, or used to divide circumferences of circles into a given number

Working Group 12

of parts. Traditionally the sides are labelled with circles (to divide a circumference into 6, 7, 8 ..., 20 parts); lines (to enlarge a given line with a scale factor from 1 to 10); planes (to enlarge a given area with a scale factor from 1 to 10); solids (to enlarge a given volume with a scale factor from 1 to 10). The two legs are equal in length and the central slide allows the pivot to move, thus in effect creating two similar triangles. I have produced replicas in card that students cut out and make, using a paper fastener to act as a pivot. This gives a practical use of ratio and develops an understanding of similar triangles, enlargement and dividing a line in a given ratio. The accuracy is quite astounding!

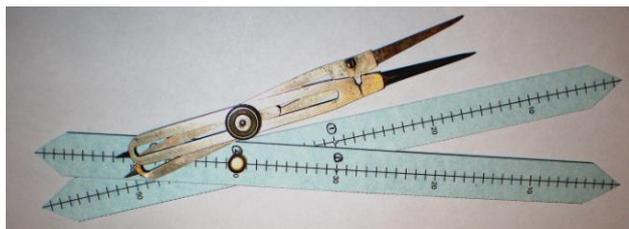

Fig 8: Actual and student made proportional dividers

SURVEY ANALYSIS

No formal survey was conducted when developing the materials due to time limitations in the classroom. However there was an opportunity in January 2011 to collect some data from a group of 24 students aged 15 and 16 from the Southbank International School who attended a session at the Brunel Museum at Rotherhithe, London. The students were at the museum for just over 3 hours which included a visit to the shaft that Brunel built. The purpose of the visit was to work with previously unused handheld technology to collect data that could be analysed in the classroom when they returned. This was a joint venture between the mathematics and science departments and both a mathematics and a science teacher were present from the school. The students were told to write down the data so that further study could take place when they returned to school. This meant that there was not much time available at the session to actually engage in the theory of the mathematics and science and that probably explains why the students gave it higher marks for enjoyment rather than for what they had learnt!

50 minutes was spent on each of the activities described (plus another 50 minutes on air resistance) and in the final 5 minutes an evaluation sheet was given to each student to gauge some opinion of each activity. They were asked to circle a number out of 10 for each activity and give some opinions. There were three lines available for students to write about what they had learnt and their comments.

The data was analysed using TI nspire Teacher Software and some of the screen shots of the analysis are shown below.

Working Group 12

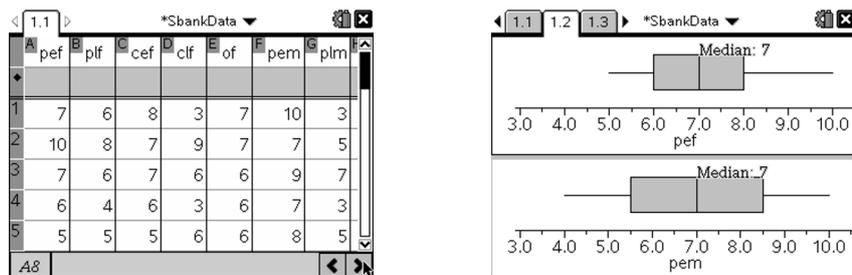

Fig 9: Spreadsheet results with box and whisker plot comparing gender enjoyment

This shows part of the spreadsheet with the column headings. The following abbreviations were used: p (for the pendulum activity), c (for the chains activity), e (for the enjoyment of the task), l (for the learning that took place), f (for a female response), m (for a male response), o (for the overall enjoyment). Therefore **pef** refers to the number given on the **p**endulum activity for the **e**njoyment by the **f**emales.

Here two box and whisker plots compare the pendulum enjoyment of males and females. We see that the median in each case is 7 and dispersion for males is more than that for females.

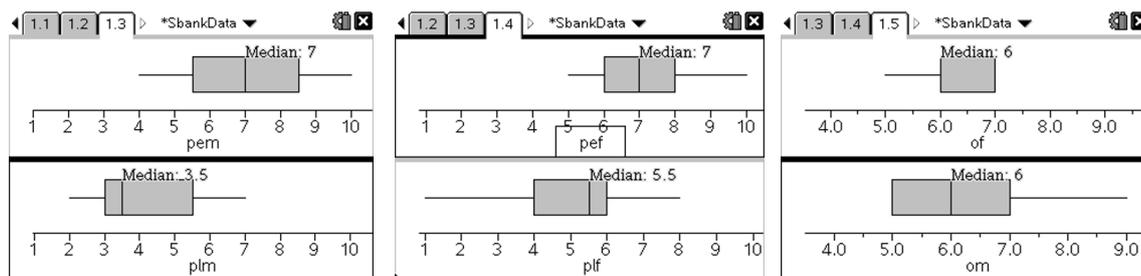

Fig 10: Box and whisker plots of enjoyment and learning for each gender together with the overall enjoyment of each gender

It is perhaps more interesting to compare what the students felt about their learning with their enjoyment. The screen shot on the left compares the males enjoyment and learning; that on the right compares the females enjoyment and learning for the pendulum activity. It appears that the females felt they learnt more than the males, though the small sample size means that further investigation would be needed before any firm conclusions could be deduced. Since no formal testing of the learning took place I make no claims for the efficacy of the activities apart from the enjoyment factor!

Some of the comments, being an open response, were not very illuminating. Here are some which were more relevant:

‘I learnt the difference between a catenary and a parabola.

It was fun and interactive, made learning easier.

I learnt how to find the equation of a curve.

I learnt how the length of the string affects the time.

Working Group 12

I learnt how to use the calculator to adjust the graph.
Good and interesting.’

It was a pity that I did not have more time with this student group to have more input into the analysis of the data collected with the activities, but the prime purpose of the day was to collect the data for them to analyse in their lessons. The historical aspect combined with the handheld technology provided the enthusiasm to make this an enjoyable experience overall as the third screen shot above shows.

Nobody scored the event below 5 and both the male and female median value was 6. The mean value by both genders was 6.2 (to 1 d.p.).

CONCLUSION

My experience with using history in the mathematics classroom is in relating the mathematics students do with episodes from history when it was used. I believe students need to see where mathematics has been used to appreciate its importance. These activities were developed for use in the classroom and masterclasses, not as a research project, so the evidence of their success (or failure) is mainly ephemeral through comments received by participants after each session.

INTRODUCTION TO THE PAPERS OF WG13: “EARLY YEARS MATHEMATICS”

Ingvald Erfjord, Ema Mamede, Götz Krummheuer

This Working Group dealt with the research domain of mathematics learning and mathematics education in the early years, age 3 to 7. The working group met for the second time during a CERME Conference. Several members met in CERME VII for the second time. As already found at the first meeting at CERME VI, this research group has to cope with a tremendous variety of educational approaches in preschool and kindergarten in the different countries. The following table gives an overview of the national origins of the presenters of working group 13:

Country	Number of papers	Number of posters	Presenters
Cyprus	1		1
Germany	3		5
Israel	2		2
Italy	1		1
Norway	3	1	6
Portugal	1		2
Spain	1		2
The Netherlands	1		1
United Kingdom		1	1
TOTAL	13	2	21

Table 1: Number of papers, posters and presenters from different countries

In these countries, especially Kindergartens serve different tasks. This variety is related to the diverse societal conception of early years education, with major differences in what role direct teaching of mathematics and other academic subject matters play and to the individual diagnosis of learning progress in these domains. Due to these differences, certain research questions and methods which are highly relevant for one country are almost unimaginable to consider in another one. This diversity offers a great challenge and opportunity to establish an European wide leading research group.

Working Group 13

In congruence to this initial situation, the group was confronted with a wide array of research questions and their related theoretical founding, which is shown in the following table:

Main theoretical orientation	Topics
Educational psycholgy	
<ul style="list-style-type: none"> • Conceptual development 	Concept of half Geometrical knowledge Concept of numbers and operations
<ul style="list-style-type: none"> • Classroom teaching experiment 	Fractions Early algebraic thinking
Educational science	Relationship of playing and learning
Cultural psychology	Co-learning Mathematical and communicative competence
Sociology, socio-linguistics	Mathematics learning Support system Codes and frames Multi-culturalism
Semiotics	Gestures

Table 2: Different theoretical orientation and topics

Despite this large range of theoretical interests, the members of working group 13 accomplished a conversation of mutual respect and partly envisioned options of „bridging“ the gap among the different theoretical paradigms with respect to the topic of the development and teaching of early years mathematics.

ISSUES ON CHILDREN'S IDEAS OF FRACTIONS WHEN QUOTIENT INTERPRETATION IS USED

Ema Mamede

CIFPEC, University of Minho

Manuela Oliveira

EB1 Campo

This paper focuses on children's understanding of fractions when quotient interpretation is used to introduce them this concept. An intervention program was conducted with a 7-years-old classroom, from a public primary school, in Fafe, Portugal. This intervention program comprised seven sessions in which children learned the representation of fractions and were challenged to solve some problems of ordering and equivalence of fractions. These sessions were organised following the official curricular content (starting by the equal sharing problems) but also according to the children's rhythms and demands. Children's performance and their arguments solving the tasks of ordering and equivalence of fractions are presented here. Issues on their learning process are characterized and discussed.

FRAMEWORK

Fractions is one of the most complex concept that children have to learn during the elementary school, but also a necessary one. Literature already provided information about students' difficulties (see Behr et al., 1984; Hart, 1981; Kerslake, 1986) with fractions. More recently, literature has been discussing the issues related to the effects of the interpretations for fractions on children's understanding of this concept (see Mamede, Nunes & Bryant, 2006; Mamede & Nunes, 2008; Nunes, Bryant, Pretzlik, Wade, Evans & Bell, 2004) and on the children's schemes of action (Nunes, 2008; Nunes & Bryant, 2008).

Distinct interpretations of fractions seem to affect differently children's understanding of the ideas of fraction. At the primary school, the children are supposed to understand at least fractions in quotient, part-whole and operator interpretations. But in these interpretations the meaning of the numerator and denominator differ. In part-whole interpretation, the denominator designates the number of parts into which a whole has been cut and the numerator designates the number of parts taken. So, $\frac{2}{4}$ in a part-whole situation means that a whole – for example – a chocolate was divided into four equal parts, and two were taken. In quotient interpretation, the denominator designates the number of recipients and the numerator designates the number of items being shared. In a quotient situation, $\frac{2}{4}$ means that 2 items – for example, two chocolates – were shared among four people. Furthermore, it should be noted that in quotient situation a fraction can have two meanings: it represents the division and also the amount that each recipient receives, regardless of how the chocolates were cut. For example, the fraction $\frac{2}{4}$ can represent two chocolates shared among four children and also can represent the part that each child receives, even if each of the chocolates was only cut in half each

Working Group 13

(Mack, 2001; Nunes, Bryant, Pretzlik, Evans, Wade & Bell, 2004). In operator situations, the denominator indicates the number of equal groups into which a set was divided and the numerator is the number of groups taken (Nunes et al., 2004). In an operator interpretation, if a boy is given $\frac{2}{4}$ of 12 marbles, means that the 12 marbles are organized into 4 groups (of 3 marbles each) and the boy receives 6 marbles – that is 2 groups of the 4 into which the 12 marbles were organized. Thus number meanings differ across these interpretations. These differences affect children's understanding of fractions when building on their informal knowledge.

Mamede, Nunes and Bryant (2006) conducted a survey on 80 first-grade children, aged 6 and 7 to compare their understanding of ordering and equivalence of fraction presented to them in quotient and part-whole interpretations. These children had received no school instruction about fractions. The results show that children's performance on problems presented in quotient interpretation was much better than in part-whole interpretation. In quotient interpretation the rates of success were 55% for 6-year-olds children and 71% for 7-year-olds children, for ordering problems; and 35% for 6-year-olds and 77% for 7-year-olds children, for equivalence problems. In part-whole interpretation the rates of success were 24% for 6-year-olds children and 20% for 7-year-olds children, for ordering problems; and 9% for 6-year-olds and 10% for 7-year-olds children, for equivalence problems. The children's resolutions were also analysed giving evidence that strategies based on correspondence combined with partitioning were popular among the group of children who solved the problems in quotient interpretation whereas partitioning was the strategy adopted by those who worked in part-whole situations.

More recently Mamede (2008) conducted an intervention program with 37 first graders (ages 6-7) to introduce fractions in distinct interpretations. The children were addressed randomly to work in part-whole, quotient and operator interpretations of fractions. Again the children had received no instruction about fractions. The results showed that those who were introduced to quantities represented by fractions in quotient interpretation could succeed in ordering, equivalence and labeling tasks; those who were introduced to fractions using part-whole and operator situations were able to succeed only on the labeling of fractions, but not on the ordering and equivalence tasks.

Thus, the type of interpretation used to work with fraction in the school interferes with students understanding of fractions. This idea is also supported by Nunes et al. (2004) who describe the results of a survey conducted with 130 students in Year 4 and 5 (8- and 9-year-olds) to analyse the pupil's ability to compare equivalent fractions presented in Quotient and Part-whole situations. In quotient situation item the pupils were asked to compare the fractions $\frac{1}{4}$ and $\frac{2}{8}$; in part-whole situation they were asked to compare $\frac{2}{4}$ and $\frac{4}{8}$. Results show that the rates of correct responses were 46% for the part-whole item and 77% for the quotient item. Thus, in

spite of considering different fractions in each situation, these results suggest that children perform differently in these two situations.

Research has been giving evidence that quotient situations are more suitable for children to build on their informal knowledge for fractions. The informal ideas about fractional quantities appear much earlier than the formal learning of fractions in school. Research developed with younger children shows that in a division situation, there are some children as young as 6-year-olds who can understand the inverse relation between the divisor and the quotient, when the dividend is the same (Correa, Nunes & Bryant, 1998) when discrete quantities are involved, and when continuous quantities are involved (Empson, 1999; Kornilaki & Nunes, 2005). This understanding of the inverse relation between the divisor and the quotient can be seen as a precursor of understanding of the logic of fractions: the greater the divisor (which would be represented by the denominator in a quotient interpretation), the smaller the quantity.

Streefland (1991, 1997) recommends the use of quotient situations to introduce fractions to children because these situations rely on the idea of fair sharing, which can provide the model for fractions and the part-whole concept related to equivalence and operational relations. The author not only recommends but also provides evidence of success in the use of the quotient interpretation to introduce fractions to children, describing a theory for teaching fractions based on the realistic approach that uses this type of interpretation to introduce fractions to children (see Streefland, 1991). Starting from problems using situations taken from daily life focused on division situations, Streefland produced good improvements on children's understanding of fractions, helping them to perceive the meaning of numerator and denominator as connected to each other, forming a correct mental object for the concept of fraction.

Traditionally, in many European countries, including Portugal, and the U.S. (see Behr, Harel, Post & Lesh, 1992; Behr, Lesh, Post & Silver, 1983; Kerslake, 1986; Mack, 1990; DEB, 1998) children are introduced to fractions at school using the part-whole interpretation and then this work with fractions is extended to include operator situations. In Portugal, in the primary school levels (1st to 4th-grades) students are introduced to fractions representation using the part-whole interpretation, and in some cases students have their first contact with fractions on the 5th grade. Portugal is experiencing a new curriculum for the elementary school levels. This new curriculum refers that fractions should be introduced to children in an informal way, in the second grade, relying in partitioning and equal sharing; and explored in the third and fourth grades in the quotient, part-whole, operator and measure interpretations should be explored. Nevertheless that document gives no other indication for teachers to introduce and explore fractions in the classroom. Literature already provided evidence of success when children are introduced to fractions in quotient interpretation (see Streefland, 1991, 1997; Mamede, 2008).

However, for many Portuguese primary school teachers the concept of fraction only makes sense when the part-whole interpretation is involved. Knowing that quotient interpretation of fractions can help children to build on their informal knowledge with understanding, how can teachers explore this interpretation in the classrooms? This paper tries to give evidence of a well succeeded experience conducted in the classroom in which fractions are introduced to children using quotient interpretation.

The study reported here describes children's understanding of fractions when they experience partitioning and equal sharing activities, and then received instruction on fractions using the quotient interpretation. The teaching experiment follows the Portuguese official curriculum for the 2nd grade mathematics, but goes further anticipating children's first contact with fractions to this level. Previous related studies give evidence of success of children's understanding of quantities represented by fractions when quotient interpretation is used but they do not follow the Portuguese curriculum in the classroom.

The part of the study reported here focuses on children's understanding of fractions when they are introduced to them using quotient situations, after a contact with partitioning and equal shared activities. It tries to address two questions: (1) How do children understand ordering of fractions when introduced to this concept using the quotient interpretation? (2) How do children understand the equivalence of fraction in this interpretation?

METHODS

An intervention study was conducted using qualitative methods to describe children's performances and characterize the processes involved in their learning to represent and compare fractions. Children's answers, as well as their arguments and solving strategies were analysed to reach an insight on their ideas of fraction.

Participants

The participants were a class of 8 students from a public primary school from Fafe, in the north of Portugal. The children were all 7 years-old. The teacher of the class is one of the researchers. These children had received no instruction about fractions.

Design

The intervention comprised 7 sessions, of approximately 90 minutes each, in which children were introduced to fractions using quotient situations. In the first two sessions children were challenged to solve problems involving equal sharing; they were also introduced to the symbolic representation of fractions, in which the quotient situation or interpretation was used. The remaining sessions were designed to explore ordering and equivalence of fractions in quotient situations.

There were 6 tasks of ordering of fractions and 4 of equivalence of fractions. The fractions used in these tasks were all less than 1. In the ordering tasks children were

asked to solve a problem such as: “Two girls are going to share fairly a chocolate bar, and there is nothing left; four boys are going to share fairly a chocolate bar and there is nothing left. These chocolate bars are equal. Do you think that each girl is going to eat more chocolate than each boy, each boy is going to eat more chocolate than each girl, each girl and each boy are eating the same amount of chocolate? Can you write the number that represents the amount of chocolate that each child eats?”. They were also asked to compare fraction given only symbolically. Analogous tasks were presented to them involving equivalence of fractions, in a problem such as: “Two girls are going to share fairly a chocolate bar, and there is nothing left; four boys are going to share fairly two chocolate bars and there is nothing left. These chocolate bars are equal. Do you think that each girl is going to eat more chocolate than each boy, each boy is going to eat more chocolate than each girl, each girl and each boy are eating the same amount of chocolate? Can you write the number that represents the amount of chocolate that each child eats?”. In some sessions the ordering and equivalence problems were presented with no pictorial support.

Procedure

In all sessions the tasks were presented to the children with the support of PowerPoint slides. Each child had a worksheet with the same information presented by the teacher, in which they could draw as they wish; and manipulative aid was provided as coloured paper with squared, rectangular and circular shapes were available. In each session the tasks were presented by the teacher to the class orally to ensure children’s understanding of the problem, as they usually do in the math class. Then children were asked to solve the problems presented to them and justify their results. Then the teacher challenged them to write down their arguments and verify their solutions.

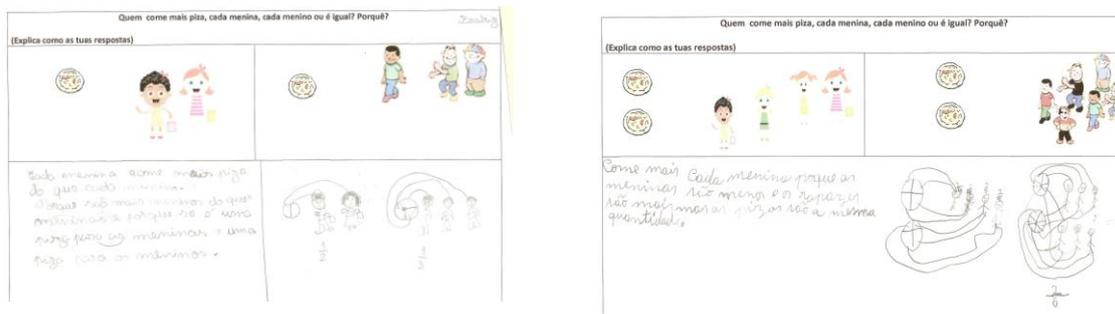

Data collection was carried out with the use of video and audio records, students’ worksheets and field notes taken by the researcher.

Results

In this section it is presented the results concerning children’s performance and arguments solving ordering and equivalence problems of fractions. The children solved the tasks individually and wrote their answers on their worksheet; then they wrote their justification and only after that they were challenged to verify their solution.

When the children were asked to compare $\frac{1}{2}$ and $\frac{1}{3}$, 7 of the 8 children succeeded; these 7 children gave a correct answer and then wrote down the explanation. Majority of children wrote down the explanation and then drew the pictures in their worksheets to verify their reasoning. Children’s performance was even better when they were asked to compare $\frac{2}{4}$ and $\frac{2}{6}$. Figure 1 gives examples of children’s performance on these ordering problems.

Working Group 13

'Each girl eats more pizza than each boy. Because there are more boys than girls and there is one pizza for the girls and one pizza for the boys.'

'Each girl ate 1/2. Because there are only two girls. And the boys ate 1/3.'

Figure 1: Children's resolutions comparing $1/2$ and $1/3$, and $2/4$ and $2/6$.

The children's arguments were improving along the sessions. By the fourth session it was possible to hear valid explanations such as "... each girl eats more pizza because there are fewer than boys and there is equal pizzas" referring to the equal number of pizzas; or "Each girl eats more pizza because each girl eats a bigger piece and the boy eats a smaller piece than the girls"; or "Each girl eats more because there are two pizzas for four girls and each boy eats less because there are two pizzas for six boys". The children's arguments were improving along the sessions.

In another episode involving an ordering task, the children were able to recognise and generalize the inverse relation between the divisor and the quotient, when the dividend is the same, as it shows the following transcription of children's discussion.

- Tutor: So, if you wish to get the biggest amount of paper which fraction would you choose?
- M: One half... it's more than the others.
- Tutor: How do you know that is more?
- M: One paper for two children is more than one paper for three...
- J: And more than for four and more than three...
- Tutor: If it is so, what sign did you write J?
- J: The 'bigger' sign...
- Tutor: Why did you put the 'bigger' sign?
- J: It's always 1 paper and there is always more children. They were 2, then 3, then 4....
- R: The smallest is one-fifth... I circled that one!

Transcription 1: Children's explanation of the inverse relation between divisor and quotient for the same dividend.

Working Group 13

The children were also able to solve problems of equivalence of fractions (7 out of 8 succeeded in all these tasks). Some episodes in which children revealed difficulties will be presented in the conference.

Figure 2 shows children's resolutions on two equivalence tasks. In these tasks some children found more difficult to explain their arguments in a written mode, in spite of solving the tasks correctly. These examples as well as children's difficulties will be presented in the conference. However, their oral justifications improved after drawing their schemes to verify the solutions, as their pictures were giving them some support in this task.

Quem come mais, cada menino ou cada menina?
 Quem come mais não se sabe porque $\frac{1}{3}$ é igual a $\frac{2}{6}$.
 Eu pus o sinal igual porque $3+3=6$ meninos e $1+1=2$ chocolates.

Escolhe o sinal adequado e coloca o entre as frações.

$\frac{1}{3}$	$=$	$\frac{2}{6}$
$\frac{1}{3}$	$>$	$\frac{2}{6}$
$\frac{1}{3}$	$<$	$\frac{2}{6}$

'No one eats more because 1/3 is equal to 2/6. I put the equal sign because 3+3=6 boys and 1+1=2 chocolates.'

Quem come mais, cada menino ou cada menina?
 Quem come mais não se sabe porque $\frac{1}{3}$ é igual a $\frac{2}{6}$.
 Eu pus o sinal igual porque $3+3=6$ meninos e $1+1=2$ chocolates.

Escolhe o sinal adequado e coloca o entre as frações.

$\frac{1}{3}$	$=$	$\frac{2}{6}$
$\frac{1}{3}$	$>$	$\frac{2}{6}$
$\frac{1}{3}$	$<$	$\frac{2}{6}$

'Eat the same because if we cut two-sixths the pieces are the same of one-third.'

Coloca o sinal adequado entre as frações. ($>$, $<$, $=$)
 Explica a tua resposta.

$\frac{1}{3} = \frac{2}{6} = \frac{3}{9}$

$\frac{1}{3}$ é igual a $\frac{2}{6}$ porque é um chocolate e três meninos em todos os sitios.

'1/3 is the same of 2/6 because there is one chocolate and three children in all places.'

Figure 2: Children's resolutions of distinct equivalence tasks.

In the majority of the tasks presented, children seemed to rely on the use of correspondence to reach the solution. When solving equivalence tasks the use of correspondence is even more evident as in many cases this idea is also supported by their justifications (see Figure 2).

When asked to compare $\frac{1}{3}$ and $\frac{2}{6}$ almost all succeeded (7 out of 8 children). Children's resolutions relied mainly on partitioning and correspondence. But a few children seemed to reveal some type of proportional reasoning when presenting their justifications. This is suggested when they try to explain that fact with numbers and expression familiar to them, such as ' $1+1=2$ ' and ' $3+3=6$ ' trying to express the double of quantities involved (see Figure 2).

DISCUSSION AND CONCLUSIONS

The results of this study allow us to establish some remarks. First, this experience gives evidence that children can understand fractions when introduced to them in quotient situations, in agreement with Streefland (1991, 1997), Mamede, Nunes and Bryant (2006), Mamede and Nunes (2008) who previously studied this issues. In the sessions of this study, the ordering problems seemed to help the children to easily understand the inverse relation between the divisor and the quotient, when the dividend is the same. This relation is essential to understand the meaning of fractions. Second, these children learned easily fractions labels. They were introduced to the representation of fractions in the beginning of the intervention, and soon they master the symbolic representation of fractions, when quotient interpretation was used. In this type of interpretation, the magnitudes involved in the fractions refer to two variables of different nature (Nunes *et al.*, 2004), - numerator refers to the number of items to share, denominator refers to the number of recipients - and this may facilitate children's learning of fractions labels. Third, because in quotient interpretation the numerator and the denominator relate to variables that are different in nature (Nunes *et al.*, 2004), children easily relied on the use of correspondence to solve many of the tasks. This finding was also documented previously by Mamede, Nunes and Bryant (2006) when observing 6-7-year-olds children's strategies solving ordering and equivalence problems, when interviewed individually. Nunes (2008) argues that in a division situation, there are two types of action schemes: partitioning, which involves dividing the whole into equal parts; and correspondence which involves two quantities (a quantity to be shared and a number of recipients of the shares). The development of these action schemes defers. Children of 5 to 6-year-olds can establish correspondence to produce equal shares (see Kornilaki & Nunes, 2005; Mamede, Nunes & Bryant, 2006; Nunes, 2008), but they find more difficult to accomplish partitioning of continuous quantities. These schemes of action (Nunes, 2008) are fundamental for the learning of the mathematical concepts. Fourth, the equivalence problems presented in quotient interpretation gave the children an opportunity to promote their proportional reasoning. When solving the equivalence problems many children establish a proportional relation between the numbers of items to share and the number of recipients in order to reach the solution; some of them could express that relation in a written way, others by drawings. Proportional reasoning was also a strategy identified by Mamede (2007) and Nunes *et al.* (2004) when analysing students' strategies solving equivalence problems presented to them in quotient interpretation of fractions. To conclude, this short intervention program allowed the teacher to understand children's possibilities of success with fractions when they are introduced to the children using quotient situations. We hope that this experiment can contribute to promote a change in the classroom practices, following the Portuguese official curriculum, giving the primary teachers an example of a well succeeded experience. As correspondence seems to have an important role on children's reasoning on

fractions problems, it seems to be relevant to give young children the opportunity to develop sharing experiences based on correspondence (one-to-one and one-to-many) since kindergarten.

More research is needed in order to explore other ways of introducing fractions to children in the classroom, using quotient interpretation of fractions. In this experiment, the children learned the fraction representation in the beginning sessions. For further research in this area it would be interesting to develop a longitudinal research to analyse the influence of interventions based on quotient interpretation of fractions on young children's understanding of other interpretations of fractions.

FINGER-SYMBOL-SETS AND MULTI-TOUCH FOR A BETTER UNDERSTANDING OF NUMBERS AND OPERATIONS

Silke Ladel and Ulrich Kortenkamp

CERMAT, University of Education Karlsruhe, Germany

Basic concepts of numbers and operations are fundamental for mathematical learning. Suitable materials for developing such basic concepts are hands and fingers. Among other things, this is because of their natural structure of 5 and 10. To support the development of concepts and the process of internalization a linking between different forms of representations by the computer can be helpful. To benefit of both, the advantages of the hands and fingers and the automatically linking, we suggest using multi-touch-technology, i.e. computer input devices that are able to recognize several touch gestures at the same time. Here, children can present numbers with their fingers that produce virtual objects. These objects can be automatically linked with the symbolic form of representation.

THE ORDINAL AND CARDINAL CONCEPT OF NUMBERS AND OPERATIONS

“How many things are there?” – For parents as well as for mathematicians, this is a common question to pose, if a child already has knowledge about numbers. For the child, this question is almost always the initiation to start counting verbally by saying the number words in a row (Fuson, 1988). The fundamental principles needed for answering the question are a) the one-one-principle that relates every single object to exactly one numeral (Gelman & Gallistel, 1978), b) the stable-order-principle prescribing the correct order of numbers (Fig. 1, left), and c) the last-word-rule that assigns the last said numeral not the last counted object, but to the quantity as a whole (Fig. 1, right).

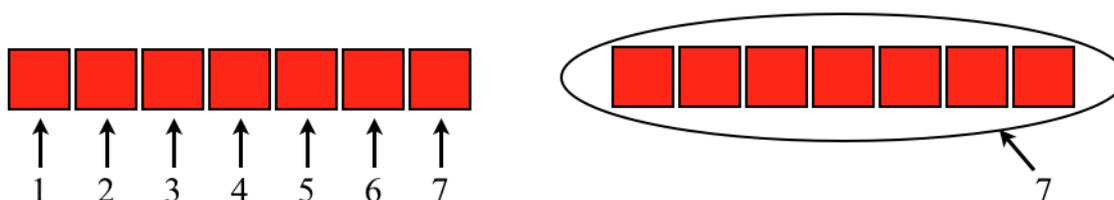

Figure 1: ordinal (left) and cardinal (right) concept of numbers

Here, the change from the ordinal concept of numbers, where the numeral is part of the numeral row, to the cardinal concept of numbers, where the numeral identifies a quantity, is necessary. It is not necessary to count a quantity in order to know it, that is, the ordinal concept is not a necessity for the cardinal concept. Resnick (1991) distinguishes the development of mathematical knowledge by two components that are developed independently: *protoquantitative schemata* and the *mental number line*. To build-up a well-developed concept of numbers, these two threads of

development have to be linked. For many children this is a critical problem. Fuson refers to the following example: a child counts a quantity of five cars. As an answer to the question „*How many?*“ the child points to the last-counted car and says: „*This is the five cars.*“ (Fuson, 1992 p. 63).

Children who do not have a proper linking between the two concepts can misinterpret addition and subtraction as a demand to count forwards or backwards (fig. 2 left). As long as the children calculate with numbers smaller than 20 they can apply this strategy successfully. But, for instance, when they want to add 55 to 27 and begin to count „28, 29, 30, 31, ...“ there is no chance to come easily and quickly to the correct result. Thus, it is important that children acquire a part-whole schema of numbers as a foundation for addition and subtraction (fig. 2 right).

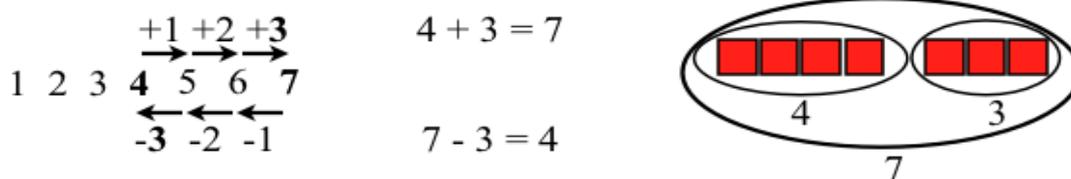

Figure 2: Addition and subtraction with the ordinal (left) and the cardinal (right) concept of numbers

„*The protoquantitative part-whole schema is the foundation for later understanding of binary addition and subtraction and for several fundamental mathematical principles, such as the commutativity and associativity of addition and the complementarity of addition and subtraction. It also provides the framework for a concept of additive composition of number that underlies the place value system.*“ (Resnick, 1991 p. 32).

For example when you want to add 6 and 8 with the use of the part-whole schema you can split and add in lots of ways (e.g. fig. 3).

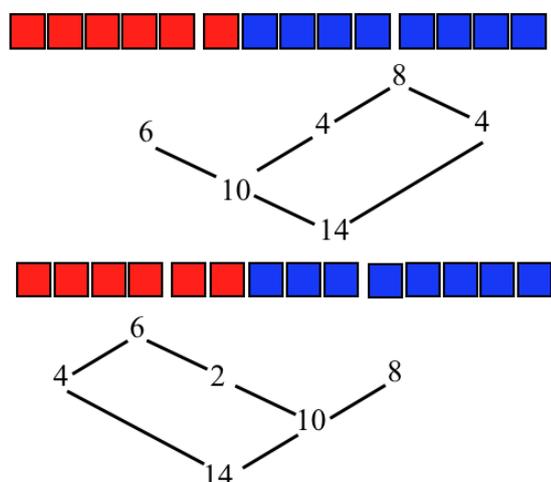

Figure 3: different ways to add with the part-whole-schema

Because of our decimal number system and with regard to the decimal analogy the secured understanding of the number range up to 10 is assigned a key position in the development of mathematical competences (Claus & Peter, 2005 p. 11). If you know all the possible decompositions of the numbers up to 10, you are able to add and subtract in bigger number ranges easily, e.g. if $7 + 8 = 7 + (3 + 5) = (7 + 3) + 5 = 15$, than $67 + 8 = 67 + (3 + 5) = (67 + 3) + 5 = 75$. The missing knowledge of and fluency in decompositions of the numbers up to 10 as much as the lack of capability to recall them quickly and effortlessly is the cause of many subsequent difficulties in mathematical learning.

FINGER SYMBOL SETS

Calculating with fingers has a very bad reputation in mathematics lessons, as it is usually seen as an indicator for counting. Most children do as they have learned from young days on and count objects by „Counting-Word Tagging to Number“ (Brissiaud, 1992). According to the ordinal concept of numbers each finger is related to exactly one numeral. But if each finger is labelled by a number, counting children are encouraged to stay with their strategy and this consequently leads to further problems. To illustrate this we ask what happens if the sixth finger is buckled? The „name“ of the last finger, that indicated the quantity, was „10“ before, but now the finger has to be renamed into „9“ (Fig. 4).

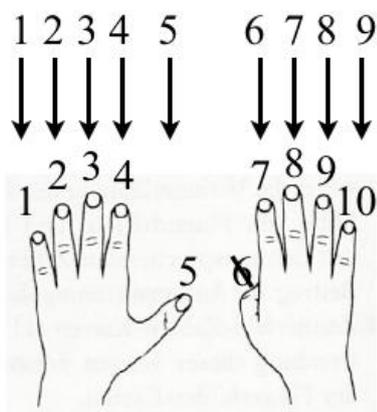

Figure 4: Order-irrelevance principle

This procedure can puzzle some children. Therefore it is important not to assign names the fingers – there is no “6-finger.” The child has to know that it is irrelevant which fingers it uses to present a quantity. To present „3“, the thumb, the index finger and the middle finger can be used as well as the little finger, the middle finger and the thumb, or any other combination of three fingers. As we point out below, the cognitive process behind this fact can be experienced and thus supported by the use of multi-touch-technology.

Amongst others, the advantages of fingers and hands are their permanent availability and their natural structure in 10 fingers per child with 5 fingers per hand. The 10 fingers qualify the hands to work out questions about the decimal number system,

e.g. „How many children do we need to see 30 fingers all at once?“ The 3 children stand for 3 tens. Just as well, the different decompositions of all numbers up to 10 can be presented with the hands. The „power of five“ (Krauthausen, 1995) is due to the ability to instantaneously recognize quantities (subitizing) up to 4. Applying this to the hands, the shown quantity of the fingers of one hand can be conceived simultaneously and hence the fingers of both hands can be conceived quasi-simultaneously. Furthermore, one hand gets a special status because children tend to present numbers greater than five sequentially (Brissiaud, 1992 p. 61). For example, to present „7“, they tend to use one full hand and then add two fingers of the other hand. In this way the decomposition of the numbers from 1 to 10 with the power of five can be worked out. But not only these, also all other decompositions are possible (Fig. 5) and can be conceived quasi-simultaneously.

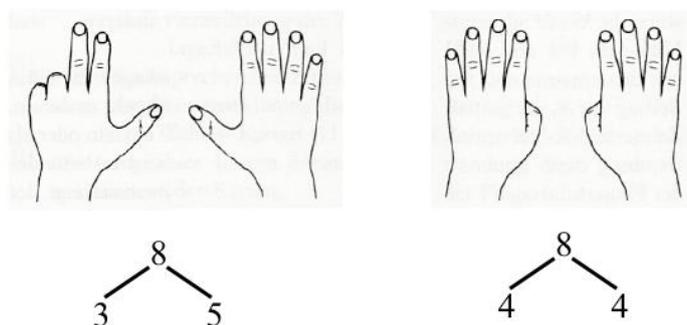

Figure 5: Decomposition of numbers with finger-symbol-sets

If the fingers are used like this, in sense of the part-whole schema, they are a qualified working material for a well-developed concept of numbers and operations (cf. Steinweg, 2009). Brissiaud (1992) coined the notion „From Finger Symbol Sets to Number“:

„Certain children who were not exposed early to the use of finger symbol sets may become counters, whereas children who were encouraged to use finger symbol sets may preferentially choose finger strategies“.

He could show that this way of gestured representation of quantities by some children is established early and in parallel to the development of the numerical row as an autonomous type of numerical representation.

The decompositions of all numbers up to 10 that were acquired in this way can now be utilised in the following process of mathematical learning of addition and subtraction (Fig. 6).

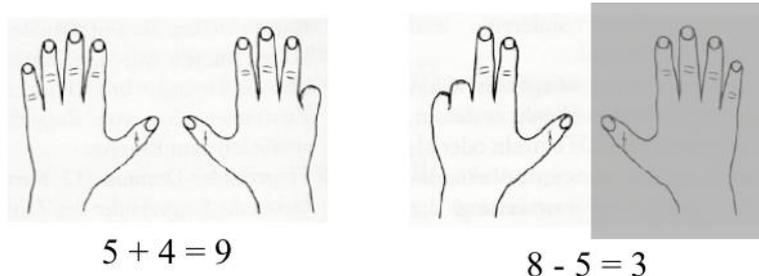

Figure 6: addition and subtraction with finger symbol sets

If children have a part-whole schema of numbers the transition to addition and subtraction is easy. It is just another way of nonverbal-symbolic representation of the fact that „two parts make a whole“.

Further strategies like variation in the opposite or in the same direction can than be worked out easily: If one finger is buckled, than another finger must be stretched to keep the same quantity. To get the difference of two quantities, e.g. of 9 and 7, you can vary the numbers in the same direction. For example, a whole hand can be omitted, which corresponds to subtracting five from each quantity. It is evident that the difference of 9 and 7 is the as the difference between 4 and 2 (Fig. 7).

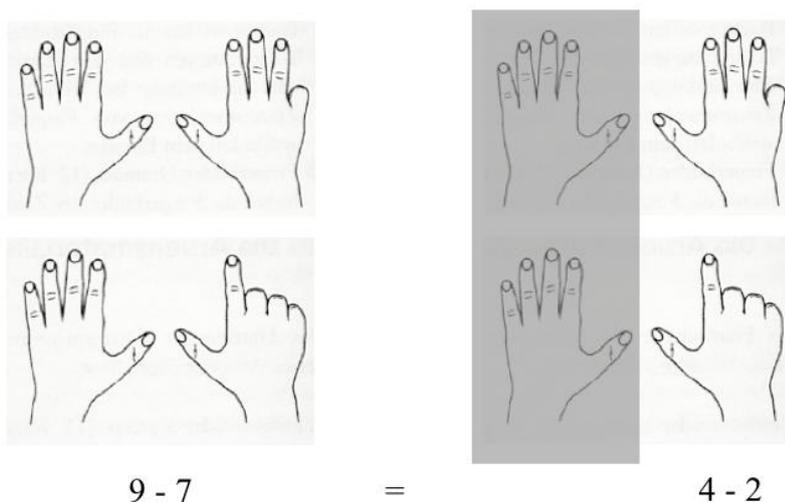

Figure 7: Strategy of variation in the same direction with finger symbol sets

Based on such strategies the decadic analogy can be build up.

It is important to pay attention to the fact that the children stretch their fingers *simultaneously* to represent quantities with them. If they show them one-by-one the positive effects of these strategies are lost and the children will still use counting for addition and subtraction.

As well as addition and subtraction, multiplication and division can be presented via hands and fingers. If 5 children all show 6 fingers, this represents five times six. The inverse operation is found when we start with 30 fingers that shall be represented by 5 children.

This introduction can only serve as a small insight into the possible representations of numbers and operations by hands and fingers and their usage in early arithmetic. It is the process of internalization that is of essential importance: How can the children benefit from the mathematical content of these representations and actions and use them in their mental processes?

THE PROCESS OF INTERNALIZATION SUPPORTED BY THE USE OF MULTI-TOUCH-TECHNOLOGY

According to Aebli, the process of early mathematical learning follows four stages, independent of the arithmetical subject (Grissmann & Weber, 2000; Aebli, 1987). Coming from concrete manipulations with different objects (stage 1), the children have to abstract these manipulations and operations to pictorial representations (stage 2). Subsequently they pass over to symbols (stage 3) with the aim to automate their actions (stage 4). For us, stage 2 is of special importance, because there the process of internalization takes place. The child has to comprehend the manipulation of concrete objects as a representation of a quantitative structure and it has to capture the structure and the relations of the concrete manipulation in an intellectual activity (Gerster & Schultz, 2004 p. 47). Lorenz calls this process „focus of attention“. To facilitate this process of focus and abstraction and to develop it, a dialog is essential (Lorenz, 1997): *„In talking about the working material and the relations between numbers and operations that it represents, the concepts in development of the learner are going to be clarified by verbalisation.“* In this sense, Aebli (1987) suggests that the children should review their concrete manipulations and make forecasts about further actions. Doing this, they comment their own manipulations by iconic illustrations till they are able to reproduce the structures and relations of the manipulations in conceptions. To support this process Aebli (1987 p. 238) established the following rule:

„Every new, more symbolic representation of the operation must be linked as closely as possible with the precedent one.“

As shown in Figs. 5 to 7, the enactive form of representation with finger symbol sets should be related to the nonverbal-symbolical form of representation (MER¹) (Ainsworth, 1995; Mayer, 2005). But as studies show some of the children even don't link the different forms of representations when they are designed in form of MERs (Clements, 2002). For them, an automatic linking designed with the computer (MELRs²) can help them to experience the relations (Thompson, 1992; Clements, 2002; Ladel, 2009). This experience should be as natural and directly as possible. In this article we suggest to use multi-touch-technology for this experience, where the children can manipulate with their hands and fingers and an automatic linking with all other forms of representation can take place. In the remainder of this article we assume the availability of a multi-touch-enabled table. Such a table consists of a

display surface connected to a computer and some tracking hardware that can recognize several touches on the display simultaneously and report them to the computer software. Similar technology with a different form factor is available in desktop monitors, tablet computers and devices like the Apple iPad, or mobile phones. With the availability of hardware as already imagined by Kay (1972) we now have to answer the question of the educational implications more than ever.

The basic underlying idea for all the activities sketched only briefly in the following is that the computer can track the children's actions on the table and give nonverbal-symbolic representations of either the current situation or the action that lead to it in form of a written protocol.

In a first scenario, the children represent numbers with their hands and fingers as described before. This enactive form of representation shall produce an iconic one on the display. The computer creates quadratic pads on the surface of the multi-touch-table. Already at this stage, the focus of attention of the children can be laid on the fact of bundling the 5 fingers of one hand to a bar of 5 and the 10 fingers of two hands to a bar of 10. Through the contact of the fingers with the multi-touch-interface there is not only a link between the enactive form of representation with other forms of representation but also between the tactile and the visual sense. While representing numbers enactively and thus iconically, there is an automatic link to a nonverbal-symbolic form of representation. This representation can be imagined like a paper tape or sales slip and serves as a kind of protocol for the manipulations the children do. Such a protocol can support the focus of attention and the numerical aspects of a task (Dörfler, 1986).

In this activity it is possible for children to experience that it is of no particular importance which fingers they use to present quantities. Using the thumb and the index finger or using the little finger and the ring finger both yield the number "2". At a table, it is also possible that the children work in teams: Two children can "share the work" to present two fingers if each touches the table with one finger. While this sounds funny for the number two, it is of great importance for partitions of larger numbers. Two partners can try to find all ways to partition numbers up to 20 into two numbers up to 10.

Working in teams or groups the children are also able to present numbers greater than 10, emphasizing the social aspects of learning. Because the protocol immediately reflects the actions of the children their focus of attention is on the mathematical content of their actions automatically, guiding them to abstraction.

We can also use the technology as a diagnostic tool for the number concepts of children. Recording the way the children touch the table with their fingers it is possible to measure the time intervals between the touches of each finger. We can judge whether the children are still counting to put a given number of fingers onto the table, or whether they work already with suitable finger symbol sets.

Working Group 13

Just showing the number of fingers touching the surface can also help the children to experience the difference between the ordinal and the cardinal aspect of numbers. The child can touch the table with its fingers in different sequences, different positions or with different fingers – in all cases the protocol just depends on the quantity of fingers.

It is also possible to support the four basic arithmetic operations and their basic concepts in such an environment. Regarding addition, students can develop the basic concept of a union by manipulating the virtual objects (pads) and arrange them close to each other. For example, if the child merges a group of 3 pads and a group of 5 pads the protocol will show the symbolic representation of this action as „ $3 + 5 = 8$ “. Here the focus of attention lies on the fact that this action constitutes a basic concept of addition, together with its nonverbal-symbolic form of representation. In multi-touch-technology there is also the possibility to draw a circle around some pads with the effect that these pads are bundled (a so-called lasso-gesture). This again is a manipulation based on the basic concept of union. Another task in the realm of addition and subtraction may be that 3 pads are shown and the child should create so many pads that in the end there are 7 ($3 + _ = 7$).

The basic concept of balance can be represented as well. Children can create quantities, remove from them, manipulate them with their fingers, and see the consequences of the manipulation at the same time in the nonverbal-symbolic protocol. Likewise it is possible to give instructions in the nonverbal-symbolic form and to see the output in the iconic forms with the pads.

It is rather easy to imagine that addition and subtraction can be done in such an environment, and we have shown some ways how the action or the state can be linked to a nonverbal-symbolic representation. For multiplication and division it is advisable to take advantage of the time as another dimension. The temporal-successive idea of multiplication that can be traced back to a repeated addition is mapped to a repeated touch action of the same quantity of fingers several times. The protocol may then show, for four touches with five fingers, „ $5 + 5 + 5 + 5 = 20$ “ as well as „ $4 \cdot 5 = 20$ “. Thus the children can see, that there are different ways to protocol their manipulation. If several children are working together they can take advantage of the spatial-simultaneous idea of multiplication, creating the same quantity by several children at the same time. For division, one example activity would be to move pads and build piles of the same amount to divide a given number of pads.

FORECAST

We are currently working on implementing the above scenarios using a multi-touch-table built at CERMAT. A first study that examines the critical point in translating numbers and operations from and in different forms of representation is going to take place in October 2010. At the same time we will conduct a pre-study about the way

Working Group 13

children touch with their fingers and present quantities on a table. The programming of the multi-touch-learning-environment is currently in progress using a multi-touch extension of a dynamic geometry software system.

Finally, we aim to answer the research question about the impact of the availability of such multi-touch-learning-environments regarding the diagnosis and the support of acquiring basic concepts of numbers and operations.

SIMILAR BUT DIFFERENT - INVESTIGATING THE USE OF MKT IN A NORWEGIAN KINDERGARTEN SETTING

Reidar Mosvold, Raymond Bjuland, Janne Fauskanger, and Arne Jakobsen

University of Stavanger [1]

In the last decades, a lot of research regarding the professional knowledge of mathematics teachers in school has been conducted. Far less research has been done concerning the professional knowledge of kindergarten teachers, and there is little evidence regarding what kind of mathematical knowledge for teaching that is needed by kindergarten teachers. This paper analyzes a case study from a Norwegian kindergarten and discusses how the tasks of teaching [2] that have been observed in this kindergarten setting differ from those of teachers in school. Based on the analyses, we suggest that part of the theoretical framework has to be adjusted before it can be used in a kindergarten setting.

INTRODUCTION

In the last decades, a lot of research has been conducted in order to learn more about the mathematical knowledge that mathematics teachers need in their teaching practice and the impact of such knowledge (e.g. Ponte & Chapman, 2006). Researchers agree that knowledge is important (e.g. Hiebert, Gallimore, & Stigler, 2002), and some suggest that there is a connection between the teachers' mathematical knowledge and the students' results (Hill, Rowan, & Ball, 2005; Baumert et al., 2010). So far, most of the research has focused on teachers in elementary and middle school.

Based on results from several studies, Ball and her colleagues (e.g. Ball, Thames, & Phelps, 2008) present a framework of mathematical knowledge for teaching (MKT). According to their framework, mathematics teachers need a combination of content-specific knowledge and pedagogical content knowledge in order to facilitate learning of mathematics. Although their framework has been developed from studies of mathematics teachers in elementary and middle school (in the U.S.), it is tempting to suggest that kindergarten teachers also need some kind of MKT in their practice. When reviewing the literature, however, attempts to investigate the kind of mathematical knowledge needed by kindergarten teachers has so far been scarce. Lee (2010) is one of very few examples, but her focus is on pedagogical content knowledge, and she does not mention the MKT framework. Carlsen, Erfjord and Hundeland (2010) have investigated the competence of kindergarten teachers from a sociocultural view (and so have others), but they did not in any way build upon or relate to the MKT framework. In this paper we use a case study from a Norwegian kindergarten as a context for a first attempt to investigate some possibilities and limitations of using the MKT framework as an analytical tool in a kindergarten context. The following research question has been formulated:

What are the similarities and differences between the “tasks of teaching” of mathematics teachers in school and those of kindergarten teachers?

THEORETICAL BACKGROUND

Before going into the MKT framework in more detail, it is important to clarify a few issues related to the Norwegian kindergarten context. As identified in *Starting Strong II* (OECD, 2006, chap. 3), there is often made a distinction internationally between two main traditions in early childhood education. The Nordic countries (including Norway) and some countries in central Europe are often placed within what is referred to as a social pedagogy tradition in early childhood education. Within such a tradition, kindergartens are viewed as institutions where a broad concept of pedagogy is used, and a combination of care, upbringing and learning is emphasized (*ibid.*). The other main tradition is referred to as the pre-primary tradition, and within this tradition, kindergarten is viewed as an institution with a main focus on preparing the children for school. Within the social pedagogy tradition, free play is emphasized, whereas kindergartens in countries with a pre-primary tradition often have a stronger resemblance with traditional schools (*ibid.*). Such differences are important to have in mind when discussing the use of the MKT framework in a kindergarten setting.

Another important aspect when discussing Norwegian kindergartens is related to a particular political initiative. In 2009, the Norwegian Government decided (through law regulations) that all children (1-6 year olds) should have the right to go to kindergarten (Kunnskapsdepartementet, 2009). As a result, a number of new kindergartens were built. This massive increase of kindergartens did not lead to a corresponding expansion of kindergarten teachers, and several municipalities still experience a severe lack of educated kindergarten teachers. At the same time, the knowledge and competence of the kindergarten teachers was strongly emphasized by the Government (*ibid.*). Norwegian kindergartens are thus faced with a huge challenge, and in this connection it is appropriate to approach the question of what kind of mathematical knowledge these kindergarten teachers need.

The focus in research concerning teacher knowledge has shifted from using the number of courses or study points as an indicator (e.g. Begle, 1979) in order to document teachers' apparent lack of understanding about the mathematics that their students are supposed to learn (Cooney, Shealy, & Arvold, 1998), to a focus on the many facets of teachers' mathematical knowledge for teaching (e.g. Ball et al., 2008). A large proportion of the research that includes the latter focus builds upon Shulman's (1986) conceptions of the different aspects of teachers' professional knowledge. His model originally distinguished between seven different kinds of knowledge, whereas three of those had a subject-related content: pedagogical content knowledge, content knowledge, and knowledge of curriculum. Shulman's model has now been developed further by Ball and her colleagues (e.g. Ball et al., 2008), and

Working Group 13

these researchers from the University of Michigan present a content specific model for teachers' mathematical knowledge for teaching.

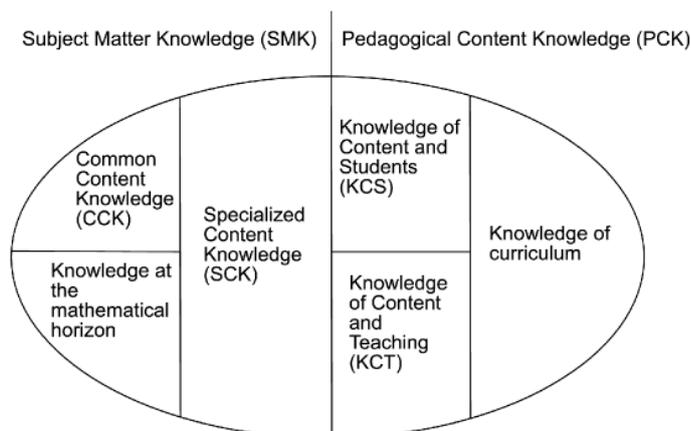

Figure 1. Aspects of MKT (from Ball et al., 2008, p. 403).

These researchers have a particular focus on the so-called work of teaching, and as a result of their studies, a list of some distinct and important tasks of teaching was proposed [2]. Although these tasks of teaching have been identified from studies of mathematics teachers in school, it is interesting to investigate whether or not kindergarten teachers are faced with the same tasks in their work. We discuss this in the context of a shopping game in a Norwegian kindergarten, and we focus on a selection of tasks that appeared relevant for this particular context.

METHODS

The context for the study is a group of 3-year old children in a Norwegian kindergarten. Mary is the main kindergarten teacher in this class, and she does not have an approved education as kindergarten teacher yet. The reason for selecting Mary and her group as a case in this connection, is that we believe that analyses of her teaching practice can be used as a starting point for identifying the MKT that kindergarten teachers need, and which she appears to be in the process of developing. Hiebert, Gallimore and Stigler (2002) argue that practitioner knowledge along with professional public knowledge provide a knowledge base for the teaching profession, and this argument can be used as rationale for our selection of case as well.

In a larger context, Mary and her group had been part of a developmental study for about half a year at the time of this case study. During that year, a number of visits had been made to the kindergarten by the main researcher in order to discuss, plan and evaluate learning activities with the kindergarten teachers.

The data we analyze here is from an activity where Mary decided to stimulate the development of the children's concept of number and counting in the context of a shopping game. In addition to video recordings of the actual activity and field notes,

data were gathered from audio recording of interviews and discussions with Mary in connection with the planning and evaluation of the activity.

The recordings of audio (and video) were transcribed, and these transcripts were analyzed through content analysis (e.g. Kvale, 1996) with MKT as a theoretical lens.

RESULTS

When the interview starts, Mary and the researcher have a little discussion about their last project. In that project, their focus had been on figures and shapes, and now they want to shift their focus towards numbers and counting. The children had already made experiences with numbers (or numerals) in relation to emergency numbers (somewhat equivalent to 911, only there are three different in Norway). They had talked about these numbers and linked them with photos of an ambulance, a police car and a fire engine respectively. Mary starts elaborating on her ideas and thoughts so far, and a discussion about the new project evolves. Mary does not want to leave their previous focus on shapes and figures completely behind, but she still wants to shift her main focus somewhat. She discusses this with the researcher:

Researcher: Yes. Mmm. Then I think it sounds reasonable that you choose something [an issue] that you really [want to] spend time on.

Mary: Yes, because I observe that, when we have spent so much time on circles and triangles, then they manage it! And then ... then we know that we should spend some more time on other things [issues] as well. And then ... no, I think that the counting [in itself], that [issue] we manage to connect with most [of our activities], both in songs, books, in assembly - well, we simply count all kinds of [objects]. Then we'll be able to manage it.

They keep discussing how the issue of counting appears in different settings, like in games. When playing games, especially board games where dices are used, the children need to count the steps while they are moving pieces along the board. This kind of counting appears to be difficult for the children in Mary's group, she reveals. In their continued discussion, they focus on the connection between counting out loud and making a one-to-one correspondence, which the children have to master when counting objects. Mary and her colleagues have experienced that the children count asynchronously in many occasions. This particular kind of knowledge, which might be defined as knowledge of content and students/children, appears to be of importance to the kindergarten teacher. In order to be able to support the children's learning, a kindergarten teacher needs some knowledge about how children develop number sense, counting skills etc. Mary tells the researcher that the children in her group know the numbers 1-3, and some children can even count further, but something recently came up which surprised her:

Mary: Yes, they do! Well, some even manage to count till 10 in both Norwegian and English. But even though he is counting both in Norwegian and English

Working Group 13

till 10, then I was actually surprised when we were sitting down reading in that “duck-book” - that counting book - eh ... that counting by pointing, and I didn’t quite manage to connect the dots there. So it became a bit: Oh, [inaudible] that counting by pointing then it went a bit pell mell, so ... and then I was a bit worried based on what I maybe had anticipated, because I expected something [more] from a child who speaks so extremely well! And [he] manages to explain himself incredibly well. But maybe it was ... I hadn’t actually - then I got a bit surprised.

Here, Mary shares her experiences from a situation that emerged when she was reading together with a boy who she believed could count really well. He knew his numbers from one through ten in both English and Norwegian, but he still appeared to have problems using the counting as a tool in order to find the quantity. This illustrates a kind of knowledge of content and students/children, and in this example it was a matter of Mary discovering that there was something she did not know about before she experienced this situation.

Mary decides to facilitate the playing of a shopping game in her group, and she intends to use this as an arena to stimulate the children’s further development of counting skills. The children need to figure out how much a certain good costs, count out the correct amount of money, pay for the goods, and possibly receive the correct amount of change if they have paid more than the costs. Mary’s idea was that all of this would provide a nice context for stimulating the children and provide them with rich experiences in relation to numbers, quantity and counting.

The next time the researcher visits their kindergarten Mary and her colleagues have already started experimenting with the shopping game. They had decided to keep the prices low, and they agreed to represent the prices with a numerical representation along with the correct number of dots. This decision relates to a task of teaching where the kindergarten teacher needs to select the appropriate representation for particular purposes, and the knowledge involved in this process can be labeled as what Ball and colleagues (2008) refer to as knowledge of content and students.

The starting point, based on Mary’s experiences with a particular boy, was a belief that the children would not be so skillful in pointing by counting. When they started playing the shopping game, Mary soon experienced that she had to adjust her goals somewhat:

Mary: No, what has happened is that ... well, before we managed to finish this properly, we were very focused on that counting by pointing. And suddenly then all managed to ... [count] till more than 10. I think there are two - we had a round at an assembly, and then they counted, yes then they counted till more than 10. I think there were two [of the children] who started to shake with the finger at 6.

Researcher: Mmm.

Working Group 13

Mary: So, they have managed to come very far with this [already]!

Researcher: Yes.

The children were obviously motivated to play the shopping game, and all of a sudden most of them were able to count objects up till 10 and even appeared to understand about the price tags. Then something happened:

Mary: What became a little bit funny was when [laughs a bit] Kari [a colleague] came to film [laughs a bit more]. Then they easily understood [about] the prices. They did, that was not a problem. What became difficult [for them] was to count out the correct amount of money. They didn't manage that ... properly. Then they were ... actually, they were more concerned with those items ... and the shopping part. They were very eager to shop.

The children had rather quickly developed their counting skills, and they were able to count the number of coins they possessed. When they were going to use their counting skills to "count out" the correct amount of money from a larger amount, however, many children struggled.

Mary: But it became difficult when they had - when I had given them some money, and said: "How many [coins] do you have to pick out then?"

Researcher: Yes, so finding the correct amount [of money], that was difficult.

Mary: It was a bit difficult in the beginning. Yes, but I don't think it will take long before they understand that as well.

Researcher: No, because there is a little difference in asking about how many coins there are, and finding ... four coins, in a way.

Mary: Yes, because that was a bit difficult [for them], because they had to pick out that many [coins] when I had given them more, or when I held them [those coins] in my hand and said: "Yes, but now - how many [coins] do you need now in order to pay for that thing?" Then they just wanted to take all the coins. Actually, even though it was 7, and maybe they should only use 4 (...)

Mary's experiences in this situation apparently went beyond the practice based knowledge and experiences that she had made before.

The discussions between Mary and the researcher indicate that counting is a complex activity. To use a context like this in order to facilitate children's learning, a particular kind of knowledge is needed. In the discussions below, we investigate how the tasks of teaching that Mary face are related to some of the tasks of teaching that were identified by Ball and colleagues (2008) in their studies of mathematics teachers in U.S. schools.

DISCUSSION

In a typical Norwegian kindergarten, there are no mathematics lessons, no mathematics textbooks, no blackboards, and no traditional classroom with desks. The

Working Group 13

children's learning takes place in everyday activities and play situations. As a result, the (Norwegian) kindergarten teachers are faced with challenges that are different from those of mathematics teachers in school. When discussing a possible application of the MKT framework in a Norwegian kindergarten setting, such contextual (and cultural) differences are important to be aware of.

The dialogue between Mary and the researcher has indicated that Mary has some kind of MKT about counting that she makes use of in the context of the shopping game. She relates previous experience from shapes and figures to the new topic of counting. The need for some kind of pedagogical content knowledge (including knowledge of content and students/children in particular) appears evident in this situation. The challenge is to try and distinguish what kind of content-related knowledge (specialized content knowledge in particular) that kindergarten teachers like Mary need. A focus on tasks of teaching is a relevant tool to use when approaching such a challenge. Mary is also involved in work related to presenting ideas. Mary's work of teaching is, however, quite different from that of a mathematics teacher in school. In our particular case, Mary introduced an activity that she believed would provide the children with various experiences related to counting. She would not, however, present ideas of counting to a whole group of children in a lecture-like way. Instead, she has to react to challenges as they appear within the context of a play situation. Mason and Spence (1999) propose that the absence of the active knowledge (knowing-to) blocks teachers and students from responding constructively in the moment. In the same way, it is an important feature for a kindergarten teacher to act in the moment and to show awareness in a particular teaching situation. In Mary's situation, we might refer to this as situated knowledge of responding to the children's questions. The question she had to respond to, however, just appeared from the children's acting in the play situation. It was not asked directly by the children.

For a mathematics teacher in school, teaching is often related to a particular textbook or other curriculum material. The teacher presents a mathematical idea to the class, and appropriate examples are used to illustrate or make specific a certain point. A Norwegian kindergarten teacher, like Mary, does not have a mathematics textbook. Instead, she presents a mathematical idea by using examples as they appear naturally in the play situation, and she is trying to facilitate a context in which the children can experience a certain idea. We would suggest that a reformulation is necessary in order for the tasks of teaching to be relevant in a kindergarten context. One suggestion is to merge the two tasks that were originally defined as "presenting mathematical ideas" and "finding an example to make a specific mathematical point" into "facilitating activities that enable children to experience mathematical ideas".

Another task of teaching that we identify in this case is that of connecting a topic taught with topics from prior years. Several issues appear problematic when trying to apply such a description to the tasks involved in Mary's practice. Most importantly,

she is not teaching the children in a traditional sense, and Norwegian kindergarten teachers (and educators) often avoid using the word “teaching” altogether. Different topics are covered through experiences from play situations and informal discovery activities, and it is therefore hard to track previously taught topics in Norwegian kindergartens. She facilitates the children’s learning and exploring in a play context. The aims that she has set for the activity are based on her impressions of where the children are in their mathematical development rather than knowledge of previously taught topics. It becomes a challenge for Mary to figure out what kind of informal knowledge the children have previously built in relation to this topic. Oftentimes, they have made experiences in free play (where Mary has not been present), or their informal knowledge has been built from experiences in everyday situations at home or in kindergarten. Whereas a mathematics teacher in school can go back to curriculum materials (like textbooks), previous tests or worksheets, Norwegian kindergarten teachers do not have this possibility. The task of connecting with previously taught topics thus becomes a different task of teaching when compared with that of teachers in school.

Other tasks of teaching (as presented by Ball et al., 2008) are more relevant for describing the work of teaching of Norwegian kindergarten teachers, but the ones discussed above are somewhat problematic.

CONCLUSIONS

When Ball and colleagues (e.g. 2008) proposed their theoretical framework of MKT, they also included a list of common tasks of teaching that were intended to describe the work of teaching of mathematics teachers in school. The research that this framework builds upon was conducted in the U.S. only, but the tasks of teaching as well as the theoretical framework as a whole were still supposed to be of a more universal nature. When trying to apply this framework to describe the professional knowledge of a Norwegian kindergarten teacher, some problematic issues appear. Although the model’s distinction between various aspects of teacher knowledge appears to be applicable in a kindergarten setting, some of the proposed tasks of teaching have to be modified. The main reason is that the work of teaching of a Norwegian kindergarten teacher is very different from that of a mathematics teacher in U.S. Schools. Whereas mathematics teachers in school are constantly faced with challenges regarding how to present mathematical ideas, the entire concept of presenting mathematical ideas needs to be described differently in order to apply as a description of the work of teaching that Norwegian kindergarten teachers are involved with. Although it can be described as a similar kind of challenge, the way a kindergarten teacher has to use play situations and everyday activities in order to facilitate children’s informal experiences with mathematical ideas is quite different from when mathematics teachers in school attempt to present mathematical ideas to their pupils. Our suggestion is to merge the two tasks that were originally defined by Ball and colleagues (2008) as “presenting mathematical ideas” and “finding an

Working Group 13

example to make a specific mathematical point” into “facilitating and using activities and play situations that enable children to experience mathematical ideas”. Similarly, the task of teaching related to connecting a topic taught with topics from previous years also needs some adaptation. For a Norwegian kindergarten teacher, it becomes more of a challenge related to uncovering and building upon the children’s previous informal knowledge and experiences from everyday activities and play situations.

The Norwegian kindergarten belongs to a social pedagogy tradition (see OECD, 2006), and we suggest that some of the challenges with using the MKT model in a kindergarten context might be relevant for other kindergartens and kindergarten teachers within such a tradition. The work of teaching of kindergarten teachers within the pre-primary tradition (ibid.) is probably more similar to that of mathematics teachers in school, and the MKT model along with the proposed list of tasks of teaching might be more directly transferable in such a context. We believe that further research is needed in order to learn more about the tasks of teaching that kindergarten teachers are faced with. Although the MKT model can be used to describe some relevant aspects of the professional knowledge that is needed in a kindergarten setting, vital differences between the work of teaching as well as the tasks of teaching of kindergarten teachers and those of mathematics teachers in school exist. Further studies are needed in order to investigate such similarities and differences, and we believe that special attention needs to be made in relation to cultural as well as situated aspects.

NOTES

1. Our research project has been supported by OLF, The Norwegian Oil Industry Association.
2. *Tasks of teaching* refer to a specific list of challenges that have been identified. The complete list includes: Presenting mathematical ideas, Responding to students’ “why” questions, Finding an example to make a specific mathematical point, Recognizing what is involved in using a particular representation, Linking representations to underlying ideas and to other representations, Connecting a topic being taught to topics from prior or future years, Explaining mathematical goals and purposes to parents, Appraising and adapting the mathematical content of textbooks, Modifying tasks to be either easier or harder, Evaluating the plausibility of students’ claims (often quickly), Giving or evaluating mathematical explanations, Choosing and developing useable definitions, Using mathematical notation and language and critiquing its use, Asking productive mathematical questions, Selecting representations for particular purposes, Inspecting equivalencies (Ball et al., 2008, p. 400).

KINDERGARTNERS' PERSPECTIVE TAKING ABILITIES

Aaltje Berendina Aaten*, Marja van den Heuvel-Panhuizen*, Iliada Elia[^]*

*FIsme, Utrecht University, the Netherlands

[^]Department of Education, University of Cyprus, Cyprus

This study investigated kindergartners' imaginary perspective taking (IPT) abilities by examining their ability to imagine whether an object is visible from another viewpoint (IPT Competence 1) and how an object looks from another viewpoint (IPT Competence 2). The participants were 308 4- and 5-year-old kindergartners in the Netherlands. A paper-and-pencil test of various perspective-taking pictorial tasks was developed and administered to the children. The results show that IPT Competence 2 is more difficult than IPT Competence 1, and that both competences develop during the kindergarten years. Also, for both IPT Competences 1 and 2 a positive relationship was found with mathematics performance, while no gender difference was found on either IPT Competence.

Key-words: Kindergartners, Spatial reasoning, Perspective taking ability, Gender

SPATIAL GEOMETRY FOR YOUNG CHILDREN

Geometry is an indispensable part of contemporary early childhood curricula and educational programs (Sarama & Clements, 2009). It is not confined to plane geometry, but spatial abilities play an important role as well. For example, in the Standards of the National Council for Teachers of Mathematics (NCTM, 2000) in the K-2 grades much attention is paid to *Specifying locations* (which includes interpreting relative positions in space) and *Using visualization* (which includes creating mental images of geometric shapes using spatial memory and spatial visualization and recognizing and representing shapes from different perspectives). Similarly, the TAL teaching/learning trajectory for geometry (Van den Heuvel-Panhuizen & Buys, 2008) includes the sub-domain *Orienting* which focuses on localizing and taking a point of view in both the first and second year of kindergarten (K1 and K2).

This emphasis on a spatial interpretation of geometry for young children is not surprising. It is the natural way in which children encounter geometry. They discover the world around them while they walk, play, and look around. They are in fact investigating their environment all the time; by doing so, they learn to find their way, to determine their own location within the environment, to describe to others their own position or the position of an object such as their teddy bear. Also visualization and spatial reasoning abilities develop through children's activities, such as playing hide-and-seek. Children try to hide in a place in which they will not be visible to the child that is looking for them. As such, they try to imagine or to reason what the other child will and will not be able to see while wandering around.

Although the above seems very plausible now, in the past the teaching of geometry to children started with plane geometry. It was Freudenthal (1973) who argued strongly for changing this and starting with spatial geometry at an early age.

“Geometry is grasping space . . . that space in which the child lives, breathes and moves. The space that the child must learn to know, explore, conquer, in order to live, breathe and move better in it.” (Freudenthal, 1973, p. 403)

Enhancing young children’s spatial abilities is important for several reasons. As described above, spatial abilities help children to understand their environment. Furthermore, the development of spatial abilities is important for the development of mathematics ability in general. According to Clements (2004, p. 267), “[g]eometry and spatial reasoning form the foundation of much learning of mathematics and other subjects.” Spatial reasoning in particular is recognized by mathematicians as a useful strategy in mathematical problem solving, for example through the use of diagrams and drawings to solve problems (Casey, Andrews, Schindler, Kersh, Samper, & Copley, 2008). Moreover, teaching spatial ability enhances children’s mathematical attitude (Casey et al., 2008; Van den Heuvel-Panhuizen & Buys, 2008).

Altogether, spatial abilities are important for young children to learn and therefore, it is worthwhile to gain more insight into how they develop these abilities. In this study, we focused on a specific spatial ability of kindergartners, namely their competence to mentally take a particular point of view.

IMAGINARY PERSPECTIVE TAKING

Important research on imaginary perspective taking (IPT) has been done by Piaget and Inhelder (1956). One of the tasks that they used to investigate children’s IPT was the “Three Mountain task”. In this task children were positioned on one side of a table and asked to describe how the scene on the table would look from the opposite side. In this way it was found that children up to the age of nine tended to describe the way the scene looked from their own position. They were not able to take a perspective from another position than their own.

Flavell, Everett, Croft, and Flavell (1981) came up with a distinction into two abilities of perspective taking. The so-called Level 1 competence concerns the *visibility of objects*: a child that has achieved this competence is able to deduce which objects are or are not visible from the other viewpoint. The Level 2 competence relates to the *appearance of objects*: a child that has attained this competence is able to indicate how an object looks as it is observed from a different viewpoint. Hughes (1975, as cited by Donaldson, 1980) has independently proposed a very similar model, in which “projective” and “perspective” abilities correspond respectively to Level 1 and Level 2 competence.

In connection to the distinction into two abilities, Flavell et al. (1981) also found that the abilities differ in their rate of development. Children of three years of age performed well on the Level 1 tasks but had difficulties with the Level 2 tasks.

Mathematics performance

Many studies (e.g. Burnett, Lane, & Dratt, 1979; Casey, Nuttall, & Pezaris, 1997; Geary, Saults, Liu, & Hoard, 2000) have found positive correlations between mathematics performance and spatial ability, but most of these studies were done with high school and university students. Only a few studies were carried out with young children. For example, Robinson, Abbot, Berninger, and Busse (1996) found a high correlation between two-dimensional reasoning and quantitative skills in precocious preschoolers and kindergartners. Guay and McDaniel (1977, as cited by Lean & Clements, 1981), who did a study with primary school students, focused on a broader range of spatial abilities not only compassing two-dimensional visualization tasks, but also tasks involving three-dimensional mental images and mental transformation of these images. The results indicated a positive correlation between mathematics performance and two- and three-dimensional spatial tasks in primary school students.

Gender

The findings with respect to the relation between gender and spatial ability are various. Several studies found a male advantage for three-dimensional mental rotation (Casey et al, 2008), two-dimensional mental rotation as well as translation (Levine, Huttenlocher, Taylor, & Langrock, 1999), and spatial visualization (Tracy, 1987) already in existence at kindergarten age. Horan and Rosser (1984) investigated children aged 4, 6, and 8 years who were offered dimension-transcending tasks in which the questions and the answers were formulated in a different dimension: a three-dimensional object was shown and the child was asked how this object looked to an observer in another position after the object was rotated 90°. The child could answer the question by selecting the correct two-dimensional picture. In these dimension-transcending tasks, boys performed better than girls. However, if the question and the answer were both presented in the form of two-dimensional pictures, girls performed better than boys.

Some studies, though, did not reveal a gender effect for spatial ability. For example, Lachance's and Mazzocco's (2006) longitudinal study on children in lower primary school did not show sustainable gender differences in spatial ability in general. Also, Newcombe and Huttenlocher (1992) did not find gender differences with respect to perspective taking in their study in which they asked young children which object would be in a certain position relative to another observer.

RESEARCH QUESTIONS AND HYPOTHESES

In light of the above, we formulated three research questions to gain more insight into kindergartners' imaginary perspective taking abilities:

Working Group 13

1. How able are kindergartners in IPT Competence 1 (determining whether an object is visible from another viewpoint) and IPT Competence 2 (imagining how an object looks from another viewpoint)?
2. How are these IPT competences related?
3. How are these IPT competences related to kindergarten grade, mathematics performance and gender?

Based on previous research we could only formulate two hypotheses:

1. Kindergartners will perform better on tasks requiring IPT Competence 1 than on tasks requiring IPT Competence 2.
2. There will be a positive relation between mathematics performance and the IPT competences.

METHOD

Assessment Instruments

Assessment of IPT. To answer our research questions, we developed a paper-and-pencil test to measure kindergartners' perspective taking abilities. This test contains two booklets of test items, and was administered in two test sessions. The test items consist of a picture illustrating what each question is about and four pictures depicting the possible answers. Before implementing the test items in our study, we piloted them to ensure children's correct understanding of the test items.

In Figure 1a, an example of a test item is given. This *Basket* item is meant for measuring IPT Competence 1. Figure 1b shows the *Mouse* item, meant for measuring IPT Competence 2.

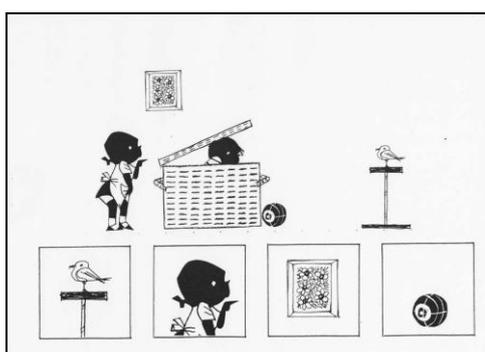

Figure 1a: *Basket* item

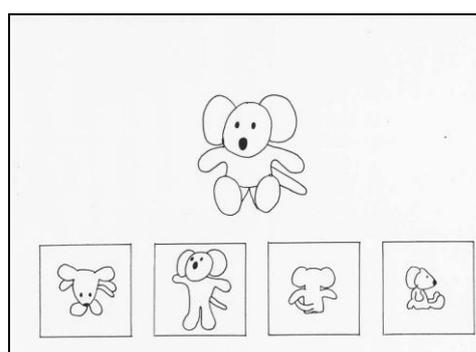

Figure 1b: *Mouse* item

The questions were read to the children by trained test administrators. For the *Mouse* item, the question was: "How do you see Mouse if you look at him from above like a bird?" Children answered the question by underlining the picture that shows the correct answer. Correct responses were coded as 1, and incorrect ones as 0. Six items in the test concerned IPT Competence 1 and five items concerned IPT Competence 2.

Assessment of mathematics performance. To assess children's mathematics performance, we made use of a standardized mathematics test for kindergartners, the CITO Test Ordering, which is in nation-wide use. This test has separate versions for the first (K1) and second year of kindergarten (K2); the Cronbach's alphas of both versions are .85 and .81 respectively (Van Kuyk & Kamphuis, 2001).

Participants

Our study involved 384 Dutch kindergartners. Children who did not do both test booklets were excluded from the analysis, which diminished our sample to 308 children, 146 girls and 162 boys; 109 children attended K1 and 199 children were in K2. The K1 children had an average age of 4 years and 8 months and the K2 children were on average 5 years and 8 months old.

RESULTS

Kindergartners' abilities in IPT Competences 1 and 2

The data analysis showed that the kindergartners achieved a significantly higher success rate on test items that require IPT Competence 1 ($M = .73$, $SD = .20$) than on the IPT Competence 2 items ($M = .34$, $SD = .22$) [$t(307) = 26.42$, $p < .01$], see Figure 2.

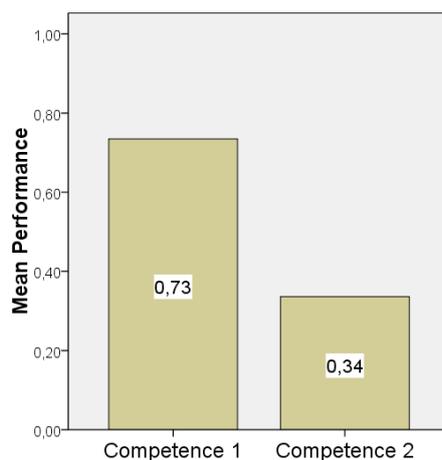

Figure 2: Mean performance on IPT Competence 1 and IPT Competence 2 items

Relationship between IPT Competences 1 and 2

A statistical implicative analysis (Lahanier-Reuter, 2008) was used to investigate the relationship between the two competences based on the children's responses to the test items. Statistical implicative analysis leads to results such as "if we observe success on item a in a subject, then in general we observe success on item b in the same subject". We conducted this analysis for both kindergarten grades separately. In Figure 3 the results for K1 are depicted on the left and the results for K2 on the right. The figure shows how the items are related. The item names indicate what competence the item measures. For example, the item *C2cucumber* requires IPT Competence 2. The diagram shows that in K1, success on this item implies success on two IPT Competence 1 items. The probabilities of these implications are 90% for the grey arrows (e.g.

$C2cucumber \rightarrow C1tower$) and 95% for the blue arrows (e.g. $C2cucumber \rightarrow C1hole$).

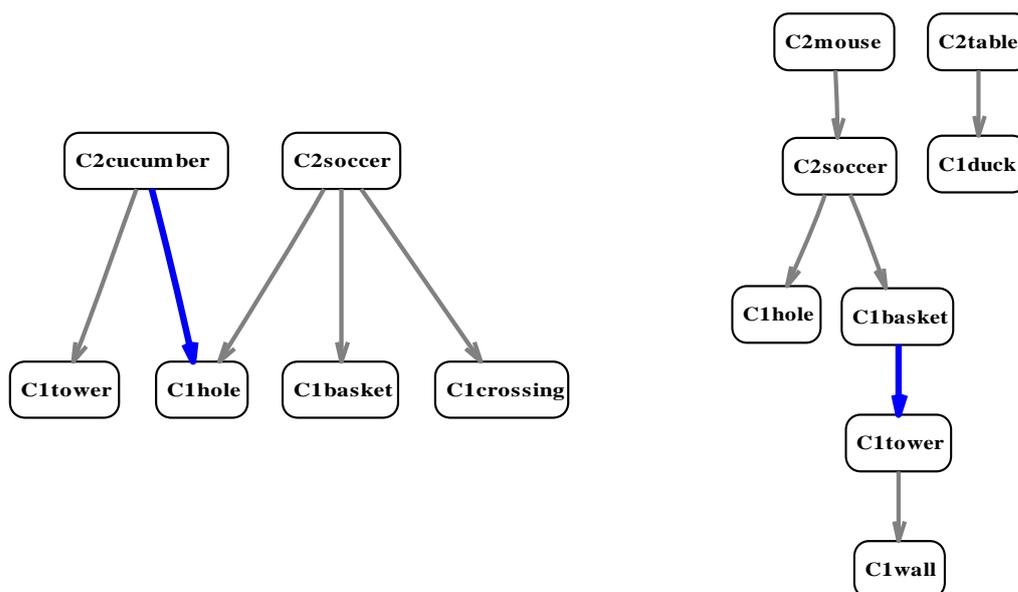

Figure 3: Implicative Relationships between successes on test items by K1 children (left) and K2 children (right)

The implicative diagrams for the K1 and K2 data show a similar pattern. In both diagrams, the items that measure IPT Competence 2 are high up in the diagrams, whereas the IPT Competence 1 items are positioned below them, i.e. success on the IPT Competence 2 items implies success on the IPT Competence 1 items.

Development of IPT Competence 1 and 2

To gain more insight into the development of IPT Competences 1 and 2, we compared the performance on items measuring these IPT competences between kindergartners in K1 and K2 by carrying out independent samples t-tests.

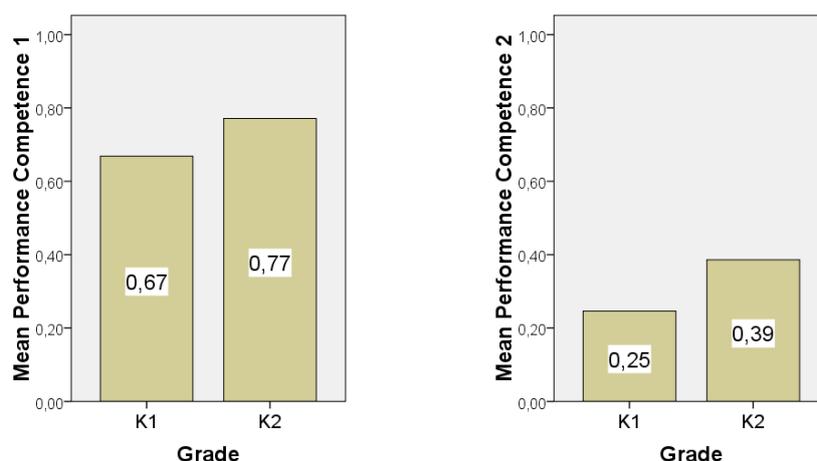

Figure 4: K1 and K2 children on IPT Competence 1 items (left) and IPT Competence 2 items (right)

As illustrated in Figure 4, K2 children's performance on IPT Competence 1 items ($M=.77$, $SD=.18$) was significantly higher than the K1 children's performance ($M=.67$, $SD=.21$) [$t(306) = -4.44$, $p < .01$]. Also on IPT Competence 2 items, K2 children performed better ($M=.39$, $SD=.22$) than K1 children ($M=.25$, $SD=.19$) [$t(306) = -5.59$, $p < .01$].

Mathematics performance and IPT

To investigate a possible relation between IPT Competences 1 and 2 with mathematics performance, one-way analyses of variance (ANOVA) were carried out with the IPT competences as the dependent variables and children's mathematical achievement level as the independent variable. Children's mathematical achievement level was based on their score on the CITO Mathematics Test. The scores on this test are indicated by a letter. An A-score means that the test score belongs to the highest 25% scores of the complete Dutch population of kindergartners, a B-score stands for the next 25%, a C indicates that the score is in the third quartile, while D concerns the next 15% of scores and E the 10% lowest scores. The results of the analyses are shown in Figure 5.

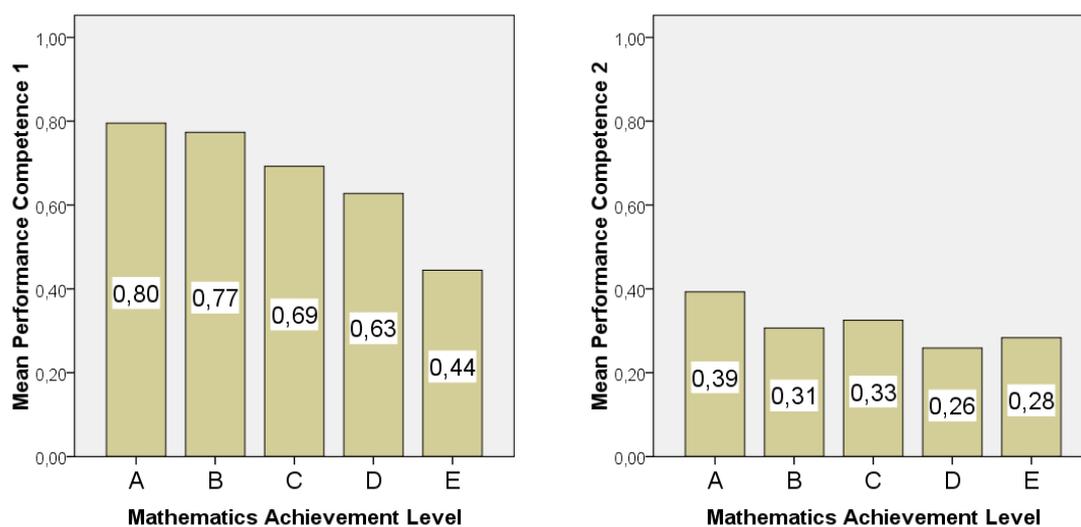

Figure 5: IPT Competence 1 (left) and IPT Competence 2 (right) relative to mathematics performance

For IPT Competence 1 [$F(4, 298) = 14.56$, $p < .01$] as well as for IPT Competence 2 [$F(4, 298) = 3.12$, $p = .02$] we found a significant relationship with the children's mathematics performance level.

Gender and IPT

Independent-samples t-tests were used to compare boys' and girls' performances on the items measuring the two IPT competences. The results indicated no gender difference on either IPT Competence 1 (Boys: $M=.73$, $SD=.20$; Girls: $M=.74$, $SD=.21$) [$t(306) = -0.12$, $p = 0.90$] or on IPT Competence 2 (Boys: $M=.34$, $SD=.22$; Girls: $M=.33$, $SD=.22$) [$t(306) = 0.57$, $p = 0.57$], as is illustrated in Figure 6.

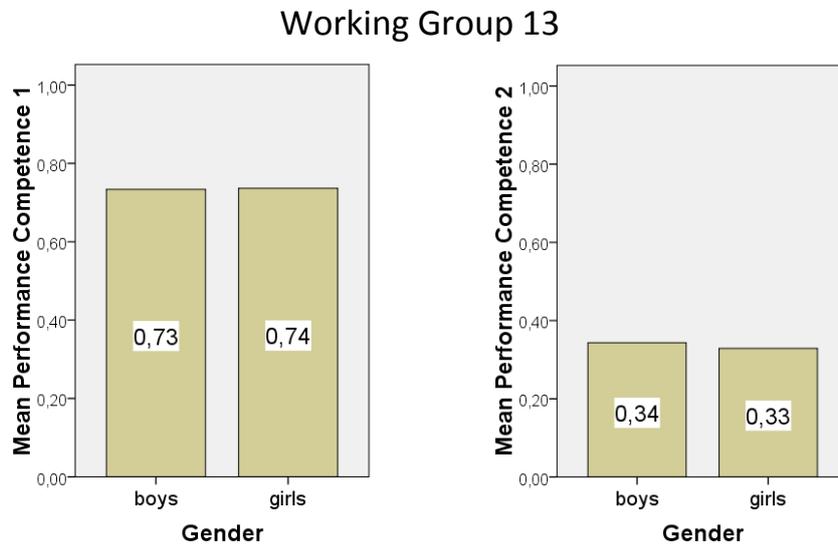

Figure 6: Performance in IPT Competence 1 (left) and IPT Competence 2 (right) by boys and girls

DISCUSSION

In this study we investigated kindergartners' competences in determining the visibility and appearance of objects as seen from another point of view. In particular, we examined how these abilities are related, how they develop, and how they are related to gender and mathematics performance.

Concerning kindergartners' ability to determine whether an object is visible from a different viewpoint (IPT Competence 1), we found an overall success rate of 73% while the success rate on items that require the ability to determine the appearance of an object from a different point of view (IPT Competence 2) was significantly lower, i.e. 34%. This result indicates that the IPT Competence 2 items are more demanding for the children than the IPT Competence 1 items (Hypothesis 1), which is in line with previous studies (e.g. Flavell et al., 1981).

Statistical implicative analysis showed that success on several of the IPT Competence 2 items implied success on either other IPT Competence 2 items or on IPT Competence 1 items. The other direction, an implicative relation of an IPT Competence 1 item and an IPT Competence 2 item, was not found. This suggests that the development of IPT Competence 1 precedes the development of IPT Competence 2. This conclusion is in agreement with our finding that the children performed better on the IPT Competence 1 items than on the IPT Competence 2 items.

Children at kindergarten age experience major development in many fields. This turned out to be the case for the IPT competences as well. In our study we found that both IPT competences increase significantly from K1 to K2.

With respect to factors that possibly influence IPT we found that the children's mathematics performance level is significantly related to their IPT competences. This is in line with earlier findings on the relation between spatial ability and mathematics

performance. However, in our study the relationship between mathematics performance and IPT was stronger for Competence 1 than for Competence 2. Future research could explore the causes of this difference and whether it changes over time.

Comparison of IPT competences from the view of gender did not reveal significant differences. Both for the IPT Competence 1 items as well as for the IPT Competence 2 items, the results were similar for boys and girls. This finding is in agreement with previous studies on perspective taking, but contrasts with studies into the relationship between gender and spatial ability as assessed, for example, by rotation and translation tasks. Spatial ability clearly has a multi-dimensional structure of which the different aspects might have a different gender profile. Further research is indicated on this topic.

THE LINGUISTIC CODING OF MATHEMATICAL SUPPORTS

Anna-Marietha Hümmer

Goethe-University Frankfurt a.M., Germany

Within the framework of recent research in mathematics education a subject specific performance of children and the learning of mathematics is not only depending on cognitive dispositions, which are mediated by individual performance motivation, but in a large part constructed socially. Mathematical concepts and procedures as well as the description of accepted participation in mathematics thereby are not conveyed explicitly, but transmitted implicitly in terms of so-called “codes”, which have a socio-linguistic dimension. In the micro sociological focus of this paper the question should be addressed, to which extent the acquisition of basal mathematical knowledge in early childhood is regulated by the ability to recognize such linguistic codes and their meaning. In that case sequences from mathematical situations with children age 4 are analysed concerning to (subject specific) socio-linguistic theories according from Bernstein (1996) and Carruthers and Worthington (2006). First theoretical considerations and empirical results will be presented.

INTRODUCTION

According to the later work of Basil Bernstein (1996), verbal skills and the ability of “reading” and reproducing linguistic codes in interactions are playing a significant role in learning mathematics and for the performance of mathematics’ discourses (e.g. Schütte 2010; Gellert/Hümmer 2008; Lubienski 2004). “Success” in learning mathematics therefore seems to be dependent to the ability of decoding relevant meanings and rules of participation in mathematical interactions on the verbal and non-verbal plane in order to comprehend the mathematical content and subject specific mathematical demand on presenting a content. With respect to this approach the paper focuses on the question, to which extent the development of mathematical thinking and learning in early childhood is regulated by the ability to recognize such linguistic codes and to decode their meaning. To put it in more concrete words: What kinds of codes can be specified in discourses within the kindergarten context and which impact do they have on the acquisition and the learning of mathematics in the early years.¹

On the theoretical plane this paper tries to concatenate the socio-constructivistic approach of Bruner (1983) concerning learning theory with the socio-linguistic models of Basil Bernstein (1996) to take in to account the impact of linguistic representations on the process of negotiation of meaning.

From a socio-constructivist point of view the individual ability of learning mathematics and to participate successfully in mathematical discourses develops in the course of interaction with other members of the culture. Bruner (1983) emphasizes that it is impossible for an individual to acquire knowledge without

social interaction. The participants construct in their interactional moves a system of linguistic codes. For this reason, we analyze the mathematical situations of play and exploration that we initiated in day care centres by reconstructing this process of “code-production”. In the following analysis there is chosen a situation with exemplary character to give a short but detailed look towards the research questions and the current work within the project.

THEORETICAL PERSPECTIVE

From a socio-reconstructivistic perspective the acquisition of mathematical knowledge is not only an act of the (inner-psychological) internalization of concepts and procedures, rather it is a process that is conditional on the negotiation within interactions. The cognitive development of the individual itself is seen as constitutive product moderated through the participation in such interactions. The social interaction therefore is a condition for the probability of learning (e.g. Miller 1986, p. 27f; Krummheuer 1989, p.241f). Within these interactions conducive instants can probably emerge.

Supports as a condition of mathematical learning

Concerning to Bruner (1983) the process of learning starts when an adult and a child „create a predictable format of interaction that can serve as a microcosm for communicating and constricting a shared reality“(Bruner 1983, p.14). In this interactional framework „ shared procedures of interpretation and negotiation “ (ibid., S.17) take place. Bruner developed, in the first instance without knowing Vygotsky’s work, a theoretical approach within learning is afforded by a so-called “Supportive system”, which is moderated by a capable other. With regard to the acquisition of mother tongue, which Bruner observed, he considered such a “Language Acquisition Support System“ (LASS) (ibid., p.32) as necessary for the activation of the inborn “Language Acquisition Device” (LAD). On the empirical plane Bruner reconstructs the so-called “format”(ibid., p.33) for which he accounted a supportive or rather a conducive function during the process of learning. The “format” hereby is “a standardized, initially microcosmic interaction pattern between an adult and an infant that contains demarcated roles that eventually becomes reversible“ (ibid., p. 120). For Bruner increasing autonomy within these “formats“ was seen as an indicator for learning progress. In his later approaches Bruner sees a direct conjunction between his perception and the “zone of proximal development” developed by Vygotsky (1978). This way he introduces the concept of “scaffolding” (Bruner 1990). Krummheuer (1989) proves these supportive structures also in mathematical learning processes in discourses in primary school.

Codes within mathematical supports

From a perspective on learning theory the supports that are mentioned before have the function to afford the acquisition of knowledge and transmit the rules of accepted

participation in a specific discourse on the structural plane. This way they establish conditions for the learning process and can be understood as structural and structuring elements of a pedagogical situation. Thereby both the plane of meaning as regards contents and the social plane of accepted participation are structured by the formatting of meanings and attitudes. Though in his research Bruner focuses mainly on the function of supports concerning to the early acquisition. The difficulties given by the form of this structures (supports) and their influence on the development of meanings he leaves untouched. How these difficulties arise on a verbal plane Schütte (2010) describes. He perceives in his work on the linguistic plurality in mathematics classroom that the implicit transmission of knowledge and subject's content are main phenomena in interactions of the mathematics classroom. Therefore he obtains to the concepts of Basil Bernstein who speaks within his theory of codes of an "invisible pedagogy" (e.g. Bernstein 1996). According to Bernstein pedagogical situations and interactions are affected by regulative principles, so called codes. They are determined by implicit rules, which select and integrate relevant meaning, the way of realisation and the generating context (Bernstein 1996, p.111). Bernstein in that case speaks of the classification and the framing of the pedagogical knowledge (Bernstein 1996). The classification he assumes from the sociological concepts of Durkheim. It describes what belongs to a specific discourse and what is not part of it. This way the focus of the description is not the conjunction between different discourses rather the description is focussing on the boundaries between discourses. The classification also affects which content and meanings are valid for a specific discourse. It regulates which kind of content and meaning are acceptable within the interaction. This content and meanings have to be recognized. Bernstein calls this the „recognition-rule“ (Bernstein 1996, p. 30ff.). The second abstract, theoretical concept Bernstein introduces is the concept of "framing". It controls the social accepted behavior and accordingly the participation. It controls thereby the social relationship, the hierarchy and the performance on presented content. In case of the concept of framing Bernstein introduces parallel to the concept of "recognition rules" the approach of "realisation rules". On the one side both concepts deal with the rules of recognizing which symbols or gestures are closely connected with which meanings and on the other side how the accepted realisation of acquired knowledge looks like. In other terms: What is the relevant message of the communication and how a reply has to be communicated. These are two functions that are fundamental to each communicative situation. Schütte (2009) describes that concerning to the implementation of new contents in mathematics these rules should be transmitted explicitly to make the acquisition more easy for a child. This way the process of acquisition would be more successful. To which extent the acquisition of early mathematics also follows this appraisal should be observed and discussed in the following on an empirical and theoretical plane.

Another approach which Bernstein mentioned in his earlier work from the sixties and seventies and which he extended till his death in 2000 are the concepts of the

restricted and the elaborated code (e.g. Bernstein 1970; 1985; 1996). As elaborated the production of texts and contributions are seen if they are independent from every day expressions and generally admitted. As restricted are seen those, that depend on a specific situation and a context and only concern the given symbols and meanings (e.g. Bernstein 1972; Leufer & Sertl 2010; Lubienski 2004).

Formal and informal speech

The approach of Carruthers and Worthington (2006) concerning the learning of Mathematics of preschoolers can be seen as an amplification of the further concepts of Bernstein. Similar to Bernstein, for them Mathematics takes place in two different languages: the informal every day language and the formal language of mathematics which is determined through specific technical terms and algorithmic diagrams. Thereby the transfer between both “languages”, as Carruthers and Worthington declare, is not distinctive or does not exist. So there is a discrepancy between formal and informal mathematics language. Over the intervening years children develop a so-called multi-competence, which enable them to have more than one ambassador of a linguistic approach simultaneously in mind. A kind of “interims speech” which is determined by rules and structures the children produces by themselves takes the part of connecting informal aspects with the formal ones. The knowledge of the informal every day language therefore is used to develop a formal speech. A main competence of children according to the acquisition in the early years seems to be inferential to develop such a multi-competence und to switch flexibly between both (the formal and the informal) languages and their assignment of meaning.

Together with the further concepts of Basil Bernstein the result for the examination of subject specific codes in Mathematics can be diagrammed in the following Matrix.

	socio-linguistic	restricted	elaborated
subject specific			
formal			
informal			

plane of meaning

Fig. 1: Matrix of the mathematical codes

Interactions in mathematical Supports therefore can be coded at the same time as well formal mathematical as verbal restricted. This seems to be confusing at the first glance, but it is characteristic for mathematical Codes. One example is the use of the term “if... then” which is characterising the mathematical logic of proof. Concerning to the interactionistic perspective of negotiation and accordingly the situational emerging meanings in interactions the theoretical approaches of Bernstein and

Carruthers and Worthington get a third dimension – the plane of meaning. In the following analysis this dimension should be useful for the exemplary description of the development of mathematical concepts and procedures and give a deeper insight.

METHODOLOGY

Process of reconstructive analysis

Having regard to the theoretical approaches and the attempt to identify support structures and their coding in mathematical interactions, in the following there is conducted an analysis of interaction, which refers to the interactional theory of learning (Cobb & Bauersfeld, 1995). The method was devised by a working group round Bauersfeld in reference to ethnomethodological conversation analysis (Eberle 1997; Sacks 1998; Garfinkel 1967). It focuses on the reconstruction of the meaning and the structure of interactions (Krummheuer, in press). Therefore it is proper to describe and analyse topics with regards to contents and the negotiation of meaning in the course of interactional processes with a supportive character. Thus the verbal coding within the supports and the connected concept of the “formatting” (as a distinguished structural element in the analysis) is focussed in the analysis there is an emphasis on elements of the conversation analysis. Therefore the analysis lays stress on the functional aspects of the interactional process and highlights the rules and methods by which the actors construct the communication. It should be asked, how the functional aspect effects the performance of the process of learning.

Short description of the sample

The analysed sequence is part of the empirical work within the project erStMaL (early Steps in Mathematics Learning) at the Centre on Individual Development and adaptive Education of Children at Risk (IDeA) in Frankfurt a.M. (Germany). The research design contains the observation of 277 children age 3,5 to 6. The children come from 12 day care centres in the area of Frankfurt a.M. in Germany.

ANALYSIS - „ AND WHICH ARE BELONGING TOGETHER“

Short description of the situation

The situation of play and exploration, which is described in the following chapter is accomplished by a nursery teacher. She is the attachment figure of the children and their group leader at the day care centre. Additionally she is in charge of the group of the so-called “small researchers” in the kindergarten. The nursery teacher achieves the specification of the mathematical domain for the accomplishment of the situation, which is “Measurement”. The children who are taking part in the situation are: Hannah (3;3 years), Michael (3;7 years), Bettina (4;7 years) und Martha (5;3 years).

The material the nursery teacher uses in the situation is: two green paper circles with different diameters (0,5m and 1,0m), a gunnysack which is filled with ten different objects in each case in two different sizes. During the time of the sequence the

Working Group 13

children are sitting on a carpet together with their nursery teacher. To paper circles are lying on this carpet in the way that the children are able to sit in a hemicycle around it. The sequence takes place in the middle of the situation. In the sequence before the nursery teacher asked the children to allocate the object to the two paper circles according to their size. It takes some turns till every object is related to a circle.

Analysis – *Focusing linguistic codes within the supports*

The sequence is opened through the comment of the nursery teacher. Therefore she structured the proceedings by her question, which the children should answer. This way she implicates a call for action. Through the temporarily advice towards the immediate presence of the question which is given on the verbal plane, the nursery teacher confines the sequence from the previous one. The content of this section was the children distribute the objects according to their relative dimension to the two paper circles. But this confining is also denoted implicitly and is not fastened as regards contents (of the previous sequence). On the content plane the expected structuring thereby is not taking place. Thus the reference, which is underlying the given question, can be only understood in mathematical terms by decoding informal verb “belong”. The realisation rule that marked the accepted participation on the thematically plane extensively last open. In that case one can speak of an informal, restricted coding.

Bettina seems to be able to decode. She marks two objects of similar form and different measure. The regulating system, which forms the basis of her action, seems to be formal. She develops a reference, which can be seen as a subset of the implicated system of the teacher. She abridges the system through the addition of the attributes form and measure. Both of these attributes can be seen as formal mathematical issues, which are representations of the mathematical domain geometry. Same counts for the centric dilatation, which is essential to a proof of congruence. The teacher does not amplify, neither positively, nor negatively. She “replies” through a further call for action <006-009>. This way she is structuring another time. The call for action from the beginning of the sequence is now being extended towards system of rules: the objects should not only being marked, they have to be collected and placed in line beside the paper circles and separated from the other ones. However there is no direct reference to the action of Bettina and obviously Bettina could not integrate the extended aspects of the system to her own. Probably the previous action effects a controversial conflict for Bettina and she takes another object. The teacher impairs another time in a structuring way and references implicitly to her system: two objects should be marked <011>. Also this turn lingers informal verbal and restricted in the linguistic code. However Bettina seems to understand and takes a second pin. In the following expression <012> the nursery teacher repeated the second aspect of the call for action from line <006-009> and specifies the placement of the objects as well through her verbalisation as trough her gesture, which can be seen as exemplification. That way she structures the interaction another time. Bettina decodes also this expression as a call for action, which has to be complied. This becomes obvious through her action in line <014-016>. The formal interpretation of the implicit, informal-coded and extended system

of meaning, which is given by the teacher, here has to be speculative. The subsequent positive evaluation by the nursery teacher in line <019> “Exactly\ this way\” can be seen as structural limiting point of the sequence. Her non-verbal action in line <019-021> indeed can be seen as a further add-on of the system, but it may also an exemplarily given advice for the next action. It is underlined by her comment in line <021> through which she invites the other children to take part in the situation.

Concerning to the structure of the support one can assume that the formatting of the nursery teacher is characteristic for supportive structures in learning situations as they are observed in case of child-parents-discourses (e.g. Tiedemann 2010) and also discourses in mathematics classroom. Thereby the content and the accepted participation in the discourse is - in terms of the invisible pedagogy – strongly framed and classified. Both classification and framing is obvious through the so-called „Trichtermusters“ (e.g. Bauersfeld 1978). This pattern structurally partitions the interactional sequence und sequences or rather “portions” the contributions of the child. The strong classification is also observable through the format of content, which is underlined through the gestural exemplification or rather diagrammatics in terms of Peirce and focuses concrete systems of mathematical meanings.

SUMMARY

In the context of the analysed sequence supports in the acquirement of basal and mathematical concepts and procedures seem to be strongly categorized and regulative formatted, but they are mostly implicit in terms of content. On the verbal plane this is expressed by an informal and mostly restricted codification. However the regulative system, which is underlying the supports in mathematical interactions, has to be seen as formal and elaborated.² This has enormous consequences for children concerning their process of learning: Namely there can emerge conducive moments in the interaction through the strong formatting of the course within the supports in mathematical situation³, though in terms of content children have to provide an enormous performance to decode the implicit, informal remarks respectively to their implicated, formal mathematical meaning. The presentation of the solution process has also to correspond to this implicit formal regulation system. The decoding becomes more complicated by the fact that the implicit and formal reference of framework is probably subjected to a fast changing development process. Though there is mostly just a little gap between the changing references or framings⁴, which can be seen as exemplifications attending to foster the process of learning, but the implicit coding seems to make it difficult for the children to understand the change in meaning of these exemplifications. The result can be the persistence on the previous reference and framing. With respect to the previous theoretical considerations and the approach referring to Carruther’s and Worthington’s concept of „multi-competence“ (2006) children have to develop the ability to translate not only between informal and formal language, but also between

informal and restricted language and the implicated formal meaning. In what way the so called “invisible pedagogy” (u.a. Schütte 2009; Gellert/Hümmer 2008; Lubienski 2004; Zevenbergen 2001) has to contemplate out of a development process, which is determined by the implication in the insemination of mathematical concepts and procedures, remains open. Hereto the longitudinal study erStMaL analyses primary empirical data, which can convey incipient stages. erStMaL accompanies children in their development from kindergarten to primary school. Another question to be answered empirically is, whether the phenomenon of the implicit insemination of mathematical knowledge can be seen as cross-cultural and equally occurring in all social classes. In the style of Bernstein’s early remarks to specifics in the learning process in the sixties and seventies may be assumed that the social status plays an important role (vgl. Bernstein 1985). Considering the cultural and linguistic plurality (Schütte 2009) future research has to explore to which extend migrant children from the aforementioned settings have advantages or disadvantages in the learning of mathematics and giving good performances in mathematics.

NOTES

1. Hereby the concept of acquisition (as a uncontrolled and “natural” way of comprehension) is used additionally to the concept of learning (as a controlled, curricular process) in this paper. Both processes (the controlled as well as the uncontrolled one) are taking part and overlapping in mathematical discourses with children and nursery teachers in the kindergarten. They also both have an impact on the development. This way the dichotomic aspects of both concepts will not be focussed any further in this paper.
2. This conclusion corresponds with the findings from the empirical research of Leufer and Sertl (2010), which find out that subject specific linguistic codes in mathematics classroom are always elaborated.
3. This is commensurate to the description of the acquisition of mother tongue by Bruner (1983)
4. Framing here has to be seen in terms of Goffman (1990).

ANALYSIS OF MATHEMATICAL SOLUTIONS OF 7 YEAR OLD PUPILS WHEN SOLVING AN ARITHMETIC PROBLEM ON DISTRIBUTION

Edelmira Badillo*, Vicenç Font**, Mequè Edo* & Núria Planas*

*Universitat Autònoma de Barcelona, **Universitat de Barcelona

We analyse mathematical solutions of 7 year old pupils when they individually solve an arithmetic problem. The analysis has used “the configuration of objects”, an instrument provided by the onto-semiotic approach to the mathematical knowledge, combined with the organisation of data into a “systemic network”. Results are illustrated by three cases. The aspects inferred from the overall analysis of the mathematical solutions include the use of iconic representations as a counting instrument, and the demonstrative nature of the arguments developed by the pupils.

INTRODUCTION

The objective of this research is to analyse the written and verbal mathematical solutions of 7 year old children when solving an arithmetic problem in an individual context of work.

Solutions by children when solving arithmetic problems tend to have a predominance of iconic and symbolic representations and a lack of explicit verbal argumentations (for example, Saundry & Nicol, 2006). For this reason, different research projects have shown an interest in studying the representations produced by children when solving problems (Edo, Planas & Badillo, 2009; Saundry & Nicol, 2006). To analyse the productions made by pupils we take their representations and other elements such as calculation procedures, argumentations, etc. This is why in order to analyse the underlying mathematical activity of pupils we use instruments of the onto-semiotic approach to the mathematical knowledge -OSA (Godino, Batanero & Font, 2007).

We start with a brief review of the literature. We then present the theoretical and methodological instruments that have been applied to our analysis. After that, we describe part of the design of the study and present some of the most relevant data. We end with a discussion of results and final conclusions.

REVIEW OF THE LITERATURE

Many research works have shown that students can solve a different multiplicative problem before the instruction about the multiplication and the division has been given (Mulligan & Mitchelmore, 1997). Carpenter et al. (1993) founded out that even students of early years could learn how to solve multiplicative problems. Such Studies have also been carried out with “diverse” students (Nunes et al., 2009)

Much research has been done on primary age arithmetic problems on distribution in which the task is to share a number of elements that are to be shared out one by one among a variable number of participants; for example, to share out a number of cookies among different children on the basis of questions with multiple solutions (Davis y Hunting, 1990). Research has also been done on problems that work on the idea of the division of units and distribution. Charles and Nason (2000), in a study of the development of the concept of fractions among 8 year old children, proposed a type of problem in which the unit(s) is/are divided into parts.

We examine the particular case in which the context requires the elements to be separated into groups, which involves a distribution in which not everything is a unit (or several units) that has to be divided into parts, but in which everything has to be separated into discrete sets, that can(not) have a different cardinal.

THEORETICAL AND METHODOLOGICAL FOUNDATION

Some studies involving the OSA (Malaspina & Font, 2010), in which mathematical solutions have been analysed, first consider the mathematical practices and then the mathematical objects and processes that are activated in them. In this study we adapt such approach with the pupils' practices being the reading of the text of the arithmetic problem and the production of a written answer. Due to space limitations, we will only analyze the mathematical objects that are activated by said practice.

If we consider the mathematical objects activated in undertaking a practice that enables the resolution of a problem situation (e.g. tackling and solving an arithmetic problem), we observe the use of verbal, iconic, symbolic and other representations. These representations are the ostensive part of a series of concepts/definitions, propositions and procedures that intervene in the production of arguments to decide whether the practice is satisfactory. So, when a pupil performs and evaluates a mathematical practice s/he activates a conglomerate formed by problem situations, representations, concepts, propositions, procedures and arguments, which are articulated in the configuration of Figure 1 (Font & Godino, 2006, p. 69).

To move from the individual analysis on pupils' mathematical solutions to a more general analysis on the whole group, we used a systemic network. This is a classical instrument from the organisation and interpretation of qualitative data proposed by Bliss, Monk and Ogborn (1983).

DESIGN OF THE STUDY

The participant sample was made up of 21 primary school pupils (7 years of age) at a school in Barcelona, Spain. The mathematical task presented to the pupils, which was to be solved individually and in writing, was: 1) an arithmetic problem involving distribution in which everything had to be separated into discrete sets of various elements, which could (not) have a different cardinal; 2) an open-ended situation;

Working Group 13

and 3) a feasibly resolvable task using the pupils' prior knowledge. The problem was: "If you have 18 wheels, how many toys with wheels can you have?"

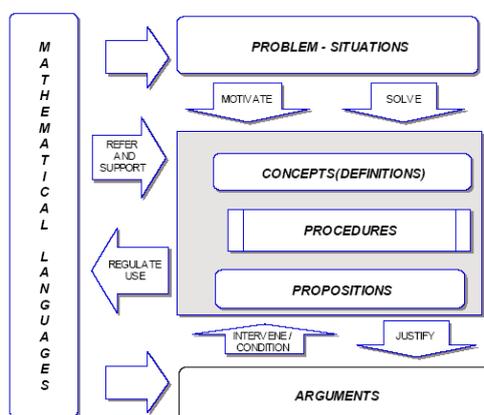

Figure 1. Configuration of objects

The problem was read aloud and the pupils were expected to solve it with paper and pencil during a one-hour class. When they finished the task, they were individually asked, "what did you do?" Their answers were recorded in audio and transcribed.

DATA ANALYSIS

Two types of analysis were performed, an analysis of each of the cases and then a global one of all of the mathematical solutions. For the former, an analysis (Figure 1) was made of each pupil's solutions. Table 1 illustrates part of an example.

Following the categories suggested by Malaspina and Font (2010), the data was analysed as indicated in Table 2. Each pupil's mathematical practice was analysed individually, paying attention to 1) representations, 2) concepts, 3) properties, 4) procedures, and 5) arguments. We present the analysis of one of the mathematical practices by one of the pupils, Pupil 15.

Figure 2 shows the systemic network obtained from the overall analysis. It is organised into categories and aspects (using the terminology by Bliss, Monk and Ogborn, 1983). We use braces ({} to represent inclusive aspects and lines to group exclusive categories (|).

The analysis of the mathematical practices leads to two main categories. First we have pupils that put the emphasis on the cardinal of the set. Here there are three subcategories: 1) those which give a single answer (e.g. Pupil 10 says, "if I had 18 wheels I'd have 6 toys with wheels"); 2) those whose answers suggest more than one answer (e.g. Pupil 15 writes, "I could have four toys with wheels"); and 3) those who give more than one answer (the only case is Pupil 18 who gives four different answers "...you could have 9 motorbikes, you could have 6 tricycles..."). Second we have pupils who point to the set and only refer to it by extension (e.g. Pupil 12 says,

“I have made a car, a bike, a car, a scooter and another scooter”) or give the cardinal for the subsets (e.g. Pupil 6 says, “four cars and a bicycle make 18 wheels”).

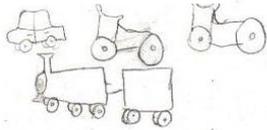

Written production	Verbal production
<div data-bbox="229 450 639 510" style="border: 1px solid black; padding: 2px;"> <p>Si tens 18 rodes, quantes joguines amb rodes podries tenir?</p> </div>  <p data-bbox="284 667 632 734">Un cotxe, dues motos i un tren tenen 18 rodes.</p> $4 + 2 + 2 + 6 + 4 = 18$ <p data-bbox="341 786 663 831">Podria tenir 4 joguines amb rodes.</p>	<p data-bbox="751 439 1394 685"><i>I have drawn a car that has four wheels, a motorbike that has two, another motorbike that has two and a train that has ten wheels. And here I have explained what I have drawn and how many wheels they all have. And here I have added them up and this is the answer.</i></p>

Table 1. Data from Pupil 15

For each of the five subcategories above, we organised the data on the basis of the mathematical objects following the configuration of objects in Figure 1. We considered each object as an aspect in the systemic network. On this occasion, we have grouped the procedures and properties as a single aspect and we have left the argument aspect for another occasion. Given the richness of the responses, for each aspect we have introduced meanings that have been used as categories; we do not go into the details of all of them. We now illustrate three significant cases.

The case of Pupil 15

Pupil 15 solves the problem well by giving the cardinal of one of the possible sets and concluding, “I could have 4 toys with wheels”. We consider that she is suggesting there is more than one answer, as she uses the verb tense “could”. First, we examine the richness of her representations. She starts with an iconic representation of the toys in perspective (Table 1) and then translates this into a symbolic numerical representation ($4+2+2+6+4=18$) and a verbal one (one car, two motorbikes and one train have 18 wheels).

In relation to concepts, this pupil breaks down the set of wheels (18) into parts or subsets (she draws a 4-wheeled car, two 2-wheeled motorbikes and a 10-wheeled train). She is then able to treat each of the subsets as an element (a toy) in a new set (the set of toys). Finally, she implicitly distinguishes between a set and the cardinal of a set, because in her answer she refers to the cardinal of the set of toys.

Working Group 13

If you have 18 wheels,
How many toys with
wheels can you have?

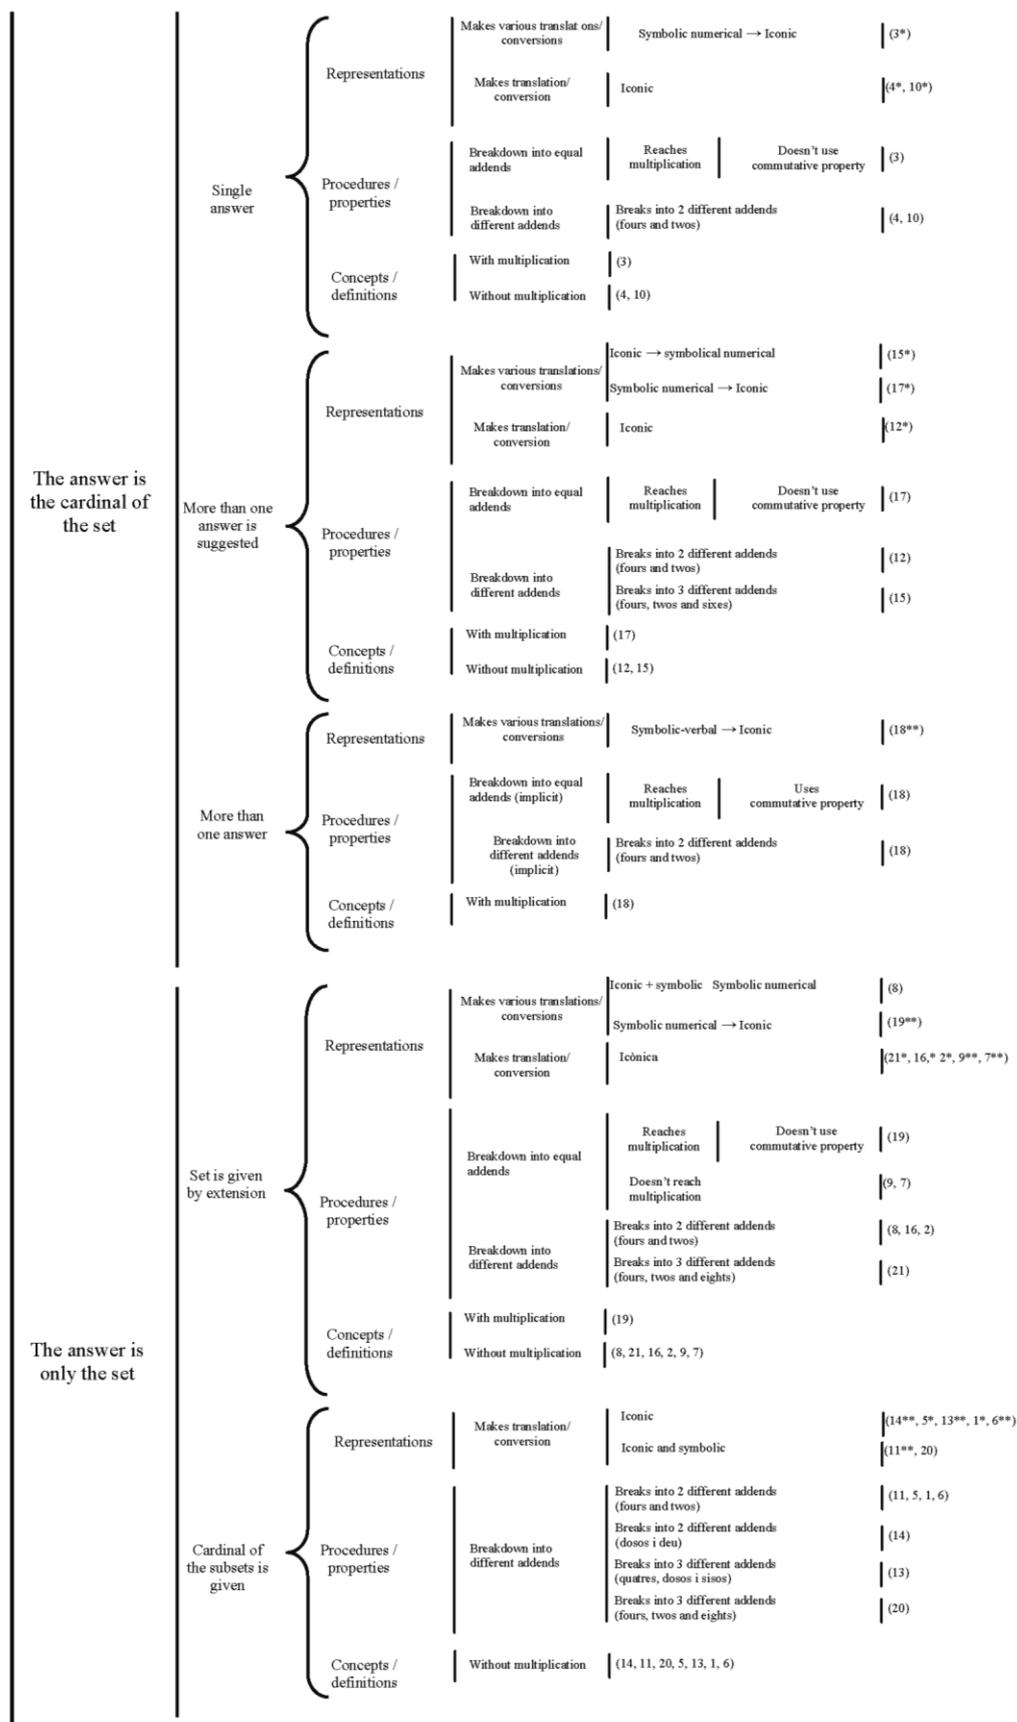

Figure 2. Systemic network from the overall analysis of the pupils' answers²

Working Group 13

This pupil applies the property that “a number can be broken down into the sum of smaller numbers”, in order to break down 18 (into three different addends) and 10 (into two different addends): $4+2+2+2+6+4$. We consider this pupil to be aware of the application of this property because she writes $(6+4)$ and draws a two-carriage train with 6 and 4 wheels, though in her verbal answer she refers to a train with 10 wheels.

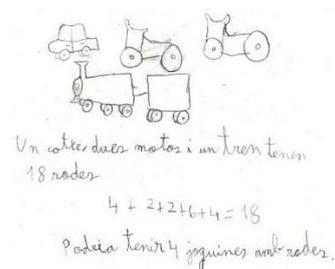

<i>Mathematical Object</i>	<i>Mathematical practice</i>
Problem situation	If you have 18 wheels, how many toys with wheels could you have?
Representation	<ul style="list-style-type: none"> • Iconic with perspective • Symbolic <ul style="list-style-type: none"> - Verbal (one, four, two, ten) - Numbers (4, 2, 6, 18) - Signs (+, =) 
Concepts	<ul style="list-style-type: none"> • Addition (Previous) • Implicit terms of the addition (addends and results) • Number (Previous) • Subtraction (implicit) • Set • Elements of a set
Properties	<ul style="list-style-type: none"> • A number can be broken down as the sum of smaller numbers (this is applied to 10 and to 18)
Procedures	<ul style="list-style-type: none"> • Combination of numbers to obtain 18 • Add and subtract (mentally) • Determination of a set by extension
Arguments	<ul style="list-style-type: none"> • Explicit thesis: I could have 4 toys with wheels (to make 18) • Graphic argument: draws the 4 toys • Verbal argument: describes the elements of the set (a 4-wheeled car, two 2-wheeled motorbikes and a 10-wheeled train) • Numerical-written argument: $4 + 2 + 2 + 6 + 4 = 18$

Table 2. Configuration of objects in Pupil 15’s answer

In relation to procedures, she uses the previous property to break down number 18. She seems to take a first number (she draws a 4-wheeled car), then adds another number (she draws a two-wheeled motorbike), and as the result is less than 18, she adds another addend (a two-wheeled motorbike); given that the result is still less than 18, she adds another addend (a ten-wheeled train). She iconically determines the set by extension.

Finally, the explicit thesis of her demonstrative argument (she could have 4 toys with wheels) is justified by the ostensive presentation of the set (iconic representation and verbal description) and by the numerical-written verification ($4+2+2+2+6+4=18$), of which she is aware because she says, “...and here I have added them up...”.

The case of Pupil 19

Pupil 19 solves the problem implicitly in that he draws 6 tricycles (Figure 3). We consider this to be implicit because the pupil expresses the cardinal of the set of wheels (18), which leads to start the solving process using symbolic representations.

This pupil starts his answer with a symbolic-numerical representation based on the sum ($3+3+3+3+3+3=18$) and translates this to another symbolic expression based on multiplication ($3 \times 6=18$, see Figures 2 and 3). Later, he switches to an iconic representation without perspective.

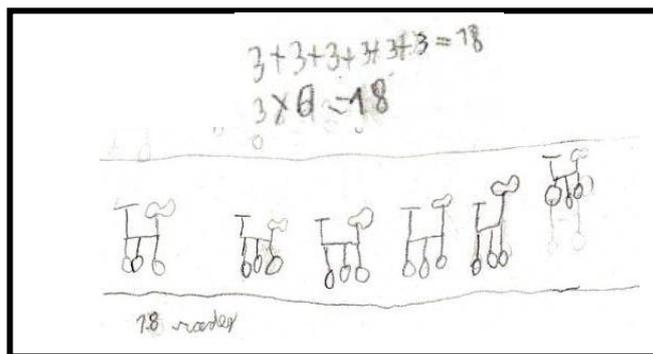

Figure 3. Representations used by Pupil 19

In relation to concepts, this pupil comes to the concept of multiplication and seems to be clear of its concept as a repeating addition. We consider this because he uses a mathematical property: “18 can be broken down as the repeated addition of number three”. In relation to procedures, he uses the previous property to break down number 18. He likely takes a first number, 3, then adds another 3, and given that result is still less than 18, he adds another addend (3), and so on successively until he reaches number 18. He iconically determines the set by extension.

Finally, the explicit thesis of his argument (6 tricycles make 18 wheels) is justified by the ostensive presentation of the set (iconic representation). He gives a verbal description of the procedure he used to get to number 18 (I did three plus three...).

The case of Pupil 20

Pupil 20 solves the problem implicitly, as he draws two cars, a truck and a scooter (Figure 4). He also gives the cardinal of the subsets as a verbal response (2 cars, 1 scooter and 1 truck). We find his type of representation significant, and we have named it in the systemic (Figure 2), iconic and symbolic (Figure 4) networks. The drawings are not in perspective but the pupil represents the total number wheels on each toy using numerical symbols (). The only conversion he makes is to switch from an iconic and symbolic representation of the set of toys to a verbal and written description of the cardinal of the subsets.

In relation to concepts, he breaks down the set of wheels (18) into parts or subsets (he draws 2 cars with 4 wheels, 1 scooter with 2 wheels and a truck with 8 wheels).

Working Group 13

After, he gives the cardinal of the subsets (2 cars, 1 scooter and 1 truck). Meanwhile, he implies the mathematical property: “18 can be broken down into the sum of smaller numbers” in order to break down 18 (into four addends, three of which are different): four, four, two and eight.

In relation to concepts, this pupil uses the previous property to break down the eighteen. We consider that he takes a first number (he draws a four-wheeled car), adds another number 3, then adds another (he draws another four-wheeled car), and as the result is less than 18 he adds another addend (and eight-wheeled truck). He iconically determines the set by extension. The explicit thesis of his demonstrative argument (2 cars, 1 scooter and 1 truck) is justified by the ostensive presentation of the set (iconic representation and verbal-written description).

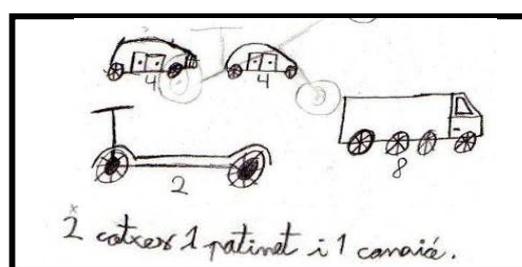

Figure 4. Representations used by Pupil 20.

CONCLUSION

All of the pupils make an iconic representation of the set of toys. It could be said that this is because of the need at this age to work using contextualised scenarios. However, there is also the need to use drawing as a counting instrument, as has been shown by Saundry and Nicol (2006). In our study, this use of iconic representations as a counting instrument is made clear in the representation that we have called iconic and symbolic (Figure 4). This is a type of representation (used by Pupils 8 and 20), that can be considered an intermediate step between flat representations (used by Pupils 6, 7, 9, 11, 13, 14, 18, 19) and representations in perspective (used by Pupils 1, 2, 3, 4, 5, 8, 10, 12, 15, 16 17, 21).

There are three pupils (3, 17, 19) who separate the set of 18 wheels into discrete sets with an equal cardinal and start solving the problem using written symbolic-numerical representations (they break 18 down into equal addends). In all three cases, they translate this representation into another written symbolic expression in which they use the concept of multiplication (Figure 5), to end with a conversion to an iconic representation of the set of toys. In cases 3 and 17 this is in perspective and in case 19 without perspective (Figure 3).

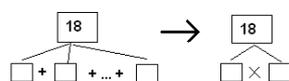

Figure 5. Breakdown of equal addends into multiplication

Working Group 13

Pupil 18 uses multiplication in his four different answers (which are given verbally and iconically). But he does not use written symbolic-numerical representations, so we suppose he reached his answer by making mental calculations. From his verbal responses, we infer that he makes an implicit use of the commutative property (“you can have 6 tricycles with three wheels or you can have 3 limousines with 6 wheels and you also get 18”) and that, unlike the three previous pupils, he does not need to explicitly break 18 down into equal addends to break 18 down into the product of two factors. He does not need to add first in order to get to multiplication.

All of the pupils implicitly or explicitly use the property of breaking 18 down into addends (we include the extreme case of Pupil 18 who breaks 18 down using $4 \times 4 + 2$). When the addends are equal, this facilitates the use of the concept of multiplication, and on the other hand, facilitates the process of giving the cardinal for a set of toys of a certain type (e.g. Pupil 17’s answer, “6 tricycles”), which implies that the term “toy”, which is more abstract, is not used. However, the two pupils that explicitly use that term in their answers (e.g. Pupil 15, “I could have 4 toys with wheels”), break number 18 down into different addends.

In this last case we have the close relationship between properties and concepts. The use of a certain mathematical property (a type of breakdown of number 18) conditions the use of certain mathematical concepts (addition or multiplication). Meanwhile, the use of multiplication -a concept that is considered, in curricular terms, to be more difficult than addition- involves, in this case, less abstraction in solving the problem.

We observe two fundamental procedures. One is related with the application of the mathematical property/ies that guarantee the breakdown of number 18 into addends. The pupils mentally apply addition and subtraction, and even multiplication, to reach that breakdown. The other is the determination by extension of the set (via an iconic representation). This latter method, used by all pupils, is the one that enables them to defend, explicitly or implicitly, their answer. These are demonstrative arguments that consist of the ostensive presentation of the set (the drawings of the toys).

We consider the theoretical categories provided by the OSA to facilitate an in-depth analysis of the pupils’ solutions and to reveal the complexity of objects (concepts, representations, properties, etc.) that are activated when solving arithmetic problems.

The systemic network has also been a powerful instrument of organization that has led to construct a taxonomy of the pupils’ responses when they solve a problem in which the whole has to be separated into discrete sets of various elements, which can also have (or not) a different cardinal.

ACKNOWLEDGEMENTS

The research is part of Projects EDU2009-07113/EDUC and EDU2009-08120/EDUC, from the Spanish Ministry of Science and Innovation.

NOTES

1. *The represented drawings are in perspective. ** Without in perspective.
2. The pupils that draw an iconic representation and give a verbal description of the set of toys (almost all), are part of the aspect “makes a translation/conversion”. When the pupil also makes another type of translation/conversion, s/he is part of “makes several translations/conversions”.

KINDERGARTNERS' USE OF GESTURES IN THE GENERATION AND COMMUNICATION OF SPATIAL THINKING

Recent studies have advocated that mathematical meaning is mediated by gestures. This study explores how kindergartners use gestures in a semiotic transformation activity involving the description of spatial relationships between objects. The two 5-year-old children that participated in the study used gestures throughout the whole activity, mainly iconic gestures (representing images of objects) and gestures combining iconic and deictic (locating objects in space) properties. A multidimensional linkage between children's gestures and speech, as well as, a significant effect of the researcher's gestures on one child's gestures were found. Findings showed that gestures are essential in the construction and communication of early mathematical meaning and raise important questions for future research.

Keywords: gestures, kindergartners, spatial thinking, semiotic transformation

INTRODUCTION

The semiotic approach to the learning and teaching of mathematics constitutes a very important trend in the research field of Mathematics Education (e.g. Gagatsis, 2003; Presmeg, 2006). A new trend of this research area concentrates on the examination of bodily movement and particularly on gestures. In the last years gestures and bodily movement have been considered as a source of information and a contributor in mathematical thinking and communication (Edwards, 2009).

The study of gesture is still a young research field within mathematics education and many theoretical and methodological questions remain open (Radford, 2009). Existing research in the mathematical domain has focused on the role of gestures in the generation and the communication of meaning by students in primary and secondary education level. To our knowledge, the gestural activity of preschool and kindergarten children in relation to communicating and thinking about mathematics has not been addressed to a great extent yet. In this paper we analyze gestures as a semiotic resource used by kindergartners into the learning process of mathematics and specifically in a semiotic transformation task of spatial character, involving the conversion of a visual spatial array into verbal description.

THEORETICAL FRAMEWORK

Semiotic representations and gestures in mathematics education

Mathematics education includes a wealth of ideas and concepts and constitutes an area of human activity and thinking, which is characterized by the use of multiple

representations. Gagatsis, Michaelidou and Shiakalli (2001) support that the advancement of mathematical knowledge is accompanied by the creation and development of new semiotic systems that coexist and operate simultaneously with the first and basic system, that of natural language.

Representations are often concerned as connected with a sign. Saussure defined the sign as a combination of two mental constructs, roughly translated as a “signified” together with its “signifier” (Presmeg, 2006). Within this wide conception of sign Arzarello, Paola, Robutti and Sabena (2009) regard gestures as an important semiotic resource related with the more traditional signs (such as spoken or written language, mathematics symbols, and so on).

Gestures are defined as spontaneous movements of the arms and hands, closely synchronized with the flow of speech (McNeill, 1992). Parrill and Sweetser (2004) define the meaning of a gesture as “the relationship between how the hands move in producing a gesture, and whatever mental representation underlies it, as inferred both from the gesture and the accompanying speech” (p. 197).

McNeill (1992; 2005) proposes five dimensions of gestures with respect to their meaning: 1) *deixis* (locating existing or virtual objects and actions in space with respect to a reference point), 2) *metaphoricity* (presenting an image of an abstract object or idea), 3) *iconicity* (standing for images of concrete entities and actions), 4) *temporal highlighting* (simple repeated gestures used for emphasis) and 5) gestures that modulate *social interactivity*. These dimensions play essential roles in communicating and thinking about mathematics.

The role of gestures in mathematical thinking

Mathematical cognition is not only mediated by written symbols, but is also mediated, by actions, gestures and other types of signs (Radford, 2009). Particularly, children’s semiotic activity in mathematics includes action, gestures and speech. When mathematics is seen as an embodied, socially constructed human product, gestures constitute a particular modality of embodied cognition (Edwards, 2009).

Roth and Thom (2009) claim that gestures are genuine constituents of thinking. Radford (2009) describes gestures as the very texture of thinking and as important sources of abstract thinking. Gestures, along with speech and inscriptions, jointly support the thinking processes of students (Arzarello et al., 2009). When a better understanding occurs, actions become shorter and gestures and language become more relevant (Radford, 2009). McNeill (1992) noted that, “Speech and gesture are elements of a single integrated process of utterance formation in which there is a synthesis of opposite modes of thought” (p. 35).

Gestures can be fundamental for the effectiveness of mathematical communication (Roth, 2001), as well. Along with oral speech, written inscriptions, drawings and graphing, gestures can serve as a window on how learners think and talk about mathematics (Edwards, 2009) and on inner thoughts or as conveyors of ideas that are

already somewhere in the mind awaiting the proper material, namely, verbal expression (Radford, 2009).

Spatial thinking in early childhood mathematics

Geometry and spatial thinking are very important areas of mathematics learning in all educational levels, including early childhood education (Sarama & Clements, 2009). They involve grasping the space in which the children live and move (Freudenthal, in NCTM, 1989). A major spatial competence is spatial orientation, which involves the understanding and operating on relationships between various positions in space (Sarama & Clements, 2009).

Mathematical understanding and, in terms of this study, understanding of spatial concepts and relationships evolves through the transformation of semiotic representations (Duval, 2006). Thus, as children link their spatial knowledge to verbal, analytic knowledge they move beyond visual thinking which is restricted to surface-visual ideas. Connecting spatial representations to language can help children develop the ability to reason and communicate about space and thus gain spatial sense (Sarama & Clements, 2009).

In the present study, a spatial orientation activity is designed and used. This activity requires semiotic transformations, that is, conversions between spatial representations and verbal descriptions.

Gestures and spatial thinking

In activities that entail communication about space, besides words, people frequently use gestures (Ehrlich, Levine & Goldin-Meadow, 2006). A number of studies have revealed that gesture and spatial thinking are connected to one another. Krauss (1998) has found that people use gestures more frequently in defining spatial words than non-spatial words. Gestures occur often in people's descriptions of their navigation in space (Emmorey, Tversky & Taylor, 2000).

Despite the growing evidence about the link between spatial skills and gestures, limited attention has been given on the role of gestures in the development of spatial thinking (Ehrlich et al., 2006). Ehrlich et al. (2006) explored the strategies 5-year-old children used to solve spatial transformation tasks. The findings of the particular study showed that children frequently produced gestures whose meaning was not necessarily expressed in the accompanying speech. Children who referred to spatial information in their gestures but not in their speech were more likely to succeed. These findings suggest that gesture has the potential to improve early spatial skills.

The present study addresses the issue of the role of gestures in young children's ability to mentally manipulate spatial information, by examining the gestures kindergartners produce in a spatial orientation task that requires describing a spatial array of objects the children constructed themselves to another person who could not see it. Specifically, the questions we tackled were the following:

Working Group 13

1. What are the dimensions of the gestures kindergartners produce when carrying out conversions from a spatial representation to verbal description?
2. What is the relationship between the kindergartners' gestures and language in carrying out a conversion from a spatial representation to verbal description?
3. What is the effect of the researcher's gestures on the kindergartners' gestures in the conversion activity?

METHOD

The participants were two five-year-old kindergartners from a private kindergarten in Nicosia, Cyprus. In this study we will refer to the two children as *child 1* and *child 2*.

The spatial orientation activity, in which the children were involved, was designed on the basis of a method of the Didactics of Mathematics that refers to the designation of students' mathematical thinking and focuses on situations of mathematical engagement and communication. According to this method, students solve problems in pairs or in groups, in order to have the chance for oral or written communication between them. This method allows for a precise analysis of students' answers and a specification of their mathematical ideas (Brousseau, 1997).

Thus, the activity, which had the form of a game, required two players, one of which was the researcher. Each player had to use wooden bricks of different shape in order to make a construction. The two players sat opposite each other, having a small wooden wall in the middle, so that each player was not able to see what the other player was constructing. The aim of the activity was the first player to create the same construction with the opposite player, based on the latter's description. The activity involved three parts (rounds) and was carried out separately for each child. In the first and the third part of the activity the child had to make the construction and describe it to the other player (researcher), while in the second part the researcher was the player that had this role.

To examine children's gestures and language, their reactions and utterances during their participation in the activity were video-recorded.

RESULTS

To identify the dimensions of children's gestures during the activity (Research Question 1), McNeill's (1992; 2005) proposed dimensions of gestures were used. This analysis showed that the meaning of children's gestures was multidimensional. Many gestures used by both children were of *iconic* nature. They used the iconic gestures mainly to present the shape of the various bricks they used. An example concerns the shape of cylinder, for which child 1 moved her finger to make a round line vertically in the air. For the same shape, child 2 used her pointing finger and thumb to form a circle (Figure 1).

Figure 1: Iconic gestures for the shape of cylinder by (a) child 1 and (b) child 2

In both children's gestures we also distinguished a great number of gestures that can be considered as *deictic and iconic* at the same time. Children used deictic and iconic gestures when speaking of spatial relationships between bricks. For instance, to explain the placement of four bricks in her construction, child 2 used the expression "one on the top, one at the bottom, one on the left and one on right" moving both her hands to the corresponding positions (deictic property). At the same time she opened her hands to form a flat surface and put them next to one another in a horizontal direction and opposite to one another in a vertical direction, respectively, in order to present the image of the orientation of the parallelepipeds (iconic property) (Figure 2).

Figure 2: Child's 2 iconic and deictic gesture (a) for the placement of the parallelepiped at the bottom of the construction in a horizontal direction, (b) for the placement of two parallelepipeds on the left and on the right of the construction in a vertical direction

A small number of gestures were identified as only *deictic* for both children, who used them to present the location of some bricks with respect to bricks that they were already described. For instance, to show the position of a brick, which was on the right side of another brick, child 2 moved her right hand up and down once (Figure 3a).

Temporal highlighting gestures were used even less frequently by the children, mainly in trying to emphasize and enforce to the researcher what they were saying. For example, child 2 moved her hands repeatedly one on top of the other tapping them at the same time in order to highlight that three bricks should be put on top of each other (Figure 3b).

Metaphoric gestures were the most rarely produced. Child 1 was found to use a metaphoric gesture for the concept "small". As she was explaining to the researcher

to “*take two circles (meaning cylinders), but small*”, for the word “*small*”, she moved her hands close to her face and formed fists (Figure 3c).

Figure 3: (a) Child’s 2 deictic gesture for the position of a brick on the right of another brick, (b) Child’s 2 temporal highlighting gesture for the placement of three bricks on top of each other, (c) Child’s 1 metaphoric gesture for the word “*small*”

With respect to the connections between language and gestures (Research Question 2), we observed that children were using gestures and language simultaneously. In some cases, the meaning of children’s words and gestures coincided. While the children were trying to explain to the researcher where to place the bricks, they were like holding the brick and placing it in the position they were trying to explain. An example is the verbal expression of child 2 “*...take a roof and place it on top*” which was accompanied by the gesture shown in Figure 4a.

In other cases children replaced verbal expressions with gestures, in order to explain what they were thinking. When the children tried to describe the position of a brick, they frequently used the expressions “*like this (not this)*”, “*place it... emhhh, place it this way...*”, “*place it here*” and simultaneously produced a gesture to illustrate what they mean. For example, child 1 while trying to explain to the researcher how to place the two “long shapes” (parallelepipeds), she was showing with her hands their position, highlighting that they should be placed “*like this*” (apart) and “*not like this*” (not together) (Figures 4b, 4c).

Figure 4: Child’s 1 gesture accompanying the verbal expressions (a) “*...take a roof and place it on top*”, (b) “*put them like this*”, (c) “*not like this*”

An aspect of the linkage between language and gestures that was examined was how this connection changed over time during the activity. An interesting example is that in the first part of the activity child 1 opened her hands, one hand to the left and the other to the right side of her body (iconic gesture) to represent the “long shape”,

meaning the parallelepiped (Figure 5a). In the third part of the activity, every time child 1 used the particular term, she produced a different iconic gesture consistently. She stretched out one hand vertically to her body and formed a straight line in the air by moving her hand near her chest (Figure 5b). This is explained by the different position of the parallelepiped between the first and the third part of the activity. In the first part of the activity, the brick was in a horizontal position while in the third part it was in a vertical position. However, the last time she referred to this shape, she did not use any gesture. For the same shape, child 2 used consistently a “smaller” iconic gesture than child 1, during the first part of the activity. When talking about the shape (e.g. “take 4 lines”) she moved her pointing finger vertically towards her body to draw a small straight line in the air (Figure 5c).

Figure 5: (a) Child’s 1 gestures for the parallelepiped in the first part of the activity, (b) Child’s 1 gestures for the parallelepiped in the third part of the activity, (c) Child’s 2 gestures for the parallelepiped in the first part of the activity

This gesture was not used in the third part of the activity when child 2 used the verbal expression “line”. It is noteworthy that both children, when using words referring to the position of this shape (where to put the parallelepiped), such as “in front of”, “on the right”, “on the left”, produced the same form of (iconic) gesture, consistently, changing only the corresponding place of their hand in space. In particular, they opened their hand(s) keeping the fingers closed to form a flat surface (iconic property) and moved it to the corresponding place and direction (deictic property).

The researcher had an obvious effect in the way child 1 was behaving during the activity (Research Question 3), since she was imitating her expressions and gestures in respective situations. In one case, child 1 even “extended” the researcher’s gesture. Specifically, in the second part of the activity, while the researcher was explaining that two bricks are attached to each other she put the palms of her hands together. In the third part of the activity, when child 1 had to describe the relative position of two bricks and in particular that they should be apart from one another, she used the same gesture and the “opposite” gesture that she observed before from the researcher. In particular, the child first moved her hands away from one another highlighting that they should be placed “like this” (apart from each other) (Figure 5b) and then put the palms of her hands together clarifying that they should not be

put in this way (not attached) (Figure 5c). On the contrary, the gesture or language used by child 2 was not influenced by the researcher's behavior.

CONCLUSIONS

This research examined the gestures two kindergarten children use while communicating in the context of a semiotic transformation activity which involved spatial orientation abilities. Children were found to use gestures throughout the whole activity. The most commonly used gestures were the iconic gestures and the gestures that combined iconic and deictic properties. This finding can be attributed on the one hand to the spatial and geometric nature of the activity which encourages imagistic thinking and on the other hand, to children's developmental stage which is characterized by concrete thinking processes. Metaphoric and temporal highlighting gestures were rarely used by the children. In contrast to producing iconic and/or concrete deictic gestures, in which children only think about the object or spatial relationship the gesture is representing, producing these types of gestures are cognitively complex, involve meta-cognitive abilities and therefore are developed in later years (McNeill, 1992). Further investigation on how the occurrence of abstract gestures varies in activities of spatial context or other mathematical domains among young children and the associations of this gestural behavior with children's mathematical achievement and other child characteristics (e.g. age, gender) could be theoretically and practically important.

A close multidimensional relationship between gestures and language was revealed. This relationship appeared in students' behavior in three distinct ways. Firstly and most frequently, while describing their constructions children's gestures had the same meaning as their verbal expressions. Secondly, in some cases children replaced language with gestures and thirdly, children's gestures complemented and enriched their verbal descriptions. Although previous research (McNeill, 1992) suggests that by the age of five gestures co-occur with speech, the use of gestures only without the corresponding words, by the children of this study, in some cases, could be explained by a lack of flexible knowledge in the construction of sentences for describing spatial relations. Furthermore, the spatial character of the activity, and the fact that the spatial arrangement the children described had been constructed by themselves and was in front of them, probably endorsed the visual elements rather than the analytic elements of their thinking. As a consequence, gestures were stronger than verbal utterances in some parts of their descriptions.

That some dimensions of the children's thought, such as the orientation of the shape, were presented in the gesture and others, such as, the form of the shape, were presented in linguistic form provided evidence for the complementary role of gestures to speech. Each mode of representation made its own contribution to the whole and was essential and valuable in representing children's spatial thinking. In other words, children's thinking for a number of spatial or geometric concepts was characterized by a dialectic of gesture (imagistic thinking) and language (analytic

thinking), that is, a synthesis of language and gesture into one comprehensive presentation of meaning (McNeill, 1992).

A main concern of the study was the role of the researcher's gestures in the communicative process during the activity. In the specific activity the choice of having each child to start the game, the researcher to follow and then the child to play again, gave us the opportunity to identify the effects of the researcher's behavior on the children's behavior. Zooming at the interaction between the researcher and the children during the game, it emerged that only one of the two children was influenced by the researcher's gestures. This child not only emulated the researcher's gestures, but added a contrast to the gesture of the researcher. Specifically, the position of two bricks in the child's construction (apart from each other) was opposed to the position of the two bricks of the researcher's construction (attached) made previously. The child used a gesture that represented the relative position of two separated bricks in her construction, and then a gesture to show how this position differs from the image of two attached bricks (counter-example), which had been previously represented by the researcher's gesture. According to McNeill (1992) adding contrasts is considered as a mechanism by which gestures can affect thought. Thus, this finding provides further evidence for the important role of gestures in young children's development of spatial thinking. Evidence is also provided for the influential role of the teacher in the mathematics classroom, as the teacher is often a model for the students, who tend to be affected by her actions and expressions. However, there was not an effect of the researcher's gestures on the other child's gestures examined here. This inconsistent finding between the children raises an important question regarding the relationship between mathematics teaching and gestures: What factors influence the extent to which teachers' gestures affect children's gestures and their learning outcomes in mathematics instruction? The child characteristics, such as the child's prior knowledge, the complexity of the learning activities and the characteristics of the teacher's behavior could be some of the factors that future research may explore in concern with this issue.

HOW DO CHILDREN'S CLASSIFICATION APPEAR IN FREE PLAY? A CASE STUDY

Vigdis Flottorp

Oslo University College

I analyze an episode from a field work in a multilingual kindergarten in Oslo, using semiotic theory. I examine verbal and non-verbal expressions of two boys playing in a sandpit. A key part of their play is creation of structure. My findings indicate that this structuring become conscious experiences to the children. I would argue that we cannot know about the children's mathematical and communicative competence without knowing the physical context, the play in the sandpit, and the friendship between the boys.

BACKGROUND

In Norway we got a new *Framework Plan for the Content and Tasks of Kindergartens* in 2006, which had a separate chapter devoted to mathematics, named 'Numbers, spaces and shapes'. It says:

(...) the staff must listen and pay attention to the mathematical ideas that children express through play, conversation and everyday activities (...) and support the mathematical development of children on the basis of their interests and modes of expression. (Ministry of Education, 2006:42)

The Norwegian Framework stresses that mathematics have an intrinsic value for children, not only a value for the future. This concerns the justification for mathematics in kindergarten. According to some political signals, mathematics is important first of all for school readiness. A white paper brings out:

In school many pupils struggle with doing arithmetic as a basic skill. There is a need for creating more positive attitudes to the subject. The general work in kindergartens and especially with the learning area 'Numbers, spaces and shapes' is important in this context. (Ministry of Education, 2009:77)

In the recent years *learning* has been stressed, focusing on basic skills. In Norway the kindergarten became a part of the educational system with the transition from The Ministry of Children and The Family to Ministry of Education.

This has caused a revived debate concerning the concepts of play and learning. Most people agree that kindergarten shall be a learning arena. The question is *how* this can be realized in mathematics, and what the concept of learning implies.

Much research on mathematics in the early years is based on experimental situations, often with single children. It's harder to find research on mathematics in free play and in informal everyday situations. Some studies though, I have found. Björklund (2007) uses video and analyses toddlers in order to discover how they come to understand different aspects of mathematics like parts and whole, similarities and

differences. Her findings indicate that the children become aware of how things can be seen as a group of items with similar qualities, by first experiencing units as being separate from other units. The children tend to focus on *visual* characteristics of items especially when they *differ* from others. The study is interesting because of her focus on very small children in everyday activities, and because it reveals methodological problems interpreting the actions of small children.

Fauskanger (1998) analyzes an incident where some children are playing pirates for weeks on a farm in the countryside. Measuring, counting and making record of prisoners are central parts of their play. Her study focuses on how the children construct mathematical knowledge in social context meaningful to them. This is similar to my case study, but while the episode I am analyzing is lasting for some minutes, hers is going on for weeks.

Tudge & Doucet (2004) investigate children's engagement in mathematical activities of a complete day, comparing white and black children. The variation among them cannot be explained by ethnicity or class. Seo & Ginsburg (2004) perform a similar study, but include parents' income. These studies reveals challenging methodological issues, concerning how to record mathematical engagements in daily life activities.

The latter study is indicating that enumeration is a relatively small part of the children's mathematical activities compared to shapes and patterns. My interest from the beginning was on geometrical phenomena more than enumeration. The research on small children's number sense is waste, while studies on their geometrical understanding are relatively sparse (Clements, 2003). When findings indicates there is less enumeration than other types of mathematics in kindergarten, but more research on enumeration, then my interest coincides with what seemed important to focus on.

The main aim for my field work was to study the mathematics in children's everyday activities, focusing especially on geometrical concepts and on how children express them. I needed a tool for analysing all kinds of expressions - actions, gestures, body language and verbal utterance, and that's why I chose a semiotic approach.

THEORY

Semiotics is the study of culture as signs, where signs incorporate all kinds of tools used in communication, from linguistic to physical tools. Since these tools are human made, all concepts can be regarded as historically created. This also applies to mathematical concepts.

Ideas and mathematical objects (...) are conceptual forms of historically, socially and culturally embodied reflective, mediated activity. (Radford, 2006:42)

Mathematical concepts are like «lighthouses that orient navigators' sailing boats» (ibid.), but they are not ideas separated from our world. Their abstract and general

aspects are results of human activity, and new constructions can arise in another context. Consequently, knowledge is created and recreated in every situation.

Traditionally, *thinking* is regarded as a mental activity. Radford (2009) advocates a multimodal perspective, where language, gestures and tools are considered as “*genuine constituents*” of cognitive activity. “Thinking does not occur solely in the head, but *in* and *through* language, body and tools. (Radford, 2009:113). Accordingly, mathematics can become manifest in many ways.

Concept formation is closely related to the context. This does not imply that knowledge can be reduced to individual constructions, because we use tools in the concept formation, tools which already have content. The relation between the subjective and the cultural content are like two sides of the same coin (Radford, (2006). One side is the subjective comprehension, intimately related to the person’s experience. On the other side is the cultural content, transferred through the cultural tools in the act of meaning making (ibid., 52). This is why participation is regarded as crucial for learning, rather than acquisition.

Sociocultural psychologists prefer to view learning as becoming a participant in certain distinct activities rather than as becoming a possessor of generalized, context-independent conceptual schemes. (Sfard, 2001, p. 23)

Mathematics can be conceived in many ways. As a subject matter in school, three conceptions can be distinguished (van Oers, 2001). According to the first one, mathematics is synonymous with arithmetical operations. The second conception says that mathematics is about abstract structures applied to concrete situations, and the last one advocates that mathematics is about problem solving with symbolic tools. The second conception presupposes that structures are stable and a priori. This is not consistent with a sociocultural view, whereas the third conception is. According to this view, mathematical activity organizes human experience in a systematic way, also called *mathematising*.

I myself insist on including in this one term the entire organizing activity of the mathematician, whether it affects mathematical content and expression, or more naïve, intuitive, say lived experience, expressed in everyday language. (Freudenthal, 1991:30)

What make Sfards *distinct activities* and Freudenthals *lived experiences* mathematical? According to Mason and Johnston-Wilder (2004) desirable mathematical activity consist of some ways of acting; stressing and ignoring, specializing and generalizing, distinguishing and connecting, imagining and expressing, conjecturing and convincing, organizing and characterizing.

Bishop (1988) argues that *classifying* is a fundamental part of *explaining*, which is one of what he sees as the six universal mathematical activities (explaining, counting, measuring, locating, designing, playing,). Explaining is a central part in all activities, because it is basically about exposing relations between phenomena, and he claims that the most important connection between phenomena has to do with

similarities. The quest for explanation is the quest for “unity underlying apparent diversity” (ibid:48). This is what happens in classification.

METHOD

I visited a kindergarten in Oslo weekly for one year. The kindergarten is a preschool for practicum, located in an area with a high amount of minority speaking people. The section I followed, had 17 children aged 2-6 years. Five of the children had Norwegian as first language.

In order to find out what was going on in the children’s activities, I became participating observer. I could not plan the children’s play or give them instructions, but followed their daily activities. Since I wanted to study what children do alone, I tried not to give them too many suggestions.

I was interested in the social aspects of meaningmaking, and consequently I focused on situations with interaction between children. I was also curious about the role of the verbal language in a multilingual kindergarten. Hence, I concentrated on children with verbal language.

I looked for situations with mathematical potential, like block building, drawing, games and conversation. Quite soon I distinguished some children because of their concentration and creativity. These children seemed to participate in the most interesting mathematical episodes. I do not infer that there is coherence between concentration and mathematics. My data selection does not tell anything about what is common or typical, but they can suggest *how* children express mathematical ideas.

My data consist of notes, photos and videos. I classified the material, using Bishops categories. First I transcribed the videos roughly, dividing them in episodes after distinct activities. Then I chose the most interesting ones and transcribed them more thoroughly. In the interesting episodes some kind of problem arose, and these episodes were rich with regard to meaning and expression. Usually these episodes lasted over some time. Some episodes were interesting because they were surprising. Sometimes it was hard in advance to spot the interesting episodes.

ANALYZE

The episode lasts for only 3-4 minutes. When I start recording, the boys have placed different toys on the edge of the sandpit. It ends when another child enters the scene.

One of the boys, Mohammed [1], excels with his interest in systems and numbers. The other one, Waqas, is a quiet and concentrated boy. They speak Norwegian with each other as their first languages are different.

The sandpit toys constitute an essential part of the activity. They are artifacts with cultural meaning, which in this case is ambiguous. They are *toys* for children, but at the same time they resemble *articles for daily use*, - some look like kitchen equipment, other like miniature garden utilities. The cones are special since they are

Working Group 13

neither kitchen nor garden utilities. They are the only items which I have given a mathematical name. The boys never mention any of the toys by name, but their actions reveal what kind of meaning they give to them. They pretend to drink from the cups and stir in the pans. From earlier observations I know that the children often use the toys for making food. Sometimes they expand this activity by making a restaurant, - pretending to serve and sell food.

It looks like the play is about doing the same, because when one of the boys is drinking or stirring, the other one is mimicking. Consequently, it is essential to have the same types and the same number of sandpit toys, which they do not have.

Mohammed	Waqas
cup	cup
cone	cone
2 pans	1 pan
sea star	sieve

Fig 1: The distribution of the sandpit toys in the beginning

The problem with Waqas having only one pan, is solved easily. He throws the sieve away and finds a frying pan. This item he bangs in the frame of the sandpit, declaring: “Look what I’ve found!” A frying pan is without holes and can have the same function as a cooking pan. This common feature becomes pronounced, when Waqas suggest that they put sand in “everything”. Mohammed responds that he will put sand “only in two”. Then both put sand in their pans, including the frying pan, showing that they agree on what “everything” shall mean.

The difference between sea star and sieve, is more difficult to solve, since there is no extra sea star around. Mohammed watches the toys, turns around, grasps the sieve and places it on Waqas’ side, second to the edge. At the same time he points at his own sea star, saying: “Look, sea star!” Then he turns the sieve *bottom up*. Then he controls the system by making one-to-one correspondence: He touches Waqas’ toys one by one while he follows his own toys with the eyes, saying “putting it there” for every item. In the end he declares: “Now everything is alright.”

Fig 2: Mohammed pointing at the cones while he declares:” Now everything is alright.” The sea star is hidden second from the end to the right.

Mohammed creates a double similarity between the sea star and the sieve. First, he makes up a new criterion for classification – *bottom up* – which distinguishes the sea star and sieve from the other toys. Secondly, he creates a common feature by reflective symmetry, *next further out*.

Waqas					Mohammed				
pan	sieve	pan	cup	cone	cone	pan	pan	sea star	cup

Fig 2: The categories and the sequence of the toys on the edge of the sandpit.

The symmetry is not incidental, because short afterwards the spades are placed in the sequence. Mohammed places his spade furthest out to the end with the handle turned to the middle. Waqas asks for help, consequently he must have understood that the placement is special and important. Mohammed puts his spade on his knee, handle turned to the middle, saying: “It’s like this.” Then Waqas places his spade on *his* side, the handle turned to the middle.

The symmetry is not perfect, but Mohammed still declares that everything is alright. The purpose of the symmetry is to create a similarity between the sea star and the sieve. What is right in the play for the boys, is the essential condition, which is to do the same with the same number and kind of toys. This can be interpreted like a token of friendship where the boys mimicking each other.

Friendship is an essential part of socialization. In this episode Mohammed is the one in command, and many would argue that reciprocity and balance are necessary for a friendship. According to Greve (2009) every friendship has its own style and history. What matters, is that the children have experiences which give them a *common we*. It looks like this is the case in this episode. They have a common project that they communicate to each other without misunderstandings.

DISCUSSION

The play in the sandpit has many similarities with desirable mathematical activity described by Mason and Johnston-Wilder (2004). The boys are creating structure and order of the artifacts by stressing and ignoring, distinguishing and connecting. The toys can be classified in many ways, for example after size, color, form or function. The boys distinguish the pans from the rest by size. The pans and sieve are separated from each other by stressing topological aspects. By looking at form, the boys distinguish the cones from the rest. The sea star and the sieve are connected by placement and symmetry, ignoring all other aspects.

The boys cognitive activity becomes manifest first of all through their *communicative actions*. They show, throw, bang and fill sand in the toys. Sometimes the artifacts themselves are mathematical expressions, for example when the spades are placed symmetric. The boys have few verbal utterances, and most of the utterances are *deictic*: “I will get one like *that*,” says Waqas, searching for an equivalent to a pan. “It is like *this*,” demonstrates Mohamed to his mate demonstrating how to place the spade. These words do only have meaning in the context, which is common to the boys. They talk well Norwegian, but still they communicate without many words because they do not need it. Their actions and deictic signals are sufficient. Accordingly it is irrelevant that they are bilingual. They do not use any mathematical words, yet they have made a structure of classification and symmetry. This can be compared to ethno mathematical studies, for example of children’s geometrical patterns (Gerdes, 2007). These are describes in a mathematical language which is as strange to the children of Angola, as it is to these boys. Neither the patterns, nor the boys’ system are coincidental. While the boys’ structure is ad-hoc, the patterns of the Angolan children are stored knowledge, supported by tradition. The boys are making their own unique genre; they do not repeat a pattern. Most of the studies of children’s mathematical classification concerns geometrical forms, based on features with unambiguous definitions. The studies examine usually to what extent children are able to separate the defining features from the irrelevant ones (Clements, 2003).

While all mathematical concepts have a clear definition, the daily life concepts are often ambiguous. What makes a triangle to a triangle, are the human made definitions which have to be learned. Without them, a form with tree corners and curved lines could be a “triangle”. In the boys’ classification, nothing is defined beforehand. They make up their own criteria, depending on the play and the feature of the toys. Their play reflects the adult’s word, but at the same time it is different because they make the rules. They are in our world and in a make-believe world at the same time.

Structures are just temporarily stabilized ways of approaching a problem. Mathematical activity in school – in order to be realistic – should focus above all on the processes of

Working Group 13

structuring instead of the mastery of fixed and prescribed structures. (van Oers, 2001, p. 63)

In this episode the boys solve a problem, but do not use any traditional mathematical concepts or tools. Their actions, gestures and toys are semiotic signs which create a structure.

CONCLUSION

One single case cannot *prove* anything about the mathematics of small children. The analyses *show* that physical experiences and actions are fundamental in classification. It looks like all the communicative signs are intended. Hence, the children's mathematical experience cannot be unconscious. The children communicate in the most efficient way in the situation. In this case it means very few words. We emphasize the importance of verbalization, but in efficient communication we avoid unnecessary information. It is a challenge for the staff to create situations where verbalization is *necessary* and meaningful to the children. They should be encouraged to verbalize because of the benefits of using word, not to please the teacher.

The study shows how classification is useful to children in their play, and that mathematics can have an intrinsic value for children. Often the structures are less sophisticated than in this case. Anyhow, classification is a structuring process and an informal learning situation, stimulating children's logical ability.

The article started with a quote from the *Framework Plan* which stated that the staff should "support the mathematical development of children on the basis of their interests and modes of expression" (Ministry of Education, 2006). The structuring in this case study is an example of this. There is a need for much more research on how the staff can support and develop learning situations on basis of children's activities.

NOTES

¹All the names are anonymous. They have been translated culturally, - for example, children with Urdu names have got usual Pakistani names.

ERSTMAL-FAST (EARLY STEPS IN MATHEMATICS LEARNING - FAMILY STUDY)

Ergi Acar

Mathematics Education in Goethe University

Abstract. In this paper social-constructivist approaches of learning-as-participation will be applied. In this study, from a socio cultural perspective, we focus on family situations, which deals with mathematical problems as an everyday affair. It will be primarily presented as a comparison of an identical mathematical play situation of two immigrant Turkish families. The basic research questions: (1) cultural differences while playing, (2) the participation of siblings and (3) code switching during the play.

Key words. Early Childhood Mathematics, Family, Code switching

ERSTMAL AND ERSTMAL-FAST

erStMaL, early Steps in Mathematics Learning, is a research project of the interdisciplinary research center of IDeA, Individual Development and Adaptive Education of Children at Risk, which is extensively interested in the development of children at risk. This project is designed as a longitudinal study and relates to the investigation of mathematical cognitive development in preschool and early elementary school age from a socio-constructivist perspective. The Family Study of the erStMaL Project is named as erStMaL- FaSt, early Steps in Mathematics Learning-Family Study. It is also designed as a longitudinal study, which belongs to the erStMaL Project.

THEORETICAL FOCUS OF ERSTMAL-FAST

This project deals with the impact of the familial socialization for mathematics learning. In empirical level, we know from research projects like CEMELA and MAPPS (Civil 2005), that familial activities in mathematical context are corner stones of children's mathematical abilities and acquisitions. As Mills pointed out, parents are their children's first and continuing educators and nobody knows their own children like themselves. (Mills 2002,p.1) Thus, the family functions as parallel to an ongoing "support system", parallel to preschool, kindergarten and (primary) school for the learning of mathematics. The more children experience mathematical situations in their families, the more learning of mathematics in early years occurs in the different emerging forms of participation in everyday situations in their families.

By the term "support system" it is referred to the idea of any socio-constructivist theory, which means that the cognitive development of an individual is constitutively bound to the participation of this individual in a variety of social interactions. They move on learning -but inevitably- they also support his/her development. With respect of Bruner's concept of a Language Acquisition Support System (LASS) that

exists beside an internal Language Acquisition Device (LAD), we propose a similar concept for the learning of mathematics, which we call analogically the “Mathematics Acquisition Support System” (MASS) (Bruner 1990).

The process of engagement with the adult enabled the children to refine their thinking or their performance to make it more effective. Hence, the development of language and articulation of ideas was central to learning and development. (Atherton 2010) In these sense, familial contexts in multi-ethnic societies-like in Germany-, immigration, multilingualism and multiculturalism also inevitably have roles in early childhood mathematics education. As Suárez-Orozco & Suárez-Orozco write in their study on immigrant children "Immigrants are by definition in the margins of two cultures. Paradoxically, they can never truly belong either 'here' nor 'there.'" (2001, p. 92) Thus, in bilingual immigrant families it is clear that their children at risk.

From Zevenbergen’s perspective (2003), according to social and cultural differences the way in which action and practice are structured highly influences the social and individual construction of identities while learning mathematics. Thus, especially in this study I am interested in mathematical discourse in the context of bi-cultural families.

As authors Suárez-Orozco point out, the identity issues that immigrant children confront in feeling caught between their parents’ culture and the culture in their new country: “Children of immigrants become acutely aware of nuances of behaviors that although ‘normal’ at home, will set them apart as ‘strange’ and ‘foreign’ in public...Immigrant parents walk a tightrope; they encourage their children to develop the competencies necessary to function in the new culture, all the while maintaining the traditions and (in many cases) language of home” (Suárez-Orozco, Suárez-Orozco 2001, pp. 88-89).

As H.Coffey explained, a practice of moving among variations of language in a different context is defined as a “code switching”. He identifies “code switching” as the practice of switching between a primary (L1) and a secondary (L2) language or discourse in an educational context. In P.Auers’s (1998) opinion, code-switching can be related to indicative of group membership in particular types of bilingual speech communities, such that the regularities of the alternating use of two or more languages within one conversation may vary to a considerable degree between speech communities. The conversations in bilingual immigrant families are usually the mixture of two languages in mathematical play situations. Paradoxically, with these multi-culturalism and -lingualism they create a new language, which occurs by both languages.

Li Wei sorts Code Switching in 4 Categories:

Inter-sentential switching occurs outside the sentence or the clause level (i.e. at sentence or clause boundaries).

Working Group 13

Intra-sentential switching occurs within a sentence or a clause.

Tag-switching is the switching of either a tag phrase or a word, or both, from language-B (L1) to language-A (L2), (common intra-sentential switches).

Intra-word switching occurs within a word, itself, such as at a morpheme boundary.

As mentioned above, tag switching and also intra-word switching can be performed by immigrant bilingual families in everyday affairs. Especially with regard to the young age of the children of erStMaL-FaSt, it can be assumed that these forms include intensive narrative argumentation (Krummheuer 2009, Van Oers). In mathematical play situations with families, explanations and narrative presentations which are strongly linguistic are used. By linguistic matters, code switching can be strongly influenced by the functioning of MASS in bilingual familial context. Through all these aspects, it will be interesting to find out the functioning of MASSs in bilingual families.

METHODOLOGY OF ERSTMAL-FAST

For the Family Study, 12 children who are about 4 years old are chosen from a larger sample that belongs to the project erStMaL. The criteria are the ethnic background (German or Turkish), duration of the formal education of the parents and sibling situations within the families.

Our research design can be shown in the following table:

		more than one children	only one child
Higher Educational Families	Turkish		
	German		
Lower Educational Families	Turkish		
	German		

Figure 1: Table of research design.

As shown above, two comparable families with different nationalities are matched.

For erStMaL-FaSt, four play situations are conceived, which refers to the two mathematical domains: geometry and measurement. They are constructed according to specific design patterns, which will not be explained here.

Data collection comprises of recorded videos and their transcripts. The erStMaL child is recorded with the members of family while they are playing.

The data collection is organized according to following table:

Settings	A)	erStMaL child as single child	B)	erStMaL Child as sibling
erStMaL Child is playing with	A-1)	mother or one member of family (e.g. father)	B-1)	mother or one member of family(e.g. father) and sibling
	A-2)	mother and one member of family (e.g. father)	B-2)	mother, sibling and one member of family (e.g. father)

Figure 2: Table of research setting.

In this paper, I want to present two mathematical play situations of two different immigrant Turkish families as in Setting B-1.

EPISODE- “BUILD”

The mathematical play “Build” refers to geometry and spatial thinking. From given wooden bricks, the children and their families build three-dimensional bodies whose two-dimensional image is given on the playing cards. Supposedly, they perform the relations between two- and three-dimensional representations.

All playing cards are placed face down on the table. Each card has of difficulty level from 1 to 3. The cards with the number 1 are the easiest ones and the cards with the number 3 are the hardest ones. To be clear in explanation, each dimension of a wooden brick is named also as follows:

Figure 3: Examples of playing cards.

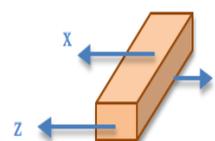

Figure 4: Dimensions of a wooden brick.

The player chooses one card from the pile of playing cards and tries to build the image on the card with the wooden bricks. In the transcription of two Scenes, to show the code switching, Turkish talks are written in bold; German talks are written in bold and cursive style.

Scene 1

In 1st Scene, family Gül performs a “polyadic interaction”. (Krummheuer 2007). Necessary information about Family Gül is given in the table below:

Working Group 13

Can	Didem	Berk	Family Gül	
	erStMaL	Child	Berk	4;9 years old speaks Turkish and German
	Older Brother	Can		11 years old speaks Turkish and German goes secondary school
	Mother	Didem		studied 7 years (Low-Educated)

Figure 5: Information about Family Gül.

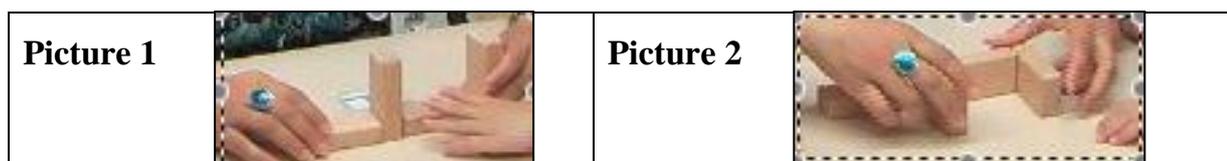

Play round begins with Berk. He takes a card, with number 1, the top of the pile of playing cards and builds it with the support of his mother and brother. After his turn, Can chooses one of the playing cards which is number 3. Although the card is of the hardest degree, he builds it easily without any help. Then mother Didem's turn comes. She chooses a card, with number 1, from the pile of playing cards.

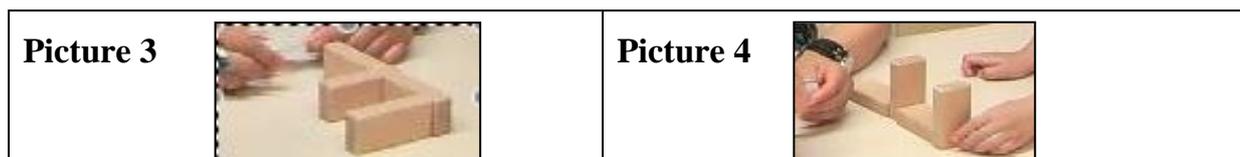

Figure 6: Chosen Card-Family Gül.

At the first sight as Didem sees her card, she reacts, as it is too hard to build this figure. But opposed to her react, Can says that it is easy to build that figure, while she is looking obsessed to her card. After a while, Didem starts out to build and lays two wooden bricks on x side with her both hands in front of her. But again Can reacts contrary to his mother and tells her that she is doing it the wrong way. After she takes another wooden brick, she lays all of them on y side. Berk also reacts same as his older brother and he says that she is doing it the false way. While Can backs up Berk, Didem reacts *just a momeeennt*<93>. Up to now, although the three family members speak Turkish, for the first time, Didem changes language, makes a tag switching and moves from Turkish to German.

After a while, Can seems that he cannot be patient and interferes the figure which is builded by Didem, by saying how she should do. But Didem looks this building just a second and changes the direction of whole figure as showed below:

But Can instantly denies and says **No you can't** <98>. He takes a card in front of her, holds it up and shows her **you are looking like that. That's why it is like that**<99>. Then he puts it back in front of her. Didem turns the whole figure 90^0 as showed on picture 3:

Then she says **it doesn't matter if it lays like that..or like that.** Can denies her again and responds **then it is not difficult it must stand up then it is difficult** <100-101>. We understand here, the word “stand up” refers to the y coordinate axis in a Cartesian coordinate system. It also shows us the differences between home-language and school-language as an inter-sentential switching.

Then Can takes a card from his mother's hand and by looking the card, he changes the position of the bricks again as showed above on the picture 4. At the same time, Berk reacts **off maamm please it is soo. yeess sooo**, and he smoothly regulates the wood bricks <117-118>. Berk's this reaction can be seen as a tag switching again. In the sentence, he moves from Turkish to German and then again from German to Turkish back. With this utterance, he addresses to his mother, and it seems that he got bored from the discussion between his mother and brother, too.

Didem holds up the card, looks it again by showing to Can and says **look I'm looking like this** . In return of Can, he takes the card from her hand and by showing says **that's why it's up on your head** <120-123>. Here, it is seen again inter-sentential switching with the sentence “it's up on your head”. As a logical nexus, this sentence might refer again to y coordinate axis in a Cartesian coordinate system. On the other hand, between Didem and Can a direct participation occurs due to addressing each other. Afterward, Can regulates again the figure and changes places of two wooden bricks as shown as red lines in Figure 7.

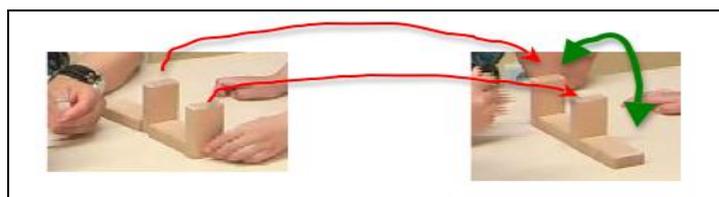

Figure 7: Putting order of the bricks.

But Didem interrupts him and tells that there is no difference among both figures and in conclusion, both figures are F. By explaining the form of the figure on the card, Didem refers it as an F, which can be named an intra word switching. It also shows us, how an adult can configure the mathematical figures and introduce them to her/his child (ren). After Can responds **you don't understand.it must be like on the card** <137-139>, Didem expresses that she just understands. Hereby Didems' turn ends up.

Scene 2

In 2.Scene, Family Ak performs and occurs “dyadic interaction”. (Krummheuer 2007). Necessary information about Family Ak is given in the table below:

Leyla	Aleyna	Family Ak	
		erStMaL Child Aleyna	4;8 years old speaks Turkish and German
		No Sibling	
		Mother Leyla	studied 12 years (High-Educated)

Figure 8: Information about Family Ak.

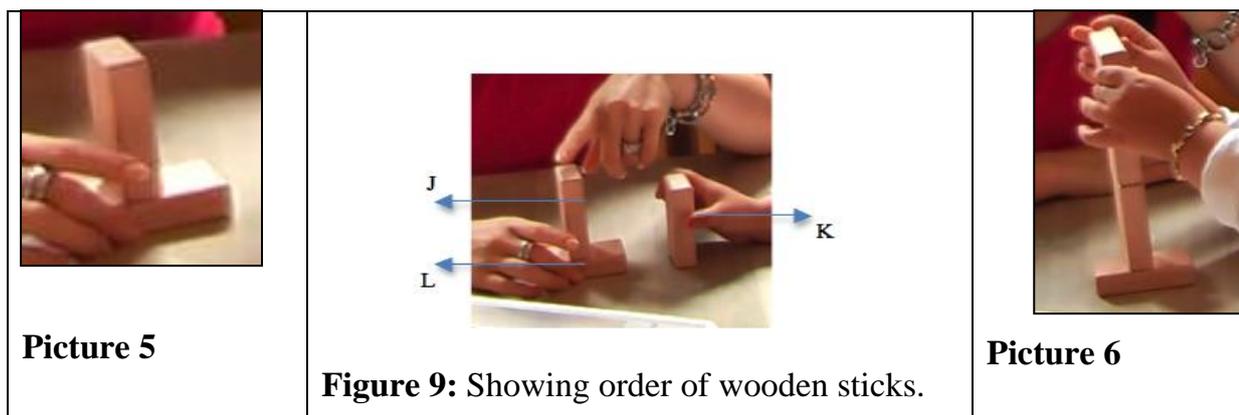

Play round begins with Aleyna. They play 4 turns each. They mostly pick up second-degree cards. But the figures, they built, interestingly are not the same figures on the card. This situation follows at the fifth turn of the mother, which will be exemplified in this part, too.

Figure 9: Chosen Card-Family Ak.

Leyla picks up an upper given card, takes 2 wooden bricks from the box and lays them on the x side with her both hands in front of her. Then she regulates them as shown in picture 5. She asks for help to Aleyna while she is going on building the figure. By shaking her head up and down, Aleyna reacts. This reaction can be seen as a positive meaning, just like a confirmation of Aleyna. Right after, Aleyna attempts

to put a wooden brick, like her mother, near the other one. But Leyla denies her and shows with her finger up on the wood stick by saying *up on it. up.* <294>. (see fig.9)

Aleyna puts K on L in the same art, just like how J stands. While Leyla is assisting Aleyna by putting up, she says *you look around the card* <296>. It is not clear enough what she really means, but it can be meant as an opposite side that Aleyna looks the card from the opposite side of her mother. As it is seen although they speak only German, there can be different utterances by using second language (L2/ German) as a first language (L1/ Turkish) because of thinking in Turkish. But it cannot mean that is a Tag switching.

Meanwhile Aleyna takes another wooden brick from the box and puts the new taken wooden brick on y side by centering up on the K as in picture 6, Leyla reacts *no no that must be like round*, shows to Aleyna the card with her finger and adds *look like that look should be an L.* <306-308>. But Aleyna lets the wooden brick stand upon the K as just before. By this explaining the form of the figure on the card, Leyla refers it as an L and makes a type of code-switching. It also shows us again as in Family Gül, how an adult can configure the mathematical figures and can introduce her child. Although it is not so clear, which wooden bricks she means (E or H or I), they built something else as another figure. Leyla takes this brick out and puts the wooden brick in the same coordinate axis on the K but towards the front. Her act shows us what she means by L for a while. However, Aleyna clicks her tongue: *tth.* <329>. By this react, Tag-switching and typical reaction of Turks are seen, which means no.

Then Aleyna follows by showing a card with her finger and tells that it doesn't look like that. By centering up again the same wooden brick on the K, she expresses that it has to be like that. Surprisingly, her mother acclaims and acknowledges her mind. But Aleyna seems not to understand and asks unintelligible by showing on the card *it must be like a hammer* <403>. Leyla responds by showing it upon the wooden bricks *we had already. it was the hammer like here on the front.* <407-411>. Thereby, they finish the play. By the explaining the form of the figure on the card, Aleyna and Leyla refer it as Hammer and make a type of code-switching. The word Hammer can be implied such as a sum of two functions in a x,y coordinate axis. This utterance is

just like a metaphor and with this sense; it can be named as an “Intra word switching”.

CONCLUSION

In this paper, a scene from Family Gül and Ak is introduced and reconstructed with the reference to the concept of learning-as-participation. With respect to their learning-as-participating, they cooperate by their discussion. They paraphrase a given figure on card and bring it in a new idea or perspective. Therefore, these forms are new representations of the sensitizing concept of learning-as-participation (Krummheuer, G. 2011). Considering the dynamics of the interactional turn-taking processes and specific relationships among utterances in Family Gül, it can be said that in a learning process a high degree of attentiveness occurs. In the first given scene, clearly learning-as-participation in a family is seen. While Didem comes up with a figurative meaning, Can insists on dealing with the cards according to the play-rules. There are not fixed roles in this family situation. However, the attitudes of the elder brother also affect his brother. Due to Berk’s utterances, it can be clearly seen that he perceives his brother as a recipient. At this point, we see the importance of the participation of the sibling. The elder brother initiates an emerging mathematical process in the way he is discussing with his mother.

In this point, a question comes to mind: what would be or happen, when elder brother does not exist in this play? In this sense, Scene 2 can be given as an answer. Because only the mother is an adult and a supportive person, it cannot be seen such an interactional turn-taking processes on the example the Family Gül. There is a high degree of attentiveness but no one remains true for playing card. Thus, Leyla supports her child not in a way, which would be based on the rules of the game. She does not act according to these rules and replies her daughter in the whole episode as if she is right, although the figure they built is completely different from the figure on the card. On the contrary of Family Gül, in Family Ak’s situation, there are certain roles. Unfortunately in this familial situation, a defective emerging mathematical process is occurred by false building the figure and not enough or intensive discussing to justify the built figure. Due to Leyla’s utterances, it can be said that her understanding of the support can be just to give a positive feedback to her daughter by saying “yes, right or you are doing very good”. Possibly this supportive system lacks an older sibling, as in Family Gül, who would be able to show the right way of the playing game.

While we see often code-switching during the turn taking in an interaction of Family Gül, in an interaction of Famils Ak seldom code-switching occurs.

On this account, it can be shown as a reason: emotional expressiveness. While the family member is disturbed, bored, or stressed, then he/she moves from one language to other language. For that several reasons, weak vocabulary, false grammar knowledge, cut corners, to be integrated etc can be given. When it is taken into

account that this family is an immigrant Turkish family, it will be not a surprise to cause code switching because of their emotions. To show a high emotion or reaction is a clear cultural difference between Turkish and German families. Hence, it is really often that they are seen 'normal' at home, 'strange' and 'foreign' in public. With these multi-culturalism and –lingualism, they create a new emergent mathematical model in the learning process with their different attitudes. It remains still open, if this hangs a positive or negative effect. In both families, the common situation is to describe the figures as a letter of the alphabet. It can be explained as an effort of the adults to decrease to level of comprehension for their children.

In conclusion, one might ask whether this newly created emergent mathematical model by immigrants can be used or improved by the researchers as a model for mathematical learning process in the immigrant families as a new learning process in multi-ethnic countries. More Research is needed in order to declare a model of mathematics learning in everyday situations of immigrant families. These first insights limit at some mathematic theoretical concepts, like zone of proximal development, capable adult etc.

CHANGING MATHEMATICAL PRACTICE OF KINDERGARTEN TEACHERS. CO-LEARNING IN A DEVELOPMENTAL RESEARCH PROJECT

Per Sigurd Hundeland, Martin Carlsen and Ingvald Erfjord

University of Agder (UiA), Kristiansand, Norway

The aim of this paper is to report results from a three-year project concerning collaboration with kindergarten teachers in implementing mathematics in the kindergarten. In our co-learning with the kindergarten teachers we all participated in a developmental project. The frame for analysing our data was developmental research. The analysis shows that the kindergarten teachers changed their practice throughout and because of their participation in the project. These changes were exemplified through increased mathematical consciousness in orchestrating mathematical activities, emerged emphasis on disseminating thoughts and ideas to colleagues, and changed ways of communicating with the children.

introduction

During the last few years, mathematics has gained increased focus as a separate subject area as regards the content of Norwegian kindergartens. In particular, this was due to an increased emphasis on mathematics in the present curriculum for the kindergarten. In this curriculum mathematics is explicitly mentioned as an area with which children are supposed to be engaged; an emphasis not made before. This increased focus on mathematics, made by the authorities, put the kindergarten teachers in a challenging situation as to how to implement and orchestrate mathematical activities in the kindergarten.

A professional development project called Learning Better Mathematics (LBM⁶³) has been initiated as a joint project with teachers in our university region and didacticians at the University of Agder (UiA). This project has enrolled in close relationship with a research project called Teaching Better Mathematics (TBM⁶⁴) initiated at the University of Agder. In these two projects, teachers and didacticians are collaborating in order to promote mathematics teaching and learning (cf. Carlsen, Erfjord, & Hundeland, 2010). In this paper we report from some of the results of this collaboration, analysing to what extent the kindergarten teachers' practices have changed due to their participation in LBM. The study focuses on the kindergarten teachers' conceptions about their own development in orchestrating mathematical activities. We use the notions of *co-learning* and *co-learning agreement* (Wagner,

⁶³ The LBM project was supported by The Competence Development Fund of Southern Norway, Tekna and Vest Agder County.

⁶⁴ The TBM project was supported by the Research Council of Norway (NFR no. 176442/S20) and The Competence Development Fund of Southern Norway.

1997) in order to describe the nature of our collaboration with the kindergarten teachers. According to Wagner (1997), co-learning agreement is described as follows:

In a co-learning agreement, researchers and practitioners are both participants in processes of education and systems of schooling. Both are engaged in action and reflection. By working together, each might learn something about the world of the other. Of equal importance, however, each may learn something more about his or her own world and its connections to institutions and schooling (Wagner, 1997, p. 16).

We are aware that the kindergarten teachers (practitioners) and we as didacticians (researchers) bring different kinds of expertise when engaging in collaborative activities. These different resources contribute to one another as to possibly develop the orchestration of mathematical activities in the kindergarten. With this as background it is interesting to scrutinise the outcomes of the kindergarten teachers' participation in LBM. The following research question has therefore been formulated: *In what ways have the kindergarten teachers' mathematical practices changed, due to their participation in the project?*

Project organisation

The project Learning Better Mathematics encompassed nine schools and four kindergartens. One important element of this project was workshops at UiA. The content of these workshops was devoted to mathematical topics such as geometry and number calculation combined with didactical topics such as communication in mathematics teaching and learning and designing of mathematical tasks. At these workshops there were plenary sessions and group sessions. In the group sessions, the kindergarten teachers were organised in separate groups, discussing, to them, relevant issues of how to engage the children in mathematical inquiry relative to the mathematical focus of the workshop. Thus, they shared thoughts, ideas, and engaged in mathematical activities. Another important element of the project was institutional visits by didacticians in kindergartens. At such visits, kindergarten teachers and didacticians discussed and reflected on how to implement and orchestrate mathematical activities in the kindergarten, and didacticians often observed kindergarten teachers' mathematical activities with children.

Theoretical framework

A theoretical ground for this study is a sociocultural perspective on learning and development. We view learning as a fundamentally social and situated process of appropriation where individuals, i.e. kindergarten teachers and didacticians, make concepts, tools, and actions their own through their collaboration and communication (Rogoff, 1990; Wertsch, 1998). The reason for situating our study within this theoretical position is our aim of scrutinising and making sense of the institutionalised interaction and learning activities taking place. By studying the

professional development of kindergarten teachers through interviews, we are analysing their processes of appropriating ways of orchestrating mathematical activities.

According to the project's theoretical stance in general (cf. Jaworski, 2007), *inquiry* is a central theoretical notion. The aim and intention of the project has been to collaborate with teachers in order to promote development of mathematics teaching through inquiry (Wells, 1999; Jaworski, 2005). According to Wells (1999), inquiry is a process described as “a willingness to wonder, to ask questions, and to seek to understand by collaborating with others in the attempt to make answers to them” (p. 121). Moreover, according to Cochran-Smith and Lytle (1999), the core of inquiry is a position they call an *inquiry stance*. That is, when one as a researcher and/or teacher takes a positively, critical position towards ones own practice, reflecting on this practice and asks critical questions in order to make a way into the deeper substance of the practice. In our case the practice is thus that of the kindergarten teacher, the what, how and why behind the mathematical learning activities orchestrated in the kindergarten. In our study, the notion of inquiry serves as a tool to describe how the kindergarten teachers' practice has changed.

Developmental research

The methodology of this study is developmental research (Freudenthal, 1991; Gravemeijer, 1994). Didacticians and teachers collaborate in order to change and develop the mathematical practice in the classroom, engaging in these developmental processes, critically reflecting on these practices, and discussing their teaching experience. The basic assumption is hence made, that if there is going to take place any changes in the mathematical practices in schools and kindergartens, it is the teachers that have to bring such changes about.

In developmental research there is a cyclical relationship between research and development. The research guides the development and the development nurtures the research (Goodchild, 2008). In combining this methodology with co-learning (Wagner, 1997), both teachers and didacticians get the opportunity to participate in the research process. The project activities are hence designed within such a frame. By adopting this methodology our aim is to experience “the cyclic process of development and research so consciously, and reporting on it so candidly that it justifies itself, and that this experience can be transmitted to others to become like their own experience” (Freudenthal, 1991, p. 161). Furthermore, our aim is to make contributions both to the field of mathematics education researcher and to the field of practitioners in their orchestrations of mathematical activities in the kindergarten. Through developmental research we simultaneously study both the promotion of development and the developmental process as such (Bjuland & Jaworski, 2009).

Analysis and Results

Working Group 13

The empirical basis for our analyses was three focus group interviews, one in each kindergarten, made by one of the didacticians within the project, as well as observations in these kindergartens. The three kindergartens are approximately equal in size, both as regards number of staff (25) and children (70-80). Eleven kindergarten teachers participated as indicated in Table 1. In Norway, kindergarten teacher education before 1994 did not include any mathematics course. After 1994 only a minor course (6 ECTS) was included. In our study, the majority of the participants was educated before 1994.

Name of kindergarten:	Naturbarnehagen	Pinocchio	Andungen
Name of the of kindergarten teachers in the interview:	Else, Sam, Marit, Ronny	Julie, Maiken, Lotte	Vilde, Line, Unni, Venke

Table 1: Overview of participating kindergarten teachers in the interviews

We took a systematic and iterative approach to the analysis of the interviews. We scrutinised one interview each and identified emerging issues. We discussed and compared these issues and agreed to examine them further in a new phase of analysis, based on commonalities and relevance for our research question. This second phase of analysis revealed three findings:

1. Increased consciousness regarding mathematics in the kindergarten.
2. Willingness to disseminate thoughts, ideas, and experience.
3. Improved ways of communicating mathematical ideas with the children.

In our data there are several parallel utterances confirming the same finding. Thus, we will here present and analyse only some of the kindergarten teachers' utterances as regards to three findings.

Increased consciousness regarding mathematics in the kindergarten

When the kindergarten teachers were asked to make their own experience from participating in the project explicit, we found three types of comments with respect to increased consciousness:

- An extended view on the nature of mathematics and how it may look like in the kindergarten practice.
- A changed personal relationship to mathematics.
- Development of experience regarding implementation and orchestration of activities with inquiry in mathematics sessions in kindergartens.

As regards the first bullet point, one of the kindergarten teachers, Lotte, claims that she has changed her way of thinking of mathematics in the kindergarten because of her participation in the project: "It is much easier for me to open up for more mathematical aspects to include in the activities and to think about how I can include these aspects. Now I have several mathematical ideas that I will develop further"

(Lotte, Pinocchio, line 292). A common expressed argument by the kindergarten teachers was that they now were in a position where they were more able to exploit and facilitate mathematical activities with the children. Such a view was by one of them expressed in the following way: “We have all developed experience making us more alert and ready to exploit the potential (for mathematics activities) when they appear. Perhaps we observed similar things before too but then we were unconscious of the mathematics” (Unni, Andungen, line 196). Marit from Naturbarnehaugen added to the picture of what mathematics is and may look like in the kindergarten environment. She expressed that playing activities may be a good arena to promote mathematics: “It is wonderful to see that we can play mathematics” (Marit, Naturbarnehaugen, line 114). These utterances we interpret as reflecting the kindergarten teachers increased consciousness with respect to what mathematics may look like in the kindergarten environment and in unfolding mathematical activities in the kindergarten. They have apparently changed their approach to the mathematical practice as well as developed their view and experience as regards orchestrating mathematical activities in the kindergarten.

With respect to the second bullet point, the kindergarten teachers talked about an earlier fear for mathematics which is no longer present. One of them expressed: “I have been one of those who have disliked mathematics, but now I very much appreciate it” (Venke, Andungen, line 73). Ronny at Naturbarnehaugen said: “It has been fun to see that colleagues I have talked with in our kindergarten, which have had problems to see the meaning of including mathematics, now have started to change their view of mathematics”. Marit, one of Ronny’s colleagues, exemplifies this argument: “We see that the project has contributed in making mathematics less fearful for us” (Marit, Naturbarnehaugen, line 15). We interpret these utterances as confirming that they have changed their personal relationship to mathematics.

Concerning the third bullet point increased consciousness and the changed personal relationship to mathematics have lead to new actions with the children. Throughout the project, many of the kindergarten teachers several times expressed that inquiry was well known and familiar to them. This was repeated in the interviews: “The method inquiry is not new to us. It is an old method in kindergartens” (Venke, Pinocchio, line 73). However, it appeared that working with *mathematics* in an inquiry way was new to them. Maiken argues: “We have worked with mathematics before, but not in this way, not so actively (Pinocchio, Maiken, line 26). Related to the third bullet point, several of the kindergarten teachers commented on what it means to interact and communicate with children in an inquiry way; the third main finding of this study.

The kindergarten teachers emphasised how they have progressed in their implementation of mathematical activities. They pointed to the workshops as an important arena to discuss and share ideas. Line reflected on her development: “During the workshops, my brain starts to work and I am thinking on how I can use

Working Group 13

this, whether it is too difficult to implement or if I can use parts of it? In the workshop on symmetry (in a plenary, pictures of symmetric leaves and flowers were presented), I thought that this is useful and possible because we are, in our kindergarten, always focusing on outdoor activities.” (Line, Andungen, line 102). This utterance indicates a readiness to implement mathematics in the kindergarten. On a more general level, Lotte said: ”I believe it is important to move beyond the stage ’mathematics is everywhere’ and ’we are counting’. I believe we have to move further than that. Of course, we are counting, but we have to be more thorough, to be more systematic, and justify what we are doing as regards mathematics” (Lotte, Naturbarnehagen, line 274). This was not only at a superficial level, but they were aware that in order to support and facilitate mathematical activities with the children, they needed to be more systematic and comprehensive.

Willingness to disseminate thoughts, ideas, and experience

From our analysis of the focus group interviews we found that the kindergarten teachers are eager to disseminate the basic ideas of the project to other kindergarten teachers in their own kindergarten, to kindergarten teachers in the project, to fellow kindergarten teachers in their local city, and to parents.

Only a small number of kindergarten teachers in each kindergarten participated in the project and came to workshops at the University. But kindergarten teachers in the project paid attention to disseminating project ideas to their colleagues, including assistants without pedagogical education. Unni said: “The whole kindergarten participates. Thus, it becomes a part of the kindergarten, not only something a few are familiar with. Everyone becomes part of it.” (Unni, Andungen line 7). Also at Naturbarnehagen and Pinocchio they prioritised dissemination to colleagues. Maiken at Pinocchio talked about the situation at her department of the kindergarten, saying that: ”I think the whole group of staff is more involved now than they used to be” (Maiken, Pinocchio, line 26). Staff meetings were mentioned as an arena for dissemination within the kindergartens: ”In the staff meetings, apart from project information, we have sometimes worked in groups and we have had visits from UiA where inquiry and the project have been focused” (Unni, Andungen, line 14).

A second kind of dissemination took place *between* kindergartens in the project. In all the interviews, kindergarten teachers emphasised the learning benefit of sharing ideas. Julie stated this in the following way: “We are learning from each other” (Julie, Pinocchio, line 119). In fact Unni expressed that she would have liked to share even more with the other project participants: “Sometimes, when we have finished the work in groups (in the workshops at UiA), I think we could have shared more” (Unni, Andungen, line 137). Thus, the kindergarten teachers participating in the project apparently shared their ideas and experience with utilising inquiry in orchestrating mathematical activities.

Dissemination to *other kindergartens* were also taking place, for instance through arrangements for kindergarten staff in the local city. When referring to an upcoming planning day for those people, where Lotte and Julie were going to give a lecture, Lotte said: “We are going to tell how we have worked with mathematics in our kindergarten, and we have planned to give several examples of inquiry in mathematics to the audience, because that is what we believe the audience is interested in” (Lotte, Pinocchio, line 390). One of the authors of this paper collaborated with these kindergarten teachers in giving this lecture. Therefore, we are able to conclude that dissemination of basic ideas indeed took place.

The fourth kind of dissemination was related to involving the children’s *parents* in the ideas of inquiry as an approach to mathematics. The kindergarten teachers reported about concern raised by some parents to implementation of mathematics in the kindergarten. However, this situation has changed: “They were afraid that the children would lose the possibility to play freely and they were unsure about this (the mathematics). But gradually we now only get good feedback, excellent feedback from the parents” (Venke, Andungen, line 47). The kindergarten teachers also reported that they have got feedback indicating that some parents with children in other kindergartens were jealous since their children were not approaching mathematics in the same way: “Other parents in other kindergartens, they are a bit jealous” (Unni, Andungen, line 54). These utterances we interpret as confirming a desire to disseminate project ideas broadly. For instance, dissemination took place through documentation of activities with posters used in staff meetings and meetings with parents. Written documentation gave possibilities for disseminating ideas to assistants and substitutes in order for them to engage with mathematical inquiry. They also had a wish to create a resource bank electronically available for the staff.

Improved ways of communicating mathematical ideas with the children

From the interviews we found evidence of improved ways of communicating with children in mathematical activities. One of the kindergarten teachers pointed to inquiry as a tool that increased the awareness of how to communicate: “Inquiry in a way makes us much more conscious about how we talk (Else, Naturbarnehaugen, line 17). Ronny reflected about how inquiry facilitates profound and prolonged discussions with children: “It is fun to sit together and talk with them. It is an excellent method for children to have a long conversations; a good long conversation” (Ronny, Naturbarnehaugen, line 179).

Maiken at Pinocchio emphasised the importance of children answering questions and coming up with new questions themselves: “I have to let the children get the possibility to answer. Now I have to let them get the opportunity to find possible answers and to come up with new questions, and resist putting words in their mouth” (Maiken, Pinocchio, line 22). A similar concern for questions was visible in a dialogue between the kindergarten teachers Marit, Else and Ronny at Naturbarnehaugen:

Working Group 13

- 31 Marit: I am now much more conscious when I am together with the children,
what I say to them and I am concerned what they might come up with
- 32 Else: They are now more clever to ask and we draw on the opportunities
arising in daily life and use them actively.
- 33 Marit: We now pay more attention to this issue
- 34 Ronny: We see it much clearer.

Marit gave an example of how she facilitated mathematical communication. An example is the word “under” in connection with an outdoor track which included hurdles: “I asked him afterwards, how did you move?. He answered that he crawled *under*. It is important that they use their own words; it is not me who should tell them (Marit, Naturbarnehaugen, line 29).

We did not explicitly find utterances concerning new ways of communicating in the interview at Andungen. However, in Carlsen et al. (2010) we reported from a mathematical activity led by Unni at Andungen. The communication was dominated by a variety of question giving the children opportunities to participate and contribute with ideas and arguments in the mathematical activity. In our conversation with Unni after the activity, she claimed that this intensive use of questions was due to her participation in the project.

To summarise, we found that the kindergarten teachers wanted the children to take more active roles than before. This awareness gave children several opportunities to inquire; taking charge of finding solutions, asking their own questions and creating new mathematical challenges. We interpret this as a shift in the relationship between kindergarten teachers and the children.

Discussion

We set out the following research question for this paper: *In what ways have the kindergarten teachers' mathematical practices changed, due to their participation in the project?* We argue, based on the kindergarten teachers' comments, that they by being participants in the LBM project have changed and developed their view of mathematics. Furthermore, they have developed experience in implementing mathematical activities in kindergarten. They claimed that these changes have resulted in a more focused orchestration and facilitation of mathematical activities characterised by inquiry. We interpret these changes as indicating a changing practice. We will argue that the kindergarten teachers' changed practices are due to their participation in co-learning processes (Wagner, 1997) at different arenas; between didacticians and kindergarten teachers, between kindergarten teachers and between kindergarten teachers and children. When participating in such processes, the kindergarten teachers increased their consciousness as regards mathematics, they disseminated thoughts, ideas and experience, and they improved their ways of communicating and discussing mathematical ideas.

Working Group 13

The kindergarten teachers' awareness and valuing of the role of questions and contributions by the children in such activities, illustrate that the teachers have taken an inquiry stance towards mathematical activities in the kindergarten (Cochran-Smith, & Lytle, 1999; Jaworski, 2005, 2007). In accordance with how Wells (1999) describes an inquiry process, the kindergarten teachers critically scrutinised their own practice, which facilitated the children's possibilities to inquire into the mathematics. In their orchestration of mathematical activities, the kindergarten teachers emphasised the social and interactive dimensions of learning. This was also visible in our observations, where the kindergarten teachers organised goal-directed mathematical discussions among themselves and a small group of children. We will argue that these indicators exemplify the kindergarten teachers' processes of appropriating inquiry as a tool and as a way of being as regards mathematics (Rogoff, 1990; Wertsch, 1998).

We would also like to argue that developmental research, as a methodology for conducting the kind of research presented in this paper, has been fruitful when it comes to scrutinising the various aspects of how the kindergarten teachers have changed their own practice of orchestrating mathematical activities. The development of the practice has indeed nurtured our research, and it is our hope that our research may guide possible development in the future (cf. Freudenthal, 1991; Goodchild, 2008; Gravemeijer, 1994).

The kindergarten teachers claimed that they currently think differently about mathematical activities. They reflected more thoroughly in their approach to orchestrating these activities, including careful considerations of how to communicate mathematically with children. Furthermore, they were eager to disseminate their thoughts and ideas at several arenas as regards mathematics in the kindergarten. They also claimed that they have gained from their participation in the project, by making references to ideas and tasks presented and discussed at workshops and staff meetings. These transformations we interpret as exemplifying what Jaworski (2005) means by appropriate inquiry as a way of being in orchestrating mathematical activities in the kindergarten. Through our three-year collaboration with the kindergarten teachers, we have observed their orchestration of mathematical activities, their discussions of mathematical and didactical issues at workshops, and their dissemination of ideas and experience from the project. These observations, together with the analytical findings reported in this paper, contribute to our argument that they have changed their practices. In Norway, in-service training typically has been offered as short term ad hoc courses. Our study implies that professional development is achievable through long term co-learning and fostering of inquiry communities among didacticians and kindergarten teachers.

The three findings that have been identified as regards the research question, all address in what ways the kindergarten teachers' have changed their practice. However, we do not consider this as evidence of successfulness of the project as

such. Further research might reveal constraints and problematic issues as regards implementation of the project's aims and ideas.

“LOOKING FOR TRICKS”: A NATURAL STRATEGY, EARLY FORERUNNER OF ALGEBRAIC THINKING

Maria Mellone

Dipartimento di Matematica e Applicazioni “R. Caccioppoli” – Università Federico II di Napoli

Starting from the assumption that very young children exhibit some naïve forms of algebraic skills, in this work we present and discuss an episode occurred within a grade 2 classroom experimental work. This work is centred on an exploratory activity (namely, looking for regularities) in the domain of natural numbers. We observe that this kind of activity, if suitably managed, can activate the search for tricks to help mental calculation, inducing in children a first shift from an arithmetic behaviour, based on search for results, to an algebraic attitude, based on the search for relationships. Moreover, we notice how a guided use of suitable representations can transform children’s natural bent to look for regularities into ‘awareness of, or attention to, structure’, in the sense of (Mason et al., 2009).

Key-words: natural strategy, algebra, structural thinking

INTRODUCTION AND THEORETICAL FRAMEWORK

In the last years an increasing number of researches pointed on recognizing naïve forms of algebraic thinking in very young children (Carragher *et al.*, 2001; Lee and Freiman, 2004; Malara and Navarra, 2008; Radford, 2010). Along these lines, the quite simple view that identifies a one-way “ontogenetic” path from the arithmetic thinking to the algebraic one has been doubted (Radford, 2001, 2010), while a more complex relationship has been hypothesized.

Among many attempts to deeply investigate on children’s abilities in mathematical generalization and abstraction, various research experiences have been developed concerning the study of pattern work at early school years (see for example Stacey, 1989; Lee and Freiman, 2004; Radford, 2010 and Rivera, 2010). The work of Lee and Freiman, carried out also at kindergarten level, “confirmed [...] the more positive observation, that children engage easily and enthusiastically in pattern work having little or no difficulty in ‘seeing a pattern’”, but at the same time stressed “the more negative observation, that the final stage of pattern work, checking the generalization, appears to be absent” (Lee and Freiman, 2004, p. 2). Before, Stacey in her work (1989) already noticed a similar behaviour in primary school students by observing a certain reluctance to generalize or the presence of only some rough forms of generalization: “students have demonstrated a willingness to grab at relationships without subjecting them to scrutiny” (Stacey, 1989, p. 163).

A different view is adopted by Radford (Radford, 2010). His study, besides deeply analyzing some early forms of algebraic thinking, in the conclusions faces the problem of monitoring their development. In other words, the relevant question is

not only to identify what children can or cannot do at an early stage, but also how to favour the development and possibly to improve these embodied, non symbolic forms of algebraic thinking. In this direction, the question arises that is crucial in the present study: what kind of early work leads to the development of algebraic thinking?

Indeed, whilst it is now widely acknowledged that very young children are capable of some forms of algebraic skills, it seems also evident that “*algebraic thinking does not appear in ontogeny by chance, nor does it appear as the necessary consequence of cognitive maturation. To make algebraic thinking appear some pedagogical conditions need to be created*” (Radford, 2010, p. 79), but “*the task of creating appropriate didactical tools for the teaching of algebra in the early grades [...] has barely begun.*” (Lee & Freiman, 2004, p. 1).

In our research group, the methodological and didactic aspects and the related teaching proposals for an early approach to algebra, follow from a basic cognitive assumption, supported also by some neuroscience results, namely that (i) the aptitude to abstraction is typical of human nature and spontaneously exerted from the very early age, and that (ii) the purpose of education is just to refine and to formalize the forms of abstraction and to become conscious of them, what can be obtained in situations of cultural immersion and social interaction, together with a progressive development of linguistic skills (Iannece & Tortora, 2008). Therefore, in the last years we have been particularly interested in finding and analyzing all the *natural strategies* that can be seen as rough forms or precursors of the mathematical procedures, abilities and structures, and in designing suitable didactic interventions with the aim of let them emerge, be exploited and refined (Iannece *et al.*, 2009 and Iannece *et al.*, 2010).

In the case of algebraic thinking, if we start from the assumptions that the algebraic thinking can be viewed as a particular way of expressing abstract relations and processes (for example arithmetical ones) and that children have a natural tendency to abstraction, the purpose is to lead learners to what Mason *et al.* have called the *awareness of, or attention to, structure* (Mason *et al.*, 2009). As they emphasize in their work, learners manifest *awareness of, or attention to, structure* when they begin to focus on what stays and what changes – that is, “*becom[e] accustomed to considering invariance in the midst of change*” (p. 13).

Assuming a vision of thinking as interpersonal communication (Sfard, 2008), but also as intrapersonal communication made tangible by social practice and materialized in the body, in the use of signs and artefacts (Radford, 2010), algebraic thinking can be seen as a kind of “discourse” (inter/intrapersonal) in which we can recognize this *attention to structure*.

In this study we will show how an activity of free exploration in natural numbers domain can promote this attention, in particular when the need of obtaining untrivial

arithmetic results favours the search for tricks to easily perform mental calculations, inducing in children a first shift from an arithmetic behaviour (simple execution of correct operations), to an algebraic attitude, based on *attention to structure*. Furthermore we analyze how this first form of attention to structure can develop into more ‘formal’ knowledge and into sound linguistic formulations, taking advantage from the guided use of suitable representations (objects, drawings, etc.) for the sake of social interaction.

ARITHMETIC EXPLORATION

In this section we present a second grade classroom experimentation. It is based on an exploratory activity on natural numbers, which starts with the following task:

Take three consecutive numbers and add them up. Repeat this several times, using other groups of three consecutive numbers. What do you observe?

It is an open task, that we usually propose to students of different grades, with more or less deep goals, depending on their age. In our case (grade 2), the “simple” calculation of several sums, possibly of big numbers, is in itself a demanding task. This is not made by chance: indeed, it is just the obstacle consisting in children’s still poor calculating skills, that stimulates a sort of tension between arithmetic and algebraic behaviours. As we will better see in the sequel, also due to teacher’s mediation, children are forced to look for tricks that enable them to perform quite difficult calculations. In this way their attention naturally shifts from the simple search for the result of a calculation to the detection of a general structure.

In our opinion, our experience corroborates Radford’s view (Radford, 2001, 2010) that the ontogenetic relation between arithmetic and algebra is quite complex. In fact, the described activity has been naturally intertwined with the usual arithmetic curriculum of grade 2, in particular with the normal acquisition of calculation skills. But the insertion of this kind of activities can help to move from the diacronic feature of arithmetic (where the mental processes of calculations are linearly distributed in time, and the results are obtained from the action of an individual) toward the time-free and impersonal features of the structural world of algebra.

As suggested by Mason *et al.* “*any sensible work approach to teaching combines work on understanding concepts with work on mastering procedures, and combines tasks designed to stimulate learners to express their own thinking using technical terms with task designed to highlight the use of important routines*” (Mason *et al.*, 2009, p. 26). We think that the activities of exploration with natural numbers, suitably managed, can stimulate a structural vision of procedures. In this direction we have found very effective as an interpretative tool the distinction proposed in (Mason *et al.*, 2009) between *empirical counting* and *structural generalization*. In the forthcoming analysis we will try to distinguish between an action performed by a child in order to obtain a particular result and an action performed in the attempt to clarify the underlying structure.

Research Method

The episode that we present here took place in Winter, 2010, in a class of 19 Grade 2 students. The class teacher is in service for many years, with her own more or less unconscious pedagogical beliefs, and her own educational experience. During the 2010 the teacher was involved in a professional development course, held by our research group, arranged around several topics, among which the early approach to algebra⁶⁵. The activity of exploration on natural numbers above described, is formerly faced in collaborative way during this professional course.

During the experimentation in her class, the teacher alternated work in small groups (5 groups composed by 3-4 children) and work within the whole class group. A member of our research team recorded the class discussions and took some notes regards the gestures performed by students. The collected data consist in the class discussions transcripts, in representations produced by children during the small group activities and in the observing researcher's notes.

According with the vision of thinking as interpersonal and intrapersonal discourse I conducted a multi-semiotic analysis of young students' behaviours (representations use, artefacts use and linguistic expressions) in order to follow the development of linguistic skills. Here I choose to analyses some excerpts of the activities in order to show how the guided use of suitable representations supports the development process of linguistic abilities.

Results of the analysis

At the beginning of the first lesson the teacher presents the task and divides the children into groups. Going around, she observes that in this first phase the pupils' natural behaviour is to arrange the numbers in the ordered sequence and then to obtain the various terns grouping all numbers by three. So, since all the groups choose their various terns not by chance but arranged in regular sequences, it seems that even though the task doesn't deal with patterns, the children autonomously build some patterns: 1-2-3; 4-5-6; 7-8-9; etc. Then, all the groups concentrate on the search of relationships among the sums of consecutive terns. Similar behaviours have been already observed in pattern work studies, for example Lee and Freiman say: "*What surprised us was how strong that urge to see a pattern is – strong enough to compel the student to impose a pattern by modifying or ignoring some elements in a given configuration*" (Lee & Freiman, 2004, p. 5). Here our hypothesis is a bit more refined: namely, a task like the above one, where the attention has to be directed toward a generic element of an infinite set, requires a harder abstraction jump in comparison with a typical pattern work which deals with an already ordered infinite

⁶⁵ An analysis of possible changes in teacher's practice and beliefs should be interesting, but it is not the focus of this work.

Working Group 13

set, asking to determine the n^{th} element of a given succession. But children, looking for patterns, perhaps exhibit the ability to split this jump in easier steps.

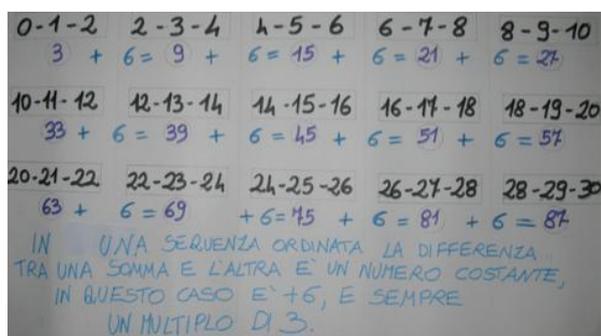

Almost one hour later the groups are invited to communicate their findings to the rest of the class. The regularities recognized by children, expressed in natural language, are: ‘the alternation of odd and even numbers in the sums’, ‘the possibility to obtain any successive sum by adding 9 to the previous one’ and, finally, the only one destined to survive, ‘all sums are multiple of three’.

The teacher, respecting the children’s need to work with terns arranged in a regular way, suggests a slight variation, that is to work with different sequences, but ‘ordered’ (as the children call them) as before:

$$0-1-2; 1-2-3; 2-3-4; 3-4-5; \dots$$

$$0-1-2; 2-3-4; 4-5-6; 6-7-8; \dots$$

Here, the teacher’s management of the activity utilizes, more or less consciously, children’s predisposition to look for “what stays and what changes”, that is one of the central points of Mason’s ‘variation theory’: “*human beings naturally detect similarity through becoming aware of variation*” (Mason *et al.*, 2009, p. 12). Indeed, the children realize very quickly that in the new sequences the difference between two consecutive sums is still a constant but not 9 anymore, and moreover, working with the last sequence, they also see that the regularity of ‘alternation of odd and even numbers’ doesn’t work. Finally, only the regularity ‘all the sums are multiple of three’ works. The teacher helps the children to synthesize this first experience on a poster, to record their findings (Fig. 1)

0-1-2 3	2-3-4 9	4-5-6 15	6-7-8 21	8-9-10 27
10-11-12 33	12-13-14 39	14-15-16 45	16-17-18 51	18-19-20 57
20-21-22 63	22-23-24 69	24-25-26 75	26-27-28 81	28-29-30 87

IN UNA SEQUENZA ORDINATA LA DIFFERENZA
TRA UNA SOMMA E L'ALTRA E' UN NUMERO COSTANTE,
IN QUESTO CASO E' +6, E SEMPRE
UN MULTIPLO DI 3.

Fig. 1

During the second lesson the teacher decides to work with the whole class group and proposes to choose a sequence of terns not ‘ordered’ as before, but to take groups of three consecutive numbers at random. In a natural way the children start taking into consideration scattered terns: Gabriele, for example, takes 1-2-3; Giuseppe 12-13-14; Angelo 39-40-41, Ivan 83-84-85 and so on, with even larger numbers. In this way the children soon face the problem of calculating quite large sums, not easily manageable by mental calculation. Some children spontaneously use the additive algorithm which can be interpreted as *empirical counting*. Clearly, not all the young children are experts with the additive algorithm when the sums become so big.

Working Group 13

Pointing on this difficulty, the teacher asks to carefully observe the three consecutive numbers and to try to find an easier way, a trick, to calculate their sum. As Mason *et al.* observe, “*inviting children to find ‘quick way’ to do arithmetic calculations [...] can be an entry into appreciating structure.*” (Mason *et al.*, 2009, p. 14).

The children work in groups for a little time and then, after several attempts, Ivan observes: “Teacher, I understand! It’s enough to do 84 times 3”. He seems to become suddenly aware of an action that he has repeated many times. In this way Ivan seems to generalize not a figural pattern, but an ‘action’ pattern.

Not all the other children seem to understand Ivan’s observation, therefore the teacher invites Ivan to explain his finding, also because the rest of the class is not working on this particular tern. “If we take away one unit from 85 and give it to 83 than they become three 84, and so if we do 84 times three, we do it faster.”⁶⁶. We can recognize in Ivan’s statement an attention to structure in which his *empirical counting* performed on the particular tern moves toward a *structural generalization*. Here an able teacher’s intervention is needed in order to stimulate a more structural vision. Indeed, the teacher invites Ivan to use some objects like the rulers, or to draw a picture, to better explain his thinking. After a few time Ivan comes to a graphic representation, so clear and convincing that the whole class decides, following teacher’s advise, to put it on a poster (Fig. 2).

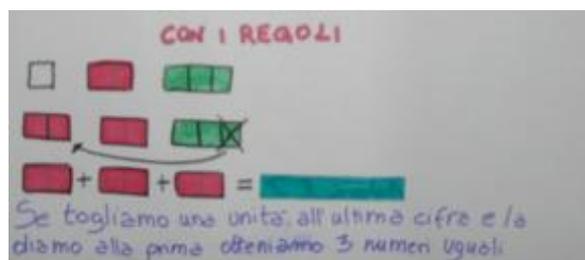

Fig. 2

It is interesting to note how Ivan’s drawing, based on the rulers, though obviously concerning a single, and even very simple numerical case, bears a true generalization, much as in the use of geometrical figures. In fact, even if Ivan uses the “little square” to represent two different things, namely the generic number and the unit, we can recognize in his representation a naïve form of notational symbolism. Quoting Mason again, “*there is a basic awareness based on physical manipulation of objects which tells the people the answer without having to do particular cases*” (Mason *et al.*, 2009, p. 15). Moreover, it is the need to communicate his hypothesis to the rest of the class that allows Ivan to go a step farther and to produce a graph with some algebraic feature, thereby to reach a form

⁶⁶ Unfortunately, we cannot report here about the interesting gestures by which Ivan accompanied his words, since we don’t have any video recording of the episode, but the observing researcher describes the gestures as a kind of forerunner of the representation in Fig. 2.

of algebraic thinking, sophisticated enough. That the use of such representation strongly induces a clearer structural vision is proved by the fact that Ivan, after his drawing, is able to articulate a refined explanation in natural language: “If we take away one unit from the last number and we give it to the first one, the three numbers become equal, and if we multiply this number by three, we are done!”

The search for regularities continues also in the following lessons, but what is remarkable here is that all the children begin to use Ivan’s finding to calculate large sums, in other words the children like the “trick” so much, to transform it into a patrimony of the class. Furthermore, in the following lesson the children use the discovery to perform the inverse task, which is given a number multiple of three to identify the consecutive numbers tern of which this number is the sum. This kind of task is suitably chosen by the teacher to allow the children to grasp a more clear structural vision of the relationships involved in the problem. Through a collective discussion mediated by the teacher the children easily understand that they can find middle number of the tern by dividing the number for three.

SOME CONCLUSIVE REMARKS

We have tried to show how some guided activities of exploration and search for regularities in the domain of natural numbers can promote algebraic thinking in very young children. In particular, the activity presented here, profiting from young children’s poor calculation skills, stimulates the invention of tricks to succeed in performing calculations. In our opinion, this invention can be seen as a first kind of ‘attention to structure’; in other words, ‘looking for tricks’ can act as a very early forerunner of the abstraction process, typical of the algebraic thinking. Therefore to induce in children the need for simplifying difficult tasks can be a good way to start them off towards the algebraic thinking.

Many questions still remain to be faced. For instance, since it happens that some children, like Ivan, are more ready to develop algebraic thinking than others, how to let the intuitions of an individual be acquired by others; and, even more crucial, which kind of didactic mediation can help to transform a possibly deep but unstable intuition of a child into a more formal knowledge. The questions are not easy, and in our opinion cannot be solved in a simple or unique way: in this sense we agree with Tall’s perspective, according to which, “*the study of ‘early algebra’ needs to be seen not only as an activity in itself but also as part of a longer-term development.*” (Tall, 2001, p. 152).

Anyway, a small contribution to both questions can come from the use of suitable representations and from a good context of social interaction, as we hope to have shown before. Indeed, teacher’s invitation to use representations seems to help Ivan to reach more sophisticated forms of structural thinking and, from the other side, the proposal of exposing Ivan’s discovery in a poster contributes to transform his trick into a patrimony of the whole class.

CAN YOU TAKE HALF?

KINDERGARTEN CHILDREN'S RESPONSES

Dina Tirosh, Pessia Tsamir, Michal Tabach, Esther Levenson, and Ruthi Barkai

Tel Aviv University

The notion of 'half' is familiar to children from their everyday experiences before formal schooling begins. This study explores kindergarten children's ability to take half of an increasingly large amount of discrete items and the strategies they employ while doing so. It also explores the difference between taking half of a set of discrete items and half of a set of continuous items where each item may itself be halved. Results indicate that kindergarten children know that taking half implies two sets and that they employ different strategies when halving different amounts.

BACKGROUND

The importance of engaging children with mathematics during their early years has recently come to the fore. This is reflected in both position papers and national standards which often mention number and operations as a key domain to be developed during these years. The notion *half* is included in the domain of number concepts. For example, in their guidelines for grades Pre-K through grade 2, the Principles and Standards for School Mathematics states that "All students should... understand and represent commonly used fractions, such as $\frac{1}{4}$, $\frac{1}{3}$ and $\frac{1}{2}$." (NCTM, 2000, p. 78). The Israel National Mathematics Preschool Curriculum (INMPC, 2008) states that "a child should be familiar with the concept of half and its practical use in everyday life" (p. 17). In addition it states that, "the concept of half relates to half of one unit, such as half a pita bread, as well as half of a quantity, such as half of the cookies in a box...In kindergarten, it is unnecessary to introduce the graphic symbol of half." (p. 45). In Australia, the New South Wales K-6 curriculum (2002) states that for Early Stage 1, students should learn about "using the term 'half' in everyday situations", and "use fraction language in everyday situations e.g. 'one-half of a cake has been eaten'" (p. 60).

Previous studies investigated young children's notion of half within the context of fair-sharing. Fair-sharing contexts relate to situations where the total resources available are divided equally among the users. Thus, if an amount is shared equally between two people, we may say that each person has received half of the amount. Regarding the sharing of a continuous item, Hunting and Sharpely (1988) investigated the behaviours of preschool children requested to share a blanket and a skipping rope between two dolls. They found that while most children understood that a single partition was necessary, most lacked an anticipatory or a verification strategy for assessing the resulting equality. Regarding discrete items, it was found that young children were able to divide 12 crackers between two dolls by dealing one cracker at a time to the dolls (Hunting & Davin, 1989 in Davis & Hunting, 1990).

Yet, in an unstructured interview, when it came to sharing 12 jelly beans between two children, the same children did not share equally (Davis & Hunting, 1990). Davis (1989) found that students learning division may not take into consideration the reality of a problem. When asked to share five balloons between two children, one student suggested cutting the fifth balloon in half.

While the previous studies investigated children's notion of half within a fair-sharing context, this study investigates the notion of half when it is not explicitly related to fair-sharing. Such situations arise when a child eats half an apple or takes out half of the blocks from a container. These situations are very different from fair-sharing contexts. For example, Parrat-Dayana and Vonech (1992) found that giving half of six apples to one doll is more difficult than carrying out this sharing task with two dolls. "Asking a child for half of six apples forces him or her to think of the six apples as a totality, such that the union of the parts forms a whole, where the two parts are disjuncted." (Parrat-Dayana & Voneche, 1992, p.74).

Our current study continues and expands upon previous investigations in two ways. First, it investigates young children's notion of half when fair-sharing is not explicit, in situations when it is possible to take half and in situations when it is not possible to take half. In addition, previous studies did not focus explicitly on children's strategies for taking half. This study focuses also on the strategies.

Our research is guided by the following questions: (1) To what extent can kindergarten children take half of a set of homogenous discrete objects before they are explicitly taught the concept of half and what strategies do they employ when doing so? (2) Given two sets of objects, one where the objects themselves are continuous and may each be halved and one where each of the objects is discrete and cannot be halved, is there a difference between kindergarten children's success in taking half of the set?

METHOD

Participants

Four preschool classes in low-socioeconomic neighbourhoods participated in this study. Each class consisted of approximately 30 pre-kindergarten and kindergarten children between the ages of four and six years old. In this paper we focus on all 64 kindergarten children (between the ages of five and six years old) who were expected to enter first grade in the upcoming school year. The kindergarten teachers were participating in a two-year professional development program, *Starting Right: Mathematics in Kindergarten*⁶⁷. The children worked with their teachers on tasks from various mathematical domains, including geometry, measurement, and number and operations. Counting was part of the children's daily routine. Other

⁶⁷ This research was conducted in collaboration with the Rashi Foundation.

mathematical activities included composing and decomposing numbers and dividing objects into two, three, or more sets, equal as well as unequal sets (e.g. Tsamir, Tirosh, Tabach, & Levenson, 2010). Fractions and the concept of half were not explicitly taught.

Tools

Individual interviews were conducted in a quiet corner of the kindergarten during the last month of the school year. The interviewer followed a set protocol and was responsible for writing down each child's actions as well as utterances. Each interview consisted of eight tasks. Table 1 presents the tasks and accompanying questions as well as the settings of each task, in the order in which they were implemented. The tasks were implemented in the same order for each child.

	The setting	The tasks
1.	Six bottle caps, all the same size, but not necessarily the same color, are placed on the table in a bunch.	Please take half of the caps. How do you know you took half of the caps?
2.	Six bottle caps are placed on the table in a bunch. The interviewer tells the first part of a story and then removes four caps from the table. The interviewer continues with the questions.	Yesterday I was in a different kindergarten and asked a girl named Dina to take half of the caps. Here is what Dina did. (The interviewer removes four caps from the table.) Do you think Dina was correct? Explain why.
3.	Five bottle caps are placed on the table in a bunch.	Please take half of the caps. How do you know you took half of the caps?
4.	Five congruent pieces of note paper are placed on the table in a pile.	Please take half of the papers. How do you know you took half of the papers?
5-8.	Four (eight, ten, and 14) bottle caps are placed on the table in a bunch.	Please take half of the caps. How do you know you took half of the caps?

Table 1: The interview settings and questions

The interview began with the placement of six bottle caps on the table. We began with this amount because we considered it non-trivial and yet not too large for five year olds to handle. The second task of the interview presented a situation where the child's role was reversed. Instead of asking the child to solve a problem, the child was presented with an incorrect solution given by a fictitious child and then requested to evaluate that child's actions. We were interested in investigating if the child would be swayed by a countersuggestion (Kamii, 1982).

For the next pair of tasks, five objects were used – first five caps and then five pieces of note papers. We began with the caps and not with the note papers because the first two tasks had used caps and we did not want to change both the amount and type of

object at once. A bottle cap cannot be halved. On the other hand, the pieces of paper used in the study were such that they could be torn in two without the use of scissors, resulting in two halves of a piece of paper. Thus, taking half of five bottle caps cannot be executed whereas one could take half of five papers by taking two and a half pieces of paper. These tasks had two aims. First, would children accept and acknowledge that not every task may be executed? Second, would children differentiate between taking half of five bottle caps and taking half of five pieces of paper?

The last part of the interview consisted of a sequence of four similar tasks, taking half of an even amount of bottle caps, in which the amount of caps gradually increased from four, which was thought to be quite simple, to eight, ten, and finally fourteen caps. This allowed us to investigate if the children would be able to take half of a growing number of elements. It also allowed us to investigate the children's strategies for taking half of a different number of caps.

Methods for data analysis

Data analysis consisted of three components. The first component related to the correctness of the child's final result or response. For example, did the child take four caps when requested to take half of eight caps? Did the child correctly respond that he could not take half of five caps? In the case of taking half of five pieces of paper, we considered a correct solution to be the tearing of one piece of paper into approximately two equal halves, thus producing two and half pieces of paper.

The second component related to analyzing the methods employed by the child when he or she attempted to take half of the presented objects. Methods were recorded regardless of the final outcome and were derived from the actions performed. Some children immediately took half of the objects without any observable strategy. Others employed one of three identified strategies: (1) Children who first counted all of the caps in the given set, concluded how many would be considered half, and took this amount employed the *count all* strategy. (2) *Divide and adjust*, was displayed by children who either arbitrarily or perhaps by visual estimation, divided the given set into two subsets, counted the number of caps in each subset, and then adjusted the two subsets by moving a cap or two to equate the number of caps in each subset. (3) Children who built two subsets simultaneously, putting one cap at a time in each of two subsets, until all the caps were used up were said to *build stepwise*. Some children using this strategy put two caps at a time in each new set. Finally, some children took actions that did not fall into any category.

The third component in the analysis related to children's explanations. As expected from young children, the explanations were brief phrases and not necessarily full sentences. Qualitative analysis of explanations added a dimension to our understanding of why children acted as they did and the possible reasons for their responses. They also provided some insight into the children's conceptions of half.

RESULTS

In this section we begin by presenting results of the first two tasks – halving six and responding to an incorrect suggestion for halving six. We follow with the next two tasks, halving five caps and five pieces of note paper. Finally we report on responses to the sequence of halving an increasing even amount of caps.

Half of six

Most children (90%) correctly took three caps out of the set of six caps. Out of those who explained their actions, some pointed to each pile of three caps, claiming "half and half" or "both are equal". This type of explanation could possibly be referring to the child's attempt at fairness. Some children merely reiterated what they had done. For example, one child commented, "Three, half is three". Some children decomposed the number six stating, "Three and three is six". Of the children who did not take three caps, five children took two caps explaining, "a half is a little bit". This is in line with studies which have shown that children refer to any part of the whole, but preferable the smaller part, as a half (Parrat-Dayana & Voneche, 1992). One child did not take any caps at all nor did he respond verbally. Children's methods for taking half of six are discussed along with the results of the last four tasks where children were repeatedly requested to take half of an increasing amount of caps.

Regarding the second question, 81% of the children correctly rejected Dina's suggestion. Similar to children who in the first task merely reiterated what they had done, here, some children pointed out the result of what Dina had done saying, "Here there are two [caps] and here there are four." Others pointed out, "It should be equal." Others told the interviewer what Dina should have done, "She (referring to Dina) did not take three." Among the 19% of children who incorrectly accepted Dina's suggestions, the explanations varied. One child claimed that Dina was correct because "she left some for the others as well". Another child seemed to sympathize with Dina claiming that "she wanted to play with the caps". Finally, just as children decomposed six into three and three, one child claimed that Dina was correct because "four and two is six". Table 2 presents the results of the first two tasks.

	Took 3 caps	Did not take 3 caps	Total
Accepted Dina's suggestion	12	7	19
Rejected Dina's suggestion	78*	3	81
Total	90	10	

*Correct response to both tasks

Table 2: Frequency (%) of responses to Tasks one and two.

We first note that while only 10% of the children did not answer the first question correctly, 19% did not answer the second question correctly. Perhaps, countering a

proposed suggestion is more difficult than proposing one's own solution. Regarding consistency, most of the children (85%) were consistent while answering the two questions - 7% gave incorrect responses in both cases while 78% gave correct responses for both tasks. Regarding children who were not consistent, we note that 12% of the children correctly took three out of six caps but then accepted Dina's incorrect suggestion. One such child explained his correct solution to the first task by claiming that "three and another three is six." His explanation to his incorrect response on the second task was "four and two is six." In other words, this child used the same type of explanation for both tasks, decomposing the number six.

Half of five

Tasks three and four related to taking half of five, first five caps and then five pieces of paper. The same child, who did not respond to the first two tasks, did not respond to these tasks either. Results, summarized in Table 3, indicated that almost 80% of the children responded that it is not possible to take half of five caps. Of those that claimed it was possible, one child took all five caps for himself. Six children took three caps and six children took two caps. All of the accompanying explanations reverted to describing what was just done. As one child claimed, "I took two."

Response	Cannot take half of 5 caps	Can take half of 5 caps	Total
Cannot take half of 5 papers	70	2	72
Can take half of 5 papers			
Tore one piece of paper	3*	2	5
Did not tear one piece of paper	5	16	21
Total	78	20	

*Correct response to both tasks

Table 3: Frequency (%) of responses to tasks three and four, taking half of five items.

Regarding the 78% of children who correctly claimed that half of five caps could not be taken, many tried to take half, moving the caps back and forth in an attempt to take half or to create two sets with an equal amount of caps. Accompanying explanations included, "This is two and this is three" or "You have half and I don't". Others suggested how the situation may be remedied, claiming either, "One cap should be added" or "One cap should be removed." Others simply stated, "It is not possible".

Most of the children (70%) claimed that one cannot take half of five, regardless of the object at hand. It could be that not being able to take half of five caps influenced children's performance on the paper task. In fact, children's explanations for why they could not halve five pieces of paper were similar to those they gave for the bottle caps. Only 5% of the children suggested halving one of the papers. The

Working Group 13

children who did so first asked permission from the interviewer, asking if they could tear one of the papers. When granted permission, each of the children tore one of the papers into two approximately equal parts, gave two and a half papers to the interviewer and took two and a half papers for themselves. They then claimed, "Three papers for me and three for you." Perhaps children were relating to the torn piece as a whole piece. Regarding the 21% who claimed that they could take half of five papers but did not tear any of the papers, one child took four pieces of paper, 10% of the children took 2 pieces of paper and 10% took three pieces of paper.

Halving an even number of bottle caps

Recall that the last four tasks requested of the children to repeatedly take half of an increasing amount of bottle caps. Interestingly, the one child who did not respond to the first four tasks did complete the last four tasks. It is possible that it took some time for this child to warm up to the interviewer. Table 4 summarizes children's responses to these tasks. (C denotes the number of caps presented.)

Responses	C=4	C=8	C=10	C=14
Correct response	98	92	85	70
Took less than $C/2$	--	3	6	8
Took more than $C/2$	--	5	3	2
Did not complete the task	2	--	6	20

Table 4: Frequencies (%) of children's responses to Tasks 5-8, taking half of an even number of items

First, we note a difference between children's responses when taking half of four and ten caps, and again between ten and 14 caps. Among incorrect responses, approximately a third of the responses consisted of taking less than half while approximately a fifth of the responses consisted of taking more than half. Among them were two children who correctly took half of four and eight caps (and also of six caps in the previous task) but then took four caps out of ten and again four caps out of fourteen. These children, as did most children who completed the task incorrectly, did not explain their actions.

When the number of caps was 14, seven (11%) children did not even attempt to complete the task. A fifth of the group attempted the task but did not complete it. As one girl commented, "It's too many. I won't succeed." Another girl claimed, "I can't. It's hard for me." Others acknowledged that taking half of 14 might be difficult but persisted. Faced with 14 caps, one child who eventually correctly completed the task, commented, "Wow, this will take time". On the other hand, almost all of the children immediately halved four caps. We also note that one child consistently took two caps and one child consistently took all of the caps, regardless of the amount of caps presented. Neither of the children explained their actions.

Working Group 13

Children employed a variety of methods when attempting to take half of the caps. As noted in the method section, three strategies were identified: *count all*, *divide and adjust*, and *build stepwise*. Table 5 presents the percentage of children who employed each strategy and gave a correct solution. Strategies are presented in order from the most to the least frequently used strategy. Regarding incorrect solutions, when the number of caps was less than 10, no specific strategy was noticeable. When there were 10 caps, 5% of the children attempted to use the build stepwise strategy and the rest (10%) did not have a noticeable strategy. When there were 14 caps, 11% of the children did not even attempt the task, 5% of the children attempted to use the divide and adjust strategy and the rest (14%) did not have a noticeable strategy.

Method	M=4	M=6	M=8	M=10	M=14
Immediate	96	88	39	--	--
Strategy					
Build stepwise	2	2	28	27	38
Divide and adjust	--	--	14	27	19
Count all	--	--	11	23	3
Other	--	--	--	8	10
Total	98	90	92	85	70

Table 5: Frequencies (%) of children's methods accompanying correct halving

We first note a difference between the amount and types of strategies employed by the children when dealing with four and six caps versus the larger sets. Approximately 90% of the children immediately and correctly took half of four and six caps while none of the children even tried to do so when there were 10 or 14 caps. One reason for this difference may be children's ability to subitize – "the direct and rapid perceptual apprehension of the numerosity of a group" (Kaufman, Lord, Reese, & Volkman, 1949, in Clements & Sarama, 2007) that allows children to easily handle sets with a small number of caps. Perhaps being able to rapidly identify two and three allowed the children to easily take half of four and six without employing more complex strategies.

The build stepwise strategy was the strategy most frequently used. The count all strategy was the strategy least employed. In fact, only two children even attempted to use this strategy when presented with 14 caps. On the other hand, it consistently led to a correct solution. This was not the case with the divide and adjust strategy. Some children, who attempted to use this strategy when halving 14, divided the caps into two not necessarily equal subsets and then found it difficult to adjust them. That is, they could not figure out how many caps should be moved from one set to the other in order for both to have the same amount of caps.

Not being able to complete the task also occurred when using the build stepwise strategy. Three children, who used this strategy for taking half of ten, started off by placing two in one set, two in another set and again two in the first set and then two in the second. They then ended up with two caps and concluded that the task could not be completed. Perhaps because they used two caps as a building block, it did not occur to them that this block could also be divided. When it came to taking half of 14 caps, two of the children adjusted the strategy. One child began as before, building stepwise with a block of two caps. When again faced with two caps he paused and said, "This is hard." He then thought a little more and separated the two caps, adding one to each set, successfully completing the task. The second child adjusted the strategy by building stepwise using one cap instead of the two she had previously used. Thus, she had no difficulty in halving 14.

DISCUSSION

This study set out to investigate children's concept of taking half of a set of items. Being that the sample was relatively small and came from one country, we cannot make any generalizations. However, for the most part, children in this study succeeded in taking half of the objects presented to them, carefully constructing two sets with an equal number of elements and then taking one of these sets. There are two equally important components of this understanding. The concept half implies two sets. The concept half implies equal sets. While both of these are necessary components of half, it seems that the necessity of two sets may be more dominant or rooted than the necessity for the sets to be equal. None of the children thought to divide the caps into more than two sets and only one child consistently took all the caps for himself. Children who completed the tasks incorrectly almost always divided the caps or papers into two sets that were not equal. These children may have related the halving task to an everyday sharing task, where sometimes, it is important to share but maybe less important to share equally. This is similar to the study mentioned in the background of children's unequal sharing of 12 jelly beans (Davis & Hunting, 1990). It is important to note also that some children knew that their answer was incorrect or incomplete, but could not fix it. It could be that these children had not yet developed the skills to use a strategy efficiently and flexibility.

Halving five pieces of paper turned out to be a complex task. This complexity may be related to the items themselves. On the one hand, the pieces of paper are discrete items. On the other hand, each piece is continuous and may be halved. It could be that just as very young children may be reluctant to cut a cake in half (Piaget & Szemirska, 1952), some children may be reluctant to tear paper in half. Perhaps a more authentic problem, such as taking half of five chocolate bars, would have prompted the children to break one bar in half. Or it could be that children were responding to a social norm whereby tearing paper is unacceptable. Recall also that 20% of the children claimed that they could take half of five caps. It could be that these, as well as other children were responding to a didactical contract (Brousseau,

1997) and specifically the implicit rule that all problems must have a solution. Regarding children's incorrect response to Dina, young children may be more naïve than older children and believe that if Dina took four caps, she must have had a good reason to do so. In other words, children's knowledge of half is fragile.

In addition to increasing our understanding of children's conception of half, this study also points to the importance of implementing a variety of tasks when trying to assess children's knowledge as well as requesting children, even young children, to explain their actions. Had we not presented the children with Dina's incorrect solution, we may have missed how their empathies may affect their mathematics. Had we not gradually increased the amount of caps to be halved, we may have missed the opportunity to investigate children's strategies for taking half. Asking children to explain each action also proved insightful. We may have thought it sufficient and correct when a child explained why three is half of six by decomposing the number six into three and three. However, when the same child explained his incorrect acceptance of Dina's actions by decomposing six into four and two, we realized that our previous assessment may have been haste and that this child may not yet relate equality of sets to the notion of half.

Finally, we note that little difference was found between this study, which investigated the children's conception of "taking half", and that of studies which investigated the notion of half within a fair-sharing context. Will taking a third be similar to fair-sharing between three? Will taking a fourth be similar to fair-sharing between four? We suggest more research into children's conceptions of half, as well as other fractions, which will offer insight into the different tasks we might implement with kindergarten children, as well as the different items we may employ in these tasks, in order to promote young children's initial fraction knowledge.

INVESTIGATING GEOMETRIC KNOWLEDGE AND SELF-EFFICACY AMONG ABUSED AND NEGLECTED KINDERGARTEN CHILDREN⁶⁸

Pessia Tsamir, Dina Tirosh, Esther Levenson, Michal Tabach, and Ruthi Barkai

Tel Aviv University

This study investigates kindergarten children's identifications of examples and nonexamples of triangles, pentagons, and circles and their self-efficacy related to these tasks. The participants of this study included children who had been abused and neglected. When comparing the group of abused and neglected children with other children, results indicated that both groups of kindergarten children had high self-efficacy beliefs which were not significantly related to knowledge. Significant differences in knowledge were found between the two groups.

Early knowledge of mathematics is often seen as a predictor of later school success (Jimerson, Egelstad, & Teo, 1999). Abused and neglected children⁶⁹ are especially at risk, as these children lag behind their peers in cognitive development (Gowen, 1993). During the elementary school years, the mathematics achievement scores of abused and neglected students are significantly lower than their peers, even when controlling for socioeconomic status (Kendall-Tackett & Eckenrode, 1996). One of the key mathematical domains during the preschool years mentioned by many national guidelines is geometry. During these years, children are developing and refining their spatial and geometric thinking. The first aim of this study is to investigate the geometrical knowledge of kindergarten children, including abused and neglected kindergarten children. Are differences in geometrical knowledge already noticeable in kindergarten?

Abuse and neglect during the preschool years can have a significant, as well as lasting impact on an individual's self-perception (Waldinger, Toth, & Gerber, 2001). One aspect of self-perception related to the promotion of knowledge is self-efficacy (Bandura, 1986). Bandura (1986) defined self-efficacy as "people's judgments of their capabilities to organize and execute a course of action required to attain designated types of performances" (p. 391) and claimed that, "...beliefs of personal efficacy make an important contribution to the acquisition of the knowledge structures on which skills are founded" (Bandura, 1997, p. 35). Primary caregivers, as they provide feedback of children's performances, play a significant role in developing children's self-efficacy (Bandura, 1993). Thus, abusive parents may contribute to negative self-efficacy. On the other hand, an inflated self-efficacy belief

⁶⁸ This study was supported by the Haruv Institute (R.A.) of Israel.

⁶⁹ Throughout the paper, the term "abused and neglected children" refers to children who have either been abused or neglected or both.

may result as a form of self-protection in the face of parental abuse and neglect. In such cases, a high self-efficacy gives the child a false sense of self. The second aim of this study is to investigate kindergarten children's geometric self-efficacy beliefs, that is, beliefs related to performing geometrical tasks. Is there a difference between the geometry related self-efficacy of abused and neglected children and other children?

When investigating children's knowledge it is important to consider both real achievement and perceived achievement in tandem. One study of elementary school children found that maltreated children, more so than nonmaltreated children, tend to overestimate their level of competence, particularly for arithmetic (Kinard, 2000). The third aim of this study is to investigate the relationship between children's geometric knowledge and self-efficacy beliefs. We investigate this relationship among kindergarten children, including abused and neglected kindergarten children.

Theoretical background

Two main issues are at the heart of this study: young children's geometric knowledge and young children's self-efficacy beliefs. This section begins by describing previous studies related to young children's geometric knowledge and then reviews studies related to mathematics self-efficacy.

Young children learn about and develop concepts, including geometrical concepts, before they begin kindergarten. At this age, young children begin to perceive attributes but need guidance in order to assess which attributes are critical for identifying a figure and which are not (van Hiele, 1958). For example, studies have found that when a triangle is not oriented with a horizontal base, children may not identify it as a triangle (e.g. Burger & Shaughnessy, 1986). Children may also accept curved sides, either concave or convex, when identifying triangles (Clements, Swaminathan, Hannibal, & Sarama, 1999). Within the domain of geometry, the Early Years Foundation Stage Statutory Framework in England (2008) and the mandatory Israel National Preschool Mathematics Curriculum (2008) specifically require that by the end of kindergarten children use mathematical language to describe two-dimensional figures. This study focuses on identifying triangles, pentagons, and circles.

Few studies have investigated preschool children's self-efficacy. This may be due to children's difficulty in differentiating between what is real and what they desire to be real (Stipek, Roberts, & Sanborn, 1984). Research findings are mixed. Some studies have found that young children may have overly high self-efficacy beliefs (Stipek, Roberts, & Sanborn, 1984) while others have found that young children are able to understand the process of self-evaluation and may fairly judge their own competence (Anderson & Adams, 1985). "Mathematics self-efficacy...is a situational or problem-specific assessment of an individual's confidence in her or his ability to successfully perform or accomplish a particular task or problem" (Hackett & Betz, 1989, p. 262).

Research related to self-efficacy and mathematics has shown that regardless of mathematical ability, students with a higher self-efficacy tend to expend more effort on mathematics tasks than students with lower self-efficacy (Collins, 1982). Such students are willing to rework problems, discarding faulty strategies in favor of trying new ones, and in general display a more positive attitude towards mathematics than students' with a lower self-efficacy. Studies have also shown that students' self-efficacy beliefs predict mathematics performance (Bandura, 1986; Pajares, 1996) and do so to a greater degree than mathematics anxiety (Pajares & Miller, 1995). Among first and second graders, academic self-efficacy was found to be related to mathematics achievement (Liew, McTigue, Barrois, & Hughes, 2008). It is important to note that self-efficacy beliefs may be domain specific or general. Most studies related to mathematics self-efficacy measured a very general belief in mathematics self-efficacy which did not necessarily relate to specific mathematics topics (i.e. Usher, 2009). This study will focus on the child's self-efficacy while engaging in geometrical tasks and will investigate the relationship between kindergarten's children's geometric knowledge and their geometric self-efficacy.

METHODOLOGY

The participants of this study included 141 kindergarten children, ages 5-6 years old, living in low socio-economic neighbourhoods. All of the children were scheduled to enter first grade during the following school year. Of the 141 children, 69 children were labelled as abused and neglected by the social welfare department of their municipality. All of the children attended municipal kindergartens in their local neighborhood in the morning. While most children go home after school is over, the 69 abused and neglected children were bussed after school to day-care centres run by their municipality where they received hot meals and enrichment.

The research took place in the last three months of the school year. A structured interview was developed for this study interweaving questions related to geometric self-efficacy with questions related to geometric knowledge. Children who were identified by the social welfare department of the city as being abused and neglected were interviewed individually in a quiet corner of the day-care center which they attended in the afternoons. The other children were interviewed individually in a quiet corner of their kindergartens in the morning.

The focus of this study was on identifying and reasoning with triangles, pentagons, and circles and associated self-efficacy beliefs. The interview began with the following self-efficacy questions: If I show you a picture of a shape, will you be able to tell me if the shape is a triangle? Are you very sure or only a little bit sure? These self-efficacy related questions were based on the *Pictorial Scale of Perceived Competence and Social Acceptance for Young Children* (Harter & Pike, 1984). In that study, children were shown pictures of two children engaging in some task, one successful and one not successful. The interviewer asked the child to point to the child he or she identified with. After the child pointed to the appropriate picture, the

child was asked if he or she was a lot like the child in the picture or a little bit like the child in the picture. Thus, a four point scale was created. Likewise, in the current study, the first two questions, taken together, created a scale of 1-4 describing children’s belief in their ability to identify triangles. For example, if a child answered “yes” to the first question and “a little bit” to the second question, his self-efficacy was graded at 3. If he answered “no” to the first question and “very sure” to the second question, his self-efficacy was graded at 1.

Children were then presented one at a time with four figures, each figure drawn on a separate card, and asked, “Is this a triangle”? Why? The entire set of questions, including the first two self-efficacy related questions, was then repeated for a pentagon and a circle with a different set of figures presented for each shape. Figure 1 displays the figures presented for each set of questions. Figures were presented in the order shown in each row.

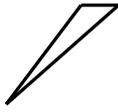

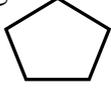

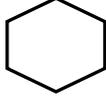

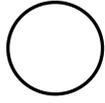

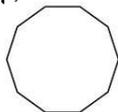

Is this a...	Intuitive example	Non-intuitive example	Non-intuitive non-examples	
triangle?	Equilateral triangle 	Scalene triangle 	Rounded-corner “triangle” 	Pizza 
pentagon?	Regular pentagon 	Concave pentagon 	Curved-sides “pentagon” 	Hexagon 
circle?	Circle 		Spiral 	Decagon 

Figure 1: The set of figures presented in this study

In choosing the figures, both mathematical and psycho-didactical dimensions were considered. When considering triangles, the equilateral triangle may be considered a prototypical triangle and thus intuitively recognized as a triangle, accepted immediately without the feeling that justification is required (Hershkowitz, 1990; Tsamir, Tirosh, & Levenson, 2008a). The scalene triangle may be considered a non-intuitive example because of its “skinniness”. Whereas a circle may be considered an intuitive non-example of a triangle, the pizza-like “triangle” may be considered a non-intuitive nonexample because of visual similarity to a prototypical triangle (Tsamir, Tirosh, & Levenson, 2008a). Similarly, the regular pentagon was thought to be easily recognized by children who had been introduced to pentagons whereas studies have shown that even among children who had been introduced to pentagons, the concave pentagon is more difficult to identify (Tsamir, Tirosh, & Levenson, 2008b). Triangles and pentagons may vary in the degree of their angles providing a

wide variety of examples. In contrast, the circle's symmetry limits the variability of its characteristic features. Thus, only one example of a circle was given. The nonexamples of each shape were also chosen in order to negate different critical attributes. Due to the young age of the children, we chose to limit the amount of figures presented to each child and thus did not include in this study intuitive nonexamples. Finally, we hypothesized that, in general, the triangle and circle would be figures known to the children from their surroundings whereas the pentagon is a figure less known but part of the preschool mathematics curriculum.

RESULTS

This section begins by describing children's self-efficacy beliefs related to identifying the different shapes. It then describes the results related to children's actual identification of the figures. Finally, it analyzes the relationship between self-efficacy and knowledge.

Self-efficacy beliefs

Recall that a scale of 1-4 was used to grade children's self-efficacy, 4 being very high and 1 being very low. Results, presented in Table 1, indicated that, in general, the children had a high self-efficacy related to identifying the different shapes. In addition, no significant difference between the self-efficacy of the two groups of children was found for any of the shapes.

Children	Abused and neglected children		Other children	
	M	SD	M	SD
Triangle	3.7	.62	3.7	.67
Pentagon	3.1	1.1	3.5	.75
Circle	3.7	.75	3.9	.46

Table 1: Children's geometric self-efficacy per shape per group

Cronbach's alpha was used to investigate internal consistency between the self-efficacy scores for each shape per group of children. A weak internal consistency was found in both groups, $\alpha=.50$ for the group of abused and neglected children and $\alpha=.34$ for the other children. These results indicate that, for these children, self-efficacy may be task or shape specific. This is consistent with previous self-efficacy studies which claimed that mathematics self-efficacy may be problem-specific (Hackett & Betz, 1989). On the other hand, when considering that the self-efficacy questions all related to identifying shapes mentioned in the preschool curriculum, we allowed that a general geometric self-efficacy grade may still be calculated for each group. Results indicated no significant difference between the geometric self-efficacy of the abused and neglected children ($M=3.7$, $SD=.43$) and the geometric self-efficacy of the other children ($M=3.5$, $SD=0.61$).

Geometric knowledge

Working Group 13

We begin by describing children’s identifications of the individual figures presented to them. Due to limited space, this paper does not analyze the children’s explanations which accompanied identifications but provides sample illustrations where relevant. Results, summarized in Table 2 indicated that all of the children correctly identified the equilateral triangle. This coincides with studies which have found that the equilateral triangle with a horizontal base may be considered a prototypical triangle and is thus intuitively identified as such (e.g. Tsamir, Tirosh, & Levenson, 2008a).

Figure name	Abused and neglected children	Other children
Equilateral triangle	100	100
Scalene triangle	20	35
Rounded-corner “triangle”	19	22
Pizza	46	56
Regular pentagon	71	71
Concave pentagon	29	24
Curved-sides “pentagon”	57	70
Hexagon	26	32
Circle	100	100
Spiral	51	61
Decagon	83	85

Table 2: Frequencies (in %) of correct identifications per figure per group

The rounded-corner “triangle” was the most frequently misidentified figure. As one child claimed, “It has the shape of a triangle”. Interestingly, the equilateral pentagon was identified correctly by less than three-quarters of the children in both groups, though learning to identify pentagons is part of the kindergarten curriculum. As expected, few children in both groups identified correctly the concave pentagon. One child explained, “It looks like a bridge and has only four points.” Regarding the circle, although all of the children correctly identified the circle, approximately half of the children incorrectly claimed that the spiral was a circle. Perhaps, the children focused on the roundness of the spiral and the absence of sides. One child claimed it was a circle and added “it continues to roll.” Finally, although few children correctly identified the scalene triangle, when comparing the groups of children, this was the only figure for which a significant difference was found $\chi^2(1, N=138)=4.33, p<.05$.

After reviewing the results of children’s responses to the individual figures, we grouped together the figures according to the shape they were intended to investigate. For each shape, triangles, pentagons, and circles, the mean score was configured resulting in a grade for each child ranging from 0-100% for each shape.

Working Group 13

Results, presented in Table 3, indicated that abused and neglected children had a significantly lower triangle grade than other children, $p < .05$. No significant differences were found between the two groups of children for the other shapes. Finally, averaging all 11 figures and creating a general geometric knowledge grade, we noted that the neglected and abused children scored significantly lower ($M = .57$, $SD = .11$) than the other children ($M = .62$, $SD = .14$), $t(117) = 241$, $p < .05$.

Children	Abused and neglected children		Other children	
	M	SD	M	SD
Triangle	.46	.20	.54	.20
Pentagon	.46	.18	.50	.19
circle	.78	.24	.82	.24

Table 3: Children's geometric knowledge per shape per group

Relating geometric knowledge and geometric self-efficacy

The third aim of the study was to investigate if children's geometric knowledge was related to their geometric self-efficacy. Nonparametric correlations were configured for each geometric shape per group of students. Results for both groups of children indicated that no significant relationship was found between children's ability to identify triangles, pentagons, and circles and their respective self-efficacy beliefs. Finally, when considering general geometric knowledge and general geometric self-efficacy, no significant relationships were found in either group.

SUMMARY AND DISCUSSION

This paper describes an investigation of geometric knowledge and geometric self-efficacy among kindergarten children, including children who were abused and neglected. We begin by discussing similarities in self-efficacy and then similarities in knowledge. We then discuss differences, which for this group, arose when comparing geometric knowledge.

When asked to assess their abilities to identify triangles, pentagons, and circles, children in both groups reported a high self-efficacy, believing greatly in their ability to identify each of the mentioned shapes. There are several possible reasons for this response. First, it could be that children have a tendency to reply in a positive manner or to the high end of any question or scale posed to them. Thus, asked if they can or cannot do something, they respond almost automatically in the positive. Perhaps a naïve belief in one's own capabilities is indicative of all children who are young. While these, and possibly other reasons, may explain the high self-efficacy rating children exhibited, it remains that for the participants of this study, there were no significant differences between the self-efficacy of abused and neglected children and other children. In addition, children's high self-efficacy did not correlate with their knowledge. As mentioned in the background, young children may find it

Working Group 13

difficult to differentiate between what is real and what they desire to be real (Stipek, Roberts, & Sanborn, 1984). And yet, among first and second graders, academic self-efficacy was found to be related to mathematics achievement (Liew, McTigue, Barrois, & Hughes, 2008). Perhaps, between kindergarten and first grade, there is a leap in the development of children's sense of self. Perhaps differences between the two groups of children regarding geometric related self-efficacy, and possibly other academic related self-efficacy, may come to the fore at a later age.

Regarding children's identifications of geometric shapes, if we focus on the first example of each shape presented to the children, the equilateral triangle, the equilateral pentagon, and the circle, we note that the frequencies of correct identifications were exactly the same for each group of children. That is, figures which are symmetrical and possibly prototypical of their shape in general, may be easily identified by all kindergarten children regardless of their home backgrounds. In addition, there were no significant differences between the two groups of children in their general knowledge of pentagons and circles. Regarding pentagons, this finding may not be surprising. The pentagon is less common in children's everyday experiences and is usually first introduced in kindergarten. On the other hand, knowledge of circles was also similar between the two groups. It was thought that knowledge which might stem from the child's everyday experiences might produce different results for the different groups.

When looking at the differences between the two groups, less correct identifications were noted among the abused and neglected children than among the other children for the non-intuitive scalene triangle, as well as for each of the nonexamples of triangles, and a significant difference between the two groups of children was found in their general knowledge of triangles. Finally, when the results of the other shapes were also taken into consideration, abused and neglected children exhibited significantly less knowledge than other children. These findings indicate that even before children begin first grade, differences are detectable between the two groups of children. Knowledge of geometric shapes most often begins before formal presentation in school. As such, these differences may possibly stem from the home environment.

Abused and neglected children learn in the same kindergartens as other children. Thus, in order to plan lessons and interventions, it is important to note both the similarities and differences among these children. A high self-efficacy which is not realistic is an issue common to both groups of children and needs to be addressed. In addition, the non-intuitive examples of triangles and pentagons were incorrectly identified by most of the children in both groups. Thus, it is important to actively promote this knowledge among all kindergarten children. And yet, differences do exist. Equity is not only about giving a fair chance to children from different socio-economic backgrounds or minority students. It is about providing "high expectations and strong support for all students" (NCTM, 2000, p. 12). Children who have been

abused and neglected have special needs. Schmid (2007), in his report on children at risk in Israel, suggested that identification of risk factors in early childhood may prevent or minimize problems which develop later on. This study is a first step in considering the mathematics educational needs of children at risk. Additional research is needed to address possible interventions which take into consideration both similarities and differences in knowledge, self-efficacy, and possibly affective issues when promoting mathematics for all children, including children at risk.

PLAYING AND LEARNING IN EARLY MATHEMATICS EDUCATION – MODELLING A COMPLEX RELATIONSHIP

Stephanie Schuler

University of Education Freiburg

Playing and learning – in early childhood often used synonymously, later on antithetically – are both key concepts in educational contexts. Considering theoretical models and empirical research on the relationship of playing and learning there remain no objections on learning while playing. But learning is not without requirements and depends on situational conditions. In the empirical study children are videotaped using selected materials and games in every day kindergarten contexts. The research results in descriptions of mathematical learning opportunities and their situational conditions.

Keywords: play, games, arithmetic skills, early childhood education, video study

INTRODUCTION

Concerning early mathematics education there are often brought up two important questions: *What* and *how* should children learn in the early years (3 to 6 years old)? Answers to the first question are mostly connected to fundamental mathematical ideas like quantitative and spatial thinking, patterns and relationships, contents that are not only relevant for a preschool curriculum. In distinction from formal school education there is consensus that young children acquire these skills primarily in a playful way (cf. Moyles, 2010, Pramling-Samuelsson & Fler, 2009). Kindergarten, the place of early childhood education, is shaped by free play, open offers and informal learning opportunities. Thus *play* and the *relationship of playing and learning* have to be explored more closely when talking about mathematics for the early years.

Play is probably one of the most dubious notions. It withdraws defining, because it comprises very different phenomenon.⁷⁰ However there are many attempts to describe play with different characteristics. Depending on the *theoretical approach*, phenomenological (cf. Scheuerl, 1990), action-theoretical (cf. Oerter, 1993), cultural-historical (cf. Vygotskij 1933/80), these characteristics differ in quantity and label. Following an *empirical approach* play cannot be uniquely defined but just case-by-case explicated. Hence different types of play and the same concrete activity can be more or less play (cf. Einsiedler 1999). This conclusion matches with the synopsis of a literature review: “In essence, play could be viewed in its broadest

⁷⁰ Above there exists a linguistic and a cultural problem: E.g. in German “Spiel” includes “play”, “game”, “match” and “gambling”. Beliefs about play and learning vary in different countries (cf. Pramling-Samuelsson & Fler, 2009).

sense as describing almost all the activities that young children engage in” (cf. Fleer, 2009, 2).

In a *historical perspective* the *role of play* during childhood is described manifoldly. Play is attributed an emotional (cf. Oerter, 1993), a social (cf. Parten, 1932) and a cognitive role (cf. Piaget, 1969). During infancy and toddlerhood play is associated with learning mainly in the context of training and rehearsal. In early childhood, the so called play age, play becomes in terms of Vygotskij (1933/80) not the predominant but the leading activity. It creates the zone of proximal development and allows the child to rise above itself while following challenging rules. Exponents of play pedagogy remark that the utilisation of play is not possible, because children create their own learning contexts in play broadly independent from adults’ learning intentions (cf. Flitner 2002).

Summarising play in early childhood is the motor of development and hence associated with learning. Consequently the underlying question seems not to be “Can children learn while playing?” but rather “How can learning while playing be modelled?” and “Can children learn mathematics while playing?”.

THEORETICAL MODELS ON THE RELATIONSHIP OF PLAYING AND LEARNING IN CHILDHOOD

Einsiedler (1982, 5) compares two basic models referred to the relationship of playing and learning:

- Every play implies learning.

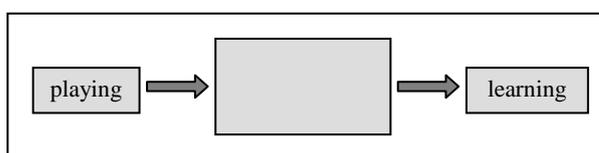

Figure 1: Simple Input-Output-Model

- Learning while playing is an interactive relationship between personal and situational conditions.

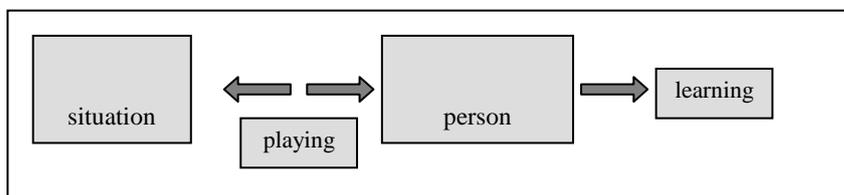

Figure 2: Person-Situation-Model

The former model is a historical position against the supposition that playing and learning are incompatible. The latter model points out that learning while playing is possible but depends on personal and situational conditions. Einsiedler (1989, 297) refers to this dependence as the problem of contingency of learning while playing.

Given constructivist assumptions it is disputable if the contingency of learning in play must be considered as a special problem. Even intentional learning, the increasingly leading activity during primary school, is not utterly controllable by teaching. Knowledge is constructed individually linked to former experiences and mental structures. Constructivist, social-constructivist but also cultural-historical theories highlight the organisation of *situational conditions of learning* (cf. Gerstenmaier & Mandl, 1995).

EMPIRICAL STATEMENTS ON THE RELATIONSHIP OF PLAYING AND LEARNING

Mainly there are two different types of empirical studies in the context of playing and learning. First there are short or long term *intervention studies* which are interested in *learning effects* when inserting games (commercial or didactical) in kindergarten or first/second grade (cf. Ramani & Siegler 2008; Kamii 2004; Peters 1998; Floer & Schipper 1975). Second there are *observational studies* which are interested in the context of playing in kindergarten settings and in the *conditions for learning* in these settings (cf. van Oers 2010, Ginsburg 2009).

Studies of the first type with a control group design could show that playing with particularly chosen games (e.g. games with mathematical potential for number concept) are similar successful as teaching. In kindergarten games can foster mathematical abilities of disadvantaged children.

Observational studies draw the conclusion that children in kindergarten need adult guidance or more knowledgeable others in the context of play to promote their mathematical thinking. Ginsburg (2009, 413f) states that developing mathematical thinking depends on the environment, play and the teachable moment. Quite similar van Oers (2010, 34) summarises his studies: „The emergence of mathematical thinking in young children is a culturally guided process, wherein mathematical meaning can be assigned to actions of the child. These actions can be further developed through collaborative problem solving with more knowledgeable others in the context of activities that make sense to the children.”

In essence empirical research on playing and learning in early childhood underlines the central role of the educator and the quality of materials, games and activities.

RESEARCH QUESTIONS

The study generally follows the question if early mathematics education can be organised by playing games. The goal is shortly outlined as follows⁷¹:

How can learning opportunities develop in informal contexts like free play and open offers with educational materials and games to acquire the number concept?

⁷¹ Further information about research questions and research results can be reread in Schuler & Wittmann 2009.

In detail we ask the following research questions:

1. What (theoretical) potential for children's construction of number concept do these materials and games have in principle?
2. Under what conditions can learning opportunities occur while playing these games or with these materials?

RESEARCH METHODS AND METHODOLOGY

The study is rooted in the methodological frame of *Grounded Theory*, one type of theory generating qualitative research (cf. Strauss & Corbin, 1996). According to the research questions it is a two-phase design (cf. figure 3) that will lead to a (grounded) theory about the conditions for learning opportunities in informal contexts:

- The first phase is a *theoretical analysis of games and educational materials* (cf. Schuler & Wittmann, 2009).
- The second phase is an *empirical evaluation of selected, theoretically proved games and educational materials*.

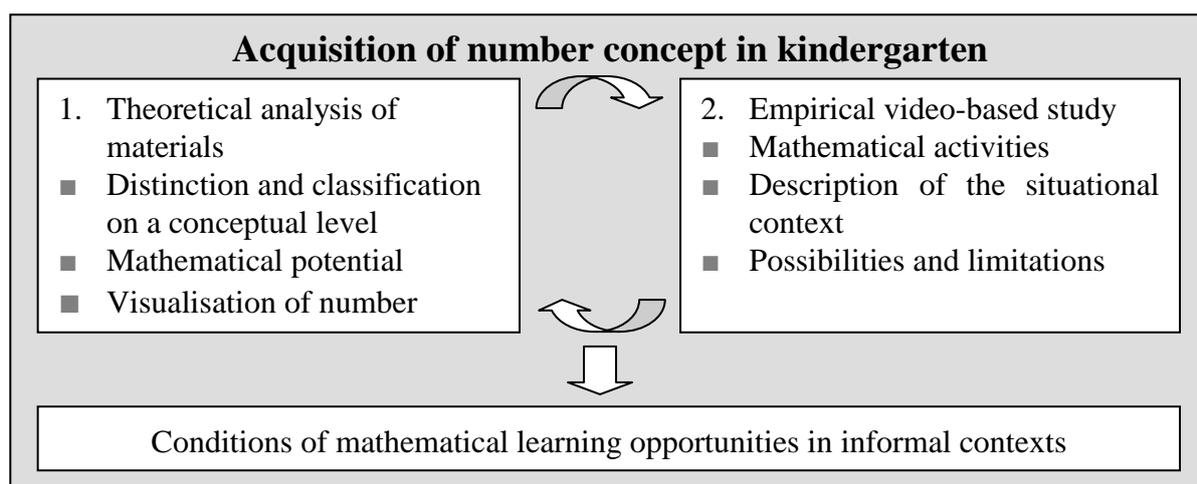

Figure 3: Two-phase research design

According to the *methodology of Grounded Theory*, there are several phases of video propped data inquiry. Children are recorded while playing with selected materials and games during free play and open offers.

Basis of the data analysis are transcripts of video sequences. These are analysed by the following tools of *videography* to deduce and reduce the complexity of video data (cf. Dinkelaker & Herrle, 2008):

- The *segmental analysis* surveys the sequential process and the phases of the whole scene.
- The *configurational analysis* surveys the spatial organisation of the whole scene.
- The *sequential analysis* enables the reconstruction of the sequential meaning.

The following tools of *Grounded Theory* data analysis support the development of theoretical concepts and their relationship and result in a local, data grounded theory (cf. Strauss & Corbin, 1996; Kelle & Kluge, 1999; Mey & Mruck, 2007):

- *Theoretical sampling* means the ongoing change and interplay between action (data inquiry) and reflection (data analysis and theory construction) (cf. Mey & Mruck 2007, 13). Hypotheses are continually phrased and conduct further data inquiry. Video sequences are purposefully chosen for theoretical saturation.
- *Theoretical coding* is not only a description and classification of phenomena but the creation of theoretical concepts that explain the phenomena.
- *Comparative analysis* contrasts phenomena and contexts in order to develop theoretical concepts.

Mathematical learning opportunities while playing games in kindergarten

For brevity of the article it is not possible to show the whole process of data analysis. Referring to one transcript I illustrate some of the tools mentioned above and coincidentally highlight learning opportunities that may occur while playing the Quips game (cf. figure 4) during the informal context of free play.

Game: Quips (Ravensburger)

Player: (1) 2 to 4

Material: 4 boards, 90 chips in 6 colours,

1 die with colours, 1 die with sets one to three

Rule: Each player gets a board and plays the two dice. The cast of dice determines the colour and the quantity of chips that each player can take and put into his board. Surplus chips have to be put back or given away to another player.

Figure 4: Rules of the game “Quips”

The segmental and configurational analysis (cf. table 1) survey the sequential process and the spatial organisation of the whole scene. The scene starts with the open offer of the Quips game during free play and closes with the end of the game. The scene is structured in four segments.

During free play the educator creates liability by proposing a game. Leni takes up the suggestion. Christian and Leon join the two. Their choice reveals social affordance that can be observed quite often in informal contexts. Segment 2 lasts approximately 15 minutes. Each of the players dices four times. Segment 3 lasts 12 minutes and each player dices fourteen times. Christian and Leon primarily want to put chips into the holes on the board (affordance of the material). They have difficulties following the rules: waiting to have a turn, recognizing and naming the colours, counting objects, comparing sets. They leave the game after four rounds. Moritz changes from the status of a spectator to the one of a player (affordance of the game). The game

Working Group 13

accelerates and the three players finish the game (liability through rules and the play group).

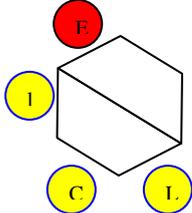

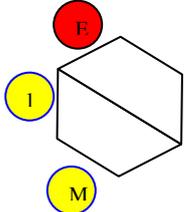

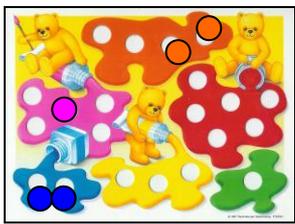

00:00	<p>1. Choice of game, formation of the play group</p> <p>The Educator puts the game „Quips“ during free play on the table. Leni (2;11) takes a seat at the table and opens the box. The educator sits down as well. Christian (3;1) and Leon (3;0) enter the room and come to the table. They want to play too.</p>	
03:04	<p>2. Game with four players (four dice rounds)</p> <p>The rules of the game are clarified while playing the game. Moritz joins the game as a spectator.</p>	
18:40	<p>3. Game with three players (fourteen dice rounds)</p> <p>Leon and Christian leave the game and the room. Moritz (4;10) takes Christian’s seat and game board.</p>	
30:53	<p>4. End of game, putting away the game</p>	

Table 1: Short segmental and configurational analysis

The following transcript (cf. table 2) is located in segment 2. Its Leni's turn and her fourth cast of dice. Moritz follows the games as a spectator. Leon has already announced that he wants to leave the game. The right column contains figures of dice and game boards and above open codes.

Time	Speaker	Transcript	Materials and codes
16:35	E	LENI THROWS DICE How many have you got Leni?	 question(ing)
	Leni	One two. LENI LOOKS ON HER BOARD	 counting objects
	E	You need two and how many have you diced?	comment(ing) question(ing)
	Leni	Two. LENI POINTS TO THE DIE WITH COLOURS	subitizing
	E	How many are there? How many dots? EDUCATOR POINTS TO THE DIE WITH	question(ing)

Working Group 13

		SETS	
	Moritz	Three. LOW VOICE	subitizing
	Leni	One two three. LENI POINTS SYNCHRONOUSLY ON THE DIE WITH SETS	counting objects
	E	Exactly, then you can take three orange chips. LENI TAKES TWO ORANGE CHIPS Have you already got three orange chips?	request(ing)
	Leni	No you must two LENI SHOWS THE EDUCATOR THE TWO ORANGE CHIPS IN HER HAND	arguing
	E	But-	arguing
	Leni	Because I have two. LENI PUTS THE TWO ORANGE CHIPS INTO THE HOLES ON HER BOARD	 reasoning
	E	But you have diced three, you can give away one.	arguing, requesting comparing exactly
17:30	Leni	Yes. LENI TAKES ONE ORANGE CHIP AND PUTS IT IN CHRISTIANS BOARD	following request

Table 2: Transcript from segment 2 with codes

Mainly one mathematical activity can be observed in this transcript: counting objects. Leni counts holes on her board, dots on the die and she takes chips out of the box. The other observation is an argument between the educator and Leni that is based on a different reading of the situation. Leni reads her cast of dice from her board: she needs two more orange chips. She does include the die with sets probably just in a vague but not in an exact manner. Beyond that the educator considers the exact set on the die and compares it with all other boards. The rule to give away surplus chips requires this complex reading. After the argument Leni follows the educator's request that she can give away one. The scene offers *learning opportunities* related to the content idea *quantitative thinking* and to *process ideas*:

- counting objects, subitizing
- comparing sets and units of sets
- reasoning, arguing

The learning opportunities are embedded in the educator's questioning, commenting, requesting and arguing and are based on the game's rules.

RESEARCH RESULTS AND FURTHER CONCLUSIONS

The focus of our research is on the situational conditions of learning (cf. figure 5). They are necessary requirements for learning but they do not guarantee it. The design of our study does not allow any statements on what single children have learned while playing the game, but just what opportunities to learn may occur (see previous section). Furthermore we can describe more closely situational conditions that support these learning opportunities (cf. Einsiedler 1982). So far we could emerge three main blocks of situational conditions: Affordance, liability and conversational management.

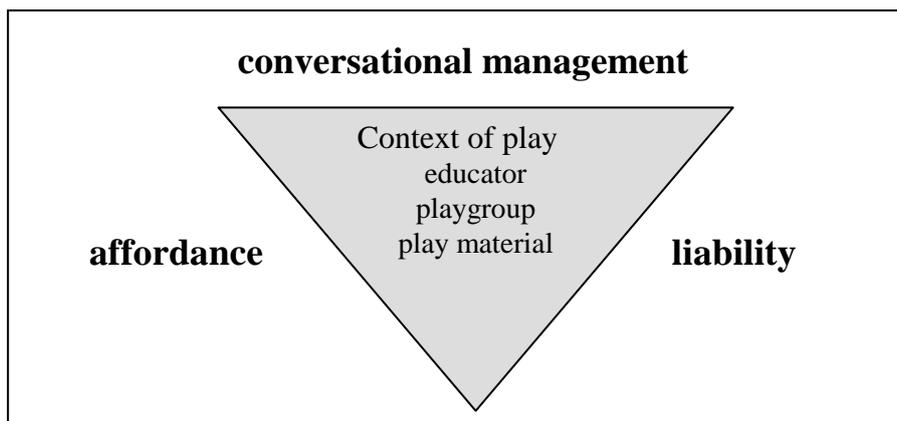

Figure 5: Situational conditions of learning while playing

The context of play is generally contingent on three variables: the educator, the playgroup and the play material. Materials and games introduced in kindergarten should offer a *mathematical potential* concerning central content ideas. This potential can be analysed in advance (cf. Schuler & Wittmann, 2009). Abridged affordance and liability encourage children to start, to maintain and to repeat a game. The conversational management is crucial for mathematical learning opportunities.

Affordance and liability

Each *material* possesses an *intuitive affordance* (cf. Lewin following Heckhausen 2006, 31, 105ff) that supports the involvement with the material, but which does not necessarily lead to mathematical activities. Boards and chips of the Quips-game for example invite children to put the chips into the holes on the board or to pile them up. As we have seen in the transcript above, *rules* can offer mathematical activities beyond a material's intuitive affordance and thus *create liability*. Intuitive affordance of materials is replaced in games by (*the affordance of*) keeping the rules and winning *the game*. In the informal context of free play we can observe that children leave or change a material after a short time and others stay and play the game until the end. No rules or overcharging rules promote the abandoning of materials and games. Individually challenging rules lead to a longer lasting and repeated involvement. Thus the educator has to be sensitive to individual competencies and possible variation of rules. This seems to be a particular challenge in informal

contexts where children of different age and competence play together. *Liability* is also produced *by temporal, spatial and social standards*: e.g. announcing special periods for playing games, playing games at a separate table, presence of the educator. Not only materials are equipped with affordance but also social contexts. Playing with other children and playing with the educator exerts a *social affordance*.

Conversational management

As we have seen in the transcript above the *conversational management* influences the mathematical potential that develops in interaction. Besides content ideas like comparing sets, counting objects there occur process ideas like arguing and reasoning. These general mathematical skills are not material inherent, cannot be analysed in advance and depend on the educator's conversational competence (cf. Schuler & Wittmann 2009).

Mathematical potential develops through the educator's comments on the game's course, through questions that stimulate explanations, reflections on actions and thoughts, and reasoning. She has to communicate individually challenging rules through stimuli, comments, questions and requests what requires a sensitivity for possibilities and variations in the games course.

Further conclusions

Potentially suitable materials and games need a competent educator with regard to didactical and conversational aspects. The educator has to analyse, assess, choose and present materials and games. She has to discern the child's or children's individual approach to the material and has to consider the mathematically productive aspects. Through temporal and spatial organisation she creates liability and she utilises the case of social affordance to involve children in playing. Considering these situational conditions learning opportunities occur during play regarding central mathematical content and process ideas.

To organise early mathematics education in informal contexts like free play with potentially suitable materials and games educators need a mathematical, didactical, pedagogical and conversational competence that cannot be taken for granted. The qualification of present and future educators needs to take into account these aspects.

INTRODUCTION TO THE PAPERS OF WG14: UNIVERSITY MATHEMATICS EDUCATION

Elena Nardi¹

Alejandro S. González-Martin², Ghislaine Gueudet³,

Paola Iannone¹, Carl Winsløw⁴

¹University of East Anglia (UK), ²University of Montreal (Canada), ³University of Rennes-1 (France), ⁴University of Copenhagen (Denmark)

Research on university level mathematics education is a relatively young field, which embraces an increasingly wider range of *theoretical approaches* (e.g. cognitive/developmental, socio-cultural, anthropological and discursive) and *methods/methodologies* (e.g. quantitative, qualitative and narrative). Variation also characterises research in this area with regard to at least two further issues: the *role of the participants*, students and university teachers, in the research – from ‘just’ subjects of the research to fully-fledged co-researchers – and the *degree of intervention* involved in the research – from external, non-interventionist research, to developmental/action research in which researchers identify problems and devise, implement and evaluate reforms of practice (Artigue et al, 2007).

2011 marks the 20th anniversary of the publication of *Advanced Mathematical Thinking* (Tall, 1991), a volume that is often heralded as a first signal of the emergence of this new area of research. A few years later a second signal was given by the 1998 ICMI study that resulted in *The teaching and learning of mathematics at university level* (Holton, 2001). In the meantime Advanced Mathematical Thinking (AMT) groups ran both in previous CERME and PME conferences; sessions exclusively on university mathematics education are part of the EMF conferences since 2006 ; the RUME, UMT and Delta conferences emerged in the USA, the UK and South Africa respectively; the International Conferences on the Teaching of Mathematics at University Level were launched in 1998; etc.

WG14 (*University Mathematics Education*, hereafter UME) emerged out of the above developments and out of the realisation that this is a distinct area of mathematics education research. Its distinctiveness can be attributed to several characteristics. Firstly, the classic distinction between ‘teacher’ and ‘researcher’ does not always apply in UME as researchers in mathematics education in this area are often university-level teachers of mathematics themselves. In particular there is a growing group of mathematicians specializing in research on mathematics education at university level, where advanced mathematical knowledge and experience is really an asset (if not a necessity). Secondly, mathematics education theories and research methods find new uses, and adaptations, at the university level. These adaptations are often quite radical as the post-compulsory educational context is different in many ways – the voluntary presence of students, the important role of mathematics as a

Working Group 14

service subject, the predominance of lecturing to large numbers of students, the absence of national programmes for university education, to mention but a few. In this sense UME is a distinct area of mathematics education research, not merely a mirror of mathematics education research at a more advanced educational level. Finally, in recent years, research in this area has been growing in different parts of the world. WG14 is one opportunity to collate evidence of this growing research activity from Europe and beyond.

The WG14 Call for Papers invited contributions from as wide a range of research topics as possible. These included: concept formation, mathematical reasoning and proof in university mathematics; teaching at university level (including the perspectives of university mathematicians); ICT in the teaching and learning of university mathematics (including curriculum design); socio-cultural, anthropological and discursive approaches in university mathematics education; affective and social aspects of the learning and teaching of university mathematics; the transition from secondary to tertiary mathematics; novel approaches to teaching mainstream (e.g. calculus and linear algebra) as well as more advanced topics, both to students of mathematics and other areas (e.g. engineering, sciences, finance); theoretical approaches to the study of teaching and learning mathematics at university (including a focus on specific approaches and on contrasting or combining approaches).

This report draws on the presentations, reactions-to and discussions of the 21 accepted papers that met these terms. The number and quality of these papers marks the recent surge in the quality of research outputs and a move away from the earlier days of perhaps more naïve, less rigorous research in this area – brought about partly by the university sector's increasing urge to adapt teaching to changing student cohorts and by a growing, and wider, tendency towards an in-depth probing into traditional teaching practices in higher education.

Across the WG14 discussions certain themes and questions emerged as crucial. These included: exploring whether UME needs to generate new theories or adapt already existing ones; attending to issues of both theory and practice; acknowledging that research on teaching and learning in higher education develops also outside mathematics education, and benefiting from these developments; working towards the generation of new theories while valuing already accumulated knowledge in the field; etc. Colleagues observed that, beyond staple references to classic constructs from the *AMT* era (such as concept image – concept definition; APOS theory, process – object duality etc.), several works presented in WG14 employ (often in tandem with the above) approaches such as the Anthropological Theory of Didactics (ATD: Chevallard, 1985), and discursive approaches (e.g. Sfard, 2008).

Generally speaking papers seem to be classified into those with a focus on the teaching and learning of particular mathematical topics (calculus continues to attract more attention than other topics) or on wider, cross-topical issues such as the

Working Group 14

transition to university mathematics, use of IT, language, motivation, teacher knowledge and development, curricular, pedagogical and institutional issues, etc.. Furthermore an area of growth is of studies that examine the different role of mathematics in courses towards a mathematics degree, courses for pre-service teachers, as a 'service' subject (physics, biology, economics etc.). While a substantial number of papers remains in the increasingly well-trodden area of students' perceptions of specific mathematical concepts (again calculus prevails in these), a focus on university teachers and teaching is also emerging, if often a little timidly, and diplomatically, resulting in descriptive, openly non-judgemental studies. In conjunction with those studies a genre of collaborative studies, with mathematicians engaged as co-researchers, also seems to be on the rise. In the nutshell descriptions of the WG14 papers that follow the order of presentation is loosely structured around some of the themes mentioned above.

Xhonneux & Henry is one of the papers that employs the ATD framework to distinguish between *mathematical* and *didactic* praxeologies in the context of teaching and learning of Lagrange's Theorem in calculus courses to mathematics and economics students. *Gyöngyösi, Solovej & Winslow* is another: in it a part of a transitional course in Analysis was taught with a combination of Maple and paper-based techniques and resulted in mixed reception and performance by students. A third is *Barquero, Bosch & Gascón*: from its analyses 'applicationism' emerges as the prevailing epistemology of mathematics in science departments that potentially hinders the teaching of mathematical modelling to science students.

Another set of approaches that was employed by a number of WG14 papers were discursive. *Jaworski & Matthews* employed such approaches to trace university mathematicians' pedagogical discourse and suggest links of this discourse to their ontological and epistemological perspectives. *Biza & Giraldo* described how computational inscriptions – in this case differentiability – have potentialities and limitations that can be helpful in students' exploration of newly introduced mathematical concepts. Three papers made use of Sfard's commognitive framework. *Viirman* employed this framework to trace the variation in the pedagogical discourses of mathematics lecturers in the course of their introducing the concept of function. *Stadler* described students' experience of the transition from school to university mathematics as an often perplexing re-visiting of content and ways of working that seem simultaneously familiar and novel (for example in the case of solving equations). *Nardi* outlined interviewed mathematicians' perspectives on their newly arriving students' verbalisation skills; and, observed that discourse on verbalisation in mathematics tends to be risk-averse and not as explicit in teaching as necessary. Several papers focused on the transition from school to university mathematics (including *Gyöngyösi, Solovej & Winslow* and *Stadler* mentioned above). *Biehler, Fischer, Hochmuth & Wassong* proposed that blending traditional course attendance with systematic e-learning study can facilitate the bridging of

school and university mathematics. *Faulkner, Hannigan & Gill* noted the shifting profile of students who take service mathematics courses (in the context of an Irish institution): many more are diagnosed as at risk, fewer have an advanced mathematics secondary qualification and the percentage of non-standard (e.g. mature) students has grown. *Zimmermann, Bescherer & Spannagel* described MaSE-T, a mathematics self-efficacy test designed to measure the impact that self-efficacy perceptions have on choice of studies. *Vandebrouck* noted that in the transition from school to university, mathematics students need to reconceptualise the concept of function in terms of its multiple representations and its process-object duality. Finally, *De Vleeschouwer & Gueudet* observed that students can learn to appreciate the duality in linear forms (described here in micro-macro terms) if given an appropriate set of tasks that require them to engage with these concepts at both levels.

Many of the papers mentioned above had a clear focus on a specific mathematical concept or issue. In addition to these, *Iannone & Inglis* discussed a range of weaknesses in Year 1 mathematics students' production of deductive arguments (rather than in the oft-reported perception that a deductive argument was expected of them). *Juter* reported the highly individual and not easily classifiable character of pre-service secondary mathematics teachers' concept images of elementary Calculus concepts. And *Souto-Rubio & Gómez-Chacón* mapped out students' difficulty with developing visualisation skills in the context of the Riemann integral.

Some papers focused on particular curricular and pedagogical aspects of university mathematics. *Agathokleous* argued how teaching Abstract Algebra to pre-service primary teachers can facilitate students' appreciation for the connectedness across mathematical domains. *Jukic & Dahl*, through data collected in the Croatian and Danish context, aimed to illustrate that students taught in different styles are likely to perform differently. *Bergsten* presented evidence that students tend to find lectures useful and attractive, despite their bad press in some education quarters.

Finally, a few papers addressed theoretical issues directly. *Barton* outlined efforts to combine the three-fold activity of research, development and theory building into LATUM, a model for learning and teaching university mathematics that is proposed as a model for designing alternative university mathematics delivery. And, *Pettersson* proposed 'threshold concepts', a theoretical construct from the general education literature, as a means for gaining insight into student learning and engaging teachers in pedagogical discussion.

WHY ABSTRACT ALGEBRA FOR PRE-SERVICE PRIMARY SCHOOL TEACHERS

Eleni Agathocleous

Cyprus Ministry of Education and Culture

There has been a rapid increase in the volume of research papers focusing on mathematics teacher education and in particular on the characteristics that should describe the desired mathematical knowledge for teachers. In this paper, it is suggested through theoretical discussion on the character of Abstract Algebra and via Peirce's semiotics, that a one-semester course in Abstract Algebra, specially designed for pre-service primary school teachers, can enhance the development of the basic, multifaceted characteristic of connectedness. Some concrete examples are given in the end of the paper, taken from in-class observations and reflections on a similar course taught by the author, for two consecutive semesters.

Key words: Teachers' mathematical knowledge, Connectedness, Abstract Algebra, Semiotics.

INTRODUCTION

In this paper I argue that a course in basic notions of Abstract Algebra, specially designed for pre-service primary school teachers, can help teachers regroup and enrich their existing mathematical knowledge, as well as achieve connectedness across various mathematical domains as well as across time, as a mathematical idea develops and extends. These basic notions of Abstract Algebra include the notions of group, ring and field, accompanied by a very basic introduction to functions, modular arithmetic and complex numbers. Unlike a standard introductory course in Abstract Algebra intended for mathematicians, the aim of this course would not be the teaching of group theory, quotient rings or maximal ideals for example. But instead, the introduction of groups, rings and fields as a means to put existing mathematical knowledge (such as the number systems \mathbb{N} , \mathbb{Z} , \mathbb{Q} , \mathbb{R}) or new mathematical knowledge (such as the number systems \mathbb{C} and \mathbb{Z}_n) into new forms, in order to reveal more information on the structure of these mathematical systems as well as present new ways of understanding old knowledge. The theoretical discussion in this paper focuses on the unifying character of the basic notions of group, ring and field, and I employ Peirce's Semiotics to show how the use of these notions is on the highest level of the hierarchy, helping the learner make the desired connections suggested by the literature on teachers' mathematical knowledge.

TEACHERS' MATHEMATICAL KNOWLEDGE

What mathematical knowledge does it take to teach primary mathematics well? Is it a matter of quantity? Of depth? Or is it a matter of different quality? There has been a rapid increase in the volume of research papers focusing on the relatively new area of

mathematics teacher education (Adler, Ball, Krainer, Lin, & Novotna, 2005) and investigating the “unsolved” (Ball, Lubienski, & Mewborn, 2001) problem of teachers’ mathematical knowledge (see, e.g., Davis & Simmt, 2006; Ball & Bass, 2000; 2003; Ball *et al.*, 2001). It is a shared belief that if a teacher does not know mathematics, then he/she cannot teach mathematics (Ball & Bass, 2003; Murphy, 2006). However, one of the first attempts to investigate the relevance between teachers’ knowledge and students’ achievement showed that the number of advanced mathematics courses taken by teachers, was not relevant to students’ achievement (Begle, 1979). Even though Begle’s findings as well as views concerning research in mathematics education, were later doubted by critics (see, e.g., Elerton & Clements, 1998; Howson, 1980), many others since then have argued in favour of this view, i.e. that advanced mathematics courses offered by mathematicians for mathematicians might be of no value to teachers and can even have negative effects on their pedagogical approaches (Cooney & Wiegel, 2003; Davis & Simmt, 2006; Murphy, 2006). Relevant studies by Askew, Brown, Rhodes, Wiliam, and Johnson (1997), Ball and Bass (2000; 2003), Ball *et al.* (2001) and Davis and Simmt (2006), point out a need for different mathematics for teachers. Davis and Simmt (2006) suggest that teachers’ mathematical knowledge is not a matter of “more of” or “beyond”, but it is of a different quality. This ‘new’ mathematical knowledge should foster teachers’ understanding of mathematics in a broader and unifying sense, so as to enable them to make connections across mathematical domains and help students build a coherent mathematical knowledge (Askew *et al.*, 1997; Ball & Bass, 2000; 2003; Ball *et al.*, 2001). Furthermore, teachers are to anticipate the way mathematical ideas change and grow; hence, they should also be able to make connections across time, as mathematical ideas develop and extend (Ball & Bass, 2003).

Even though there is no general agreement as to the level or the type of mathematical knowledge teachers should have, we see from the above discussion that the multifaceted characteristic of connectedness - across various mathematical domains, conceptual aspects of one same notion, or even across time as a mathematical idea develops - is widely present in the literature. Another example is the study of Ma (1999), in which she compares Chinese and U.S. elementary teachers’ mathematical knowledge. Ma uses the term “profound understanding of fundamental mathematics” to describe teachers’ mathematical knowledge, which is later described by Ball and Bass (2003) as “a kind of connected ... and longitudinally coherent knowledge of core mathematical ideas” (p.4). Ball and Bass (2000) explain that “depth” for Ma is the connecting of ideas with the larger and more powerful ideas of the domain, “breadth” is related to the connecting of ideas of similar conceptual power and “thoroughness” is what groups everything together into a coherent whole.

The need for a connected mathematical knowledge for teachers is also suggested by studies that focus on the teaching and learning of specific mathematical ideas. One such example is a study by Lamon (1996) of children’s partitioning strategies and the

development of their unitizing process. In her section *Implications for Instruction* she writes

The many personalities of subconstructs of rational number that children must conceptually coordinate may all be understood as compositions and recompositions of units. Because the rational numbers are a quotient field, partitioning itself is an operation that plays a role in generating each of those subconstructs ... Students need extensive presymbolic experiences involving these conceptual and graphical mechanisms in order to develop a flexible concept of unit and a firm foundation for quantification, to develop the language and imagery needed for multiplicative reasoning, and to conceptually coordinate the additive and multiplicative aspects of rational numbers. (p.192)

All of the above concerning the multiple faces of a rational number, the multiplicative versus the additive structure, the development of flexible concepts, etc. are characteristics of the students' desired knowledge. One can only begin to understand how complex, rich, versatile and flexible teachers' content knowledge should be, so as to be able to correspond to such high and demanding expectations.

WHY ABSTRACT ALGEBRA

Abstract Algebra is an advanced mathematics course usually meant for mathematics students, and it is no surprise that the literature concerning the pedagogy of Abstract Algebra, focuses on the teaching of the course to university students majoring in mathematics, or to high-school mathematics teachers (see, e.g., Burn, 1996; Dubinsky, Dautermann, Leron, & Zazkis, 1994; Leron & Dubinsky, 1995; Simpson & Stehlíková, 2006). The subject is hard enough, even when taught to mathematics majors and we have the, apparently famous, quote: "The teaching of Abstract Algebra is a disaster, and this remains true almost independently of the quality of the lectures" (Leron & Dubinsky, 1995, p. 227; Simpson & Stehlíková, 2006, p.347). So why should one attempt to teach notions of Abstract Algebra to pre-service primary school teachers?

History, Character and Basic Definitions

Until the end of the eighteenth century, Algebra was concerned with mainly the study of polynomial equations and was regarded as a generalization of Arithmetic. The nineteenth century was for Algebra the period of transition, of complete reform. Some of the basic characteristics of the mathematics of the nineteenth century were a turn toward rigor and the need for axiomatization, and the emergence of abstraction. Following Geometry, Algebra became another branch of Mathematics that mathematicians tried to axiomatize. Furthermore, the attention was now turned to the study of mathematical objects, such as vectors, matrices, transformations, etc, and various operations acting on them, which expanded the role of Algebra to the study of form and structure, giving birth to Abstract Algebra. It is in this century that we have the explicit formulation of the fundamental concepts of a group, ring and field, which grew out of the work of many mathematicians such as Galois (1811-1832),

Cayley (1821-1895) and Dedekind (1831-1916). These three concepts constitute the focal point of the Abstract Algebra course that we propose, since they have by definition a unifying nature. In the preface of his book, Herstein (1999) mentions that one aspect of the role of Abstract Algebra is "... that of a unifying link between disparate parts of mathematics ..." (Herstein, p.xi); and Robert (1987) refers to concepts of the theory of groups as "unifying and generalizing concepts" (in Dorier, 1995, p.175). But what is it exactly that gives the concept of a group such unifying powers? Let us first recall the definition:

Definition1: A non-empty set G is said to be a group if we define an operation $*$ in G such that: (1) If $a, b \in G$ then $a*b \in G$, and we say that G is closed under $*$, (2) Given $a, b, c \in G$ then $a*(b*c) = (a*b)*c$, and we say that the associative law holds in G , (3) There exists a special element $e \in G$ such that $\forall a \in G, a*e = e*a = a$. This element e is called the identity or unit element of G , (4) $\forall a \in G$ there exists an element $b \in G$ such that $a*b = b*a = e$. We write this element b as a^{-1} and we call it the inverse of a in G . If in addition, we have that (5) $\forall a, b \in G, a*b = b*a$, i.e. the commutative law holds, then we say that G is an abelian group.

From the definition alone, one can recognize the shift of attention from specific objects and operations, to the interrelationships between objects produced under the action of some operation. Seeing for example that $(\mathbb{Z}, +)$ and $(\mathbb{Q}^\times, \cdot)$ are both groups, implies, among other things, the realization that 0 in the first example and 1 in the second play exactly the same role, and therefore the 'identification' of these two seemingly unrelated objects. Similarly, z and $-z$ connect together in the same way that q and q^{-1} in the second example do, where z is any integer and q any rational. Another very useful example involves the even and odd numbers and the realization that $(2\mathbb{Z}, +)$ forms a group whereas $(2\mathbb{Z}+1, +)$ does not since closure fails to hold in the second case. Proving this requires seeing the even and odd numbers in their general form as $2k$ and $2k+1$ respectively, where k any integer. And this in turn, requires the learning as well as the use of the definitions of these two kinds of numbers, which is a type of knowledge that is expected from the teacher (see Ball & Bass, 2000, the Introduction).

Definition2: A non-empty set R is said to be a ring if there are two operations $+$ and \cdot such that: (1) $(R, +)$ is an abelian group, (2) if $a, b \in R$ then $a \cdot b \in R$, (3) $a \cdot (b \cdot c) = (a \cdot b) \cdot c$, for $a, b, c \in R$, (4) (i) $a \cdot (b+c) = a \cdot b + a \cdot c$ and (ii) $(b+c) \cdot a = b \cdot a + c \cdot a$. If in addition we have that (5) $\forall a, b \in R, a \cdot b = b \cdot a$, then we say that R is a commutative ring and the axiom 4(ii) is unnecessary.

The axioms for a ring look familiar since they are a generalization of what happens to the integers. The object $(\mathbb{Z}, +, \cdot)$ is indeed a commutative ring with unit. One can see that what rings are 'missing' from behaving like the rationals or the reals are the multiplicative inverses and of course the need for the multiplicative identity element,

equivalently called unit, which we denote by 1 . What we are about to define as a field, has exactly these two extra axioms. Therefore

Definition 3: A non-empty set F is said to be a field if there are two operations $+$ and \cdot such that: (1) $(F, +, \cdot)$ is a commutative ring with unit, (2) for every non-zero $a \in F$ there is an element $a^{-1} \in F$ such that $a \cdot a^{-1} = 1$.

And so a teacher can now say that $(\mathbb{Q}, +, \cdot)$ is a field. What have we exactly achieved by that? This is the type of questions that will be answered in the next two sections.

Groups, Rings, Fields - A Semiotic Perspective

In this section, through Peirce's semiotic hierarchy I expect to show how the learning and the use of the notions of a group, ring and field lie on the highest level of the hierarchy, thus leading to the making of the desired connections suggested by research on teachers' mathematical knowledge.

Semiotics is the study of signs, especially as elements of a system, and as such, semiotics serves as a natural theoretical framework for the learning and teaching of mathematics, since mathematics requires certain sign systems "to keep a record of and code the knowledge" (Steinbring, 2006) and mathematization "means representing problems or facts by means of symbols, indices and relational representations" (Hoffmann, 2006, p.279).

For Peirce, a sign is anything that "stands for something (its object)" in such a way as to generate meaning (called its interpretant) (Otte, 2006, pg.23). The signs are of three types. On the first level we have the icons, which are, as the word says, icons – pictures – likenesses of what they represent. A number is an example of an icon; i.e. " 1 " stands for the number or the idea of "one". If now we choose to write " m " to imply any integer, then " m " becomes a name, an index, of something existing. An index is on the second level of the hierarchy. Other examples of indices are the ideas of "unit", "additive inverse" and "identity element", when these are considered as names or categories for the appropriate icons. One way to think of what an index does is that it organizes icons "in higher order relationships" (Davis & McGowen, 2001, p.10). However, if we make the realizations (i.e. prove) that for every integer m , $-m$ is the "additive inverse" of m , $1 \cdot m = m$, $0 + m = m$, etc. then we are on the third level of the hierarchy, the symbolic level, as the aforesaid realizations are of a law-like nature and they are generalizations regarding the behaviour of the integers. In Peirce's words, the symbol, which is on the third and highest level of the hierarchy, refers to its object "by virtue of law" (in Radford, 2000, p.252). But we see that it is through an index that we can say that the integers have a certain quality. It is the index "additive inverse" for example, that allows us to say that all integers have an additive inverse. In the words of Peirce again

A symbol is a conventional sign which being attached to an object signifies that object has certain characters. But a symbol, in itself, is a mere dream; it does not

Working Group 14

show what it is talking about. It needs to be connected with its object. For that purpose, an index is indispensable. No other kind of sign will answer the purpose (in Otte, 2006, p.30).

If we now consider all the indices that appear in the definition of a ring and the way these organize the icons of the integers, such as the numbers themselves, the signs “=”, “+”, etc., then we have, according to Peirce, the connection between the symbol, if I may denote it by “the ring $(Z, +, \cdot)$ ”, and the integers. And as we attach to the integers the symbol “the ring $(Z, +, \cdot)$ ” we automatically ‘see’ in the integers all those properties that we all learn from our early years until university. Deacon (1977) refers to the shift to the symbolic level of the hierarchy as

... a way of off-loading redundant details from working memory, by recognizing a higher order regularity in the mess of associations, a trick that can accomplish the same task without having to hold all details in mind. (in Davis & McGowen, 2001, p.10)

The notions of group, ring and field behave exactly like that: they allow which ever object we are investigating, i.e. the integers, the complex numbers, the 2×2 invertible matrices, to be “apprehended, pretty much all at once” (Davis & McGowen, 2001, p.10), i.e. through the symbol “the ring $(Z, +, \cdot)$ ”, “the group $(Z, +)$ ”, “the field $(C, +, \cdot)$ ”, “the group of 2×2 invertible matrices $GL(2, R)$ ”, etc., without having to hold all details in mind. As such, the notions of group, ring and field are systems of symbols and they form a part of a connected symbolic system, the symbolic associations of which are being understood from the “myriad connections” between the indexes (Davis & McGowen, 2001, p.10) organized by this system.

From the above discussion we see that by moving up on the hierarchy, we achieve a shift in understanding: a shift from the specific and isolated, i.e. the number 1, 0, 2, -2, $\frac{1}{2}$, to ideas such as “unit”, “additive or multiplicative inverse”, “the ring $(Z, +, \cdot)$ ”, etc., which connect together seemingly different parts of our knowledge, putting them into a coherent whole.

IN-CLASS OBSERVATIONS AND REFLECTIONS

This last section aims to provide the reader with some concrete examples from, and suggestions, if you will, regarding the teaching of basic notions of Abstract Algebra to pre-service primary school teachers.

While being a Lecturer in Mathematics Education at a university in Cyprus, I taught a course for pre-service primary school teachers, called General Topics in Mathematics. This was the second and last part of a series of mathematics courses for primary school teachers, and it was optional. Only the first course was obligatory. I taught this course for two consecutive semesters. The spring semester course ran over a period of thirteen weeks and my students and I met once a week, for three hours. The summer semester course was seven weeks long and we met twice a week, for three hours each time. I kept the syllabus for both courses the same. I chose a

Working Group 14

variety of topics from traditional Algebra, Logic, Set Theory, etc. and during the last three lectures I gave a brief introduction to the complex numbers and the notions of group, ring and field, including examples from areas they had already seen before, as well as some basic examples from modular arithmetic. In class observations and discussions revealed similar reactions and results from both classes.

The following are some examples from in-class observations as well as from the students' answers in the final exam: (1) The students seemed to have appreciated more the importance of the distributive law, as they saw how it connected together the abelian groups $(Q, +)$ and (Q^\times, \cdot) for example, in order to give the well-known field $(Q, +, \cdot)$. This is a concrete example of the symbolic (in Peirce's language) character of the notions of a group, ring and field in the sense that it shows how the groups $(Q, +)$ and (Q^\times, \cdot) and the field $(Q, +, \cdot)$ are part of a symbolic system and their association is being understood from the connection between the indexes, via the distributive law (see also the quotes from Davis & McGowen, 2001, in p.6 above). (2) It appeared that the notion of closure was being brought to their attention for the first time. They did not understand the necessity of this axiom in the definition of a group. Their reactions were pretty much along the line "if you add a number you will get a number and that is pretty much obvious, so why do we need this statement?" I asked them: what happens if you add 0 and 4? -2 and 100? 1000 and 44? So we concluded that when you add two even numbers you seem to get an even number. What followed was the realization that this does not happen with the odd numbers. The next step was to prove that even + even = even and odd + odd \neq odd. The notion of "closure" in this example, intended to force the students to focus their attention on specific sets of numbers and to help them see a 'different' distinction between them. 'Different' distinction in the sense that when examining whether even and odd numbers are groups, these sets stop being just the sets of icons (the lowest level of Peirce's hierarchy): $\{0, 2, 4, \dots\}$ and $\{1, 3, 5, \dots\}$ but instead, they become systems of connections in the highest level of the hierarchy, since statements of the form " $(2Z, +)$ is closed" and " $(2Z+1, +)$ is not", lie on the symbolic level. (3) One of the earlier topics that were presented in this course was the notion of function. The concept of a function came up again in one of the examples, were they had to prove that the following set G of functions is a group: $G = \{T_{a,b} : R \rightarrow R \mid T_{a,b}(r) = ar + b, a, b \in R, a \neq 0\}$. At first, there was an immense reaction (expected) from the students about the impossibility of this exercise due to its highly symbolic (not symbolic in Peirce's language) character, or in their words, to the appearance of "too many letters". When I explained that the function $T_{a,b}$ is merely a generalization of functions like the ones they saw before, for example like the function $f(x) = 3x+2$, etc., then the complaints seized. It was very interesting and rewarding to see their surprised faces when they realized that (a) the identity element is the function $T_{1,0}$ and that this object behaves in exactly the same manner as 0 in $(Z, +)$ for example, or 1 in (Q^\times, \cdot) , (b) even if this problem is so different from everything they saw before,

the procedure to find the inverse element of G was exactly the same as the steps they followed earlier in the course, in order to find the inverse of a specific function. In other words, they were very surprised to see that the same method could work in such different, for them, situations. As was already discussed in the section above, recognizing different kinds of inverses, i.e. 1, 0 and $T_{1,0}$ in this example, imply the making of connections that lie on the highest level of Peirce's hierarchy. Furthermore, these are examples of connections that help teachers build connections across different mathematical domains, since in this case we were comparing number systems with groups of functions. The students presented difficulty however, which was also shown in the final exam, in showing that the inverse $T_{a,b}^{-1}$ is still a member of G ; i.e. even though almost everyone showed that $T_{a,b}^{-1}(r) = \frac{1}{a}r - \frac{b}{a}$, not everyone could see why we are not done until we write $T_{a,b}^{-1} = T_{1/a, -b/a}$, $1/a \neq 0$. (4) Difficulty for students also presented in the case of modular arithmetic. Since there was not enough time to really digest this new kind of "numbers", even though they were pretty quickly able to find the additive and multiplicative inverses of Z_5 for example and they appeared to understand why not every non-zero element of Z_6 has a multiplicative inverse, in the exam when they were asked to explain why (Z_4^\times, \cdot) is not a group, the majority did not succeed. However the majority succeeded in the two more familiar examples where they had to explain why $(2Z+1, +)$ and (Z^\times, \cdot) are not groups. (5) The two new topics, modular arithmetic and complex numbers, created some problems for the students because of time shortage. However, the introduction to complex numbers that the students had, gave them some sort of continuity regarding the number system and it helped them realize and understand the, up until then unknown to them, relationship $N \subset Z \subset Q \subset R \subset C$. The last two examples emphasize the need for a one-semester course on these topics, as these new ideas seem to take time to get through to the students.

CONCLUSION

As it is pointed out by Dorier (1995, p.1), concepts such as the concept of a group, were invented not only to solve new problems but "mainly to find general methods to solve different problems with the same tools" (Dorier, 1995, p.1). All of the above different examples from the area of functions, modular arithmetic, as well as the various number systems, were solved by using the same 'tools', i.e. the concept of group, ring and field. This 'proves' in a way how the unifying character of these 'tools' can be used in the training of future teachers, in order to help them achieve the desired connections. However, a remark regarding the cost of such a course should be added here, since its potential difficulty can cause problems if the course is taught in universities where teachers do not have to take any kind of actual mathematics courses, but only courses in mathematics education instead.

As it is pointed out throughout this paper, this is a theoretical attempt to show how the concepts of a group, ring and field can help to regroup and enrich teachers'

mathematical knowledge in a way agreeable with the literature on teachers' mathematical knowledge. What can follow this paper and produce useful and insightful information, is research that investigates which part of this knowledge and in which form, teachers actually transfer into their own classroom, and which also examines the actual effect of such a course on teachers' mathematical knowledge.

‘APPLICATIONISM’ AS THE DOMINANT EPISTEMOLOGY AT UNIVERSITY LEVEL

Berta Barquero*, Marianna Bosch** & Josep Gascón***

*Universitat Pompeu Fabra (Barcelona), **Universitat Ramon Llull (Barcelona)
***Universitat Autònoma de Barcelona

Recent research on the teaching of modelling highlights the existence of strong institutional restrictions on the widespread and long-term diffusion of mathematical modelling practices in current educational systems. We present a research project that aims at studying these restrictions in first year Sciences University degrees, especially those arising from the ‘prevailing epistemology’ concerning the role attributed to mathematics in Natural Sciences. We characterise this epistemology as ‘applicationism’ and describe its main features. The analysis of teaching materials and a survey and interview to science university teachers bring concrete evidence to the prevalence of such ‘applicationism’ and the way it may hinder the teaching of mathematics as a modelling tool.

THE ‘ECOLOGY’ OF MATHEMATICAL MODELLING

This paper focuses on studying the teaching of mathematics in Natural Sciences in universities degrees. It focuses more specifically on the didactic problem of studying the ‘ecology’ of mathematical modelling in these institutions. By ‘ecology’ we mean the necessary conditions for an activity to ‘live’ in an institutional environment and the restrictions hindering the evolution of implementing this activity. The origin of this ecological problem, which was first applied to mathematical objects and practices before being enlarged to a wider institutional perspective, can be located in the study of the process of *didactic transposition* and its related phenomena (Chevallard 1985, see also Bosch & Gascón 2006). More recently, to study the ‘ecology’ of the mathematical practices that exist (or could exist) in a teaching institution and the possible ways of constructing them (the didactic organisations), Chevallard (2002, p. 42) introduced a hierarchy of ‘levels of didactic co-determination’ that consists in the following sequence:

Civilization ↔ Society ↔ School ↔ Pedagogy ↔ Discipline ↔ Domain ↔ Sector ↔ Theme ↔ Subject

As we indicated in Barquero *et al.* (2010b), this hierarchy goes from the most generic level –Civilization– to the most concrete one – the subject or questions that are to be studied by a group of persons. The lower levels going from the *discipline* to the *subject* are considered as the *mathematical levels* if the considered discipline is *mathematics*. The didactic transposition process (Chevallard 1985) tends to provide a structure of taught disciplines into different domains, sectors and themes that usually comes from the scholar discipline but is modified according to the education

institution considered. For instance, in Spanish universities, a first year course of mathematics for science students is usually structured into three domains: calculus, linear algebra and differential equations, divided into classical sectors such as ‘real-valued functions’, ‘limits’, ‘derivatives’, ‘integration’, etc. containing different themes, to which every subject or question to study belongs. At secondary school level, other domains appear depending on the curricular reform in force. These low levels are the ‘specific’ ones and are used to analyse the constraints coming from the specific way of organising teaching contents at school: from the division into disciplines and blocks of contents, until the low-level concatenation of subjects.

The upper levels of determination refer to the more general constraints coming from the way Society, through School, organises the study of disciplines (pedagogical level). They concern the status and functions traditionally assigned to educational contents and the general way of organising teaching and learning activities at school. These levels offer important conditions – and also set a lot of constraints – that concretely affect what the teacher and students can do in the classroom. For instance, the amount of hours and sessions assigned to the teaching of a concrete discipline, the possibilities for disciplines to interact more or less easily, the way students are grouped (by age, by level, by gender, etc.), the organisation of the school space, etc. All those conditions and constraints belong to the *school level*, while the *pedagogical level* refers to those only affecting the teaching and learning of ‘disciplines’. The way disciplines are grouped, valued, linked, diffused belongs to this level, as for instance the choice of an interdisciplinary way of studying questions or the way of presenting disciplines as independent. The *society and civilization levels* concern the way the rationale, functions, aims of school instruction is considered and valued.

We focus here on the general problem of integrating mathematical modelling, considered a central aspect of mathematics (see Barquero *et al.* 2008 and 2010b), into current educational systems. Our objective is to study, analyze and describe some institutional constraints that hinder the implementation of these modelling activities. From our perspective, the study of these constraints and the way new teaching proposals can overcome them appear as a necessary step for the dissemination of mathematical modelling activities at all school levels.

Taking into account the different levels of didactic co-determination is not only useful to reach these variety of constraints acting on the classroom activities, but also to know better at what level it is necessary to act in order to set up suitable conditions that make the development of this mathematical modelling activities possible⁷². In this paper, we focus on analyzing some restrictions which come from

⁷² Within the framework of the ATD, most of the research related to mathematical modelling and teaching practices (Artaud 2007, Bolea *et al.* 2004, Barquero *et al.* 2008, Barbé *et al.* 2005) takes into account the problem of the ‘ecology’ of didactic organisations, which has to be located at the core of all research aiming to integrate mathematical

the most generic co-determination level, especially all those related to what we call the ‘dominant epistemology’ in university institutions. By ‘dominant epistemology’ we understand the way in which the university as an institution and, more specifically, the community of university teachers (and students) consider what mathematics is and how it is related to the natural sciences. This situation can be summarized in the formulation of the following didactic problem:

In which way does the university community understand the role of mathematical activity and, especially of mathematical modelling in the development of Natural Sciences? What restrictions are derived from this ‘prevailing epistemology’ in relation to the ‘life’ of mathematical modelling in university settings? What conditions, at what level of co-determination, can help overcome these restrictions?

GENERAL CONSTRAINTS ON THE TEACHING OF MODELLING ACTIVITIES

2.1. A characterization of ‘applicationism’

At the levels of *society* and *school*, we focus on investigating the *dominant epistemology* in the teaching institution considered (the university), and its effect on the different mathematics teaching practices. Our first hypothesis is that the widespread understanding of mathematics and its relation to natural sciences is what we can call ‘applicationism’ and this can be depicted in the following way: first mathematical tools are built within the field of mathematics and then they are ‘applied’ to solve problematic questions from other disciplines, but this application does not cause any relevant change, neither in mathematics nor in the rest of disciplines where the questions to study appeared. ‘Applicationism’ thus assumes a strict separation between mathematics and other disciplines. For example, in the majority of the Spanish university courses we have examined, the study of population dynamics is a subject located in the sector of differential equations under the label of ‘application’, as if some dynamic laws could exist without any mathematical tool to describe them and, in the same way, as if differential equations could independently exist without any extra-mathematical problem to solve. In this context, mathematical modelling is understood as a mere ‘application’ of previously constructed mathematical knowledge or, in the extreme, as a simple ‘exemplification’ of mathematical tools in some extra-mathematical contexts artificially built in advance to fit these tools.

To be more specific, we propose to characterise ‘applicationism’ using the following indicators (Barquero *et al.*, 2010a):

Working Group 14

I₁: Mathematics is independent of other disciplines ('epistemological purification'): mathematical tools are seen as independent of extra-mathematical systems and they are applied in the same way, independently of the nature of the system considered.⁷³

I₂: Basic mathematical tools are common to all scientists: all students can follow the same introductory course in mathematics, without considering any kind of specificity depending on their speciality (biology, geology, etc.).

I₃: The organisation of mathematics contents follows the logic of the models instead of being built up from considering modelling problems that arise in the different disciplines. All occurs as if there were a unique way of organising mathematical contents and different ways of applying them.

I₄: Applications always come after the basic mathematical training: the result is then a proliferation of isolated questions that have their origin in the different systems. The first thing is to learn how to manipulate the mathematical concepts and later learn about their use. The models are built from concepts, properties and theorems of each theme independently of any extra-mathematical system.

I₅: Extra-mathematical systems could be taught without any reference to mathematical models, that is, there exists the belief that natural science can be taught without any mathematics.⁷⁴

To empirically contrast to what degree applicationism prevails in university institutions, we decided to use these indicators to analyse teaching materials (syllabi and textbook prefaces) and to interview and survey some geology and biology teachers of a science faculty in Catalonia.

2.2. Applicationism in syllabi and book prefaces

The analysis of about 30 syllabi of mathematics for Natural Sciences university courses of 10 different Spanish universities constitutes a good indicator of the mathematics proposed to students. Here we consider the particular case of a first course of mathematics in the degrees of biology, geology, chemistry and environmental sciences. The written description of different mathematical courses of Spanish first year university scientific programmes states that the teaching of mathematics follows a double objective: on the one hand, they strive to give students basic mathematical training; on the other hand, they try to introduce students to mathematical modelling [**I₁**, **I₂**]. For instance, in the case of a geology degree (2006/07) at the UAB university, the following is proposed (our translation):

⁷³ This indicator is more general than the others, as it refers to a characteristic of mathematics as a discipline, and not to the way it is taught.

⁷⁴ This is an extreme indicator of the independence between mathematics and natural sciences (especially in the case of biology and geology) that is surprisingly widely shared to the point that, in most cases, people state that scientific systems could be studied without any mathematical tool.

Working Group 14

This program claims a double objective. The first and most important one is to give students the basic mathematical training focused on linear algebra and on one-variable differential calculus, which will allow them to understand the language of Science. The second aim is to introduce them to the field of Geology, that is, to mathematical modelling, using simple examples that could be analyzed by previously introduced mathematical tools.

In a more detailed analysis of the mathematical contents of these courses, we notice they are organized in ‘topics’, ‘themes’ or ‘modules’ centred on a main concept (limits, derivatives, integration, linear applications, diagonalisation, ordinary differential equations, etc.) each including a number of definitions, properties, theorems, proofs, various techniques and types of problems. At the end of the study process, problems tend to turn into ‘applications’ such as giving a ‘rationale’ to the contents and showing their functionality [I₅]. The corresponding study programme is generally structured in three main areas: linear algebra, one-variable differential and integral calculus, and ordinary differential equations [I₃]. Always left to the end, the teaching of modelling problems is basically absent from Spanish ‘real’ university curricula.

It stands out that the ‘traditional’ organization is not structured around modelling problems or ‘applications’, but rather follows a very standard list of topics or blocks of themes. We also observe that this organization places the technological and theoretical block at the origin of mathematical activity. As a consequence, it tends to propose types of problems, which are particularly limited and isolated, to obtain examples of all the notions and properties of each topic [I₄, I₅]. This situation leads us to think that these mathematical tools only provide ‘qualitative’ information on the study of scientific facts. It suggests the possibility that natural sciences could be taught without mathematics [I₅].

Similarly, some of the prefaces and content organizations in most of the recommended books for these courses helped us to uncover the presence of applicationism. Good examples of this are Salas & Hille (1995) and Anton (2003). The main aim of these books is to introduce students to a ‘basic common language’ for all scientists and in a completely independent way of natural sciences disciplines. [I₁, I₂]. Salas & Hille (1995) explain it in the following terms (our translation):

In this edition, you will find some easier applications to physics and, as extra chapters, some more difficult applications. [...] Despite the incorporation of more applications, this book is still a mathematics book, not a science book or an engineering book. It is about calculus and its main basic ideas are limits, derivatives and integrals. The rest is secondary; the rest could be left out. Salas & Hille (1995, p. 7)

The organization of these books is again and again structured around several blocks of themes, following a purely deductive logic. The common structure of most textbooks contains the following blocks of themes: limits and continuity,

differentiation, mean-value theorem and applications, integration, applications of integrals, transcendent functions, integration techniques, conic sections, sequences, infinite series [I₃]. The references to applications usually appear at the end of each chapter as an example of how to use the mathematical tools introduced. Often, these applications are included in a separate section labelled ‘additional exercises’, which offers an expansion of the field of problems that can be solved with the mathematical techniques introduced in that chapter [I₄].

2.3. Applicationism as described by teachers and researchers in Natural Sciences

The next step of our research was to look into the discourses of university teachers and researchers when they are asked about the criteria used to design and manage mathematics teaching in Natural Sciences degrees. For this purpose, we first conducted a survey on the indicators that characterize applicationism. The survey was distributed and answered by 30 teachers and researchers in the departments of biology, geology and environmental sciences at the Autonomous University of Barcelona (UAB). In a second phase of the research, we completed the findings with interviews to four teachers that had participated in the survey, with the objective of explaining and expanding their answers. The results obtained in the survey were, for most questions, quite clear. We next summarize some of the main findings and complement them with the explanations provided in the interviews.

In the first question, more than 50% of the respondents did not agree on the fact that the mathematics taught in their respective scientific disciplines were any different from the ones taught in the rest of Natural Sciences. One can hence confirm that the mathematics taught in one particular science is not specific to it [I₂]. Respondent C added:

“I think that the differences between programs need not be very significant. The mathematical language is unique, and the attraction for mathematics can come from different scientific perspectives but is always the same. Nevertheless I think that details matter, the type of examples, the adaptations, being able to visualize that those equations can be translated into specific phenomena [...]”

1. “The mathematics of the first year Biology degree is different from the rest of Natural Science degrees.”		
1. Strongly disagree	8	27%
2. Disagree	8	27%
3. Neither agree nor disagree	4	13%
4. Agree	3	10%
5. Strongly agree	1	3%
6. I do not know	6	20%
TOTAL	30	100%

2. “Mathematics is generally introduced independently of the biological systems that can be mathematically modelled.”		
1.. Neither agree nor	2	7%
2. Agree	15	50%
3. Strongly agree	13	43%
TOTAL	30	100%

Where people agreed most was in the second question: 93% agreed (43% strongly agreed) that mathematics is introduced with independence from scientific systems [I₁]. Regarding that idea, respondent A agrees with this separation:

Working Group 14

“I do not think that mathematics should be introduced linked to geological systems. How could one link it with such basic mathematics? I do not find it convenient or pertinent because we do not have to explain why mathematics is needed in each one of our courses. Mathematics must be there, for their own sake.”

90% of the respondents agreed with the third statement (37% strongly agreed), that the mathematics that is taught is structured around problems of a mathematical nature, and not of a scientific nature [I₃]. On this point, respondent C explains:

“I think that (the mathematics taught) are still centred on mathematical problems, but I do not know whether this is bad, I find it natural. I said earlier that programs did not have to be completely different and the differences should appear in the examples. What I meant is that I am glad that the mathematics programs for physicists and for bio-scientists do not contain large differences and share a common body, which cannot be physics, chemistry or biology: it has to be mathematics [...]”.

3. “Mathematics is structured around mathematical problems and not around biology problems.”		
1. Strongly disagree	0	0%
2. Disagree	3	10%
3. Neither agree nor disagree	0	0%
4. Agree	16	53%
5. Strongly agree	11	37%
TOTAL	30	100%

It is also quite clear that the respondents disagreed with the fourth statement (47% strongly disagreed, 40% disagreed), that mathematics are only taught after the need for it arises from the study of scientific phenomena [I₅]. On the other hand, 90% disagreed (40% strongly disagreed) with the idea that extra-

4. “Mathematics is taught only after the study of biological systems requires it.”		
1. Strongly disagree	14	47%
2. Disagree	12	40%
3. Neither agree nor disagree	3	10%
4. Agree	1	3%
TOTAL	30	100%

5. “Biological situations where mathematics is applied are linked to a general biological problem that is relatively unified.”		
1. Strongly disagree	12	40%
2. Disagree	15	50%
3. Neither agree nor disagree	3	10%
TOTAL	30	100%

mathematical situations where mathematics are used appear linked to a general Natural Science problem that is relatively unified rather than a set of independent questions. This idea, introduced by I₄, supports the progressive disappearance of a general scientific problem. Instead, there is a proliferation of isolated problems (arising from

different systems). The interviews suggest a similar trend:

“A set of isolated and separated questions appears, and, I must add, it is a shame. But this is what is done. It is not only that there is no relationship with the instrumental courses, but also that there is no relationship between the descriptive courses! They are all satellites on their own isolated orbits [...] We could look for very serious reasons, but one always ends up finding the usual suspects, inertia and lack of unity.” (Respondent C)

Working Group 14

“Each one seems to reign over his/her little kingdom, and explains the topics separately. The student will never have a global view, but I think that we, the teachers, do not have it either. There is no tradition of working in community, of meeting and agreeing on the content of each subject [...] I do not see how it can be possible to avoid this tradition in the future, to escape from this inertia around us.” (Respondent A).

Regarding the last statement in one of the most extreme indicators of applicationism, we find divided opinions, only 10% remaining neutral. Around 47% disagree that it would be possible to teach a Natural Science degree by reserving mathematics only for the quantitative aspects. But what we find surprising and to some extent worrying is that approximately 44% agree with the statement. This suggests that it would be possible to achieve a relatively complete and deep study of scientific phenomena without using mathematics.

6. “An entire Biology degree can be taught almost without using mathematics”		
1. Strongly disagree	5	17%
2. Disagree	9	30%
3. Neither agree nor disagree	3	10%
4. Agree	10	33%
5. Strongly agree	3	10%

The interviews also reflect this divergence of opinions. Those who agree with that possibility add:

“Yes, it would be possible. I have known several students that have obtained their degree without passing the mathematics subjects, and even worse, without even trying.” (Respondent A). “One could do it, but the degree would be incomplete, it would be merely descriptive [...] But as soon as one would need to study deeper or establish relationships between phenomena, then mathematics are needed.” (Respondent B).

Respondent C is clearly opposed to this point of view:

“Absolutely not. In fact, one cannot live without it at any degree. One should have the capacity of not being afraid of an abstract formulation of any discipline, and even more so for sciences. It would be madness that someone suggested removing mathematics or said it is not necessary. Anyone that tries to do forecasting or modelling will need it.”

Lastly, respondent D insists on the ‘error’ of thinking of mathematics as being unique:

“I would say that if the mathematics taught in secondary schools were well understood by a large percentage of students, one would not need much more mathematics, especially in the more general subjects. The problem is that this is not the case. It is a different matter when one needs some type of specialization that requires some specific mathematical tool. But it would be a mistake to think that all kinds of biologists require the same kind of mathematics.”

3. CONCLUSIONS

One of the main characteristics of ‘applicationism’, which represents one of the strongest restrictions on the normal life of mathematical modelling, is that it establishes a *clear distinction between mathematics and the rest of natural sciences*.

It is furthermore supposed that both ‘worlds’ evolve with independent logic and without many interactions. This fact, which partly results from the first three indicators of applicationism, leads to greatly reduce the possible ways of teaching *mathematics as a modelling tool* for the study of scientific systems. In general the mathematics that are taught at first year sciences degrees present a highly stereotyped and crystallized structure that does not mingle with the systems that are modelled and, besides, the taught mathematics are never ‘modified’ as a consequence of being applied in the construction of such models.

This radical separation between mathematics and natural sciences makes it very difficult for students to consider *mathematics as a constituting tool* of natural sciences and, thus, to value the necessity of its learning. This is one of the most generic restrictions that hinder mathematics teaching at this level, a restriction that appears at the general levels of *society* and *school* at the scale of didactic codetermination levels.

Our research on the implementation of modelling activities into the teaching system through ‘Study and Research Courses’ (Barquero *et al.* 2008 and 2010b) shows, on the contrary, how problematic scientific questions can be successfully situated at the origin and core of the mathematical activity that is taught in natural sciences degrees. It has been seen how the study of these questions starts a process of mathematical modelling that ends up with the construction of an entire mathematical organisation. This ‘first’ process generates new questions of an extra-mathematical nature that must not be abandoned or ignored but must generate new modelling processes. In these dynamics it no longer makes sense to think of two kinds of different and independent logic that rule both ‘worlds’, the mathematical one and the world of the rest of the scientific disciplines. It even becomes necessary to think of a single world, the world of scientific activity of which mathematical modelling is an integral part.

Another restriction of ‘applicationism’ on the life of mathematical modelling shows up in the usual organisation of mathematical study programmes taught at natural science degrees. In fact, neither the structure given to the contents nor the way of developing them in class make it possible to carry out mathematical modelling work based on the study of problematic questions that arise in scientific fields which are close to the speciality chosen by the students. The *raison d’être* (mathematical or extra-mathematical) of the contents, which are part of this basic mathematical training the students need to acquire, is not part of the study programme. The ‘modelling activity’ is restricted and limited to the simple illustration or occasional and anecdotal exemplification of certain pre-established models to systems fitted out with pre-established problems. This set of restrictions, which greatly limits the ‘nature’ and ‘structure’ of the possible mathematical activities taught in natural sciences degrees, may first of all be situated at the levels of *pedagogy* and *discipline*. However, these restrictions have a great impact on the more specific levels, that is,

on the specific way how mathematics taught are organized in *areas, sectors, themes* and *questions*.

The characterization of ‘applicationism’ appears as a useful tool to analyse the *restrictions* on the life of mathematical modelling which are derived from the current interpretation of mathematical activity and its role in natural sciences. It seems clear that research cannot ignore the proper level of the scale of levels of co-determination in which these restrictions appear, as general a level as it could be. Only by knowing these restrictions well, will we be able to put forward the necessary conditions to achieve a ‘real’ integration of mathematical modelling, conditions that have to take into account the necessary evolution of the prevailing epistemology and the establishment of a ‘new epistemology’ as, for instance, the one proclaimed by Chevallard (2006). These are the questions that lead our current research project.

DESIGNING ALTERNATIVE UNDERGRADUATE DELIVERY: OIL & MASSAGE

Bill Barton

The University of Auckland

As we reconsider undergraduate mathematics, we need to pay attention to theory, practice, research, and development. I draw on a theory-building project, an intimate examination of practice, a radical re-examination of undergraduate delivery, and diverse research literature, to identify some key features of undergraduate mathematics education. The interplay of constructs labelled 'mathematical essence' and 'learning culture' emerges as a useful focus of attention for my understanding of the undergraduate teaching and learning. Not only does it encompass the recurring themes of the three activities, but, connected with the concept of 'curricular contribution', it helps me design new developments and research questions.

Key words: undergraduate mathematics, research framework, mathematical knowledge, learning culture.

Sheer pleasure is any academic's reaction to fortuitous conjunctions of their teaching practice, current research, and aspirations for development. It should be no surprise that validated insight and significant advance in understanding also result. This year I have experienced such a feeling as I engaged with colleagues in three activities concerned with the undergraduate experience. My aim has been to find a way to explain, or even just talk analytically about, some phenomena of the undergraduate mathematical environment. This paper creates a framework that will help.

Two features of mathematics learning emerge, Phoenix-like, from recurring discussions in all three activities. The Phoenix refers to the resurrection of ideas that can be found in much mathematics education literature, but they are burnished anew by a focus on undergraduate mathematics, and the intimate examination of practice. I identify these constructs as 'mathematical essence' (the real oil) and 'learning culture' (the pedagogical environment that massages our actions).

But let us start by describing the three activities, and follow with three recurring themes within those activities.

THREE ACTIVITIES

Research: Videoing Lecturers

In 2009 a group of researchers began a three-pronged investigation of undergraduate mathematics. The Lecturer Perspective component, based on Alan Schoenfeld's 'Knowledge Orientation Goal' framework (2008), involves a group of lecturers videoing their lectures and discussing excerpts as a professional community. As one of the lecturers involved, this intensely personal experience has given me insights

into both my own practice, but also my own practice *vis a vis* that of my colleagues (Barton, Oates, Paterson, & Schoenfeld, 2009). The Student Perspective component builds on the work of Rodd and Bartholomew (2006) characterising the mathematical identity of university students (both mathematical majors and others). The Interactions component focusses on the way questions can be used in lectures and tutorials to promote deeper mathematical engagement.

A Public Lecture: The Pleasure Principle

In April, 2010, I argued that undergraduate mathematics was founded more on tradition and habit than on any consideration of educational aims or research. The US National Research Council report *Revitalizing Undergraduate Mathematics* (1991) endorses and gives detail to such a view. The challenge to my department to consider a radical revision of how we present mathematics to undergraduates has been taken up. A group are preparing a proposal for a course in mathematics for those not intending to major in the mathematical sciences. Given the economies of scale of the existing course (that is, existing student/staff ratios and workloads), how might we rationally design the programme for improved learning? Can we design a course that will give non-majoring students a sensation of the intense pleasure in mathematics experienced by researchers (see related discussion in Madsen & Winsløw, 2008)?

Theory: Building a framework

During 2010 an opportunity arose for researchers in England and New Zealand to meet three times to discuss a framework for describing undergraduate mathematics. Previous frameworks (e.g. APOS theory of Dubinsky and colleagues, see Asiala et al., 1997) focus on learning theory more than the whole environment. The framework is intended to help us formulate research questions that will explain the phenomena we observe in mathematical science teaching and learning. The meetings were driven by an awareness that much of the existing mathematics education research literature is based on school assumptions. In what ways is the undergraduate experience different and similar? What research conclusions are likely or unlikely to be valid? What frameworks are in use in undergraduate research, and what important issues are being overlooked? Opportunities for a wider-ranging approach exist in the recent emergence of university centres dedicated to undergraduate learning and teaching at The University of Auckland (CULMS <<http://www.math.auckland.ac.nz/CULMS/>>) and Loughborough University (MEC <<http://mec.lboro.ac.uk/>>).

RECURRING THEMES

Recurring Theme #1: Responsibility for learning

The most explicit recurring theme in the three activities is student responsibility for their own learning. It was quickly identified as a significant point of difference between school and undergraduate environments in the theoretical framework

Working Group 14

discussions. In schools, teachers assume (or have thrust upon them) responsibility for getting the students to complete homework, engage in tasks in class, and reach mathematical understanding. At university, voluntary lecture attendance may be ameliorated by terms requirements of tutorial participation or assignment submission, but failure is firmly a student failure, not a lecturer failure. In our developmental discussions of course delivery mechanisms, it is no surprise that university conventions around lecture and tutorial attendance are also major issues. However the complexity of learning expectation and responsibility was driven home in the research activity when examining a video-tape of my own lecturing.

With my senses honed by the accompanying critical eyes of my colleagues, I saw myself on video act under unwarranted assumptions about what students would do to support their own learning, and also I undermined their learning independence. For example, several times I adjusted my expectations of what the students would have done with respect to revision of the previous lecture, thereby eventually removing all consequences of a student not having taken the responsibility for getting themselves prepared. Alerted to the phenomenon, I saw repeated versions of it in subsequent videos of both myself and my colleagues. The unintended changes in outcome are reminiscent of the Topaze effect of Brousseau's theory of didactic situations (1987, p25). Recent analysis of this effect in undergraduate mathematics has been done by Grønbaek, Misfeldt and Winsløw (2009).

The combined effect of these experiences is an awareness of the interaction between the assumptions and the actions of lecturers and students. We claim increased student independence at university, but as lecturers we may rarely address the issue explicitly and our actions may counteract any statements of expectation. The didactic contract (to again use Brousseau, 1987) is complex, and our resulting actions can be contradictory, in my own case at least.

Recurring Theme #2: The Discipline of Mathematics

A second theme to emerge from all three activities is an abiding concern for mathematics as a discipline—and this word is intended in both meanings. Mathematics is a field of enquiry, and mathematics is a mode of being. I include the connotations of strictures and suffering. Our theoretical framework discussions repeatedly harked back to the role of research mathematicians as pedagogues and how that defined some aspects of university education both positively (direct contact with the discipline and authentic mathematical “modes of enquiry” (Watson & Barton, 2010)) and negatively (lack of attention to pedagogical theory). Our course development discussions very rarely descended into arguments about content or sequencing, but often reached swift agreement on the need for ‘mathematical habits of mind’ and extended debates about what, exactly, these constituted. The group contained several mathematicians, and personal accounts of wrestling with mathematical problems at the research level exposed a common core of experiences and emotional attachments that would be beneficial for students, even those not

Working Group 14

entering mathematical careers. The ultimate aim of non-continuing mathematics courses were expressed as the ability to recognise the mathematical nature of a problem and not fear the need to address it, possibly by learning new mathematics for oneself. Much discussion concerned the nature of a mathematical mind.

Attention to the ‘mathematicality’ of the undergraduate experience emerged also in the videos of lectures. We noted a difference between lecturers who were mathematics educators and lecturers who were mathematicians. The former, who came from school teaching backgrounds, expressed concern about the correctness of their mathematics and wanted to discuss the mathematical implications of the videoed excerpt. The latter, who have mathematics research credentials, were more worried about the pedagogical consequences of their actions. Judy Paterson referred to this as our teacher selves and mathematical selves, focusing attention on the way our conceptions of ourselves affects the teaching, and hence learning, experience.

In both the development and research environments the correctness of the mathematics is also regularly discussed. On the surface the discussion is about how much an introduction to a mathematical concept can be limited in the interests of simplicity, and what are the downstream effects of the resulting misconception. For example, what are the consequences of introducing all vectors as free vectors for later definitions of vector spaces? Differing perspectives of the same concept is related to what Mike Thomas calls versatile thinking (Thomas, 2008) and developing students’ ability to “see” many perspectives is non-trivial.

But correctness in the sense that there is a right way to present material also implies a certain attitude towards mathematics, or at least towards undergraduate mathematics education. A focus on correctness, especially when the teaching mode is a transmission one, conveys the assumption (intended or not) that mathematics is a given—it is like this, learn it and use it in this way. Any other way is wrong. That such a view is, in fact, held by many mathematicians emerges from Leone Burton’s (2001) study of seventy mathematicians. Such an attitude contradicted our other discussions about the essential nature of mathematics being a rational exploration of the consequences of possible constructs, and the idea (also found amongst mathematicians in Burton’s study) that mathematics is a social construct.

In all three activities the changing and contemporary nature of mathematics was also discussed (Lóvasz, 2006). Compared with the average ten-year period for major school curricular revisions, university courses are minimally revised individually rather regularly, but the whole programme is typically extremely stable over long periods. Personal and factional investments in each part of the programme make changes to keep pace with the evolution of the subject very difficult.

Recurring Theme #3: The Tyranny of Examples

Viewed cold, I was surprised at how much my lectures focused on doing examples and exercises rather than teasing out problems, asking open questions, or exploring

deep understanding. Compared with my goals (which the research project required me to write down prior to the lecture and reflect on afterwards), I devoted a much larger proportion of the time available to short-term technicalities of standard mathematical exercises.

The mathematical paucity of practice like mine has been noted before many times.

Just as any sensitive human being can be brought to appreciate beauty in art, music or literature, so [they] can be educated to recognize the beauty in a piece of mathematics. The rarity of that recognition is not due to the “fact” that most people are not mathematically gifted but to the crassly utilitarian manner of teaching mathematics and of deciding syllabi and curricula, in which tedious, routine calculations, learned as a skill, are emphasised at the expense of genuinely mathematical ideas, and in which students spend almost all their time answering someone else’s questions rather than asking their own. (English mathematician and Bletchley Park code-breaker, Peter Hilton, 1998)

Nevertheless the dominance of exercise mode, and the perception amongst students (enhanced by assessment practices) that successful mathematics means solutions to exercises, is an enduring phenomenon in schools and universities. Changing students’ focus on exercises emerged as a problem to be solved in both the theoretical and developmental discussions.

EMERGING CONSTRUCTS

These three (and other) recurring themes speak to both the mathematics and the learning culture. The parallels with Bernstein’s concepts of classification and framing are noted, and his strong and weak characterisations can be applied (Bernstein, 1990).

What I wish to call the “mathematical essence” refers to the focus on mathematics not just as a syllabus list of content, but as a research and practical discipline. Mathematics in all its manifestations is the “real oil” that makes learning at this level different. At university level, practitioners in the field interact with learners for the first time. How they act shapes the perception of mathematics, its nature, its uses, and what it is like to act mathematically. Mathematical essence has several components which we can, artificially, categorise into three groups: content and ‘horizon’ knowledge (Ball, 2003); processes, habits of mind (Cuoco, Goldenberg, & Mark, 1996) or modes of enquiry (Watson & Barton, 2010); and attitudes and VPRO’s (an amalgam of values, philosophy, roles and orientations, (see Barton, 2009)). We know sufficiently well from the research literature in each of these areas that all aspects of the mathematical essence need to be taken into account in any framework that purports to characterise undergraduate mathematics teaching and learning.

On the educational side, rather than approach teaching and learning from a pedagogical perspective, I argue (from the experiences above) that it is more

Working Group 14

productive to consider the students' and lecturers' personal experience of pedagogy, that is, take a cultural point of view. Hence I will talk about a learning culture.

The concept of a learning culture is common in business (for example, Conner & Clawson, 2004) where it refers to the atmosphere in a corporation that either promotes or hinders development (in particular of management) in such matters as client relations or employee participation. Culture massages us in particular ways. In the undergraduate mathematics environment I use the term to refer to the expectations, intentions and actions of both students and lecturers with respect to pedagogical structures (many of which will be university conventions). For example, what do lecturers and students expect of, and how do they respond to, grading requirements, the physical layout of lecture theatres and tutorial rooms, enrolment processes and prerequisites, course guidelines and notes, opportunities to interact, and a myriad of other components of university life?

Another way of understanding learning culture is through the concept of the hidden curriculum (Snyder, 1970). He discusses the inferred tasks a student experiences "that are rooted in the professors' assumptions and values, the students' expectations, and the social context in which both teacher and taught find themselves" (Chpt.1.) and notes that neither professors nor students desire the resulting study habits.

Perceiving the educational situation in a personal way enables me to examine actual events rather than abstract constructs: I am forced to think about how I write an examination (and what that means) rather than examinations themselves as objects; I must worry about the advice I give to students for their next courses (and how they could respond) rather than focus on calendar entries of pre-requisites; I pay attention to the use I make of my lecture time rather than to an abstract concept of a lecture.

So far, however, all I am proposing is a re-categorisation of mathematics and pedagogy, or, perhaps, a re-viewing from a more elaborate and personal perspective respectively. But my experiences this year have made me realise that my interest lies not in each of these separately, but in the interplay between the mathematical essence and the learning culture (see Madsen & Winsløw, 2008, for a detailed study of this relationship). Teaching is located in the tensions between them, and the teaching task is to make them work together to create better learning. Student learning is the background against which the effectiveness of teaching is judged.

Yet now I wish to introduce a further dimension, adapted from the work of French mathematics educator Michèle Artigue (2002). In discussing the role of technology in mathematics education, Artigue distinguishes between three "values". The pragmatic value refers to the productivity of the technology, how does it help us in the mathematical action we are currently undertaking, how efficient is it, how useful? For example, a calculator allows us to multiply real numbers efficiently without pencil and paper algorithms. The epistemic value refers to how technology helps students understand the mathematical objects they are dealing with. For example, the

Working Group 14

ability of a graphics calculator to flip between tabular, algebraic and graphical representations of a function promotes a versatile understanding of function in general. The heuristic value refers to how technology contributes to understanding future concepts, or how technology prepares students for more advanced concepts. For example, the ability of Matlab to draw first a surface, and then its contours on the domain, paves the way for a visual understanding of the grad of a function as a vector field.

Let us apply these three values to undergraduate mathematics. Let us call them curricular contributions rather than values. The pragmatic contribution refers to the way that an educational expectation, intention or action is directly addressed to the learning of some aspect of the mathematical essence. For example, what sort of assignment will contribute to a students' use of a partial derivative. Does it expand their ability to use them into other contexts, does it help the student evaluate them?

The epistemic contribution refers to the way some aspect of mathematics is more deeply understood. For example, can I write an examination that will contribute to a students' understanding of a partial derivative? Does it expand the contexts for partial derivatives, does it help a student see partial derivatives as elements of a matrix?

The heuristic contribution refers to future understanding, or future mathematical pathways. How can a lecturer increase the range of situations in which students will consider partial derivatives? What attitudes can I impart that will encourage students to learn about partial derivatives beyond that presented in my course?

Layering these contributions onto the interactions between the mathematical essence and the learning culture, I end up with a framework as in Fig 1.

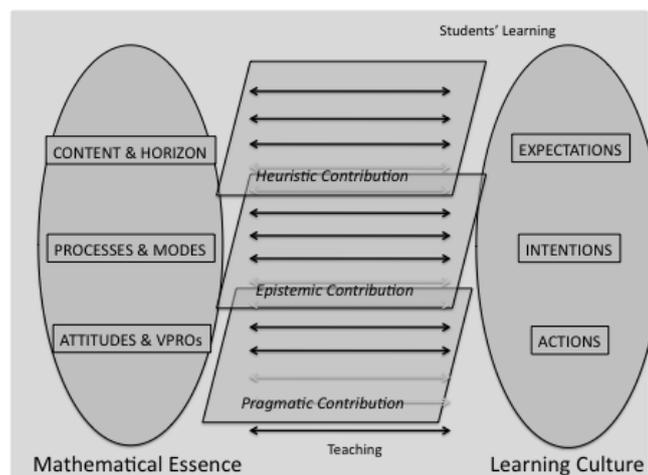

Fig 1: A model of Learning And Teaching in Undergraduate Mathematics (LATUM)

The LATUM model enables me to talk about many phenomena observed in researching, practising, and theorising about undergraduate mathematics. For

Working Group 14

example, from Recurring Theme #1, a students' acceptance for responsibility for learning is dependent on the value they put on the mathematics, whether they see it as content or a mode that is being learned, and which of the contributions they perceive to be at play (for example, a pragmatic "I need to understand this so that I can find eigenvalues from matrices presented to me in tests and examinations", or an epistemic "doing these exercises will show me what eigenvalues are all about"). We can see immediately that responsibility based on a perceived heuristic contribution ("eigenvalues are a stepping stone to advanced methods in stochastics") will only occur if a lecturer has actually pointed to such a possibility. Do we do this routinely?

Describing responsibility in this way immediately generates researchable questions of direct practical value. What are the contributions perceived to be at play by students who do take responsibility for learning compared with those who do not? Do students who take responsibility for learning focus more on modes and processes (rather than content) than their less responsible companions? What values, philosophies, roles and orientations are communicated by lecturers who best elicit student responsibility?

From Recurring Theme #2, what of the lecturers with a school background who are worried about the way they present as mathematicians? The LATUM model presents undergraduate mathematics as an interplay between learning culture and mathematical essence. A lecturer's role, therefore, is to keep the two aspects in balance, ensuring that the learning environment is not dominated by either pedagogy nor mathematics. School teachers are adept at managing a learning culture (they do not survive otherwise), and it has become second nature to most. We should not be surprised, therefore, that their attention should be on the mathematical essence, and particularly on those parts of it where they lack confidence, in order to be able to maintain the required balance. And *vice versa* for research mathematicians.

The research question arising from this is to observe the way the balance is held in a lecture or tutorial, and investigate whether bringing this to the attention of the lecturer will result in better balances. Can we treat "lecture balance" as a variable in student learning? Does better balance result in better learning?

The tyranny of examples (Recurring Theme #3) fits naturally into the LATUM model. My observation of university mathematics leads me to postulate that, in the mathematical essence, content is dominant; in the learning culture, assessment is dominant; and the curricular contribution most at play is the pragmatic contribution. Both students and lecturers buy into these preferences. The tyranny of examples is the result. Note that, in this construction, the tyranny of examples is an output of the undergraduate mathematics environment, not a cause of learning outcomes.

Hence, an intervention style research project that upsets the dominance of one (or a combination of) content, assessment, and pragmatism in a systematic way over a long period of time is strongly indicated. What will replace the tyranny of examples?

Ultimately, of course, we want to be able to manipulate the environment to produce a set of prior agreed learning outcomes. This is didactic engineering (Brousseau, 1987) on a macro scale, and has previously been theorised by Winsløw (2006).

CONCLUSION

As we teach in undergraduate mathematics courses, as we reflect and theorise about what happens, as we research questions of interest, we find that certain themes recur. These are not new insights—we can find them talked about amongst our older colleagues, and read about them in the earliest writings on undergraduate teaching. Who has sat in a common room and not heard complaints about the lack of preparation of students? Who has walked university corridors and not met enthusiastic students wanting to share their latest insight? Who has walked into a lecture theatre and never had the experience of a student coming up afterwards and asking a question that showed they lacked the prior knowledge you had assumed? Who has leaned, pen in hand, over a tutorial group and never learned something new from a student who saw a problem in an unexpected way? Who has marked finals examinations and not had moments of despair about their own ineffectualness?

The complexity of the environment requires a framework that will help us to explain, or just talk analytically about, some of these phenomena. We also need ways to ask relevant questions. I find the framework presented above helps me with some, (not all), of my wonderings as I seek alternative answers to some of my own practices.

ACKNOWLEDGEMENTS

The research project is funded by the NZ Council for Educational Research's TLRI fund. I am indebted to the work of my colleagues at The University of Auckland. The development project relies on the work of a group of colleagues from The University of Auckland's Department of Mathematics and Centre for Academic Development.

The theoretical framework project is an ongoing collaboration between Barbara Jaworski (Loughborough University), Elena Nardi (University of East Anglia), Tim Rowlands (Cambridge University), and Mike Thomas (The University of Auckland).

WHY DO STUDENTS GO TO LECTURES?

Christer Bergsten

Linköping University

This paper investigates, from a student perspective, the fact that, despite arguments put forward against the educational value of large group lectures, this teaching format prevails and attracts students in undergraduate mathematics education.

Keywords: mathematics lectures, students' attendance, case study.

INTRODUCTION

Doubts about the value of large group lectures as a teaching format at universities have been raised frequently (Bligh, 1972; Fritze & Nordkvelle, 2003; Holton, 2001). The lecture is an efficient model of teaching as an outcome of the massification of higher education. In case of an eminent scholar who presents a new theory or view, a lecture is certainly appropriate. Given that undergraduate mathematics courses are highly standardised (and so the teacher could be viewed as “exchangeable”) and often based on textbooks, the purpose of the lecture format is questionable. Students might rely on texts and might want to spend more time in study groups, where they could ask questions after studying the texts. Consequently it would be of interest to investigate how students view lectures. One can assume that they go to lectures because they get something out of it. In this paper it will be discussed what this “something” may refer to. Reasons may not only be related to learning mathematics as disciplinary content, but also to issues such as becoming informed about examination specifics or social issues such as participation in the academic community.

RESEARCH ON MATHEMATICS LECTURES

Fritze and Nordkvelle (2003) identify, from a systems theory perspective, three different functions of a lecture. The lecture reflects both scientific truth, by ways of argumentation and reflection, and educational decisions in order to make this scientific content accessible to students. Thirdly, since students regard lectures in a course as “a part of a socialization scheme”, the lecture takes on a third function of an “organization activity” (ibid., p. 232). The case study reported in this paper, aimed at further differentiating the first two of these functions.

Much of the literature on tertiary mathematics education focuses on the quality of teaching and learning of subject content matter (e.g. Bradley, Sampson, & Royal, 2006). In the general context of tertiary education, Biggs (2003, p. 75) lists four aspects of teaching/learning that from the literature seem to support quality learning of content matter: (i) a well-structured curriculum; (ii) an appropriate motivational context; (iii) learner activity, including interaction with others; and (iv) self-monitoring. The minimal extent to which the third of these categories applies to large group lectures has been given as an argument for the low learning potential of

lectures (Fritze & Nordkvelle, 2003; Bligh, 1972). However, what the “learner activity” consists of remains unspecified. The educational value of large group lectures has been questioned for several additional reasons:

- students’ attention cannot be maintained during a whole lecture (Bligh, 1972);
- lectures are often not understood by the students (Rodd, 2003, p. 15);
- lectures are most often linearly well ordered outlines of a ready made mathematical theory, not offering a view of mathematics as a human social activity, coloured by creativity, struggles, and other emotional aspects involved in mathematical activity (Alsina, 2001; Weber, 2004), thus showing only what sometimes is called the “front” of mathematics and hiding the “back”;
- students do not learn much from lectures (Leron & Dubinsky, 1995);
- lectures are not effective in stimulating higher-order thinking (Bligh, 1972);
- lectures do not provide feedback and social interaction (Bligh, 1972).

However, despite such research results on lecturing, “the lecture survives, probably because it serves many functions not so well observed in the present research” (Fritze & Nordkvelle, 2003, p. 328). Rodd (2003) argues that “university mathematics departments recognise the potential of lectures, not as information-delivery venues, but as a place where the ‘awe and wonder’ of mathematics can be experienced” (p. 20), and claims that ‘active participation’ and ‘identity and community’ can also be experienced as a ‘witness’, similar to the act of experiencing a theatre play. Effects of inspiration may thus be an essential outcome from a good lecture. Related to this, the lecturer as a person, and humour, have been seen as critical for how lectures are appreciated (Fritze & Nordkvelle, 2003). The notion of *teacher immediacy* (Frymier, 1994) thus refers to issues of closeness in classroom student-teacher interaction. Arguments for the importance of *personalisation* in a mathematics context can be found in several studies (Anthony, 1997; Anthony, Hubbard, & Swedosh, 2000; Forgasz & Swedosh, 1997), and the lecturer can be seen to provide a personalisation of the formal mathematical discourse (Anthony et al.; 2000; Wood & Smith, 2004). Inspiration is also emphasised by Alsina (2001, pp. 3-6). Weber (2004) identified three teaching styles used in undergraduate mathematics (small group) lecturing. In the *logico-structural* style a strictly formal way of working was used. While the *procedural* lecture style had the main focus on the technical work, the *semantic* style emphasized the intuitive meanings of the concepts. In large group lectures these styles can be mixed (e.g. Bergsten, 2007), as well as the linguistic modes used. Wood and Smith (2004) noted that “[l]ecturing is a mixed mode activity” (p. 3), using verbal and non-verbal means to organise students’ attention to “written language, mathematical notations, visual diagrams” (p. 3). The authors also noted that “in the spoken text... the lecturer makes use of a range of words like *actually*, *fairly*, *obviously* to personalise and introduce values and judgments into the presentation” (p. 7). Wood and Smith conclude that these

differences of modes and representational forms require a lot from the students. The study by Anthony (1997) showed that the importance given to lectures was higher by students than by lecturers, both for success and failure, including “boring presentations of lectures” and “non attendance of lectures.” Students also “placed more importance than lecturers on active learning and note-taking” during lectures. Successful students found “the availability of worked examples in lectures and tutorials” and “clear presentation of lectures” more important than did non-successful students (pp. 60-61). Moreover, the study by Hubbard (1997) showed that students value the information about what is “important” provided by lectures but are often dissatisfied with the format of a lecture as well as lecturers’ ability to teach. This may well be due to a discrepancy in beliefs and perceptions about the role of lectures between lecturers and students (Anthony et al., 2000, p. 250).

In the case study by Bergsten (2007) of a mathematics lecture in a large group of first year engineering students, a key observation was how the complexity and richness of different educational aspects of a lecture in undergraduate mathematics can come into play during a time of only 90 minutes. Within a TPA format (theorem-proof-application), the observed lecture/lecturer was content-driven and rich in information; used a mixed mode of semantic-procedural teaching styles; exhibited a formal separation of theoretical and practical knowledge; showed an overall strong coherence, higher in rigour than the aims stated; displayed a dominance of an algebraic mode over an imagistic; was rich in gestures and informal language but at the same time establishing mathematical norms for the course and for Mathematics; created a relaxed atmosphere of doing mathematics as it seems together; and used various semiotic means to objectify the target knowledge, as he conceived it, for the students. With an aim to structure this complexity, Bergsten (2007, pp. 69-70) outlined a systemic triangular model for critical characteristics of a mathematics lecture, consisting of mathematical exposition, teacher immediacy, and general quality criteria for mathematics teaching. Mathematical exposition involves the dynamic interplay of mathematical content, mathematical process, and institutionalisation.

A CASE STUDY

Method

Lectures make up a substantial component of beginning calculus courses in many university engineering and science programmes. These lectures are directed towards large student populations and thus have a major impact on mathematics education at the tertiary level. It was therefore an obvious choice for this study to choose lectures within this context. The case studied, two experienced lecturers running a calculus course with engineering students, one group of 141 engineering students specializing in industrial economy, and one group of 132 students studying physics and electric engineering, thus represents a common situation for the problematique in focus.

Working Group 14

All data were collected by the author, who videotaped the lectures (which took place in an early part of the course), distributed and collected a questionnaire immediately after the lectures, and interviewed a sample of the students attending the lecture (after the lectures). In this paper only data from the questionnaire will be reported.

Bergsten (2007) identified critical aspects that could influence students' appreciation and attendance of lectures. These aspects provided the basis for the questionnaire used in the present study. To enhance validity, the questions in Part 2 (see Table 1) were discussed with a research colleague and tried out in a small pilot study before the final questionnaire was used. It employed four level Likert items and was structured in three main parts; Part 1: four items concerning attendance, reading and note taking (see Table 2); Part 2: 16 items on views about lectures in general; Part 3: 18 items on views about the particular lecture just attended. The answers could be commented and a final open question was asked. In this paper the analysis will focus only on Part 1 and Part 2 of the questionnaire. The items in Part 2 were designed to address the overall question *Why do students go to lectures?* more or less explicitly (item group A), more implicitly by asking on some specific issues that should be provided by lectures (item group B), or by asking if some aspects count as important for mathematics lectures (item group C). Finally, two questions were asked (item group D) to investigate whether students find that lectures generally employ too much formal mathematics. On the following statements in Part 2 of the questionnaire the students were asked to mark one of the categories Fully Agree, Agree, Partly Agree and Disagree. The items from the different groups were mixed in the questionnaire according to their order numbers given in Table 1:

<i>Group A items</i>	1. It is easier to understand the course material by attending a lecture than reading the textbook only 2. It is from the lectures that one understands what is important for the examination 7. It is by way of the lectures that I learn to understand what proof is and why proof is needed
<i>Group B items</i>	4. A mathematics lecture should link the pure mathematical results to applications outside of mathematics 6. A mathematics lecture should present formal definitions and proofs for those mathematical concepts and results that are being treated 12. Lecturers in mathematics should sometimes use everyday language, gestures and diagrams to illustrate the mathematical concepts and methods used 14. A lecture should provide extra inspiration to continue working with mathematics 15. A lecture should make the strength and beauty of mathematics visible 16. A lecture should include some humour
<i>Group C items</i>	3. It is better when the lectures cover as much as possible of the content of the course, instead of going into some selected topics more deeply

Working Group 14

	<p>5. In lectures in mathematics it is important to show methods for solving theoretical tasks and tasks where mathematical definitions and theorems must be used</p> <p>8. It is more important that a lecturer in an intuitive way explains the meaning of the mathematical concepts and results than providing formal definitions and proofs</p> <p>10. It is better to highlight the important ideas in a proof than doing each step of the proof in detail</p> <p>11. In a lecture it is more important with examples that show how to solve tasks than to prove the theorems that are used</p>
<i>Group D items</i>	<p>9. The lectures in mathematics normally employ too much algebraic calculations</p> <p>13. The lectures in mathematics normally employ too much proof</p>

Table 1: Part 2 of the questionnaire with items ordered by groups.

In addition to answer frequencies, a simple correlation analysis was performed to base the interpretation of the data. The answers were also analysed for each of the two lecture groups, showing no significant difference between the groups concerning the frequency distributions, or pair wise item correlations for Part 2. This homogeneity can also be interpreted as an indication of reliability, as the groups are comparable in terms of previous mathematics studies.

Questionnaire results

In this section the results from the questionnaire will be presented before discussing them in the section that follows. Table 2 shows that more or less all students who attended the observed lectures always go to the calculus lectures, while the attendance to the classes (study groups) is lower but still high. A great majority of the students also take extensive notes during lectures. This strong focus on the importance of lectures is also witnessed by the high percentage of students who do not study the corresponding sections in the textbook in parallel.

Statement \ answer category	always	often	sometimes	rarely	N
I attend the lectures in this course	92	7	0	1	273
I attend the classes in this course	58	33	6	3	273
	almost everything	a lot	a little	almost nothing	
During lectures I normally take notes on	85	11	2	2	271
	before	after	both	neither	
I normally read the relevant chapter in the textbook before or after the lecture	8	35	12	44	266

Table 2: Part 1 of the questionnaire: Statements and frequencies (%).

Working Group 14

In Part 2, the answers to item group A (see Table 3) point to the common view among the students that by attending lectures it is easier to understand the content than only by textbook study; one understands what is important for the exam; and one learns to understand what proof is and why it is needed.

On group B items the students agreed or strongly agreed that a lecture should present formal definitions and proofs for those mathematical concepts and results that are being treated; sometimes use everyday language, gestures and diagrams to illustrate the mathematical concepts and methods used; provide extra inspiration to continue working with mathematics; make the strength and beauty of mathematics visible; and include some humour. The students agreed or partly agreed (on item 4) that a lecture should link the pure mathematical results to applications outside of mathematics.

Item	Fully Agree	Agree	Partly Agree	Disagree	Mean	Median	N
1	81	15	4	1	1.3	FA	273
2	25	51	22	2	2.0	A	271
7	23	40	31	6	2.2	A	269
4	16	41	36	7	2.4	A	269
6	28	42	25	5	2.1	A	269
12	56	31	10	3	1.6	FA	273
14	41	40	16	3	1.8	A	272
15	34	41	20	5	1.9	A	269
16	59	29	8	3	1.6	FA	273
3	33	42	21	4	1.9	A	271
5	62	30	7	1	1.5	FA	270
8	45	40	13	2	1.7	A	269
10	40	34	19	7	1.9	A	267
11	43	31	22	4	1.9	A	273
9	1	12	51	36	3.2	PA	263
13	11	29	42	18	2.7	PA	272

Table 3: Frequencies (%), means and medians for Part 2 of the questionnaire (ordered by item groups; A: 1 2 7, B: 4 6 12 14 15 16, C: 3 5 8 10 11, D: 9 13).

Within item group C the students agreed or strongly agreed that it is better when the lectures cover as much as possible of the content of the course, instead of going more deep into some selected topics, indicating that students want lectures to give a full overview of the course; it is important to show methods for solving theoretical tasks and tasks where mathematical definitions and theorems must be used; it is more important that a lecturer in an intuitive way explains the meaning of the mathematical concepts and results than providing formal definitions and proofs; it is better to highlight the important ideas in a proof than doing each step of the proof in detail, and it is more important with examples that show how to solve tasks than to prove the theorems that are used.

The answers to item group D showed that the students generally do not find that lectures employ too much algebraic manipulations or proof. Individual correlations

Working Group 14

between the items 1-16 are shown in Table 4, which is structured by item groups A-D (within group correlations are marked in bold). The item groups A, B, C and D are analytically defined and not empirically observed categories. Therefore correlations between items from different groups are also to be expected, due to their content in other aspects than those defining the groups. Nevertheless, it is evident from Table 4 that items within the item groups are positively correlated (to different degrees), most strongly in group B with items related to the teacher immediacy dimension. One exception here is item 6. This item correlates naturally with item 7 and that items 6 and 7 both have a negative correlation with item 13 makes sense. However, the negative correlation between item 6 and both items 8 and 11 opens up for the interpretation that the students want the lectures to present formal aspects of mathematics but that intuitive and exemplary ways of explaining are seen as more important ingredients of a calculus lecture. The strong correlations between the three items 8, 10 and 11 within group C point to a preference among the students for a more intuitive presentation of mathematics than giving full formal proofs, an interpretation supported also by the positive correlations between item 13 and items 8-12. Item 12 correlates naturally with several items (on intuition, ideas and examples), thus indicating how those presentations are preferred.

Table 4: Pearson correlations between individual items of Part 2 of the questionnaire.

To the final open question: *What is it that makes a good lecture?*, there was a great variety among the 200 answers delivered. A first categorization of around 50 different aspects was made, where the most common were the following (with the number of comments found in brackets along with some illustrative student quotes):

- The lecturer as a person (100; e.g. inspiration 38, humour 26, engagement 17, pedagogical 9, using easy and clear language 5). Quotes: *The charisma of the lecturer!* ; *Humour and contact with the audience*; *That it is easy to listen to the lecturer, not boring or monotonous*; *The lecturer speaks clearly and uses*

Working Group 14

an everyday language. The lecturer should also be funny so that I do not fall asleep during the lecture.

- Demonstration of examples (40; how to do it, usefulness for exams). Quotes: *Examples, examples, examples, how to solve the problems. Tricks and methods to approach the tasks; Many examples, applications so that one understands how to use theorems/proofs.*
- Good explanations, to support understanding (35; one can follow, what it is for, why it works). Quotes: *When it says click and you feel you understand a problem and the structure of its solution, then mathematics all of a sudden is fun!; Illustrative diagrams and the engagement of the lecturer.*
- Clarity (33; not skipping linking details, structure). Quotes: *A good structure, with a mix of theorems, proofs, examples and humour; Structure and good writing on the whiteboard; That you understand what the lecturer is saying.*
- A comfortable pace (20; not too quick, not too slow, calm). Quote: *Pace combined with understandability.*
- Coherence (15; read thread). Quote: *A red thread that is interesting to follow.*
- Good mix between theory and methods (11). Quote: *A good mix of examples and theory, and an inspiring lecturer.*

Some students gave only one or two aspects, while others combined several to a whole. Further comments pointed to the importance of a good balance of level of difficulty and pace, also to be able to take notes. Interesting mathematics and applications were asked for, as well as providing a good complement to the textbook and aha-experiences, and be forced to be active.

DISCUSSION

Students in this study go to lectures. In the previous study (Bergsten, 2007), the interviewed lecturer also stated that his students normally go to the lectures:

I don't know why. It is an easy way to get something done, they think they can use things from the lecture, collect materials, thinking the lecturer will say something that is useful for the exam. (p. 63)

The data presented here show that students do not only value such usefulness. Explicit answers to the main question *Why do students go to lectures?* point to the view that it is easier to understand the mathematical content of the course by attending lectures than only by studying the textbook. Another reason is that one understands what is important for the examination, as found also by Hubbard (1997), and what mathematical proofs are and why they are needed. There is a strong emphasis on the value of both, intuitive explanations (diagrams, metaphors, gestures) and formal presentations (definitions, proof, algebraic calculations), as well as examples, but less strong need of applications from outside mathematics. The data indicate that that the semantic mode of presentation is a stronger factor in attracting students to lectures than the procedural or logico-structural style (in the sense of

Weber, 2004), even if clarity and coherence were emphasised. It was a strong agreement among the students about the importance of teacher immediacy, that the mathematics lecturer should inspire to study mathematics and use humour, make the strength and beauty of mathematics visible, and use everyday language, gestures and diagrams to illustrate the mathematical concepts and methods used. The dissatisfaction with the lecture format and the lecturers' teaching ability, as found by for example Hubbard (1997), was completely absent in the questionnaire responses reported here. The high attendance as well as the closed form items and the open comments indicate, rather, that the opposite view was dominating. In relation to Bergsten's (2007) triangular model for a quality lecture, the importance of the dimensions teacher immediacy and mathematical exposition find strong support in the data presented here, while general criteria for quality teaching (Biggs, 2003), not directly addressed in the questionnaire, are more implicit in aspects such as coherence, clarity, applications, pace, and student activity in terms of note taking.

That lectures have impact on the students at a diversity of aspects and levels was evidenced by the great variety of descriptions on what characterizes a good lecture. This points to the complexity and "richness" of the lecture format, as discussed above with reference to Bergsten (2007). It is clear from the students' open comments in the present study that one main reason for the "success" of a lecture is given to the lecturer as a person, being able to engage and inspire the students. This emphasis on teacher immediacy has been pointed to by several authors and can be seen as part of the game of lecturing, as features of acting. Illustrating also adds non-symbolic and non-discursive elements to the semiotic objectification of knowledge, which can function as critical elements in the meaning-making processes of the students. Wood, Joyce, Petocz and Rodd (2007) found that despite availability of textbooks and online material, for their learning students value lectures higher.

Other aspects mentioned by many students in the questionnaire, such as clarity and coherence, a mix of (many) examples and theory, an optimal pace, clear language and writing, can be related more to lecturers' pedagogical awareness (Nardi, Jaworski, & Hegedus, 2005) than personal *charisma*. An aspect less discussed in the literature is the importance of the opportunity for students to take notes. From the data in this study, including student interviews not reported here, it is evident that this is a student activity component of the lecture format that is essential for what the students' get out from attending a mathematics lecture.

The results presented here will be critically discussed in the full study, where all questionnaire data will be analysed in relation to student interviews and an analysis of the video recorded lectures as well as interviews with the lecturers.

ACKNOWLEDGEMENT

The author wishes to thank Eva Jablonka for sharing her knowledge in the field through critical comments during the writing of this paper.

DESIGNING AND EVALUATING BLENDED LEARNING BRIDGING COURSES IN MATHEMATICS

Biehler, R.*; Fischer, P.R.**; Hochmuth, R.**; Wassong, Th.*

* University of Paderborn, Germany, ** University of Kassel, Germany

Varying mathematical skills, rising dropout rates and growing numbers of first year students confront the universities with major organizational and pedagogical problems. This paper describes an innovative way of teaching and learning that claims to improve this situation by specific bridging courses particularly including self-diagnostic e-assessment and supporting self-regulated learning. In order to give an overview of our whole bridging-course programme we will discuss our material with regard to content-related and pedagogical aspects as well its integration in various course scenarios. Focusing on selected results of an accompanying evaluation study we will finally substantiate the acceptance and success of our courses and highlight some interesting findings regarding our learners.

Keywords: bridging courses, eLearning, blended learning environments.

INTRODUCTION

The transition between school and university studies is a difficult one. The gap between school and university seems to be larger in mathematics than in other subjects (cf. Gueudet, 2008, Bescherer, 2003, de Guzman, 1998, Holton, 2001, Tall, 1991).

In 2003, the project VEMA – “**V**irtuelles **E**ingangstutorium **M**athematik (Virtual Entrance Tutorial for Mathematics) (<http://www.mathematik.uni-kassel.de/vorkurs>) started the development of multimedia resources primarily for supporting the pre-term bridging courses, which are intended to bridge this gap. VEMA was initiated at the University of Kassel and was extended to the Universities of Darmstadt and Paderborn later on. During the years the project extended its concern and redesigned the whole pre-term courses by new course scenarios that better integrate the multimedia learning material into the course. The material as well as the course scenarios have been continuously improved taking into account our yearly experiences and evaluations.

THE INTERACTIVE MATERIAL OF VEMA

The content of the VEMA-material

In order to support students to individually recapitulate certain topics we decided to structure the content into small learning units called “modules”. Each module essentially concentrates on one mathematical topic. In its latest version the learning material contains six chapters: “Arithmetic”, “Powers”, “Functions”, “Higher Functions”, “Analysis” and “Vectors”. On average each chapter has about 10

modules. The clear module-structure supports self-regulated learning and helps teachers in choosing content suitable for the field of study of their students.

Structure of a learning unit

We chose a well-defined and consistent structure for all modules, i.e. each module consists of identical types of *knowledge units*. This structure helps learners in their navigation through the material, which is further supported by the layout of the interactive book: There are two navigation frames. One enables learners to choose the modules to which they like to switch and the other enables selecting the different units of a chosen module by clicking on the corresponding icons.

The structure of a module mainly consists of the units: *overview*, *introduction to the domain*, *info*, *Info/Interpretation/Explanation (IIE)*, *application*, *typical mistakes*, and *exercises*. Before and after learning with a module, learners can perform a *diagnostic test* to assess their knowledge of the domain.

- i. The *diagnostic pre-test* contains 4 to 5 exercises and gives the opportunity to the students to test their pre-knowledge concerning the content of the module. After a student has performed all tasks, the system automatically corrects his answers and provides feedback in form of a score for each exercise and for the test as a whole, a model solution, an individual feedback on his mathematical competencies and provides learning advice for further working on the module. With this individual feedback the students are supported in structuring their learning.
- ii. Then the modules start with the *overview* unit, which essentially consists of a list of the major topics and learning goals.
- iii. The second unit is called *introduction to the domain*. It uses discovery-based, inductive and exemplary approaches to familiarize the learner with the content. We also support the knowledge construction process by interactive exercises: learners have the opportunity to make mistakes, to withdraw them and to recapitulate the task until finding a correct solution. The content is presented to learners on a concrete level, with visualizations and references made to their assumed previous knowledge.
- iv. The third *info* unit lists the definitions, theorems and algorithms of the module. These are the central concepts of the module. The *info unit* presents the content on an abstract mathematical level, the pure definitions, theorems and algorithms are presented without examples or exercises.
- v. The fourth *IIE* unit (*Info / Interpretation / Explanation*) repeats the central definitions, theorems and algorithms of the *info* unit. A network to other concepts is built. Illustrations, concrete examples and explanations are added. In case of theorems one can find plausible arguments and/or proofs for their correctness. The learners also find interactive exercises, flash-films and animations they can interact with and which help them to developing a deeper

understanding of the concepts. Since the learners can look at the concepts from various perspectives the memorisation of knowledge is supported, too.

- vi. The fifth unit is called the *application* unit: Here such applications inside and outside mathematics are presented that show the connection of the actual domain to other mathematical and non-mathematical domains. This unit may contain examples e.g. from engineering contexts that are relevant for the engineering students but may be also relevant for other students to see the practical relevance of mathematics. The inner-mathematical applications are used to connect the definitions, theorems and algorithms within mathematics.
- vii. The sixth unit is called the *typical-mistakes* unit: In this unit erroneous argumentations or solutions are presented to the learner, who is invited to find the mistakes, to correct them and to explain possible reasons for them. These exercises are provided to train the learners' diagnostic competencies and to depict misconceptions in order to avoid them in the future. The learners can check their answer by comparing to a correct argumentation or solution. For future mathematics teachers this is important for training their diagnostic competence (cf. Wittmann 2007).
- viii. The last unit is the *exercises* unit: This unit is important for the learners for checking their understanding of the topic and to give opportunities for practicing the concepts. For each exercise a model solution is available to compare own solutions with. These model solutions can also be used as hints for getting an initial idea or for helping when the solution process gets stuck.
- ix. The *diagnostic post-test* has the same structure as the diagnostic pre-test. Its idea is to give the students the opportunity to check their performance after having worked on a module. The diagnostic pre- and post-tests also aim at the elaboration of the students' abilities in self-regulation and self-evaluation, which are major factors for successful learning (Ibabe & Jauregizar, 2010).

TYPES OF BLENDED LEARNING SCENARIOS

For our bridging courses we combined self-directed and externally-regulated learning types of instructional formats (cf. Niegemann et al., 2008, p.66). Both formats have their justification in the specific case of bridging courses: on one hand learners are new at the university, so they have to acclimatise themselves with the new learning environment. Here attendance phases can help them to familiarize before the terms start. On other hand learners at university level have to be more self-directed in their learning than at school. Here eLearning phases can help to adapt their learning behaviour (cf. Mandl & Kopp, 2006). For our bridging courses we developed two different blended-learning course scenarios: a course scenario with an extensive attendance part (P-course) and a course scenario with an extensive eLearning part (E-course). When registering to the bridging courses each learner can freely choose between these types according to individual preferences.

The P-course

This course scenario is structured and led by the teacher while the learner has fewer opportunities for self-regulated learning. The course lasts 4 weeks; each week consists of three days with attendance at university with three hours of lectures and two hours of practice-session each. The remaining days are free for individual learning and homework. This homework consists of two parts: one part has exercises on the topics that were taught in the lectures and another part has specific tasks for individual working on the modules, aiming at recapitulating or preparing content for the next attendance day. Some of the diagnostic tests are available and recommended to the students.

The E-course

This course covers 4 weeks with 6 days attendance at the university. The remaining time is to be spent for online learning. The first week starts with one or two orientation days, where the learners are introduced to the learning system and course material and get advice how to learn with the material. The first modules are presented by means of lectures. Later in the course there is only one attendance day at the end of every week. The learners have the opportunity to ask questions about the content in the first part of the morning session and can pre-select the topics for the lectures in the second part of the morning. The afternoon is devoted to small group learning with exercises related to the content of the morning lectures. The small group work is supported by a tutor.

The rest of the learning time is free for learning with the online resources. Questions that come up in this process can either be asked and discussed on the next attendance day, posted in the forum of the learning platform or posed to the human online tutor, who is available during all normal working hours, including opportunities for online chatting. Moodle supports the learners in choosing their learning paths: The diagnostic tests with the individual feedback support students in structuring their learning, and a list of recommended modules for every study programme helps to identify the most important topics. Besides, we provide a text that explains the use of the material, the diagnostic tests and the role of the days at the university

THE EVALUATION-STUDY

In context of his PhD-project the second author of this paper extensively investigated the 2008 bridging courses in Kassel. His PhD project aims at designing, evaluating and refining the bridging course scenarios as described above. Major questions of the study were the identification of the reasons for the students' choice of the course variants, the description of the participants concerning personal aspects, the investigation of the course effects on the learners' performance and attitudes, the analysis of the acceptance and the rating of both, courses and learning material, and the investigation of the students' use of the learning material (cf. Fischer 2008).

For data collection, three questionnaires, one at the beginning, one in the middle and one at the end of the course, and two assessment tests were used. The questionnaires were anonymous online-forms requiring a personal key that enables us tracing the students' answers while keeping the students anonymous to us. Part of the items were adapted from different studies (Prenzel et al., 2002, Baumert et al., 2008, Bescherer, 2003) and items from the general course evaluation questionnaire of Kassel University. Thus we composed a new instrument for an investigation of blended learning scenarios for mathematical bridging courses. An electronic pre- and post-test was administered under exam conditions in a computer room for measuring students' mathematical proficiency levels. While the pre-test included exercises from school-mathematics, the post-test focussed on the bridging courses' content. In the following we can discuss only a few selected results of the study.

The courses from the learners' perspective

For investigating the acceptance of our bridging courses in general as well as the two course scenarios in specific, the students had to answer to three questions: 1. *"In general I was satisfied with the bridging course"*, 2. *"The participation in the bridging courses is absolutely recommendable"* and 3. *"I would decide for the E-/P-course of the bridging course again"*. A Likert type scale with four answering categories was used here: (1) "is not true", (2) "is rather not true", (3) "is rather true" and (4) "is true".

Question	P-course			E-course		
	M	SD	N	M	SD	N
1: <i>"In general..."</i>	3.57	0.62	254	3.64	0.53	96
2: <i>"The participation in..."</i>	3.69	0.62	254	3.69	0.56	96
3: <i>"I would decide for ..."</i>	3.67	0.68	254	3.48	0.79	96

Table 1: Results for questions concerning the acceptance of the courses.

Table 1 reveals very high scores for the courses in general and similar results for the two course types. Hence we can state that the learners were very satisfied with the bridging course type they had chosen. This proves the success of our course design decisions from this point of view.

Results from pre- and post-test assessments

The pre-test showed very similar results for both course types, but for the post-test, the results in the E-course are even better than in the P-course (see Table 2).

An analysis of variance for the results of the post-test considering the course variant as dependent variable and the results of the pre-test as covariant showed that the difference in the results of the course variants is highly statistically significant.

Working Group 14

Test	Results for P-course			Results for E-course		
	M	SD	N	M	SD	N
Pre-test 2008 Maximum: 19 points	8.52	3.14	226	8.52	3.64	146
Post-test 2008 Maximum: 20 points	9.21	3.13	131	10.93	4.02	72

Table 2: Assessment results.

Since we only hoped to achieve at least comparable results for both course types in order to disprove the argument that the E-course may be a popular scenario for some students but it will not improve the students' performance as much as by traditional scenarios, we were happy to have such positive results.

Students' reasons for choosing a course variant

The students had to indicate which factor of a given list was relevant for their decision for a course variant and how important the respective factor was (Likert type scale). For each factor we calculated the mean in order to identify reasons with a high impact and reasons with a low impact.

For the **E-course** we found that the mean scores for extrinsic factors such as job-related restrictions, living situation, being on vacation or other external reasons had low values between 1.24 and 2.4. In contrast, the questions for intrinsic reasons revealed high mean scores from 2.73 to 3.52. Therefore we can interpret them as main factors for the decision: this includes reasons concerning the opportunity for a more self-regulated learning within the E-course, the possibility of individual timing as well as a personal interest in eLearning as a learning method. It is not surprising that the reduced numbers of days with compulsory attendance was a further important reason for the students' choice ($M = 2.7$).

The results for the **P-course** showed again that extrinsic reasons like the availability of a computer, the internet or an internet-flat rate had very low mean scores from 1.06 to 1.32. Aversions to learning with the computer ($M = 2.13$) or bad experiences in eLearning ($M = 1.33$) were also reasons with a low impact. Instead the opportunities of personal contact with other students ($M = 3.4$) and with the teacher ($M = 3.64$) as well as the opportunity of experiencing typical lectures were reasons with high mean scores (between 3.4 and 3.64) and can therefore be interpreted as main factors. We also asked for doubts in one's ability of self-regulated learning ($M = 2.6$) and doubts concerning the method eLearning itself ($M = 2.61$) but these results show that these are not strong factors for or against the choice of the course variant.

At the beginning of the study we assumed that especially those students would decide for the E-course who either have an affinity to working with the computer or who already have made (positive) experiences in learning with the PC. That's why

we asked for these aspects in both course-scenarios and surprisingly found no substantial differences between the answers of the P- and E-course participants:

Question	Results for P-course			Results for E-course		
	M	SD	N	M	SD	N
<i>"I have already experiences in eLearning"</i>	1.97	0.4	376	1.95	0.33	209
<i>"I like to learn with the PC"</i>	3.23	0.74	376	3.4	0.7	209
<i>"In the last year in school I have already learnt with a PC"</i>	3.32	1.58	376	3.39	1.55	209

Table 3: Results for questions on learning with computer. Answering categories for the third question: (1) almost every day, (2) 2-5 times a week, (3) about once a week, (4) 1-2 times per month, (5) less often, (6) never.

Usage of the learning material within the E-course

Within the E-course the students were asked questions concerning their use of the diagnostic tests and of the modules. The participants had to indicate how often they had used the diagnostic tests. The results can be found in Table 4:

Test	(1) practically all	(2) most of them	(3) some of them	(4) barely none	M	SD	N
Pre-tests	28.5%	33.8%	22.5%	15.2%	2.25	1.03	151
Post-tests	19.9%	30.5%	23.8%	25.8%	2.56	1.08	151

Table 4: Use of the diagnostic tests.

The results show a slightly higher average usage of the diagnostic pre-tests, which is also supported by the user data that were collected in moodle: The number of pre-test-users is always higher than the respective number for the post-tests. The variability in the test usage is fairly high.

We also asked the participants to indicate how helpful the diagnostic tests were for them. Those students who didn't use the pre-tests (10.6% of the interviewees) or the post-tests (19.9%) could indicate it separately and were filtered out. The following table shows very positive results for both test types.

Tests	(1)	(2)	(3)	(4)	(5)	(6)	M	SD	N
Pre-tests	30.4%	42.2%	19.3%	6.7%	0.7%	0.7%	2.07	0.97	135
Post-tests	21.5%	48.8%	23.1%	4.1%	2.5%	0%	2.17	0.9	121

Table 5: Acceptance of the diagnostic test by those you used them. Answering categories: (1) "helpful" ... (6) "not helpful at all".

Working Group 14

Since the students had the opportunity to use a CD offline instead of learning online with moodle, we asked them “*Did you learn online within the learning platform or offline with the CD?*” For this we used a scale with options from (1) “only online” over (3) “nearly equal” up to (5) “only offline”. The quite high spread of SD ≈ 1.4 however revealed quite varying student opinions, so we decided to have a more detailed look at the results.

Hence we analyzed the results differentiating four different groups in view of the fields of study: E1 (electrical engineering & computer science), E2 (construction engineering & mechanical engineering), E3 (bachelor of mathematics or science & mathematics teachers for grammar schools) and E4 (teachers for primary and lower secondary schools):

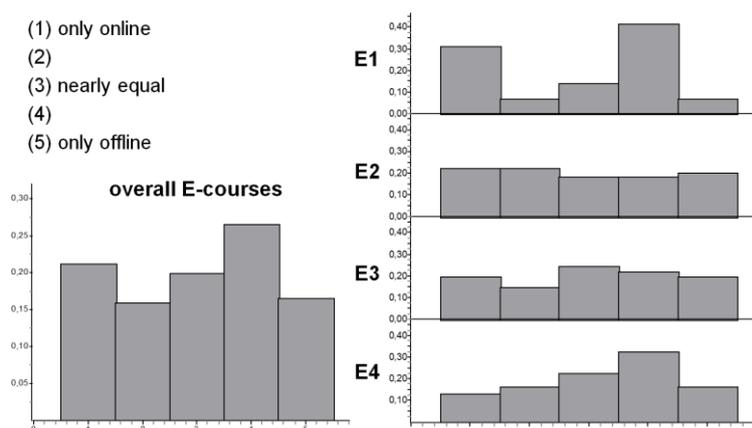

Figure 1: “Did you learn online within the learning platform or offline with the CD?”

It is noticeable that the groups E2 and E3 answered very similarly, while group E4 tends to learn offline. For group E1 we can identify two subgroups: One that is only learning online and another one that is learning almost only offline. Further data analyses showed that this split into subgroups can neither be explained by gender nor by the field of study (construction engineering & mechanical engineering).

Obviously there seem to be typical learning approaches that depend on the field of study, while others are independent of it. This assumption is further emphasized by an analysis of the students’ use of the modules. We asked the students to indicate for each module unit within the first three chapters how intensively they have typically used them. We calculated the percentage of all users that indicated an intensive usage and visualized the results for the groups E1-E4 in figure 2. The y-axis of this diagram displays the percentage of “intensive users” of the respective module unit that can be found on the x-axis. For comparing the profiles of the different groups, we sorted the units on the x-axis with respect to the results of group E3 (Bachelor of mathematics and science, mathematics teacher for grammar schools) in decreasing order.

Working Group 14

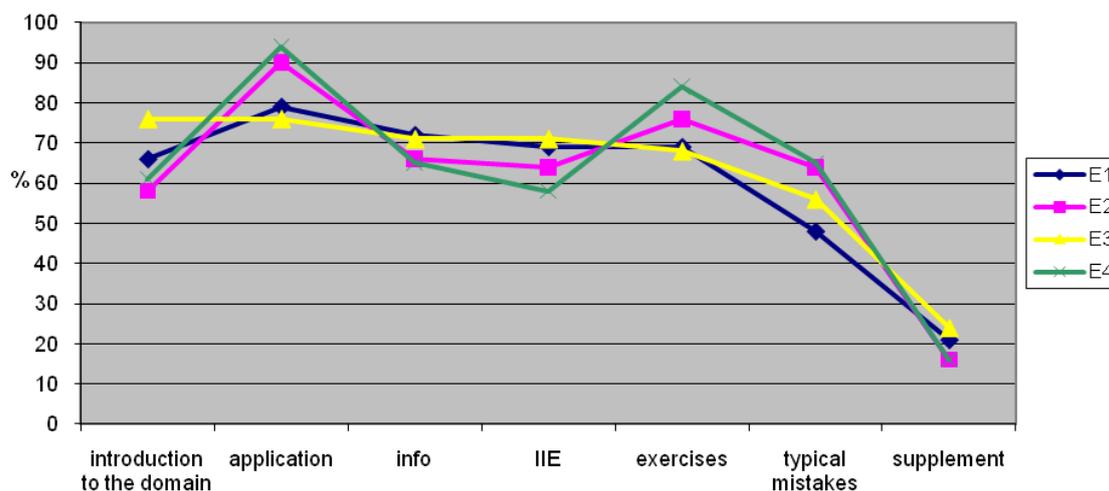

Figure 2: Percentage of intensive users for the units of a module.

We see that the learning profiles of the groups E1 and E3 are very similar as well as the profiles of the groups E2 and E4. This result was not expected since the fields of study of the groups would rather imply a different pairing. This suggests that it is not only sensitive to evaluate the courses with regard to the variants and the fields of study but also to classify different types of learners and to explore them.

PERSPECTIVES

The second author of this paper is currently working on different aspects of the evaluation study in the context of his PhD project. We have collected data on learners attributes e.g. personality, motivation, attitude towards mathematics and abilities in self-estimation and self-regulation. A classification of different types of learners and of typical learning strategies will be related to the learning behavior in the course and the effects of the courses on students' mathematical knowledge and attitudes. The data on students' rating of different elements of the courses and the learning material will be used for identifying aspects for improvement of the course design. We also revise our diagnostic tests, develop new content and design a new course structure in moodle for a better integration of interactive material. We expect that the instruments that we have developed will also be useful for the evaluation of blended learning bridging courses in general.

NOTES

This paper is partly elaborated in Biehler, R., Fischer, P. R., Hochmuth, R., & Wassong, Th. (in press). Self-regulated learning and self assessment in online mathematics bridging courses. In A.A. Juan, M.A. Huertas, S. Trenholm, & C. Steegmann (Eds.), *Teaching Mathematics Online – Emergent Technologies and Methodologies*. Hershey, PA: IGI Global.

EMPLOYING POTENTIALITIES AND LIMITATIONS OF ELECTRONIC ENVIRONMENTS: THE CASE OF DERIVATIVE

Irene Biza* and Victor Giraldo**

*Loughborough University (UK), **Federal University of Rio de Janeiro (Brazil)

Abstract. The aim of this paper is to discuss potentialities and limitations (and the suitable balance of these) of electronic environments in the development of students' understanding of the derivative. We re-analyse results of two studies in which the property of local straightness was used. In the first (Greek) study sufficiently accurate computer inscriptions are used to build students' understanding on the derivative and tangent line. In the second (Brazilian) study explicitly inaccurate inscriptions shake a student's faith in the computer's reliability, towards more solid theoretical understanding.

Keywords: teaching and learning of Analysis, derivative, tangent line, local straightness, electronic environments.

INTRODUCTION AND THEORETICAL BACKGROUND

In this paper we address the role of dynamic electronic environments in students' understanding of advanced mathematical notions and critical mathematical thinking. Particularly, we discuss how inscriptions of mathematical objects in certain electronic environments and their pedagogical use may interact with students' understanding of these objects. As an inscription, we consider any representation of mathematical objects (e.g. graphs, figures etc.) on the computer screen. Our focus is on the pedagogical role of the potentialities of these representations, as well as their limitations associated with the electronic and software technical constraints.

Especially, we address the case of *local straightness* (Tall, 1989) as a property of a curve with twofold particular interest. Firstly, this property can express the differentiability (or non-differentiability, through its lack) of a function at a point. In this sense it can be used towards introducing the definition of derivative and the general definition of tangent line. Secondly, the examination of this property on *critical examples* of functions offers the pedagogical opportunity to contrast the infinite mathematical processes (e.g. limit) with the limitations of the electronic inscriptions. In this sense it can be used towards facilitating students' more sophisticated mathematical understanding (Giraldo, Carvalho & Tall, 2003).

To this aim we report and highlight connections between results from two studies. In the first one (Greek study), students are introduced to the concept of derivative with the mediation of an electronic environment in which *sufficiently accurate inscriptions* of local straightness are offered (Biza, 2008). In the second study (Brazilian study), the students have been previously introduced to the notion of derivative through the property of local straightness in an electronic environment,

and now are asked to investigate cases of functions in which the inscription is *explicitly inaccurate* (Giraldo, 2004). By *sufficiently accurate inscriptions* we refer to the inscriptions that are designed to be as faithful as possible to the mathematical theory (e.g. the graph is not deformed when it is zoomed on); and by *explicitly inaccurate inscriptions* to the ones that are purposely conceived as in conflict with the mathematical properties (e.g. when a continuous graph seems discontinuous). Given the space limitation, we provide only the necessary methodological and theoretical information for each study and we confine ourselves to some of the results in order to discuss the interaction between students' perspectives with the inscriptions in the electronic environments.

Research highlights that, for the purpose of conceptual understanding in Analysis, instruction should be focused not only on the use of algebraic representations but additionally should take into account the geometric and intuitive representations of the corresponding mathematical objects as well as the interactions among these representations (Kaput, 1994). Such modes of instruction have been gaining strength also due to the advances in computer technology (Habre & Abboud, 2006). The introduction of technology in the teaching of Analysis in recent years proved very "important to facilitate students' work with numerous epistemological discontinuities such as discrete/continuum, finite/infinite, determinate/indeterminate" (Ferrara, Pratt & Robutti, 2006, p. 257). Using technology for the introduction of limit and derivative demands an approach that can balance and bring together intuitive and formal perspectives (ibid). One such approach is suggested by Tall's (1989) dynamic and visual idea of *local straightness*. This notion refers to the fact that, if we focus close enough to a point on a function graph, where the function is differentiable, then this graph looks like a straight line. This *straight line* estimates the tangent line of the graph at this point. The introduction to derivative through the local straightness can be supported by zooming tools in appropriately designed software (Tall, 1989).

Nevertheless, the visual representation of analytic concepts – in which mainly the limit is involved (e.g. continuity, derivative) – often contrasts with the formal status of these concepts. Giaquinto (2007) claims that there is a mismatch between these concepts and their visualisation and in order "to employ visual means to arrive at analytic beliefs we have to import assumptions that link the perceptual with the analytic" (p. 179). However, he acknowledges that "visual thinking can increase a student's understanding" (p. 184). Furthermore, the use of technology in the teaching of analytic concepts may be influenced by the limitations of the electronic environments due to their finite structure (e.g. finite step calculation, graph sketching through polygonal estimation, etc.). Giraldo et al. (2003) introduced the term *theoretical-computational conflict* to describe "situations in which a computational representation for a mathematical concept is (at least potentially) contradictory to the associated theoretical formulation" (p. 63). If these conflicts are exploited within a suitable pedagogical approach – rather than avoided – they may facilitate the

enrichment of students' understanding (Giraldo & Carvalho, 2006). Taking into account the above discussion, we consider electronic environments as artefacts that offer special means for students in their interaction with mathematical objects.

the Greek study

The context of the study

The participants of this study (Biza, 2008) were fifteen Year 12 students (aged 17-18 years) of a Greek secondary school. The students were selected because of their availability and their previous experience in the use of Dynamic Geometry (DG) environments in their school mathematics. This group of students aimed for tertiary studies related to mathematics, science, engineering or medicine and, according to the Greek curriculum, they had to attend an introductory course to Analysis. By the time the research took place, the students had been taught functions, limits and continuity and were about to be introduced to the derivative. In addition, in their previous studies, the students had encountered the tangent line to the circle in Euclidean Geometry (Year 10) and to other conic sections (parabola, hyperbola and ellipse) in Analytical Geometry (Year 11) courses. This previous experience was regarded as crucial on the design of the experiment, which was based on previous research results about students' understanding of tangents (e.g. Biza, Christou & Zachariades, 2008; Vinner, 1991, Castela, 1995). These results have highlighted the strong influence of the circle tangent on the students' general perspectives on tangents. For example (Biza et al., 2008), students who had met the tangent line in different mathematical contexts (Geometry and Analysis) demonstrated *Intermediate* perspectives on tangents between the *Analytical Local* perspective – the tangent is defined through the slope or the derivative applied locally at the tangency point – and the *Geometrical Global* perspective – the tangent preserves geometric properties applied globally on the entire curve. These *Intermediate* perspectives are a fusion of geometric and analytic properties applied either globally on the entire graph or locally at a neighbourhood of the graph. These perspectives may prove to be inappropriate when non-trivial cases are dealt with, such as cases in which the tangent line has more than one common point or when it coincides with the curve, as well as in cases of *inflection* and *edge* points.

The aim of the experiment was the reconstruction of previous restricted perspectives about tangents; the introduction to the local straightness as a property of a curve that has tangent line; and, the creation, through the introduction of the derivative, of a more general understanding of tangency. To this end the experiment intended to deploy the dynamic visual graphics in the electronic environment – especially the magnified image of a part of the graph in comparison with the entire graph – and the symbolic expressions – especially the limit of rate of change and the derivative – as *mediators* in students' understanding about tangency. According to the above aim the inscription of the magnified graph in the electronic environment and the selected examples had to be accurate enough in order to be in accordance with the

mathematical properties. For the needs of the experiment the mathematical classroom was transformed into a laboratory with five portable computers and a sixth linked to an overhead projector. The students were working in groups of three in each of the five computers and they kept notes on worksheets prepared for the needs of the instruction. The experiment was run by the researcher (first author) who was operating the sixth computer, with the support of the classroom teacher. Data was collected through post- and pre- teaching experiment questionnaires, audio recording of the experiment, students' responses on the worksheets and notes.

This experiment was developed in the context of the European Union funded project called *CalGeo* (<http://www.math.uoa.gr/calgeo/en/>) and utilised a DG software named EucliDraw (<http://www.euclidraw.com>). In addition to DG facilities, this software offers a function editor and function graph sketch environment as well as some tools appropriate for Analysis instruction. Indicatively, I refer to the magnification tool that can magnify a specific region of any point on the screen in a separate window. This magnification can be repeated as many times as the user specifies through a magnification factor. The graph and its magnification are presented at the same time on the screen. Technically, the highly magnified graph is produced by recalculation and redesign of the graph. Especially for the functions used in the experiment the magnified image was accurate enough and not restricted by the size of the pixels. Thus, the produced curves were not deformed.

In the analysis we used the Vygotskian term of semiotic mediation (1978) in order to describe students' interaction with the DG environment and their construction of the meaning of differentiability and tangent line. The visible objects (e.g. mathematical formulae, graphs, drawings, and diagrams) mediate students' understanding and the analysis focused on the evolution of students' attribution of meaning and the role of the DG environment, the examples and the researcher as teacher in this evolution.

Interpretation of the image towards students' introduction to tangency

In the first stage of the experiment, the students had constructed the tangent line and a secant line to a point A of a circle in the DG environment and they had been introduced to the local straightness as a property of a circle. They also had used the magnification tool in order to see how the two lines and the circle's curve were represented in the magnified image of a region around point A . The aim of this introductory activity was to connect the existence of a tangent line at a point of a curve with the property of this curve to look straight in the magnification window, if we focus on this point close enough. Just after this point the classroom was invited to investigate this property in the case of the semicircle in order to generalise it later for any function graph. The students worked on the semicircle, initially with pencil and paper in their worksheets and then in the electronic environment (Figure 1), in which the tangent line and the secant line AB had different colours. The point B could be moved along the curve and the region close to the point could be magnified as many times as the students wanted.

Working Group 14

At this point the students were invited to comment on the magnified image and a student, Alexandros, responded: “[The tangent] seems to coincide [with the semicircle] because if the magnification number is big, we cannot see the difference. That is because of the low resolution of the screen”.

For this student the inscription of the magnified graph was connected with the inherent technical limitations of the electronic environment although that was not the case. Given that students at this age are computationally literate the above comment was not unlikely. However, the previous discussion on the local straightness and its connection with the existence of a tangent line led us to expect responses based on the mathematical meaning of the magnified image. Thus, from the perspective of the instructional design, Alexandros’ response was welcome but unexpected and led to a slight – but crucial – change of the initial lesson plan.

Firstly, we discussed the differences between the images of the tangent line and the secant line AB (Figure 1). The secant line AB did not visually coincide with the curve whereas the tangent did. We argued that if the screen resolution was an issue, both lines and circle should match. Despite this comparison the students could not connect this image with the curve’s properties. Another example of curve was needed, maybe a case in which the curve does not have a tangent at a point. For that reason the class was invited to examine the same situation if the point A is a vertex of a parallelogram. In this case the line could not coincide with the curve regardless of how big the magnification factor was (Figure 2). During the comparison of these two cases and trying to explain the differences between these two inscriptions the same Alexandros exclaimed: “this happened because the line is the tangent of the circle”.

Figure 1: Magnification on a circle point **Figure 2: Magnification on a vertex**

This incident indicated the conflict between the meaning the instructor (first author) had given to the image in the magnification window and the meaning given by the student(s). The inscription in the electronic environment had been constructed in order to be as accurate as possible and mediate students’ understanding about tangency. However, the students’ brief experience of the discussion on the locally straight image of the circle (stage one) was not enough to raise their awareness of the mathematical meaning of the magnified image. As a result another explanation was put forward by a student who blamed a perceived inaccuracy of the electronic environment. As long as there was a tangent and the curve became straight in the magnification window the image acted as a physical illustration without any connection with the curve’s properties. The connection started to be made only when

Working Group 14

we considered a case in which the property could not be applied (Figure 2). Using this case moved the students away from the distracting perception of the computational inscription as inaccurate and helped them focus solidly on the intended properties. Let us now consider a somewhat different case where a knowingly inaccurate computational inscription is used for a similar purpose.

the brazilian study

The context of the study

Participants were six Year 1 students, attending a mathematics undergraduate course for prospective mathematics teachers in a major mathematics department in Brazil. Participants were selected among the students who volunteered to the experiment and had not had contact with the limit and derivative concepts previously at school (Calculus is not included in the Brazilian secondary school regular syllabus). At the time of the experiment, they were in the end of the first term of the academic year, attending the *Calculus I* course. During this course, they had regular weekly lectures in the computer lab, where they used Maple V (Waterloo Maple Inc., 1997) software to perform tasks such as: sketching and analysing graphs; interpreting a graph's behaviour under the change of graphic windows (e.g. by zooming in/out); and, determining derivatives and tangent lines (both numerically and symbolically). The study aimed to analyse the influence of *theoretical-computational conflicts* (Giraldo et al., 2003) in the participants' understanding of derivatives and limits.

The empirical study was organized in structured (G0, G1, G2) and semi-structured, task-based (T1, T2, T3, T4, T5, T6) individual interview sessions, which run alternately (G0, followed by T1/T2/T3 set, G1, T4/T5/T6 set, and G2). The whole interviewing process took approximately one month. All the interviews were audio-recorded and fully transcribed. The structured interviews included questions about the participants' conceptions of limits, derivatives and the use of the computer to study Analysis, and aimed for mapping out how these conceptions evolved through the experiment. In the semi-structured interviews, participants were given tasks intentionally designed to engender theoretical-computational conflict situations. They were asked to interpret results produced by the computer, which would apparently clash against mathematical theory due to the computational algorithms' intrinsic limitations. These results included, for example, graphs looking polygonal when they should be smooth or continuous when they should be discontinuous. Thus, a confrontation between the finite structure of the computer algorithms and infinite mathematical processes was likely to emerge.

Data analysis was based on the concept image/concept definition theoretical perspective (Tall & Vinner, 1981). Thus, we aimed to trace out the influence of theoretical-computational conflict situations on the participants' concept images. Data analysis was organised in two steps. Firstly, conflict episodes were identified in each participant's task-based interviews and then these episodes were compared to

their answers in the structured interviews. This allowed us to outline a map of the development of each participant's understandings throughout the experiment. Secondly, we investigated these maps for the effect the conflict episodes had on the participant's conceptions. These effects were classified into five categories: *confirmation*, *reformulation*, *reconstruction*, *inclusion* and *reversion* (Giraldo, 2004). Our aim was not to draw up a general taxonomy for the effects of theoretical computational conflicts. Rather, we aimed to identify and understand the effects that emerged from our data. In the next section we follow and discuss the development of Júlio's (one of the participants) perceptions and attitudes. Júlio had good grades in the courses and was generally regarded by lecturers as a student above average.

Interpretation of the image towards the elaboration of students' understanding

In the beginning of the study, Júlio had expressed his belief that computer results can be used to check mathematical correctness. In the first structured interview (G0) Júlio talked about the role of the computer in the verification of the symbolic calculation without expressing any doubts on the reliability of the image:

Júlio: We calculate the derivative and then we can put the function on the computer to see if it is really right. (Giraldo, 2004, p. 102)

Later, in interview T1, Júlio was given the algebraic formula of the function $h: \mathbb{R} \rightarrow \mathbb{R}$, $h(x) = \sqrt{x^2 + 1}$ and its function graph sketched in the graphic window $-100, 100 \times 0, 100$ of the software (Figure 3). Based on the above he was asked to decide whether the function was differentiable at $x_0 = 0$ or not. Note that, even though this function is differentiable at $x_0 = 0$, the image in Figure 3 suggests the opposite. Júlio, relying on this image, and despite of his familiarity with elementary functions like this, claimed that the function is not differentiable at $x_0 = 0$ and justified his claim as follows:

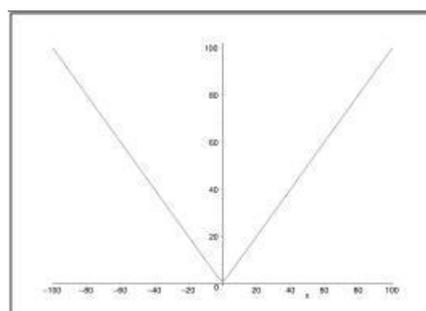

Figure 3. The graph of $h(x) = \sqrt{x^2 + 1}$ on the graphic window $-100, 100 \times 0, 100$.

Júlio: It was a second degree thing, then we took the square root and the degree became 1. It is going to be a modulus.

Interviewer: But do you think it's differentiable?

Júlio: Because I'll take out the square root, when I take the square root it's going to be the modulus of the thing that is coming out. Then, the modulus function has a corner [...] that's why this one is going to have one too. (Giraldo, 2004, p. 102)

Following his claim above, he insistently tried to eliminate the square root with algebraic manipulations, without success and no attempts or references to the

necessity of changing the graphic window. During the interview, he didn't touch the computer and considered as correct the image of the graph in the screen. Finally he attributed his failure to express the function formula with modulus to his algebraic weaknesses.

Later, in interview T2, Júlio was asked to explain the local magnification process of the curve $y = x^2$ as it is represented in Figure 4.

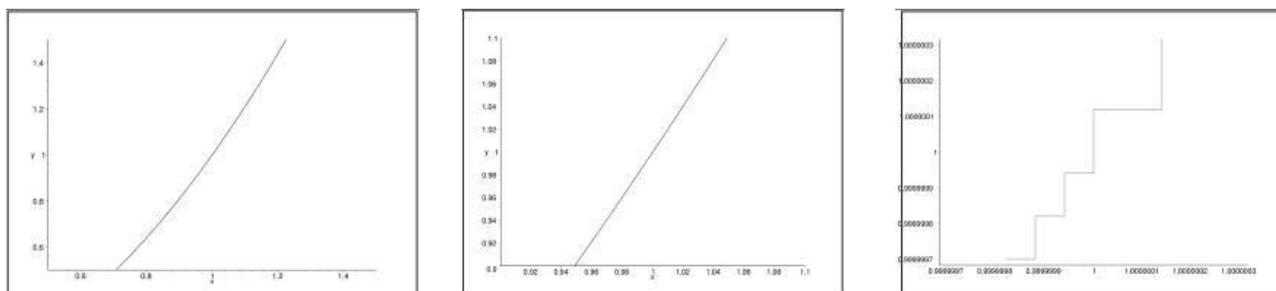

Figure 4. A curve that is differentiable, but seems not to be.

After thinking for a while, Júlio explained:

Júlio: That's weird. [...] I think that's because the computer cannot recognise it. The approximation is too small. It no longer distinguishes the curve.

[after zooming in a bit more]

Júlio: Even more. [...] It just links the points and the approximation is way too small. The sketch is coming out deformed. This is not what it's supposed to be! (Giraldo, 2004, p. 168)

Júlio's use of the images in the electronic environment in interviews T1 and T2 is remarkably different. In the former, he trusted the image in the computer and he tried to find an algebraic explanation for it; whilst in the second, his familiarity with the graph of the function generated a resilient and confident doubt about the image. In the first case, not having any knowledge about the function graph, he did not experience any conflict and relied on the graph with somewhat blind faith. This behaviour is consistent with the belief he had expressed in the first interview (G0). Whereas in the second this belief had started to be shaken and Júlio reconsidered the correctness of the computer's image and juxtaposed it with his knowledge about the function. Júlio's attitudes in the following interviews remained similar to the ones he had in interview T2. Later in the final structured interview (G2), he showed that his perspective had considerably changed:

Júlio: What I find cool is that [...] sometimes, one function you have no idea what's going to happen, you put it on the computer, you can make experiences, you can turn it inside out, and upside down. Then, you can figure out what is going on, at least for most of the functions. So, the computer helps to understand things, it gives us a more global comprehension.

[and later]

Júlio: It is cool, but I only rely on it [...] how am I to say [...] I only trust on the computer using the theory I know. [...] Because the computer flaws too, like in many, many times we have seen here. [...] So, we have to use the computer, you know, to make experiences, but always together with the theory (Giraldo, 2004, p. 166).

In the last interview, Júlio kept regarding the computer as an important mean for investigation. However, he no longer considered the computer as a warrant for mathematical truth. Rather, he claimed that the computer outcomes need to be checked through mathematical theory.

CONCLUDING REMARKS

In the first (Greek) study the students are introduced to local straightness through the visual representation of this property in the electronic environment. To this aim the chosen examples and the inscriptions were designed to be as *faithful* to the mathematical theory as possible. However, for Alexandros, the image of the *straight* curve had no mathematical meaning and thus he attributed inaccuracies to a sufficiently accurate inscription. Actually, the episode evidences a conflict between the teacher's and the student's meanings. The conflict is resolved through the use of a counterexample illustrated in the same electronic environment.

The example from the second (Brazilian) study follows almost a reverse path. The student has been introduced to the property of the local straightness and the concept of derivative and now he discusses some cases in the context of a knowingly (to the teacher) inaccurate inscription in the electronic environment. The aim was to shake the student's somewhat passive faith in the environment. Indeed, Júlio was initially carried away by the image on the graphic window. Then the engagement with familiar examples shook his faith in the computer and, at the end, he stated very clearly that computational inscriptions can contain inaccuracies and that they have to be verified through mathematical theory.

The presented examples are complementary. In both cases the electronic environment mediates the students' understanding: in the first one through sufficiently accurate representations and in the second through explicitly inaccurate representations. In the first we ask the students to trust the electronic environment and in the second to mistrust it. We claim that both of these approaches should be welcome in the teaching and learning process. We need strong and dynamic inscriptions to visualise mathematical objects and properties and at the same time we need to be aware of the limitations of some of these inscriptions. In both cases, the confrontation between the students' previous conceptions and the features of the inscriptions (potentialities and limitations), within suitably designed pedagogical approaches, played a crucial role to change, and possibly deepen, the students' understanding.

ACKNOWLEDGMENT

We would like to thank Elena Nardi for her helpful comments on earlier drafts of this paper. The re-analysis of the data from the two studies we draw on in this paper was made possible through a Visiting Professor's grant of the postgraduate mathematics education programme in the institution of the second author.

THE CHANGING PROFILE OF THIRD LEVEL SERVICE MATHEMATICS IN IRELAND (1997-2010)

Fiona Faulkner¹, Ailish Hannigan¹ and Olivia Gill²

¹Mathematics and Statistics Department, University of Limerick, Ireland

²NCE-MSTL Department, University of Limerick, Ireland

In 1997 diagnostic testing was introduced in the University of Limerick (UL) to identify and notify students who were likely to require help to complete first year service mathematics courses successfully and proceed through to second year. A database of diagnostic test and end of semester examination results was initiated in 1997 and is updated annually by the authors. It has been observed by the authors that the student profile and their needs have changed in the 13 years since the initiation of the database. In this paper the authors describe the profile of the current student cohort in first year service mathematics courses in UL and how it has changed in the last 13 years. Furthermore the implications of such changes are outlined¹.

Keywords: Student profile, at risk, diagnostic testing.

BACKGROUND AND METHODOLOGY

Diagnostic testing in the University of Limerick

The University of Limerick (UL) has used diagnostic testing since 1997 to help identify students who may be at risk of failing service mathematics examinations (O'Donoghue, 1999; Gill, 2006). Diagnostic testing is now commonly used in third level education, both in Ireland and abroad, to identify weaknesses in basic mathematical skills (Abou Halloun & Hestenes 1985, Edward 1996; Malcolm & McCoy, 2007). The diagnostic test has aided the identification of the changing student profile in UL both in terms of students' mathematical competency levels and the educational backgrounds of the students. Such changes have been echoed in documentation from other Universities in Ireland such as Dublin City University (Ni Fhloinn 2009). O'Donoghue, a professor of mathematics education in the University of Limerick, developed the UL paper based test in 1997. A number of quality controls were used in the design of the test to ensure it fulfilled its function. The ¹Ordinary Level Leaving Certificate mathematics syllabus, the SEFI core level zero syllabus for engineers (Barry and Steele, 1993) and an extensive literature review were all used to inform its content and structure. After the test was piloted in a number of second level schools and feedback on the prototype from six mathematics lecturers in UL was received, the test was finalised. Each test is marked by hand so as to enable closer inspection of a script if required (O'Donoghue, 1999).

The two largest service mathematics groups in UL, Science Mathematics and Technological Mathematics, are tested annually. 3,389 students have taken Science Mathematics within the period 1998-2010 and 4,439 have taken Technological Mathematics. The diagnostic test consists of 40 questions covering nine topics, the majority of which are aimed at Ordinary Level Leaving Certificate Mathematics² standard or below. The diagnostic test has not changed since it was first developed in 1997. The test is distributed to students in their first mathematics lecture of the academic year without prior warning. If students receive 19 out of 40 or below in the test they are encouraged to avail of the support services provided by the Mathematics Learning Centre (MLC). These students are categorised as being ‘at risk’ (O’Donoghue, 1999). 19 was chosen as the cut off point as these students were considered to be seriously deficient in the basic mathematical knowledge necessary for third level mathematics and therefore were categorised as being at risk and in need of support. It should be noted however that there is “a strong argument for extending the ‘at risk’ category to students with higher scores” (O’Donoghue, 1999, p. 15). Research on the changing student profile in the University of Limerick was carried out in 2008. This paper aims to update those findings to the year 2010.

Research Methodology

Descriptive analysis is used throughout this research paper. The analyses is carried out using the statistical software package SPSS (Statistical Package for the Social Sciences Version 16). The data has been described using summary measures, such as means and standard deviations, and graphs, such as box plots, are used to represent cohort changes over time. The documentation of trends over time amongst UL students was informed by the work of O’Donoghue (1999) and Gill et al (2010) and guided by the work of Hunt and Lawson (1996). The investigation into the implications of the changing profile of students in terms of changes in support services needed over the time period 1998-2010 was carried out by detailing the chronological order in which new mathematics support services were introduced to UL. The pilot study in 1997 examined data on the Technology mathematics students only and so the changing profile of both the Science and Technology service mathematics students is most effectively analysed between the years 1998-2010.

MAIN FINDINGS-THE CHANGING STUDENT PROFILE (1998-2010)

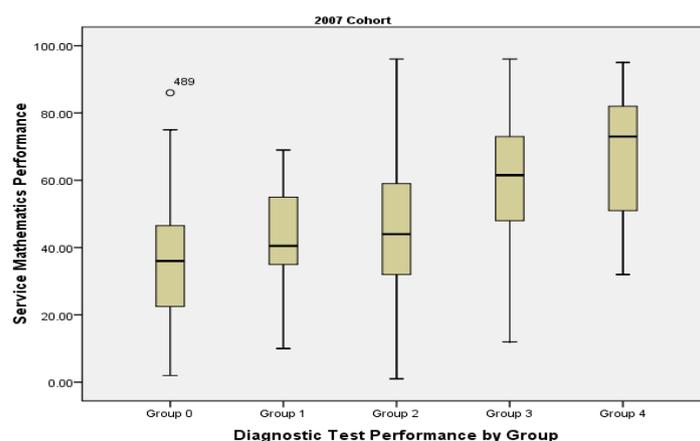

The student profile of Science and Technological Mathematics courses in UL has changed greatly between the years 1998 and 2010 (see Table 1). Changing student profiles of service mathematics students such as this, which have been shown to impact on the teaching and learning of mathematics in third level education, have been documented internationally (Kitchen,1999).

Degree Programmes

The number of degree programmes required to take Technological and Science Mathematics has increased between 1998 and 2010. Within Technological Mathematics there had been an increase from 8 to 9 degree programmes. Science Mathematics has seen a large increase from 8 degree programmes in 1998 to 15 in 2010 with courses such as Health and Safety and Psychology now being required to take Science Mathematics.

Percentage of ‘no-show’ and ‘at risk’ students

In 1998 100% of students registered for Technological and Science mathematics sat the diagnostic test i.e. they were present in their first lecture of term. The number of Technology mathematics students sitting the diagnostic test has declined to 82.6% in 2010, which represents a 21.1% decline from the 1998 baseline. A slightly larger decline to 76.5% occurred for Science mathematics students, which represents a 30.7% decline from the 1998 baseline (see Table 1). The reasons for these students not turning up to their first lecture to take the test has not yet been examined however upon analyses of the ‘no-show’ students’ end of semester results from a previous year (2007) the vast majority of ‘no-show’ students performed below average when compared to the rest of the cohort (see Figure 1). Figure 1 highlights that students who do not turn up to take the diagnostic test may be at risk of failing their end of term examinations as well as those who perform poorly in the diagnostic test. There has been an increase in the percentage of ‘at risk’ students, i.e. students who receive 19 out of 40 or below in the diagnostic test. The number of ‘at risk’ students in the Technological mathematics group increased by 25.2% in 2010, which represents a 77% increase from the 1998 baseline. An even larger increase of 24.9% occurred for Science students in 2010, which represents a 117% increase from the 1998 baseline (see Table 1).

(Note- 0= did not sit the test, 1= 1-10 in test, 2=11-20 in test, 3=21-30 in test, 4= 31-40)

Figure 1 ‘No-show’ students’ performance in end of term test against the performance of students who sat the diagnostic test.

Working Group 14

A decrease in mathematical standards such as this may be due to, as suggested by Hunt and Lawson (1996), a shift in emphasis of second level mathematics towards topics not covered in the diagnostic test. Although the suggestions of Hunt and Lawson (1996) may hold in an Irish context, it is thought that the increase in at risk students may also be explained by the decrease in students taking Higher Level Leaving Certificate Mathematics, a decrease of 12.7% and 16.4% occurred within Technological and Science Mathematics cohorts respectively in 2010, which represent a 31% and 30% decline from the 1998 baseline. From Table 1 it is evident that within the Science and Technological Mathematics student cohorts the percentage of students taking Higher Level Leaving Certificate Mathematics has declined over the period (1998-2010). This is an important finding as performance in mathematics in third level education has been shown to be better when students have higher level mathematics as pre-requisite knowledge (Barry & Chapman, 2007).

The increase in the number of non-standard students is also contributing to the decline in diagnostic test performance over time. Non-standard students consist of mature students (i.e. those over the age of 23), non-national students and those who have completed previous degree/diplomas/certificates and have used these as an entry qualification to UL. A 12.4% and 8.6% increase of non-standard students occurred in Technological and Science Mathematics respectively in 2010, which represents a 4133.3% and 600% increase from the 1998 baseline (see Table 1). A change in student intake such as this has been shown to influence overall mathematical performance in UL as well as in other institutions such as Coventry University (Lawson, 2003). Second Level mathematics can no longer be assumed as the previous knowledge of students. Lecturers of these modules are therefore faced with new challenges which call for adaptations in teaching styles to cater for the current cohort and not that which sat in front of mathematics lecturers twelve years previous (Hourigan & O'Donoghue, 2007). The measures put in place to cope with these changes are discussed in section 4.

Year	1998	2010		1998	2010
Technological Mathematics			Science Mathematics		
% of total taking test	100%	82.6%		100%	76.5%
% 'at risk'	32.8%	58.0%		21.3%	46.2%
% doing HL	41%	28.3%		55.4%	39.0%
% doing OL	58.7%	69.8%		43.1%	59.4%
Non-standard students	0.3%	12.7%		1.5%	10.1%

Table 1: Profile of students in Science and Technological Mathematics

PROFILE OF NON-STANDARD STUDENTS IN 2009

Due to the large increase in the prevalence of non-standard students undertaking degree programs which involve service mathematics it is useful to examine the performance of these students and how it may impact on mathematics education within the University of Limerick. This examination focuses on non-standard students' performance in 2009 as at the time of writing the current non-standard students have not yet sat their end of term examination.

Performance of non-standard students in the diagnostic test

Mature students make up the majority of the non-standard cohort in UL, therefore the majority of non-standard students have not engaged in mathematics for a number of years. This is apparent in their diagnostic test results (see Figure 2). Non-standard students have mean diagnostic test scores below that of the standard students who have come directly from Leaving Certificate. According to their performance in the diagnostic test, the majority of non-standard students are at risk of failing their end of semester examinations. Figure 2 highlights that non-standard students are mathematically less prepared entering UL than standard students are.

Performance of non-standard students in end of semester examination

Non-standard students' performance improves in their end of semester examinations, for both Science and Technological cohorts, when compared to their diagnostic test performance. When Figures 2 and 3 are compared it is clear to see that the gap between standard and non-standard students is less obvious in terms of their examination performance. There is still a gap between the performance of standard and non-standard students in end of term service mathematics. However the majority of non-standard students pass their semester 1 examination (the pass mark being 40%) despite the fact that the majority of them were considered to be at risk of failing as highlighted by the diagnostic test (see Table 2 and 3 and Figure 3). Probable reasons for this improvement in performance are discussed below.

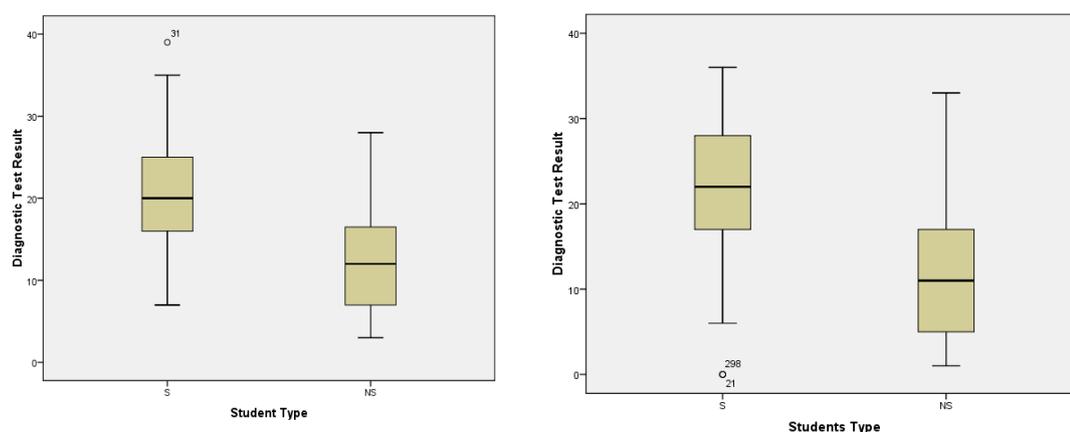

Figure 2: Comparison of diagnostic test performance for Standard and Non-standard students- Technological (left) & Science (right) Mathematics (2009)

Working Group 14

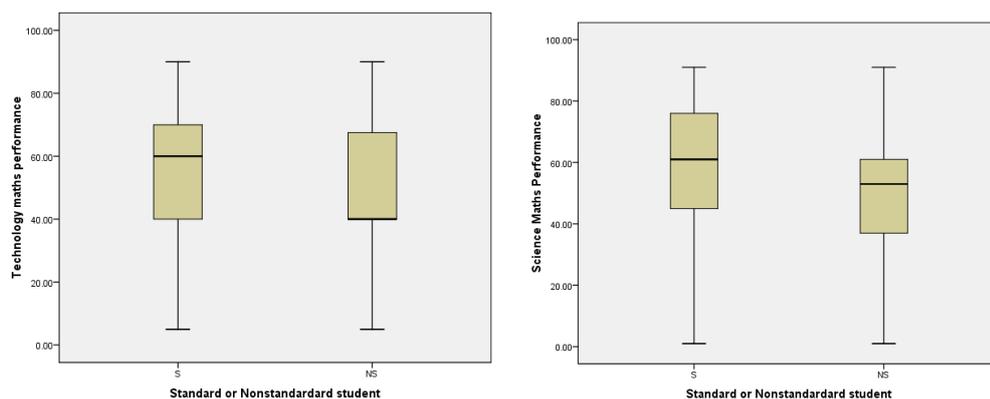

Figure 3: Comparison of end of semester 1 examination performance for Standard and Non-standard students-Technological (left) Science (right) Mathematics (2009)

		Science Students	
Diagnostic Test	Mean value out of 40(SD)	Diagnostic Test	Mean value out of 40(SD)
Standard students	51.5 (16.3) n=260	Standard students	55.5 (17.0) n= 290
Non-standard students	31.8 (16.5) n=44	Non-standard students	30.2(20.0) n= 49
Semester 1 examination	Mean value out of 100(SD)	Semester 1 examination	Mean value out of 100(SD)
Standard students	54.8 (6.0) n=257	Standard students	60.4 (19.8) n=254
Non-standard students	49.4 (23.9) n=43	Non-standard	47.1(24.0) n=46

Table 2 Technological and Science Mathematics students' diagnostic tests (expressed as a percentage of correct answers out of 40 questions) and end of semester results in 2009

Comparison of attendance at support tutorials of standard and non-standard students

Tables 2 and 3 and Figures 2 and 3 highlight that the non-standard students improve in their mathematical performance between the beginning of the semester and the end. Why might this be? The percentage of non-standard students attending support-tutorials, run by the Mathematics Learning Centre (MLC), is much higher than that of the standard students (support tutorials will be outlined in greater detail in section 4). Technological and Science Mathematics students are offered a weekly support tutorial in addition to their regular weekly tutorial. The findings shown in Figures 2

and 3 and Tables 2 and 3 reveal positive indicators for engaging in support services such as support tutorials and one-to-one consultations in the Mathematics Learning Centre. These findings could also be accredited to the fact that non-standard students may be more motivated than standard students (Hirst, 1999).

IMPLICATIONS OF THE CHANGING STUDENT PROFILE-INCREASE IN SUPPORT SERVICES

The provision and uptake of support structures in place in UL reflect the changing student profile which has been documented thus far.

Support services were initiated in 1997 when O'Donoghue carried out his pilot study to measure the extent of the errors and gaps in students' mathematical knowledge. 'Front-end' tutorials were set up in the first two weeks (one each week) of the first term to enable students to revise fundamental mathematics skills in arithmetic and algebra. In addition, students were strongly encouraged to attend a 'support tutorial' on a weekly basis throughout the entire term. Support tutorials run alongside regular tutorials and cover the same material at a slower pace and in a smaller group. The Department of Mathematics and Statistics acknowledged that further support was warranted so in 2001, the Mathematics Learning Centre (MLC) opened. This fully supervised drop-in centre is a place where students can study and/or receive 1-1 attention. This service is provided for 20 hours a week. In the first year of operation, 1516 visits to the drop-in centre were recorded. In 2009/10, a total of 1,129 individual students availed of the drop-in centre making 4527 contacts/attendances over the academic year. Significant increases in the number of support tutorials has also occurred since 1997, when two support tutorials (one for traditional students and one for mature students in Technology Mathematics) ran on a weekly basis. In 2009/10, a total of 228 support tutorials in 21 modules were provided by the MLC with a total of 3,835 contacts/attendances recorded at these classes. This was an increase of over 1,400 contacts on the previous academic year. Between the drop-in centre, examination revision and support tutorials, 8,946 contacts were made with the MLC.

Online support was set up by the MLC with the view to increasing contact time with students who needed mathematics support. Fact sheets tailored specifically for UL service mathematics courses were designed and peer reviewed by colleagues from the Department of Mathematics and Statistics, and made available online for all students. Past examination papers and sample solutions are made available on the site as are links to useful websites such as the University of Loughborough's Engineering Mathematics website (<http://www.ul.ie/~mlc/support/Loughborough%20website/book.html>).

One further development made by the MLC to cope with growing numbers of non-standard students was the introduction of a one week refresher mathematics course, entitled 'Head Start Mathematics'. This course was designed to help students who

had been away from formal mathematics education for a long period catch up on essential mathematics skills they were likely to need for their service mathematics courses. The course, which is run in August before students start in UL, is free of charge and covers topics such as number systems, algebra and graphing etc. In August 2010 2 weeks of this course were run to accommodate the increasing numbers who wished to receive the free tuition. The feedback from participants thus far has been very positive (Gill 2010).

The mathematics learning centre is currently putting together screen casts of areas of mathematics which students often have difficulty with in order to try to alleviate some of the pressures put on the centre by the growing number of students. This additional means of mathematics support is currently being developed in collaboration with Swinburne University in Australia.

DISCUSSION- IMPLICATIONS OF THE CHANGING STUDENT PROFILE

Gill et al (2010) highlighted, through the use of diagnostic testing, the declining mathematical standards of third level students entering Technological and Science Mathematics courses in UL. This paper offers a discussion on a probable contributor to this decline i.e. the changing profile of students within these service mathematics courses. The main changes in student profile between 1998 and 2010 can be summarised as follows:

- An increase in the number of degree programmes within the service mathematics courses
- An increase of 77% of Technological Mathematics students being labelled at risk and an increase of 117% of Science Mathematics students being labelled at risk from the 1998 baseline
- The proportion of students entering UL with Higher Level Mathematics has declined along with a corresponding increase in the proportion of students entering with Ordinary Level Leaving Certificate maths
- The percentage of non-standard students has gone from approximately 1% of the entire cohort to almost 12% for Science and Technological Mathematics combined
- The ‘no-show’ students, i.e. those who did not sit the diagnostic test in their first mathematics lecture, perform poorest in their end of semester examination. These students along with those who perform poorly in the diagnostic test are currently being targeted for an intervention, the results of which are to be reported in a future paper.

An investigation of the non-standard students’ performance in 2009 revealed that they perform below average in the diagnostic test when compared to the standard students but improve by the time they sit their end of term examination. Non-

Working Group 14

standard students are more likely to avail of the support services put in place by the Mathematics Learning Centre. A major implication of the changing student profile was the need for increased mathematics support services which were more tailored to the specific/changing needs of the UL students within the period 1997 and 2010.

The increase in support services is but one of the changes that needs to occur in mathematics education in order to attempt to cater for the varying backgrounds of new student cohorts. Lecturers and tutors of mathematics need to take note of the changes which have occurred over time and plan their teaching content and style accordingly. A lack of willingness to change to suit the needs of the current student profile would be likely to lead to “deterioration in the effectiveness of the learning” in UL and indeed in other third level institutions which are experiencing similar changes in student profile (Hunt & Lawson, 1996, p. 171). The need for yearly assessment of the student profile is imperative if student-appropriate teaching is to take place.

NOTES

¹ This paper revisits the UL database which was formally reported on up to 2008.

² Leaving Certificate Mathematics can be taken at three levels in Ireland; Higher, Ordinary and Foundation Level. The Higher Level curriculum is the most advanced level. It covers more topics and to a more sophisticated standard than the other levels. The minimum mathematics entry requirement for direct entry to third level education in Ireland is a grade C or higher in Ordinary Level Leaving Certificate Mathematics.

USING CAS BASED WORK TO EASE THE TRANSITION FROM CALCULUS TO REAL ANALYSIS

Erika Gyöngyösi, Jan Philip Solovej, Carl Winsløw

EG⁷⁵ and CW: Department of Science Education, University of Copenhagen

JPS: Department of Mathematical Sciences, University of Copenhagen

We investigate how the integration of a computer algebra system (Maple 13) in parts of students' work may help students relate theoretical and practical aspects of convergence of sequences and series of real numbers and functions.

TRANSITIONS IN INTRODUCTORY ANALYSIS: THE PROBLEM

Many universities are aware of the difficulties students experience during their first months of study, and they therefore introduce a variety of measures to ease the institutional transition. In particular, university mathematics programmes adapt the first courses to the students' background from upper secondary school. In Denmark this means for instance that basic differential and integral calculus are revisited and extended progressively to functions of several variables, along with other standard topics from the field of calculus. Following the style of North American calculus text books, these first courses focus on students' practice with concrete calculations and analysis of functions, while the theoretical part (precise definitions, theorems and proofs) is left in the background or it is entirely omitted. If the basic courses are shared with students from other specialties like physics or engineering, this may further motivate such a choice.

However, the problem will not go away. Mathematics students soon encounter real analysis where a rigorous approach to topics such as continuity and convergence is inevitable not only as something talked about in lectures, but also as something worked on by students. As pointed out by Winsløw (2008) the students are in fact presented with two types of challenges or transitions, often in rapid succession:

- (1) they will have to do autonomous work on theoretical aspects of practices they previously encountered in calculus (calculations with "ordinary functions")
- (2) they will also encounter new practices and theories which are based on these theoretical elements (eg. function spaces, abstract metric spaces, norms,...).

Our research addresses mainly the first transition. More concretely, we investigate – theoretically and also empirically – concrete designs for integration of a computer algebra system (a CAS, in this study *Maple 13*) in parts of students' work, aiming to help students relate theoretical and practical aspects of *convergence of sequences and series of real numbers and functions*. In particular we are interested in designing new types of tasks which may realise the *lever-potential* and the *materialization*

⁷⁵ Permanent address, EG: University of Miskolc, Hungary. EG was supported by Eotvos Hungarian State scholarship.

potential (cf. Winsløw, 2003), and we are particularly interested in the effects, for “weak students”, of such *reasoned instrumentation* (cf. Elbaz-Vincent, 2005, 63).

INSTRUMENTED TECHNIQUES AND INSTRUMENTATION

We now outline the theoretical framework for this study. Our basic model for the mathematical activity of students comes from the anthropological theory of didactics (Chevallard 1999; Barbé et al., 2005, sec. 2). That is, we consider the work of students (and any mathematical activity) as organised by types of tasks T , carried out using a technique τ ; the discourse about the practice block (T, τ) is organised in a *technology* θ , which may pertain to a whole family of practice blocks; and several technologies are structured and justified within a wider *theory* Θ , which in our study is essentially the theory of convergence of series of functions and numbers within the mathematical domain of real analysis (involving several definitions, theorems and so on). This way, a mathematical activity is always modelled with a *praxeology* $(T, \tau, \theta, \Theta)$. Of course, the main point regarding the use of a CAS is that it provides an inventory of *instrumented techniques* (where by “instrumented” we indicate that a more or less powerful tool is involved in the technique; cf. Artigue, 2002). These may at first present themselves simply as alternative techniques for solving an existing type of task, such as determining the limit of a sequence of real numbers. But in practice, the new techniques rarely correspond exactly to existing types of tasks, and at the same time they often need to be combined with non-instrumented techniques. Moreover the theory blocks may need to be adjusted – not least at the level of technology – to accommodate such combinations.

Elbaz-Vincent (2005) studied examples and principles of how *Maple* computes limits of functions and series in symbolic mode (these routines are essentially based on power series expansions); it disposes of a range of other techniques for numerical computations. As any techniques, instrumented techniques will only provide meaningful or correct answers for a restrained type of tasks, which could in principle be determined theoretically. However, most users – including students – will have to relate to the results in a more pragmatic way. Even in situations where all that matters is to solve a given task, it then becomes important to develop practical means to evaluate the result (or absence thereof) from applying an instrumented technique. This also means that, most of the time, a complex interplay of instrumented and non-instrumented techniques will have to be constructed, made explicit and reasoned within theory blocks which become, as a result, different from what they are in the absence of instrumented techniques. In this paper, we will give a number of examples of such modifications of praxeologies to be developed by students and teachers.

These modifications will have to be understood relatively to the affordances of the involved techniques, as defined by Artigue (2002, 248): their *pragmatic value*, i.e. the efficiency for solving tasks; and their *epistemic value*, i.e. the insight they

provide into the mathematical objects and theories to be studied. These values may be experienced to differ greatly, especially by teachers.

Such differences may be studied in more detail from the point of view of *semiotic representations* of mathematical objects (cf. Winsløw, 2003). An instrumented technique provides, within its scope, access to transformations of representations (eg. symbolic or graphical) whose epistemic value depends both on the users' means to access or perform intermediate steps (the absence of which is often referred to as a *black box effect*). It also depends on the users' means to relate them to a didactically targeted theoretical block. The possibility of using instrumented techniques leading to a stronger focus on, and access to, theoretical objects and principles, is referred to as the *lever potential* and the *materialization potential*, respectively.

To achieve this we need to construct entirely new organisations of tasks for students, involving instrumented techniques in a way that develop their *epistemic* value for students (cf. also Artigue, 2010, 467f). In the present project, this means that students' work with the designed instrumented practices should be related to, and support, their work with theory blocks, and so facilitate the transition (1) mentioned in the introduction. This way instrumented techniques should also become a more integrated element of the students' developing praxeological equipment, instead of a set of alternative techniques which are at best tolerated because of their pragmatic value. While this process of *instrumental genesis* may be studied in an individual perspective, it is clear that in didactic contexts it can be also heavily dependent on institutional conditions and norms, as the teaching institution takes more or less responsibility to organise and evaluate the use of instrumented techniques. This aspect of teaching is often referred to as *instrumental orchestration* (Trouche, 2005).

To establish and study efforts towards reasoned instrumentation at this institutional level, taking into account in particular the potential effects of instrumented semiotic representations, is indeed the overall purpose of this study. We now proceed to outline the concrete mathematical and institutional context in which it is situated.

SERIES AND SEQUENCES – INSTRUMENTED TECHNIQUES

At the University of Copenhagen, the bases of mathematical analysis are taught in three courses during the first year: an introductory course involving mainly practical blocks of calculus in one and several variables; a follow-up course (*Analysis 0*) in which theoretical blocks, in particular evolving around “ $\epsilon\delta$ -arguments”, are also worked on by students; and finally a more advanced course (*Analysis 1*) in which notions related to convergence, series (including Taylor and Fourier expansions), and metric spaces are to be studied, with a strong focus on theoretical blocks.

In the introductory course as well as in a corresponding course on linear algebra, instrumental orchestrations based on *Maple* have become an integrated and relatively stable part since the first developmental project around the year 2000 (data from that

project were analysed in Winsløw, 2003). In particular, students become familiar with basic use of *Maple* techniques in common tasks in these areas. But until now, the more advanced courses have not made systematic efforts in this direction, probably because of the more theoretical focus.

At the same time, while the introductory course has a very high passing rate, *Analysis 0* and in particular *Analysis 1* seem to filter out a number of students (up to 25% in recent years), who then drop out of the programme – a state of affairs of concern to the institution and to Danish society, in which mathematicians are sorely needed, not least for teaching positions in upper secondary schools.

The hypothesis that these problems reflect a transition problem of type (1) has been further elaborated by Winsløw (2008), and it is likely to mirror the situation in many similar institutions. On the other hand, there seems to be little research done on instrumental orchestration in this context. This motivated us to explore the potentials of resuming *Maple*-based instrumental orchestrations in the course *Analysis 1*, through the design of tasks which explicitly appeal to instrumented techniques. The aim was to realise materialization and lever potentials through the facilitation of students’ autonomous work with technology and theory, facilitated by the use of instrumented techniques to solve at least part of the problems presented to them. Before going into the theoretical and empirical analysis of concrete problems, we first map out the target praxeologies appearing in the first weeks of *Analysis 1* and considered in this study, with a special regard to the design of tasks.

Target praxeologies

The praxeologies focused on here are all concerned with deciding on the following questions for a given *sequence* or *series* of *numbers* or *functions*: does it converge? How? To what? And why? This gives, as a first “map” of the praxeologies concerned, the “grand tasks” shown in Table 1.

	SEQUENCES	SERIES
NUMBERS Given (a_n)	T_{11} : is (a_n) convergent? T_{12} : if so, what is the limit? T_{1k}^* ($k=1,2$): prove answer	T_{21} : is $\sum a_n$ convergent? T_{22} : if so, how (absolutely,... ?) T_{23} : ...and what is the limit? T_{2k}^* ($k=1,2,3$): prove answer
FUNCTIONSG iven (f_n) , e.g. $f_n(x) = a_n x^n$	T_{31} : is (f_n) convergent? T_{32} : if so, how (uniformly ?) T_{33} : ...where (eg. interval(s))? T_{34} : ... what is the limit? T_{3k}^* ($k=1,2,3,4$): prove answer	T_{41} : is $\sum f_n$ convergent? T_{42} : if so, how (uniformly ?) T_{43} : ...where (eg. interval(s))? T_{44} : ...what is the limit? T_{4k}^* ($k=1,2,3,4$): prove answer
“REVERSE”	T_{5c} : Given number or function, find approximating sequence or series according to some criteria c (eg. a power series...)	

Table 1: Grand types of tasks, further subdivided according to techniques

According to the techniques employed, the tasks listed in Table 1 are further subdivided. For example, T_{21} is associated with a number of *particular techniques*, such as the ratio test $\tau_{21,RT}$ whose domain of application correspond to a type of task $T_{21,RT}$ for which the limit of $|a_{n+1}/a_n|$ can be found using a technique for T_{11} (and the result is either less than 1, in which case the result is yes, or greater than 1, in which case the answer is no). We notice that in this case the technique involves solving a task of type T_{11} , and in fact several techniques corresponding to the “grand tasks” T_{ik} listed in Table 1 involves solving another task $T_{i'k'}$ (often but not always with $i' < i$), which is why the didactical process will often address the tasks more or less in the order of the table. It is also clear that the non-instrumented techniques for types of tasks included in T_{ik} are typically closely associated with theory (theorems and definitions) which, when it comes to solve T_{ik}^* , are to be used explicitly and with attention to precise conditions.

The instrumented techniques (in fact common to all T_{2k}) offered by Maple consist in symbolic ($\tau_{2,S}$) or numeric ($\tau_{2,N}$) evaluation of sum ($a_n, n=1..infinity$); while their domain of validity may be less clear, it nevertheless corresponds to types of tasks $T_{2,S}$ and $T_{2,N}$. The technology pertaining to these techniques involves further explanations related to the syntax of *Maple*, variations that can be tried, etc. While the pragmatic value of these techniques is high (for tasks belonging to these types) their epistemic value is “low” in the sense they are not associated with satisfactory techniques for T_{ik}^* . In fact, the *theory* according to which technologies are to be justified and related is still that of convergence of functions and series, involving definitions and theorems pertaining to various special cases (closely related to the non-instrumented techniques, which will then have to be mobilized eventually, for the solution of T_{ik}^*).

The types of tasks covered by T_{5c} include, in particular, determining a power series that approximate a given function. It is inverse to the task $T_{44,PS}$ of determining, for a power series that converge on some interval, the corresponding function.

Designing tasks for instrumented work

We now give some examples of how instrumented techniques were integrated into the work of students, all coming from the first two of the four “take home exams” based on which the students were graded in this course.

Example 1. The students were given four series, including

$$(a) \sum_{n=1}^{\infty} (3n^2 + 7n + 1)^{-n} \quad \text{and} \quad (c) \sum_{n=1}^{\infty} (-1)^{-n} \frac{n^2 + n - 1}{3n^2 + n}$$

The instruction is to use *Maple* to compute five partial sums, or alternatively do a point plot, in order to get an idea of whether the series converge or not; and also to see if *Maple* can decide this directly. Finally the students should give an answer with proof to the question of whether the series are divergent, conditionally convergent or absolutely convergent (tasks included in T_{21} , T_{22} , T_{21}^* , T_{22}^*). As regards T_{21} , a

Working Group 14

general challenge consists in determining the *type* of the given task and hence that will solve it. Having an idea of whether the series converges or not is indeed helpful, and this is where the instrumented techniques come in. The most immediate, $\tau_{2,S}$, does not work for the given tasks (so they do not belong to $T_{2,S}$), while $\tau_{2,N}$ apparently works for both (as it returns finite numbers):

> **A:=sum((3*n^2+7*n+1)^(-n), n=1..infinity);**

$$A := \sum_{n=1}^{\infty} (3n^2 + 7n + 1)^{(-n)}$$

> **C:=sum((-1)^n*(n^2+n-1)/(3*n^2+n), n=1..infinity);**

$$C := \sum_{n=1}^{\infty} \frac{(-1)^n (n^2 + n - 1)}{3n^2 + n}$$

> **evalf(A), evalf(C);**

0.09228936139, -0.07614037580

However the partial sums ($\tau_{2,PaS}$) and even more the point plot method ($\tau_{2,PoP}$) reveal that the series (c) alternates between two values (about 0.09 and -0.24) and the value given by $\tau_{2,N}$ is the average of these. This means that the series (c) does not give a task of type $T_{21,N}$, while students may in fact be confused by the apparent contradiction of the results achieved with $\tau_{2,N}$ and $\tau_{2,PaS}$ or $\tau_{2,PoP}$. The task (c) thus demonstrates the necessity of combining instrumented techniques with other ones – an important point brought out here by careful instrumental orchestration. At the same time, the materialization potential realised by $\tau_{2,PaS}$ or $\tau_{2,PoP}$ helps to choose non-instrumented techniques for T_{21} , T_{22} , T_{21}^* , and T_{22}^* (for (a), root criterion, for (c): divergence criterion related to a task of type T_{11} or T_{12} to show that $|a_n| \rightarrow 0$).

Example 2. For the power series $\sum x^n/(n(n+1))$ the students were asked to find the sum function (T_{44}) using *Maple*, then prove the result (T_{44}^*). Here, the symbolic technique $\tau_{44,S}$ gives:

> **sum(x^n/(n*(n+1)), n=1..infinity);**

$$-\ln(-x + 1) + \frac{\ln(-x + 1)}{x} + 1$$

which the students might not easily find by other methods. However, using the Taylor series of \ln and the above formula, it is easy to solve T_{44}^* . This use of $\tau_{44,S}$ also helps in reasoning about the convergence of the series at 0 and ± 1 , which are in play in later parts of the exercise, and thus to a realization of the lever potential.

Example 3. Students were asked to use *Maple* to compute the exact value of $s = \sum_{k=1}^{\infty} k^{-4}$ using *Maple* (the result $s = \pi^4/90$ is immediate, using $\tau_{2,S}$) and then to investigate which of the sequences $a_n = \sum_{k=1}^n k^{-4}$ and $b_n = \frac{1}{3}n^{-3} + \sum_{k=1}^n k^{-4}$ gives the best approximation to s . This task belongs to T_{5c} (approximate numbers by sequences or series). Here, using numeric computations or point plot one sees that

$a_n \leq s \leq b_n$ for all n , and that in fact b_n is closer to s than a_n for $n \geq 3$. The students are finally asked to prove their hypothesis. This is achieved using non-instrumented techniques, taken from the proof of the integral criterion, but the experiment with numeric values of the sequences can support this transition to the theory block when materialization of the two sequences has already suggested a hypothesis. A further epistemic value of the instrumented technique in this task resides in the fact that students may (in fact should) develop themselves the criterion c for the “best” approximation, by looking at the numeric values of $s-a_n$ and $s-b_n$.

Example 4. The students were asked to produce a plot of the functions $f_n(x) = 1/[1 + \exp(n(2-x))]$ for five values of n , in order to “illustrate the convergence properties of the sequence”. This in fact involves T_{3k} for all k . Just as in the previous example, the materialization potential can be realized to generate strong hypotheses for later work (on T_{3k}^*) if the instrumented techniques related to simultaneous plotting are used well (this includes the choices for n and the interval on which the functions are plotted).

SOME FIRST RESULTS

The instrumental orchestrations exemplified above were first used in the spring 2010 edition of *Analysis 1*, with about 150 students (divided in 6 classes for exercise sessions). Although all students have easy access to computers with *Maple*, the course had previously not involved instrumented techniques. For this and other reasons, a “modest” approach was adopted, with *Maple* being involved in just a few classroom exercises per week, and in about 20% of the questions in the take home exams (these were handed in by students in two paper copies, including print-outs of *Maple* sheets). The main purpose of this intervention was to get basic information about the effects of the tasks and the feasibility of more ambitious designs in this and similar courses. The goal of these elements of instrumental orchestration was of course to support students’ access to tasks that require more autonomous work with theoretical blocks, but we did not expect that the limited experiment would result in major documented impact of this kind. Instead we analysed, more locally, the performance of students on tasks with instrumented techniques, mainly in their written productions in the two first take home exams. We present the results for the four examples given in the previous section below. Also, secondary and more informal evidence was collected from teachers and students. In particular, the standard course evaluation questionnaire filled by students at the end of the course was extended with items about their experience with *Maple*-use in the course. Some of this evidence is also presented below.

Performance on exam tasks: instrumented techniques vs. overall performance

In Tables 2, we present the overall results of students’ work on the four examples of exercises that were explained in the previous section. The tables show the number of

Working Group 14

students in groups defined by the following rough but objective criteria (so that, for instance, the sum of the first row gives the number of students in group H):

H: overall high achievers, with at least 75% of points in the take home exam

L: overall low achievers, with less than 75% of points in the take home exam (still plenty of room to pass the course - the limit is an average of 50% in the four exams).

+I: correctly used instrumented techniques in the exercise(s) described in the ex.

-I: did *not* (or *not correctly*) use instrumented techniques in the exercise(s) described

The first three tables (corresponding to example 1, 3, 4) pertain to the same set of exercises, so the groups H/L are the same.

Ex.1	+I	-I
H	73	9
L	42	17

Ex.3	+I	-I
H	71	10
L	40	21

Ex.4	+I	-I
H	77	4
L	47	13

Ex.2	+I	-I
H	73	4
L	54	1

Tables 2: Performance of students on exam tasks involving instrumented techniques

We notice the similarity of results for Ex.1 and 3, probably because they require students to work with very similar combinations of instrumented techniques for computing series and sums. While the *Maple* commands to be used are in themselves quite basic, most mistakes in group L are in fact also quite basic, like using or plotting the first five partial sums to conclude that a series is not convergent (while in fact it is). Similar errors are found in Ex. 3 where the first terms may also confuse. Also, error messages like “Float(undefined)” are misinterpreted as “divergent” by a few students. In Ex. 4, the difficulties with instrumented techniques appear slightly smaller for both groups, probably because only one (plotting) is required and works (unlike in Ex. 1 and 3 where one must carefully select and combine techniques). The difficulty is the choice of plotting interval – some students, who choose a wrong one, just get a bunch of parallel lines.

We finally notice that virtually all students have used the required instrumented technique correctly in Ex. 2 (the four students in $-I \cap H$ simply abstained from *Maple* use, a phenomenon further discussed later). This can be easily explained by both the ease and the pragmatic value of using the instrumented technique ($\tau_{44,S}$) here. Moreover this occurred at a later stage of the course where the students had seen many more complicated uses of *Maple*, including Ex. 1 and 3. The absence of challenge does not mean that this type of use of *Maple* is useless (it works, in this case, as an intelligent “table of series”), just that the lever potential achieved is of a more pragmatic value than in the cases where strong theoretical perspectives are activated in the choice of an instrumented technique.

Student questionnaire : diverging ‘voices’

Working Group 14

It is not surprising that students with an overall lower performance also commit more errors in using instrumented techniques. Our purpose was not to make easy tasks but to include practical (and instrumented) elements in the tasks that would ease the transition to more theoretical parts, at least for low achieving students. To know about this would require a rather intensive study of these students' work during the course, which we did not manage to do. The weaker but easier alternative, structured interviews based on select tasks, had to be given up because we did not get a sufficient number of volunteers (exam period was followed immediately by summer holiday).

Nevertheless, interesting evidence is found in the course evaluation, done via the course website towards the end of the course and with student replies being anonymous. Three questions concerned the use of *Maple* in the course. In the two first, students are asked to indicate their level of agreement with the propositions "I think that the use of *Maple* in the home exercises contributed to my understanding of them", and "I think the use of *Maple* in the home exercises improved my solutions". Here, the 80 responding students are divided rather equally on agreeing and disagreeing. The third question invites for "comments and suggestions regarding the use of *Maple* in this course" and is of course with open field response. As many as 32 students have responded to this field; they can not be considered "representative" but they do represent strong opinions on the matter. These are also divided roughly in two halves, students who think the use of *Maple* is superfluous or tedious, and students who found it useful and supportive. Here are some examples of these comments (translated from Danish):

I think it was good that the Maple part was relatively simple, and without it certain exercises would have been difficult to get into.

Maple is not necessary in a course like An1. The pure mathematical methods totally suffice to understand and solve all the exercises (...) without ugly tricks like numerical evaluation of expression. In all my home exams I did everything without Maple, and in the end I did the Maple part without being surprised of any result.

I am pretty sure I didn't get more understanding from the use of Maple, and I have understood from older students that we will not need Maple in the future [authors: more advanced courses in the mathematics programme]. It's irritating.

The extent now [authors: of Maple use in the course] is fine, but it shouldn't be more (maybe a bit less). But it clearly helps your understanding.

CONCLUDING REMARKS

Combined with our analysis of take home exams and observations in a few classes where *Maple* was used (often computers were missing), we think that two minorities of students may be identified relatively to the categories of Table 2:

Working Group 14

$-I \cap H$ (“the proud purists”): Relatively successful students who don’t think *Maple* has its place in a “real” mathematics course and who sometimes choose to deliberately not do the *Maple* part (according to the course policy, declared in the first weekly, they are not penalised for this if they solve the non-*Maple* parts correctly).

$+I \cap L$ (“the challenged but helped”): students who have troubles with several of the exercises, particularly the more abstract and technically demanding ones, but who appreciate and succeed with the parts where instrumented techniques can be used. This is in part because these parts are relatively easy (according to one instructor, they even take some *L*-students above the “passing line” of 50%) but also, at least for (and according to) some students, because these parts help their “understanding”.

Making the optional character of *Maple*-use more apparent could probably satisfy the first group. The needs and work of students in the latter group has to be studied more intensively than we were able to in this study.

UNDERGRADUATE STUDENTS' USE OF DEDUCTIVE ARGUMENTS TO SOLVE "PROVE THAT..." TASKS

Paola Iannone¹ and Matthew Inglis²

¹ School of Education and Lifelong Learning, University of East Anglia, UK

² Mathematics Education Centre, Loughborough University, UK

In this paper we report findings from an investigation of 222 proof attempts produced by 74 year-one undergraduate mathematics students at a university in the UK. We classify the proofs according to an extended classification originally used by Stylianides and Stylianides (2009). We found that already at the beginning of Year 1 most undergraduate students in our sample associate the request for a proof of a statement to the production of a deductive argument. Moreover, when students failed to produce a correct proof this was mostly because of difficulties in producing deductive arguments. We suggest that more attention should be given to the process of producing deductive arguments rather than to the types of non-deductive arguments that some students produce as proofs.

INTRODUCTION

Undergraduate students' difficulties with proof production at university level have been widely documented in the literature (Moore, 1994; Harel & Sowder, 1998, 2007; Weber, 2001; Selden & Selden, 2003; just to cite a few examples). Indeed in 2009 the ICMI Study 19 was dedicated to "Proof and proving in mathematics education" with one study group solely focusing on proof and proving at tertiary level. Much of the attention of researchers in this field has been devoted to the types of arguments that undergraduate students produce when asked to solve "prove that..." tasks. One of the most popular theoretical frameworks for analysing students' proofs (not only at undergraduate level) has been proposed by Harel and Sowder (1998, 2007). This framework offers a comprehensive taxonomy of students' Proof Schemes, where

...a person's proof scheme consists of what constitute ascertaining and persuading for that person. (Harel & Sowder, 1998, p. 244)

The taxonomy offered by Harel and Sowder (1998) is based on extensive empirical work at all levels of school and at university. The authors describe three categories of proof schemes (each one comprising several sub-categories) which they call *External Conviction proof scheme*, *Empirical proof scheme* and *Analytical (deductive) proof scheme* (ibid. p. 245). An *External Conviction proof scheme* is found when students

... merely follow formulas to solve problems, they learn that memorisation of prescriptions, rather than creativity and discovery, guarantees success. And when the teacher is the sole source of knowledge, students are unlikely to gain confidence in their ability to create mathematics. (ibid. p. 245)

An *Empirical proof scheme* is one in which

... conjectures are validated, impugned, or subverted by appeals to empirical facts or sensory experiences. (ibid. p. 252)

and an *Analytic Proof Scheme* is

... one that validates conjectures by means of logical deduction. (ibid. p. 258)

Harel and Sowder (1998) also indicate that the latter is the proof scheme that students should aspire to and the one generally held by the community of mathematicians. Because of the prominence that Harel and Sowder (1998) give to deductive arguments, and the statement that this is indeed the proof scheme shared by professional mathematicians, we will take deductive arguments to be the desired outcome of “prove that...” tasks. In fact Harel and Sowder (2007) refine their definition of Analytical proof scheme as to include two proof scheme classes: Transformational proof schemes and Axiomatic proof schemes and state that:

All the transformational proof schemes share three essential characteristics: generality, operational thought, and logical inference. (ibid. p. 7)

In the studies cited by Harel and Sowder (2007) a picture emerges of university students still uncertain about what the role and place of proof at university level is, with students gaining conviction about mathematical statements through various types of arguments, including many students relying solely on empirical arguments. To cite just one more example of research in this direction, Recio and Godino (2001) reported that only very few of the university students in their sample were successful in proof tasks and that 40% of the students in the sample relied on empirical arguments as proof. Whilst proof schemes offer a “truly comprehensive” (Harel & Sowder, 2007) perspective on learning and teaching proof, it can be argued that much of the focus of this framework is on the *types* of arguments that students find convincing when asked to solve proof tasks rather than the *process* they use to produce such arguments. In this paper we examine what types of arguments year-one mathematics students at a high-ranking university in the UK produce when asked to solve proof tasks and we argue that, at least in this case, students are aware of the requirement of proof but their difficulties lie in the process of producing correct deductive arguments.

THE STUDY

The main aim of the study reported in this paper was to find out whether self-efficacy is an accurate predictor of academic performance, and in particular of proof production. For the scope of this study we have defined self-efficacy, following Bandura (1977), as the judgment students make of their own capability of performing a given task (in our study the task is proof production). The results of this part of the study were presented in Iannone and Inglis (2010). For the scope of his paper we have analysed the proofs that the students produced in the second part of the

Working Group 14

questionnaire they were asked to fill in. Seventy-six first year students in mathematics (or on a joint degree with a substantial mathematics component such as computer science or natural sciences) at a high-ranking university in the UK took part in this study. Data collection took place in week 8 of the first semester during one of the Linear Algebra lectures. A booklet of questions was given to each participant, and the students were asked to work through the questions at their own pace. The first section of the booklet consisted of 28 statements; ten consisted of our Proof Self-Efficacy Scale (Iannone & Inglis, 2010), designed following Bandura's (2006) guidelines. A further ten statements were formed from the items of the General Self-Efficacy Scale (Schwarzer & Jerusalem, 1995). Eight extra items were also introduced to readdress the balance between forward- and reverse-scored items (taken from the Need for Cognition scale, Cacioppo & Petty, 1982). The participants were asked to read and decide the extent to which they believed the statements were characteristic of them, using a five-point Likert Scale (from "extremely uncharacteristic" through to "extremely characteristic"). The order in which the statements appeared was randomised for each participant. The second part of the booklet consisted of four proof construction tasks novel to the students and designed in collaboration with a mathematics lecturer so that they would represent appropriate tasks for this cohort, in the sense that they were tasks similar to ones that the students had encountered during the lectures. The order in which the proof tasks appeared was again randomised for each participant. The participants were given 20 minutes to work on the proof tasks.

The proof tasks included in the booklet were:

- A. Prove that the sum of two odd numbers is even.
- B. Prove that the sum of the first n natural numbers is equal to $\frac{1}{2}n(n+1)$.
- C. Let d , a and b be integers. Prove that if $d \mid a$ and $d \mid b$ then $d^2 \mid (a^2 + b^2)$.
- D. Prove that if the sum of the digits of a natural number is divisible by 3 then the number itself is divisible by 3.

The proof Task D was introduced even if after the meeting with the mathematics lecturer it was deemed to be too demanding for this cohort. As we will see in the analysis of the data this was indeed the case. A marking scheme was devised to evaluate the proofs. Each proof was marked out of five. In Appendix we report the questions in the questionnaire, the marking scheme and the model solutions to the tasks. We analysed the proofs and classified them following the refinement of a proof classification originally developed by Stylianides and Stylianides (2009) in the context of a study with primary prospective elementary teachers. Whilst categories M1, M4 and M5 of the original classification served our aims, categories M2 ("valid general argument but not a proof", *ibid.* p. 246) and M3 ("unsuccessful attempt for a valid general argument", *ibid.* p. 246) were too broad and we decided to divide them

Working Group 14

further in categories P1 to P5. So we obtained the following classification of proof tasks:

Type	Description
M1	Correct proof
P1	The last part of the proof is missing
P2	The hypothesis are expressed correctly but the proof stops after the statement of the hypothesis
P3	The solution does not represent the most general case
P4	The solution resembles the correct proof but there are not enough details to see whether this is correct or not
P5	The solution follows a correct deductive argument but some mistakes in the calculations occur
M4	The solution consists of an empirical argument
M5	Some mathematical statement is presented but this is unrelated to the proof requested
0	Task left blank

Table 1: Responses categories

Before we discuss the classification of the proof tasks we give here some examples to clarify the categories mentioned above. We assume that the categories M1 and 0 are self-explanatory so we will very briefly discuss the other categories giving some examples from the students' work.

P1 – The last part of the proof is missing

Solutions in this category comprise deductive arguments without conclusions. Typical examples here are proofs by induction (Task B) which stop at the end of the inductive step.

P2 - The hypothesis are expressed correctly but the proof stops after the statement of the hypothesis

In several of the solutions for the proofs Tasks A and C students wrote the hypothesis correctly (for example stated correctly that $d \mid a$ means $a = kd$ with k an integer number) but were unable to proceed. Attempts of proof of this kind resonate with Moore's (1994) findings who observed that students can sometimes state the hypothesis in the theorem to prove, but are unable to start the proof.

P3 - The solution does not represent the most general case

Solution:

Let $n \in \mathbb{R}$

An odd number can be denoted by $(2n-1)$.

Two odd numbers added together:

$$(2n-1) + (2n-1) = 4n-2$$

if a number is divisible by 2 then it is even
(given it doesn't give irrational answer).

$$\frac{4n-2}{2} = 2n-1.$$

This is an odd number, ~~so not irrational.~~

Then the number $4n-2$ is even.

□

Fig. 1: Example of category P3

This category was mostly found in the solution of Task A. An example is reported in Fig. 1 above. In this case the student failed to express the most general case, proving instead the statement: the sum of two equal odd numbers (i.e. twice an odd number) is even.

P4 - The solution resembles the correct proof but there are not enough details to see whether this is correct or not

An example in this category is the following:

Solution:

Proof by exhaustion: odd numbers must end in either 1, 3, 5, 7, 9 so combining all possible combinations of these numbers only gives even numbers as a result. □

Fig. 2: Example of category P4

In this example the student has tried to give a verbal argument for the proof. However lack of clarity and details mean that it is not possible to ascertain whether the argument is correct or not.

P5 - The solution follows a correct deductive argument but some mistakes in the calculations occur

Typically this occurred in the proofs by induction where the students made a mistake in the calculations for the inductive step.

M4 - The solution consists of an empirical argument

In this category we have grouped examples of “proof by example” where students gave a numerical example as a proof. This is clear in the following example:

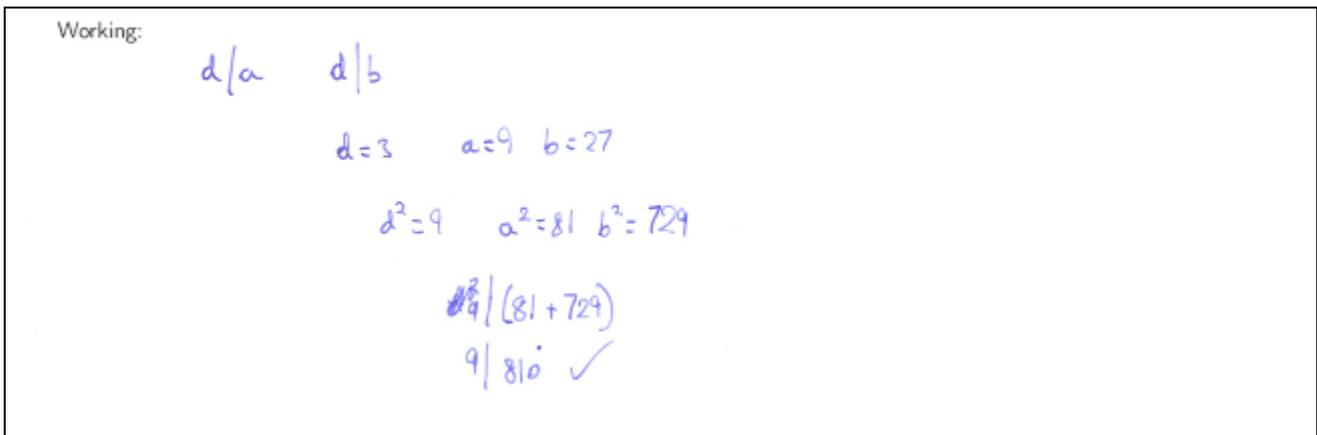

Fig. 3: Example of category M4

Here the student gave one numerical example and terminated the answer with a tick – perhaps signaling that s/he was satisfied with the answer or was satisfied with having found a confirming example.

M5: Some mathematical statement is presented but this is unrelated to the proof requested

Responses in this category included all sorts of unrelated mathematical facts, but no recognisable deductive arguments.

ANALYSIS AND FINDINGS

Two participants were removed from the analysis of the data as they attempted none of the proof tasks. This left us with 74 responses.

A classification of the proof tasks excluding Task D, according to the categories outlined above yield to the following table:

	A	B	C	Total
M1	28	34	21	83
P1	0	11	5	16
P2	3	8	8	19
P3	30	0	1	31

Working Group 14

P4	3	2	2	7
P5	0	3	6	9
M4	0	0	2	2
M5	7	4	6	17
0	3	12	23	38
Total	74	74	74	222

Table 2: Classification of the proof tasks excluding Task D

We excluded Task D as it was solved correctly only two times across the sample, with only five students accruing marks for it.

The distribution of the marks over the three remaining proof tasks had mean 7.76 and standard deviation 4.35, suggesting that the three tasks were suitable for this cohort of students (i.e. not at ceiling or floor levels). As for the classification of the proof tasks Table 2 shows that 37% of the total number of tasks attempted by the students were correct, with the task solved correctly the most times being task B (solved correctly 34 times) followed by Task A (solved correctly 28 times) and Task C (solved correctly 21 times). Considering categories P1, P5 and P3 as (attempts at producing) deductive arguments and category P2 as manifestation of the inability to produce a deductive argument (we infer this by the formal statement of the hypothesis but the lack of any other writing to follow, see also Moore, 1994) the distribution gives the following frequencies:

Deductive arguments (M1, P1, P2, P3, P5)	158
P4	7
M4	2
M5	17
0	38
Tot	222

Table 3: Summary of the types of arguments used across the tasks

Table 3 shows that more than two thirds of the arguments that the students produced (or attempted to produce) were in fact deductive arguments. Only two arguments produced out of 222 were empirical arguments.

CONCLUSIONS

In this paper we have classified 222 solutions to proof tasks collected during a study involving year-one mathematics students in a university in the UK. Our classification of proof tasks aimed at investigating what type of arguments students produce when

Working Group 14

asked to give a proof a mathematical statement. We found that the students in our sample, at a very early stage in their university degree, know largely what the result of a proof construction task ought to be (at least in algebra), namely a deductive argument. Their difficulties were mostly related to failure to produce a correct deductive argument rather than failure to recognise that a proof involves some kind of deductive argument. Remarkably, in our sample, we found only 2 “empirical proofs” pointing to the fact that our students on the whole did not regard investigating one or more examples of a conjecture to be sufficient proof. Our findings resonate with other findings in the research literature (e.g. Weber, 2001; Weber & Alcock, 2004) where researchers have repeatedly pointed out to the difficulties students have in producing correct deductive arguments. Our findings also seem to be in contrast with other research findings on proof production (for example Recio & Godino, 2001) where researchers have pointed out the reliance of university students on empirical arguments to solve “prove that...” tasks. One possible explanation for this is that the students in some of these research projects are not always mathematics students. For example in the paper by Recio and Godino (2001) we have cited previously, participants were “students who took a mathematics subject in different faculties and polytechnic” (p. 84). Although the authors do not give more details about their sample, we argue that this could include students from many departments and not necessarily sciences. The participants in our sample were mostly mathematics students, with some students coming from other disciplines with a strong mathematics component (e.g. computer science, natural sciences, mathematics with economics). Perhaps it is the background of the students that accounts for such discrepancies in the findings. The data we have presented seem to indicate that the students in our sample (e.g. students with a strong mathematics background) already operate with an analytical proof scheme, and therefore the goal of instruction in this case should be to help the students become versed in the production of deductive arguments rather than the elaboration of their proof schemes. If we confront this with Harel and Sowder (2007) where they write:

We emphasize again that despite this subjective definition the goal of instruction must be unambiguous—namely, to gradually refine current students’ proof schemes toward the proof scheme shared and practiced by contemporary mathematicians.

(Harel & Sowder, 2007, p. 7)

we would argue that perhaps more attention (in research and in teaching) should be given to the *process* by which students produce evidence to gain conviction about statements and write deductive arguments to produce proofs rather than to what are the *types* of evidence that students at university level offer as proofs.

APPENDIX

In this appendix we report the questions included in the questionnaire we gave to the students (labelled here Task X), a solution designed according to what the students would have seen in the lectures and the marking scheme (the last two items not included in the questionnaire).

Task A: Prove that the sum of two odd numbers is even.

Working Group 14

Proof: Let $n = 2k_1 - 1$ and $m = 2k_2 - 1$ be odd numbers. We have

$$m + n = 2k_1 - 1 + 2k_2 - 1 = 2(k_1 + k_2) - 2 \text{ even.}$$

2 points for expression of odd number; 2 for expression of sum; 1 for conclusion

Task B: Prove that the sum of the first n natural numbers is equal to $\frac{1}{2}n(n+1)$.

Proof: For $n = 1$: $\frac{1}{2}n(n+1) = 1$.

Suppose this is true for $n - 1$ and show this is true for n . We have

$$S_{n-1} = \frac{1}{2}(n-1)(n-1+1) = \frac{1}{2}(n-1)(n).$$

$$\text{Add } n \text{ and obtain } S_n = \frac{1}{2}(n-1)(n) + n = \frac{1}{2}n(n+1).$$

Hence this is true for all n in N .

2 points for base step; 2 for inductive step; 1 for conclusion.

Task C: Let d , a and b be integers. Prove that if $d \mid a$ and $d \mid b$ then $d^2 \mid (a^2 + b^2)$.

Proof: $d \mid a \rightarrow a = kd$ and $d \mid b \rightarrow b = md$, hence

$$(a^2 + b^2) = (kd)^2 + (md)^2 = k^2d^2 + m^2d^2 = d^2(m^2 + k^2) \rightarrow d^2 \mid (a^2 + b^2).$$

2 points for expression of divisibility; 2 for expression of sum of squares; 1 for conclusion.

Task D: Prove that if the sum of the digits of a natural number is divisible by 3 then the number itself is divisible by 3.

Proof: Let d be a natural number. Let $d = d_k d_{k-1} \dots d_0$ its expression in digits. If we expand this expression in base 10 we have

$$D = 10^k d_k + 10^{k-1} d_{k-1} + \dots + d_0 \text{ we can write this as}$$

$$d = (10^k - 1)d_k + (10^{k-1} - 1)d_{k-1} + \dots + 9d_1 + d_k + d_{k-1} \dots + d_1 + d_0$$

Note that all the items in the form $10^x - 1$ are divisible by 3 (they are in fact a string of 9s). So we can write $d = 3A + d_k + d_{k-1} \dots + d_1 + d_0$. Hence d is divisible by 3 if and only if $d_k + d_{k-1} \dots + d_1 + d_0$ is divisible by 3.

2 points for expression base 10; 2 for changing into $(10^{k-1} - 1)$ etc; 1 for conclusion.

HOW WE TEACH MATHEMATICS: DISCOURSES ON/IN UNIVERSITY TEACHING

Barbara Jaworski and Janette Matthews,

Loughborough University, UK

A series of seminars called “How we Teach” has focused on the teaching of mathematics at university level. Participants are mathematics educators and mathematicians in a university School of Mathematics. Video recordings of the seminars have been analysed to uncover a teaching discourse in the mathematical community involved. Analysis reveals the preferred approaches to teaching (within institutional boundaries), the resources teachers use and the ways teachers think about students’ learning of mathematics. Issues arising are illustrated by key quotations and the paper offers a first attempt at characterising the discourse and suggesting implications for teaching development and the education of new teachers.

Keywords: university mathematics teaching, discourse, community, development.

INTRODUCTION

This paper results from analysis of data from a series of seminars presented by university mathematics teachers on the topic “How we Teach”. They take place within a *School of Mathematics* which includes a *Mathematics Education Centre* and focus on research into university mathematics learning and teaching. Over two and a half years, with 20 seminars to date, most have been video-recorded and 10 seminars have been analysed. We have chosen to analyse seminars regarded as being most representative of an established university discourse. They were each presented by a mathematician or a mathematics educator, to a mixed audience, all of whom teach mathematics to mathematics or engineering students.

Our intention is not to reveal how mathematics teaching *is*, but rather how those teaching mathematics *talk about* their teaching within their institutional setting. We have recorded and analysed what teachers *say they do*, how and why, and the related discussion between seminar participants, covering approaches to teaching, reasons behind these approaches, and issues arising for the presenter, or in discussion.

WHAT DO WE KNOW ABOUT TEACHING AT UNIVERSITY LEVEL?

Various members of the international research community suggest that we do not, as yet, know very much about how mathematics is taught at university level. For example, from New Zealand and the US respectively, we have:

It is apparent on inspection of the literature that ... there is relatively little research into teaching and learning of mathematical sciences at the undergraduate level and very few academic journals that focus on publishing such research. (Barton & Thomas, 2010, p. 1).

... while some mathematicians have written *about* their teaching,, others have analysed aspects of their teaching and students' learning in innovative collegiate courses, ... very little research has focused directly on teaching practice – what teachers do and think daily, in class and out, as they perform their teaching work (Speer, Smith & Horvath 2010, p. 99). Speer *et al.* (2010), point to five (rare) examples of published research on “collegiate teaching” in the US which provide

... empirical analyses that describe teaching at a sufficiently fine level of detail that teachers and other researchers can inspect and learn from the instructional choices and learning of others.

Some current research in Europe is also looking at university teaching with such level of detail in trying to characterise teaching practices, inform our community and open up a wider awareness of what we are doing to allow us to address how we might do it better (e.g., Jaworski, Treffert-Thomas and Bartsch, 2009; Ioannou & Nardi, 2009; Petropoulou, Potari, & Zachariades, 2010). Clearly we need more of this kind of research as well as outlets for publishing it.

The research reported in this paper aims to open up the field of study of university teaching for better communication and developing awareness. However, its focus, in seeking *a teaching discourse*, is not on the practice of teaching per se, but on how the mathematical community expresses its thinking about teaching and the design of its teaching. Concomitantly, this research, and the actual practice of the research (in this case, the motivation for and holding of the seminars), can draw teachers' attention to alternatives to common practice, encourage critical approaches to thinking about teaching, and foster teaching development.

Two words that have appeared in the above text and perhaps need further remarks are *discourse* and *community*; although space restricts what it is possible to say. Rom Harré and Grant Gillet (1994) write: “Actions and acts they accomplish make up discursive practice” which is “the repeated and orderly use of some sign system, where these uses are intentional, that is, directed at or to something” (p. 28). Also, “... a discursive practice is the use of a sign system, for which there are norms of right or wrong use ...”(p. 29). Derek Edwards (1997) writes that a focus on discourse shifts notions of human actions as rule governed and based on cognitive representations “towards a concern with norms and descriptions”, and that “norms do not govern actions, but ... actions are done and described in ways that display their status with regard to some rule or expectation (p. 7). Harré and Gillet write further, “The crucial insight that allows us to explain psychological phenomena as patterns of discursive acts is that norms and rules emerging in historical and cultural circumstances operate to structure the things people do” (p.33). We would claim that, in the teaching of mathematics, we are dealing with multiple *sign systems*, each with their own “norms and rules”. Mathematics itself offers symbolic sign systems, as well as conventions for writing mathematics, for example, proof structures. Teaching mathematics uses a complex set of sign systems, which include the

Working Group 14

mathematical: these would encompass ways of describing teaching and learning with all the ontological and epistemological associations on which such descriptions rest.

We work within a community of practitioners in mathematics, including teachers and researchers and various areas of research in both mathematics and mathematics education. We can talk here of a “community of practice” in which

The concept of practice connotes doing, but not just doing in and of itself. It is doing in a historical and social context that gives structure and meaning to what we do. In this sense practice is always social practice (Wenger, 1998, p.47).

Etienne Wenger describes three ‘dimensions of practice’ which he explains are ‘the property of a community’; these are ‘joint enterprise’, ‘mutual engagement’ and ‘shared repertoire’ (p. 73). Briefly, they involve common purpose and activity and a shared language. Ways of interpreting or describing such a community can be seen as a *discourse* as set out briefly above. So, in our study reported in this paper, we seek to identify aspects of both community and its discourse about teaching mathematics, as seen through analysis of the words uttered by practising mathematics teachers in *How we Teach* seminars.

METHODOLOGY

One intention in creating the seminars was to provide a forum for such a discourse to become overt and consequently open to challenge. We wished to reveal common practices, taken for granted assumptions, and differences in ways of seeing established practices, and, through making all of these more visible, give our community a chance to look critically at *what* we do, and *how* and *why* we do it. In one sense we wished to flesh out our ‘joint enterprise’, ‘mutual engagement’ and ‘shared repertoire’, or recognise issues which challenge such concepts. One essential recognition was the institutional norms and expectations within which modes of practice were taken for granted. For example, programmes of study are modularised and the main medium of teaching is the lecture addressed to a given cohort of students (up to 250 in some mathematics modules). Our data shows an overwhelming focus on teaching through *lectures*: those who teach are most commonly called lecturers. Although seminar participants address tutorials and other media for learning, discussion of the activity of lecturing by lecturers predominates. This makes it harder to see alternative modes of teaching except in the context of how they would fit into a lecture mode. In addition, the two constituencies, of mathematicians and mathematics educators, may actually see things differently. So we have needed to look critically at *who* is making the observations we note.

We have analysed data from 10 seminars. Our choice has been to analyse those which have seemed to contribute most centrally to an established university discourse at this university – that is those dealing with the mainstream teaching of mathematics to students studying mathematics as part of a mathematics or engineering degree. Thus, we have four from established mathematicians (who do

Working Group 14

research in mathematics), two from former mathematicians (who now do research in mathematics education), three from mathematics educators (who do research in mathematics education) and one from a university teacher (who does no research). The excluded seminars are not so centrally focused and are seen as more peripheral to our main aims for analysis.

Analysis has involved several stages:

1. To ground perspectives, two researchers viewed together the video-recording of one seminar and discussed their interpretations of what the data reveals.
2. Two researchers independently analysed one further seminar, noting key episodes and identifying their content in a linear pass through the recording.
3. Discussion in (2) suggested a style of analysis for the other seminars as follows:
 - a. One researcher produced a data reduction of the recording with a timeline noting factual details of episodes and highlighting significant ideas.
 - b. The same researcher produced a synoptic, descriptive account of the seminar, including the main themes and issues.
 - c. Both researchers discussed the analysis in (a) and (b), seeking justification for interpretations, and starting to identify key ideas and issues in the data. This led to identifying categories in the data.
4. Periodically, two researchers reviewed analysis to date and mapped out an interpretative account of the seminars, seeking a trustworthy description of the discourse overall, a characterization supported by significant quotations, and further analysis of these quotations as indicated below.

INITIAL CATEGORISATION

Broad categorisation has suggested the following areas of focus:

What is included in teaching? This includes institutional practice, students groupings, a VLE (LEARN), and the various (other) resources that are used in teaching.

Strategies/Approaches to teaching: These include use of questions, tests, examples, group work, animations, video, weblinks, Electronic Voting Systems (EVS), and Computer Assisted Assessment.

Provision of resources for students: This includes provision of notes, problem sheets, solutions, and a series workbooks (HELM)¹ provided free to students.

Approaches to/relationships with students: This focuses on different ways in which lecturers and students meet each other and kinds of interactions that result.

Links to research: This includes references to research either that undertaken at this university or research in the public domain.

ISSUES EMERGING DURING CATEGORISATION

Categorisation, as summarized above, may seem unsurprising. What was more interesting (for us as we worked on the data) were the issues that emerged from discussion around the various approaches to teaching, use of resources and interaction with students. We have grouped these issues within further categories or themes. We give examples below and provide key quotations, essential in highlighting the differing voices that make up the discourse. We refer to particular seminar contributors as M or ME to denote Mathematician or Mathematics Educator respectively. So, M2 or ME5 is always the same person.

Some lecturers brought mathematical examples to engage other participants and provide a basis for discussion. However, in the main, the discourse was meta-mathematical, assuming the basis of mathematics but talking about processes and practices rather than focusing *in* the mathematics. There were identifiable *levels* within this discourse, that is levels of reflective pedagogic perception of the teaching process (see Nardi, Jaworski & Hegedus, 2005 for a spectrum of pedagogic discourse). So far we have categorised these as follows: A) *What we do, how we do it and why* – this is offered with a certainty of action and purpose; B) *What the issues are that we are trying to address* – this points to questions relating to students and the uncertainties inherent in trying to promote desired outcomes for students; C) *What we don't know, but that it would be useful to know* – genuine questions to which it would be valuable to know some answers, but which we cannot address with any certainty at the moment. In addition we see remarks which suggest some underpinning theory, even if implicit. It seems clear that lecturers' words often carry with them something of the lecturer's beliefs about learning and how teaching relates to learning. While it is not our intention to associate individual lecturers with theoretical positions, it does seem worth recognising possible areas of theory on which discourse can be seen to be based. We start with 3 such areas, each dependent on perceptions of knowledge.

1. I need to convey knowledge to students (e.g., absolutist/Platonist theory).
2. Students construct their own knowledge (e.g. constructivist theory).
3. We are bringing students into our mathematical culture (e.g. sociocultural theory).

As a starting point for further consideration we have annotated the quotations below as to whether they can be seen to fit into one or more of these levels and areas.

Why should students come to a lecture?

There were differences in viewpoint, among seminar participants. as to whether students should attend lectures. Some lecturers design modules to encourage students to attend, others leave it to students to make their own decisions as to how to study and, correspondingly, make resources fully available to all.

Working Group 14

[ME2] says, “I don’t care if they don’t come to lectures because it is all on LEARN. They have got all the workbooks. All the learning resources are there”. I think, when you say that, you do yourself a huge disservice. Because you are missing all the little things that you do [in a lecture] that are of benefit to the students, [ME3: B/2/3].

There is recognition that students do not always choose wisely.

I don’t care [about attendance] if they can manage; but it is clear from exams there are students who would benefit from coming who are not. [M1: B/1]

Others see poor attendance as a reflection on their teaching.

I see poor attendance as a challenge. Some say it doesn’t matter if they turn up as long as they are learning ... poor attendance is a sign I am not doing something right. [ME4: B/1]

It therefore seems important to consider what aspects of lectures would make students find the experience valuable enough to wish to come.

We certainly don’t ever define what the place of a lecture is. And we all look at this very differently ... and have different expectations of students. And that might be confusing for students. [ME2: B/C/1]

I think they [lectures] can be fantastic for providing inspiration and structure to students about how a topic should be thought about. [ME5: A/1]

What I would like is for students to come to lectures and be able to do something at the end that they could not do when they came in. [ME3: A/3]

What is the role and nature of lecture notes, and who produced them?

It was an implicit assumption that students need ‘good notes’. There was considerable discussion on the nature and value of good notes, and disagreement on who should provide them, how and why. Some thought students need to learn how to make good notes for themselves. Some lecturers provide a full set on LEARN, and work through these in a lecture. Others produce “notes with gaps” where spaces are left for students themselves to fill in solutions to examples. If they want to be given the solutions, they have to attend the lecture.

I think they need to ... read my lecture notes in advance, come to lectures ... listen to my exposition, make their own notes about the key points, certainly get extra examples down. Then they can go away and use the workbooks productively. [ME8: A/2]

They think they don’t need to attend the lectures. If they have the notes, that is all they need So they had to turn up to get a full set of examples. I don’t know if that is a good way of doing it. [M7: C/3]

So what I have evolved is ... having gappy notes ... There are bits of writing and then there are big gaps where the students do more bits of writing. What this allows me to do ... is put in quite a lot of commentary about ‘this is what we are doing’ and ‘this is what we are supposed to be thinking about’. So it is not really like getting a text book where it says definition, theorem, proof and so on ... all that stuff that I want to say ..., can already be there for the students but they still have this sort of interaction with the notes

Working Group 14

where they are writing a lot of the mathematics. It allows for the notes to become something that you have but that you ... physically do something with during lecture time. [ME5: A/2]

I think you should treat students like adults. You should put in front of them all they need to do well. You must not restrict their knowledge in any way. [ME2: A/2]

How do students come to understand mathematics?

Possibly related to these different viewpoints on what a lecture can or should provide, there were differing views on what students can gain from a lecture.

Should we teach the students that in lots of situations they shouldn't expect to learn during a lecture but they should be expected to do something after the lecture? [ME3: C/2]

... you give them the materials, make it tolerably understandable but they don't understand a subject until they have done the tutorial sheets, worked their way through it, gone back to lecture notes and then they understand. [M2: B/2]

Consideration of the issue of understanding suggested that perhaps we had differing perspectives on what we mean by "understanding" and how understanding emerges. Some seemed to suggest that understanding will emerge through lots of focused practice, perhaps working through many examples. Perhaps students also believe this.

Maths is not a spectator sport. You can only learn maths by doing it yourself. [M3: A/2]

You know the technique. Once you have done a few hundred [*examples* e.g., differential equations, integration by parts], you do begin to understand. ... The understanding comes in when you have done enough. [M2: B/3]

In an ideal world, the anticipation is that they will be going away and practising and they have a great resource to do it." [HELM workbooks]. [ME8: A/2]

Many of the students want to know the procedure for getting through the problem and if they have that they are less concerned about the conceptual underpinning ... What I would really like to do is get them thinking about the concepts as well as be able to answer the question that is being set. [ME7: B/C/3]

What kinds of things can we do to promote understanding?

Approaches that were discussed include use of examples, discussion of errors and use of tests or quizzes. Examples are seen as important to illustrate/explain mathematical concepts and procedures.

A certain amount of time is taken up with basic definitions of theorems and proofs and the rest should be examples. Maybe what they don't appreciate is that I design the examples to illustrate the concepts of what I am teaching but not necessarily to give examples that are problems they will meet in the exam. [M1: A/1]

I don't worry if they don't understand everything at start. I don't think they will until they have worked their way through some examples. [M2: A/2]

Working Group 14

Asking students to come up with their own examples requires them to engage with the mathematics rather than memorise.

If you know a test like this is coming ... you can memorise a bunch of definitions. If you are asked to give examples, that requires you to do something...to really think about what does it takes to satisfy two different properties at once. [ME5: B/2]

But perhaps examples alone are not enough.

[it is] important to discuss the conceptual background of the material because examples are much easier for most students. If I do only that [examples], students miss the most important part. [M4: A/B/3]

Some lecturers use short tests at start of lecture, or quizzes to be taken weekly online.

Everyone knows something they did not know a few minutes ago about their own knowledge ... are they up to date with what we have studied in the last few weeks and can they apply it to examples. [ME5: B/2]

By frequently testing and making them go back over past work, I am hoping they will have an overview of all the techniques to a certain level, all the time. [ME8: B/3]

A focus on errors can offer valuable feedback.

Giving students information on the errors that they have made is I think a very valuable way of giving feedback for bright students... I collected in the errors they made on their course work and asked them if they can spot where the errors are. [ME3: A/3]

There was discussion of ways in which our teaching differs according to our perception of students' mathematical strength, or whether students are main stream mathematicians or in some other programme such as engineering.

[Teaching in Context] is motivating for [engineering] students [who] tend to give [it] very good feedback. They start to see the relevance of mathematics. [ME4: A/3]

For the very weakest engineers...I would give them some graphs. I would ask them to describe in their own words some of the properties of some of these functions ... a way of introducing students to some of the terminology. [ME3: A/3]

[I] direct material to an averagely competent student. In narration, I give simplified explanations for those below averagely competent. [M1: A/1]

I feel I have to give something to the good students who are going to get high firsts and who may do research. Perhaps it is just a handful of students in the room but they pay tuition fees like everyone else. [M1: A/2]

Use of technology in lecture presentation

The medium of the lecture is very important for some lecturers, especially those who favour a chalk or white board. For some, use of a chalk board is what *used to* happen when they were students, but has now been superseded by current technology – e.g., overhead projector (OHP). For others, there is value still in a large chalk board:

Working Group 14

Students need to see the whole calculation. They need to keep looking back to where they started from, see the key points [M2: A/2]

A problem with, for example, OHP or PowerPoint is that only the most recent part of the mathematical argument is visible at any time. Some mathematics lecturers still prefer to use a chalk board to present material in a lecture because the large expanse of board allows (potentially) a view of the whole argument at one time. The university gives credence to this argument by maintaining a number of lecture rooms for this purpose, despite the fact that chalk dust is detrimental to electronic equipment which needs also to be provided. Those using boards also suggest that students like notes to be written in real time – a PowerPoint presentation is too fast to take notes.

At the other end of the technological spectrum a few lecturers are using electronic voting systems (EVS) in lectures, and see many advantages in doing so, both for the students who gain insight into the thinking of their peers and for lecturers who can see the spread of response in their students as a whole.

Students like to see others getting it wrong – know they are not on their own. [They are] getting an experience they don't get by just reading at home on their own. [ME4: B/3]

Resources for teaching and learning.

Use of the LEARN environment for supporting teaching and learning is highly emphasised in the university. However, could the placing of resources on LEARN be a panacea? Should we consider more overtly whether students use these materials?

The advantage for me ... I am more comfortable lecturing knowing there is this material available [e.g., HELM workbooks]. If you don't like what I am doing in lectures that's fine, just read the book. [ME2: A2]

I suspect we don't teach students how to use books [ME3: C/3]

And many students looking at a page of mathematics look at the formula and ignore the words [ME5: B/1/3]

Some lecturers questioned the role of the student and how students learn to learn.

What do you need to know in order to be a successful student who can go to a lecture, take appropriate notes and then go away and do something with those notes that will be productive in terms of increasing your understanding? [ME5: C/2]

DISCUSSION

The characterisation offered above recognises certain aspects of the discourse; it also offers opportunity for discussion of the underlying issues and how they relate to teaching and its development. The discourse has been highly *meta*-mathematical. By this we mean talking *about* teaching mathematics, talking about students, our goals *for* and perspectives *on* students, talking about the resources we use and our reasons for doing so – often in terms of our intentions for students. Where mathematical examples have been used, they have been designed to stimulate a focus on teaching

approaches. So far, we have not looked explicitly at how lecturers treat particular mathematical content – despite the fact that we have a project looking explicitly at the teaching of linear algebra (Jaworski *et al.*, 2009). We have plans to do this more explicitly in the near future. Recently, the seminars have become a part of the University’s professional development programme for new mathematics lecturers; here, the characterisation above can contribute to clearer visions of how the ways we talk about teaching relate to the actual teaching and its promotion of learning.

A final point brings us back to the nature of our community in the School of Mathematics, consisting as it does of both mathematicians and mathematics educators. Readers might discern, from the A, B, C categorisations above, positions of particular individuals with respect to their views on teaching. With regard to our community as a whole, where our *teaching* is concerned, we can justify the terms “mutual engagement” and “shared repertoire” although we have demonstrated small differences in the latter. A “joint enterprise” is harder to justify, and this possibly relates to our categorisation. At level A, teachers operate within their own certainty of what it means to teach and why, and we see here differing kinds of certainty. However, in areas B and C, we see recognition of the complexity of decisions and related issues for teachers, a willingness to question and consider other possibilities, and a growth of common understandings, or at least respect for alternative points of view. These seem to relate to what Nardi *et al.* (2005) call “reflective and analytic” and ‘confident and articulate’ positions in their *spectrum of pedagogic awareness*. In our development of teaching and the education of new lecturers, increased pedagogic awareness, leading to possibilities for changing and improving teaching, seems essential. Categories relating to theoretical positions are much more tentative at this stage and we offer them as starting points in thinking about how theories and beliefs can influence the ways we teach. We welcome discussion on this with other researchers who address such connections.

¹ HELM: *Helping Engineers Learn Mathematics* is a series of booklets developed specifically for engineering students, focusing on basic mathematical concepts and used with various groups of students in mathematics and engineering

WHAT AFFECTS RETENTION OF CORE CALCULUS CONCEPTS AMONG UNIVERSITY STUDENTS? A STUDY OF DIFFERENT TEACHING APPROACHES IN CROATIA AND DENMARK

Ljerka Jukić

University of Osijek, Croatia

Bettina Dahl (Soendergaard)

Aarhus University, Denmark

This paper reports a parallel study of two university calculus courses in Croatia and Denmark using different teaching approaches. Both have lectures to a large group of students but they use different types of exercises. In Denmark, the exercises are student-centred, while the Croatian university uses a teacher-centred approach. The content of the courses are similar regarding the concepts we study in this paper. The students' retention was tested two months after the course exam on these concepts. Our statistical data analysis shows that the Danish students of our sample performed significantly better than the Croatian students of our sample on the conceptual questions, and vice versa for the procedural ones.

INTRODUCTION

The teaching of basic calculus concepts at the undergraduate level is wide and many students who study calculus are not in mathematics study programmes. Calculus at university level is usually taught by professional mathematicians who do not all seem to realize that there may be problems of communication between them and the students who study in non-mathematics study programmes (Maull & Berry, 2000; Guzman *et al*, 1998). When compared to mathematics students, engineering students seem to change their understanding of mathematical concepts as they progress through their studies (Maull & Berry, 2000). In order to gain more insight into the calculus knowledge of non-mathematics students, we investigated the level of retained knowledge in students from technical and natural sciences studies programmes. Our previous survey (Jukić & Dahl, 2010) showed that the students taking part in our experimentation had forgotten a large portion of notions regarding the derivative concept in differential calculus, and furthermore the surveyed students with the lowest course passing grades outperformed the students with high passing grades two months later in our questionnaire. The study reported in the present paper examines the retention of core calculus knowledge at two different non-mathematics student populations.

THEORETICAL BACKGROUND

Conceptual knowledge describes knowledge of the principles and relations between pieces of information in a certain domain and procedural knowledge is knowledge of the ways in which to solve problems quickly and efficiently (Hiebert & Lefevre, 1986). Haapasalo and Kadijevich (2000) redefined conceptual knowledge,

highlighting its dynamic nature; it concerns the ability to browse through networks consisting of concepts, rules, algorithms, procedures and even to solve problems in various representation forms. Grundmeier *et al* (2006) showed that students generally choose a procedural over a conceptual way of dealing with problems in integral calculus. Pettersson and Scheja (2008) discovered that students developed their knowledge in integrals in an algorithmic way, not because of misconceptions, but because it was more suitable for them and enabled them to deal functionally and successfully with the presented tasks. Mahir (2009) investigated conceptual and procedural performance in integration in a group of undergraduate students who successfully completed a calculus course. She found that the students did not have satisfactory conceptual knowledge of integration, but those who had some conceptual knowledge, also showed some good procedural performance.

Teaching strategies can roughly be divided into student-centred and teacher-centred teaching (Killen, 2006). In the teacher-centred model, the teacher has direct control over what is taught and how the learners are presented the information they should learn. In the student-centred model, the learner is put at the focus of the teaching/learning process, instead of the teacher. The teacher has less direct control over how and what the students learn. An example of such approach is the use of small group work or cooperative learning. Studies showed that teaching strategies employed in the class can influence the development of one type of knowledge more than another; teacher-centred methods would favour the development of procedural knowledge and student-centred methods would favour the development of conceptual knowledge (e.g. Garner & Garner, 2001; Allen *et al*, 2005).

We examine what calculus knowledge is retained by students from two different mathematical populations two months after the course instruction and examination have taken place. Since these two populations are not completely comparable, we regard this as a parallel study, so caution is needed when making statements comparing the two populations.

THE TWO POPULATIONS: INSTITUTIONAL SETTINGS

In this section we will describe the institutional settings in the two universities where our survey was conducted: the University of Osijek in Croatia and Aarhus University in Denmark. In order to examine the calculus courses and their contexts, lectures and exercises were observed at the universities. Furthermore the teaching materials, exams and curricula were examined and interviews with lecturers, department heads, and teaching assistants were conducted at both universities to gain insight into the similarities and differences of both study programmes.

The Croatian University

The calculus course consists of lecture lessons and exercise lessons where the teaching approach is teacher-oriented. Lectures are given in a traditional form to a large group of students, and exercises are based on direct instructions, used in groups

Working Group 14

of 30 students where a problem-solving or performance procedure is shown to the students. Conceptual ideas are taught in the context of procedural methods. A first year calculus course is divided in two one-semester courses, entitled Calculus 1 and Calculus 2. Differential calculus is part of Calculus 1 and integral calculus is part of Calculus 2. Part of Calculus 1 is oriented on repetition of high school A-level, using formal mathematical theory, what makes it different from high school mathematics. Also, the majority of the calculus courses are focused on functions in one variable. Every science study programme has its own calculus courses, but these courses have 70% of the content in common. The courses differ not just in course content, but also in the number of teaching hours. They may vary between 60 and 105 hours per semester, altogether for lectures and exercises. The process of examining the students' knowledge begins during the calculus course. Students have several written partial exams with open-ended questions during the semester as a substitution for the final exam at the end of semester. Students have to pass all partial exams and their grade is determined after the last partial exams. Those who fail any of the partial exams during the semester have to take the final exam to pass the course. Students' knowledge in formal mathematical theory in theorem-proof style is also examined. Students get the final grade for both calculus courses separately.

The Danish university

The calculus course is a joint course for all mathematics and science study programmes. The course is organized into traditional lecture lessons and exercise lessons. Lecture lessons are given to a large group of students, but exercise lessons use small group work, based on problem solving where the teaching approach is more student-oriented. A first year calculus course is divided in two courses where functions of one variable and several variables are connected to differential and integral topics. Topics investigated in the questionnaire belong to Calculus 1. Both calculus courses take place during a seven-week half-semester (quarter) period with 63 hours, altogether for lectures and exercises. The process of evaluating students' knowledge starts after Calculus 1, where students take a multiple choice test, which determines whether or not the student can take the final written exam after Calculus 2. The grade obtained in the final exam is a joint grade for Calculus 1 and 2.

About comparing the two universities

The calculus content investigated in this paper belonged to the core of all programmes. One of the major differences between the populations was the teaching methods, but that is not the only difference that might explain how the students answer the questions in our survey. This means that pointing to one single factor causing the difference is not possible, therefore caution is needed and we cannot identify a single cause to the differences in the results of both populations.

METHODOLOGY

We conducted a survey examining a selected number of core concepts in differential and integral calculus through questionnaires given to first year non-mathematics students. The survey took place in the spring of 2009 at University of Osijek and in the autumn of 2009 at Aarhus University.

The Croatian students were given two questionnaires. The first examined their knowledge of derivatives, from Calculus 1, and the second examined their knowledge of integrals, from Calculus 2. The participants were students from the following study programmes: electrical engineering, civil engineering, food technology, physics, and chemistry. 227 students participated in the first questionnaire and were surveyed two months after the exam in differential calculus. 225 students participated in the second questionnaire and were surveyed two months after the exam in integral calculus. More than 94% of the students answered all questions in the first questionnaire and more than 97% of them answered all questions in the second questionnaire.

The Danish students were given one questionnaire combining the questions from the Croatian questionnaires since those concepts are covered in Calculus 1. The students belonged to the following study programmes: biology, chemistry, chemistry & technology, computer science, geology, geo-technology, information technology, molecular biology, medical chemistry, molecular medicine, and nano-science. 147 students participated in the questionnaire. More than 94% of the surveyed students answered all the questions.

The Danish university does not have engineering programmes and the Croatian university does not have all the study programmes surveyed in the Danish university. Since the aim of our parallel study was to examine knowledge retention in non-mathematics students, we do not consider these differences as significant. We wanted to get some insight into the knowledge of non-mathematics students from two different populations, and not in students belonging to a particular study programme. Even though the Danish and Croatian students have met calculus concepts in high school, the university courses provide different approaches to calculus (building calculus conceptions using formal theory) and build relationships between calculus objects (e.g. connecting them with functions of several variables). This diversity in teaching styles between high schools and universities has also been noted by various researchers (e.g. Guzman *et al*, 1998). We wanted to examine the retention of knowledge related to core calculus concepts after university calculus in students coming from different programs, contexts and teaching methods.

Questionnaire design

We designed the questionnaires with multiple choice questions where the wrong options represented typical misunderstandings and errors. Before being given to the students, professional mathematicians and the lecturers of the courses were consulted

about the relevance of the questions, formulation, and appropriateness of the options of answers as offering typical misunderstandings. We wanted to examine the students' retention of concepts about derivatives and integrals in a short period of time, since the questionnaire had to be filled out by the students while they attended their class/lecture (the permission to pass the questionnaire during lecture time is easier to get, so multiple choice questions seemed to be a very convenient way to assess the students in a short period of time).

There were four questions about derivatives. The question *Tangent* deals with the geometric interpretation of the derivative of a function at a given point. In *Quotient* our intention was to test the students' knowledge about the quotient differentiation rule. *Composite* examines how the students deal with the derivation of a composite function. *Slope* incorporates several key concepts from differential calculus: slope of tangent line as the derivative of the function f at the given point and the process of differentiation. There were also four questions about integrals. *Area* deals with the geometric interpretation of the integral. It can be argued that among the offered answers "none of the above" would be the correct one, since the answer "the area between the curve $y = f(x)$ and the x -axis for x between a and b " is correct only in the special case where $f(x) \geq 0$ for $x \in [a, b]$ and $f(x)$ is bounded. However, as we had conjectured that the students were likely to overlook or ignore the subtlety of the case of non-positive or non-bounded functions, we did not consider "none of the above" as the right option (and we are aware this can be a potentially contentious choice). *Antiderivative* asked what the anti-derivative of a function is. Depending on the approach that was used in teaching, two of the offered answers could be considered as correct. Therefore, in the data analysis we labelled both possibilities as correct. *Method* asked for the most appropriate/easy method for solving a particular indefinite integral. The integration by parts is considered as the only correct option. The use of substitution for this example is "non-standard", and students would need a table to recall the integral of the logarithm. *Basic integrals* consisted of two indefinite integrals that are usually given in the tables of basic integrals and two possible solutions for each integral. The number of offered options for this question was inspired by the number of possible misunderstandings we considered for each integral. All the questions can be seen in the Appendix. The questions can be grouped as mainly involving either procedural or conceptual knowledge. The conceptual category consists of the questions *Tangent*, *Slope*, *Area* and *Antiderivative*, whereas *Quotient*, *Composite*, *Method* and *Basic integrals* are classified as procedural. However, this categorisation in conceptual or procedural questions is not absolute. Some questions could be placed in both groups, since they involve both kinds of approaches. For instance several differentiation rules have to be connected in *Composition*, and this, at least in some cases, can be considered as conceptual knowledge. On the other hand, it is possible that some students had experienced tasks like *Slope*, and thus their solution could be based only on recalling the method without any conceptual knowledge. This is the reason why the question

is formulated in a little tricky way, so that if the students apply a procedure without carefully thinking, they will fail to answer it correctly. Also, in our case, the students were more exposed to the chain rule of differentiation, unlike the question *Slope*.

RESULTS OF THE QUESTIONNAIRE

Table 1 below shows the distribution of correct answers for all questions in the two populations. No question was answered correctly by all students.

Type	Topic	Question	Croatia		Denmark		Fisher's p-value
			#/total	%	#/total	%	
Conceptual	Differential calculus	Tangent	102/214	46	93/140	66	0.0007
		Slope	34/217	16	51/142	36	<0.0001
	Integral calculus	Area	160/224	71	141/143	99	<0.0001
		Antideriv.	(170+37)/223	93	(109+30)/142	98	0.0504
Procedural	Differential calculus	Quotient	167/221	76	90/139	65	0.0312
		Composite	144/218	66	94/141	67	1.000
	Integral calculus	Method	142/224	63	64/140	46	0.0011
		Integral a	99/223	46	22/141	16	<0.0001
		Integral b	145/220	65	81/142	57	0.0963

Table 1: Distribution of correct answers. P-values here indicate the size of the differences among the populations.

There was a significant difference in how the Croatian and Danish students answered six of the nine questions, eight if we accept an alpha of 0.10. The Danish students significantly outperformed the Croatian students in almost all the conceptual questions, but in the procedural questions, the Croatian students significantly outperformed the Danish students in four of the five questions. The fifth question (*Composite*) had an almost identical rate of correct answers.

Table 2 below shows how well each of the two populations solved each of the conceptual questions compared to each of the procedural questions.

The results of Table 2, and data from Table 1, show that for the Croatian students there was a significantly different performance in 16 of the 20 comparisons of the two groups of questions. Of the 16 comparisons which showed a significant difference (alpha of 0.10), nine times the procedural question was answered the best, while seven times, the conceptual question had the best answer rate. Hence it appears that there is almost no difference in how the Croatian students answer the conceptual and procedural questions, just a small preference for the procedural ones. Among the

procedural questions, the Croatian students achieved better results in the derivative questions than in the integral questions. In the conceptual group, their results were better in the integral questions than in the derivative question.

Croatia		Conceptual				Denmark		Conceptual			
		Dif		Int				Dif		Int	
Procedural		Ta	Sl	Ar	An	Procedural		Ta	Sl	Ar	An
Dif	Qu	* p	* p	3356	* c	Dif	Qu	8017	* p	* c	* c
	Co	0001 p	* p	2588	* c		Co	1.000	* p	* c	* c
Int	Me	0011 p	* p	0864 c	* c	Int	Me	0007 c	1151	* c	* c
	Ia	5031	* p	* c	* c		Ia	* c	0001 c	* c	* c
	Ib	0002 p	* p	2207	* c		Ib	1126	0005 p	* c	* c

Table 2: Fisher's p-values comparing answers to the procedural and conceptual questions by population. * denotes $p < 0.0001$. P-values are noted without 0. The letters p (procedural) and c (conceptual) denotes which question had the best answer rate.

For the Danish students there was also a significantly different performance in 16 of the 20 comparisons of the two groups of questions. Of the 16 comparisons which showed a significant difference (alpha of 0.10), three times the procedural question was answered the best, while 13 times, the conceptual question had the best answer rate. Hence, it appears that the Danish students of our sample perform much better at the conceptual questions than at the procedural ones. In the procedural group of questions, the Danish students achieved better results in the integral questions than in the derivative questions. In the conceptual group, their results were better in the integral questions than in the derivative questions.

DISCUSSION AND CONCLUSION

Having in mind that the questionnaires took place only two months after the examination, and that the questions were multiple-choice, we regard the obtained overall results as weak. There was only one question where both populations had a correct answer rate above 80% (*Antiderivative*). The lowest Croatian result is seen in the question *Slope* (16%) and the highest in the question *Antiderivative* (93%). The Danish students achieved the lowest result in the question *Integral a* (16%) and the highest result in the question *Area* (99%).

Both student populations were taught procedural and conceptual knowledge. In terms of long-term retention, procedural knowledge is quite fragile, meaning that procedures are often forgotten quickly or remembered inappropriately (e.g. Allen *et al.*, 2005). This is perhaps reflected by the fact that Table 2 shows that 12 times a procedural question did better in comparison with a conceptual question, 20 times the opposite. Also Table 1 shows that no procedural question had a correct answer

Working Group 14

rate above 76%, while three of eight times, the correct answer rate to a conceptual question was above 90%. Hence, our data lead us to think that the Danish students retained more conceptual knowledge than procedural knowledge, while the Croatian students were almost equally strong/weak in the conceptual and procedural questions. In terms of long-term retention, conceptual knowledge is stable, but possessing conceptual knowledge without procedural fluency is considered to be ineffective (Bosse & Bahr, 2008).

The results of our study can be connected with a long dispute on which type of knowledge is more important and in which order they should be learnt (Rittle-Johnson *et al*, 2001; Haapasalo, 2003). Today, we regard both types of knowledge as important and complementary, thus universities should focus on attaining balance between conceptual and procedural knowledge. Learning new concepts and practicing the skills associated with those concepts are strongly interconnected, therefore, a balance of learning concepts and procedures with explicit connections to those concepts will enhance the long term retention of both (Schoenfeld, 1988).

If we have a look at the results of our two populations, the Croatian students showed significantly better performance in the procedural questions, and the Danish students were significantly better in the conceptual group of questions. The teaching approach at the Croatian university is teacher-centred while it is more student-centred at the Danish university. One may wonder if these results are connected with the teaching approaches. Some studies showed that the teaching strategies employed in class can influence the development of one type of knowledge over the other; teacher-centred on procedural knowledge and student-oriented on conceptual knowledge. Garner and Garner (2001) found similar results in the case of applied calculus examining the retention of students' knowledge after eight months, but Allen *et al* (2005) found significant differences only regarding conceptual knowledge, and no difference in procedural knowledge between students exposed to different teaching strategies in differential equations, examining them after one year. Schumacher and Kennedy (2008), who examined calculus knowledge in students exposed to teacher-centred and student-centred teaching approach, found no statistical significance in success between the two groups of students. The studies that we refer to here had investigated students' retention in courses that only differed in the teaching approach and in the number of course hours. Students in our study also had some further differences in terms of previous training, of course content and of examination styles. Therefore, caution is needed when trying to point to *one* factor explaining the difference. This will be the topic of future research.

APPENDIX

Derivatives questions surveyed with given options for answers

1. Question *Tangent*: What is the geometric interpretation of the derivative of the function

Working Group 14

$f : R \rightarrow R$ at the point x_0 ? Offered answers: maximum/minimum of the function f at x_0 ; slope of tangent line to the curve $y = f(x)$ at x_0 ; continuity of the function f in the given point; none of the above.

2. Question *Quotient*: Differentiate the function $f(x) = \frac{x^2 + 2}{x^3}$. Offered answers: $\frac{x^3(2x) - (x^2 + 2)(3x^2)}{(x^3)^2}$; $\frac{x^3(2x) - (x^2 + 2)(3x^2)}{x^3}$; $\frac{x^3(2x) - x^2(3x^2)}{(x^3)^2}$.
3. Question *Composite*: Differentiate the function $f(x) = \sin^2 6x$. Offered answers: $2\sin(6x)$; $12\sin(6x)$; $12\sin(6x)\cos(6x)$.
4. Question *Slope*: Calculate the slope of the tangent line to the curve $y = (3x)^2$ at the point $x = 1$. Offered answers: 9; 18; 6.

Integral questions surveyed with given options for answers

1. Question *Area*: What is the geometric interpretation of the definite integral $\int_b^a f(x)dx$?
Offered answers: The area between the curve $y = f(x)$ and the x -axis for x between a and b ; The arc length of the curve $y = f(x)$ on the interval $[a, b]$; continuity of the function f on interval $[a, b]$; none of the above.
2. Question *Antiderivative*: What is an antiderivative of a function f ? Offered answers: $\int f(x)dx$; every function F such that $F'(x) = f(x)$ holds; The set of elementary functions; none of the above.
3. Question *Method*: Which method should be used for computing the integral $\int xe^x dx$?
Offered answers: substitution $t = e^x$; integration by parts; trigonometric substitution; none of the above.
4. Question *Basic integrals*:
 - a. $\int \frac{dx}{1+x^2} = ?$ Offered answers: (a) $\ln(1+x^2) + C$ and (b) $\arctan x + C$.
 - b. $\int \frac{dx}{x^3} = ?$ Offered answers: (a) $-\frac{1}{2}x^{-2} + C$ and (b) $\ln(x^3) + C$.

UNIVERSITY STUDENTS LINKING LIMITS, DERIVATIVES, INTEGRALS AND CONTINUITY

Kristina Juter

Kristianstad University and Linnaeus University, Sweden

Mathematical concepts are mentally represented differently depending on individual, context and existing conceptions of related concepts among other things. The present paper reports on a study of students' representations in analysis with an emphasis on the types of representations and the links they have between their representations. The data collection was designed to evoke different parts of the students' concept images and also to return to the concepts several times over time at every data collection session. The results show that formal and intuitive representations in combination are rare. The number of links between concepts is not in itself a measure of the quality of the concept image, as there is a vast number of erroneous links misleading the students to think they understand the concepts.

INTRODUCTION

Students' experiences of understanding a mathematical concept have a range from being able to explain all aspects of the concept in relation to other concepts (as defined by for example Hiebert and Lefevre, 1986) to just having heard of the concept, depending on how understanding is assessed and personal definitions of understanding. Prior research reveals university students' unjustifiably strong self confidence about their own mathematical abilities of understanding limits of functions (Juter, 2006) despite their inability to explain core features of the concept. The capability to solve routine tasks gives a sense of mastery of the concept that is not changed from an episode of failure in a special case, like the interview sessions in the study. A sense of understanding, false or otherwise, prevents further learning in the particular topic area, which in turn may lead to a weak mathematical ground for new learning. This is serious for future mathematics teachers who are going to provide opportune learning situations for their students. If their concept images (Tall & Vinner, 1981) are weak, or in worse cases wrong, there is no room for the flexibility and deep conceptual discussions necessary for appropriate teaching. This paper reports part of a study of pre-service teachers' understanding of limits, derivatives, integrals and continuity and links between the concepts. The study also concerns teacher identity from a social as well as a cognitive perspective (see for example Juter, 2010). The following research questions were raised: How do the students connect limits, derivatives, integrals and continuity to other concepts? How do the students represent (graphically, formally, through examples or other descriptions) the concepts for themselves? How do their representations with connections work as a base for analysing graphs with respect to the four concepts examined?

Data analysis resulted in a classification system (table 1) useful for categorising students' traces of connections between concepts in their concept images in form of mathematics actions such as problem solving, proving and explaining solutions or methods.

UNDERSTANDING AND REPRESENTING CONCEPTS

Skemp (1976) distinguished understanding a concept from its core features, *relational understanding*, which enables implementation of the new concept to existing concept images (which is how Hiebert and Lefevre, 1986, defined conceptual knowledge, p 3), from understanding by just being able to perform a particular operation in what he denoted *instrumental understanding*. Either way to understand a new concept requires mathematical development of existing representations. Tall (2004) introduced a model describing development in three different modes, *the conceptual-embodied world* with an emphasis on exploring activities, *the proceptual-symbolic world* focusing the dual features of concepts as objects and processes expressed in symbols or *procepts* (Gray & Tall, 1994), and *the formal world* where mathematical properties are deduced from the formal language of mathematics in definitions and theorems. Students' concept images develop through the worlds with different emphasis on the three modes allowing them to understand concepts differently. Based on Pinto's and Tall's (2001) definitions of *formal learner* and *natural learner* together with Tall's three worlds and Skemp's definitions of understanding, I created a set of categories to classify students' links between concepts presented in table 1 (see Juter, 2009, 2010, for further details). Examples of classifications of students' links from the present study are provided in the table.

The last four types of links are not desirable for the students, who often are unaware of the quality of the links, particularly if irrelevant or invalid links are mixed with valid ones. Links are formed in different situations, e.g. at lectures, with peers or in solitude. Textbooks, lecturers' selections and general interests of the group of students frame the learning environment and therefore affect the representations students are using. Students' abilities, ambitions and confidence also influence their representations. Representations used when learning a certain topic may become vague if they are not endurable enough, e.g. not sturdily linked to other concepts. If a person learns a new mathematical topic in the embodied world and his/her abilities then develop to symbolic treatment he/she has changed the way of thinking to a proceptual-symbolic mode (Tall, 2008). If the learning phase in the conceptual-embodied world has been too short or otherwise inadequate, parts of the concept image may become disjoint or vague, rendering the person unable to explain core features of the concept. In the present study all students are future mathematics teachers, but they are taught at different universities, by different teachers and under

Working Group 14

various circumstances which gives them a range of various learning environments to develop mathematical representations from.

<i>Type of link</i>	<i>Definition</i>
Valid link, procedural (vp)	True relevant link with focus on calculations or applications, ex: <i>The derivative of velocity gives acceleration</i>
Valid link, naturally conceptual (vn)	True relevant link revealing a core feature of the concept, not formal, ex: <i>Derivative is the slope of the tangent at a point</i>
Valid link, formally conceptual (vf)	True relevant link formally revealing a core feature of the concept, ex: <i>If the limit $\lim_{x \rightarrow a} f(x) = f(a)$ exists in every point then $f(x)$ is continuous</i>
Irrelevant link, no reason (ir)	No actual motivation for the link is provided
Irrelevant link, no substance (is)	Peripheral true link without substance relevant for the concept, ex: <i>You can add derivatives</i>
Invalid link, misconception (im)	Untrue link due to a misconception of the concept, ex: <i>Continuous means the same change everywhere</i>
Invalid link, counter perception (ic)	Untrue statement contradicting prior statements ex: <i>$\sin x$ is continuous and continuous means linear</i>

Table 1. Definitions of links between concepts. Examples in italics.

THE STUDY

Students from four groups, two from each of two different universities in Sweden, were part of the study. All students, a total of 42, were pre-service teachers in mathematics who were studying to teach grades 7 to 9 and upper secondary school. The study started with one group, group 1, two years before the remaining three groups were added to the project as table 2 indicates. All students in the four groups were enrolled in the study.

<i>Group</i>	<i>Autumn 1</i>	<i>Autumn 2</i>	<i>Autumn 3</i>	<i>Spring 4</i>	<i>Autumn 4-5</i>
1	Questionnaire Tasks	Interview 1	Interview 2	Interview 3 observation	
2-4			Questionnaire Interview 1	Interview 2	Interview 3 observation

Table 2: Data collection times for the groups in years 1 to 5

The first data collection in three of the groups (1, 2 and 4) was at the beginning of the students' analysis course where they filled out a questionnaire aimed at revealing their pre-knowledge of the concepts investigated. The questions were openly formulated for the students to be able to answer without influence from other formulations. Questions about the concepts were "Describe the concept of limit of a function/derivative/integral", "What do you use limits/derivatives/integrals for?" and "What does it mean for a function to be continuous?" There were some questions about the course and a mathematics teacher's main qualities as well. The students'

responses to the questionnaires were used to determine which students to interview. The selection was done to reflect the variety of representations, e.g. formal or intuitive, in the descriptions of concepts among the entire group of students. The purpose of the questionnaire in group 3 was the same but it was somewhat differently designed since the students had completed their analysis course at the time of data collection. The questions about what to use the concepts for was replaced by some of the tasks the other groups got after the course. The questions and tasks in the questionnaires and interviews were designed to make the students respond to the four concepts in various contexts and to come back to the same concept repeatedly. This way the responses were confirmed and clarified and different contexts evoked different parts of the students' concept images allowing a more nuanced picture from the data. All interviews were individually conducted and audio recorded. Data was collected from a teacher identity point of view as well, and methodology and results from that part are presented in Juter (2010). Focus in what follows is on the cognitive representations of the students.

The aim with the first interview in groups 1 and 3 was to investigate the students' representations of the concepts as traces of their concept images, and links among the concepts. The questions and tasks were quite open at first to let the students choose their own formulations of the concepts. Then the instruments used were more directed to different aspects of the concepts. One instrument was a table of 29 words and phrases used with the purpose to work as stimuli for the students to recall parts of their concept images. The words were for example tangent, border, sum, slope, rate of change, infinity and interval (see Juter, 2009 for details). The students were to describe the evoked parts or say if there was no recollection linked to a particular concept (results in table 3). This matrix was used in all groups about half year to a whole year after their analysis course to let the students' conceptions stabilize after the course. Four graphs (figure 1) with different characteristics linked to the four concepts studied were also given to the students to determine whether or not the represented functions have limits, are differentiable, integrable and continuous in every point (results in table 4).

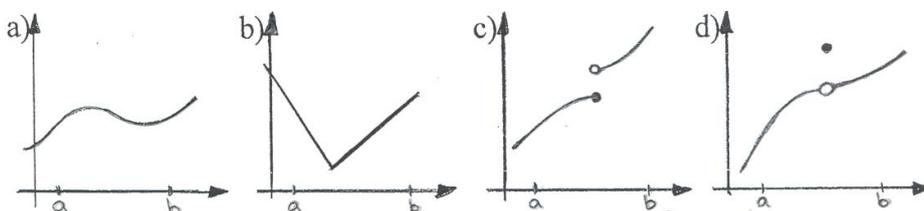

Figure 1. Graphs of functions for the students to analyse

For each of the four concepts, a set of four descriptions was presented to the students on separate cards. The aim was to let the students respond to the different ways of representing the concepts. First they got a formal definition and were asked if they could see which concept it was. Then they got a picture describing the definition which could help them determine which definition it was. After that they got a

sentence intuitively explaining the concept and then an example that included calculations related to the concept. The students were asked to choose their preferred representation and also to explain how they would use different representations in their own teaching. They got the concepts in the order limit, derivative, integral and continuity and therefore the last concept could easily be guessed. This was obvious in a few cases when the students were asked to explain the link between the picture and the definition (results in table 5). The first interview in groups 2 and 4 did not include the matrix of recalled links since their analysis courses took place during the same semester. The matrix was presented to those students in the second interview about six months after the analysis courses. The open questions used in the questionnaire were used again in the interviews to reveal how the concepts had developed in the students' concept images. Conceptual issues were addressed again in the second interview in various forms. The first and second interview comprised the same components together for all students, but differently disposed depending on the time of their analysis courses.

RESULTS

The results are divided in three sections according to the data collection with the matrix of words to evoke the students' concept images, the four graphs in figure 1 for the students to analyse, and the cards with various sorts of representations. The analysis was done to reveal the students' perceptions of the concepts, including links between concepts, as traces of their concept images from a range of various mathematical settings. In table 3 the interviewed students' links from the word matrix are classified in the categories defined in table 1. The numbers after the categories determine the number of links of each kind. The students were divided into three groups, I, II and III, according to their conceptions. The three students in the first group, group I, had few valid links of which none were formally conceptual (vf). Several links were irrelevant (ir, is) or invalid (im, ic). The four students in group II had more valid links than the students in group I, but also no formally conceptual ones. The students had few irrelevant or invalid links. Group III comprised three students with many valid links, including formally conceptual links and very few irrelevant or invalid ones. The labels by the students' names in table 3 indicate which group they belong to. The students are listed in order of strength of their concept images with the weakest first.

Table 3. Links between concepts categorised according to table 1. The categories Invalid link, misconception (im) and counter perception (ic) are merged in mc

Some students readily talk about their conceptions and views while others are not so forward in an interview situation. It is therefore important to take the total number of links for each student into account when reading table 3. Andy had a large number of irrelevant or invalid links but few valid ones, particularly for continuity where he had no relevant links. He had a lot to say about the concept, for example that a continuous function has to be linear, has no peaks in its graph and changes the same way everywhere, but nothing substantially valid. Andy had a total of 59 links of which 34 were irrelevant and 12 invalid. He showed traces of a stronger concept image for limits than for the other concepts. An example of a valid naturally conceptual link (vn) is his explanation of limits as intervals: “a limit is a form of interval which is shortened to a great extent”, and he explained further by drawing a figure of a graph with an interval on the y-axis, i.e. the function values, around a point and saying “it [the graph] closes in on the point from both ways and you press together like this [the endpoints of the interval at the y-axis]”. Other parts of the study confirmed his naturally conceptual understanding of limits, i.e. he was able to discern and explain vital aspects of the concept. Elise had 27 links in all of which 17 were valid, i.e. a considerably larger part of the total number of links than Andy had (13 out of 59 valid). She showed a high level of natural conceptual understanding of the concepts of derivative and integral. John had 53 links. He had 10 formally

Working Group 14

conceptual links of his total of 43 valid links, leaving 10 irrelevant links. John showed an overall strong and rich concept image of the concepts studied through the data collection. Continuity was the concept with the least amount of links for John, but also for the other students, which may come from the fact that derivatives and integrals are a major part of the required upper secondary school courses and limits are therefore to some extent dealt with, but not necessarily continuity. The students have consequently not had the same time to implement continuity to their concept images as the other concepts.

<i>Graph a</i>	<i>Yes</i>	<i>No</i>

Integrable	CEFI	ABDGHJ

Table 4. Students' answers to whether the four graphs have limits, are differentiable, integrable and continuous in the indicated intervals in the graphs in figure 1

Graph *a* was not a problem to most of the students. On the other hand, it was harder for the students to determine whether Graph *b* is differentiable or not. The peak made them confused and seven students answered incorrectly. Andy, Betty, Elise and Ivan responded correctly to all the limit parts of the tasks and in the last two tasks. Elise, Frank and Ivan were all wrong concerning differentiability. The traces of the concept images in table 3 of these students were very different and in this part of the data collection there is no pattern showing who is high achieving and who is not, or who has a strong concept image or not. Betty, Elise and Ivan had the highest number of correct answers in table 4, but table 3 indicates that they belong to different groups (I, II and III respectively). This type of task is not typically what the students had

Working Group 14

seen in their courses so it was new to all of them. Chris, Diana and Glenn had the highest error rates. Diana and Glenn were both in group II in table 3 implying a rather strong concept image for the concepts except for limits. Both students had three of the four limit tasks wrong in table 4. Andy and John, in each end of table 3, had the same score in table 4.

Table 5 shows how the students represented the concepts from the cards with four different representations, formal, picture, calculated example and sentence, for each of the four concepts.

<i>Students</i>	<i>Limit</i>	<i>Derivative</i>	<i>Integral</i>	<i>Continuity</i>
Andy	<i>P, DC</i>	<i>F, P, D_pC</i>	<i>P, DC</i>	<i>P, D_uC</i>
Betty	<i>P, D_pC</i>	<i>S, DI</i>	<i>P, E, S, DI</i>	<i>P, S, DI</i>
Chris	<i>P, S, DI</i>	<i>F, P, E, S, D_pC</i>	<i>P, S, DC</i>	<i>E, DI</i>
Diana	<i>E, DI</i>	<i>F, P, D_pC</i>	<i>P, S, DI</i>	<i>P, DI</i>
Elise	<i>E, DI</i>	<i>F, P, E, S, D_pC</i>	<i>P, S, DC</i>	<i>S, DI</i>
Frank	<i>S, DC</i>	<i>E, S, D_pC</i>	<i>S, DC</i>	<i>S, D_uC</i>
Glenn	<i>S, DI</i>	<i>P, E, DC</i>	<i>P, DI</i>	<i>S, D_uC</i>
Harry	<i>F, P, DC</i>	<i>P, E, DC</i>	<i>P, E, DC</i>	<i>E, S, DC</i>
Ivan	<i>F, P, DC</i>	<i>F, P, DC</i>	<i>F, P, DC</i>	<i>S, D_pC</i>
John	<i>P, DC</i>	<i>F, DC</i>	<i>P, DC</i>	<i>S, DC</i>

Table 5. Students' preferred representations of the concepts (*F*: Formal, *P*: Picture, *E*: Example, *S*: Sentence) and their abilities to recognise the formal definitions (*DC*: Definition correct, *D_pC*: Definition + picture correct, *D_uC*: Definition correct but unable to explain, *DI*: Definition incorrect)

Table 5 reveals that continuity was the concept hardest to recognise from the definition, followed by limit. The fact that continuity was the last concept addressed helped the students understand which one it had to be. This became apparent when they were asked to explain the formal representation in relation to the picture (those cases are marked *D_uC* in the table). All students except Betty recognised the definition of derivative and a majority could identify the definition of integral from the card. Derivative was the concept the students had most kinds of representations for. Chris and Elise both used all four representations intertwined. Students who could recognise the formal definitions (*DC* in table 5) often used pictures to represent the concepts. Pictures in combination with formal representations were also common in the cases where the definition was recognised from the formal representations. Students who were unable to determine which formal definition a card represented, but could determine it from the added picture (marked *D_pC* in the table) often preferred pictures as a representation for the concept. Betty, Frank and Glenn did not use any formal representations in this context. The students are listed in the same order as in table 3 where the first students have weaker concept images and the last ones have stronger concept images. Andy, who is in the first group, is

different from the others with his ability to recognise the concepts from their definitions despite his results reported in table 3. Among the students who could not recognise the definitions (*DI* in table 5) sentences were the preferred alternative, and never formal which could be expected. The sentences were intuitively stated and typically chosen as alternatives to formal representations. There were only two cases of formal and sentence representations together, and in both cases all four representations were used (Chris and Elise).

DISCUSSION

The students' links between topics were very diverse and the data collection reported in table 3 gives a picture of continuity not being implemented in their concept images with very few links of all sorts. The other concepts were more elaborated with more links but the links do not only imply understanding. A large number of links may be misleading the students to believe they understand, like in Andy's case, since they are able to talk about the concept. If counter perceptions, which for example Andy and Chris showed evidence of, can be evoked simultaneously the students are more likely to see their flaws than if their misrepresentations are just invalid without a contradiction.

Andy and Betty represented the concepts mainly in pictures (table 5) and that is reflecting how they read the graphs in table 4 as well. Andy and Betty were among the students with the highest rates of correct answers when analysing the graphs (table 4) and the ones with the weakest concept images in the matrix of words (table 3) which is a surprising result. They were often unable to explain their claims correctly, which is a problem especially for future teachers, but they had a sense of the characteristics of the concepts. Ivan, one of the students with the strongest concept images in table 3, had three errors concerning differentiability in the analysis of the graphs (table 4). Ivan's representations in table 5 are mainly formal and by pictures, moreover table 3 reveals that the derivative is in fact a concept he can handle procedurally, conceptually and formally, yet table 4 shows that he is uncertain of the core features of the concept. This type of overarching non-routine tasks requires the students to know more than just definitions in isolated mathematical contexts. They need to be able to relate the characteristics of the concepts to the graphs with their different properties and to use their representations in their analysis. A strong concept image is not enough for students to discern the necessary features. Comparing with Andy and Betty, the similarities are pictures as preferred representations. Dissimilarities are that Andy and Betty do not use any formal representations in either of the contexts reported in table 3 and 5 except one in Andy's case, whereas Ivan does in both. Ivan has an overall richer representation of all concepts studied and uses and refers to formal formulations, but it appears as if he uses his formal representations without having a clear and flexible understanding of them linked to his other representations of the concepts in situations new to him.

Table 3 and table 5 match each other when it comes to the students' use of formal representations and they indicate that a strong concept image means formal representations as opposed to a weaker concept image. Table 4 reveals a complete lack of trends in relation to tables 3 and 5 and the students' representations reported therein. The traces from their concept images depicted in these three tables imply complex relations between abilities to make assumptions about graphs from the various sorts of representations investigated. Rich concept images, including formal representations, do not imply higher abilities to distinguish the essence of the four concepts from the type of tasks used (figure 1).

‘DRIVING NOTICING’ YET ‘RISKING PRECISION’: UNIVERSITY MATHEMATICIANS’ PEDAGOGICAL PERSPECTIVES ON VERBALISATION IN MATHEMATICS

Elena Nardi

University of East Anglia (UK)

***Abstract.** In this paper I draw on interviews with university mathematicians in order to discuss their comments on Year 1 students’ verbalisation skills. Analysis was conducted in the spirit of enculturative and discursive theoretical perspectives and here focuses on: the role of verbal expression to drive noticing; the importance of good command of ordinary language; the role of verbalisation as a semiotic mediator between symbolic and visual mathematical expression; and, the precision proviso for the use of ordinary language in mathematics. I conclude with the observation that discourse on verbalisation in mathematics tends to be risk-averse and that more explicit, and less potentially contradicting, pedagogical action is necessary in order to facilitate students’ acquisition of verbalisation skills.*

KEY WORDS: university mathematicians, verbalisation, enculturative and discursive perspectives, student learning.

Being able to use ordinary language in order to construct and convey mathematical meaning is an indispensable tool of the mathematical thinker. The mathematics community has always revered eloquent mathematical exposition and, at least until a collectively accepted and used symbolic mathematical language became increasingly dominant from early 19th century onwards, substantial ideas in mathematics (by luminaries such as Cauchy and Lagrange) were often conveyed in ordinary language.

Yet research on how mathematicians and their students acquire verbalisation skills is scarce or subsumed in broader studies of mathematical expression. In the early 1990s research on students’ handling of the verbal and symbolic elements of mathematics language often focused on students’ comprehension and response to mathematical texts, rather than students’ own generated verbal utterances. For example, Furinghetti and Paola (1991) discussed students’ understanding of mathematical texts in the context of difficulties with formal proof. Dee-Lucas & Larkin (1991) found that: proofs written in ordinary language resulted in better student performance than equation-based proofs on problems related to both equation and non-equational proof content; the presence of equations cause students to shift attention away from non-equational content; and, learners have more difficulty processing equations than verbal statements of the same content. With regard to students’ own writing some studies (for example, MacGregor, 1990) have suggested that writing sentences helps students write correct symbolic expressions.

In this paper I explore some of the characteristics that make verbalisation skills an important component of mathematical learning. I also discuss some provisos for an appropriate and effective use of verbal expression in mathematics. To this purpose I draw on data collected for a broader study (Nardi, 2008) which aimed to elicit university mathematicians' perspectives on the teaching and learning of mathematics at university level. In the following I introduce briefly the study and the theoretical underpinnings of the discussion I present in this paper.

A STUDY OF MATHEMATICIANS' PEDAGOGICAL PERSPECTIVES

The study I draw on in this paper is in an area that has been gaining increasing interest in university-level mathematics education research in recent years: the study of university teachers and teaching, with a focus on the pedagogical and epistemological perspectives of university mathematicians (e.g. Jaworski, 2002). The study has its theoretical origins in several traditions of educational research such as: *clinical partnerships* between researchers and practitioners (Wagner, 1997); *communities of practice* (Wenger, 1998); Schön's (1987) *reflective practice*; and, Chevallard's (1985) notion of *transposition didactique*. From these traditions the study has acquired the following characteristics – see (Nardi, 2008, p6-9) for an elaborate account. It is: *collaborative* (namely, it brings together mathematicians and researchers in mathematics education in a collective discussion of pedagogical issues); *context-specific* and *data-grounded* (namely, this discussion is conducted in the specific context of, and with data from, the participating mathematicians' teaching experiences); *non-deficit* (namely, the discussion, while encouraging *self-reflection* and critique, does not primarily aim at the identification of problematic aspects of mathematicians' teaching by the mathematics educators); and, *non-prescriptive* (namely, the discussion, while it encourages the identification of preferred and recommended practice, does not lead to explicit pedagogical prescription). Of course given above characteristics a study of this type clearly serves the dual purpose of research and university teacher development.

The data collected for the purpose of the study consist of *focused group interviews* (Wilson, 1997) with twenty-one mathematicians of varying experience and backgrounds from across the UK. In acknowledgement of the loose sense in which the term 'community' (Wenger, 1998) may have among mathematicians, these backgrounds included pure and applied mathematics, as well as statistics. Eleven interviews with groups of three to five mathematicians were conducted, lasting between two and four hours. Discussion in the interviews was triggered by *Student Data Samples*, namely samples of students' written work, interview transcripts and observation protocols collected in the course of earlier studies of (overall typical in the UK) Year 1 introductory courses in Analysis / Calculus, Linear Algebra and Group Theory. See (Nardi, *ibid*, p9-14) for summaries of these studies. The *Samples* were sent to the interviewees at least a week prior to the interview with a request to read and reflect on them in preparation for the interview.

Working Group 14

In accordance with data-grounded theory techniques (Glaser and Strauss, 1967) the approximately 250,000 words of interview transcript were initially arranged in clusters of episodes on the following six themes: four focused on *student learning* (students' mathematical reasoning; in particular their conceptualisation of the necessity for proof and their enactment of various proving techniques (1); students' mathematical expression and their attempts to mediate mathematical meaning through words, symbols and diagrams (2); students' encounter with fundamental concepts of advanced mathematics such as Functions (3) – across Analysis, Linear Algebra and Group Theory – and Limits (4)); one focused on *university-level mathematics pedagogy* (5); and, one focused on *the often fragile relationship between the communities of mathematics and mathematics education* (6). There were 80 episodes. The data I discuss in this paper concern the issue of students' verbalisation skills and collate evidence interspersed in 7 out of the 80 episodes.

The discussion here is in the light of *enculturative* and *discursive* perspectives on mathematical learning. In terms of the former (e.g., Sierpinska, 1994; Wenger, *ibid*), students are seen as incoming participants to the practices of the mathematics community; learning occurs communication and practice; and, in this process the main role of their university teachers is to introduce them to these practices.

In terms of the latter (e.g. Sfard, 2007), the learning of mathematics involves a change of discourse, where discourse is meant as a distinct form of communication that a community engages with. A discourse is made distinct by the community's *word use*, *visual mediators*, *endorsed narratives* and *routines*. *Words* include mathematical terminology. *Visual mediators* include diagrammatic and symbolic representations of mathematical meaning. *Endorsed narratives* include definitions and theorems. And *routines* include practices such as conjecturing, proving, estimating etc.. Sfard (*ibid*) describes the changes of discourse involved in mathematical learning in terms of two levels: *object-level* (namely adding endorsed narratives, e.g. accumulating knowledge of new definitions and theorems) and *meta-level* (namely adding new objects, changing rules of the discursive game, changing word use etc.). Below I outline the analysis of the episodes – overall but particularly those clustered under theme (2) above – in the terms of these two perspectives.

Students' mathematical expression – whether verbal, visual or symbolic – is expected to undergo a substantial shift, particularly in the early parts of their university studies. At least in the UK where the study was conducted, mathematical discourses in school and at university are markedly distinct. Brief examples of the differences between the two discourses involve *routines* such as proving (in school students are rarely, if at all, expected to provide a formal proof of a claim that they make) or the employment of certain *visual mediators* (in school students are not generally expected to make extensive use of formal mathematical language, symbols such as quantifiers etc.).

The interviewed mathematicians paid particular attention to the tension that they see

Working Group 14

their students experiencing while undergoing this discursive shift. Below I list five characteristics that, according to the participating mathematicians, typify this tension:

- *Inconsistent Symbolisation*: students' attempts at producing 'acceptable' mathematical writing result in inconsistent use of symbolic language;
- *Ambivalent Visualisation*: students' appreciation of the role of visualisation in gaining and presenting mathematical insight is ambivalent. Their use of it is lacking in confidence or lacking altogether.
- *Undervalued Verbalisation*: students undervalue, and often avoid entirely, expressing their mathematical thoughts verbally.
- *Premature Compression*: students' mathematical writing is typically prematurely compressed, namely ridden with gaps, leaps of logic and omissions.
- *Appearances*: students often enact their perception of the need to *be* mathematical (use the discursive norms of mathematical reasoning such as providing justification or proof etc.) as a need to *appear* mathematical (appear to make extensive use of mathematical symbols, terminology or expressions).

The last two characteristics can be seen as combined repercussions of the first three. Data substantiation of each of the five can be found in (Nardi, 2008, mainly Chapter 4). Further elaboration on relationships across all five is part of a longer paper that is currently in preparation. Here I draw on the developing text of that paper in order to provide a sampler of the data analysis concerning these five characteristics: to this purpose I focus on data from one of the five, *Undervalued Verbalisation*.

the MaTHEMATICIANS' case and provisos for verbalisation

Across the seven episodes the interviewed mathematicians reported extensively the students' lack of ability in and appreciation for verbal expression in mathematics. At the heart of this reporting was the concern that students' inadequate appreciation for verbal expression was an indication of the students' difficulty with – and lack of awareness of their obligation for – making their thinking as transparent as possible. The mathematicians also appear concerned about the students' lack of awareness of the benefits that come with the mastering and employment of verbalisation skills in mathematics. In what follows the discussion of the data is structured around four key issues: *the role of verbal expression to drive noticing and emphasise*; *the role of good command of ordinary language*; *the role of verbalisation as a semiotic mediator between symbolic and visual mathematical expression*; and, *provisos for (and issues emerging from) the use of ordinary language in mathematical expression*.

The interviewees stressed that the mere presence of symbols in a mathematical sentence is not sufficient for driving students' attention to the key mathematical idea

Working Group 14

in the sentence. As a helpful and efficient *routine*, that the students currently lack but need to adopt the interviewees propose the assistance on this matter from verbal adjuncts to the symbolic expression. They offer the definition of convergence as an example of a statement where such assistance can be potent. The premise for their discussion of this example is the following mathematical problem:

Write down a careful proof of the following useful lemma sketched in the lectures. If $\{b_n\}$ is a positive sequence (for each n , $b_n > 0$) that converges to a number $s > 0$, then the sequence is bounded away from 0: there exists a number $r > 0$ such that $b_n > r$ for all n . (Hint on how to start: Since $s > 0$, you might take $\frac{1}{2}s = \epsilon > 0$ in the definition of convergence.)

Notes on Solutions

Let $\epsilon = \frac{s}{2}$ in the definition of convergence. Then there is an N such that $n > N \Rightarrow |b_n - s| < \frac{s}{2} \Rightarrow b_n > \frac{s}{2}$. Then, for any n , $b_n \geq r = \min\{b_1, \dots, b_N, \frac{s}{2}\}$ which is the minimum of finitely many positive quantities, hence is positive.

Fig.1 A Year 1 Calculus question requiring emphasis on the meaning of quantifiers
Typically students responded with omitting a small but significant number of terms:

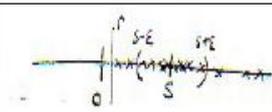

<p>⑥ $\{b_n\}$ is positive $\forall n, b_n > 0 \rightarrow s > 0$ prove $\exists r > 0$ such that $b_n > r \forall n$.</p> <p>\therefore Greater definition of convergence for this sequence $\forall \epsilon > 0, \exists N : n \geq N, b_n - s < \epsilon$ base $\epsilon = \frac{1}{2}s > 0$</p> <p>Hence $b_n - s < \frac{1}{2}s$ i.e. $\frac{1}{2}s < b_n < \frac{3}{2}s$</p> <p>$\therefore \exists r (= \frac{1}{2}s) > 0$ such that $b_n > r \forall n$</p>	 <p>b_n converges on S $b_n > 0$ $b_n > r \forall n$</p> <p>Want to show that $\exists r, \forall n : b_n > r$ Choose $\epsilon = \frac{1}{2}s$ Then $\exists N$ such that $n \geq N$ $\Rightarrow b_n - s < \frac{1}{2}s$</p> <p>$s > 0, b_n > 0$ $b_n < \frac{1}{2}s + s$ and $b_n < s - \frac{1}{2}s$ $b_n < \frac{3}{2}s$ $b_n < \frac{1}{2}s$ \downarrow upper boundary \downarrow lower boundary $\therefore r \geq \frac{1}{2}s$</p>
<i>Student N</i>	<i>Student H</i>

Fig. 2 Two typical responses to the question with missing emphasis on quantifiers
Discussing what could possibly trigger students' noticing the need to cover all terms of the sequence, the interviewees highlight the importance of full sentences:

'It seems that after all the **presence of the quantifiers** themselves in the text of the question is **not emphatic enough** to suggest universality or existence to the students. And **words, sentences, those creatures ever-absent from students' writing** exist exactly for this purpose: of **emphasis**, of **clarification**, of **explanation**, of **unpacking the information within the symbols.**' p151

Working Group 14

The more skilled students are in producing such sentences, the better the cognitive support they will gain from verbalising their mathematical thought. Hence the interviewees' discussion of *the importance of good command of ordinary language*. The following mathematical problem is the premise for their statements on this:

Suppose A in an $n \times n$ matrix which satisfied $A^2=0$ (the $n \times n$ zero matrix).

1. Show that A is not invertible.
2. Show that I_n+A has inverse I_n-A .
3. Give an example of a non-zero 2×2 matrix A with $A^2=0$.

Fig.3. A Year 1 Linear Algebra question requiring clarification on implication order

In part (ii) of this question the students need to show that, because the product of I_n+A and I_n-A is I , I_n-A is the inverse of I_n+A . The interviewees notice that one student (Fig.4) starts her response with a different, and incorrect, statement of her intentions:

(ii) Show $I_n + A$ has inverse $I_n - A$
 If this is true, then the product of $I_n + A$ and $I_n - A$ will be I_n .
 $\# (I_n + A)(I_n - A)$
 $= I_n^2 + AI_n - AI_n - A^2$
 $= I_n^2 + A - A - 0$
 $= I_n^2$
 $= I_n$
 $\therefore (I_n - A)$ must be the inverse of $(I_n + A)$

Student LD, part (ii)

Fig. 4 A typical response to the question with apparently muddled implication order

This student script was commented upon as follows:

‘I am not very keen on *if this is true, then the product of $I-A$ and $I+A$ will be I* , even though she is doing the absolutely right thing, starting from the product and ending up with I . You know why? Because it’s getting so close to **appearing as if she is assuming what she is supposed to be proving**. What she wants to be saying is really *this is true because...* There is a subtlety missing there regarding the converse statement and their **Grammar is not up to scratch** to help them see the difference.’
 p59

Unlike the previous example – in which an emphasis on the need to offer a universal coverage of the sequence’s terms could have been provided by a verbal accompaniment to the symbolic expression – here the student’s inaccurate verbal expression does not lead her astray. However the interviewees take the opportunity provided by such inaccuracies in students’ writing in order to stress the strong link between command of ordinary language and ‘good mathematical writing’:

‘It should be made clear to the students that this type of **command of the language** [for example, people being unable to distinguish between a main and a subordinate clause...] is **not irrelevant to good mathematical writing**. And that applies all the way through to completion of their studies. I sometimes see final year students and I wonder whether they deserve marks for a response that I could only detect as correct amidst grammatically incorrect statements. **When you put things on paper with**

such ambiguity and inconsistency, such as sentences without verb or subject etc., **maybe you should expect a lesser reward too.**' p151

In the above, the interviewees state that mathematical writing that is characterised, for example, by grammatical ambiguity and inconsistency deserves lesser rewards. They also wonder whether students' awareness about the significance of grammatical and syntactical correctness needs to be emphatically raised. In the concluding remarks in this paper I return to this suggestion in order to discuss briefly whether this appreciation of the role, and employment, of ordinary language in mathematics is perhaps more disproportionately expected from the students than their exposure to, and systematic practising of, this valuable *routine* reasonably allows for. But first, I cite the participants' statements on what they appear to see as the most valuable aspect of verbalisation skills in mathematics: *the role of verbalisation as a semiotic mediator between symbolic and visual mathematical expression*.

The interviewees cite the definition of convergence as a case illustrating the value of the connection between symbolic, verbal and visual forms of mathematical expression. Students' first encounters with the hefty symbolisation employed in this definition are some of the first occasions in which students realise that this mode of expression is the *discursive norm* in mathematical writing and a norm they are expected to accustom to quite quickly. The interviewees stress that verbalisation is a meaningful way to help students face 'what they see as madness' at this stage and steer them away from construing the strings of symbols in the definition as little other than 'formalistic nonsense'. The example of the student in the following is telling:

'...a student who wrote down a neat response to a convergence question – **applying the definition impeccably – and then asked why does this prove the convergence?!** What an excellent question! I tried to explain that this is the *definition* of convergence but students **don't quite understand the relation between this expression and what convergence ought to mean exactly.**' p187

Elaborating on the sources of difficulty with the definition, the following link across visual, verbal and symbolic accounts of the definition was offered:

'... the **difficulty** lies with the **successive appearance of quantifiers in the definition** whereas the primary notion for the students ought to be that *no matter what I specify the ε region about the A, from a certain point onwards everything fits inside this box*. **Making this link between this image and the formalisation** behind this is utterly important. Otherwise the definition is **nothing other than formalistic nonsense.**' p188

Verbalization can then invest a symbolic account of the definition with meaning:

'... this is exactly the meaning into **words such as eventually and arbitrarily**, which I constantly put in my writing in my attempt to convey the idea underlying the formal expression of the definition. Most students however simply **ignore them as**

irrelevant waffle and copy the definitions only in their notes. I even try grouping the various parts of the definition with **different colours of chalk!**' p188

But then, if a verbal account offers an opportunity to face difficulty with understanding a complex definition such that of convergence, why, we may wonder, do students typically bypass this opportunity? One explanation is offered below:

'But using words is risky: I have seen verbal explanations of the definition which are in fact wrong! Like many textbooks are! Which is not embarrassing given the long debates about acceptable verbalisations of the definition. **Verbalising, geometrising it etc. is fine as long as we stay this side of correctness!**' p189

What the above seem to suggest is that resorting to ordinary language is seen as potentially containing some inherent risk, a jeopardy for mathematical precision. Is it therefore conceivable that the students, in their avoidance of, or trepidation towards, verbalisation are simply adopting the risk-averse discourse of the community towards 'verbalising' and 'geometricising'? The following seems to suggest so:

'... sometimes **steering clear of intuitions and pictures** etc, yes, working through strings of quantifiers, even though one may not be so sure of what is going on, **can be seen as less messy, less risky**. I think some students may in fact see it this way and be happy to work this way and **just do what they are told**. You can view this as the recipe, you can do this, you do this and you do this... You just follow the steps. And in some ways they are **safer this way** because they will not make mistakes as long as they are technically doing the right steps.' p189

Wordless discourse seems to exert some allure on mathematicians (see two examples in Fig.5) perhaps because of its capacity to convey meaning with curt elegance. But does this trepidation towards verbalization contrast with – even contradict... – the expectation that students will appreciate and employ verbalisation in mathematics? I conclude with a few thoughts on this potential contradiction.

A contrast between expectations and practice?

In the above the interviewed mathematicians make a strong case for verbalisation in mathematics: it can drive our noticing of key mathematical ideas and can act as a crucial semiotic mediator between symbolic and visual mathematical expression. They also stress that, for verbal skills to deliver on this potential, good command of ordinary language is important. They observe that students avoid verbalising their mathematical thoughts and they describe this student tendency as missing an opportunity to overcome difficulty with understanding certain complex ideas in mathematics. In discussing certain provisos for what makes verbalisation an acceptable part of mathematical discourse, they cite attention to precision as one such proviso and express their weariness with the potential risk of ambiguity in verbal expression. Their discourse seems to be quite risk-averse and they recognise that students' avoidance of verbalisation may be underlain by a similar aversion to risk.

What is conspicuously absent in the discussion above is the acknowledgement that, if verbalisation skills are an important part of students' learning at this stage (with 'learning' meant as a 'change of discourse' (Sfard, *ibid*)), then **explicit and systematic pedagogical practice has a role to play in facilitating this discursive shift**. At least in these interviews the pedagogical strategies employed towards this facilitation appeared mostly implicit in the interviewees' statements – that they strive for eloquence in their exposition in lectures and that they aim to set a good example, for instance, through their own writing on the board. Given the rather severe absence of mathematical eloquence from most of the student scripts we examined in the course of these interviews, it seems that a more explicit and systematic approach to developing students' verbalisation skills in mathematics is necessary.

ENDNOTES

¹The interview data sampled here are presented in the format of a *re-storied narrative*. The narrative approach of *re-storying* (Clandinin and Connelly, 2000) adopted in this work involves reading the raw transcripts, identifying and highlighting experiences to be told across this raw material and then constructing a new narrative that represents these experiences. So, while fictional, the new narrative is entirely data-grounded. In this sense the interviewee utterances quoted in this paper were constructed entirely out of the raw transcripts of the interviews with the mathematicians. A quotation typifies and condenses the views expressed by a substantial number of participants. (For an example of the re-storying construction process as well as other influences on the data analysis see p27-28 in (Nardi, 2008)).

THRESHOLD CONCEPTS: A FRAMEWORK FOR RESEARCH IN UNIVERSITY MATHEMATICS EDUCATION

Kerstin Pettersson

Department of Mathematics and Science Education, Stockholm University

A threshold concept is a 'portal' or a 'conceptual gateway' that leads to a previously inaccessible, and initially troublesome, way of thinking about something. A new way of understanding may thus emerge – a transformed view of the subject. The framework of threshold concepts has been used for some years in research of teaching and learning in higher education in several subjects but there are only few articles in mathematics education using this framework. The aim of this paper is to introduce threshold concepts into mathematics education. The result of searching papers in mathematics education using threshold concepts is presented. The need for more research using this framework to create a meeting point for mathematicians and educationalists and to improve students' learning is pointed out.

Keywords: Mathematics education, students' conceptions, threshold concepts, troublesome knowledge, university student learning.

INTRODUCTION

The aim of this paper is to introduce threshold concepts (Meyer & Land, 2003) as a framework for research in mathematics education. This framework has for some years been used in research of higher education in several subjects but is nearly missing in the mathematics education research. Using the framework of threshold concepts can be very powerful for improving student learning, by providing a language for discussing learning and a meeting point for educational researchers and mathematicians. Threshold concepts have been used successfully to engage subject specialists into pedagogical discussions (Cousin, 2009). My own experience is that the notion of threshold concepts works well also in mathematics (Pettersson, 2008).

Students who are confronted with a mathematical concept sometimes find learning troublesome. There is a large body of research on students' difficulties in shaping their conceptions in accordance with the expectations of the learning environment. For example, the research on students' conceptions in calculus has shown that the learning of several concepts is problematic for the students (for an overview, see e.g. Artigue, Batanero, & Kent, 2007). The concept of limit of functions is one of the problematic instances in the learning of calculus. The concept of limit is a central part of calculus, not only for its own sake, but also because it is used in the definitions of derivative and continuity. Also to get good conceptions of integrals there is a need of a good conception of limit, even though not all definitions explicitly use the concept of limit. 'Limit' is one example of a concept that could be classified as a threshold concept (Meyer & Land, 2003).

The notion of threshold concepts has for some years been used in research in higher education in several subjects. However, in searching for articles in mathematics education using the notion ‘threshold concept’, nearly no findings will appear. In this paper I will first present the theory of threshold concepts and then present some cases using threshold concepts as a framework in economics, engineering and computer science education. I will also present the result of a search for articles using threshold concepts within mathematics education research. Finally I will offer some arguments for using this framework in research on mathematics education. My contribution through this paper is to start a discussion of how focusing threshold concepts can support also research in mathematics education.

WHAT IS A THRESHOLD CONCEPT?

Meyer and Land (2003) introduced the notion *threshold concept*. In students’ efforts to develop their understanding of a subject some concepts may be more crucial than others. A threshold concept can be seen as a ‘portal’ or a ‘conceptual gateway’ that leads to a previously inaccessible, and initially troublesome, way of thinking about something. A new way of understanding may thus emerge – a transformed view of the subject. Threshold concepts are concepts that bind a subject together and the acquisition of such concepts is important to grasping the ways of thinking and practising in the subject (Land, Cousin, Meyer, & Davies, 2005). Threshold concepts are concepts that university teachers typically describe as ‘core concepts’, but it should also be noted that threshold concepts should be regarded first and foremost from a student learning perspective (Meyer & Land, 2003).

A mathematical concept is given by a definition but the definition must be interpreted by a learner. Tall and Vinner (1981) use the notion ‘concept image’ to talk about a student’s interpretation of a concept including everything a student connect to the concept; processes, pictures, examples and also the definition and an interpretation of the definition. Threshold concepts are concepts for which the building of a well connected concept image is troublesome. Meyer and Land (2003) presented the mathematical concepts ‘limit’ and ‘complex number’ as examples of threshold concepts. There are also several examples from other subject areas such as ‘opportunity cost’ in Economics and ‘gravity’ in Physics (Meyer & Land, 2006).

CHARACTERISTICS OF THRESHOLD CONCEPTS

Threshold concepts are characterised as initially troublesome, transformative, integrative, and irreversible (Meyer & Land, 2006). They also tend to serve as boundary markers and may get the students into a liminal space where the students’ understandings are unstable. To identify threshold concepts in a subject area we can search ‘core concepts’ and then use previous research about troublesome learning and students’ conceptions of these concepts. This will give us candidates for

threshold concepts for which we through new research can check the characteristics of threshold concepts.

Troublesome knowledge

The learning of a threshold concept is likely to be troublesome for the students. Perkins (1999) defines ‘troublesome knowledge’ as a kind of knowledge which appears counter-intuitive, alien or seemingly incoherent. A way for students to avoid this troublesome knowledge is to remain in a common sense or intuitive understanding of the concept. Pushing students to change their understanding is not unproblematic as it can involve an uncomfortable and emotional repositioning (Cousin, 2009).

Transformative

Understanding a threshold concept will bring about a significant shift in students’ perception of a subject or a part thereof (Meyer & Land, 2003). It is not just a new understanding of the concept; it involves transformation of the understanding of the whole subject area where the concept is located. It includes an ontological as well as a conceptual shift. The shift in perspective may lead to a reconstruction of subjectivity. It is likely to involve an affective component. The transformation may be sudden, but it is mostly stretched over a long period.

Integrative

Threshold concepts are concepts that bind a subject together. Understanding a threshold concept will expose previously hidden relations between concepts in the subject area (Meyer & Land, 2003). Mastery of threshold concepts helps the student to overcome a fragmented view of the subject, things fall into place (Cousin, 2009). Integrating prior understandings is also part of the transformation of understanding of the whole subject area (Davis & Mangan, 2007).

Irreversible

The change in perspective brought about in the course of developing an understanding of a threshold concept is unlikely to be forgotten or will be unlearned only by considerable effort (Meyer & Land, 2003). This does not exclude modification or rejection for a more refined understanding. One problem in this irreversibility is for teachers, who have transformed their understandings, to look back across thresholds to be aware of the kind of understandings the students are likely to have before transformation has occurred (Cousin, 2009).

Boundary markers

Threshold concepts tend to be bounded in that they “serve as boundary markers for the conceptual spaces that constitute disciplinary terrain” (Land, Meyer, & Smith, 2008, p. x). A student entering a new conceptual space by grasping a threshold concept will find that this new conceptual space will be surrounded by other

threshold concepts. These threshold concepts form a frontier to new conceptual areas.

Liminal spaces

During the process of mastery of a threshold concept the students may enter a liminal space (Meyer & Land, 2006). The notion is taken from the word *limen*, a Latin word meaning boundary or threshold. This space could be compared with the period of adolescence; not yet being an adult, not quite a child. In this unstable state the learner may oscillate between old and new understandings just as adolescents move between acting as a child and as an adult. These liminal spaces are spaces of transformations. Most of the students in this state will oscillate between grasping the concept and then losing that grasp. A learner engaged with the project of mastering a threshold concept would enter the liminal space and hopefully the learner will come out from this space with a transformed understanding of the concept. However, the liminal space can also become a 'stuck place' for the student. Reaching a transformed perspective can be blocked for some students by the 'epistemological obstacles' inherent in the threshold concept (Mayer & Land, 2005). These students will then fake understanding through the practice of mimicry, learning by rote or learning how to solve typical problems (Cousin, 2009).

THRESHOLD CONCEPTS IN SEVERAL DISCIPLINES

Over the past few years, research using the framework of threshold concepts has been carried out in different subjects, such as economics, engineering and computer science (Land, Meyer, & Smith, 2008). Starting with the ETL-project, Enhancing Teaching-Learning Environments in Undergraduate Courses, in UK where several institutions took part, threshold concepts is "now moving from a position of being a leading edge new perspective to one which is catching the interests of academics educational researchers in a growing number of countries" (Meyer & Land, 2006, p.xii).

In a project aimed at empirically identifying threshold concepts in computer science Zander, Boustedt, Eckerdahl, McCartney, Moström, Ratcliffe, and Sanders (2008) used interviews and questionnaires to obtain data from teachers and students. 'Object-oriented programming' and 'memory/pointers' emerged as candidates for threshold concepts. The project also investigated how students understand these concepts with the aim to improve teaching and learning.

Shanahan and Meyer (2006) studied a threshold concept in Economics; 'opportunity cost'. The results points out that there are important implications for the manner in which students are introduced to threshold concepts. When learning threshold concepts 'first impressions matters'. Efforts to make the concept easier by simplifying students' first impressions may set students on a path of ritualised

knowledge that creates barriers to a deeper understanding and prevents students from crossing the threshold.

In electrical engineering Carstensen and Bernhard (2008) considered the troublesome concepts 'frequency response'. They propose that certain concepts can function as a 'key' that opens up the portal of understanding. Teaching such 'key' concepts do not just open up for understanding of that concept, but also the learning of other concepts related to it. Using the tool 'Bode Plots' to illustrate frequency response was found to function as such a 'key'. The results from focusing the teaching on these 'key' concepts opening up for understanding the threshold concepts showed an improvement in the scores achieved by students on a test at the end of the course.

Just a few examples are given within this paper; many more findings have been published (e.g. Land, Meyer & Smith, 2008). Recently a new book on threshold concepts was published (Meyer, Land, & Baillie, 2010). However, there is a lot more to do, especially in relation to mathematics education.

THRESHOLD CONCEPTS IN MATHEMATICS EDUCATION

The notion of threshold concept is established in the research of higher education in general but searching for articles in mathematics education using the notion threshold concepts gives just a very few findings. Using the database ERIC and the combination 'mathematics' AND 'threshold concept' searching in all text produced five hits when searching in the period of 2003-2010 (access 2010-09-06). Two of these five articles are about 'threshold values' of variables used in physics and resources on the Internet. The remaining three articles are published in Educational studies in mathematics (Williams, 2009), European journal of engineering education (Masouros & Alpay, 2010) and Higher education (Scheja & Pettersson, 2010).

Using the database Academic Search Premier and the combination 'mathematics' AND 'threshold concept' searching Boolean/Phrase in all text produced 32 hits of peer reviewed articles when searching in the period of 2003-2010 (access 2010-09-06). However, scanning the list of these articles only seven are in the area of mathematics education; that is reporting research about teaching and learning in mathematics courses. These seven articles include the three articles found in ERIC. The other four are published in Educational studies in mathematics (Bramby, Harries, Higgins, & Suggate, 2009), European journal of engineering education (McCartney, Boustedt, Eckerdahl, Moström, Sandres, Thomas, & Zander, 2009; Booth, 2008) and International journal of mathematical education in science and technology (Pettersson & Scheja, 2008).

Threshold concepts are in focus in two of the articles. Scheja and Pettersson (2010) discuss the transformative aspect of threshold concepts suggesting that the transformation involves a transformation of the students' conceptions as these develop through shifting contextualisations of the concepts. McCartney and

Working Group 14

colleagues (McCartney et. al., 2009) also focuses threshold concepts, but mostly related to software engineering. The article summarizes findings concerning how computer science students experience the liminal space and discuss how this might affect teaching.

In the other articles threshold concepts are more or less just mentioned. Masouros and Alpay (2010) focuses on the design of a computer-based mathematics resource. When discussing the mathematics content of the resource they emphasize that special effort should be given to troublesome topics that lead to a transformation in understanding, mentioning threshold concepts and referring to Meyer and Land (2003).

Williams (2009) puts forward the notion ‘threshold moment’ where seeing and grasping at the nexus of two or more activities often seem to be critical to breakthroughs in learning. In a footnote Williams makes a note on literature on ‘threshold concepts’ and also points out that not very much has been published about threshold concepts in mathematics.

Barmby, Harries, Higgins, and Suggate (2009) discuss children’s understanding and reasoning in multiplication. When the authors talk about key representations for a concept they relate this to the notion of ‘key development understandings’ defined by Simon (2006). They make a quotation from Simon and in this quote parallels with the notion of ‘threshold concepts’ are mentioned. Barmby and colleagues do not take this any further.

Booth (2008) addresses the issue of teaching and learning engineering mathematics based on a form of understanding that goes beyond facts, theorems and algorithms. She points out that the mathematicians as mathematics teachers in the engineering education mostly are interested in the learning objects, in what to learn, also mentioning that educational researchers have much knowledge about the ways students might be comprehending the learning objects, “in particular when it comes to ‘threshold concepts and troublesome knowledge’ ” (p. 383) referring to Meyer and Land (2003).

Pettersson and Scheja (2008) explore the nature of students’ understanding of the concepts limit and integral. As a reason to study these concepts it is argued that these concepts are threshold concepts giving references to Meyer and Land (2005, 2006) and to previous research about students’ conceptions in calculus.

Looking at these articles found by searching databases it could be seen that the notion threshold concepts until now is just used in really few research articles in mathematics education. In the next paragraph I point out that this framework is very useful also in mathematics education.

TO BE USED IN MATHEMATICS EDUCATION

Using the framework of threshold concepts is potentially even more successful in mathematics than in other subjects. In mathematics the concepts are an important part of the curriculum and the concepts are explicitly defined in a way that is uncommon in other subjects such as economics and engineering. The concepts and the relation between them build the core of mathematics (Davis & Hersh, 1990).

In my own research (Pettersson, 2008; Pettersson & Scheja, 2008; Scheja & Pettersson, 2010) I have studied students' conceptions of function, limit, derivative and integral. Looking through previous research about students' learning of calculus (e.g. Artigue et. al., 2007) these concepts are candidates as threshold concepts. The characteristics of threshold concepts, as integrative and transformative in the learning process, points out the importance of research about conceptions of these concepts. Pettersson and Scheja (2008) points out the students' algorithmic way of interpreting the concepts of limit and integral. Looking at these concepts as threshold concepts and focusing on the transformative aspect of the threshold showed that the students started to pass the threshold (Scheja & Pettersson, 2010). Challenging questions in the interviews showed to be important to start this transformation. Threshold concepts can in this way be used to focus on powerful transformation points in the students' learning; they are 'jewels in the curriculum' (Land, Cousin, Meyer, & Davies, 2006, p. 198). They give the students opportunities to develop fundamental conceptual understanding. Using threshold concepts in teaching a subject offers an opportunity to focus on the points that are really useful in mastering the subject (cf. Carsetensen & Bernhard, 2008). Focusing the most important concepts of the subject will also be a way of avoiding an overstuffed curriculum (Cousin, 2009).

Threshold concepts are characterized as potentially troublesome. The students are likely to encounter troublesome knowledge and experience conceptual difficulty. These concepts are potentially 'stuck points'. The students get into the liminal space with uncertainty and oscillation in understanding. This unsecure phase of learning may be necessary and unavoidable but we do not want the students to stay for a long time in the liminal space. Scheja and Pettersson (2010) argue that the students' shifting from an algorithmic contextualization to a contextualization inviting reflection on conceptual dimensions of limit and integral is a way to move on from the liminal space. Threshold concepts are rarely mastered at a specific point of time, an 'aha' moment, mastery might take years to complete (McCartney et. al., 2009). However, teachers listening to the students' uncertainties give possibilities for helping the students through the liminal space. Knowledge about these potentially stuck places is important in the teaching. Shanahan and Meyer (2006) pointed out the importance of the first impression; to simplify the threshold concepts do not help the students.

Working Group 14

One of the big advantages of research on threshold concepts is that it animates interests and discussions among academics. This kind of educational research gives centrality to the subject specialists and gives a platform for partnership between educational researchers and subject specialists. Such a focus on threshold concepts is also a good way to involve both subject specialists and educational researchers in a discussion on student learning, curriculum design and teaching the subject. Getting academics together to discuss and identify threshold concepts in their subject area has proved to be very fruitful (Cousin, 2009). My own experience of discussing teaching and learning mathematics at university with mathematicians is that threshold concepts appear to fit very well in mathematics. Presenting the idea of threshold concepts to mathematicians always bring up discussions about what threshold concepts there can be in calculus, in linear algebra and other subject areas. These discussions usually spark ideas about students' conceptions and how to improve student learning. The metaphor of a threshold to pass seems to be easy to take in and to be a good starting point for educational discussions.

Research using the framework of threshold concepts has the possibility to improve the teaching and learning of mathematics. The framework will be powerful in research of university mathematics education but it can also be used in research on mathematics teaching and learning at other levels such as primary and secondary school.

CONCLUSIONS

The framework of threshold concepts has successfully been used in educational research into several subjects. However, there are still few publications related to mathematics education. Using this framework in mathematics education will contribute to mathematics education in several ways. There are several concepts in the subject of mathematics that are troublesome for the learners. Knowledge about concepts which are transformative and integrative will help us to improve teaching and learning. To focus on threshold concepts is a way to avoid an overstuffed curriculum (Cousin, 2009). Research has also pointed out that the students scored higher when the teaching was focusing threshold concepts (Carstensen & Bernhard, 2008). The notion of threshold concepts also creates a meeting point for educationalists and mathematicians. The notion provides a language for discussions about how to improve teaching and learning. There is a growing body of results about threshold concepts in several subjects, but there is a lot more to do in relation to mathematics.

CHALLENGES WITH VISUALIZATION: THE CONCEPT OF INTEGRAL WITH UNDERGRADUATE STUDENTS

Blanca Souto Rubio and Inés M^a Gómez-Chacón

Universidad Complutense de Madrid

In this paper, some components of a conceptual framework for the study of visualization processes from a cognitive point of view are presented along with a discussion of examples of empirical data relating to the concept of integral: (1) the coordination of registers of representation for explaining some of the students difficulties in the understanding and learning of mathematical concepts (the integral); (2) characteristics of visualization (in Calculus): it is related to the use of the graphic register in coordination with other representations and accompanied by a global apprehension; (3) the use of the graphic register (non-visual, mixed and visual methods are identified) and the higher cognitive difficulty of visual methods.

Key- words: *Visualization, Representations, University level, Integral.*

INTRODUCTION

This paper grew out of a study conducted in 2008/2009 with a group of first year students at the Universidad Complutense de Madrid (UCM). The main aim of this study was to improve the teaching of mathematical analysis by emphasising visualization processes (Souto, 2009; Souto & Gómez- Chacón, 2009). From the beginning, a big challenge was: how to characterize visualization processes in order to be able to observe them in our particular context? The literature review related to this topic highlighted a large diversity of terms and theories around the notion of visualization; most of them referred to primary and secondary levels (Duval, 1995, 1999; Arcavi, 2003; de Guzmán, 2002; Presmeg 1985, 2006; Eisenberg & Dreyfus, 1991). Therefore, we noticed a lack of empirical studies on visualization among undergraduate students and of a corresponding adaptation of some of these theoretical elements to this level of teaching.

For the sake of brevity, in this paper we focus on cognitive aspects of visualization. We mostly use the theory of registers of semiotic representation (Duval, 1995, 1999). Firstly, some theoretical ideas from this framework are outlined and reviewed. Secondly, some examples of empirical data are analyzed. It is not our aim in this paper to provide an exhaustive analysis of the results obtained in the previous study (Souto & Gómez- Chacón, 2009), but just to analyze examples of data chosen in order to provide insight into some of the specific knowledge on individual students' reasoning in relation to visualization processes, obtained in this study.

The concept of integral has been chosen because it offers an opportunity to discuss key issues concerning visualization. Research on the concept of integral (Mundy, 1987; González-Martín & Camacho, 2004) emphasize that during the first year of

university, students use the concept of integral in a very mechanical way due to the lack of coordination of the concept of area and of integral, among other reasons. Furthermore, in an attempt to improve the comprehension of the concept, other authors have recommended explicit attention to visualization (de Guzmán, 2002; González-Martín & Camacho, 2004).

ABOUT THE CONCEPTUAL FRAMEWORK

Within the cognitive approach, the theory of the registers of semiotic representation (Duval, 1995, 1999) was useful in order to describe and analyze students' difficulties in the learning of mathematical concepts. In order to explore visualization processes, it has been found fruitful to combine it with some results from research on the role of visualization in mathematical reasoning (de Guzmán, 2002; Arcavi, 2003), on individual differences in the preference to visualize (Presmeg 1985, 2006) or on reasons for a reluctance to visualize (Eisenberg & Dreyfus, 1991), since that allows us making choices of important aspects for visualization inside Duval's theory.

Understanding and learning of mathematical concepts

We agree with Duval (1995, 1999) that the only possible access to mathematical objects is through their representations in the different semiotic registers. From this perspective, the *understanding of a concept* is built through tasks that imply the use of different registers and promote the flexible coordination of representations. Therefore, *learning mathematics* implies "the construction of a cognitive structure by which the students can recognize the same object through different representations" (Duval, 1999: 12).

In this context, *improving learning* implies, in particular, to minimise difficulties, misunderstandings and mental blockings that could appear in different actions related to a register: representation, treatment and conversion (Duval, 1995). As we noted in the introduction, in our specific case - the understanding of the concept of integral – research conducted with the semiotic approach highlights as a source of difficulties the lack of coordination between both the graphic and algebraic registers, and the predominance of the latter in the students' answers. This leads us to pay special attention to the use of the graphical register and to visualization.

Visualization in mathematics education

According to Duval (Duval, 1999: 15), visualization can be produced in any register of representation as it refers to processes linked to the visual perception and then to vision. For the aim of the present study, this notion is too broad; although we take into account some other characteristics of visualization pointed out by Duval. We find more useful Arcavi's definition, which is limited to the use of figures, images and diagrams.

"Visualization is the ability, the process and the product of creation, interpretation, use of and reflection upon pictures, images, diagrams, in our minds, on paper or with

technological tools, with the purpose of depicting and communicating information, thinking about and developing previously unknown ideas and advancing understandings” (Arcavi, 2003: 217).

Therefore, in the frame of this research we identify visualization with the use of the graphic register. However, some remarks related to this definition are needed.

In the characterization of visualization in the context of problem solving, we find very useful the difference between *visual* and *non-visual methods* established by Presmeg in her research about preference to visualize (Presmeg, 1985). However, we have to be cautious when combining Presmeg’s and Duval’s approaches. For example, the following equivalence cannot be established: visual method (Presmeg) - use of graphic register (Duval). We must be cautious for two reasons. Firstly, when Presmeg (2006) talks about *visual images*, she includes mental images that belong to the world of mental representations, which are different from Duval’s semiotic representations (Duval: 1995: 14). We adopt this sense of mental images in relation to visualization. Secondly, the use of the graphic register does not imply that the method is visual. Duval (1999: 14) distinguishes two types of functions for the images: the *iconic* and the *heuristic*. The latter involves a global apprehension and it is related to visualization (Duval, 1999: 14). If there is use of the graphic register but there is not global apprehension or the image performs an iconic function, we will not therefore use the term *visualization*. Thus, the relevant connection is between visual methods (Presmeg) and this heuristic function of images (Duval).

Finally, Eisenberg and Dreyfus (1991) identify three reasons to explain the reluctance of some students to visualize: “*a cognitive one (visual is more difficult), a sociological one (visual is harder to teach) and one related to beliefs about the nature of mathematics (visual is not mathematical)*” (1991:30). With the help of Duval’s approach, it will be possible to describe this particular cognitive difficulty of visualization.

PARTICIPANTS AND DATA COLLECTION

The study was conducted with a first year group of 29 mathematics students at Universidad Complutense de Madrid, 15 female and 14 male. In this first year, the students followed a course called Real Variable Analysis, in which the formal definition of the concept of integral is introduced. However, they were supposed to have learned the basic rules for integration by using primitives as well as its relation to the calculation of some areas under curves already in secondary school.

For the data collection, the instruments used were a questionnaire with problems and semi-structured interviews. The questionnaire was composed of 10 non routine problems in mathematical analysis, some taken from other studies (Mundy, 1987; works quoted in Eisenberg & Dreyfus, 1991). Most of the problems are posed in the algebraic register but they also allow a visual interpretation (Eisenberg & Dreyfus, 1991). Thus these problems allow the analysis of students’ performance with regard

to the coordination of registers, and particularly the use of the graphic register. The results obtained from the questionnaire required deeper investigation into affective, cognitive and sociocultural aspects of individual students. In order to do this, 6 semi-structured interviews were conducted. These were divided into several parts: individual background, tasks about beliefs and preference of visualization, questions on questionnaire's answers. In this paper, attention is paid only to the cognitive aspects of the data.

For the data analysis, we privileged the use of systemic networks for the questionnaire and transcriptions for the interviews. Systemic networks (Figure 8) allow looking simultaneously at all the students' answers to the problems. Both, students and their answers, were labelled with a number from 1 to 29 included between parentheses. In particular, systemic networks favour the observation of the following elements: strategies and kinds of representation used by each student; frequency of use and difficulties of each register; and students' conceptions.

ANALYSIS AND DISCUSSION OF RESULTS

Students' difficulties analyzed through the theory of registers of representation

Students' answers to the questionnaire were analyzed using Duval's theory of registers of representation. The results described below are based on the analysis of the systemic network (Figure 8) associated with the following problem (Figure 7), but they are representative of what happens with other problems in the questionnaire.

What's wrong in the following calculation of the integral?

$$\int_{-1}^1 \frac{1}{x^2} dx = \int_{-1}^1 x^{-2} dx = \frac{x^{-1}}{-1} \Big|_{-1}^1 = \frac{-1}{x} \Big|_{-1}^1 = \frac{-1}{1} - \frac{-1}{-1} = -2$$

Figure 7 Statement of the first problem

Firstly, the choice of representation and register is very important for solving the problem successfully. These decisions are directly related to the conception used for the integral concept. All the students who gave valid answers, placed on the top of Figure 8, were either focused on the function (global properties as continuity or asymptotes; or local at $x=0$) or they contemplated the interpretation of the integral as the area under a curve. This led two of the students to the use of the graphic register. However, most of them (22 students) interpreted the integral as a process (calculation of primitives and Barrow Rule) which leads all of them to the use of the algebraic register. In this case, the students were not able to correctly answer the question. They repeated the same calculation or made some errors (using a different primitive, interchanging the signs when applying the Barrow Rule, considering the constant of integration, miscalculations).

Working Group 14

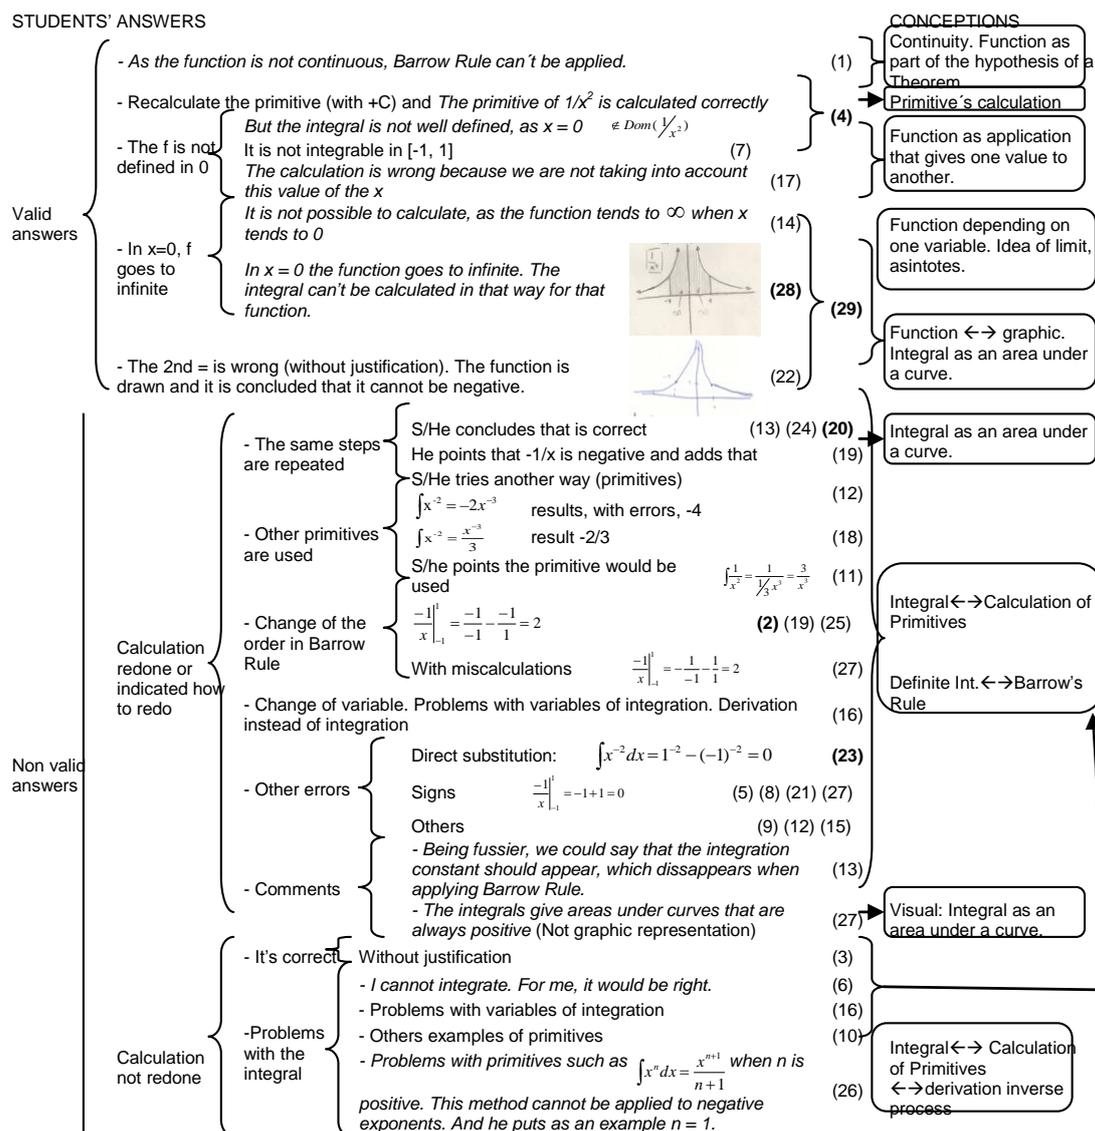

Figure 8: Systemic network associated to the problem

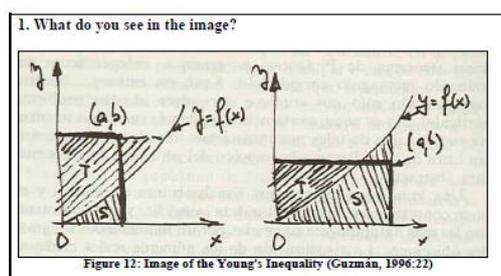

Secondly, we examine the way in which representations are used. The data show that the initial kind of representation chosen does not determine completely the success of the resolution. For example, student 4 was the only one who focused at the beginning on the integral as the calculation of primitives, but answered successfully. This was possible because of the flexible combination of this calculation with another argument about the domain of definition of the function. Moreover, the analysis of the answers highlights how the coordination of registers led to a better understanding of the problem (see in Figure 8, answers 28 and 29). However, there is a risk of making some errors (Figure 8, answers 19, 27) if the mobilisation of both registers is not accompanied by further reflection.

Thus, our results are coherent with previous research (Mundy, 1987; González-Martín & Camacho, 2004) described in the introduction. From a didactic point of view, the use of different kinds of representations and registers and their

coordination seem to be essential. But then, how to promote their flexible coordination when teaching?

Essential for visualization: the global apprehension

Global apprehension of images is required together with the coordination of registers. However, some students do not go further than having a local apprehension and cannot see the relevant global organization (Duval, 1999: 14). Our analyses adopt these ideas as we try to show with the description of the following episode from the interviews.

2. Do you find some relation with the following heading?

Theorem 3.2 (Young's Inequality). *If f has a continuous and positive derivative on $[0, c]$ ($c > 0$) and $f(0) = 0$, then for $a \in [0, c]$, $b \in [0, f(c)]$, we have*

$$ab \leq \int_0^a f(x) dx + \int_0^b f^{-1}(x) dx. \quad (3.3)$$

The equality holds if and only if $b = f(a)$.

Figure 13: Heading of Young's Inequality

Figure 9: Statement of the task based on Young's Inequality

The episode concerns Young's Inequality (Figure 9) and the interpretation of a graphic representation when asked for the connection with the theorem. Silvia is the name of the student chosen for the interview. She was selected because her responses to the questionnaire showed some preference for the graphic register, while she did not answer satisfactory any problem. The interview enabled us to go deeper into her difficulties with visualization.

At first, only the image was shown. Silvia detected isolated elements and even made some references to the integral as an area. Later, we showed her the statement of the inequality. She assumed the relation to the image, but it did not seem to be clear for her. She frequently requested help by asking questions. Afterwards the following conversation took place. In order to be able to continue with the interview, support is given to help her to identify correctly all the elements in the image with those in the statement. Thus, in spite of the fact that Silvia seemed to be able to coordinate the two registers, there was not any moment of clear understanding.

Interviewer: OK, what kind of explanations would you need with the drawing? Have you understood it completely, the drawing?

Silvia: Um... Well... [...]

Interviewer: OK, this $[ab, \text{the rectangle}]$ is equal or less than this integral, the one which is in the drawing?

Silvia: Well, it'll be this, from 0 to a (she points with the finger to an interval over the x - axis). This one, the S 's.

Interviewer: OK, and the other?

Working Group 14

Silvia: Well, T's. (Silence, she seems pensive)

Interviewer: This is a little more difficult for you to see, isn't it?

Silvia: Yes.[...] Well, to understand it [the theorem], with the drawing I wouldn't understand it.

Silvia could not go beyond the mere identification of the represented units. For her, the image was only an illustration, an iconic representation that does not work as a means of visualizing the statement of Young's Inequality. Therefore, the main conjecture for Silvia's difficulties with visualization in this case is the lack of global apprehension. From a didactic point of view, the following challenges emerge: Is it possible to teach how to apprehend an image globally? If so, how can it be done?

The high cognitive requirement of visual methods

During another task in Silvia's interview, she explained why she chooses "*the way they give [in class], the definition*" as follows: "*I don't know. It's like everything is more mechanical. In the other way [visual] you have to relate, to think. [...] It isn't that I prefer it [algebraic], but it's easier. So, instinctively, I do it*". This excerpt of the interview concerns the cognitive rationale pointed out by Eisenberg and Dreyfus (1991) for the reluctance to visualize. In order to go deeper into this issue, the students' use of the graphic register in the answers to the questionnaire was analyzed. Taking into account the distinction between iconic and heuristic functions performed by images (Duval, 1999), and its relation with non-visual and visual methods (Presmeg, 1985), different kinds of techniques for solving a problem using the graphic register have been detected: *non-visual*, *mixed* and *visual*. The data collected from the following problem (Figure 10) of the questionnaire allow us to illustrate some characteristics of each kind of technique.

If f is an odd function on $[-a, a]$ calculate $\int_{-a}^a (b + f(x)) dx$

Figure 10: Statement of the second problem

This problem was answered by 20 students, and only 8 used the graphic register. The first kind of resolution (Figure 11) appeared with higher frequency (5 out of 8 students). The images appear together with the algebraic register, in which the main reasoning takes place. The images were employed either to try to remember the definition of odd functions, or to deduce some other properties. Therefore, the image was unnecessary and it performs an iconic function. The method of resolution was considered to be *non-visual*. In fact, the example shown (Figure 11) is accompanied by an image that the student interpreted by giving an incorrect definition of odd functions. In spite of this, this misunderstanding did not affect the algebraic reasoning, which is valid.

In the other two resolutions, images were interpreted as performing a heuristic function. However, they differ according to the number of conversions made between the algebraic and the graphic registers. The second resolution (Figure 13)

Working Group 14

was given by two students. It has been called *mixed* as a first step is needed in the algebraic register, in which the additive property of integrals is applied, before converting to two graphic representations, one for each integral. As an informal conversation with the student who gives the answer in Figure 13 clarified, this conversion allowed him calculating the value of the integrals, without performing treatments in the algebraic register, and coming back afterwards to it in order to finish the evaluation of the integral. Thus, two conversions were made (algebraic-graphic- algebraic).

$$\int_{-a}^a (b + f(x)) dx = \int_{-a}^a b dx + \int_{-a}^a f(x) dx =$$

$$= (bx) \Big|_{-a}^a + \int_{-a}^a f(x) dx$$

The integral of $f(x)$ in a is going to be equal that the integral of $f(x)$ en $-a$, thus the second summand will be nil and the final result will be:

$$(bx) \Big|_{-a}^a = b \cdot a - (b \cdot (-a)) =$$

$$= b \cdot a - (-b \cdot a) =$$

$$= b \cdot a + b \cdot a = 2ba$$

$f(a) = -f(-a)$

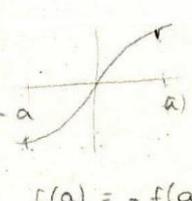

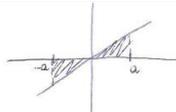

Figure 11: Non visual method

odd \rightarrow symmetric respect to $(0,0)$

$$\int_{-a}^a (b + f(x)) dx = \int_{-a}^a b dx + \int_{-a}^a f(x) dx = \int_{-a}^a b dx = b \cdot 2a$$

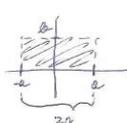

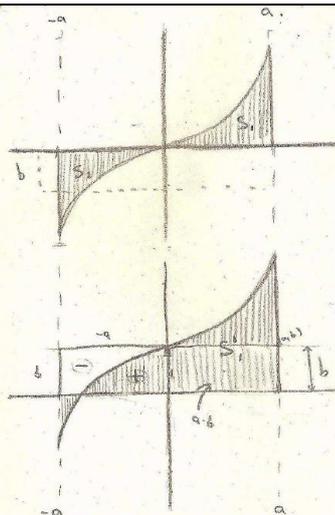

Figure 13: Mixed method

$$S_1 = -S_2$$

S_1 On the one hand
 $S_1' = S_1 + a \cdot b$
 It is, we sum $a \cdot b$

S_2 : On the other hand, we have removed the negative part the fragment marked with \ominus and we have added \oplus to the positive part. And as:

We have added again $a \cdot b$.

In conclusion: as $S_1 = -S_2$, the integral was 0, and we have added twice $a \cdot b$, the result is:

is: $\int_{-a}^a b + f(x) dx = 2ab$

We can check it:

$$\left[\int_{-a}^a b + f(x) dx = \int_{-a}^a b dx + \int_{-a}^a f(x) dx = b \int_{-a}^a dx = b(x) \Big|_{-a}^a = \right.$$

$$\left. = 2a \cdot b \right]$$

Figure 12: Visual method

The third resolution (Figure 12) is completely *visual* since it includes, at the beginning, just one conversion to the graphic register, in which the main argument is developed. In order to give this visual answer, more concepts and relations than in the non-visual ones (including the pure algebraic one) must be considered simultaneously: a visual interpretation of the integral as an area, and the odd functions as those symmetric around the origin; the recognition that adding a constant quantity to a function means a translation of its graph along the y-axis (this notion is not necessary in the algebraic reasoning); finally some image treatment of that sort of “cutting” and “gluing” areas, taking into account their signs. Therefore, this original answer given by only one student provides the opportunity to show how the cognitive theory of registers of semiotic representation serves to explain and to go deeper into the cognitive difficulty of visualization noted by Eisenberg and Dreyfus (1991). There is also at the end an algebraic answer used for checking. It follows a linear process consisting in the succession of several algebraic treatments, made without errors, giving as result $2ab$. Obviously, in both arguments, the result is

the same. However, each kind of argument leads us to see the problem in a very different way.

Therefore, from a didactic point of view, the combination of visual and non-visual arguments when teaching seems to be advisable, since it provides complementary kinds of understanding. However, as was argued in the conceptual framework and as the empirical data have shown, this should not be misinterpreted as just using the graphic register. The following challenges for teaching emerge: how to combine visual and non-visual methods in class in order to improve the understanding of the students? How can the higher difficulty of visual arguments be handled in the class?

CONCLUSION

In this paper, we aim to: (1) present some theoretical ideas found to be relevant in a conceptual framework for a cognitive perspective of visualization; (2) show the analysis of some examples of empirical data in order to provide insight into two levels, the theoretical ideas presented and the individual students' reasoning.

The theoretical framework of the cognitive theories of registers of semiotic representation (Duval, 1995, 1999) was useful in order to: (1) describe some difficulties of the students in the understanding and learning of mathematical concepts, in this case, the integral; (2) explore some conditions for visualization (in Calculus), related to: the explicit or implicit use of the graphic register, to the coordination with other representations (in the same or different registers) and, as Silvia's episode showed, to the necessity of a global apprehension of the image; (3) examine the students' use of the graphic register and the higher cognitive difficulty of visualization argued by Eisenberg & Dreyfus (1991). Moreover, visualization is related to the *heuristic function of images* (Duval, 1999) which has been identified with the *visual methods* (Presmeg, 1985). This connection led us to distinguish three different kinds of methods for solving a problem using the graphic register: *non-visual*, *mixed* and *visual*. Although this possibility has not been fully exploited in this paper, it enables us to shift our attention to individual differences in the preference to visualize.

From a didactic point of view, some challenges around a specific teaching of visualization emerge: how to use different kind of representations and registers in order to promote a flexible coordination between them? Is it possible to teach how to apprehend an image globally? How could it be done? How to combine visual, mixed and non-visual methods in class in order to improve the understanding of the students? How to manage the higher difficulty of visual methods?

THE SECONDARY-TERTIARY TRANSITION: A CLASH BETWEEN TWO MATHEMATICAL DISCOURSES

Erika Stadler

Linnaeus University

The aim of this paper is to illustrate some aspects of the transition between secondary and tertiary studies in mathematics, based on an analysis of a critical case of two students trying to solve a system of linear equations with help from their teacher. In their conversation, different aspects of the transition appear, which both can be assigned to changes in the mathematical content and differences in the way mathematics should be regarded and communicated. Students draw on a school mathematical discourse, while the teacher answers them within a scientific mathematical discourse. The notion of functional understanding is used to describe students' attempts to build bridges between these discourses.

Keywords: transition, secondary, tertiary, school mathematics, mathematics teacher

This paper reports from a case study of the secondary-tertiary transition. The study is based on an episode with two novice teacher students, working with a university textbook exercise in linear algebra with help from their teacher. The aim of the paper is to examine the transition in terms of an encounter between two mathematical discourses; school mathematics and mathematics as a scientific discipline. After a short overview of some earlier research concerning the transition, presentation of data is alternated with analyses of the two students working on the exercise with help from their teacher. The paper ends with conclusions and final comments about their transition between secondary and tertiary mathematics.

EARLIER RESEARCH ON THE SECONDARY-TERTIARY TRANSITION

Nowadays, the secondary-tertiary transition is a well-researched area. The transition has been studied from various theoretical perspectives that explicitly or implicitly point at different crucial aspects of students' learning of mathematics in a new learning environment (de Abreu, Bishop & Presmeg, 2002; Gueudet, 2008; de Guzmán, Hodgson, Robert & Villani, 1998). The transition has also been closely connected with the transition from elementary to advanced mathematics as well as from elementary to advanced mathematical thinking (Artigue, Batanero & Kent, 2007), specifically focusing on students' encounters with mathematical abstraction (Nardi, 2000). Lithner (2003) offers a more specific study of university students' work with textbook exercises. He developed different categories of students' reasoning according to what extent the reasoning is based on more superficial features of the exercise or relies on more intrinsic mathematical qualities in the task. In relation to the transition, the new institutional context where the studying takes place is crucial, as are students' actions and statements in relation to new demands on learning mathematics. This complex relation between institution and subject has

been studied within the anthropological theory of didactics where the transition can be regarded as a movement between different praxeologies (Alveres Dias, Artigue, Jahn & Campos, 2010).

Some common features that can be identified in these previous studies about the transition are changes in the way the mathematical content is treated, an increasing level of abstraction and new demands on students as learners. In this paper, I have chosen to take a very detailed perspective on these issues, zooming in on a specific episode where these features of the transition can be understood in terms of the clash between two different mathematical discourses as one additional perspective on the changes that the transition can bring about. The rationale for this approach lies in the fact that the work with textbook exercises and students' interaction with a university teacher are two main activities in university studies in mathematics, and it is reasonable to think that aspects of the transition are visible in these kinds of situations.

SCHOOL MATHEMATICS AND MATHEMATICS AS A SCIENTIFIC SUBJECT AS TWO DISTINCT MATHEMATICAL DISCOURSES

As an attempt to capture the tensions between secondary and tertiary mathematics, I have chosen to view school mathematics and mathematics as a scientific discipline as two distinct communities of discourses (Sfard, 2007) in order to describe differences between treatment of the mathematical content and the learning situation at a social institution. Because a discourse contains specific rules of how to communicate, it can both be inclusive and excluding. Mathematics can be regarded as a specific kind of discourse. According to Sfard (2007) a mathematical discourse consists of mathematical words, visual mediators, routines and narratives. Interlocutors make use of *mathematical words*, such as variables, unknowns, equations and cases, when communicating about mathematics. *Visual mediators*, such as symbolic artefacts and manipulatives, can be used as a cursor on the objects of communication. *Narratives* are descriptions or accounts of objects. These can be any written or spoken text that is used within the discourse and can be subject to endorsement, i.e. narratives can be judged as true or false. *Routines* refer to repetitive patterns in the interlocutors' actions. Routines can be due to properties of mathematical objects but can also be about the rules of the discourse itself. It is plausible to suppose that the mathematical discourse differs between secondary and tertiary mathematics education. I have chosen to give an account for these differences in terms of school mathematics and mathematics as a scientific discipline as two different mathematical discourses.

Even though the notion of "school mathematics" is frequently used, it seems to lack a scientifically grounded definition, but is used in a more common sense and everyday manner. In this paper, I will associate school mathematics with teaching methods that are commonly used in Swedish secondary school mathematics classrooms. Mathematics lessons starts with the teacher giving a short demonstration of some

standard examples. For the rest of the lesson, the pupils work individually with textbook exercises that are similar to the ones that have been demonstrated at the blackboard. A main focus is to learn what to do, i.e. an emphasis on algorithms and procedures. Mathematics as a scientific discipline concerns mathematics as it is considered within an academic and scientific discourse, for example university courses in mathematics (Robert & Schwarzenberger, 1991). The use of exact definitions, theorems and proofs is significant, which is often communicated through generic examples. Thus, a dichotomy between mathematics studies at secondary and tertiary level can be identified. From a students' perspective, the transition can be regarded as a process of enculturation into the university mathematical discourse, based on their previous knowledge and understanding. The notion of functional understanding is used to describe students' attempts to participate in the new mathematical discourse that they meet at university (Stadler, 2009), i.e. to tell new narratives and undertake new routines within a mathematical discourse that is more in accordance with mathematics as a scientific discipline, even though the students are not yet in all respects ready for it.

METHOD

The data, presented in this paper, is selected as a critical case from a more comprehensive study about the transition (Stadler, 2009). In the larger study five teacher students in mathematics were studied during their first semester of mathematics studies in Calculus 1 and Algebra during a time period of ten weeks, and Calculus 2 and Linear Algebra during another ten-week period. The students were frequently interviewed and observed during lectures, tutorials and their individual work with textbook exercises. The episode reported in this paper was audio recorded and transcribed in full. Analysis of the transcriptions was inspired by grounded theory (Charmaz, 2006) and used constant comparisons, memos, sorting and categorisation. However, instead of generating own categories, the analysis focused on empirical instances of discursive elements of school mathematics and mathematics as a scientific discipline.

The episode took place during the first week of the linear algebra course. The reason for the choice of this episode was that it constitutes a critical case of the secondary-tertiary transition, understood as a clash between two mathematical discourses. The notion of a critical case comes from Flyvbjerg (2006) and can be defined as "*having strategic importance in relation to the general problem*" (p. 229). The episode revolves around a textbook exercise that requires both routines and the use of new words and narratives and an interaction with the mathematics teacher at university. The dialogue about this exercise between the students and the teacher can be regarded as capturing many aspects of the transition in a single conversation and several empirical instances of an encounter between students' previous experiences of a school mathematical discourse and mathematics as a scientific discourse, offered by the teacher.

RESULTS AND ANALYSIS

Linear algebra has been regarded as a mathematical domain that seems to be cognitively difficult for students to learn (Dorier & Sierpinska, 2001). Vector spaces and their origins is one area that can be particularly problematic for novice university students. However in the first course in linear algebra at the university where the study took place, the course mainly treats systems of linear equations, matrices, determinants, dot and cross products, vectors, changes of basis, eigenvalues and linear transformations in two and three dimensions.

It is against this background that the task, which Jenny and Ellen are working with, should be regarded. The exercise is number 14 in the first chapter of their textbook in linear algebra. The exercise is formulated as:

Solve the system of equations for all values of the constants a and b .

$$\begin{cases} x + y + z = 5 \\ x - y + az = 3 \\ 2x + y + z = b \end{cases}$$

The students attempt to solve the task by successive elimination.

The third equation is reduced to: $-\frac{a+1}{2}z = -9 + b$

To proceed, the students would have to analyse different cases depending on the values of the constants. In particular, whether the constant a equals minus one or not will generate different types of solutions of the system of linear equations. However, Jenny and Ellen get stuck and ask the teacher for help.

Ellen: We want to find the values of these constants. We understand that if a equals minus one, then the brackets equals zero, and then b will equal nine.

Teacher: Yes, well, yes. Well, I think we should start with the basic problem here, because you expressed things slightly incorrect. You said that you should determine these constants, a and b . But that is not what you should do. You should, for all values on a and b , find the solutions of the system of equations.

The task that Ellen and Jenny are working with puts to the fore some interesting aspects of the transition in relation to previous research. There is an increasing level of abstraction (cf. Nardi, 2000) in comparison to prior tasks in the chapter. It requires the students to simultaneously handle variables, constants and parameters. These unknowns have different meanings and functions for the equations and consequently for the solution of the exercises and should be treated in different ways. From a school mathematical context, students seem used to that unknowns, represented by a letter, should be decided or determined by finding their values. Accordingly, Ellen's initial statement that they want to find the values of the constants can be interpreted as a misunderstanding of the aim with the exercise, but also as an everyday and an operational way to describe how they have worked with the task. New requirements are put on students' reasoning with the textbook exercise. The students must relate to intrinsic features of the mathematical content in the task, rather than just using a

Working Group 14

standardised algorithm for solving systems of linear equations (cf. Lithner, 2003). The teacher's emphasis on finding solutions of the system for all values on a and b can be interpreted as an attempt to highlight this distinction and inviting the students to participate in a partly new mathematical discourse.

Instead of giving the students a more direct answer to their questions, the teacher gives a more comprehensive explanation, which can be interpreted as making an effort to highlight the generic character in the exercise concerning role and function of the constants. Ellen and Jenny ask for a routine for how they should proceed to determine the values of a and b . The teacher gives them an account of the role of the constants in the system of linear equations. These different approaches can be interpreted as an expression of the transition, where the teacher focuses on the general character of the mathematical content, while the students are primarily interested in a specific routine for finding a solution of the task. Thus, there is an obvious mismatch between the students' and the teacher's mathematical discourses.

Further work with the task results in the expression: $z = \frac{18 - 2b}{1 + a}$

Jenny: If you divide with a , it should not be...

Teacher: Yes, exactly! Go on!

Jenny: Minus one.

Teacher: Yes, that's right. If we want an expression for z , we must divide by one plus a on both sides. And then, we have to be careful when, as you said, Jenny...

Jenny: ...when a equals minus one.

Teacher: Yes. Exactly. So you must start looking at... But, then you must not say that a is or must not equal minus one. You should examine both cases. If a does not equal minus one, then one plus a does not equal zero and then there is no problem with division and we can get an expression for z . But you must not stop there, you must also examine the case when a equals minus one.

That division by zero is not an acceptable mathematical operation seems familiar to Jenny, but it is a considerable abstraction from knowing this for natural numbers to apply it on a rational algebraic expression. Jenny's use of knowledge in relation to a very local mathematical context, namely the algebraic expression at hand, can be regarded as an empirical instance of functional understanding. At the same time, the teacher attempts to involve the more encompassing ideas of solving systems of linear equations and how a division with zero should be interpreted in that context.

The students and the teacher re-write the system of equations for the case when $a = -1$ and solve it.

Teacher: Okay, and now a equals minus one. Let me write a little bit here. That equals minus two z there [refers to the second reduced equation]. And in the last equation, well, if a equals minus one, the left hand side will equal zero.

Working Group 14

And then we have: zero equals minus nine plus b [$0 = -9 + b$]. So, re-write the system of equations once again for the case when a equals minus one, and use that as a point of departure for thinking. Which situation do we have now according to the last equation?

Jenny: That one?

Teacher: Yes. What conclusions can you draw?

Jenny: That if a equals minus one, then b equals nine.

Teacher: Well, we agreed that a and b should be free. You must not say that b must equal nine. If I ask you the question, if b equals ten?

Ellen: Then this is not valid. Then we don't have any solutions.

Teacher: No. Exactly. Thus, if b equals ten, then the last equation says that zero equals one. And the conclusion must be that no solution exists for b equals ten.

Ellen: Mm.

Jenny: But how do we write this in our solution? Solutions only exist if b equals nine or what?

Teacher: Yes, but we shall push things one step further and analyse which solutions we get, because we have to organize things in different cases, partial solutions.

Ellen: Oh gosh!

Teacher: But didn't you follow my example?

Ellen: Yes!

The students discuss with the teacher about how they should move on. They consider the case when $b = 9$ and the system of equations has infinite many solutions.

Teacher: So, an interesting case is when b equals nine, because then we have x plus y plus z equals five. We have minus two y minus two z equals minus two. And finally, the last condition, zero equals zero. So, what about the last equation?

Ellen: We don't need to care about that one.

Teacher: You have to have a parameter there. You'll get infinite many solutions in that case. So, if I say that z equals four, then y becomes something and we put it up there and x becomes something. And if z equals seven, well, then we'll get a y -value and then an x -value.

Regarding the last equation, $0 = -9 + b$, the teacher asks the students to analyse and draw conclusions. Jenny's and Ellen's various responses to the teacher can be interpreted as that they are working in a school mathematical context with familiar mathematical routines such as solving equations and writing down complete solutions. Once again, the teacher emphasises that the constants a and b do not have

Working Group 14

any specific values but should be regarded as “free”. As mathematical words within a discourse, these constants get a new meaning. Even though Jenny gets a remark from the teacher not to fix the values a and b , her statement “if a equals minus one, then b equals nine” could be interpreted as a first sign of understanding the new way of dealing with different cases and treating unknown constants, even if it is just a conclusion of what she thinks the teacher wants her to say. Her question about how the solution should be written indicates a focus on routines that differs from the teacher’s focus but also serves as an attempt to take part in a new way of using narratives and solving a mathematical textbook exercise. At the same time, Ellen manages to draw a correct conclusion about what happens if the last equation ends up in a contradiction or both sides equal zero, but seems to be put under pressure when the teacher wants to push the discussion a little bit further. The teacher constantly continues to push the students towards a more scientific mathematical context, where the solution is not an aim in itself but rather a tool for drawing more general mathematical conclusions.

The students and the teacher discuss the case when b does not equal nine. The last equation $0 = -9 + b$ becomes a contradiction, and in this case the system will have no solution. Then the case when a does not equal minus one is discussed.

Ellen: How do we do with this case when a does not equal minus one? Shouldn’t we do some kind of “partial solutions”?

Teacher: In general, it depends, but in this case, I can tell, it won’t be needed. Because there you have the equation when a doesn’t equal minus one. Then you can divide by one plus a on both sides to get z and then there won’t be any problems.

Ellen: Sorry, what did you say about... What were we supposed to do here, you said? If... if a does not equal minus one?

Jenny: Then we can get z and put it in the...

Ellen: But then we can have a z that does equal anything and contains both a and b ?

Teacher: Yes, and that is not an unnatural thing in any way. If you think about, well, of course the whole system depends on the parameters a and b . So it is self-evident that the solutions do so too. Or, well, it isn’t self-evident but it isn’t unnatural either, so to say.

Ellen: Mm...

The teacher leaves the students, who try to finish their work with the exercise.

Ellen: But, should we do something more with this case?

Jenny: I don’t think so.

Ellen: We shouldn’t change it with a t or something like that?

Working Group 14

At first glance, Ellen's final statements can be interpreted as self-deprecatingly ironic, directed towards their mathematical ignorance and inability. However, her comments might also be interpreted as a first attempt to use narratives within a more scientific mathematical discourse. Ellen seems to have grasped that just solving a system of linear equations may sometimes not be enough. Instead, several cases and options may occur during the work. Ellen may not have fully grasped how to deal with different cases, but using the word "case" and trying to fit it in a suitable statement can be regarded as an initial step towards taking part in a more scientifically oriented mathematical discourse.

A main feature in the episode is the discrepancy between what the students regard as their main problem while working with the exercise and the help and explanations that are offered by the teacher. The students seem to work and understand things according to a mathematical discourse, which may be described as school mathematics, based on their previous experiences from upper secondary school. For example, one difficulty for the students is to deal with three different kinds of unknowns; variables, constants and parameters. The students seem to be used to that an expression with unknowns should be solved or treated as an equation. The unknown values should be found, preferably as numerical values. To handle the system of equations by finding x , y and z and simultaneously taking all possible values of a and b into consideration can be a difficult thing to do. A simpler way to think about the different cases is to solve the system for specific values of a and b . However, one should not conclude that this is due to students' misconception. Rather, it can be regarded as a pragmatic way to handle a complex situation. What seems to be an immature way to think and act is simply the way that they manage to think and act, because this is what they are familiar with.

SUMMARY AND CONCLUDING REMARKS

In this paper, a critical case was chosen to illustrate the transition as an encounter between a school mathematical discourse and a discourse of mathematics as a scientific discipline. The episode shows several empirical instances of discrepancies between the students' and the teacher's use of different mathematical discursive elements. The students ask for routines that can be used to solve the exercise at hand. The teacher constantly tries to steer focus to more general aspects in the exercise by using words and narratives accordingly. Instead of meeting the students' demands of routines, the teacher offers narratives about the role of the unknown constants.

The mathematical exercise that the students are working with contains an inherent abstraction. On the surface, the exercise seems standardised and ordinary, but demands mixing an algorithmic solution with an extensive analysis of different cases and a new way of talking about the solutions. The switching between different kinds of unknowns also makes the exercise complex, which puts additional demands on students' reasoning (Lithner, 2003). The students encounter situations that they

interpret according to previous experiences and apply well-known routines, when these situations should be regarded and treated in a partly new way.

In the episode, it is obvious that the students and the teacher participate in different mathematical discourses, but it also shows how these students are trying to adapt their reasoning in accordance with how they understand the situation at hand. The students ask for instructions of “what they should do”, but the teacher provides explanations of “how things are” and treats the exercise as a generic example. The teacher puts new expectations and demands on the students when using new discursive elements.

Functional understanding has been defined as students’ attempts to participate in a new mathematical discourse (Stadler, 2009). In the episode, the students’ functional understanding can be identified in empirical instances where the students are trying to use words and narratives in the new discourse even though they are not yet familiar with them. Initially, the students attempt to use routines from a school mathematical discourse, but gradually change their orientations towards new words and narratives, which they are trying to operationalize into new routines within a more scientific mathematical discourse. It can be concluded that the transition from secondary to tertiary mathematics puts new demands on students’ use of mathematical words, their communication with narratives and ways of applying routines. To cope with the new learning environment that the university constitutes and the new mathematical content that they encounter, students both have to learn a partly new kind of mathematics but also learn how to learn mathematics.

The results in this study also contribute to our further understanding of the school to university transition. A recurrent theme in research concerning the transition is the changeover from elementary to advanced mathematical thinking and analysis of students’ learning of mathematics in a new learning environment (Artigue, Batanero & Kent, 2007; de Guzmán, Hodgson, Robert & Villani, 1998), characterising the transition in terms of an increasing level of abstraction (Nardi, 2000) or as a movement between different praxeologies (Alveres Dias, Artigue, Jahn & Campos, 2010). In contrast to these directions of research, where individual, sociocultural and institutional aspects are considered on a more general level, the current study does not attempt to give a comprehensive account of the transition. Instead, by making use of Sfard’s discursive framework (Sfard, 2007), it provides a fine-grained analysis of a critical case for the transition as an encounter between a school mathematical discourse and a discourse of mathematics as a scientific discipline. Specifically, the current study gives an account for difficulties that may be involved in such an encounter and what enculturation can be for novice students in a specific learning situation – namely, their attempts to participate in a new learning environment and handle partly new demands and conditions.

STUDENTS' CONCEPTIONS OF FUNCTIONS AT THE TRANSITION BETWEEN SECONDARY SCHOOL AND UNIVERSITY

Fabrice Vandebrouck

Université Paris-Diderot, Laboratoire de Didactique André Revuz

In this paper, I would like to introduce the concept of perspective and to stress the importance of dealing with perspectives on functions for students entering university. This theoretical concept is meant as complementary to the process/object duality, enriching thinking in the passage from the conceptual embodied world to the formal axiomatic one. Drawing on a typical task of the transition between secondary school and university, I point out the difficulties for students to solve tasks when algebraic techniques are not sufficient.

Key words: mathematics, functions, university students, concept image, perspective

In this article I want to investigate one problem that arises in the transition between secondary school and university concerning the concept of function. This area has been extensively studied for several decades but the context of the teaching situation, always changing, justifies that the interest is continuously renewed.

SPECIFICITIES OF THE TRANSITION BETWEEN SECONDARY SCHOOL AND UNIVERSITY

Many studies have already indicated the characteristics of this transition (Artigue 1991, 2007; Guedet, 2008). From an institutional perspective, many macro-ruptures can be identified: a shift from a course with one teacher to lectures and tutorials; acceleration of teaching time with a rapid turnover of content and lessons with faster assimilation; shorter presence of teachers; lack of familiar problems from secondary school; and, wider range of tasks that make their internalization much more difficult than in secondary school, the latter being delegated to personal work of students, who must therefore be more autonomous in their learning.

Robert (1998) also noted a distribution between the types of mathematical notions which is different from secondary school to university, especially the emergence at university level of new mathematical notions carrying a high level of formalism and generalization. She also pointed out the differences in the level and the nature of tasks (necessity of available knowledge, necessity of flexibility in this knowledge, for instance use of different settings and representation systems, new requirements in term of proofs at the university level, etc.).

THE COMPLEX NOTION OF FUNCTION

The notion of function is at the intersection of several mathematical fields (real numbers, limits, algebra, etc...), appears in many frames (Douady 1986) and requires

the consideration of several representation systems (graphical, algebraic, symbolic etc.) (Duval 1991). Functions are therefore complex objects which are still being learnt when students enter university.

The teaching and learning of functions has been studied through many different theories: Tall and Vinner (1981) introduced the distinction between concept image and concept definition, the concept image being generally different from the concept definition, especially for functions. Following Bachelard (1938), Sierpiska (1992) used the notion of epistemological obstacles regarding some properties of functions and especially the concept of limit. Another approach is based on the processes / object duality (Dubinsky 1991): the conceptualization begins with actions on previously constructed mental or physical objects. Then actions are interiorized to form processes which are then encapsulated to form objects. Sfard (1991) also claims that the abstract concepts can be conceived as two different forms: structurally, as objects, and operationally, as processes, the two views being complementary. Tall (1996) also adds the perspective of procept, an amalgam of two components: a process which produces a mathematical object and a symbol that represents at the same time the process and the object. With respect to functions, algebraic or graphical representations are procepts which can both be handled as processes and as objects. Finally, of relevance to these works are Tall's (2004) three worlds of mathematics: in this perspective growth of mathematical thinking occurs as a transition from a conceptual-embodied world to a proceptual-symbolic world and then to a formal-axiomatic world.

With regard to the teaching of functions, I claim that the transition between secondary school and university can be interpreted, in some sense, as a way to move from the conceptual-embodied world to the formal axiomatic one, through embedding a higher level of conceptualization of the notions related to the domain of analysis: indeed, the beginning of the teaching at the university level corresponds to a displacement from functional thinking to set-theoretical thinking, from utilizations of most functions as processes to utilizations as objects, with a higher degree of formalisation and a balancing in the utilization of procepts, especially the use of graphical representations moves from an object's role to a tool for supporting formalizations and proofs.

On the other hand, Balacheff and Gaudin (2002) find two types of concept image (they speak about conceptions) among pairs of students who finish secondary school: a "curve – algebraic" concept image for which functions are primarily special cases of plane curves, those having a specific algebraic form; and, an "algebraic – graphic" concept image for which a function is first an algebraic formula, the associated graph coming after. It seems that the concept image of average students is closer to the latter. They are unable to manipulate functions which are not given in algebraic forms. Moreover, these students cannot easily shift from the algebraic representation system to another. As Coppé *et al.* (2007) stress, that the current practice of teaching

in secondary schools (in France) seems to reinforce the idea that a function is only an object belonging to the algebraic frame.

THREE PERSPECTIVES ON THE OBJECT OF FUNCTION

In addition to the above works on students' concept images of functions, I consider the notion of perspectives (Rogalski, 2008). More precisely, I claim that different perspectives can be adopted on the object of function: a point-wise perspective, a global perspective and a local perspective. This distinction enriches the different levels of conceptualization introduced above.

Indeed, the balance from conceptual embodied world to the formal axiomatic one is accompanied by the development of local properties about functions: limit, continuity, differentiability, equivalent expressions, Taylor's local expansions near some points which are the basic notions of calculus. I claim that working at university level on functions implies that students can adopt a local perspective on functions whereas only point-wise and global perspectives are constructed at the secondary school. In this paper, I would like to explain some difficulties of novice students at university through associating them with their difficulties to adopt point-wise and global perspectives on functions. These difficulties appear when they are asked to solve tasks where techniques of the algebraic frame are not sufficient. Let me outline what I understand with this notion of perspective.

In the first perspective, functions are considered as correspondences between two sets of numbers, an element of the first set being associated with a unique element of the second set. This point-wise perspective is in accordance with the definition of functions given in textbooks at grade 9 in France, four years before the beginning of university. At this level, functions are represented by numerical formulas that operate as a program for calculation, such as calculus programming. A table of values is also a good representation of a function from this perspective, especially for pupils who are aware only of integers on the real line.

The second perspective is the global one, necessary to understand the notion of variation and to interpret properties such as parity or periodicity. As pointed out by Coppé *et al.* (2007), the table of variation is a good representation of a function from this global perspective. The graphical representation of a function can be manipulated from a point-wise perspective as well as a global perspective but the algebraic expression can represent a function from a global perspective only for experts. Indeed, for students, interpreting an algebraic formula as a function from a global perspective seems relatively natural only for classical functions x^2 , \sqrt{x} whose global properties are well known. For more complex algebraic formulas, the most natural perspective is the point-wise one. So, the use of graphical representations should allow easy connections between perspectives. However, a large algebraisation of tasks at the end of the secondary school tends to limit which perspective can be adopted on functions.

The third perspective is the local one. Even though the notions of limit, continuity and differentiability of functions are introduced in secondary school, the local perspective seems necessary only at university level. Again, problems of continuity or differentiability are introduced in an algebraic way and they consist mainly in calculating limits by algebraic rules. So, the algebraisation of tasks erases the point-wise and global perspective and moreover it doesn't allow reaching out to the local perspective.

Finally, I assume that reaching an object level understanding of function is not the only challenge of the secondary school. In fact, I assume that students must be able to articulate different perspectives on functions and especially have to adopt the global perspective on functions to overcome all the obstacles which come with local notions at the beginning of the university: structure of the real line, notion of equality between two real numbers, etc..

A TEST TO TRACK ABILITIES FOR ADOPTING PERSPECTIVES

In order to diagnose the difficulties that students have with adopting the point-wise and global perspectives on functions, I designed a task for which techniques of the algebraic frame were not sufficient. More precisely, this task was dealing with the function G below, defined by an integral:

$$G(x) = \frac{1}{2} \int_{x-1}^{x+1} f(t) dt.$$

In secondary school, as well as in the beginning of the university, integrals are defined as areas under curves of functions, and are approached as definite integrals. However, in the two institutions, the link between integrals of continuous and primitive functions is made quickly and students work mostly in the algebraic frame. For this link, the so called fundamental theorem of calculus is usually proven by the teacher, when the function to integrate is continuous, positive and strictly increasing.

I decided to investigate this function G because in the two institutions its study is very close to well known tasks and its level of difficulty is accessible for both secondary school students and students university. Indeed, even if they are not familiar with this kind of function G , students of both institutions had already met tasks concerning indefinite integrals over intervals of the form $[a, x]$ or $[a, \beta(x)]$ (β being a linear function) at the time of the experimentation. Moreover, questions about global and point-wise properties of G according to properties of f are more interesting in the context of this kind of integral (between $x-1$ and $x+1$), as we will see below.

The experimentation was dealing with one group of students from secondary school (15 students) and one group of students from university level (109 students from University Paris Diderot). The precise statements proposed to students were chosen

Working Group 14

by their teachers (from one side in a secondary school and on the other side in the university) with instructions for treating questions concerning global or/and point-wise properties of G .

The beginning of the test given by the teacher at the university level was the following one (a fifth question concerned a local property of limit):

Let f be a continuous function over \mathbf{R} and G the function defined over \mathbf{R} by

$$G(x) = \frac{1}{2} \int_{x-1}^{x+1} f(t) dt.$$

- 1) Show that if f is a constant function, G is also a constant function.
- 2) Show that if f is even (respectively odd), G is even (respectively odd).
- 3) Show that G is differentiable and compute G' .
- 4) Compute G when f is defined by $f(t)=|t|$.

f is assumed to be continuous. Students have to show global properties of G . They must also prove that G is differentiable and compute G' . Questions 1) and 3) can be treated only in the algebraic frame without any perspective on f and G . Problems with perspectives can appear with question 2) – if f even then also G is even – and for question 4) – find G when f is the absolute value. We will see this below with examples of student responses.

The test given by the teacher at the secondary school level was the following:

In the problem, \mathbf{D} means the set of differentiable functions on \mathbf{R} . For each f in \mathbf{D} , we define G such that for all x in \mathbf{R} ,

$$G(x) = \frac{1}{2} \int_{x-1}^{x+1} f(t) dt.$$

- 1a) Show that for each primitive F of f over \mathbf{R} , $G(x) = \frac{1}{2} [F(x+1) - F(x-1)]$.
- 1b) Compute G when f is defined by $f(t)=t^n$, n integer greater than 1. Show that if f is a polynomial function, then G is a polynomial function with the same degree.
- 1c) Compute G when f is defined by $f(t)=\cos(\pi t)$.
- 2a) Show that for all f in \mathbf{D} , G is also differentiable over \mathbf{R} , and that for all x in \mathbf{R} , $G'(x) = \frac{1}{2} [f(x+1) + f(x-1)]$.
- 2b) Show that the following properties are equivalent: (1) G is constant and (2) f is periodic with period 2.
- 3a) Suppose f is increasing over \mathbf{R} . Show that G is increasing and that for all x in \mathbf{R} , $f(x-1) \leq G(x) \leq f(x+1)$.
- 3b) Suppose f is defined by $f(t) = 4 \exp(t) / [t^2 + 4]$. Study the variations of f over \mathbf{R} . Deduce the variations of G over \mathbf{R} .

In this exercise, students can work inside the algebraic frame from questions 1) to question 2a) and also for question 3b). It means that the conception of functions as objects belonging to a functional frame (with all its complexity) seems irrelevant. The issues I want to study can appear with question 2b) – G is constant if and only if

f is 2 periodic - and 3a) – if f increases then G increases and for all x , $f(x-1) \leq G(x) \leq f(x+1)$. We will also see this below.

RESULTS AND EXAMPLES OF STUDENT RESPONSES

As I was interested in the transition between secondary school and university level, I chose to analyze only responses of secondary school students who were expected to enter university. Only five responses were analyzed. On the other hand, as I was interested only in qualitative results, the analysis of students' responses at university level was done in a separate round, in order to find the characteristics which have been identified in the five responses of the school students.

As expected, most of secondary school students' difficulties were about question 2b) and question 3a). Only one student succeeded in these two questions whereas, except for some minor errors and the second part of the question 1b) (which is more difficult), all of them succeeded in the other questions. I suppose that algebraic techniques are not sufficient to succeed in these tasks. There is a necessity to surpass the algebraic frame and to adopt global and point-wise perspectives on f and on G .

For instance, in question 2b), students have to establish global properties on f and G – f is 2 periodic and G is constant - through considering a point-wise property for f – for all x , $f(x-1) = f(x+1)$. Here is a typical response:

<p>2b.</p> <p>(1) f est une fonction constante équivalent à $f(x)=a$ (2) f est périodique de période 2 équivalent à $f(x)=f(x+2)$</p> <p>On part donc d'un membre par arriver à l'autre $f(x) = \frac{1}{2}(f(x+1) - f(x-1))$ et $f(x)=a$ donc $\frac{1}{2}(f(x+1) - f(x-1)) = a$ (1) $\Leftrightarrow f(x+1) - f(x-1) = 2a$ $\Leftrightarrow f(x+1) = f(x-1) + 2a$ $\Leftrightarrow f(x+1) + f(1) = f(x-1) + f(1) + 2a$ $\Leftrightarrow f(x+1) = f(x-1) + 2a - f(1) + f(1)$ donc (1) \Leftrightarrow (2).</p>	<p>(1) G is constant $\Leftrightarrow G'(x)=0$ (2) f is 2 periodic $\Leftrightarrow f(x)=f(x+2)$</p> <p>We start from one side to go to the other: $G'(x) = \frac{1}{2} [f(x+1)-f(x-1)]$ and $G'(x)=0$... $\Leftrightarrow f(x+1) = f(x-1)$ $\Leftrightarrow f(x+1) + f(1) = f(x-1) + f(1)$ $\Leftrightarrow f(x+2) = f(x)$ (2) so (1) \Leftrightarrow (2).</p>
---	--

Figure 1: example of response for question 2b) – secondary school student

This student explained his procedure as follows: « on part d'un membre pour arriver à l'autre membre » (« we start from one side to go to the other »). There is no quantification, useful to translate the global properties for f and G in the formal language. Moreover, equivalences are wrong. The student can not recognize the property of periodicity with the statement $f(x-1) = f(x+1)$. It is necessary for him to formulate $f(x) = f(x+2)$. Then, all algebraic techniques seem to be good: here he adds $+ f(1)$ to each side. I suppose that this student is unable to reach a global perspective on f and G . His reasoning seems to be in the algebraic frame only.

Working Group 14

On the first part of question 3a), students have to establish a global property on G – G is increasing – from a global property on f – f is increasing – through point-wise properties – for all x , $f(x-1) < f(x+1)$ and for all x , $G'(x) > 0$. But, in four of the five students' responses, these interpretations are again done formally without any quantification, in an algebraic way. Students seem unable to see the necessity of two variables x and y in order to write the property of growth. They use equivalences which are wrong. Again, I think that the reasoning is only at an algebraic level, not at all in the functional frame.

 <p>3a) On sait que f est croissante. On a donc $f(x+1) > f(x) > f(x-1)$ $\Leftrightarrow f(x+1) > f(x-1)$ $\Leftrightarrow f(x+1) - f(x-1) > 0$ $\Leftrightarrow \frac{1}{2} (f(x+1) - f(x-1)) > 0$ $\Leftrightarrow f'(x) > 0$ donc f est croissante</p>	 <p>3a) montrer que f est croissante si f est croissante f est dérivable sur \mathbb{R} (l.a) $x+1 > x-1$ $\Leftrightarrow f(x+1) > f(x-1)$ car f est croissante $\Leftrightarrow f(x+1) - f(x-1) > 0$ $\Leftrightarrow \frac{1}{2} (f(x+1) - f(x-1)) > 0$ $\Leftrightarrow f'(x) > 0$ donc $f'(x) > 0$ sur \mathbb{R}, donc f est croissante sur \mathbb{R}</p>
<p>3a) We know that f is increasing. So $f(x+1) > f(x) > f(x-1)$ $\Leftrightarrow f(x+1) > f(x-1)$ $\Leftrightarrow f(x+1) - f(x-1) > 0$ $\Leftrightarrow \frac{1}{2} [f(x+1) - f(x-1)] > 0$ $\Leftrightarrow G'(x) > 0$ So G is increasing.</p>	<p>3a) G is differentiable over \mathbf{R} (2a) $x+1 > x-1$ $\Leftrightarrow f(x+1) > f(x-1)$ because f is increasing $\Leftrightarrow f(x+1) - f(x-1) > 0$ $\Leftrightarrow \frac{1}{2} [f(x+1) - f(x-1)] > 0$ $\Leftrightarrow G'(x) > 0$ $G'(x) > 0$ over \mathbf{R}, so G is increasing over \mathbf{R}.</p>

Figure 3: examples of responses for question 3a) – secondary school students

The second part of the question 3a) – to prove $f(x-1) \leq G(x) \leq f(x+1)$ – is the most difficult task. No student really succeeded in this question. The difficulty seems to be linked to the necessity to adopt a point-wise perspective on G – the computation of $G(x)$ for a fixed x – together with a global perspective on f – for all t in $[x-1, x+1]$, $f(x-1) < f(t) < f(x+1)$.

This difficulty with perspective appears also in many responses of university students, concerning questions 2) and question 4) of the university test, as it was expected.

In question 4) (university test), there is a necessity to treat several cases according to the fact that 0 belongs or not to $[x-1, x+1]$, that is to say $x < -1$, x in $[-1, 1]$ or $x > 1$. Students must adopt a point-wise perspective on G – computation of $G(x)$ for x fixed – and a global perspective on f over $[x-1, x+1]$. However, many students treat the task at an algebraic level, thinking for instance that the absolute

Working Group 14

value can be integrated without adopting these perspectives. Figure 4 represents a typical example of this mode of reasoning in the algebraic frame:

 <p>4) Pour $f(t) = t$ On a $\int t = \left \frac{t^2}{2} \right \Rightarrow \int_{x-1}^{x+1} f(t) dt = \left \frac{(x+1)^2}{2} \right - \left \frac{(x-1)^2}{2} \right$ donc $G(x) = \frac{1}{2} \left(\left \frac{(x+1)^2}{2} \right - \left \frac{(x-1)^2}{2} \right \right)$</p>	<p>4) For $f(t) = t$</p> <p>We have $\int t = t^2 / 2 \Rightarrow$ $\int_{x-1}^{x+1} f(t) dt = (x+1)^2 / 2 - (x-1)^2 / 2$ So $G(x) = \frac{1}{2} [(x+1)^2 / 2 - (x-1)^2 / 2]$</p>
---	---

Figure 4: examples of response for question 4) – university student

In students' responses for question 2) (university test), the same kind of observations can be made. Most of students translate the global property – f even – without the quantification - $f(t) = f(-t)$. Again, the reasoning seems to be in the algebraic/formal frame in many responses as in figure 5:

 <p>2) Dans le cas où f est paire : $f(t) = f(-t)$ donc $\int_{x-1}^{x+1} f(t) dt = \int_{x-1}^{x+1} f(t) dt$ $\Leftrightarrow \frac{1}{2} \int_{x-1}^{x+1} f(t) dt = \frac{1}{2} \int_{x-1}^{x+1} f(-t) dt$ donc $G(x) = \frac{1}{2} (F(x+1) - F(x-1)) = \frac{1}{2} (F(-(x-1)) - F(-(x+1)))$ $= \frac{1}{2} (F(-x-1) - F(-x+1))$ $= G(-x)$ donc G est aussi paire</p>	 <p>2) Si f est paire alors $f(t) = f(-t)$ $G(-x) = \frac{1}{2} \int_{x-1}^{x+1} f(t) dt = \frac{1}{2} \int_{x-1}^{x+1} f(t) dt = G(x)$ $G(-x) =$ Si f est impaire alors $f(t) = -f(-t)$ $G(-x) = \frac{1}{2} \int_{x-1}^{x+1} f(t) dt = \frac{1}{2} \int_{x-1}^{x+1} -f(-t) dt = -\frac{1}{2} \int_{x-1}^{x+1} f(t) dt = -G(x)$ $G(-x) = -G(x)$</p>
<p>In the case f even: $f(t) = f(-t)$ so $\int_{x-1}^{x+1} f(t) dt = \int_{x-1}^{x+1} f(-t) dt$ $\Leftrightarrow \frac{1}{2} \int_{x-1}^{x+1} f(t) dt = \frac{1}{2} \int_{x-1}^{x+1} f(-t) dt$ so $G(x) = \frac{1}{2} [F(x+1) - F(x-1)] = \frac{1}{2} [F(-(x+1)) - F(-(x-1))]$ $= \frac{1}{2} [F(-x-1) - F(-x+1)] = G(-x)$ So G is also even.</p>	<p>If f even then $f(t) = f(-t)$ $G(-x) =$ If f odd then $f(-t) = -f(t)$ $G(-x) = \frac{1}{2} \int_{x-1}^{x+1} f(-t) dt$ $= \frac{1}{2} \int_{x-1}^{x+1} -f(t) dt = -\frac{1}{2} \int_{x-1}^{x+1} f(t) dt$ $G(-x) = -G(x)$</p>

Figure 5: examples of responses for question 2) – university students

Few responses (about 25%) show the ability for students to adopt a point-wise as well as a global perspective on the manipulated objects. Because of the brevity of this paper, it is impossible to report about them.

CONCLUSION

In this paper, I wanted to stress the importance of dealing with point-wise and global perspectives on functions for students entering university. I have claimed that this distinction enriches the process / object duality and the students' way of thinking in the passage from the conceptual embodied world to the formal axiomatic one. Through a typical task of the transition between secondary school and university – the study of the function G – I have pointed at the difficulties for students to solve tasks when algebraic techniques are not sufficient. On one hand, I think that these difficulties are linked to the students' inability to consider functions as complex objects with point-wise as well as global properties. On the other hand, I can think that these difficulties are increased by the current practice of teaching in secondary schools in France, which reinforces tasks belonging to the algebraic frame only (computations of limits, derivative, tracing graphs as objects, not as tool for reflections on tasks...) and which erases the perspective which can be adopted on these objects. In particular, tasks belonging to the graphical register are reduced while they could enrich students' perspectives on functions.

Moreover, I have claimed in this paper that these difficulties with point-wise and global perspectives on functions can be related with difficulties for students to enter on one hand in the formal axiomatic world and on the other hand to develop the local abilities which are necessary at the beginning of the university. I will continue to investigate these ideas in the future by designing a questionnaire for university students which will explore the students' perceptions of local and formal properties (the utilization of the formal definition of limit for instance). On the other hand, I will introduce tasks at the end of secondary school using new technologies to focus on the graphical register of functions, not only the algebraic one, to investigate local problems such as continuity and differentiability problems on functions.

DISCOURSES OF FUNCTIONS – UNIVERSITY MATHEMATICS TEACHING THROUGH A COMMUNICATIVE LENS

Olov Viirman

University of Gävle & Karlstad University, Sweden

This paper reports on an ongoing study focusing on the teaching of functions in undergraduate courses in mathematics at three Swedish universities. In this paper excerpts from the lectures of three teachers at one university are analysed, using commognitive theory. Characteristic features of the teachers' discourses about functions are presented. Definitions are found to be the central type of narrative, while theorems and proofs are largely absent, despite the fact that the teaching is of a traditional type, often connected to the "definition-theorem-proof" format. Three main categories of routines are found: substantiation, construction and motivation routines. It is also seen that the teachers are more concerned with questions of "why" to do things than "when" to do them.

INTRODUCTION

Students' conceptions of the function concept have been extensively studied (see e.g. Harel & Dubinsky, 1992; Schwarz & Hershkowitz, 1999; Vinner & Dreyfus, 1989). In an earlier study (Viirman, Attorps & Tossavainen, 2011) we looked at a small group of university mathematics students, investigating their concept images of the function concept, and making comparisons with the historical development of the concept. We worked within a theoretical framework building on the idea of concept image, as developed by Tall and Vinner (1981), and also on Sfard's (1991) theories of the process/object duality of mathematical concepts and of the three stages of concept formation. Out of this work grew a desire on my part to continue this research, but with a different focus, leading to the ongoing work of which a first report is given in the present paper. My main interest is now in the teaching, investigating how mathematics teachers at the university level work with the function concept, and what they do to promote the learning of this concept in their students. I believe that there is a need for studies of the actual practice of mathematics teaching at Swedish universities, hopefully gaining insight that might at a later stage be used to help improve university mathematics teaching.

THEORETICAL FRAMEWORK

Over the last decade or so Sfard has written extensively of acquisition and participation as basic metaphors underlying theories of learning (cf. Sfard, 1998). Through the acquisition metaphor learning is described in terms bringing to mind the accumulation of material goods, while through the participation metaphor learning is seen as the process of becoming a member of a certain community. The framework

used in our earlier study is very much based on the acquisition metaphor. The present work, however, takes a participationist view on learning.

In recent years, Sfard has developed a participationist theory of thinking (Sfard, 2008), drawing on ideas from Vygotsky and Wittgenstein. The foundational tenet of participationism is “that *patterned, collective forms of distinctly human forms of doing are developmentally prior to the activities of the individual.*” (Sfard 2008, p. 78, *emph. in original*) Based on this idea, Sfard defines thinking as “an individualized version of (interpersonal) communicating” (*ibid.*, p. 81), and coins the neologism *commognition* in order to encapsulate both inter- and intrapersonal communication. Different types of communication are called discourses, and these discourses are in constant development, growing and increasing in complexity. Within the commognitive framework, then, learning may be defined as individualizing discourse, becoming ever more capable at communicating within the discourse, with others as well as with oneself (Sfard 2006, p. 162). This is achieved through a process of adjusting one’s discursive activities to fit the leading discourse (or, more rarely, the other way around). The unit of commognitive analysis is the discursive activity, the “patterned, collective doings” (*ibid.*, p. 157). Hence, what I will be looking at in this study is the discourse of function, as it is manifested in the communicative practices of the teachers (and students). But what characterizes specific discourses? Sfard presents four characteristics which can be used to describe and distinguish different discourses (Sfard, 2008, p. 133ff):

word use - words specific to the discourse or common words used in discourse-specific ways

visual mediators - visual objects operated upon as a part of the discursive process. Examples from mathematical discourse could be diagrams and special symbols.

narratives - Sequences of utterances speaking of objects, relations between and/or processes upon objects, subject to endorsement or rejection within the discourse. Mathematical examples could be theorems, definitions and equations.

routines – Repetitive patterns characteristic of the discourse. Typical mathematical routines are for instance methods of proof, of performing calculations, and so on.

A more thorough presentation of the commognitive theory of mathematical discourse is beyond the scope of this paper, but a few words about routines and rules of discourse are needed. The discursive patterns are the result of processes governed by rules. Sfard distinguishes between object-level and meta-discursive rules of discourse. The former regard the properties of the objects of the discourse, while the latter govern the actions of the discursants. A routine, then, is a set of meta-rules describing a repetitive discursive action (*ibid.*, p. 208). This set can be divided into the *how* and the *when* of the routine, determining in the first case the course of action and in the second case the situations in which action would be deemed appropriate.

So, given this, the question this study aims to answer is: What characterizes the discourses about functions presented by the teachers, primarily regarding narratives and routines?

PREVIOUS RESEARCH

The teaching of mathematics in higher education, while not as well-researched as the function concept, has seen an increase in research activity over the last decade. An early example of research focusing on mathematics teaching at university outside of a teacher education context is the work of Burton (2004), studying professional mathematicians as learners, and possible implications for university mathematics teaching. More recently, the actual practice of mathematics teaching at the university level has earned growing research interest, in particular with the work of Jaworski and Nardi (e.g. Nardi, 2008; Nardi, Jaworski & Hegedus 2005), investigating university mathematicians' views about the teaching of mathematics. There are also a number of other studies, including some (e.g. Weber, 2004; Wood, Joyce, Petocz & Rodd 2007) focusing on so-called traditional mathematics instruction. In Sweden, research on the teaching of mathematics at university is rare, but one example is Bergsten (2007), discussing ways of investigating the quality of mathematics lectures, building on a case study of one calculus lecture on limits of functions.

Since Sfard's commognitive theory is relatively recent, and still under development, not that many studies have been reported using this framework, and those that do exist tend to focus on the mathematical learning of younger children (e.g. Sfard 2001, 2007; Sfard & Lavie 2005) or on elementary mathematics, like arithmetic (Ben-Yehuda, Lavy, Linchevski & Sfard, 2005). However, very little has been published on university mathematics learning from a commognitive standpoint. The one example that I'm aware of is the work of Ryve (2006), which makes use of, but also critiques, an early version of Sfard's theory, as presented in for instance Sfard (2001), in order to investigate student interaction in problem-solving. As far as I know, there is yet no published research using commognitive theory to investigate university mathematics *teaching*.

METHOD

The empirical data in my study consists mainly of videotaped lectures and lessons given by teachers in freshman year mathematics courses at three Swedish universities, chosen for diversity – one old, large university, one more recently established, and one smaller, regional university. The teachers were then selected among those giving freshman courses on relevant topics during the time available for data collection. In two cases, this, together with the obvious fact that the teachers had to agree to participate in the study, effectively made the choice for me. At the large university, where the number of possible participants was greater, I again aimed for diversity, both in topics covered and in teaching experience. One thing all teachers in

the study have in common, however, is an active interest in teaching. In the present paper, I have chosen to focus on three 45-minute excerpts from lectures given at the same university, one of the larger in Sweden. The collection and transcription of data is ongoing, and the excerpts chosen were simply the most extensive transcriptions available at the time of writing. The first excerpt is from an introductory course, mainly preparatory for calculus. The teacher (referred to as teacher A below) is a woman in her fifties, who got her doctoral degree in the 1980's, and has taught at the university for about 20 years. The second is from a course in algebra, and the teacher (B) is a male graduate student in his twenties, giving his first course as a lecturer, having earlier only served as a teaching assistant. Finally, the third is from a course in linear algebra, given by a male teacher (C) in his thirties, having recently gotten his first position following some years of post-doctoral work. The students in all three courses were first semester engineering and computer science students. The excerpts were transcribed verbatim, speech as well as the writing on the board. The transcribed lectures were then analysed, using the four characteristics of discourses described above to try to distinguish the discursive patterns characterizing the teachers' respective discourses of functions. I first analysed each lecture separately, and then looked at all three together, searching for differences and similarities. Since the unit of commognitive analysis is the discursive activity, I have intentionally chosen an outsider perspective, trying to view the unfolding discourse in as unbiased a way as possible. At the same time, I am of course aware of, and also making use of, the fact that my mathematical knowledge makes me an insider to the discourse. However, I have specifically tried to avoid making references to what is *not* present in the discourse, except in contrasting different teachers' discursive activities.

RESULTS

My focus in this paper will be on the narratives and routines characterizing the discourses of the teachers. Observations regarding words and visual mediators used will be referred to whenever they are relevant to the analysis.

A central type of narrative in all three discourses is the *definition*, which can be formal or informal in character, with informal definitions often relying heavily on metaphor. In this respect certain differences between the discourses can be seen. Teacher A consistently introduces new concepts in informal terms, and then presents a formal definition, as in the following example (all excerpts have been translated from Swedish by the author):

Teacher A maybe it's the whole of B, but maybe it's just a small part of B that actually comes out, that the machine spits out. Then we speak of the domain of f .

Teacher A (...) and that you could write like this if you want: f of a , the set of all f of a when you let a vary over all [writes: $\{f(a) : a \in A\}$]

Teacher B, however, generally starts by stating a formal definition, and then giving an informal interpretation.

Working Group 14

Teacher B but if C is a whole subset of A , then we define f of C as simply the set of all values of the function starting in C , the set of all f of x , where x lies in C . And this leads us to our last definition [writes: $f(A)$ is called the domain of f] f of A – f of the whole set A – is called the domain of f

Teacher B so the domain is all the elements in B that the function gets to

In fact, in the case of the definition of 'function', he gives no informal interpretation at all. But there is also one case (definition of injectivity) where he introduces the concept informally before giving the formal definition. Teacher C, finally, uses a third approach. He presents the definitions formally in writing, while simultaneously explaining them verbally in an informal fashion, like this:

Teacher C [writes: Definition: $R^m \xrightarrow{F} R^n$] a function from R^m to R^n is called a linear map if it is linear, that is if it satisfies two conditions

Teacher C [writes: if 1) $F(v+w)$] the first one is that it respects addition in the following way: if you have two vectors v and w , and you add them, and then you apply a function F , and get vectors in R^n then that is the same thing as if you take each of the vectors, toss them into R^n and add them there.

Teacher C [writes: $=F(v) + F(w)$]

Hence, for teachers A and C, the informal definitions provide endorsement for the formal ones. As for teacher B, he often endorses his definitions through reference to a lack or need. Before giving his formal definition of function, he says that “what we haven't learned is how we connect two sets in the sense that to each element in one set we associate an element in the other set”. Interestingly enough, his definition doesn't mention the “one-valuedness” property central to the modern concept of function (to each element in the domain there is exactly one element in the range). Instead he introduces this later, endorsing it partly through another reference to need – without it we wouldn't be able to work with functions at all – and partly by referring to the metaphorical description of the function as a machine.

As for other central narratives of scholarly mathematical discourse, *theorems* and *proofs*, these are much more rare in the discourses of the three teachers. Only teacher C actually states and proves a theorem. Instead the narratives through which the discourses are developed are mainly examples illustrating specific properties. For teacher A, these examples are almost invariably given primarily by formulas. The one exception, a fairly convoluted function, used to illustrate the fact that the rule in the definition of function doesn't require an actual method of computation, is explicitly referred to as a “silly example”. The examples given by teachers B and C are more varied, including geometrically constructed functions (rotations and projections), and functions given by tables of values.

Regarding the routines, the differences in discursive practices are more pronounced. One common category of routines is what we could call *substantiation* routines,

Working Group 14

aiming at verification or rejection of statements. These often concern the use of definitions. For instance, all three teachers present routines for checking whether a specific example satisfies a given definition. An example, from Teacher B:

Teacher B This function is injective

Teacher B Such a statement, bold as it is, you show by assuming that the values of the function are equal, and from that showing that this implies that x_1 and x_2 are equal

He then goes on using formal algebraic manipulation to show that the last statement follows from the first. On the other hand, in a passage, which unfortunately is too long to be quoted here, teacher C uses graphical representations of plane vectors to show that rotation in the plane by an angle $\pi/2$ satisfies the two conditions in the definition of a linear map. Having done one vector addition, he then appeals to the geometric intuition of the students:

Teacher C yes, I have just taken that picture and moved it here through rigid rotation, so that parallelogram addition up here has to function just like that one

Teacher C So that rotation satisfies that condition

Both are examples of substantiation routines, but the means of substantiation are different.

Other substantiation routines are those using definitions to exclude non-examples:

Teacher A if we return to this crazy example which wasn't a function, the circle

Teacher A It wasn't a function because even if we insert something between -1 and 1, we would perhaps want that it was a function with A being -1 to 1, the interval, but then when we insert something which isn't 1 and not -1 [she clearly marks the origin in an already drawn picture of the unit circle in the x - y -plane] then we get two y -values that fit, it is different

Teacher A So that the function doesn't give us exactly one, it gives us more than one

Teacher A And then it isn't a function

Here, the teacher uses a graphic argument, directly showing why the circle cannot be the graph of a function. Examples of this kind of routine can be found elsewhere in her lecture, as well as in that of teacher B. They are however not found in the discourse of teacher C.

A second category of routines commonly found in the discourses of the three teachers, but taking very different forms, are *construction* routines, concerned with the construction of discursive objects or narratives. In the discourse of teacher A we can find repeated use of routines for constructing the graph of a function given an algebraic formula, and for finding the value of a function at a point given the graph. These constructions are all very sketchily outlined, however, and it is clearly stated ("we have already talked about this when we did quadratic curves") that this is

Working Group 14

something which they have been doing for some time. Also there are several instances of routines for determining the range or the largest possible domain of a function given a formula. A typical example:

Teacher A it doesn't say on the board what V_f is. You have to look, what function is it, and then you have to try to figure out what values can come out here then

Teacher A and in this case, there's a square here, plus 2, squares can be 0 or larger

Teacher A and it can be any number larger than 0 this square, so it can be 2 plus something positive, so it can be any number larger than or equal to 2. So V_f in this example is the interval starting at 2 and continuing upwards

As we can see, this is something done by looking at the formula, not by for instance looking at the graph, which had been drawn just 20 minutes earlier (although it had now been erased). Routines for determining domain and range are also present in the discourse of teacher B, and handled in pretty much the same way.

The construction routines in the discourse of teacher C are mainly concerned with constructing maps from matrices, and vice versa. This is a central topic of the lecture, being the subject of the theorem which gets stated and proven. In fact, the proof is basically an instance of such a routine. There are variants using vector algebra and geometric reasoning, but both follow this basic pattern:

Teacher C it is easy to solve that type of problem

Teacher C if you know the images of the basis vectors under a certain linear map then you put them as columns, and that is the standard matrix of the map

A general trait of the discourse of teacher C is his frequent use of geometric reasoning. The other two teachers are much more reliant on algebraic methods.

A third, less common category of routines, which however is very much present in the discourse of teacher B, could be called *motivation* routines, dealing with presenting motives for developing new mathematics. The discursive pattern can be described in the following way: OK, so now we know this, but here is something else that we don't know. What would we need in order to find this out, or be able to do this? We would need this. OK, let's define it. We have already seen one example, in the motivation given for introducing the concept of function, and here is another:

Teacher B now that we know what a function is, then maybe one wants to illustrate it in a better way than just writing like this, like in this way you don't see, ok you know what the function does, but you don't really get any idea of what it looks like

This is followed by a description of the “function machine”, and by the definition of the graph of a function. This type of motivational pattern is not found in the discourses of the other two teachers.

DISCUSSION

First I want to comment on the invisibility of the students in what has been presented here. This is partly due to the fact that the excerpts are from lectures, where students tend to be less active. However, there is a certain amount of teacher-student interaction in the excerpts, some of it very interesting, but an analysis of this is beyond the scope of this paper. Here I will instead give some reflections on what I see as the character of the teachers' discourses.

All three teachers give traditional lectures, speaking and writing at the board. However, the traditional “definition-theorem-proof” (DTP) format (Weber, 2004) is not so apparent, theorems and proofs being largely absent. There are at least two possible reasons for this. Firstly, in all three lectures, the function concept is introduced for the first time in the course, leading to a greater prevalence of definitions and examples, with theorems possibly following later. Secondly, all three courses are first-semester courses, and as such situated somewhere between elementary and advanced courses, perhaps making the DTP format less applicable.

While sharing the overall lecture format, the teachers differ in the discourses they present. These differences are obviously to a great extent predicated by differences in course content. In the discourse of teacher A, teaching to prepare for calculus, the formula is very much the preferred realization of function. This is seen in the way she introduces examples and also in her choice of words. She almost consistently speaks of curves rather than graphs, indicating that what she has in mind is continuous functions. When she does give an example of a function not given by a formula she describes it as “silly”. Teacher B, teaching algebra, uses the language and methods of formal logic in a way neither of the other teachers do. He also presents a much more general idea of what a function might be. I have already mentioned the prevalence of geometric reasoning in the discourse of teacher C (linear algebra). But there are some surprises as well. In Nardi (2008, p. 167), the mathematician (actually a composite portrait of a number of mathematicians interviewed by Nardi) claims that the graph as a realization of function is essential in analysis but meaningless in algebra. Still, teacher B devotes quite some time to the concept of graph, discussing it at a high level of detail. A possible explanation for this could be laying groundwork for the use of functions in other courses. If so, this aim is not made explicit, something which is typical of all three lectures. Connections between different branches of mathematics are seldom made, despite the fact that functions are central to so much of mathematics. This lack is also noted in Nardi (2008, p. 167). I would also like to comment on the process/object duality (Sfard, 1991) of the function concept in the context of the discourses of the three teachers. All three primarily talk of functions in process terms. However, at the same time, they obviously view them as objects:

Teacher A it is a function; it is the function x^2 which I move one step to the right and two steps up

Working Group 14

Teacher C we speak of the domain of the function, where the function starts (...) and of the target set, where the function is going

It would be interesting to know what effect, if any, this might have on students' learning.

Sfard (2008) speaks of the “how” and “when” of routines. The “when” is seen as more problematic, due to the fact that “Presenting the *when* of routines, that is, constructing exhaustive lists of conditions under which given patterns tend to appear in a discourse of a given group or person, is more complicated, if not altogether unworkable.” (ibid, p. 209) For analytical purposes the questions of “how” and “when” are natural, since they are what can be observed. But in the actual discursive practices of the teachers, the question of “when” to use a certain discursive pattern is mostly addressed by discussing “why” it should be used. Perhaps a reason for this is that explaining why something is done can give more comprehensive criteria of when it should be done, avoiding the problem of presenting conditions of use.

SECONDARY-TERTIARY TRANSITION AND EVOLUTIONS OF DIDACTIC CONTRACT:

THE EXAMPLE OF DUALITY IN LINEAR ALGEBRA

Martine De Vleeschouwer, Unité de didactique des math., Université de Namur

Ghislaine Gueudet, CREAD, IUFM de Bretagne UBO

This contribution concerns the teaching and learning of duality in linear algebra. Combining an institutional, and a didactic contract perspective we argue that some of the novice students' difficulties can result from specific features of the university contract, at different levels. Analyzing university textbooks, we identify such features, in the case of duality. Drawing on these observations, we design an experimental teaching, aiming to support the students' entrance in the new contract, at different levels. We investigate the impact of this experimental teaching. Analyzing students' productions, we observe that they developed abilities specific to the university contract, concerning duality or more generally mathematics.

Keywords: Secondary-tertiary transition, Linear Algebra, Didactic contract, Institutions

Duality in linear algebra is recognized as an arduous topic for novice students. The general aim of our work is to understand the difficulties they meet in duality, and to propose a teaching of duality likely to overcome these difficulties. Duality can be considered as a content specific of university mathematics, far away from secondary school. It led us to situate our study within the wider issue of secondary-tertiary transition. In previous work (De Vleeschouwer 2010a), we studied the students' difficulties, and proposed categories of difficulties, using an institutional focus. The work we present here corresponds to two new directions of research. On a theoretical level, we propose to consider the change of didactic contract between secondary school and university, and to combine it with the institutional perspective. In our empirical work, we have designed and implemented an experimental teaching intervention, aiming to support the students' entrance in the new didactic contract. We investigate here its impact on the students' outputs.

In part 1, we outline our theoretical propositions, articulating the didactical contract and the institutional perspective. In part 2, we specify our analysis to the context of linear algebra, and especially to duality in linear algebra. We present in part 3 the experimental teaching; we analyse its impact, drawing on students answers to a questionnaire, in part 4.

DIDACTIC CONTRACT, INSTITUTIONS AND THE SECONDARY-TERTIARY TRANSITION

The notion of didactic contract was introduced by Brousseau (1997), to describe 'a system of rules, mostly implicit, associating the students and the teacher, for a given

piece of knowledge” (Brousseau 1997). Another interpretation of the contract, which is especially relevant in our study, is formulated in terms of sharing responsibility towards knowledge, between the students and the teacher. It seems thereof straightforward to claim, like Artigue (2007), that when a student enters university “the didactic contract is no longer the same”. Several authors retain this perspective to study novice students’ difficulties (Bloch 2005, Grønbaek, Misfeldt & Winsløw 2009). Nevertheless, the contract features identified are often very general: the students must show more autonomy, they must be able to develop reasonings involving several frames (Douady 1987) etc. These features seem to characterize general institutional expectations and not a particular mathematical content.

Considering the work of Chevallard (2005) can enlighten this last issue. According to him, a subject encounters a given mathematical knowledge in an institution. The institution frames this knowledge as a mathematical organisation, or praxeology, entailing four components: a type of tasks, a technique to accomplish this type of tasks; a technology, which is a discourse justifying the technique, and a theory. Mathematical organisations exist at several levels, from specific to general.

Considering the didactic contract with this perspective leads to distinguish several levels of contract, in a given institution:

- a general contract, independent of the knowledge at stake (Sarrazy, 2005, terms it the pedagogic contract). For example, at university in some countries attending the courses is not compulsory; taking notes is under the students’ responsibility etc.;
- a didactic contract for mathematics, concerning generally mathematics in the institution: for example, the requirement of rigorous proofs;
- a didactic contract for a given content, concerning particular mathematical notions.

With these distinctions, the main question studied in this article can be formulated as: is it possible to support the students’ entrance in a new contract at different levels, and how? We address this issue in the context of duality in linear algebra. Firstly, we identify features of the didactic contract at university, corresponding to different levels, for the teaching of duality.

INSTITUTIONAL DIDACTIC CONTRACT AND DUALITY IN LINEAR ALGEBRA

We do not consider here the general contract; we start with the level of the didactic contract for mathematics. Considering several research works about transition (Praslon 2000, Bloch 2005, Bosch *et al.* 2004, Winsløw 2008) we retain that the following difficulties of the students correspond to changes of the didactic contract for mathematics, between secondary school and university:

- difficulties with building examples;

Working Group 14

- difficulties with working in different frames, with moving between different representations ;
- difficulties with working at the technology-theory level, which means in particular producing a discourse justifying a technique.

According to the authors mentioned above, at university the student is (at least sometimes) responsible for these issues, which were only under the responsibility of the teacher at secondary school.

On a more precise level, about linear algebra and duality, we infer rules of contract by analysing textbooks (De Vleeschouwer 2010*b*).

A central change is that several concepts, in linear algebra, can change status, according to the context. For example, a matrix can be considered as representing a linear function in given bases; it can also be considered as an element of a vector space. A function can be seen as process acting on given objects; it can also be an element of a vector space. This last example is crucial in duality, where the students will have to determine the dual of a given vector space: a set of linear forms. In Belgium where our study takes place, students also encounter matrices and functions at secondary school. But these matrices and functions are not considered as elements of sets. At university, the student must be able to switch between both statuses, which are moreover not explicitly presented.

In 2008-2009 we elaborated and tested a teaching of duality taking into account these features of the contract, both at the discipline level for mathematics and at the content level for duality.

SUPPORTING THE ENTRANCE IN A NEW CONTRACT: AN EXPERIMENT AT NAMUR UNIVERSITY

We present below the main choices made with regard to the experimental teaching. Its focus is on duality, but also develops some prerequisites (as a minimum repertoire of vector spaces). We first want to situate its context, both in terms of the students involved and of teaching organisation.

The University of Namur has set up a device called “springboard operation”, aiming to support novice students, entering university (De Vleeschouwer 2008). It consists in remedial sessions proposed to the students, lasting between 2 and 4 hours each week. The first author of this paper participated as a teacher in the springboard operation, for first year students seeking a Master's degree in mathematics at the university of Namur (26 students in this first year in 2008-2009). She implemented the experimental teaching mainly in the context of this springboard operation (the variety of vector spaces was developed in a group work). This choice is the result of institutional constraints: setting up an experimental teaching in the “normal” course would have been refused by the mathematicians responsible for this teaching. Usually, only some of the students attend the springboard sessions. For the

Working Group 14

experimental teaching, all the students were invited to participate; 20 of them finally followed the sessions. Our analysis concerns these 20 students.

Before the teaching of the duality, students had already seen, in the theoretical course and in the exercises concerning algebra, the vector spaces (algebraic structures, linear dependence and dimension, sub-vector spaces); the linear functions and the associated matrices.

The experimental teaching within the springboard operation starts before the teaching of duality with a mandatory group work, aiming to provide the students with a minimum repertoire of vector spaces. Duality itself was tackled one month after the start of the academic year, in October 2008, and the corresponding teaching lasted five weeks:

- during week 1, students received a theoretical course (1.5h) concerning linear forms and dual space. Then they participated in an activity, which purpose is to make students aware of the various statuses that a matrix may have in linear algebra: element of a group, a ring, a vector space or representing a linear function;
- during week 2, we proposed to the students an activity, “linear forms and dual”, described below (1h). Moreover, a theoretical course was given (1.5h), concerning the bidual space, the reflexivity theorem and the transpose transformation;
- during week 3, illustrations of dual and bidual spaces are presented (1h);
- finally during weeks 4 and 5 students had sessions of exercises (2x2h) on duality.

We focus in this paper on the “linear forms and dual” activity. We now present this activity and the corresponding choices, described in detail in (De Vleeschouwer 2010b).

As mentioned above (§2) a function, and thus a linear form, can change status, according to the context. In the context of duality in linear algebra, different statuses of linear forms can appear in the same task.

A linear form φ_i belonging to a dual basis X' of a basis X of a vector space E combines indeed two statuses:

- the status of process, operating on the elements of a vector space E . This status appears in the relationship linking basis $X = \{x_1, \dots, x_n\}$ of vector space E to its dual basis $X' = \{\varphi_1, \dots, \varphi_n\} : \forall i, j = 1, \dots, n : \varphi_i(x_j) = \delta_{ij}$, where δ_{ij} is Kronecker's delta;
- the status of element of a vector space: the dual space of E (denoted E'), as an element of a basis of E' .

This combination of statuses can be considered as an aspect of the institutional didactic contract, at the level of a specific content. “A linear form is a process, and an element of a vector space, and students should be able to switch between these two statuses” is a rule of this contract. It is certainly linked with the process/object dialectics (Dubinsky 1991), but we do not retain here a cognitive focus: we consider

how the institution shapes the content. This rule remains implicit; and this change of status yields difficulties of the students. In the experimental teaching we organized, we have chosen to make this rule explicit to students.

We introduced for this purpose a specific vocabulary, presented to the students during the teaching in the springboard sessions. This vocabulary is thus not an analysis tool for our research; it can be seen as a meta-language proposed to students. From the researcher's point of view, it is directly connected with the levels introduced by Chevillard (2005); we can not develop the point here, details can be found in De Vleeschouwer (2010b).

We say that a linear form φ is considered at a *micro level* when it is seen as a process operating on the elements of a vector space E (on a field K). We explain to the students that this choice of vocabulary is a metaphor, indicating that φ is considered in detail, which permits to observe the transformation it operates on the vectors of E . At this *micro level*, we can consider its kernel, range, rank amongst others.

When a linear form is considered as an element of a vector space, we call it the *macro level*. In this case this linear form can be considered amongst other linear forms on the same space E , constituting thus a set. In this set, one can define addition and product laws; with these laws one obtains a vector space, the dual of E .

On both levels, the same object φ is considered, but under different statuses. We **explicitly** presented to the students these levels using the vocabulary "micro" and "macro" during teaching, and connected them by saying that the macro level is obtained by a zoom out, the micro level by a zoom in (see De Vleeschouwer 2010b for the figures associated with this metaphor).

In order to evaluate the precise impact of this experimental teaching, we proposed, four months after the experimental teaching, a questionnaire to the students who attended it, and analysed their answers. We present this work in the next section. More than their success or failure, we try to identify in the students' answers indices of their entrance, or non-entrance, in the new contract.

IMPACT OF THE EXPERIMENTAL TEACHING

We present here an extract of the questionnaire, and analyse the corresponding students' answers in terms of didactic contract.

34 Let \mathcal{P}^3 be the vector space of polynomials of degree less than or equal to 3, with real coefficients. Let, for $i=1, \dots, 4$, $p_i: \mathbb{R} \rightarrow \mathbb{R}$ such as $\forall x \in \mathbb{R}$:
 $p_1(x) = x^3 + 2x^2 + 4$, $p_2(x) = 2x^3 - x + 2$, $p_3(x) = x^3 - 1$, $p_4(x) = 2x^3 + 3$.

Prove that $A = p_1, p_2, p_3, p_4$ is a basis of \mathcal{P}^3 , and determine its dual basis.

35 Let f_1, f_2, f_3 such as:

$$\begin{array}{ll}
 f_1: \mathbb{R}^5 \rightarrow \mathbb{R} & f_2: \mathbb{R}^5 \rightarrow \mathbb{R} \\
 v = (a, b, c, d, e) & f_1(v) = 3a - 2e \quad v = (a, b, c, d, e) \quad f_2(v) = a - b + 2c \\
 \\
 f_3: \mathbb{R}^5 \rightarrow \mathbb{R} & \\
 v = (a, b, c, d, e) & f_3(v) = 3b + 6c - 2e
 \end{array}$$

- 1 Give an example of vector space comprising f_1, f_2, f_3 .
- 2 Does f_1, f_2, f_3 form a linearly independent set of vectors?
- 3 Give an example of linear form which does not belong to $\text{Span}\{f_1, f_2, f_3\}$.

36 Choose a vector space different from polynomials, \mathbb{R}^n or \mathbb{R}^n ($\forall n \in \mathbb{N}$), and give an example of linear form over this space.

Table 1 : Extract of the questionnaire proposed to the students

The methodology we employ here is based on the *a priori* analysis (Hejny *et al.* 1999) of the questionnaire. We identify, in the questionnaire, specific aspects of the university contract, and observe in the students' answers if these issues raised difficulties, or if they evidence on the opposite an entrance in this contract.

The first question is related with polynomials and refers explicitly to duality, since the students have to determine the dual basis of a given basis. The students must consider jointly the micro and the macro level of linear forms, which is typical of the new contract at the level of the 'linear forms' content. The second question concerns functions. The proposed functions f_1, f_2, f_3 are defined at a micro level. They are linear forms; nevertheless, this term is not used in the text in order to avoid that the students answer 'the dual space' to question 2.a). For their answers to question 2. b), the students must consider these functions as vectors, which means changing levels, to work at the macro level. They have to place their reasoning at a level different from the level of the text.

Question 3 requires that the students work in a frame different from the polynomials (question 1) or the algebraic frame (common in the courses). The change of frames is also typical of the university didactic contract at the discipline level. In the second part of question 3, a linear form must be proposed at a micro level, as a process acting on the elements of the chosen set.

Moreover, questions 2.a), 2.c) and 3 require to build an example. Such a task is typical of the university contract, at the discipline level; the same statement holds for the variety of frames, another feature of the questionnaire.

We now consider the students' answers, focusing on the issues identified in the *a priori* analysis.

Two main techniques have emerged from students' responses to determine if the polynomials in question 1 constitute a basis: working with polynomials or with n -tuples. Eight students (40%) prefer to work with 4-tuples instead of polynomials, but only two of them justify their reasoning (for instance a student cites the theorem asserting the existence of an isomorphism between \mathcal{P}^3 and \mathcal{R}^4). We can consider that in doing so, these students comply with the didactical contract at the discipline's level which considers that the different steps of a mathematical reasoning should be justified. All students who responded to the questionnaire were able to determine that the given polynomials were linearly independent. It does not seem to be a problem for them to work in a non-usual frame, as often required at University.

70% of the students present the linear forms of the dual basis in a complete, detailed form (departure space, arrival space and image of any vector, see Figure 1). We interpret these kinds of answers as typical from the university contract, at two levels. At the discipline level, a mathematical answer has to be as complete as possible. At the content level, a function must be characterized by these three elements, whereas at secondary school generally only the expression " $f(x)=\dots$ " or the graph is given.

Twelve students (60%) describe analytically the four linear forms p_i' and, at the same time, consider them as elements of a set (the dual base): they write explicitly " $A' = \{p_1', p_2', p_3', p_4'\}$ " (see Figure 1). In doing so, students consider the linear forms both at the macro level and at the micro level.

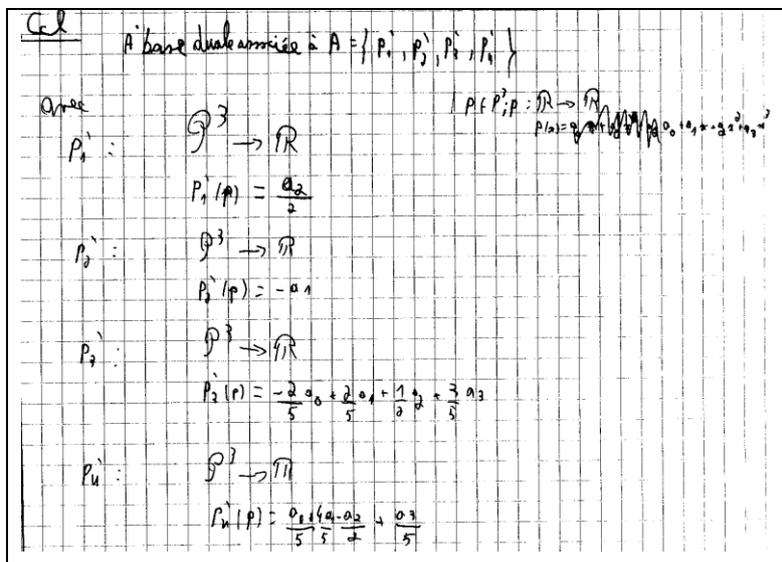

Figure 14: Conclusion of a student's answer to the second part of question 1

Concerning question 2.a) fifteen students (75%) succeed in giving a vector space comprising the given linear forms, and nine of them (45%) cite the dual space. It requires to consider at the macro level functions which have been described in the text as processes (micro level). This change of status does not seem to constitute a difficulty for a majority of students. The same statement holds for the sub-question 2.b): while the linear forms were given at the micro level, seventeen (85%) students

Working Group 14

succeed to consider them at the macro level, and answer correctly that they are linearly independent. Moreover six students convert the linear forms into 4-tuples before starting calculations (see Figure 2). We can interpret this fact as the conversion of a function from the micro level to the macro level. In Figure 2, we see that the student concludes question 2.b) by writing "the *vectors* are linearly indep." instead of "the *linear forms* are linearly indep."

Exercice 2:

(a) f_1, f_2, f_3 appartiennent à \mathbb{R}^5 par exemple car
ils sont des formes linéaires.

(b) $f_1(x) = 3x - 2e$
 $f_2(x) = a - b + 2c$
 $f_3(x) = 3b + 6c - 2e.$

$\alpha(3, 0, 0, 0, -2) + \beta(1, -1, 2, 0, 0) + \gamma(0, 3, 6, 0, -2) = (0, 0, 0, 0, 0)$

$\Rightarrow \begin{cases} 3\alpha + \beta = 0 \\ -\beta + 3\gamma = 0 \\ 2\beta + 6\gamma = 0 \\ 0\alpha + 0\beta + 0\gamma = 0 \\ -2\alpha - 2\gamma = 0 \end{cases} \Rightarrow \begin{cases} 3\alpha + \beta = 0 \\ \beta = 3\gamma \\ 6\gamma + 6\gamma = 0 \\ -2\alpha - 2\gamma = 0 \\ \alpha + 0\beta + 0\gamma = 0 \end{cases} \begin{cases} \beta = 0 \\ \beta = 0 \\ \gamma = 0 \\ \alpha = 0 \end{cases}$

\Rightarrow les vecteurs sont linéairement indep.

(c) $f_4(x)$?

$f_4: \mathbb{R}^5 \rightarrow \mathbb{R}$
 $\alpha(a, b, c, d, e) \rightsquigarrow a + b + c + d + e = f_4(x).$

Figure 2 : Example of a student's answer to question 2

Analyzing students' answers to question 3 shows that they seem to have built a variety of vector spaces: amongst the vector spaces cited by the students, eleven are vector spaces of matrices (square matrices of size 2 or 3); two are vector spaces of functions (transformations of \mathbb{R} or of \mathbb{R}^2), one can be considered as algebraic (\mathbb{R}^3 built over \mathbb{R}). The unsuccessful attempts concern \mathbb{R}^2 or \mathbb{R}^3 (cited by three students) or \mathbb{R} (cited by two students); one student makes a non-relevant answer. Note that the module structure, which generalizes the vector space structure, was not presented to students. This perhaps explains the presence of proposals involving \mathbb{R}^2 or \mathbb{R}^3 in the responses of three of them. The variety of frames for linear algebra is typical of the new institutional contract at the discipline level. Moreover eight students *justify* the label 'linear form' given to their example although seven of them give only a partial explanation: "*arrival space is the field*". It seems that the part of justification in the didactic contract at the discipline level is not obvious.

CONCLUSION

In this work we attempted to determine rules of the didactic contract at university, in the case of duality. Using previous research works, and a textbooks analysis, we identified contract rules at different levels: some of these rules correspond to precise notions, like linear forms, while others concern more generally mathematics.

We designed a teaching intervention aiming to support the entrance of students in this new contract. The objective of such a teaching is not to change the contract, by reducing the students' responsibility. In the case we presented, we chose to make explicit a usually implicit rule, at the level of a specific content (linear forms), introducing a meta-language (*micro/macro*) for students' use. We have also proposed to the students exercises where they were required to change frames, to build examples, and more generally to comply with new university expectations, at the level of the discipline. We do not claim that all the rules should be made explicit. Some of the contract rules have to remain implicit, this well-known paradox is an essential condition for learning (Brousseau 1997). Introducing the micro-macro meta-language, we did not only unveil a rule about linear forms; we contributed to raise the awareness of the students about the different statuses of mathematical objects at university, and the possible need for change of status, according to the context. The meta-language makes this new responsibility explicit.

The analysis of the students' answers to our questionnaire evidence that they at least started to enter in the new contract. We did not carry out a comparison with other students (the conditions of our study did not offer such a possibility); but the first author of the paper, as a teacher, noticed that the students do not seem to meet the usual difficulties, and we consider that the experimental teaching significantly contributed to this progress. We now intend to extend our study to other topics: the precise rules of the didactic contract at university remain largely unknown.

A DIDACTIC SURVEY OF THE MAIN CHARACTERISTICS OF LAGRANGE'S THEOREM IN MATHEMATICS AND IN ECONOMICS

Sebastian Xhonneux, Valérie Henry

University of Namur, Belgium

Abstract: Because of its many uses, the constrained optimization problem is presented in most undergraduate mathematics courses dealing with calculus for both mathematicians and economists. Our research focuses on the teaching of Lagrange's Theorem in both branches of study, mathematics and economics. This paper addresses two objectives. First, we describe the methodology of our research project concerning the didactic transposition of Lagrange's Theorem in university courses. Secondly, we compare two mathematics courses dealing with calculus given at the universities of Namur and Louvain by means of the Anthropological Theory of Didactics.

Keywords: Lagrange's Theorem, optimization, didactic transposition, Anthropological Theory of Didactics

INTRODUCTION

Constrained optimization plays a central role in optimization theory but also in economics. In fact, constrained optimization can be seen as one of the fundamental techniques that economists use to solve economic problems. Lagrange's Theorem and the derived method of Lagrange multipliers [named after Joseph-Louis Lagrange (1736-1813)] provide an appealing strategy for finding the maxima and minima of a function subject to equality constraints; so we are interested in studying the teaching of this theorem in both branches of study, mathematics and economics.

Based on the author's own teaching experiences at the University of Namur (Belgium), it is apparent that a considerable number of first year students struggle with calculus courses and, in particular, with Lagrange's Theorem. Furthermore, the mathematical exercises in these classes involve students using a large number of standardized procedures for obtaining answers to clearly delimited types of exercise questions. Dreyfus mentions in this context that

they end up with a considerable amount of mathematical knowledge but without the working methodology of the mathematician, that is they lack the know-how that

allows them to use their knowledge in a flexible manner to solve problems of a type

unknown to them. (Dreyfus, 1991, p.28)

Hence, we question in our research project whether the choice of the didactic transposition of Lagrange's Theorem may influence the students' perception and understanding. Therefore, we question whether our findings help to enlighten mathematics professors concerned with increasing students' comprehension of this theorem. In fact, we also would like to show how teachers' practices are influenced inside the didactic transposition by a combination of didactic reasons and mathematical reasons.

Next, we describe the theoretical framework used to guide our research. In order to investigate the constraints under which a professor should operate when conceiving and carrying out the teaching of Lagrange's Theorem, we analyzed existing didactic transpositions by means of the “Anthropological Theory of Didactics” (ATD) of Chevallard (1992, 1999). This model describes mathematical activity in terms of *mathematical (or didactic) organisations* or *praxeologies*. The third section provides a description of our methodology, which used ideas from the ATD, a useful tool for the analysis of mathematical and teaching activities. In the fourth section, we briefly describe the *epistemological reference model* (ERM), which constitutes our basic theoretical model used to describe the didactic transposition. Related, mathematical praxeologies are then used to describe and compare the knowledge to be taught around the Lagrange's multiplier rule as it is proposed at the universities of Namur and of Louvain. Finally, we provide conclusions and a brief survey of perspectives of our research work.

THE ANTHROPOLOGICAL APPROACH

As we utilize an institutional perspective⁷⁶ in our research, the choice of the “Anthropological Theory of Didactics” (ATD) proposed by Chevallard (1992, 1999) appears pertinent to investigate characteristics of teachers' practices. This model of mathematical knowledge envisions mathematics as a human activity involving the study of types of problems. Below, we provide a brief summary of the principal content of this theory based on a paper written by Barbé, Bosch, Espinoza and Gascón (2005).

In the anthropological approach, an object exists from the moment one person or an institution individually recognizes this object as existing, and more precisely, if someone relates to it. These relationships can be established through activities making use of the object. We identify two inseparable aspects of mathematical activity. First, the *pratico-technical block* (or know-how) is formed by types of problems or problematic tasks, T , and by the techniques, \square , used to resolve them. Studying problems of a given type (with an aim of solving them) is considered to be “doing mathematics”. Furthermore, in the anthropological approach,

⁷⁶ Institutional perspective means that we observe practices relative to a (mathematical) object, these practices are expected to differ from one institution to another.

procedural methods, resolutions of problems or accomplishments of tasks suppose the existence of a technique. This holds true even if the given technique can scarcely be explained or shown to others or even to ourselves.

Secondly, we assume in the anthropological approach that one can rarely find human practices without a copious environment of discourse. The objective of this “spoken surrounding” is to describe, explain and justify what is done. Therefore, there is the knowledge block of mathematical activity that offers the mathematical discourse necessary to justify and interpret the practical block. The knowledge block is divided into two parts: the technology, \square , refers to the technique used and the theory, \square , establishes profound justifications of the technology. In ATD, this second block is called the technological-theoretical block.

Types of problems, techniques, technologies and theories can be seen as the fundamental elements of the anthropological model of mathematical activity. We also employ them to describe mathematical knowledge, which can be considered both a means and a product of this activity. When we examine various types of problems, techniques, technologies and theories together, we entitle them mathematical praxeological organisations or, in short, mathematical organisations or mathematical praxeologies. An examination of the etymology of the word “praxeology” shows how practice (praxis) and the discourse about practice (logos) are closely connected.

ATD posits that we can analyse more than only mathematical activities. Any form of human activity can be interpreted in terms of praxeological organisation. Therefore, we also introduce the concept of didactic praxeologies when speaking about the process of study of mathematical constructions.

Given the increasing interest and demand to investigate teachers' practices and their role in the didactic relationship, an investigation on these didactic praxeologies appears warranted.

In order to achieve the aforementioned objectives, our research was guided by the following research questions amongst others:

- 37 What are the essential characteristics of the teaching of Lagrange's Theorem in mathematics and economics?
- 38 Are there similarities and differences between the teaching of Lagrange's Theorem in mathematics and in economics with respect to the mathematical praxeologies?
- 39 May it be possible to improve students' understanding/interpretation of Lagrange's Theorem by exchanging ideas between the two disciplines?

FOUR KINDS OF KNOWLEDGE

Teaching and learning are not isolated, but take place in the complex process of *didactic transposition* (Chevallard, 1991). With regard to this transposition, we need to distinguish among four kinds of knowledge: “scholarly” mathematical knowledge, mathematical knowledge “to be taught” and mathematical knowledge “as it is actually taught” by professors to students. When including students' comprehension and learning into the process, we have to add the fourth kind of knowledge – mathematical knowledge “learnt”, which is generally difficult to access. A basic theoretical model, the *epistemological reference model* (ERM) (Bosch & Gascón, 2005), is used to analyse at the same time the scholarly knowledge, the knowledge to be taught, and the knowledge actually taught and learned.

We used the following procedural methodology in order to investigate our research questions and related questions:

“Scholarly” mathematical knowledge

To understand “scholarly” mathematical knowledge, our first step consisted of an epistemological analysis of Lagrange's Theorem and of associated mathematical literature in mathematics and economics.

The mathematical knowledge “to be taught”

To gain deeper insight in the mathematical knowledge to be taught, we analyzed textbooks and course notes about Lagrange's Theorem from different mathematics courses, both for mathematics and economics students, using the ATD. In doing so, we exercised caution because only the “knowledge to be taught” can be reproduced from these textbook elements. The “knowledge actually taught” unfortunately appears only in the students' notes and in the specific teaching practices carried out in the day-to-day teaching praxeologies in classrooms.

Mathematical knowledge “taught” and “learnt”

Next, we explored teachers' and students' conceptions about Lagrange's Theorem. We contacted professors who are (or were) responsible for teaching Lagrange's Theorem in either an economics or a mathematics course (or both) dealing with calculus, or more particularly with optimization. This was done at Belgian universities in the French-speaking part of the country. By means of a questionnaire composed of 27 multiple-choice and open-ended questions, we attempted to identify, as precisely as possible, the environment and conditions of the teaching of Lagrange's Theorem. A second questionnaire built upon the first one was then designed in order to obtain information about students' conceptions and ideas. This questionnaire was composed of 14 multiple-choice and open-ended questions. Course observations and students' presentations and evaluations at exams (involving three different tasks to solve) completed our data collection process.

Note that our research is still in progress. “Scholarly” mathematical knowledge and mathematical knowledge “to be taught” are already analysed, mathematical knowledges “taught” and “learnt” are the topics we are currently concerned with.

EPISTEMOLOGICAL REFERENCE MODEL OF LAGRANGE'S THEOREM

One hypothesis to be developed, explored and possibly amended in our doctoral research study is a reference mathematical model for Lagrange's Theorem that includes five mathematical organisations MO_1 , MO_2 , MO_3 , MO_4 and MO_5 . These mathematical organisations respectively address the following types of tasks:

- T_1 : Find candidates for optimal solutions for a constrained optimization problem subject to equality constraints.
- T_2 : Solve a constrained optimization problem subject to equality constraints.
- T_3 : Develop the theory concerning Lagrange's Theorem.
- T_4 : Use an interpretation of Lagrange's multiplier.
- T_5 : Develop the theory concerning Lagrange's multipliers.

Many relationships among these mathematical organisations can be described but we limit ourselves in this paper to the following brief remarks: MO_1 originates from the original works of Lagrange, whereas MO_2 is concerned with the solving of particular constrained optimization problems. In fact, Lagrange's Theorem may or may not intervene in the technique of MO_2 . Accomplishing T_1 can therefore be one step in the process of accomplishing T_2 . MO_3 can be regarded as part of the theory of MO_1 (and also MO_2), but it is also the self-contained praxeology that deals with the proving of Lagrange's Theorem, among other tasks. MO_4 uses Lagrange's multipliers as a mathematical tool (Douady, 1986), whereas MO_5 constitutes an additional mathematical organisation concerned with Lagrange's multiplier being seen as a mathematical object in the sense of Douady (1986).

COMPARISON BETWEEN TWO TEXTBOOKS

To describe emerging mathematical and didactic praxeologies we are going to analyse existing textbooks with regard to our ERM. However, due to space limitations of this paper, the presented analysis only considers two mathematics textbooks, one from each discipline – economics and mathematics. Nevertheless, we will be able to show how the anthropological approach renders a comparison possible.

The components of Lagrange's Theorem we are considering are integrated in the course “Mathematics for Economic Analysis I” (Thiry, 2006) for first-year students in economics and business management at the University of Namur and in the course

“Mathematical Analysis II” (Ponce & Van Schaftingen, 2010) for first-year students in mathematics at the University of Louvain (Belgium).

Mathematics for Economic Analysis I (Thiry, 2006)

Twelve pages in the textbook deal with Lagrange's Theorem (in Chapter 4, “Multivariable Optimization”). We analysed these pages in terms of praxeologies. Looking at this knowledge to be taught, we can name it “Analytic solving of equality constrained optimization problems”. In fact, the textbook starts with one well-known economics-based optimization problem: the utility maximization problem⁷⁷ the consumer faces, and tries to solve it:

- first, by the substitution method,
- then, by noticing that substitution is not always possible. Therefore, the use of the method of Lagrange multipliers is announced.

After this short introduction, the textbook mathematically defines the problem it is going to solve. The textbook poses the following type of problems:

T_I : Find all the candidates for optimal solutions to the following constrained optimization problems

$$(P_1) \begin{cases} \max & f(x, y) \\ \text{SC} & g(x, y) = k, \end{cases} \quad \text{and} \quad (P_2) \begin{cases} \min & f(x, y) \\ \text{SC} & g(x, y) = k. \end{cases}$$

- T_{II} : Solve (P_1) (or (P_2) respectively).
- T_{III} : Approximately determine the maximum of (P_1) (or the minimum of (P_2)) when k is increased (or decreased) by \square .

The section about Lagrange's Theorem is followed by exercises where we can find one additional type of problem: exercises that are mainly like T_{II} but require *mathematical modelling*. We do not consider these problems in the paper due to space limitations.

Let us start with T_I . Before obtaining an appropriated technique to solve this type of problem, we switch to the technological-theoretical block and read the technology \square_1 used to justify the appropriated resolution process. In terms of a geometric interpretation and by the use of the Implicit Function Theorem, we get a characterization of the solution: a solution (x^*, y^*) of the equality constrained optimization problem has to verify

- $g(x^*, y^*) = k$ and
- there exists $\square \square \mathbb{R}$ such that $\square f(x^*, y^*) = \square \square g(x^*, y^*)$.

This necessary optimality condition is then formally stated in the third section, “Lagrange's Theorem”.

⁷⁷ This problem can be resumed by "How should I spend my money in order to maximize my utility?"

[...] the observation of the contour lines shows us that a point (x^*, y^*) , extremum of f under the constraint $g(x, y) = k$ necessarily verifies the aforementioned equations. We now formulate these conclusions in the form of a theorem (that will not be proved here). (Thiry, 2006, p. 164)

The author does not give a rigorous proof, which is why we say that the theory closest to the given statement and which justifies the technology presented before is nearly absent from the notes. The section continues by defining Lagrange's function, and reformulates the theorem by means of this function. The whole section can be considered as technology justifying the technique for “finding candidates for optimal solutions”. Section 4 finally establishes the algorithmic technique \square_I to follow to find candidates as stated in T_I . The type of tasks T_I , the technique \square_I and the technology \square_I constitute a first praxeology $[T_I, \square_I, \square_I, /]$ where “/” symbolizes the absent or implicit theory.

Finding all the candidates does not solve the problems of type T_{II} , even if a solution to T_I is necessary to solve T_{II} . We therefore need a second step in the resolution process, which is presented in the textbook in Section 5. No technological-theoretical block is presented for this second step in the resolution process, but only a proposition is provided that details the technique \square_{II} used to identify whether a candidate is effectively an optimum for the equality constrained optimization problem.

The following proposition (that will not be proved) furnishes a test based on second-order derivatives to decide whether a stationary point is effectively a maximum or a minimum. (Thiry, 2006, p. 169)

This technique is illustrated by means of an example. We say that we obtain the following praxeology $[T_{II}, \square_I \square_{II}, \square_I \square_{II}, /]$. Again, the “/” denotes that these praxeological elements are not rendered explicitly.

Then, as it is the case for T_I , the technology \square_{III} concerned with the solving of type of tasks T_{III} is presented before the technique \square_{III} and it is summarised in the proposition 4.12 (Thiry, 2006, p. 171). The associated technique then is exposed in the proposition 4.13 (Thiry, 2006, p. 172) and is completed with one exercise. We get a third praxeology $[T_{III}, \square_{III}, \square_{III}, /]$ where the slash indicates again that the theory is practically absent in the textbook.

Combining the three aforementioned praxeologies, we find that the considered knowledge to be taught is principally composed of the traces left by MO_1 , MO_2 and MO_4 . In fact, the first type of tasks is a particular case of tasks of MO_1 . Furthermore, with regard to our ERM, the first praxeology constitutes a particular reconstruction of MO_1 . The theories \square_I and \square_{II} not having appeared explicitly, we say that the scope of tasks emerging from MO_3 is not at all covered by the textbook. The second praxeology arises from MO_2 and covers a task that can't be solved only by the technique of Lagrange's multiplier rule. Hence, students have to seek techniques

from “external arguments” that are out of range of Lagrange's Theorem. We make the assumption that students, who give up on the resolution of a constrained optimization problem subject to equality constraints after having applied the multiplier rule, do not distinguish between the solving of tasks T_I and T_{II} . This may be caused by the presentation of Lagrange's Theorem as the main technique to solve equality constrained optimization problems without insisting that this theorem only describes necessary, not sufficient, optimality conditions. The third praxeology then clearly comes from MO_4 as regarded in an economical context. Finally, only a few remarks and definitions in the text can be considered as traces left by MO_3 and MO_5 .

Mathematical Analysis II (Ponce & Van Schaftingen, 2010)

Chapter 5 in this textbook covers optimization problems. The first section deals with unconstrained optimization problems, whereas the second deals with equality constraints and the third deals with inequality constraints. A last section offers multiple exercises. We are interested in the six pages treating optimization problems with equality constraints (Section 5.2). We call this knowledge to be taught “Analytic solving of equality constrained optimization problems by penalty method”.

Before looking at that particular section, let us mention that each chapter of this textbook starts with a list of questions students are going to be confronted with at the final exams. The final section of each chapter provides more exercises. For the constrained optimization problem and Lagrange's Theorem in particular, we find two relevant types of problems:

T_{IV} : Give a geometric interpretation of Lagrange's multipliers.

T_V : Given function $f: \mathbb{R}^2 \rightarrow \mathbb{R} : (x, y) \mapsto f(x, y)$ determine the minima and maxima of f constrained to $g(x, y) = 0$.

Most of problems of type T_V in the textbook treat geometric problems and use therefore technology from geometry (e.g., distances, planes, surfaces). Furthermore, the type of problems T_V resembles T_{II} , affirming that mathematics and economics students are confronted with the same type of problems.

The section about equality constrained optimization problems opens directly with a theoretical discourse and gives the mathematical formulation of Lagrange's Theorem (Proposition 5.4, Ponce & Van Schaftingen (2010), p. 162-164). Its proof needs lemma 5.5 and both propositions are rigorously proved by a so-called *penalty method*⁷⁸. One remark is then given which concerns the values the multipliers can take⁷⁹. No further explanations are provided and the section ends with two example

⁷⁸ This method consists of neglecting the constraints while adding a penalty term to the function to be optimized if the constraints are violated. A consequence of this method is the avoidance of the Implicit Function Theorem.

⁷⁹ See p. 164, Ponce & Van Schaftingen (2010).

tasks and their resolution \square_{VI} and \square_{VII} . We add these problems to the list of types of problems and therefore define:

T_{VI} : Minimize the function $f: \mathbb{R}^n \rightarrow \mathbb{R} : x \mapsto f(x)$ under the equality constraint $g(x) = 0$, where $g: \mathbb{R}^n \rightarrow \mathbb{R} : x \mapsto g(x)$.

T_{VII} : Prove the “inequality of arithmetic and geometric means”.

In summary, we conclude that, for the types of problems T_{IV} and T_V , only the most relevant theory \square is stated and proven even if, from a mathematical point of view, technique \square_{VI} could be used to solve T_V . The formulation of Lagrange's Theorem is then used as technology (without giving further argumentation) to solve T_{VI} and T_{VII} . However, neither the complete prático-technical block nor the complete technological-theoretical block is explicitly presented in the textbook to solve the introductory tasks. We obtain the following praxeology $[T_{IV} \square T_V, /, /, \square]$. As far as the two problems solved as examples are concerned, the associated technique is furnished, so that we get $[T_{VI}, \square_{VI}, \square, \square]$ and $[T_{VII}, \square_{VII}, \square, \square]$ where \square is the formulation of Lagrange's Theorem. The technology \square is a minimal discourse in the sense of furnishing only the theorem that justifies the technique. We presume that the understanding of Lagrange's Theorem may be hindered if no supplementary information is given (for example, during lectures), and that students will encounter problems in solving tasks of types T_{IV} and T_V . However, this analysis only concerns the textbook and the mathematical knowledge “to be taught” and does not represent the mathematical knowledge “actually taught”.

With regard to our ERM, the textbook does a nearly complete presentation of task of MO_3 “Proof Lagrange’s Theorem” (with one possible proof amongst others). As this trace of the mathematical organisation is presented before solving particular tasks arising from MO_2 , we see that the technological discourse concerned with these tasks of MO_2 is replaced by adding MO_3 to the theoretical discourse. Furthermore, the students have to reason the associated technique to solve tasks of type T_V by themselves. We do not find traces of MO_1 regarded as self-contained praxeology in the textbook. Finally, as far as MO_4 is concerned, the type of tasks T_{IV} arises from this mathematical organisation. However, MO_5 is completely absent.

Comparison

In order to compare the knowledge to be taught as it is presented in textbooks provided to students, we have to take into account that they target different audiences. We therefore obtain a first discrepancy between the teaching of Lagrange's Theorem in mathematics and economics. Students in economics are confronted with a detailed prático-technical bloc of MO_1 and often obtain profound technological arguments to justify the technique of Lagrange's multiplier before completely solving the equality constrained optimization problem. Traces of MO_1 and MO_2 can be found. Conversely, mathematics students are directly confronted with the more “general” task of finding solutions and tasks of MO_1 , which are

incorporated in the solving process of tasks of MO_2 . Students in mathematics directly have access to a praxeology of type MO_3 . This affirms that proving is one of the dominant activities in mathematical studies. The technological discourse of MO_2 is then reduced to the formulation of the theorem in question, and students are left to find the associated technique by themselves (or by assisting at the theoretical course or in exercise sessions).

CONCLUDING REMARKS

Data collected from our experiences still need to be analysed in more detail in order to answer our research questions. The methodology presented will be pursued to obtain more insight into the didactic transposition of Lagrange's Theorem. This paper highlighted some discrepancies between the mathematical knowledge to be taught in mathematics and in economics due to the fact that, first and foremost, the role of mathematics in each discipline is different. Even if this is not a surprising result, it demonstrates the descriptive power of ATD as a tool for our ongoing analyses. In fact, the second objective of the paper was to show how ATD can render an analysis of the complex process of didactic transposition possible. It provides a classification of the didactic material presented in the textbooks and, with regard to our epistemological reference model, makes a comparison between these textbooks possible. As already mentioned, we need to be cognizant that textbooks do not represent the mathematical knowledge “as it is actually taught”. We therefore have to refine our epistemological reference model and to carry out further analyses concentrating on the latter to get deeper access in teachers' practices and students' perceptions. Furthermore, in order to investigate the mathematical knowledges “taught” and “learnt” we aim at deploying a second theoretical framework with a cognitive perspective that ATD alone has not.

The intended outcome of this research project does not include a didactic engineering in the sense of Artigue (1989), but we expect to understand better the essential qualities of Lagrange's Theorem and how teachers can improve their practices.

A QUESTIONNAIRE FOR SURVEYING MATHEMATICS SELF-EFFICACY EXPECTATIONS OF PROSPECTIVE¹ TEACHERS

Marc Zimmermann¹, Christine Bescherer¹, and Christian Spannagel²

¹University of Education Ludwigsburg, ²University of Education Heidelberg

Knowing of the traditionally high drop out rates in mathematics courses students often expect to fail. This results in a low motivation for learning mathematics and a low mathematics self-efficacy expectation. However, self-efficacy beliefs of a person have been identified as an important factor for performing tasks successfully therefore high self-efficacy beliefs are especially important for students who are training to be mathematics teachers. In order to determine the mathematics self-efficacy expectations of students of math education and to measure the influence of pedagogical interventions on self-efficacy, an adequate instrument is needed. This paper describes the development and validation of a scale for measuring the mathematics self-efficacy expectations of prospective teachers (MaSE-T).

Keywords: self-efficacy, secondary trainee teachers, pedagogical intervention.

INTRODUCTION

Negative attitudes and expectations towards mathematics are mostly founded in low performances at school or bad experiences in math classrooms. These negative beliefs lead to an expectation of not being able to handle mathematics in general. As a consequence, for many 'non-mathematicians', e.g. students of medical, biological or economic study courses, mathematics is incomprehensible or inaccessible. Some are even scared when they see mathematical formulas or they have to solve a mathematical problem, even if they use mathematics subconsciously in everyday life. These low self-efficacy expectations in mathematics can lead to bad results in exams, which will again decrease the student's self-efficacy in mathematics. As a result the students will drop out of the study course.

The belief in one's own mathematical competence (skills and knowledge) is an important factor to perform a given task or problem successfully (Bandura, 1977). Increasing mathematics self-efficacy will get 'non-mathematicians' to dare more mathematics in everyday life as well as in the mathematics courses of their program of study. In general, it can influence their behavior and attitudes when they are faced with mathematical tasks. For these reasons a learning scenario which increases the mathematical self-efficacy besides the content knowledge should be more valuable than a course which 'only' increasing the knowledge. This means that the success of mathematical learning scenarios, e.g. at school or at university, should not only be measured by testing knowledge. Pre- and post-testing the mathematics self-efficacy expectations during a course in mathematics will provide information whether the learners' mathematics self-efficacy expectations have increased. Besides, the

development of self-efficacy beliefs of students in a learning scenario can provide an opportunity for assessing the success of learning scenarios.

Especially for students of mathematics education it is important to possess adequate self-efficacy beliefs in mathematics. On the one hand, even as a teacher, they have to be able to understand mathematical publications on low levels. On the other hand, teachers should set an example for students concerning their mathematical beliefs and serve as models. Teachers with low self-efficacy expectations will hardly motivate students to do mathematics and to believe in their own competence. This is one of the reasons why we focus on the higher mathematical education of prospective teachers in our research.

Measuring the mathematics self-efficacy expectations of students who want to become teachers, demands an adequate instrument for measuring the right level. Existing instruments in German language are either on middle school level or focus on engineering students and do not meet the requirements of German mathematics teacher education. Thus, a new instrument has been developed and validated. In this article we first give a review of the theoretical basics of (mathematics) self-efficacy. After that we describe the development of an instrument for measuring the mathematics self-efficacy of prospective teachers. Finally we validate our 15-item mathematics self-efficacy questionnaire (MaSE-T) in an adult student population. Additionally the relationships between MaSE-T and gender, preparation for primary or secondary schools, as well as the level of specialization in mathematics (major, 'middle', or minor) are investigated. The paper ends with concluding remarks and an outlook on future research.

SELF-EFFICACY AND MATHEMATICS SELF-EFFICACY

Self-efficacy can be defined as the judgement of one's capabilities to successfully perform a particular given task (Bandura, 1977; Bandura 1997; Zimmerman, 2000). These expectations and beliefs influence whether somebody starts working on a task and the intensity of the performance (Pajares & Kranzler, 1995). As a consequence people with low mathematical self-efficacy will avoid mathematical tasks or situations or will give up solving very fast.

Self-efficacy beliefs are a main factor in someone's decision making process, e.g. the choice of academic courses or career decisions (Hackett & Betz, 1981; May & Glynn, 2008). Especially low self-efficacy beliefs lead to 'negative' decisions in the related domain. Consequently, successful learning scenarios – at school or at university – should increase learners' self-efficacy expectations as well as their skills and knowledge. A main source of self-efficacy expectations is one's own successful performance. If a student completes a task autonomously with more or less feedback or gets high marks in exams, s/he develops positive expectations to handle new and unknown situations or problems. However, the effect could be weaker due to the

non-existing own performance if learners only 'consume' information about how to solve the task (Bandura, 1977).

In general, self-efficacy expectations 'are task and domain specific' (Pajares & Miller, 1995, p.190). For that, measurements of self-efficacy expectations should be always fitted to the related domain or task. For example, questionnaires have been proposed to measure self-efficacy expectations in the field of computer usage (Compeau & Higgins, 1995; Cassidy & Eachus, 2002; Barbeite & Weis, 2004) or mathematics in general (Betz & Hackett, 1983; Pajares & Miller, 1995; May & Glynn, 2008). Mathematics self-efficacy expectations indicate the belief of a person in his/her own competence to solve mathematical problems and tasks successfully. Mathematics self-efficacy is positively related to math performance (Pajares & Miller, 1994; Kabiri & Kiamanesh, 2004; Liu & Koirala, 2009). This means that the higher a person rates on mathematics self-efficacy scales, the better this person can perform on solving mathematical problems and vice versa. There are also gender differences in mathematics self-efficacy expectations. Males are usually scoring higher in mathematics self-efficacy questionnaires than females (Betz & Hackett, 1983; Randhawa & Gupta, 2000). It can be assumed that gender effects are based on social and cultural roles and the masculine image of mathematics.

The survey proposed by Betz and Hackett (1983) and the revised version by Kranzler and Pajares (1997) have widely been used in research. These surveys mainly consist of three kinds of items: math problems, math tasks used in everyday life, and performance in college courses. However, these surveys have several drawbacks: (1) some items are formulated on a level too low for students studying mathematics at German universities, for example: 'Fred's bill for some household supplies was \$13.64. If he paid for the items with a \$20 bill, how much change should he receive?' It is important that questionnaires for measuring mathematics self-efficacy expectations require an adequate level of mathematical content knowledge. (2) Math problems and real-world math tasks are not clearly separated. For example, the item mentioned before is included in the 'math problem' scale, but could also belong to the scale with real-world math tasks because it is a everyday situation. (3) It would be interesting to see whether there is a difference between the expectation to solve a mathematical problem without context and a corresponding task which is contextualized in a real-world setting. In the existing surveys, there is no link between mathematical problems and real-world tasks. Therefore we decided to construct an own questionnaire described in the next section.

THE MATHEMATICS SELF-EFFICACY SCALE FOR SURVEYING PROSPECTIVE TEACHERS (MASE-T)

The first version of the questionnaire consisted of 25 items: mathematical problems without contexts (10 items), real-world mathematical problems (10), and reasoning problems (5). In contrast to the scales by Betz and Hackett (1983) and Pajares and

Working Group 14

Miller (1997), each mathematical problem was related to a real-world mathematical problem. In table 1 there are some example items for math-problems (Xa) of the questionnaire with their corresponding real-world math problem (Xb). In addition, a third scale has been included with 5 reasoning problems, for example ‘I am confident in proving that the square root of 2 cannot be represented as fraction’. All items were arranged randomly and had to be rated on a 5-point Likert scale ranging from 1 (‘I am not at all confident.’) to 5 (‘I am totally confident.’).

item	
1a	‘I am confident in determining the approximation formula of a somewhat cuboidal geometric body's diagonal.’
1b	‘I am confident in estimating whether a 2.5 meter long board can be transported in a van.’
2a	‘I am confident to solve the systems of equations with $x + y = 7$ and $x \cdot y = 30$.’
2b	‘I am confident in calculating the length and width of a rectangle, if the perimeter counts 72 cm and the area is 288 cm ² large.’
3a	‘I am confident in calculating the side length of a perpendicular triangle by using a trigonometric function.’
3b	‘I am confident in calculating the covered difference of height by knowing the incline of the street.’

Table 1. Example items of the questionnaire.

EMPIRICAL STUDIES

In a first study, the 25-item questionnaire has been tested and analyzed aiming to reduce the number of items. In a second study, a reduced questionnaire (15 items) has been tested for reliability and validity.

Study 1: 25-item mathematic self-efficacy scale

Sample

831 first year university students of mathematics education at the German universities of education in Ludwigsburg (526 students), Schwäbisch Gmünd (126), and Weingarten (179) participated in the study. The sample consisted of 215 males and 615 females (one missing) with a mean semester count of 1.33 ($SD=0.86$; range 1-8). The overrepresentation of female students is normal in study courses of teacher education at universities in Germany.

Procedure

All students were asked to complete the questionnaire anonymously during a mathematics lecture at the beginning of the winter semester in 2008/2009. The participation was voluntarily and without any reward.

Results

Internal reliability over all items was very good (Cronbach's alpha = 0.89). This value indicates a high degree of internal consistency of the items. Despite having a three-dimension scale (mathematical problems, real-world mathematical problems, and reasoning problems), each item contributes to the measurement of a single construct (mathematics self-efficacy expectations).

Factor and item analyses conducted on the collected data lead to a four factor model (PCA method, 50.7% of total variance). All items loaded on the first factor, which suggests that all items are related to mathematics self-efficacy. Hence, the remaining three factors can be considered to be related to the three mathematical dimensions. As a result, based on reliability coefficients and factor loadings, the 25-item scale was reduced to a 15-items scale². Therefore now each of the three dimensions consists of 5 items. As a consequence, some of the former corresponding mathematical problem items and real-world problem items have been removed. Thus, for a few items the corresponding items are missing.

Study 2: 15-item mathematics self-efficacy scale

The second study aimed at testing the psychometric properties of the reduced 15-item scale. In addition, the validity of the questionnaire had been tested by correlating the mathematics self-efficacy score with the grades of the 'Abitur', the final high school exam.

Sample

The total sample (N) of the main study consisted of 1318 participants (320 males, 995 females). Participants were again first year students (*mean* semesters 1.43, $SD=0.97$; range 1 to 9) of students of mathematics educations at the universities of Education in Ludwigsburg (493 students), Schwäbisch Gmünd (166), Weingarten (174), Heidelberg (165), and Karlsruhe (320).

Additionally, the sample can be divided into different groups with regard to two dimensions. On one hand it can be separated into four groups of students by their study course specialization. Therefore the first group were students who will be future teachers for primary school ($n=640$; 90 males, 550 females). Further groups are future teachers for secondary general school ($n=189$; 58, 181), for intermediate secondary school ($n=362$; 145, 217), and future teachers of schools for special needs children ($n=120$, 26, 94). It can be assumed that students for secondary schools perform best on the MaSE-T scale. On the other hand the sample can be divided by the students' level of specialization in mathematics for study. In Baden-Württemberg, Germany, students of education can choose whether they take

mathematics or not ($n=237$; 37, 200). If mathematics is chosen as a subject it can be studied as major ($n=401$; 88, 313), ‘middle’ ($n=396$; 116, 280) or minor ($n=275$; 78, 197) subject.

Procedure

Students from the participating universities were again asked to complete the questionnaire anonymously and voluntarily during 20 minutes of their mathematics lecture at the beginning of the winter semester in 2009/2010.

Results

After the reduction of items the internal reliability, measured by Cronbach’s Alpha, was nearly the same as in the first study ($\alpha=0.84$, $n=1273$) and indicates a high internal consistency. The alpha values of the three dimensions of the scale are still acceptable (see Table 2).

The validity of the questionnaire was tested by relating the MaSE-T scores to different variables such as grades in the final high school exam, gender, chosen school type, and the level of specialization of mathematics.

First, mathematics self-efficacy scores were correlated with the grades in the final high school exam. At a first glance marks in exams don’t give information about the belief in one’s own mathematics self-efficacy expectations. At a closer look mathematics self-efficacy can be seen as a predictor for mathematical academic outcomes (Multon et al., 1991; Betz & Hackett 1983). It can be hypothesized that the final exam grade in math can also be a predictor for mathematics self-efficacy expectations. A correlation between the two scales was significant ($r=0.47$, $p<0.01$, $n=345$). This means that students with higher grades in their final school exam rated higher in the mathematics self-efficacy scale.

Second, gender differences have been investigated in order to test whether male subjects have higher mathematics self-efficacy scores than female subjects. Gender differences have been reported in earlier studies (Betz & Hackett, 1983; Randhawa & Gupta, 2000). Table 3 shows the total score of mathematics self-efficacy and the mean scores of the subscales separated into males and females. Males scored significantly higher in total MaSE-T and the subscales ‘real-world mathematical problems’ and ‘reasoning problems’ than females.

dimension	n	Cronbach’s Alpha	items
total MaSE-T	1273	0.84	15
mathematical problems	1309	0.77	5
real-world mathematical problems	1302	0.70	5
reasoning problems	1294	0.74	5

Table 2. Reliability of the MaSE-T scale.

Working Group 14

scale	males (<i>n</i> =319)		females (<i>n</i> =992)		test of significance
	<i>Mean</i> ²	<i>SD</i>	<i>Mean</i>	<i>SD</i>	p
total MaSE-T score ¹	52.1	9.7	49.5	9.1	<0.001
mathematical problems	18.5	4.3	18.4	4.1	0.812
real-world mathematical problems	19.3	3.6	17.9	3.5	<0.001
reasoning problems	14.3	4.1	13.1	4.0	<0.001

¹Higher scores in mathematical self-efficacy indicate a greater confidence in the ability to accomplish the mathematical task.

²Minimum score 15 / maximum score 75.

Table 3. Gender differences in MaSE-T scores.

Comparing the MaSE-T scores of the groups aiming for different school types (table 4), also significant main effects for groups ($F=7.80$, $F_{(3,14)}<5.56$, $p<0.01$) were identified. A post hoc analysis reveals that prospective teachers for intermediate secondary schools have a significantly higher MaSE-T score ($p<0.01$) than the other groups. Lowest MaSE-T scores had students who will become teachers for schools for children with special needs, which were significant lower than the scores of the other groups³ ($p<0.05$).

Comparing groups according to students' with different levels of specializations in mathematics with the MaSE-T score (table 5), an ANOVA revealed a significant main effect of the factor *group* ($F=33.24$, $F_{(4,14)}<9.73$, $p<0.001$). Post hoc tests showed that students who didn't choose mathematics as a subject had significantly ($p<0.001$) lower MaSE-T scores than students who have chosen mathematics, as predicted. In addition, students who have chosen mathematics as minor have significant lower MaSE-T scores ($p<0.001$) than the major and 'middle' students (see Table 5).

These two results between groups, study course specialization as well as the subject choice of mathematics, are covered by the findings of Hackett and Betz (1989). They found that mathematics self-efficacy beliefs are predictive for the choice of major. On the one hand, students with low self-efficacy expectations in mathematics avoid studying mathematics or don't choose mathematics as their major (Table 4). On the other hand, in the group of students who have chosen mathematics as a subject, the students with the highest MaSE-T score are those who will become teachers for intermediate secondary school. In contrast, students with low mathematics self-efficacy beliefs often choose to become primary school teachers because they often think that only basic arithmetic skills are needed. Secondary school teacher students

Working Group 14

know they'll have to do some 'real' math, consequently the group of prospective teachers for intermediate secondary school score the highest at MaSE-T.

Group	<i>n</i>	<i>Mean</i>	<i>SD</i>
Primary school	640	49.3	9.1
Secondary general school	189	49.2	9.7
Intermediate secondary school	362	53.3	8.5
School for special needs children	120	46.4	9.9

Table 4. Mean MaSE-T scores of different study course specializations

Group	<i>n</i>	<i>Mean</i>	<i>SD</i>
major subject	401	53.0	8.3
'middle' subject	396	52.6	8.5
minor subject	275	49.0	8.3
math not as a subject	237	42.7	9.2

Table 5. Mean MaSE-T scores for different levels of specializations in mathematics.

DISCUSSION

In this paper, a questionnaire for measuring mathematics self-efficacy expectations of prospective teachers (MaSE-T) has been introduced. The refined 15-item MASE-T scale achieved a suitable level of internal reliability ($\alpha=0.84$). Validity of the scale was indicated on one hand by producing significant gender differences. On the other hand, a positive correlation between MaSE-T and the final school exam grade has been found. The differences between samples grouped according to their chosen school type and to the different levels of specializations in mathematics also indicate the validity of the MaSE-T scale. While students with higher MaSE-T score chose mathematics as their major subject, students with lower scores avoided mathematics as field of study.

In future studies, the change of students' mathematics self-efficacy in different learning scenarios for students in mathematics education can be measured. By this, lectures and tutorials can be evaluated regarding to the change of the mathematics self-efficacy.

NOTES

¹ In this paper 'prospective teachers' means students at universities in the first phase of the German teacher education.

Working Group 14

²The reduced 15-item questionnaire can be downloaded on www.sail-m.de in a German and English version. This article is based on the German version, the English one hasn't been validated yet.

³This group contained a relative high number of students which didn't choose mathematics as subject. A closer look at the data showed that the mean of the major subject students is similar to the mean of intermediate secondary school students.

INTRODUCTION TO THE PAPERS OF WG15 TECHNOLOGIES AND RESOURCES IN MATHEMATICS EDUCATION

Jana Trgalová (INRP-ENS, Lyon, France)

Anne Berit Fuglestad (University of Agder, Kristiansand, Norway)

Mirko Maracci (University of Pavia, Italy)

Hans-Georg Weigand (Wuerzburg University, Germany)

INTRODUCTION

Technologies in mathematics education have been a topic of the working group since the CERME 1999. Since then, technologies as well as research in this field have significantly evolved. In particular, recent years have brought about an important shift in considering technologies within a wide range of resources for students, teachers and teacher educators. There have been new developments concerning software, hand-held technology, online classroom activities, but also more traditional geometry tools, curricular materials, textbooks etc. The introduction of the term “resource” in the title of the technology working group since the CERME 6 congress in 2009 reflects this shift (Gueudet, Bottino, Chiappini, Hegedus & Weigand, 2010).

Technologies and resources have become more abundant and accessible, bringing about some changes in math teaching and learning (Hoyles & Lagrange 2010). They offer new possibilities for representation, modelling, simulation and access to information and knowledge (Tooke & Henderson 2001), and suggest new ways of generating student engagement, motivation and creativity (Passey, Rogers, Machell & McHugh, 2004). Teaching methods with technologies are increasingly focusing on problem-solving approaches (Fuglestad, 2009). Technologies also offer means of collaborating and sharing resources between students and teachers (Trouche, Hivon, Noss, & Wilensky, 2010). But presently, despite the use of digital technologies in the public and business world, and the tremendous number of research and practical classroom papers, the use of technologies in mathematics education and the impact on the change of curricula are still limited (Hoyles & Lagrange, 2010).

The group organized the contributions around four main themes: (1) Design and use of technologies and resources, (2) Technologies, resources and teachers’ professional development, (3) Students’ learning with technologies and resources, and (4) Technology-based assessment in math teaching. Surprisingly, the latter does not appear as a matter of concern since all papers addressed the first three themes.

The group work was organized in two sub-groups discussing respectively the issues of technologies and resources in relation with teachers’ professional development (theme 2), and the issues related to the design of technologies and resources and their impact on students’ learning (themes 1 and 3). In the following, we give a brief overview of the group work according to the three above-mentioned themes.

THEMES IN WG15**1) Design and use of technologies and resources**

Papers related to this theme concern on the one hand the design of innovative technological tools or resources. Ladel & Kortenkamp design and develop a multi-touch technology for learning numbers and operations, Sabra & Trouche study the design by a community of teachers of online secondary school math textbook. On the other hand, the use of existing technological tools and resources are addressed, such as the use by teachers of specific curricular material accompanying TI-Nspire (Persson) or of math textbooks (Özgeldi & Çakiroğlu), students' use of TI-Nspire technology (Aldon), of a spreadsheet (Tabach) or of graphic calculators (Consciência & Oliveira; Storfossen). The question of the design of specific tools for students with special needs, such as visually impaired students (Kohanová) or students with dyscalculia, was raised. In the group discussions, *added value* of technology appeared as the most important element determining what kind of tool to use, how and what for. Various roles have been assigned to technology in math education by the participants: fostering motivation, enhancing calculation, visualization, (guided) exploration, hands-on experience on abstract models, allowing validation by providing feedback, but also helping teachers teach with systems providing individualized learning paths based on students' competence diagnosis.

2) Technologies, resources and teachers' professional development

Papers related to this theme investigate teachers' use of technologies and resources (both inside and outside the classroom), factors affecting their integration in classrooms, and issues related to teachers' professional development. These issues are addressed focusing on different aspects, from different perspectives and adopting different methodologies. The analysis of the teachers' practice in classroom is investigated at different levels of granularity, each one requiring the design and use of different methodological tools, from fine-grained analyses (Billington), through survey studies (Bretscher), to studies combining both qualitative and quantitative methods (Drijvers). As it clearly emerged, the integration of technologies and resources in the classroom poses a number of challenges to teachers, several of which can be described and discussed in terms of the Technological Pedagogical Content Knowledge that they need to develop (Fuglestad). From the instrumental perspective, some of these challenges can be related to the need for the teacher to transform an ICT tool both to a mathematical and a didactical instrument (Haspekian). All these considerations raise the issue of the teachers' professional development and how it impacts the teachers' use of technology. Studies concerning this issue regarded, for instance, the actual (Amado) or intended use (Pittalis) of technology by pre-service or in-service teachers, who attended specific training courses on technologies in math education. The issue of teachers' professional development is strictly related to the issue of the dissemination of research results

among teachers. Developing communities involving both researchers and teachers is proposed as a means to trigger collaboration and communication among them and to foster the dissemination of research results (Lagrange).

3) Students' learning with technologies and resources

Papers addressing issues related to this theme concerned both widespread technological tools, such as dynamic geometry software (Attorps *et al.*; Camacho & Santos), symbolic or graphic calculator (Consciência & Oliveira; Storfossen; Weigand), and more innovative tools like TI-Nspire handheld device (Aldon; Persson) or online games (Kolovou & van den Heuvel-Panhuizen). Some of these papers focus on *student-tool interactions* in order to study processes of students' appropriation of the tool (Consciência & Oliveira; Camacho & Santos) or students' transition between various tools (Tsitsos & Stathopoulou). These studies draw mostly on the *instrumental approach* (Rabardel 2002) as a theoretical framework specifically designed for studying teaching and learning phenomena involving technology. In other papers technologies are considered rather as a *tool mediating mathematics learning*. The choice of a tool and the design of appropriate tasks are the main concerns in these papers (Attorps *et al.*; Kolovou & van den Heuvel-Panhuizen). The task design is supported by two main theoretical approaches: *variation theory* (Marton & Booth, 1997) and *theory of didactical situations* (Brousseau, 1997). Studies involving innovative pieces of software investigate their potentialities for mathematics learning (Ladel & Kortenkamp) as well as for organizing and exploiting the internal resources (Aldon). Another important issue discussed in the group was the question of *assessment* of students' competencies (Weigand): what kind of knowledge and skills developed by the student working with technologies do we want to assess and how can we assess it?

CONCLUSION

What lessons can be learnt from the work of the WG15? Although the three themes proposed to the working group appeared as strongly articulated, some important issues emerged for each of them. The design of technologies and resources seems to be driven by the consideration of their *added-value* for the teaching and learning mathematics and relies on the *users' feedback*, which becomes part of the design process. The group discussions allowed getting a deeper insight into the *complexity of ICT integration* in teachers' practices, which requires a *double instrumental genesis* in teachers: a personal one, yielding an instrument for teachers' math activity, and a professional one, yielding an instrument for math teaching. This raises the issue of teacher training focusing on the development of teachers' technological pedagogical content knowledge. The idea of teachers' communities sharing resources and practices in using ICT emerges as a powerful means to favour teachers' professional development. In studying students' learning with technologies, the *instrumental approach* becomes widely used to analyse student-tool interaction. It

highlights a strong interconnectedness of mathematical and technological knowledge. However, the impact of technology on students' achievements appeared as very difficult to measure, mostly due to the lack of appropriate methodology.

What perspectives can be outlined for the future CERME conference? There is still a need to develop a comprehensive theoretical framework to support teachers in their integration of ICT to the benefit of students' learning and methodological tools to evaluate the impact of using ICT on students' learning and teachers' practices. Emerging topics, such as communities of practice, quality of resources or best practices, require further theoretical and methodological development. Finally, some topics, which are under-represented, would deserve researchers' interest: use of "new" new technologies, such as interactive white board, mobile devices, Web 2.0, as well as designing ICT for students with special needs.

MATHEMATICS STUDENT TEACHERS' PEDAGOGICAL USE OF TECHNOLOGIES – DIFFERENT TAXONOMIES IN THE CLASSROOM

Nélia Amado,

FCT, University of Algarve e UIDEF, University of Lisbon, namado@ualg.pt

This paper refers to the use of technologies by student teachers in the classroom. I present a taxonomy that help to distinguish the various forms of teacher and students' uses of technology. In a pedagogical perspective the use of technologies can be seen in three distinct ways: as an accessory, as a teacher-centred activity and as a student-centred activity. I present three tasks illustrating this taxonomy. The role of the teacher and role of the student, the nature of activities, the environment and the class management are three aspects whose combination is essential to understand what a pedagogical perspective on the use of technologies.

Key-words: student teacher, technologies, pedagogical perspective, tasks.

INTRODUCTION

Hoyles and Noss (2003) pointed out that technologies emerged to relieve us of the more routine and monotonous, repetitive and even somewhat less interesting work. But while alleviating this work, technology impels us to invest in higher order skills, such as knowing how to interpret a graph, making conjectures, being able to relate concepts and use them, learning to critically analyze the results, and flexibly using different mathematical representations. In turn, an appropriate use of technology may lead students to learn more mathematics and more profoundly.

On the other hand, technology if used in inappropriate manner does not produce major changes in learning. Still, the computer allows some types of activities, such as discovery, and facilitates the development of mathematical intuition in such ways that would be very difficult or even impossible to achieve without the technology.

Thus we arrive at the imperative of a substantial change on the teacher's role in the classroom, which remains a sensible current recommendation (Laborde et al., 2005). We therefore realize how important it remains to investigate how teachers introduce technologies in the classroom.

THE USE OF TAXONOMIES TO DESCRIBE THE USE OF TECHNOLOGIES

Pierce and Stacey (2001) have considered that the introduction of technologies in mathematics teaching and learning can take place at two levels: functional and pedagogical. The distinction between these levels appears to be in the student's role and access to the technology. In the functional perspective the use of technology seems to be confined to the teacher and the students' role is mainly of mere

spectators. On the other hand, a pedagogical perspective would be one that takes place in an educational context, namely a school subject or other, where there is direct interaction of teacher and students with technological tools.

Indeed, the concept of technology as a pedagogical tool entails essential aspects, such as rethinking the methods and purposes of learning mathematics, the roles of the teacher and students, the nature of the activities proposed and the class management (Kokol-Voljc, 2003). The concept of technology as a pedagogical tool is inseparable from the use that is made of it. Technologies can be regarded as pedagogical tools when three crucial conditions are simultaneously assured: the topic, the purpose and the opportunity.

In brief, the notion of pedagogical perspective is connected with the tool use and it depends on who is using it and on the classroom situation where it is used.

Galbraith (2002) and Goos (2005) developed a taxonomy on the use of technology by mathematics teachers. This taxonomy helps to distinguish the various forms of teacher and students' uses of technology. These authors presented a set of metaphors to describe how technologies can pave the way for incorporating new roles in teaching. Thus, when the knowledge and expertise of teachers in the use of technology is small or limited, and the computer use is not their personal initiative and will, but the result of an imposition of the educational system itself, we have a dominating action (technology as master) of technology on teaching practices. Today many secondary schools have interactive whiteboards, forcing the teacher even without genuine desire to use it solely for the purpose of satisfying an imposition of the educational system. The current pressure on the teacher to engage with the use of technologies can lead to concentrating on the basic contents, without any concern about the impact that technology may have beyond the immediate. The use of technology becomes the result of complying with an obligation, on a specific time.

On a second level of use the imposition or recommendation for use of technologies does not dominate. The teacher has some confidence and interest in technological advances, and enjoys knowing and using them. For example, the computer is used for word processing, for the development of materials such as worksheets and tests and technology is used to support lessons. However, there is still no change in the classroom activities. Galbraith (2002) and Goos (2005) consider that this is a use of technology as a servant (technology as servant). In addition to the worksheets or tests designed on the computer, using a PowerPoint in the classroom can be an example of a use of technology as a servant.

These two perspectives of using the technologies seem to fit the functional level, in that it does not introduce major changes in classroom activities or allow students direct interaction with technology. Students are generally spectators, although they may believe that the lesson may have been more colourful, more modern, with a few adornments out of the traditional. Sometimes students find it very nice to have a

lesson with a PowerPoint presentation or with the teacher writing on the IW instead of the blackboard but there is nothing new to the learning process, and the roles of teachers and students do not change. Similarly, the teacher can use the calculator linked to an IW to show to the whole class the results of certain operations and procedures or to display the graph of a function, managing to do it with more quickly, accurately, and using a great diversity of examples instead of just one.

A third perspective of using technology is a partnership (technology as partner). This situation occurs when technologies are used occasionally in the classroom by the teacher and students, enabling them to achieve some knowledge that would otherwise be very difficult or even impossible. In this case, teachers develop a partnership with the technologies as tools to help solving the problems and activities and as a means of promoting learning. This way of using technology gives the students more power over their own learning, but for that to happen it is necessary that the tasks should be designed and adjusted to the purposes of learning. This is where the big issue is - the nature of the tasks and how they are presented to students. These should enable the student to experiment, investigate and draw conclusions. Students need to have access to the computer in the class, and the activities proposed should be rich enough and appropriate to promote learning. Sometimes there is the simple transposition of a paper and pencil assignment to a task with technologies. A task planned for paper and pencil cannot simply be proposed to be done with technology with unchanged learning aims. It is well known that some paper and pencil problematic tasks may become trivial when solved with technology. When tasks are technology based, the situation is more complex, as adding technology deeply affects the task itself (Laborde, 2008).

Finally, the last way to use the technologies to which these authors designate by extension of self (technology as an extension of self) is the highest level of technology use. Such use must occur in a mathematics laboratory equipped with computers, adequate software, graphing calculators, view screen, sensors, and possibly an IW. At this level, effective and creative use of technology is an integral part of the repertoire of the teacher, along with their teachers' competence and knowledge of mathematics. In this case, it is very important to know how to put the technologies for students learning and promote their ability to use them in a timely, intelligent and critical way. The use of technology should not be reduced to a means of confirming answers or illustration of mathematical objects but have the function of raising questions, creating situations that lead students to think and encourage their participation in class work.

AIMS OF THE STUDY

Thomas and Cooper (2000) argue that there is great inconsistency between what prospective teachers learn about technology and their work later on in the classroom. The transposition of the experience offered by the pre-service training into the

classroom practices is a complex process. Hence, the purpose of this study is to understand how prospective teachers, with a solid and consistent preparation for the pedagogical use of computer, integrate technologies when they start teaching at the beginning of their professional practice. Several questions were formulated including:

- What is the importance and value of the knowledge and training they have acquired in the pedagogical use of technologies?
- How is their use of technology integrated in their teaching?

THE EMPIRICAL DATA

This study involved two teams of two student teachers each, in two different schools. The data collected included classroom observation, and interviews with the student teachers at different times of the school year. It has also integrated the collection of teaching materials produced to support lessons and other documents relevant to the study. The data here referred represent a small portion of all the empirical material obtained during the research that lasted for one academic year.

These student teachers were on their final year of training to become professional secondary mathematics teachers, after having taken four years of university studies in mathematics and education courses. During their academic studies they had a specific training on technologies in mathematics education as part of a course in mathematics education. They all had the same preparation on the use of several tools and software for mathematics teaching (dynamic geometry, spreadsheets, graphical calculators, applets...)

I present and analyze three lessons involving 10th grade classes (students aged 15-16) with the use of computers, each one based on a different assignment. The lessons reflect different characteristics that illustrate diverse ways of realizing the pedagogical perspective of technology use.

The taxonomies developed by the authors mentioned above have proved insufficient to categorise the data collected. As seen in other studies a combination of theoretical ideas and data supported variability justified the reason to develop a new taxonomy. This situation resembles, for example, the work developed by Drijvers, Doorman, Boon, Reed and Gravemeijer (2010), whose empirical data led to six orchestration types, placing the focus on how the teacher intentionally and deliberately organises the classroom and the use of technological artefacts in a given mathematical task. The authors describe the six types in terms of their specific features but they also divide them into two broad classes: three of the types can be seen as teacher-centred while the other three can be described as teacher-centred orchestrations.

In the case of the present study, substantial differences identified are located in the proposed tasks and in the form of presenting them to the class by the student teachers. Therefore it became necessary to distinguish and rethink about the

classroom practices of the student teachers with the use of technologies in connection to the tasks presented and the particular ways in which they were formulated. The analysis sustained the perception that technology use under a pedagogical perspective can be seen in three distinct ways: as *an accessory*, as *a teacher-centred activity* and as *a student-centred activity*. In certain aspects, this categorisation is in tune with the orchestration types (Drijvers et al, 2010) but it places an increased focus on the nature of the task as a crucial condition to promote a certain use of the computer.

Pedagogical perspective I – The equation of the circle “appears”

In this class, the student teachers (team A) wanted to lead their students to the discovery of the Cartesian equation of the circle. The activity asked students to construct circles and with the help of Cabri Geometry find the equation of the circle and obtain the centre coordinates. This is the translation of a paper and pencil activity to the computer that does not seem to have added anything new to students' learning. In the next lesson they did the same activity with paper and pencil.

Circles

Using **CABRI GEOMETRY II** follow the steps:

Select the option “Show axes” and then mark a point.

With the option “Equation or coordinates”, identify the coordinates of the point.

With the option “Circle”, construct a circle by centre in the point and any radius.

Mark a point on the circle, with the option “Point on object”.

With the option “Distance or length” measure the distance from the point to the centre of the circle.

Get the equation of the circle, with the option “Equation or coordinates”. Write the equation of the circle.

With the option “Pointer”, change the position of the centre, by drawing and check the changes in the equation. What do you conclude?

With the option “Pointer”, select the point on the circle and change the radius. What do you conclude?

Figure 1: The task about the equation of the circle

The main intention for using the computer in this class was to lead students to discover by themselves an algebraic representation of a geometric object, avoiding the algebraic manipulation. The student teachers expressed this idea as follows:

ST: We wanted that the students discovered the equation of the circle. We used the computer because they could do a series of experiments and arrive at the equation without having us writing on the board and saying: this is the equation of a circle. They could try and reach that conclusion by themselves

The equation of the circle emerges not by the hand of the teacher, but by Cabri. I argue that an essential part of mathematical knowledge was omitted; students did not have the chance to develop a mathematical concept that is associated with another one already known the distance between two points in a Cartesian plane. In an elusive way the computer allowed these students to "reach" the Cartesian equation of

the circle. The computer use can be seen as a misleading servant in that it exhibited the equation of the circle but did not allow students to perceive or understand its basis. Thus we can consider this use of the computer as *an accessory*.

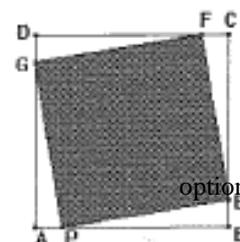

Pedagogical perspective II – The area of the square in 29 steps

The area of the square besides being a dynamic problem, allows multiple connections between mathematical contents studied in 10th grade. However, there seems to be an excess of instructions from the student teachers (team A) that totally affects the students thinking, not giving them space to reflect and to establish their own strategy for addressing the problem. It is worth noting that students were used to working with this software since the beginning of the school year and that this situation was presented at the end of the year. One possible explanation for this self-directed activity can be found in the way the student teachers conceive the roles of the teacher and students in the use of technology in the classroom. These student teachers seem to feel the need to provide the path to the students and leave them no room to find unforeseen situations.

In the twenty first steps nothing new emerged comparing to other constructions made with Cabri in previous classes. The last nine steps were those who brought something new to the students.

With **CABRI GÉOMÈTRE II**, follow the steps:

We want to make the construction shown. So we start by constructing the square [ABCD] and, afterwards we construct the square [EFGP].

- 1) With the option Segment, construct the line segment [AB].
- 2) Now we have to construct the line segment [BC] with the same length of [AB]. Use the Circle and construct a circle by center B and radius [AB].
- 3) Use the option Perpendicular Line and construct the line perpendicular to [AB], and passing through B.
- 4) Construct the point of intersection of the circle and the perpendicular line (option Intersection Points), naming it C (option Label).
- 5) With the option Parallel Line, construct the line passing through C and parallel to [AB].
- 6) Construct a perpendicular line to [AB], passing through A.
- 7) Construct the intersection of the last line and of the parallel line to [AB], and name it D.
- 8) Construct the segment lines [BC], [CD] e [DA].
- 9) Hide the circle and all the lines.

How?

- Select the option Hide/Show.
- Select the objects to be hidden.

- 10) Mark a point P on the segment line [AB], using the option Point on Object.
- 11) Measure the length of [AP], with the option Distance or Length.

How?

... ..

- 22) Tabulate the values of the area while point P moves on the segment line [AB].

Working Group 15

How?

- Select the table, with the option Pointer.
 - Activate the option Animation and click on point P, holding down this button and drag.
 - To stop the animation, click the left mouse button or the Esc key on your keyboard.
 - The values should appear in the table. If you want to view a larger number of registers increase the number of rows.
- 23) Construct a horizontal line passing through point O (the origin of axes).
 - 24) Construct a perpendicular line to previous line passing through point O.
 - 25) Use the option Measurement Transfer to transfer the length of the line segment [AP], to the x-axis and the area of the square [PEFG] to the y-axis.
 - 26) Name the previous points by Q and R.
 - 27) By each of these points construct perpendicular lines to the axes and construct the point S as the intersection the two perpendiculars.
 - 28) Activate the option Trace On/Off and click on point S.
 - 29) Animate the point P using the option Animation.

Observe the model and answer to the following questions:

- 1. Between what values can vary the displacement of point P?**
- 2. What reflects the graph obtained?**
- 3. When is the maximum area reached? And when is the minimum reached? Interpret it in the context of the problem.**
- 4. Indicate the co-domain of this function.**
- 5. Define algebraically the function.**

Figure 2: The task about the area of the square

The initial orientation seems to have been both excessive and unnecessary, given that students had done similar constructions before. This activity could have been an opportunity for students to practice and investigate ways to make the construction, using their own imagination and their understanding of the diagram, rather than following a course set by the hand of the teachers. These student teachers, like other more experienced teachers, apparently feel difficult to give their students the opportunity to create, to think independently, to imagine, and to find a way other than perhaps the one they have thought of. For these reasons, I believe that we are facing a pedagogical perspective that is *teacher-centred*.

Pedagogical Perspective III – Slicing the cube

In the study of cross sections, the students usually work with paper and pencil or manipulative materials. Students have great difficulty in visualizing the cross sections even when they are given opportunities to view and manipulate the physical object. A dynamic geometry environment is an excellent choice to promote the manipulation and visualization of the cross sections. In this case (team B), the software GEOMETRY was suggested to students, and they were given a reference guide to use the program.

Cross Sections

In this task we use the software GEOMETRIA. See the reference guide and follow the steps:

Draw a cube. In each case draw the cross section obtained by slicing the cube; identify and draw the geometrical shape produced.

a) The slicing plane is DBE.

b) The slicing plane is HFB.

c) The slicing plane is IJK, where:
 I is the midpoint of [HG];
 J is the midpoint of [GF];
 K is the midpoint of [FB].

Figure 3: The task about cross sections

In solving the various tasks proposed the students had the opportunity to choose their own strategy, issues have arisen naturally through the class and discussed with the teacher. The student teachers and their students were partners in a process of knowledge development, and together shared questions and difficulties. The students felt that technology helped them understanding the mathematics, gained confidence, and believed the computer was a useful tool in solving the problems. The student teachers themselves were pleasantly surprised with the involvement of students in the pursuit of answers and in the discussion even for students who usually seemed less motivated in mathematics classes. Thus with satisfaction they said:

ST: I am surprised. Even some of my more indifferent students were working as well as those more interested! I never saw them like this!

This was a clear case where the computer was used from a pedagogical perspective that is *student-centred*.

FINAL REMARKS

The students teachers involved in this study had the same initial training, the same preparation regarding the use of technology, which included a discussion of their potentialities, possible approaches and educational purposes, but as shown in the data, their practices diverged in many respects.

Research has shown that preparation acquired in one or more academic courses are not enough for future teachers to make an immediate transfer of this knowledge to the classroom. Adler (1996), while accepting that formal academic courses should be

Working Group 15

part of the education of future teachers argues that knowledge about teaching – in this case, how to use technology in the classroom – is not solely acquired in formal courses but rather it is developed through a continued participation in a community of teachers. Appropriate use of technology in the classroom actually requires learning through participation in a practice that is neither linear nor immediate. In each of the teams of student teachers, a pedagogical perspective of technology use in the classroom was marked by some differences that can be justified or explained by their own ways of thinking about mathematics teaching and learning and, particularly, by the way the student teachers saw the roles of teacher and students in the classroom.

These student teachers shared a willingness to have their students enjoying mathematics and engage them in learning; however they seemed to have different ideas of how to do it. One of them (from team B), a great supporter and user of technology, argued that schools should integrate all technologies that are now part of our daily life. All of them seemed to hold the idea that technology can be an important way to engage students and make them enjoy mathematics more. In team B a greater concern with the purposes and goals of the computer use in classes was prominent. The practices of these two student teachers revealed a view on using the computer that was according with the recommendations offered in the curriculum. It was clear their intention to inquire about and search, to find the best suited software to work on a particular content and the care taken in the preparation of the tasks. They were skilful in the ways in which they shared their power in the classroom, and gave their students a greater and better opportunity to engage in learning.

The other team put technologies at the same level of other materials, for example, manipulatives. Moreover, they showed a great concern with student disruptive behaviours and the fear of indiscipline was a cause for some initial tension. The second downside is related to how these student teachers perceived their role. The teacher was conceived as someone who holds all the knowledge and must pass it on to the students, which entailed to define the path that students should follow, and avoiding all difficulties in students' minds.

As mentioned above, the role of the teacher and role of the student, the nature of activities, the environment and the class management (Kokol-Voljc, 2003) are three aspects whose combination is essential to understand what a pedagogical perspective on the use of technologies means and what it may consist of.

SYMBOLIC GENERALIZATION IN A COMPUTER INTENSIVE ENVIRONMENT: THE CASE OF AMY

Michal Tabach

Tel-Aviv University

Learning beginning algebra is difficult for many students as they must master the use and interpretation of symbolic expressions. This study investigates the use of spreadsheets in a beginning algebra course and tracks the development of one student, Amy, as she moves towards the use of explicit symbolic expressions. Results indicated that the spreadsheet served as a scaffold, helping to bridge between arithmetic and algebra.

Keywords: beginning algebra, spreadsheet environment, symbolic expressions

Introducing algebra to middle grade students is a challenge. Beginning algebra students must learn to incorporate symbolic expressions in their language, manipulate them, and make sense of them (Arcavi, 1995). Several research projects have employed the use of technological tools in order to overcome some of these hurdles by bypassing the need to communicate symbolically. One such example is Kaput's *SimCalc* project (Kaput, Carraher, & Blanton, 2007) which connected graphical, numerical, and visual representations in order to make sense of changing phenomena. A different approach was adopted by Tabach, Hershkowitz, Arcavi, and Dreyfus (2008), who implemented a functional approach within a spreadsheet environment. Regardless of the use of technological tools, in many countries, students are still expected to be able to generalize or model a given situation using symbolic notations, as well as manipulate symbolic expressions in a paper and pencil environment. Under these conditions, what is the place of computerized tools in a beginning algebra course? Can a computerized environment be used as a scaffolding tool, a tool that will help bridge the gap between arithmetic and algebra but which may be released from use as knowledge evolves?

This paper follows one student, Amy, during a year long beginning algebra course, which took place in a *Computer Intensive Environment* (CIE). This environment had the following characteristics: (1) full and unconstrained access to spreadsheets (Excel) in class and at home, (2) freedom of choice about if, when, and how to use the computerized tools, as well as the strategy employed to solve the given problem situations, and (3) an ad-hoc learning textbook consisting of a sequence of problem situations and simple tasks. An explicit invitation to use spreadsheets as a working tool (including the technical instructions thereof) was only given in approximately one-fifth of the problems, mostly in order to get acquainted with the tool. In all other cases, the teacher supported and legitimized any choices made by students regarding the ways, means, and strategies used to solve the problems. Thus, the intensiveness of the environment relates to the availability of the computerized tools at all times,

but not necessarily the intensiveness of their use. By focusing on one student, this paper aims to gain insight into the learning experiences and processes afforded and supported by such an environment.

THEORETICAL BACKGROUND

Algebraic thinking involves describing phenomena and generalizations. There are several representations with which one may represent a given problem situation – story, table, graph, or symbolic expression. In a computerized environment, these representations are all dynamic notation systems. However, in a pencil and paper environment, symbolic expressions are the only notation system which stays dynamic (Kaput, 1992); hence its power and the importance of mastering it. The following sections briefly discuss student's development of symbolic generalization, including the use of symbolic expressions within a spreadsheet environment.

Symbolic generalization. In a pencil and paper environment, three stages of generalization processes by pre-algebra students may be identified (Arcavi, 1995; Friedlander, Hershkowitz & Arcavi, 1989). At the first stage, when students are aware that they should use symbols, they tend to represent quantities involved in a given situation by using different letters, disregarding existing relationships between the quantities. To demonstrate, let us consider the following situation:

Moshon had \$30 in his saving box at the beginning of the year. Moshon added \$5 to his saving box each week.

Algebra beginners may denote the amount in Moshon's saving box at the end of the first week by a , and the amount at the end of the second week by b . Such use conceals the existing connections between the amounts. At the second stage, students express relationships, but only partially. To follow our example, the amount in Moshon's saving box by the end of the first week is still denoted by a , but the amount at the end of the second week is denoted by $a+5$. Thus, the connection between the week and the amount of money is still hidden, while the connection between the amounts in consecutive weeks is explicit. Only at the third stage are students able to express full relationships among changing quantities in a symbolic way (Friedlander & Hershkowitz, 1997). That is, in our example, a will denote the week and $30+5a$ denote the amounts in the saving box at the end of week a . The first two stages explore local connections, whereas only in the third stage general connections among variables appear. Unfortunately, pencil and paper manipulations of algebraic expressions which express only partial relationships may not lead to insightful results.

Symbolic generalization in a spreadsheet environment. Within a spreadsheet environment, students at all three stages are able to operate, experiment with, reflect on, and learn about relationships between the quantities involved (e.g., Sutherland & Rojano, 1993). This is possible because a large amount of numbers representing a certain variable can be produced and arrayed in such a way that the relationship is

“visible” even without the explicit and general symbolic expressions. This can be produced by one of the following options [1]:

(a) *Multi-variable approach* — “dragging” and considering a whole array of numbers (i.e. a column in the spreadsheet) as a “variable” dependent on another one (Dreyfus, Hershkowitz, & Schwarz 2001). Consider once again Moshon from the previous example. Students may use column A by entering the constant 5 for each cell. In column B, B1 will be 30. B2 will then be the joined amounts A_2+B_1 . (b) *Recursive generalization* — the use of recursive expressions, which emphasize local relationships between consecutive elements such as contiguous cells of the same column (Stacey & MacGregor, 2001). In this case, students may describe Moshon's savings by writing 30 in cell A_1 , and in the next cell A_1+5 . (c) *Explicit expression* — explicitly expressing the full general relationship among the variables. In our example, it means expressing the savings in B1 as $30+5A_1$ (where column A represents the number of weeks passed).

It seems that students prefer recursive formula over explicit formula (Stacey & MacGregor, 2001). Such preference may indicate initial difficulties encountered when handling explicit formula even when, in many situations, it proves more efficient than recursive expressions. In fact, from a practical point of view, there is no actual difference between the output of working recursively or explicitly in a spreadsheet environment. That is, after entering any of the three types of symbolic expressions to a spreadsheet cell, and "dragging" the expression down, relevant numbers will be displayed whereas the inputted algebraic expressions remain hidden.

A main concern regarding students who use spreadsheets in their beginning algebra course is that they may come to feel too comfortable with the tool, becoming used to multi-variable and recursive expressions which express only partial relationships. In their study of students learning in such an environment, Tabach, Arcavi and Hershkowitz (2008) found that towards the end of the course, "... most students had shifted or started to shift to a pencil and paper environment, especially when they were confronted with situations requiring them to state and solve linear equations" (p. 69). This shift takes place gradually. What changes can we detect along the way? While the previous study reported on the class as a whole, this study focuses on one student in order to gain insight regarding the use of symbolic generalization in an environment which allows for both spreadsheet and paper and pencil tools.

METHODS

Amy Amy was one of 27 students in her seventh grade beginning algebra course. She was chosen for this study because of the changes she underwent during the course. In the beginning of the year, students were given a test in order to assess their problem solving skills and to investigate their initial use of algebra in this process. Amy scored below the class average on this test. By the end of the year, she had progressed and scored above average on the final exam. Throughout the course, Amy

exhibited a positive attitude towards the use of computer software while also incorporating other sources during her algebraic work.

Amy, along with the other students in her class, had been initiated into the world of symbolic generalization during the very first algebra lesson. During this lesson, they worked in a paper and pencil environment on a problem situation involving changing phenomenon. During the second lesson, the use of Excel was introduced. Students were taught how to enter an expression (formula) into a cell and drag it down in order to produce a column of values. It should be noted that, as far as the students were concerned, Excel was a tool which could be used by entering an expression for the purpose of producing a string of values.

Data Collection Several tools were used to document classroom learning processes. Classroom observations were conducted and a detailed research diary was written immediately after each lesson. All working files that students saved in their computers were collected. Written works and assessment tasks of all students were collected.

RESULTS

To follow Amy's advancement during the year we bring examples from her work on different activities which took place at different times during school year. Each example is related to one of three connected issues: (1) the use of symbolic expressions and Excel, (2) generalizing from a sequence of numbers, and (3) generalizing from a story.

Example 1: September 27, Growing Rectangles activity. The activity was concerned with the process of growth in 3 rectangles during a period of ten years and entailed comparing the areas of the rectangles during this time period (see Figure 1). Students were requested to organize their data regarding the growing rectangles in a spreadsheet table and record the formulas used to construct their table. No instructions were given as for how to organize the data.

Amy organized her data in an *Extended Table* (Tabach & Friedlander, 2004), which contained the following ten columns (i.e. variables): the year, six columns for the linear dimensions of each rectangle, and three columns for the area measures. The columns were ordered by variable (Figure 2). Amy used symbolic expressions to describe each changing phenomena. Other than the length of rectangle C (column G) all linear changes were described by recursive expressions, which express a relationship between two consecutive numbers in a sequence (columns). Each of the first elements in columns B-G was a number. Thus, for the most part, Amy missed the opportunity to express the connections between the widths (columns B, D, and F) and the year (column A) as well the relationships between the lengths (columns C, and E) and their respective widths. The areas of the rectangles were described by multivariate expressions, which used the letters corresponding to the length and

Working Group 15

width columns (e.g., $= B_2 * C_2$). The use of multivariate formulas conceals the relationships between the length and area of the rectangles. That is, at this time in learning, Amy was able to generate multivariable expressions or recursive expressions.

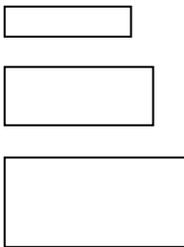

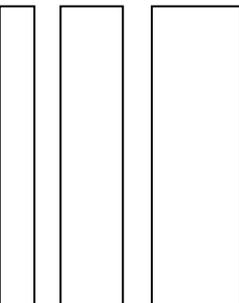

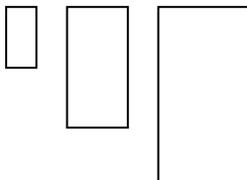

<u>Rectangle A</u>	<u>Rectangle B</u>	<u>Rectangle C</u>
		
<p>⋮</p>	<p>⋮</p>	<p>⋮</p>
<p>At the end of the first year, the rectangle's width is one unit, and it grows by an additional unit each year.</p> <p>The length of this rectangle is always longer than its width by three units.</p>	<p>At the end of the first year, the rectangle's width is one unit, and it grows by an additional unit each year.</p> <p>The length of this rectangle is constantly 10 units.</p>	<p>At the end of the first year, the rectangle's width is one unit, and it grows by an additional unit each year.</p> <p>The length of this rectangle is always twice the length of its width.</p>
<p>At what stages of the first ten years does the area of one rectangle overtake another's area?</p>		

Figure 1. Problem situation of the *Growing Rectangles*.

	A	B	C	D	E	F	G	H	I	J
1	Year	Wid. A	Len. A	Wid. B	Len. B	Wid. C	Len. C	Area A	Area B	Area C
2	1			1	10	1	2	$=B_2 * C_2$	$=D_2 * E_2$	$=F_2 * G_2$
3	$=A_2+1$	$=B_2+1$	$=C_2+1$	$=D_2+1$	10	$=F_2+1$	$=F_3 * 2$	$=B_3 * C_3$	$=D_3 * E_3$	$=F_3 * G_3$

Figure 2. Amy's Algebraic generalizations in Excel for the *Growing Rectangles*.

Example 2: October 14, Buying a Walkie-Talkie activity. The problem situation presented here concerned the weekly savings of eight children. Students were given the linear expressions which described these weekly savings (e.g., Moshon $30+5x$, Dina $7x$) and were asked to add pairs of children's savings in order to determine which pair will be the first to buy a Walkie-Talkie which cost \$400, as well as when this will occur. Amy organized her work in a spreadsheet table (Figure 3). She used three columns to describe each joined savings: two columns to describe each child's savings, and a third column to describe the joined amounts. Somewhat redundantly, she copied the savings of the same child in different columns, as can be seen in columns B and E in Figure 3. This organization of data is similar to the one observed

in the *Growing Rectangles* activity, in the sense that she used many more columns than the minimum needed. Yet, her symbolic generalization is somewhat different here. In this example, Amy used explicit expressions (columns B, C, E, and F) which reveal the full connections between the variable and the phenomena, to describe the individual savings (while in the previous activity mainly recursive expressions were used). On the one hand, these expressions were given to her and she did not have to create them on her own. On the other hand, other students in the class created recursive expressions in this activity, despite the fact that explicit expressions were given (Tabach, Hershkowitz, & Arcavi, 2008). Finally, it should be noted that the symbolic expressions created on her own in this activity used multivariate formulas to describe the joined amounts (Columns D & G).

	A	B	C	D	E	F	G
1	Week #	Dina	Karin	Dina & Karin	Dina	Moshon	Dina & Moshon
2	1	$=7*A_2$	$=10*A_2$	$=B_2+C_2$	$=7*A_2$	$=30+5*A_2$	$=E_2+F_2$
3	2	$=7*A_3$	$=10*A_3$	$=B_3+C_3$	$=7*A_3$	$=30+5*A_3$	$=E_3+F_3$
4	3	$=7*A_4$	$=10*A_4$	$=B_4+C_4$	$=7*A_4$	$=30+5*A_4$	$=E_4+F_4$

Figure 3: Amy's Algebraic generalizations in the *Buying a Walkie-Talkie* activity.

Example 3: October 18, Number Sequence task. This example concerns generalizing from a sequence of numbers. Figure 4 present a given sequence. The task was to find an expression that can be written in cell B₆, using A₆ as a variable.

	A	B
1	0	30
2	1	27
3	2	24
4	3	21
5	4	18
6	5	

Figure 4: The Number Sequence task

For Amy, finding an explicit expression for a given sequence at that time of the course was difficult. In trying to find the requested expression, Amy invented the following "story": "At the beginning of the year there were \$30 in a savings box. Each week, the amount decreased by \$3". Then she wrote the following expression in cell B₆: $30-3*A_6$. It seems that creating a story context served as mediation between the numbers and the expression, which then enabled Amy to create an appropriate symbolic expression. The idea of reverting to a story problem might have stemmed from previous mathematical tasks which were situated within a story context. In general, switching between different representations of a mathematical

Working Group 15

problem, between verbal, numerical, symbolic, and graphic representations, was common classroom practice. Still, Amy's solution method for this task was unique.

Example 4: Feb [2]. 19, Identical Columns activity. This example concerns making generalizations based on numbers and expressions. At this point in the year students had learned to present changing phenomena with symbolic expressions but had not yet learned to simplify these expressions. Children were given two sequences of numbers (in columns A and B) as well as instructions as to how the other columns should be filled in (see Figure 5 which displays the beginning of the Identical Columns activity).

Copy the following pairs of numbers to your spreadsheet:

	A	B	C	D	E	F	G
1	4	16					
2	2	13					
3	0	10					
4	-2	7					
5	-4	4					
6	-6	1					
7	-8	-2					
8	-10	-5					

1. a) Write in Column C the sum of the numbers from Columns A and B ($A+B$), and Write in Column D the sum $2*A + 2*B$
 - b) Use Columns A, B, or C in different ways, to create two additional columns that are identical to Column D.
2. a) Write in Column G the product $10*(A + B)$.
 - b) Use only Columns A and B in different ways to create other columns that are identical to Column G.

Figure 5: Identical Columns activity.

Amy's first answer to question 1b was $2*C$. Reviewing classroom transcripts revealed that this expression was based on numerical considerations, as the first number in column C is 20 and the first number in column D is 40. Amy's second answer was $A+A+B+B$. This expression was based on a more symbolic consideration - decomposing the expression $2A+2B$. Regarding question 2b, Amy used the same logic that proved to work in the first task, $A+B+A+B...$ that is decomposing the symbolic expression. Her second suggestion was $A*10+B*10$, which may have resulted from the original expression $10*(A+B)$ or from her first answer. Either way, this example demonstrates that Amy is working with symbolic expressions to create new explicit expressions. Amy used the Excel spreadsheet to verify the correctness of her expressions, checking if the created columns were indeed identical.

Example 5: March 16, The Secret Number activity. This example demonstrates generalizing from verbal instructions. During a whole class discussion, the teacher requested students to, "Choose a number, add 3 to the chosen number, multiply the sum by 2, and subtract 6". To the children's surprise, the teacher was able to guess each child's original number from the final result. Asked to solve this "mystery", Amy said that the obtained number is twice the original number. The teacher agreed, and asked for an explanation. Amy began, "Let's choose 2 as our number". She then followed the steps with her chosen number and upon reaching the step "multiple the sum by 2", explained that no matter which number is given, the result of this step is an even number. Although Amy was not able to fully explain why the resulting number is twice the original number, we see in her attempt to do so a form of "generalizing using a generic example" (Mason and Pimm, 1984). She used the number 2 as an example of "any number".

Students were then asked to invent a similar "game". Amy's game was: "choose a number, add 1,000,000 and multiply by 2, subtract 2,000,000 and then subtract the number you choose. You will get back your chosen number." This invented "game" is close to the original game which was presented by the teacher. However, her use of the number 1,000,000 shows exaggeration, as if once again, the specific example she chose was really a generic example. The use of a generic example is considered to be a step towards symbolic generalization (Mason and Pimm, 1984).

Example 6: April 15, Train story. This example was taken from a test and demonstrates generalizing from a story. Students were presented verbally with a story about a train. The train consisted of one engine and several cars. The engine had 6 wheels and each car had 4 wheels. Students were first asked to calculate the number of wheels on a train with 5 cars, and show their solution method. Students were then asked to find the amount of cars contained in a train with 34 wheels. In order to answer this question, Amy generated an explicit expression connecting the number of cars in the train to the total number of wheels, $6+4x$. She then wrote a relevant equation, $6+4x=34$, solved it, and correctly interpreted the solution in the given situation. Although computers were available for use during the test period, Amy solved this problem with pencil and paper without referring to a spreadsheet.

DISCUSSION

The discussion begins by summarizing the progress Amy made in her use of symbolic expressions. It then examines how Amy chose to use the available spreadsheet tool in this environment as she progressed in her use of symbolic expressions. In the first example, Amy used mainly recursive and multivariable expressions. In the second example, Amy was able to use given explicit expressions in a meaningful manner although on her own, she created multivariable expressions. In the third example, Amy was able to create explicit expressions, by making up a verbal story as a mediator between the sequence of numbers and the explicit

Working Group 15

expression. The fourth example showed initial considerations which were numeric, followed by transitions among explicit expressions. In the fifth example, Amy attempted to reveal hidden connections with the use of a generic example. Finally, in the last example, Amy is able to write an explicit symbolic expression related to a given problem, write an appropriate equation, and solve it.

Amy's use of symbolic generalization and the transition between the ones she used (multivariate recursive, and explicit) is dialectic – during the same activity she implemented more than one kind of generalization. This dialectic process indicates the complexity of working with symbols in general and with explicit expressions in particular. Symbolic expressions are condensed, especially explicit ones, and hence more sophisticated. Although Amy weaved back and forth between the types of expressions used, as her familiarity with the symbolic notations increased, we can detect a shift towards working more with explicit expressions.

Amy acted as a resourceful student. From the beginning of the school year she used Excel's symbolic notations in a flexible manner according to her needs. In the first two examples, she used the spreadsheet as a number generator to act upon while in the fourth example she used it as a verification tool to check her symbolic generalization. This represents a shift in the role of the tool – from a tool used in the process of production to a tool used in the process of control. Amy also had the freedom to choose when not to use the tool. In the third example, Amy turned to a different form of expression, verbal, in order to assist her in forming a symbolic expression. By the end of the school year, she was able to form an explicit symbolic expression without any mediating tools.

A tool is not automatically an instrument. "... it becomes an instrument when the subject has been able to appropriate it for himself and has integrated it with his activity" (Verillon & Rabardel, 1995, p. 84). For Amy, the spreadsheet tool became an instrument as she began to use it in a selective manner with control. By the end of the course, Amy was able to act without the tool and in this sense, the spreadsheet acted as a scaffold which was allowed to recede into the background. Amy's progress in symbolic generalization demonstrates that Excel did not limit her knowledge growth. In fact, it seems as though it facilitated her development.

NOTES

1. One may enter two numbers in two consecutive cells in the same column, and "drag" both of them together. The resulting numbers in the column will follow a sequence with fixed difference. We do not consider such an approach symbolic. For more information, see Tabach, Arcavi, & Hershkowitz, 2008).
2. During the months November, December, and January, students learned about negative numbers and the four operations, as well as Descriptive Statistics. Hence no data from this period is provided.

TEACHERS' AND STUDENTS' FIRST EXPERIENCE OF A CURRICULUM MATERIAL WITH TI-NSPIRE TECHNOLOGY

Per-Eskil Persson

Malmö University

In a pilot research project, a curriculum material intended for two mathematics courses at Swedish upper secondary school has been constructed. The material is written for the use of TI-Nspire technology, with which it forms a dynamic system. Three teachers and three classes replaced their textbooks with this material during a half semester, and their experiences, as well as the general learning outcomes for the students, were investigated using various methods. This paper describes some of the main findings of the study, along with the more important conclusions that could be drawn.

Keywords: CAS, curriculum, resource, practice, technology

CURRICULUM MATERIAL AND TECHNOLOGY

In mathematics instruction, textbooks can play a central role. This is especially true in Sweden, where it often defines the curriculum for both teachers and students. There exist strong beliefs among them that if you do not follow the textbook, you might not fulfil the curriculum and then you fail in the National Tests. These have to some degree rewarded the use of technology in mathematics education, but this has not yet provoked any more extensive changes of the textbooks. It is therefore of great interest to evaluate new types of material for classroom use that integrate technology in a more distinct way.

Within the project 'Nspirerande matematik', especially developed curriculum material was used for parts of the courses Matematik A and Matematik B at Swedish upper secondary school (student age 16-17). This material consists of both traditional texts and tasks, as in a common textbook, and of interactive material for the TI-Nspire technology (Fig. 1). These interactive files give the students opportunities to discover mathematical principles and rules, to make conjectures and justifications, to exercise their

Aktivitet AF 9: Andragradsfunktionen $f(x) = a \cdot (x + b)^2 + c$

Öppna aktivitetsfilen [andragrad_2.tns](#) och följ de instruktioner du får där.

Som du ser av bilden intill är $a = -1$, $b = 1$ och $c = 4$. Den avbildade funktionen är alltså $f(x) = -(x+1)^2 + 4$ som har ett maximum = 4 som inträffar då $x = -1$.

Vad händer om du ändrar c ?

Vad händer om du ändrar a ?

Vad händer om du ändrar b ?

Försök formulera en generell slutsats som anger koordinaterna för maximi- eller minimipunkten hos $f(x) = a \cdot (x + b)^2 + c$.

Hur påverkar a ditt påstående?

Figure 1: Example of a task for TI-Nspire

skills and to make self-tests of what they have learned. Some tasks are especially designed as activities for inquiry and collaborative learning. The material has been used in three classes from the theoretical programmes at different schools in the middle and southern parts of Sweden during spring 2010.

Both teachers and students had full access to both handheld units and computer software within the TI-Nspire technology, including links between the two. The technology used was in the form of a computer algebra system (CAS). It is important to note that the students were familiar with the handheld units prior to being introduced to the curriculum material.

PILOT TEACHERS AND CLASSES

The three teachers involved in the project were selected as well experienced and have taught mathematics for many years at upper secondary level. Technology in mathematics teaching was in no sense new to any of them at the initiation of the project. Graphing calculators have been standard equipment in all courses at upper secondary level in Sweden for many years, and skilful use of technology in different forms is especially promoted in mathematics curriculum. In the project, CAS was used in the curriculum material and also presupposed for solving some of the tasks and working with the special activities in the material. This, of course, could present different challenges to the teachers, depending on their prior experience of this technology (Weigand, 2007). A brief presentation of the teachers and their classes:

Anna is teaching at a school in the centre of a rather large city. The students at the school are mixed in several respects, and the motivation and the ability of the students also vary to a great extent. Some students have considerable problems with their mathematics studies, at the same time as some show great ambitions. In the class, which studied their first year at the Social Science programme, the students represented the whole scale, and the curriculum material was therefore chosen to be presented only in a smaller group (7-8 students). The material used was ‘Nspirerande matematik – Ma A’ (2010), more specifically the section with functions.

Carl and *Eric* are working at secondary schools in two middle-size towns. The students come from these towns and the surrounding rural areas, and both classes (≈ 25 students each) consist of combinations of those who study in the Natural Science and in the Technological programmes. The students are of mixed ability but generally rather motivated for studies in mathematics. The material used was ‘Nspirerande matematik – Ma B’ (2010), the section with algebra and functions, which represents the larger part of the course, and with probability.

AIMS FOR THE STUDY

The intention was to make a first evaluation of the use of curriculum material for the two mathematics courses, which is specially designed for the interactive use of TI-Nspire technology, based mainly on the experience of teachers and students. Of

special interest are the ways it was used in the classroom work and in the teachers' instructional practice, as well as how it affected the students' achievement. Both students and teachers had the opportunity to express their opinions of how well this material and this technology have functioned in a real educational situation. They have also been able to pinpoint possible problems and obstacles that they have encountered when using the material and/or the technology, as well as how it has affected the students' own motivation, interest and self-confidence when working with mathematical activities.

As being a pilot study, its intention was furthermore to form a basis for a larger evaluation study, which can involve more teachers and classes, and can stretch over a longer time period. In such a study, it can be possible, in other ways, to do research of more subtle outcomes of education, such as deeper understanding of mathematical concepts and methods and how robust knowledge is over time.

THEORETICAL FRAMEWORK

The theoretical background for this study rests on the classical *didactic triangle* with its three main elements student-teacher-mathematics, discussed for example by Steinbring (2005). This model has, however, been presented in various ways, depending on the overarching theory of learning and on the special context. The focus here lies on processes of mathematical interaction between individuals in the classroom (Cobb & Bauersfeld, 1998), a mainly social constructivist view. Learning takes place through experiences that are mediated by tools (Vygotsky, 1978), that can be mental (like spoken language), symbolic (like mathematical signs) or physical (like compasses), and with assistance drawn from other, competent individuals. Calculators and computer software hold a special position here, as they can be seen as tools within all three aspects.

A tool can develop into a useful instrument in a learning process called *instrumental genesis* (Verillon & Rabardel, 1995; Guin & Trouche, 1999). This process requires time and effort from the user. The user must develop instrumented action schemes that consist of a technical part and a mental part (Guin & Trouche, 1999; Drijvers & Gravemeijer, 2005). The teacher must actively guide the students in a controlled evolution of knowledge, achieved by means of social construction in a class community (Mariotti, 2002). Of special interest is the *instrumental orchestration*, which is defined as the intentional and systematic organisation and use of the artefacts available in a learning environment by the teacher, in order to guide students' instrumental genesis (Drijvers *et al.*, 2010). In the present research project, TI-Nspire CAS calculators together with emulating computer software are the physical parts of the instrumentation process. But the setting for this is within the curriculum material, which is intended as the basic mediating tool for the learning process, replacing the ordinary textbook.

Affective factors have been found to play a profound role in the outcomes of mathematical education. Debellis and Goldin (1997) suggested four facets of affective states: emotional states, attitudes, beliefs and values/morals/ethics. Especially the intentions and goals for the mathematical education that students and the teacher have are vital (Hannula, 2002). They are not always coinciding, and this is particularly the case when technological tools and mathematical texts are used in instruction. There are also other elements of attitudes and beliefs that teachers hold that can present obstacles and cause problems, such as the perceived change in their classroom practice or how they believe such teaching will impact on students' learning (Brown *et al.*, 2007; Pierce & Ball, 2009). This is especially true for CAS, which also has the problem of becoming legitimized within the school culture (Kendal & Stacey, 2002).

RESEARCH QUESTIONS

The research questions of the evaluation study are structured into three groups in accordance with the didactic triangle, and are generally based on the theoretical background and the aims for the study:

Effects on teaching practice and learners. How is the integrated system of technology and written content used in the classroom by teachers and students? What effects on classroom dialogue, student-student and teacher-student, can be detected when working with it?

Teacher experience of the system. How has the 'Nspirerande matematik' resources supported new approaches to teaching for the teachers involved in the project? Which difficulties or obstacles with using the material and/or the technology can be found?

Learning outcomes. How do the teachers in the project estimate the effects of the curriculum material on students' development of conceptual understanding? How does the use of the material together with the technology affect students' motivation, interest and self-confidence when working with mathematical activities?

RESEARCH METHODS AND DATA COLLECTION

This pilot study has the intention of giving a first and rather general view of the outcomes of the use of the curriculum material and the TI-Nspire technology, both in terms of students' and teachers' views of these and of possible learning results that can be connected with them. Thus a pragmatic use of mixed research methods has been appropriate, mainly focussing on qualitative approaches, but also with some quantitative elements concerning the ways the material and the technology are used in the classrooms.

The classes and the teachers that participated in the project were each visited twice during the project, and the methods used were the following:

Teacher lesson evaluations and observations. The teachers should fill in one form or log for each lesson in which they have used the material and the technology.

Teacher interviews. A deep, semi-structured interview with the teachers was made in connection with each visit at the schools. All interviews were transcribed.

Classroom observations. With each visit a lesson was to be observed by the researcher, using a special observation protocol.

Student interviews. Two students were chosen from each class to be interviewed in connection with the observed lesson at each visit, and these were also transcribed.

Teacher questionnaire. After finishing this pilot project each teacher was presented with questions concerning their overall experience of using the material and the technology in school instruction.

The teachers and the students used the material full time from an introductory meeting in March until the end of the semester. Visits were made as planned at the three schools by two occasions, one near the end of April and one near the end of May, at which time interviews were made and recorded. The three teachers as well as the students presented in most cases extensive answers to the questions asked, and also gave a clear impression of honesty in them. It was possible to discuss both their progress and their shortcomings with the material and the technology, and they reflected on what they had done in class, both in the middle of the project and at the end of it.

MAIN FINDINGS AND CONCLUSIONS

The acquired data from this study will not be presented in detail here. Instead some of its main findings are briefly stated and partly compared with other research.

Effects on teaching practice and the learners

The teachers made no essential alterations of their approaches or their working styles due to the system. Their lesson logs showed that they used essentially the same lesson plans and organisation of instruction during the project as before (mainly based on whole-class teacher's presentation, individual or cooperative students' work with teacher's support and finally a summary of the lesson). Maybe this was to be expected in such a short period, even if the material opens for change in many ways. For one of the teachers, this material was in line with what she was used to, but for the others it presented a challenge. However, some signs of progress and change could be detected at the end of the project for one teacher, in the direction of more exploring activities for the students. This could imply a partial change of attitude to the ways mathematics education can be performed (Brown *et al.*, 2007).

Two of the teachers did not use the calculators as tools for students own learning and exploring to any larger extent. Balling (2003) distinguishes between the use of calculators as calculating tools, teaching tools and learning tools. In the project, these two teachers mainly used them as extensions of the calculators they had used before,

which means as calculating and teaching tools. The CAS technology was also a problem for especially one teacher, who even doubted the positive impact on students' learning. This is also in accordance with what Pierce and Ball (2009) write about teachers' attitudes. Using CAS can be considered by the teacher as an extra burden, especially for weak students, and distract them from core mathematical learning.

The curriculum material replaced the usual textbooks and was printed out as compendia. In their evaluations of the material both teachers and students compared it with the textbooks in all details. In those cases where differences could be seen, many of the students, and also their parents, questioned if the material could provide the 'right' knowledge for the course, and there were worries about the results in the National Tests. Also the attitudes from colleagues and/or the principal for the school could have been of importance for the pre-attitudes (see Pierce & Ball, 2009).

The combination of the calculator and the material promoted students' discussions and presented opportunities to cooperate. In all three pilot classes, the students were used to work in pairs or in spontaneous groups. Much of the material was challenging for some students, in ways that the usual textbook did not match sufficiently. The technically advanced calculators also called for cooperation in acquiring proper action schemes (Drijvers & Gravemeijer, 2005). These two factors together created good opportunities for the students to develop a dialog on a rather advanced mathematical level, both with the teacher and with other students. Students from Erik's class:

Female student: Sometimes you want to work by yourself to get into it and understand, but it is very good to be able to help each other.

Male student: Yes, most of the time more will be done when you work in pairs. It is easier when you don't know.

Teacher experience of the system

During the project, no major obstacles or difficulties with the calculators appeared. Neither the teachers nor the students mentioned any larger problem with the technique or in the way the calculator software appears. Interesting was the description some students gave of the instrumental genesis with its different parts (Guin & Trouche, 1999) they had experienced, and what this also had taught them in terms of mathematics.

Anna's (female) student: I have no problems with new technology. I understand the calculator very well! The only thing is that you must remember all the steps, but the calculator in itself is quite simple to understand.

One teacher criticised the way CAS technology was used in the material. His impression was that this was written for the use of CAS and not for the mathematical knowledge.

Working Group 15

Erik: For the understanding of the concepts, I abandoned the technology. It is typical that CAS do it in this way, and therefore the material is adjusted for that. CAS in the centre. It rules over the material.

Belfort and Guimares (cited in Dick & Burrill, 2009) give a list of four possible shortcomings in constructing technology-based material, of which the first is: ‘The author’s interest is on mastering the use of the technology where the mathematics is secondary’ (p. 11). However, none of the other two teachers gave the same critique, and this might be misdirected in this case. The problem could instead lie in the fact that the use of CAS may change the classroom practice, which can be perceived by the teacher as a threat (Pierce & Ball, 2009).

The content of the material in combination with the technology caused problems for some students. The long texts and explanations with alternating sections of tasks were perceived as difficult by some students. This was especially true for students with lesser mathematical ability, for whom the longer activities or tasks became obstacles.

Erik’s student: It is frustrating if you are in a class and others have difficulties but not I. Then it takes very much time to get it to work for all students in the group.

Research points in diverse directions here. Ruthven and Hennessy (2002) report that access to technology enables less-able students to participate in exploration, while Tynan (2003) concludes that the technical overhead when learning new technological features could present an extra burden for these students. This is also mentioned as an obstacle by two teachers in the project, while the third one instead has observed this category of students succeeded quite well with such activities.

The opinions of how easy a teacher who is rather new to technology could start using it together with the material varied. One of the teachers perceived it as being fairly easy, calling for only a shorter introduction, another that a more thorough course was needed. The third teacher said that it was easier than he thought. One explanation to this could be that the material was used in different ways by them, and that the demands of certain knowledge therefore differed. This is in line with what other researchers have found (e.g. Ball, 2004), especially in the connection with the implementation of CAS into the classrooms. All three teachers also mentioned the need for an extensive teacher’s guide accompanying the material and that different kinds of support, mainly when they start using the material, would facilitate this implementation. Implementing in a larger scale has been researched for example by Ball (2004), and Pierce and Ball (2009). One conclusion these authors have drawn is: ‘The responses to this survey confirm that professional development for teachers needs to address attitudes and perceptions as well as technological skill development’ (p. 315). This is also the experience as expressed by the teachers in the present study.

Learning Outcomes

Two of the pilot teachers would not draw any certain conclusions about their students' development of deep conceptual understanding of mathematics. One obvious reason for this is the fairly short time-span of the project. To the teachers' meaning, such effects can only be detected in the longer perspective. However, their estimation was that the more mathematically able students have taken advantage of the material and the calculators in a way that in fact it has made it possible for them to develop this deeper understanding of concepts. At the same time, the lesser able students might be at the risk of having learned less than with the usual textbook.

One of the pilot teachers declared that her students had shown clear signs of a deeper conceptual understanding. This was also confirmed in the interviews with the students, who gave detailed descriptions of the laborious process to obtain this understanding. The students' results at the National Test gave more evidence that they really had understood mathematics at a more advanced and deeper level, and so did also the mathematical texts that the students handed in to the teacher. It is important to note that these students had not appeared to be among the most mathematically able ones when the project started.

Anna: The material is more stimulating than 'ordinary' books, and the interaction with the calculator develops a more investigating and inquiring attitude.

Anna: Before, I thought that you had to use the pencil to understand, but I see many today who 'think' with the keys.

The calculators have been stimulating for the interest, motivation and curiosity towards mathematics. This is common for all three pilot classes, even if it was not true for all individual students. It is also in accordance with what most research of the use of technology in mathematics education shows (see e.g. Persson, 2009). For most students, it was also their first contact with a more advanced calculator. In one of the groups, the students' attitudes and feelings towards mathematics had changed dramatically. Their comparison was mainly with what they had experienced of mathematics instruction at compulsory school. The details in the interviews give evidence that it was, at least to some degree, the text, the tasks and the activities in the material that caused this change. The students found the mathematics there interesting, challenging and useful, and solving the problems gave them better self-confidence and self-esteem (Hannula, 2002).

Anna's (female) student: This material has been extremely good and incredibly useful. Before, I had a hard time with maths, but now I have Anna and the material and new ways of thinking. So now I got a 'Pass with special distinction' at the National Test, which I had never dreamed of getting before. So it has improved my and the whole class' attitude towards math. And you have to think in new ways all the time, otherwise you don't find the right solutions.

Presently, a continuation of this pilot study has been initiated, in the form of a larger study involving more classes and teachers. It will take place during a whole semester, and the learning outcomes of the students will be in special focus (Artigue & Bardini, 2009). What are the conceptual and affective effects of using this kind of technology and curriculum material (now available at Nspirerande matematik, 2010), especially compared to common textbooks and the material linked to these?

TEACHERS TRANSFORMING RESOURCES INTO ORCHESTRATIONS

Paul Drijvers

Freudenthal Institute, Utrecht University

Mathematics teachers may perceive difficulties in orchestrating education which makes use of technological tools. With instrumental orchestration as a theoretical lens, we investigate into which types of orchestrations teachers transform the technological resources. In a pilot teaching sequence in grade 12 on using applets for practicing algebraic skills, this question is investigated through a case study, questionnaires, and interviews. The results show that teachers privilege orchestrations in which students work individually or in pairs, at the cost of whole-class orchestration types. Compared to their regular teaching practices and their expectations before the pilot, the involvement in the pilot causes teachers to adapt their orchestrations during the pilot.

Keywords: mathematics education, technology, teachers, orchestration

INTRODUCTION

Nowadays, teachers are confronted with a myriad of both material and electronic knowledge resources available for mathematics teaching. More and more, such resources can be accessed through technological means and are available on the internet. However, resources do not transform teaching practices in a straightforward way. Several studies show that teachers may perceive difficulties in orchestrating mathematical situations which make use of technological tools and resources, and in adapting their teaching techniques to situations in which technology plays a role (e.g., Gueudet and Trouche, 2009). Also, different teachers may adapt the same set of resources into quite different teaching arrangements.

As Robert and Rogalski (2005) point out, teachers' practices are both complex and stable. Building on this, it is argued that the availability of technological resources amplifies the complexity of teaching practices and, as a consequence, challenges their stability. It is not self-evident that techniques and orchestrations which are used in 'traditional' settings can be applied successfully in a technological-rich learning environment. A new repertoire of orchestrations, instrumented by the available tools, has to emerge. This involves professional development of the teacher, in which both professional activity and professional knowledge may change. This process of transforming sets of technological and other resources into orchestrations is the topic of this paper [1].

THEORETICAL FRAMEWORK

The main theoretical perspective that frames our investigation of teachers transforming resources into orchestrations is the notion of instrumental orchestration. It is widely acknowledged that student learning needs to be guided by the teacher through the orchestration of mathematical situations. For example, Kendal and Stacey (2002) showed that teachers privilege certain techniques for using technological tools over others and, in this way, guide the students' acquisition of tool mastery and their learning processes. To describe the teacher's role, Trouche (2004) introduced the metaphor of instrumental orchestration.

An instrumental orchestration is defined as the teacher's intentional and systematic organisation and use of the various artefacts available in a – in this case computerised – learning environment in a given mathematical task situation, in order to guide students' instrumental genesis (Trouche, 2004). We distinguish three elements within an instrumental orchestration: a didactic configuration, an exploitation mode and a didactical performance (Drijvers *et al.*, 2010). Didactical configurations and exploitation modes were introduced by Trouche (2004). As an instrumental orchestration is partially prepared beforehand and partially created 'on the spot' while teaching, we felt the need to add the actual didactical performance as a third component. Establishing the didactical configuration has a strong preparatory aspect: often, didactical configurations need to be thought of before the lesson and cannot easily be changed during it. Exploitation modes may be more flexible, while didactical performances have a strong ad hoc aspect.

Even if the metaphor of instrumental orchestration is appealing, it has its limitations like every metaphor. If we think of a teacher as a conductor of a symphony orchestra consisting of highly skilled musicians, who enters the concert hall with a clear idea on how to make the musicians play Beethoven the way he himself reads the century-old partition, we may feel uneasy with the metaphor. However, if we think of the class as a jazz band (Trouche and Drijvers, 2010) consisting of both novice and more advanced musicians, and the teacher being the band leader who prepared a global partition but is open for improvisation and interpretation by the students, and for doing justice to input at different levels, the metaphor becomes more appealing. It is in the latter way that we suggest to understand it.

Earlier research focused on the identification of orchestrations within whole-class technology-rich teaching. Drijvers *et al.* (2010) identified six types of such orchestrations, termed Technical-demo, Explain-the-screen, Link-screen-board, Discuss-the-screen, Spot-and-show, and Sherpa-at-work, with the following global descriptions. This categorization, with three more teacher-centred and three more student-centred orchestrations, resulted from a study on the use of applets for the exploration of the function concept in grade 8, and emerged from observation of three teachers in a relatively guided situation (Drijvers *et al.*, 2010). Of course, from

these limited data from a specific context, we cannot claim completeness. Rather, we wonder how specific this categorization is with respect to the type of technology, the mathematical topic, the whole class teaching format, the level and age of the students, and the amount of guidance teachers were provided with. Therefore, the goal of the study presented here is to investigate in another teaching context in which types of orchestrations teachers transform the available technological resources and how these results relate to the above categorization.

RESEARCH SETTING

The research was carried out in the context of a pilot initiated by the publisher of the main Dutch textbook series for secondary mathematics education. The publisher, seeking for ways to improve their product and to integrate technology, decided to offer to their customers' schools an online, interactive version of a chapter on algebraic skills such as rewriting expressions and solving equations for grade 12, the final year of pre-university secondary education. For this online module, the Freudenthal Institute's Digital Mathematics Environment (DME) was used. DME is a web-based environment which integrates a content management system, an authoring tool and a student registration system, and which already contains content in the form of an impressive amount of applets and modules (Bokhove and Drijvers, 2010). The module for this pilot was designed by the authors of the textbook series, supported by the Freudenthal Institute DME experts. The module includes tasks as well as video clips with elaborated examples. The levels of feedback to students' answers decreases as the module advances. A pdf file of the original textbook chapter was also made available online, with embedded links to the new online activities [2]. Figure 1 shows a part of the book file on the left, and one student's work in the digital environment on the right. The book text includes a reference to the online module and the task to solve two equations. In the right screen, the student makes a mistake in the last line, and gets feedback saying "This step contains both correct and incorrect parts. Remove or replace the incorrect parts".

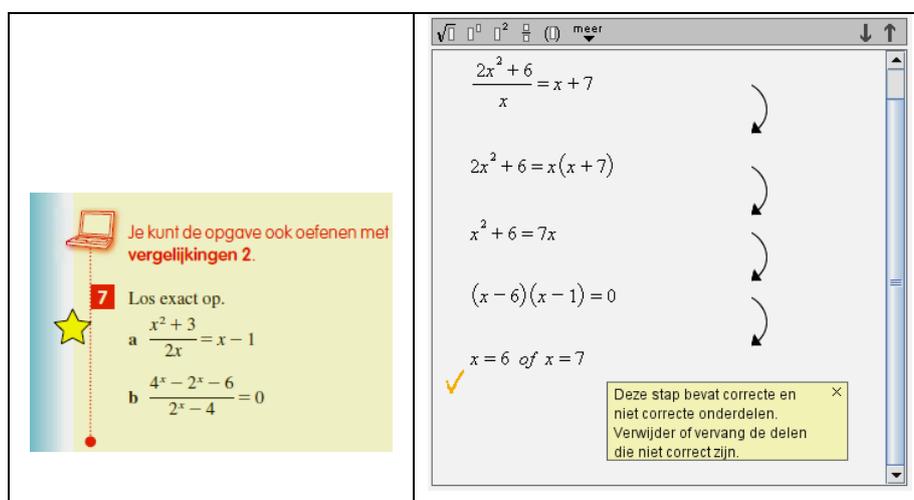

Figure 1: Screen shots from book (left) and digital environment (right)

After a message by the publisher, 69 teachers volunteered to join this pilot teaching sequence. They were provided with online guidelines for the use of the module. For the students, the resources in this pilot include the regular textbook, the online book chapter, digital modules including feedback and video clips, and the traditional resources such as paper and pencil and calculator. As the work is stored on a central server, students can access, revise and continue their work at any time and from any place with internet access. For the teacher, the resources are similar, but with the additional option of access to student work. Overviews of whole class results as well as individual student work can be monitored by the teacher through the internet.

METHODS

The research methods include a case study focusing on one teacher and a survey among all 69 participating teachers. The case study was carried out in two classes of one of the pilot schools, a school in a small, prosperous town in the Netherlands with mainly 'white' student intake. Both classes, with 30 and 14 students, respectively, were taught by the same, experienced teacher. He initially volunteered for the pilot, but later intended to step back, because computer facilities in school were insufficient and his students objected to the idea of practicing algebraic skills with the computer, whereas they would need to master them with paper and pencil in the national central examination. We were able to offer a loan set of 30 netbook computers for the period of the teaching sequence and we convinced the teacher that practicing skills with computer tools was expected to directly transfer into better by-hand skills. Then, both the teacher and his students accepted to participate. During the period of the pilot, this teacher had a heavy teaching load, with 26 50-minute lessons a week to teach. A technical assistant was available in school to set up the classes with the netbook computers, and to make other practical arrangements such as charging the batteries, et cetera.

Most of the lessons (23 out of 36 during an 8-week period) were observed and videotaped. The video registration was done by a mobile camera person, who followed the teacher very closely during individual teacher-student interactions, so as to capture all speech and screens. Data analysis took place with software for qualitative data analysis and focused on orchestrational aspects of the teaching.

The very specific data from the case study were complemented with data from a survey among all participating teachers. It consisted of two online questionnaires, one before and one after the teaching sequence. The response was 49 out of 69 for the pre-questionnaire, and 41 out of those 49 for the post-questionnaire. Non-response was caused by the fact that not all teachers who originally volunteered for the pilot really started their participation, and that some of the teachers who filled in the pre-questionnaire did not start either, or stopped the pilot before bringing it to an end. Some of them sent messages by email, indicating reasons such as time constraints, lesson cancellation because of illness, or other unforeseen circumstances.

RESULTS FROM THE CASE STUDY

In the case study one particular orchestration type was highly dominant. We call it *Work-and-walk-by*. The didactical configuration and the corresponding resources basically consisted of the students sitting in front of their netbook computers, with wireless access to the online module and their previous work as well as to the textbook chapter in pdf format. In addition to this, a blackboard or whiteboard allowed the teacher to write down additional explanations. A data projector showing the online environment was available in most lessons, but was hardly used. As exploitation mode, the students individually worked through the online module on their netbook computers, and the teacher walked by and sat down with students to answer questions and eventually monitor the students' proceedings (see figure 2). As a reaction to student questions, the teacher in some cases went to the blackboard to write down an algebraic explanation or technique, but still speaking to the individual student who had raised the issue. Concerning the didactical performance, the initiative for teacher-student interaction was taken by the student in almost all cases. If an interaction with a student led to a new insight for the teacher, such as an understanding of a technical issue, he sometimes went back to students whom he had previously spoken to on a similar issue, as to disseminate the news.

Figure 2: The teacher (left) helping a student (right) individually

One aspect of this *Work-and-walk-by* orchestration concerns the determination of students' difficulties. If a student has a question while the teacher walks by, the latter is faced with the issue of where the heart of the problem lies: is it a lack of the student's algebraic understanding or skill? Is it a technical problem caused by the student, for example a mistake in entering an expression? Or is it a limitation of the online module, which in some cases gave inappropriate feedback, and was very strict in expecting a specific answer? Determination was difficult and mismatches between student problems and teacher reactions could be observed. Determination in some cases was hindered by the technical issues. As the teacher himself was not familiar with the module, he often was unable to solve students' problems, which led to uncertainty about whether it was a mathematical mistake or a technical problem that caused the technology to report an error. There was little technical guidance or

attention to students' instrumental genesis, and Technical-demo orchestration were not observed.

Figure 3: Overview of student results generated by the DME

This Work-and-walk-by orchestration took at least 90% of the lesson time in the lessons we observed, and remained dominant throughout the pilot teaching sequence as a whole without much variation; still, some changes over time in its didactical performance, and in the type of teacher-student interactions in particular, could be noticed. First, later in the teaching sequence, when he had time to find out how it worked, the teacher used the data projector to show the overall advancements of the students, so that each individual student could monitor if he or she was more or less on schedule (see Figure 3). Second, as both teacher and students during the teaching sequence got more familiar with the online module, its technical demands and its feedback, the student questions and the student-teacher interactions gradually focused more on algebra and less on technical issues. As a consequence, the character of these interactions changed from technical discussions into ‘Explain-the-screen’ or ‘Discuss-the-screen’ interactions. Also, the teacher went to the board less frequently, but instead used the online module more often as an environment to check algebraic claims or techniques. He encouraged students to type something in to see if it is correct, and used this as a way to explain the algebra.

If we relate the findings presented in this section to the six whole-class teaching orchestrations types identified above, we already noticed some Explain-the-screen and Discuss-the-screen elements within the didactical performance of the Work-and-walk-by orchestration. The same holds, to a lesser extent, for the Technical-demo orchestration: technical issues regularly emerged in the individual student-teacher interactions, even if the teacher was in many cases not able to solve them. Elements of the Link-screen-board orchestration could also be observed, as the teacher regularly walked to the whiteboard to explain the algebra, or used paper and pencil to do so. The Spot-and-Show opportunities that the didactical configuration offers were

not exploited. The same holds for the Sherpa-at-work, even if the teacher by the end of the teaching sequence invited students to carry out a specific technique in the digital environment, which can be seen as an individual ‘Sherpa-at-work light’.

RESULTS FROM THE SURVEY

Even if the word ‘orchestration’ was not mentioned in the questionnaires, they provide insight in the orchestrational choices made by the participating teachers. For example, one question on both the pre- and the post-questionnaire was: which ICT-means were used? In the pre-questionnaire this concerned the use of technology in the teacher’s lessons preceding the pilot; in the post-pilot questionnaire, this concerned tool use during the pilot. Participants could click on more than one answer. Table 1 summarizes the findings. Data shows that the technological devices which are most frequently used during the pilot are the computer lab and students’ computers at home, which contrasts to the more teacher-driven ‘regular’ use of ICT before the pilot. Teachers seem to have changed the didactical configurations for the case of the pilot.

ICT-means used (more answers possible)	Pre-pilot (N=47) Frequency (%)	Post-pilot (N=41) Frequency (%)
Data projector	57	46
Teacher’s computer	57	32
Interactive whiteboard	55	37
Computer lab	0	83
Student computers in classroom	0	29
Students’ home computers	0	83

Table 1: ICT means used during the pilot

One question on the pre-pilot questionnaire concerned the working formats the teachers were expecting to use during the pilot, and a similar one on the post-pilot questionnaire asking which working formats they used indeed. Table 2 summarizes the findings. It shows that individual work, work in pairs and homework are the most frequently used working formats, whereas whole-class explanations and whole-class homework discussion occurred less than expected beforehand, in spite of the opportunities the didactical configuration offers for it.

Working formats	Expected (Pre-pilot, % of N=47)			Effectuated (Post-pilot, % of N=40)		
	Not	Sometimes	Often	Not	Sometimes	Often
Whole-class explanation	0	36	64	32	48	20
Whole-class demonstration	19	62	19	38	47	15
Whole-class homework discussion	4	47	49	40	47	13
Whole-class presentation	57	38	2	100	0	0
Individual work	6	26	66	2	2	96
Work in pairs	9	30	60	28	25	47
Group work	53	38	4	93	5	2
Homework	23	28	47	7	53	40

Table 2: Expected and effectuated working formats used during the pilot

A follow-up question in the post-pilot questionnaire was whether technology was used in the mentioned working formats. The results shown in table 3 confirm the previous impression, namely that technology during the pilot was mainly used for

Working Group 15

individual work, work in pairs and homework, and not so much in whole-class orchestrations.

In this light it is somewhat surprising that the option to show students' home work by means of a data projector or interactive whiteboard, and to use it as a catalyst for whole-class discussion, was hardly used, whereas the teachers usually used such technology in whole-class teaching settings according to the pre-pilot questionnaire results. Even if the teachers beforehand expected some more individual work or work in pairs, this seems to have happened to a larger extent, and opportunities for using ICT in the way they were most familiar with, remained unexploited.

ICT in working formats	Post-pilot (% of N=41)		
	Not	Sometimes	Often
Whole-class explanation	58	32	10
Whole-class demonstration	41	24	20
Whole-class homework discussion	61	34	5
Whole-class presentation	98	2	0
Individual work	15	5	80
Work in pairs	51	17	32
Group work	93	5	2
Homework	24	32	44

Table 3: ICT used in working formats

To summarize the findings from the questionnaires, we conclude that before the pilot, teachers indicated that they used technology mainly in whole-class teaching settings, probably with the teacher operating the technology. In spite of this preference and experience, during the pilot they privileged individual work and work in pairs, which turn out to be the dominant orchestrations, and thereby neglected options for whole-class teaching offered by the technology. This is in line with the findings by Lagrange and Caliskan (2009). Even if the variety among all teachers seems to be greater than was observed in the case study, the results point into the same direction. They suggest that many teachers in the pilot changed their orchestrations from whole-class teaching using tools such as a data projector or an interactive whiteboard to student-centred orchestrations, for example in computer lab and home settings. Compared to the teachers' experiences with technology in their teaching, this is a shift from the teachers using technologies such as interactive whiteboards and data projectors, towards students using mainly computer labs and home computers.

It is not clear if the six identified whole-class orchestration types also appear in the context of this pilot. The questionnaires do not offer enough information. The focus on individual work and work in pairs is clear, but we do not know what happened besides that. Spot-and-show orchestrations and Sherpa-at-work orchestrations, however, do seem to be very rare, even if some teachers in the interviews reported incidentally using these orchestration types.

CONCLUSION

A first aim of this study was to investigate in which types of orchestrations teachers transform the available technological resources. The findings from both the case study and the questionnaires – albeit the first to a greater extent than the second – suggest that individual, student-centred orchestrations are dominant when teachers use the resources that were developed in the frame of this pilot. Teachers tended to privilege students working individually or in pairs on the online module tasks, and devoted little time to whole-class explanation or homework discussion, whereas their expectation before the pilot were different. The case study resulted in the identification of a Work-and-walk-by orchestration, which in itself is not very surprising one. However, we were surprised by its dominance and by the fact that other orchestrational opportunities of the available technology were not exploited, whereas more variation could be observed in this teacher's regular lessons.

Several factors may explain this phenomenon. First, the subject, practicing algebraic skills, probably is more suitable for individual work or work in pairs than for whole-class teaching. Second, the computer labs, in which many lessons apparently took place, may be less suitable for whole-class teaching. Third, individual orchestration types are probably the easiest thing to do for a teacher, who is not feeling confident about his or her own technical skills. Fourth and final, it may be the technology itself that invites student work rather than whole-class teaching. Our impression from interviews with teachers is that all these factors play a role. Data is insufficient to decide on the impact of each of them.

A second point of interest is how these results relate to the orchestration types mentioned in the theoretical section. This typology emerged from whole-class teaching episodes, whereas in this pilot mainly individual orchestrations were found. Still, the case study observations suggest that the six whole-class teaching orchestration types identified earlier have their counterparts, or at least similar aspects, in the context of the present study. The overall conclusion, therefore, is that the six whole-class orchestration types of course are not exhaustive, but do contain elements that can be observed in other orchestrations as well. We expect the list of possible orchestrations to be extended in future, not as to strive for a complete list, but as to provide teachers with a diverse repertoire of possible orchestrations as source of inspiration to their professional activity.

A third and final point of interest concerns the change processes that occur when teachers engage in an experimental setting. The conclusion here is twofold. First, the case study provides insight in the change process during the pilot teaching sequence. The findings suggest a stable and not so dynamic orchestration, in which there is not much change, at least not at the superficial level. Meanwhile, at the level of didactical performance some professional development was observed, showing for example an increased focus on the algebra and on what we might call 'Explain-the-screen', at the cost of attention to technological issues. Second, the findings of the

Working Group 15

questionnaires shed light on the change that takes place when teachers engage in such a pilot, compared to their regular teaching practices before the pilot. The data suggest that many teachers, who were used to integrating technology in a teacher-centred way – the teacher using a computer connected to a projector, or using an interactive whiteboard – in the frame of this pilot switched to student-centred orchestrations. It seems that most of them did not extend their teaching technique repertoire during the pilot sequence with, for example, a Spot-and-show orchestration type, even if the technology supports the monitoring of student work by the teacher anytime and anyplace.

THE USE OF MATHEMATICS SOFTWARE IN UNIVERSITY MATHEMATICS TEACHING

Iiris Attorps, Kjell Björk and Mirko Radic

Department of Electronics, Mathematics and Natural Sciences, University of Gävle,
Sweden

In this paper we report on a teaching experiment regarding the definite integral concept in university mathematics teaching. The experiment was carried out at a Swedish university by using the free dynamic mathematics software GeoGebra. In our theoretical framework we apply Variation Theory, originating in the phenomenographic research tradition. The data of this study consist of the lecture plan and the engineering students' answers to pre and post tests. In the analysis of the data we applied statistical methods. The experiment revealed that by using GeoGebra it is possible to create learning opportunities of the definite integral concept that support the students' learning.

Keywords: definite integral, geogebra, learning, variation theory

introduction

There is a constantly increasing number of software packages that can be used as powerful tools in mathematics teaching. Recent research shows that computer programs such as Maple, Mathematica, Derive, Geometer's Sketchpad, GeoGebra, when used in a classroom, support creative discoveries and mathematical generalizations (Lavicza, 2006).

It has been shown that students who use technology in their learning had positive gains in learning outcomes over students who learned without technology (Camacho-Machín *et al.*, 2010; Camacho-Machín & Depool Rivero, 2003; Touval, 1997). Regardless of evidences of several benefits of using technology, the process of applying technology for mathematics education is slow and complex (Cuban *et al.*, 2001).

Several studies have highlighted difficulties that students encounter with the integral concept. In an early study carried out by Orton (1980), it was observed that students

had difficulty with the integral $\int_a^b f(x)dx$ when $f(x)$ is negative or b is less than a . In

another study by Orton (1983), it was noticed that some students found it difficult to solve problems related to the understanding of integration as a limit of sums.

Our earlier research (Attorps *et al.*, 2010), in line with other studies (Blum, 2000; González-Martín & Camacho, 2003), has even pointed out that students have an intention to identify the definite integral as an area. Further, Rasslan and Tall (2002) verified that a majority of the students cannot write meaningfully about the definition of the definite integral. In a similar way, studies concerning learning of calculus

concepts (Attorps, 2006; Rösken & Rolka, 2007; Viirman *et al.*, 2011) have shown that definitions play a marginal role in students' learning whereby intuition inherent in concept images dominates the concept learning.

Transformation from procedural to conceptual understanding of the concept of integral requires gradual reconstructions of students' perceptions. Research has however documented the limitations of standard teaching methods, showing that students become reasonably successful on standard tasks and procedures but have difficulties in developing a solid and conceptual understanding of the topics itself (Artigue, 2001).

The Variation Theory

The variation theory is a theory of learning, which is based on the phenomenographic research tradition and described by Marton and Booth (1997). The main idea in the phenomenography is to identify and describe qualitatively different ways in which people experience certain phenomena in the world, especially in an educational context. There are two main principles in variation theory. The first one is that learning always has an object, in our case the definite integral concept. The second one is that the object of learning is experienced and conceptualized by learners in different ways.

The object of learning can be seen from teacher's, student's and researcher's perspectives. The *intended* object of learning is the object of learning as seen from the teacher's perspective. It includes what the teacher says and wants the students to learn during the lecture. The students experience this intended object of learning in their own way and what they really learned - the outcomes of learning - is called the *lived* object of learning. Hereby, it is easy to understand that students' learning does not always correspond to what the teacher's intention was with the lecture. The *enacted* object of learning as seen from the researcher's perspective defines what is possible to learn during the lecture, to what extent, and in what forms the necessary conditions for specific object learning appear in a classroom setting. The enacted object of learning describes the space of learning, which students and teacher have created together. In this space it is possible for students from their previous learning experiences to discern critical aspects of the object of learning (Marton *et al.*, 2004).

In the variation theory, the experience of *discernment*, *simultaneity* and *variation* is a necessary condition for learning. Variation is the main concern in this theory and a primary factor in supporting student's learning. In order to understand what variations to use in the classroom to promote student's learning, it is first necessary to understand the varying ways students experience something. We can use this information to identify ways to encourage students to discern other aspects of the learning object, the aspects they have previously not discerned.

Every concept, situation or phenomenon has particular aspects and if an aspect is varied and another remained invariant, the varied aspect will be discerned. The

Working Group 15

understanding of the object of learning in a certain way requires the simultaneous discernment of critical aspects of the object of learning (Marton & Morris, 2002; Marton *et al.*, 2004). The theoretical elements - *discernment*, *simultaneity* and *variation* related to learning and supposed to be critical for learning to happen - can be also used as an analytical tool for analyzing teaching (ibid). As a result, learning and teaching is brought closer together.

The purpose of the study

The aim of our study is to design teaching sequences for definite integrals, using GeoGebra, which can support the students' learning in university mathematics. To that end, we seek an answer to the following question: Is it possible to use GeoGebra as a pedagogical tool within the variation theory, in order to vary critical aspects of the concept of definite integral during a lecture in an introductory calculus course?

Method and design of the study

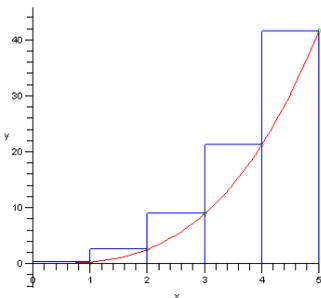

The study took place during a lecture in mathematics at a Swedish university. A total of 17 Chinese engineering students were involved in our study. The data were gathered by doing pre and post tests concerning the definite integral concept. In the analysis of the pre and post test results, statistical and qualitative analysis methods were applied.

The questionnaire

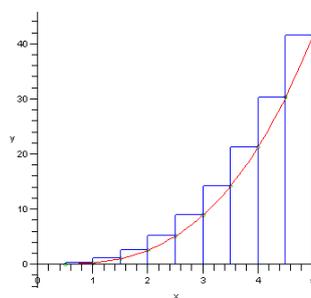

The questionnaire contained 6 questions, including not only 'typical' questions (Questions 2, 3, 5 and 6), but also intuitive questions (Questions 1 and 4). Maximal point in each question was three. Students had 25 minutes to do this test. In both pre and post tests, the same questionnaire was used. It was not allowed to use technical facilities.

Question 1. If you want to calculate the area between the curve and x-axis when $x=0$ and $x=5$ (see the graphs below) you can get an approximate value of this area by calculating the areas of the columns and by adding them.

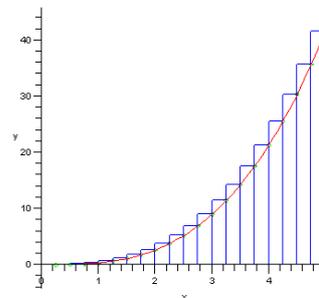

- a) Which of the following graphs should you choose in order to make the error as small as possible?

Graph 1

Graph 2

Graph 3

- b) Can you answer why?

Working Group 15

The aim of the first question was to test the students' intuitive conception about the definite integral concept as a limiting process. In this case it is about the upper Riemann sum.

Question 2. What is this $\int_a^b f(x)dx$ (the definite integral of the function $f(x)$ in the interval $[a, b]$) according to your opinion?

The second question was to test how the students grasp the conception of the definite integral.

Question 3. There are some approximate values of x and $F(x)$ below:

x	1	2	3	4	5
$F(x)$	-1	-0.61	0.30	1.55	3.05

You know that $F'(x) = \ln x$. Approximate the value of $\int_3^5 \ln x dx$.

The purpose of the third question was to test how the students can apply the Fundamental Theorem of Calculus [1].

Question 4. The following is given: $\int_{-1}^5 f(x)dx = 2$ and $\int_{-1}^7 f(x)dx = -1$. Evaluate $\int_5^7 f(x)dx$.

The intent of the fourth question was to test the students' knowledge of the properties of the definite integral concept.

Question 5. Can you find any error in the following reasoning?

$$\int_{-1}^1 \frac{dx}{x^2} = \int_{-1}^1 x^{-2} dx = \left[\frac{x^{-1}}{-1} \right]_{-1}^1 = \frac{-1}{1} - \frac{-1}{-1} = -2$$

The aim of the fifth question was to test if the students grasped when it is possible to apply the Fundamental Theorem of Calculus.

Question 6. Find the area of the region, which is limited by the functions $f(x) = 0,5x^2$ and $g(x) = x^3$. Give an exact answer.

The idea of the last question was to test how the students comprehended an ordinary high school example of the definite integral. We also wanted to find out how the students could master calculation with fractions.

Results

Before designing our lecture, we analysed carefully the pre test results in our study. The aim of the pre test was to identify if the students have some initial conceptions concerning the definite integral concept. Although the concept in China is normally introduced first at the university level (Wang, 2008), we could find that most of the

students showed quite a good intuitive conception of the concept as a limiting process (Question 1) and of the properties of the definite integral concept (Question 4). By reading earlier research, we could find that many students often have only an area conception of the definite integral (see e.g. González-Martín & Camacho, 2003). Furthermore they cannot meaningfully define the definite integral (Rasslan & Tall, 2002). Having this information about the students' conceptions, we designed our lecture. In order to create different teaching sequences that could encourage students to discern varying aspects of the object of learning, we used GeoGebra.

Teaching sequences

Teaching sequences were implemented in an ordinary lecture with teacher manipulating the computer and students observing the screen. In the first application of GeoGebra (Fig. 1), we introduced numerical approximation of the area (Lower and Upper Riemann sums), as well as the definition of the definite integral with inherent infinite processes.

Figure 1 visualizes the concept of the Riemann integral using lower and upper sums. Two points a and b are shown that can be moved along the x-axis in order to modify the investigated interval. The upper and lower values together with their differences are displayed as a dynamic text which automatically adapts to modifications. In this case we keep f and the interval invariant and vary the number of subintervals. By increasing the number of subintervals, we shorten their length. Our intention was to show that increasing the number of subintervals decreases the difference between the Lower and Upper Riemann sums, which shows that the Lower and Upper Riemann sums eventually coincide with the value of the integral.

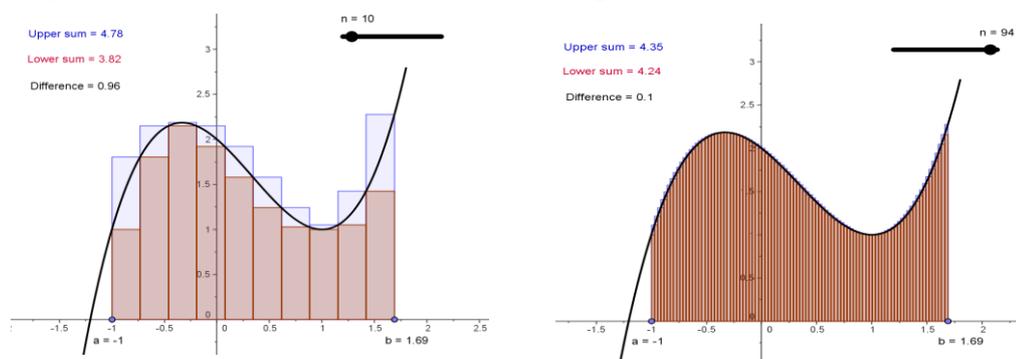

Figure 1: Lower and Upper Riemann sums and inherent infinite processes

The second example (Fig. 2 and 3) should help the students to get a wider conception of the definite integral concept. Figures 2 and 3 visualize the Riemann integral related to the area between the function f and the x-axis. Two points a and b are shown that can be moved along the x-axis in order to modify the investigated interval. The area and the integral values are displayed as a dynamic text which automatically adapts to modifications. This time we keep only f invariant and vary both the length of the interval and the upper and lower limit points. Our aim with this teaching sequence was to show that the value of the area between the function and

the x-axis and the integral-value not always coincide. While the area is always a non-negative (but not necessarily constant) real number, the integral-value can be any real number.

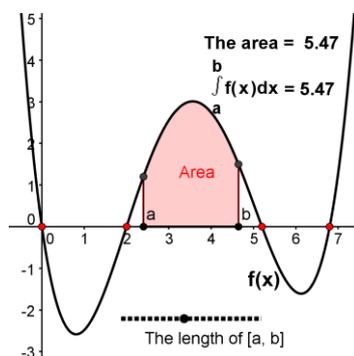

Figure 2: The value of the definite integral is identical to the area between function and x-axis in the interval $[a, b]$

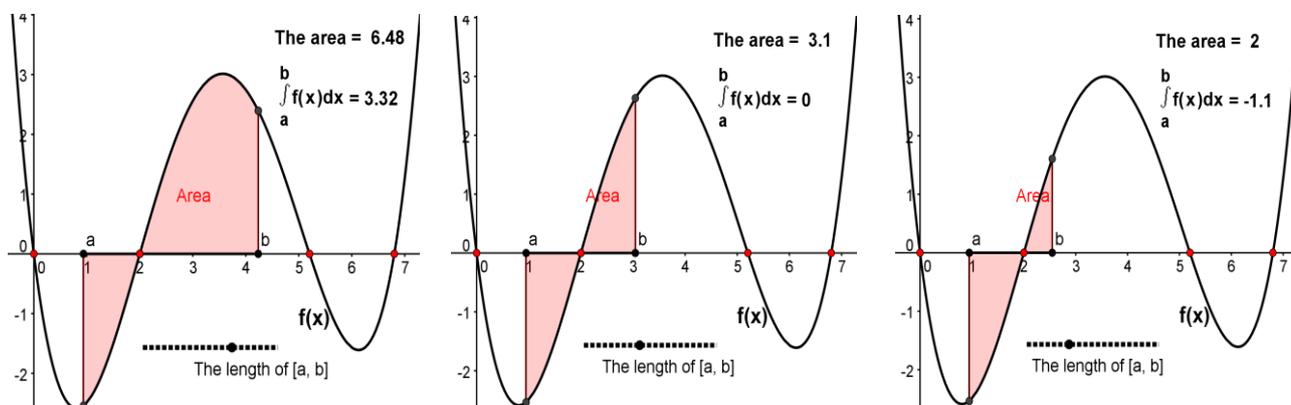

Figure 3: The definite integral as a real number, which can be positive, zero or negative

Our ambition with the third presentation (Fig. 4) was to help the students discern situations when it is possible to apply the Fundamental Theorem of Calculus and when it is not.

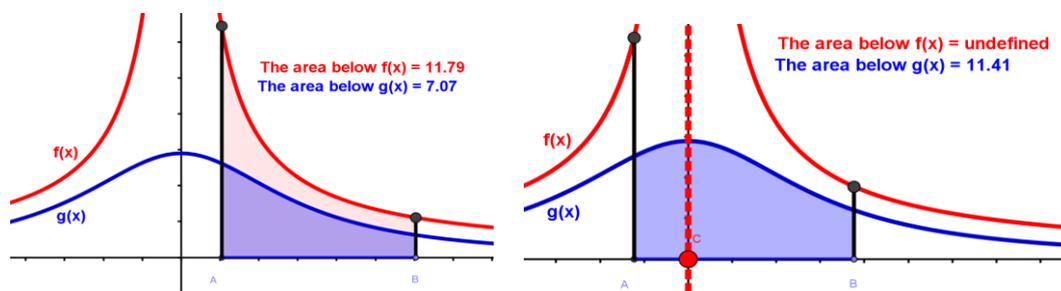

Figure 4: Visualization of the application of Fundamental Theorem of Calculus

In Fig. 4 on the left, it is possible to apply the Fundamental Theorem of Calculus, because both of the functions f and g are defined and continuous in the closed and bounded interval from A to B . In Fig. 4 on the right, it is not possible because f is not defined and by that not continuous in the interval. By moving the point A along the

Working Group 15

x-axis we can vary the position of the investigated interval. In this teaching sequence we keep the length of the interval and the functions f and g invariant.

Pre and post test results

The analysis of the data from the pre and post tests was done with a statistic program, the Minitab package. Using the significance level of 95% and a paired-samples one-tailed t -test, we compared the means of the test results for each problem. The group consisted of 17 participating Chinese students.

The pre and post test results indicate that there are statistically significant improvements in all the questions after the GeoGebra designed teaching practice.

Question number	Pre test mean	Post test mean	p	Maximum scores
1	1.588	2.059	0.014*	3
2	0.059	0.647	0.000*	3
3	0.176	2.471	0.000*	3
4	0.529	2.647	0.000*	3
5	0.000	0.941	0.007*	3
6	0.118	2.765	0.000*	3

* $p < 0.05$

Table 1: Pre and post test results for the group of Chinese students

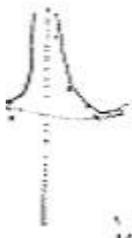

The students' scores in question 1 show that their intuitive understanding of the definite integral concept was quite good already at the beginning. One of the students explained in the post test the question 1 in the following way:

“The difference between the area of columns and the curve is smaller as the columns become smaller and smaller, more and more”.

The scores in questions 2 and 5 remained low in both pre and post tests. The most typical explanation to question 2 was:

“Points a and b are the intersection points of the two functions and we can calculate the area”.

In our qualitative analysis of the results we could notice that most of the students still grasped the integral concept as an area. Pre and post test results in question 5 showed that many of the students failed to give an adequate response in question 5; most of them could not find any errors at all. One of the students who succeeded to motivate his answer in post test explained:

The Integral is undefined on that interval, because the function is not define when $x=0$, so, the calculation is wrong, we can not calculate the integral on that interval.

We also noticed that nearly all the Chinese students in the post test were successful in question 6, showing good ability to calculate with fractions.

Discussion

The integrating of mathematical software in teaching and learning at the university level is important due to its ability to give quick feedback and help students visualize and discern simultaneously varying aspects of the object of learning (Marton & Morris, 2002). One of the aspects is the understanding of the definite integral in a wider context as a real number and not only as an area. We could observe that the use of the GeoGebra software during the lecture increased the students' possibilities to experience the intended object of learning, namely the concept of the definite integral as a real number. In our post test results we could notice that most of the students still grasped the integral concept as an area (cf. González-Martín & Camacho, 2003). Hereby, the students' learning didn't correspond to what our intention was with the lecture. In our opinion, the definite integral concept is too tightly connected with the area conception in textbooks used at the upper secondary and even at the university level. Since in traditional classroom settings typical examples from the textbooks are primarily used to introduce a new concept, it is not so surprising that the students often have narrow conceptions of the mathematical concepts. The acquired experiences from the concept learning seem to be too solid and perhaps prevent adequate learning of the intended mathematical theory.

The understanding of the definite integral concept and the Fundamental Theorem of Calculus unavoidably requires that a student must at the same time focus on quite many separate elements of knowledge. Many of them are given in a symbolic or implicit form, which presupposes that learners can distinguish several aspects of the concept simultaneously. Pre and post test results showed that many of the students failed to give an adequate response in question 5. We think that the students should be trained to use definitions as an ultimate criterion in teaching and learning of mathematics. We see a clear potential in using GeoGebra within the variation theory, but we mean that it covers only one of several representations, which could be used in mathematics teaching.

Working Group 15

Further studies need to be undertaken to identify which other factors than the integration of technology in teaching and learning of mathematics can be of benefit to both educators and students. Therefore, it would be interesting to design a study by choosing two groups of students; in one group lectures on Calculus will be conducted without any software package and in the other group the teaching block of Calculus will be created by using GeoGebra.

NOTES

1. Suppose that

a) a function $f(x)$ is defined and continuous on the interval $[a, b]$

b) $F(x)$ is an antiderivative of $f(x)$ on the interval, i.e. $F'(x) = f(x)$ for all x in $[a, b]$. Then

$$\int_a^b f(x)dx = F(b) - F(a) \quad (\text{Adams, 2006})$$

CALCULATORS AS DIGITAL RESOURCES

Gilles Aldon

INRP (Institut National de Recherche Pédagogique), S2HEP Université Lyon 1

New handheld calculators can be seen both as artefact allowing calculation and representation of mathematical objects, and resources for students and teachers allowing to store and to share data. Both teachers and students get hold of these potentialities and develop their own uses in distinct dynamics. Studying the interactions between teachers and students gives clues to understand the trajectories of these dynamics and the role played by the calculators in the construction of knowledge. Taking the opportunity of a broad introduction of handheld calculators in classrooms, we observe the conditions allowing transforming the artefacts into documents, part of the set of resources of teachers and students. The methodology takes into account long time observations, in a qualitative case study. The results show how different functionalities can be shared among teachers and students but also why and how other functionalities remain private and hidden.

Keywords: Handheld calculators, instrumental genesis, digital resources, interactions, documents

INTRODUCTION

There is a call for renewal of teaching methods in secondary science education as Rocard *et al.* (2007) state. The question of the place and the role of technology in the scientific classes in order to acquire “*good scientific knowledge and an understanding of technology*” (ibid., p. 6) should be addressed. There is a general agreement that technology brings an increase in collaborative forms of work (Peschek & Schneider, 2002; Kieran & Drijvers, 2006; Zbiek *et al.*, 2007). At the same time, new handheld calculators appear in the classrooms with calculation possibilities, functionalities for representation of data, interoperability between applications and data storing and sharing properties. This very new nature of calculators can be considered as an early variety prefiguring capabilities that will soon become available to students and teachers in portable digital work environments. It gives them a particular role in teaching and learning mathematics. The evolution of the role of a calculator in the system of resources of teachers and students, inside and outside the classroom, has to be studied. Even if the activities of storing, retrieving and sharing documentation are subsidiary to the production of meaning and understanding, they play an important role for teachers in the construction of lessons and for students in their learning process.

“The first challenge concerns extending the notions of mathematical situations and their orchestrations to out-of-school learning environments. The second challenge concerns renewing, from a practical and theoretical point of view, the notion of artefacts for learning and teaching. To enter these fields, we need to be aware that HHT [1] is no

longer an isolated artefact, but integrated in and articulated with a network of resources, particularly online resources.” (Trouche & Drijvers, 2010)

In this paper, we take into account the calculator as an element of the network of resources of both students and teachers and study the handheld calculators not only for their calculation properties but also for their documentary properties.

THE RESEARCH SETTING

We took the opportunity of a broad introduction of handheld technology in different French classes to study the impact of such a technology on teaching and learning of mathematics. In the study reported in this paper we focus on two schools. In the first school during the school year 2008-2009, all the students of the scientific classes (16-18 years old students) have been equipped with a TI-Nspire handheld calculator. In the second school during the school year 2009-2010, two classes (16-17 years old students) were equipped with the same calculator.

In the first school (called S1 in this paper), most of the teachers are experienced teachers with a low degree of technological integration (Aldon & Sabra, 2009). In the second school (called S2 in this paper), the two teachers we observed are experienced with a high degree of technological integration. These experiments appear to be *natural* experiments in the sense that the classes contexts were not built by researchers but by the teachers' teams. Both in S1 and S2 a particular teacher plays a role of a leader: J1 in S1 and J2 in S2 are involved in the French research team e-CoLab (Aldon *et al.*, 2008).

Our choice to study the introduction of this calculator is linked to its particularly new nature: apart from the fact that it includes a computer algebra system, a spreadsheet, a graphical and geometrical environment, this calculator has specific properties which allow storing, sharing and organizing data. Files can be organized into directories, each file being constituted of one or more activities of one or more pages. The different pages, using each a particular software are connected together; for example, starting from different measurements in the geometrical environment, variables can be stored and computed in other applications, such as spreadsheet or CAS, using a different framework. Finally, it is possible to link calculators and computers and to work equally with the calculator or the computer. In the two schools, computer laboratories were equipped with the software.

A team of the INRP (Institut National de Recherche Pédagogique) has monitored these experiments to study the instrumental genesis (Guin & Trouche, 2002) of both teachers and students and to explore:

- how this calculator modifies the teachers' and the students' systems of resources;
- how it impacts the interactions between teachers and students.

THEORETICAL FRAMEWORKS

The study focuses on the modifications brought by the introduction of such a technology in teaching and learning. We assume that the calculator is both a tool allowing calculation and representation of mathematical objects but also an element of students' and teachers' sets of resources (Gueudet & Trouche, 2008a, b; 2009). As a digital resource, the handheld calculators possess the main functions required for a documentary production:

“The two cognitive functions, memorization and organization of ideas, seem to be the fundamental basis for the documentary production. [...]

The function of creativity comprising enrichment due to the domain of interest related to the document surpasses that kind of organization just mentioned. [...]

The third and last constitution function of the documentary production is the transmission function.” (Pedauque, 2006, p.3)

These properties can be used in different domains of mediation: the private or individual domain, where the resource is part of the user's own documentation, of her personal library and is designed for her own use; the collective domain, where the resource is designed to be shared in a particular community and the public domain where the resource is addressed to the *public sphere*. Crossing the properties and the domains of mediations offers a grid of analysis of the position of the calculator in the students' and teachers' sets of resources. We speak here of sets of resources in a wide sense. In line with Gueudet & Trouche (2009, p. 200), we consider resources as “everything likely to intervene in teacher's documentation work: discussions between teachers, orally or on line; students worksheets, etc.” We extend this citation to students' documentation work taking into account the fact that the handheld calculator plays a specific role, both as an element of the set of resources and an artefact allowing to mediate teachers' and students' mathematical activities. Several studies (e.g., Artigue, 2002; Guin & Trouche, 2002; Laborde *et al.*, 2005) have shown that the integration of technology into the classrooms is a slow process in which the artefact becomes an instrument through a double movement of instrumentation and instrumentalization. The instrumentation is the process where the artefact modifies the user's activity and the instrumentalization is the process where the user modifies the artefact for her own use. This slow process, called instrumental genesis (Rabardel & Pastré, 2005) transforms the artefact into an instrument through the equation: artefact + scheme = instrument. A scheme, following Vergnaud (1996) is an invariant organization of an activity. We introduce a distinction between artefact and resource to stress the different properties of the handheld calculator. The functions of memorization, organizations of ideas and transmission give to the calculator a specificity: a resource may be transformed into a document through the process of *documentational genesis* (Gueudet & Trouche, 2009). This documentational genesis has a dual nature:

Working Group 15

“The instrumentalization dimension conceptualizes the appropriation and reshaping processes [...]. The instrumentation dimension conceptualizes the influence on the teacher’s activity of the resources she draws on.” (Ibidem, p. 205)

From this double movement of instrumentation and instrumentalization, resources become documents, that is to say resources with scheme of utilization at a given moment. We assume that documentary production properties are an important element of this transformation of resources into documents through the documentational genesis for both teachers and students. Looking at the calculator with its different potentialities, we consider it as an artefact with possibilities of calculation and representation (properties of creation) and as a digital resource with possibilities of data processing and data sharing (properties of memorization, organization of ideas, and communication).

METHODOLOGY

The purpose of the methodology is to capture and to monitor the dynamics of the different genesis. In this particular context, we develop our methodology to obtain information on the processes instead of the results of the processes. We have chosen to passively observe the experiments, without intervention of researchers. In S1, the teachers and students that we observed are in the last class of the high school (Lycée, Terminale S, scientific class, 18-year-old students). The choice of this class level comes from the practical examination that students have to take at the end of the year. This practical examination was an experiment carried out by the ministry of education during which students had to solve a mathematics problem with the help of software or calculators. We thought that this examination would be a good opportunity for teachers to develop the use of calculators in their classrooms and for students a sufficiently precise goal which could lead them to use their calculators in and outside the math classroom. In S2, we observed students of *première S* (scientific class, 17-year old students). We wanted to start our observations at the very beginning of both the introduction of the calculator and the beginning of scientific studies. Both teachers have a long teaching experience; this choice was done because we wanted to focus on the uses of technology in the class without being distracted by mathematics teaching difficulties. In our methodology, we cross different observations and data:

- First, the TI-Nspire calculator, as previously said, has a functionality which allows structuring its contents into directories, files, problems... Hence, we decided to observe the students’ calculators contents; more precisely, we chose *representative* students and asked them to send us the content of their calculator half-monthly from December to June. We mean by representative students with different mathematical and technological skills.

Working Group 15

- Second, we organized observations in the classroom: in the ordinary classroom as well as in the computer laboratory. During these observations, we mainly focused on interactions between students and teacher.
- Third, interviews with teachers before and after the observations give us information about the role teachers give to the calculators in the observed lessons.
- Fourth, we took advantage of the final examination to observe and to interview students about their personal use of the calculator.
- Finally, we asked students to fill in a questionnaire at the beginning and at the end of the year, focusing on the one hand on their opinions about the calculator and more generally about technology and, on the other hand, about their attitudes towards mathematics.

Although the body of observations and data analysis enlightens the following results, in this paper, we particularly focus on the study of the content of students' calculators in order to draw different types of utilization in relation with the documentary production. These data allow us to follow a part of their documentational genesis and give us information about the use of calculators outside the classroom. The contents of a small number of calculators (eight the first year, six the second year) allow us to formulate hypotheses that have to be confirmed in a future study. They give us information about the instrumental genesis as well as the evolution of the use of calculators as a part of the students' individual set of resources. In the next paragraph, we give some results about these geneses seen through the analysis of the contents of the calculators.

SOME RESULTS

We lean on the analysis of the contents of the students' calculators to draw a parallel between the main functions of a documentary production as described below and the actual students' organization of their calculators. Through the content of the calculators, we assume that we can approach the private domain of mediation and we cross our information with observations in classroom and interviews to reach the collective and public domains.

Memorization of knowledge and organization of ideas

From the viewpoint of students, the handheld calculator is a means of data storage, which they perceive as helpful:

It's reassuring in the perspective of the exam to have proofs stored, because we have to know very many proofs... and it's also possible to verify our calculations (Interview, May 19, 2009)

The folder structure of this student's calculator is a good example showing his organization of knowledge, and it is interesting to follow the contents of the folders and their evolution during the year. Figure 1 shows the general organization of the

Working Group 15

calculator which does not change during the year and Figure 2 shows the evolution of a particular folder (*Maths oblig cours* which is an abbreviation for: math lessons): Figure 2a shows its content in December and Figure 2b its content in June. We clearly see in this calculator organization a complete structure of the math course. Looking more deeply into the files, we see that this student uses his calculator as a digital notebook, giving a summary of the lesson (Figure 3) and allowing mathematics experiment: the slider shown on Figure 3 (on the right) changes the value of a and the curve of the function $x \rightarrow a^x$.

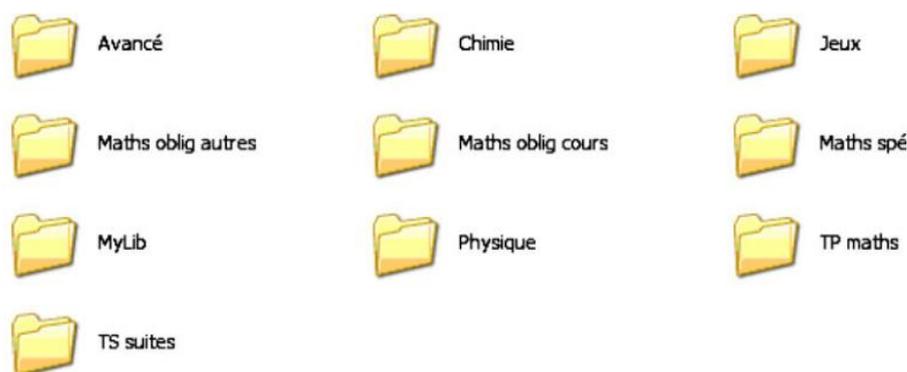

Figure 1: Organization of data in a student's calculator

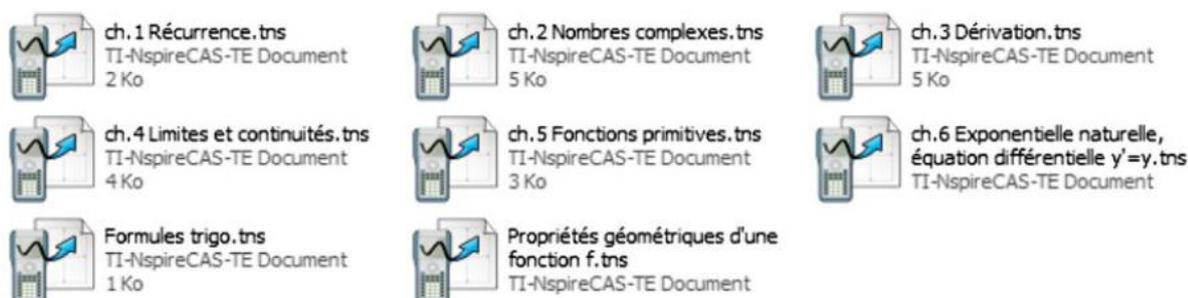

Figure 2a: Evolution of the content of “Maths oblig cours” folder (December 2008)

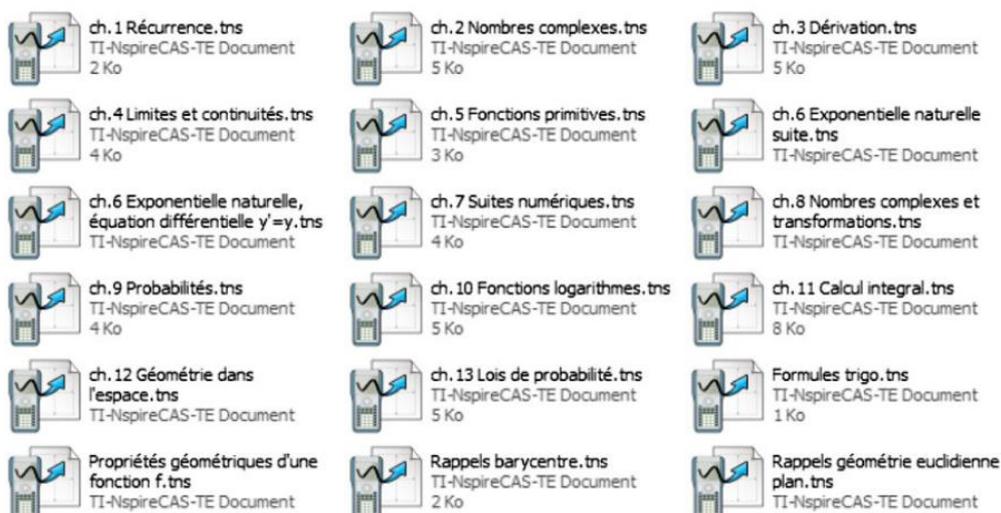

Figure 2b: Evolution of the content of “Maths oblig cours” folder (June 2009)

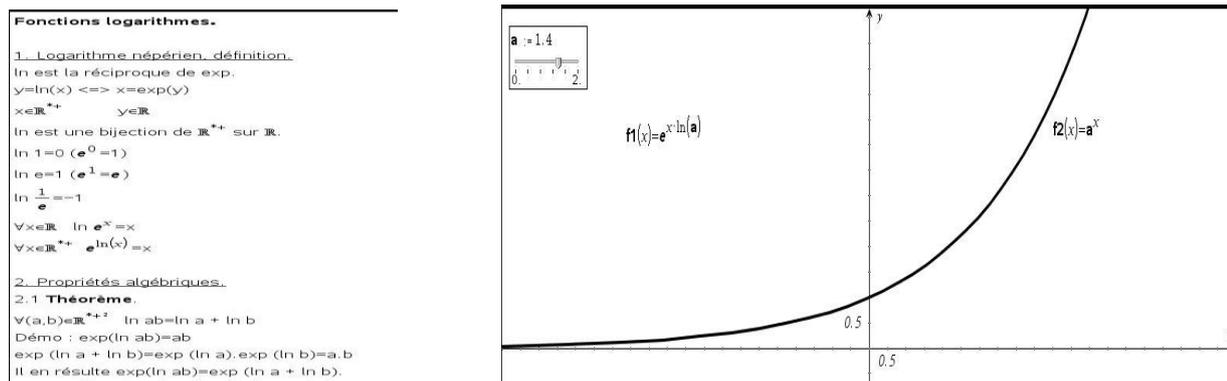

Figure 3: Two pages of the file ch.10 “Fonctions logarithmes” (logarithm functions)

Depending on the teacher’s conceptions, these properties of memorization and organization of ideas are rejected, ignored or promoted and the resource may stay hidden and private or, on the contrary, become collective and shared in the class.

Property of creation

Looking at the contents of the students’ calculators, it appears that they use them very often as a draft, using a file or a set of files to do the current calculation. For example, one of the calculator structures is made of different folders called *br1*, *br2*..., *br* being an abbreviation for the French *brouillon* (draft in English). The calculator is seen in this case as a direct creation tool bringing immediate feedback to a given question in a personal domain of mediation. The resource at a particular moment cannot become a document because the dimension of organization of ideas is not present. However, in all calculators, the dimension of creation exists through specific pages: calculation pages, representations of data and draft files linked to mathematical problems. The interviews with students confirm this fundamental aspect of the calculator and its use in the classrooms:

Yes, in math lessons, for derivative functions, integrals and so on [...] we really use it (the calculator) during math lessons. (Interview, May 19)

One very important point during the observation in the classroom was to observe the interactions between the teacher and the students related to the organization of the calculators. In S1, the first teacher did not want to interfere; it appears clearly that this teacher wants to give a private status to this property for her own calculator as well as for the students’ calculators. As a consequence, her students’ calculators are organized around the creation property, and all the data memorization remains private, and somewhere hidden. The second teacher, on the contrary, paid attention to the data organization of the calculators. It is in his class that we find the most organized calculators (see Figure 1). In S2, teachers despite their high level of technological skills do not emphasize the organization of data, and the students’ calculators are organized around particular situations that teachers institutionalize as important in the classroom. For example, a particular lesson about statistics has been

stressed, and in all this class students' calculators a folder and files are present and stay present during the year even if there is no visible organization of data.

Communication

The calculator allows for the transmission of information between students and between students and teacher. The orchestration (Trouche, 2004) plays a very important role in the transfer from a private to a collective use of the different properties of the calculator. For example, in S1, the teacher used a particular class organization: students worked with their own calculator in a face to face configuration and one student (called Sherpa in reference to Trouche's work), working under the control of the teacher, calculated and showed through an overhead projector the screen of his calculator. Such a class organization facilitates a collective communication from an individual question as shown in the next excerpt where students have to search the intersection point of two curves:

Sherpa: Madam, here...

Teacher: Yes, we can see nothing much.

Sherpa: Here, the curve is here and after there is no more curve!

Teacher: There is no more curve?

Another student: They are all at the same place, you can't see it.

Sherpa: Yes, but you must see the intersection!

A third student: Yes, but, where is your other curve?

The dialogue begins with an individual question and is continued by a dialogue in the class between students. On the other hand, the Sherpa's calculator appears to be a vector of communication between the teacher and the students, when, taking profit of a question of the Sherpa, the teacher transmits information to the whole class. In this case, the collective calculator appears to be a generic calculator which allows the teacher to regulate the class work. In other words, the teacher, through the orchestration, transforms the creation property from the private domain to the collective domain.

CONCLUSION

The teacher's demeanour has a decisive influence, and the transformation of the calculator as an artefact with calculation and representation potentialities into a resource towards a document giving a help to the students' construction of knowledge depends not only on the teachers' technological skills but also on their awareness of these possibilities and on the pedagogical exploitation of these functionalities, mainly organization of knowledge and memorization. The position of the tool as an element of a system of resources of both teachers and students makes the negotiation of the didactical contract very complex. The availability of the calculator evokes different kinds of tensions:

Working Group 15

- tensions between the memorization properties and the teachers' conceptions of students' resources;
- tensions between the property of creativity and the teacher's intentions;
- tensions between the communication property and the teachers' pedagogical organization.

Trying to explain and describe these tensions and exploring the links between the documentational genesis related to the calculators and the construction of knowledge offer new perspectives of research that can extend and complete this study.

TRANSITIONS BETWEEN MICRO-CONTEXTS OF MATHEMATICAL PRACTICES [1]

Vasilis Tsitsos, Charoula Stathopoulou

University of Thessaly

The study presented here is concerned with transitions between micro-contexts of mathematical practices. These micro-contexts are determined by the use of different software. Here we focus on a task in which students had to depict the blueprint plan of their schoolyard. The task completion demonstrates a productive interaction of tool use which combines instrumental approaches to achieve the given purpose. At the same time it provides a framework for the observation of knowledge and skills transfer during transitions from one micro-context to another.

Keywords: instrumental jumps, transitions, microcontext, mathematical practices, instrumental approach

INTRODUCTION

The way digital technologies impact or could possibly impact processes of mathematics learning / teaching has been one of the main interests of the educational research over the last two decades (Artigue & Bardini, 2010). The use of digital material is not just an added tool, but creates new conditions which deviate from the established teaching and learning environments. Some of the changes caused involve the cognitive processes, the mode of production and reproduction of knowledge and the communication behaviour of teachers and students. The teachers redefine their roles and the learning process by creating new communication situations. The role of the teacher as knowledge carrier changes and what comes at the heart of the whole process is the interaction between teacher and students as well as between students themselves through the use of digital tools (Milionis & Balta, 2001).

The role and use of tools in the educational process was discussed in the previous CERME WG7 as well. It was considered important to address several issues such as design, articulation between design and use, interaction between resources and teachers' professional practice, technologies, tools and students' mathematical activity. The role of the tools and their transformation when used for the carrying out of specific activities comprise the major issues currently of concern to researchers in the area of ICT. The tools used in the present research were: a) *Geometer's Sketchpad*, a dynamic geometry environment and b) *Microworld pro*, a Logo-based environment / Turtle Geometry software. The teaching contexts in which the materials were converted from artefacts to instruments by the students were considered to be micro-contexts. We investigated how each context relates to the way students manage mathematical operations as well as whether and how mathematical knowledge is transferred from one micro-context of mathematical

practice to another. We also looked into the process of interaction between students as well as between students and teacher as mediator.

The survey was carried out outside school hours and classroom context as part of a school environmental program called "*Environmental journeys through mathematics and technology*" and attended by 24 students, 13 of which were 7th Grade and 11 were 8th Grade. Meetings were held in the school computer room. The Math/ICT teacher was actively involved along with a Science teacher. The meetings took place for two hours each week for an entire school year.

Utilizing ethnographic and teaching experiment techniques (Chronaki, 2008) we studied the community of practice (Wenger, 1998), formed by the participant students and educators, while we introduced activities. The present paper summarizes the overall research effort and discusses research results focusing on one of the research *tasks* in which students had to depict the blueprint plan of their schoolyard.

THEORETICAL FRAMEWORK

As mentioned in the literature (Artigue & Bardini, 2010; Guin, Ruthven, & Trouche, 2004), researchers have become more and more sensitive to *instrumental approaches* (Verillon & Rabardel, 1995) to mathematical education, that is the processes of *instrumentalisation* and *instrumentation* that drive the transformation of a given artefact into an instrument of mathematical work. This perspective combines both the Piagetian and the Vygotskian theoretical frameworks. The instrumental approach is based on the distinction between an artefact and an instrument. The term artefact describes a human-made object, either material or symbolic. The term instrument describes a mixed entity with artefact-type components as well as *utilization schemes* (Trouche, 2005), which indicate the functional value of the instrument for the individual. These schemes concern the strategies developed by the individual in order to carry out a task. Utilization schemes are formed gradually through the use of the artefact. As a result the instrument is a mental construction of the individual and has psychological qualities. The process of the transformation of an artefact into an instrument is called *instrumental genesis*. This approach, is made of two interrelated processes: an instrumentation process (the artefact shaping a user's activity) and an instrumentalisation process (the artefact shaped by the users' activity).

During the instrumental genesis process the role of the teacher proves to be of paramount importance. Trouche (2004) introduced the term "*instrumental orchestration*" in order to describe the teacher's management of the individual instruments in the collective learning process. He defines instrumental orchestration as a deliberate and systematic process of organizing the different artefacts which are available for a specific project. There are two ways of organizing, namely didactic configuration and exploitation mode. The first relates to the selection and arrangement of the artefacts for the project while the second refers to the decisions

made by the teacher about how the artefacts can be used to achieve the learning objectives. Drijvers, Doorman, Boon and Van Gisbergen (2010) introduce a third way of organizing, which they name "*didactical performance*", in order to stress the ad hoc decisions taken while teaching on how to actually perform the enacted teaching in the chosen didactic configuration and exploitation mode. According to this perspective, instrumental orchestration aims at enhancing the students' instrumental genesis but also causes the instrumental genesis of the teacher/researcher himself/herself both in the process of preparing a deliberate intervention and while it is actually taking place. In this paper we focus on the on-going didactical performance mode of instrumental orchestration and discuss the results with an emphasis on what we would like to describe as *instrumental jumps*, which in our view involve situations where the use of an instrument within a context may act as a step leading to instrumental genesis in a different context. The contexts in the specific research are defined by the two types of software mentioned earlier. We chose these types of software because they mark two different environments both in terms of user access and epistemological foundation. In Microworlds pro, in order to create events students have to describe them in a symbolic way through scripting. In contrast, in a Geometry Sketchpad environment they can operate directly using basic geometric concepts and explore objects and their relationships through dynamic manipulation. Our intention to focus on instrumental jumps stems from the question whether and how knowledge is transferred from one mathematical context to another.

METHODOLOGY - THE SETTING OF THE RESEARCH

As our interest lies, on the one hand, on studying learning in specific contexts and, on the other, on exploring how students involved in learning activities think, we believe that anthropological research orientation is a suitable kind of approach. The ethnographic survey was supplemented by the implementation of teaching experiment techniques and the researcher intervened at various stages using pre-designed activities which intended to trigger events to be studied. The role of the researcher was principally that of a participant observer, who focused either on observation or on participation accordingly through the assignment of relevant activities or the learning of some software. The ethnographic equipment used included video and tape recordings, field notes, and the material handed in by the students both in final form and during the tackling of an activity.

As mentioned earlier the research was incorporated in an environmental program and so it developed along two mutually assisted directions. The environmental direction sustained the learning community for a long time while the research direction seemed to be augmenting the design of teacher intervention as well as the support of pupils. The students had the opportunity to engage in meaningful instructional situations, and teachers were supported in the design of their interventions. This mode of intervention substantially reduced the researcher's participation in defining

and developing the activities, giving him more leeway for participatory observation. What is more, the participation of students from various grades prevented teachers from applying purely formal teaching. So the community formed differed from a typical class and enabled us to systematically organize communicative relationships between pupils of the 7th and 8th grades and to observe students in a less formal framework.

The research consisted of three phases based on constructionism theory concerning learning through construction, 'learning-by-making' (Harel & Papert, 1991). The first phase involved designing digital games using symbolic expression software, Microworld pro. The second phase focused on the construction of paper digital cameras pinhole camera [5] and the use of dynamic geometry software for their digital modelling. In the third phase, certain tasks derived from the interweaving of research and the environmental program was given to the students so that they could use the instruments developed in the previous phases. This paper discusses the results of one of the tasks of this third phase, namely the dynamic depiction of the schoolyard. The examples (episodes) used to illustrate the discussion are taken from the work of two groups of 8th grade students who chose to use the environment of dynamic geometry software. This project arose from the need of the environmental program to design a dynamic depiction of the school with the aim of dynamic information encoding. Such information could contribute to immediate awareness of current failures and problems such as burnt bulbs, consumables shortage, and full recycling bins. The potential for dynamic scale manipulation of the floor plan derived from the need to view the site both centrally and in certain parts. To this end, students were given a real architectural sketch of the floor plan of the school as shown in figure 1. The mathematical concepts that were negotiated were those of reduction, growth and measurement.

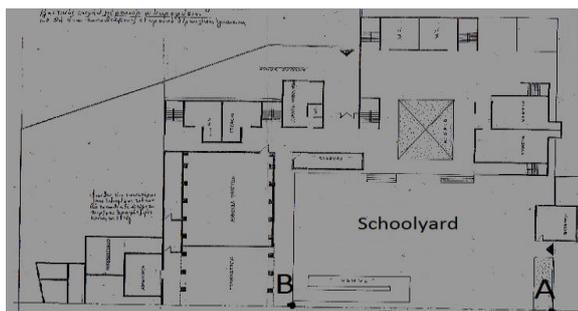

Figure 1: Floor plan of the school

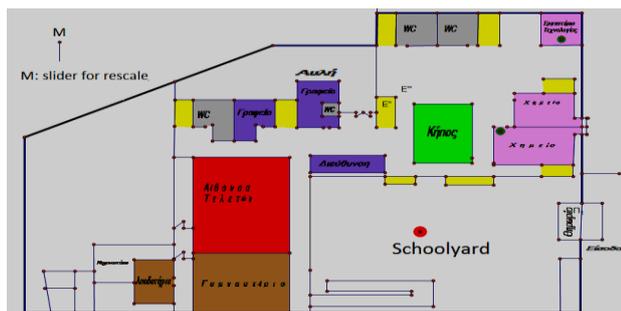

Figure 2: Final plan of student M5

Episodes / Discussion of the Episodes

Although the students' dialogues are of great interest as they reflect the students' effort to decode the blueprint given to them, in this paper due to space constraints we focus our attention on some of the episodes associated with the drawing of the plan. Specifically, students in the two groups, three boys (M1, M2, M3) and two girls (M4, M5) are working at adjacent positions and are able to communicate with each other.

Working Group 15

Before reviewing a few episodes, we present a typical episode and an initial analysis of it. It focuses on a snippet dialogue developed among three students trying to choose the starting point and design technique. The dialogue is illustrative of the different instrumental approaches that students develop through discussion.

Episode 1 and its analysis

- 404 M1: Where to start?
405 M2: From this angle.
406 M2: Let's put a point here.
407 M3: We must measure the distance, what to do with the point?
408 M2: So I've put the point here, how do I tell the point to move to the left, how long is this? I want the ruler.
409 M3: Have you confused the programs? The point is not a turtle.
410 M2: There may be a command for the point to move.
411 M3: Hey! The ruler, what do I measure?
412 M2: This is the yard. Measure, here. Come on, measure.
413 M3: 11.2 cm.
414 M2: Do we have to tell the point to move 11.2 to the left? I don't know.
415 M3: Here we go again, after I told you the point is not a turtle.
416 M3: Draw a line (he means segment), measure it.

The students have never before used the specific software to depict blueprint plans that require precise measurements. The dialogue focuses on how the two students differently understand how to start the drawing of the plan. The student M2 wants to start his plan from point A, as shown in figure1, giving this point a command to move [2], while the student M3, as revealed at the end of the dialogue [3], wants to begin his construction with a random segment. The attitude of the student M2, who remains anchored in the culture he had acquired about the movement of the turtle according to specific commands in *Microworld pro*, reveals four different aspects of the instrumental jump process. The first is the symbolic representation of a point as a turtle in the logo-based environment. For the student, this concerns not only a one-to-one point correspondence but also a transfer of the qualities of the turtle resulting from its use. The second concerns the intention of the student to bring that culture to the new situation. The third concerns the communication of his idea to the other students in an effort to elicit ways to adjust the use of the turtle. The fourth aspect relates to the fact that his idea acquires communication features through interaction, a first example of which is the discouraging response of student M3. So starting with a problematic situation in the present work context we observe an attempt of knowledge transfer from a different previous work context. The initial stage of this knowledge transfer is the instrumental jump process described just above. From the probing questions that we asked during the project we made the following realization. Unlike student M3, who rejects the idea due to his knowledge that Geometer's Sketchpad does not have Logo-based characteristics, student M2, who is

not fully aware of this distinction, dares this mental jump and tries to find ways of adjusting his idea. If adjustment of the tool use is achieved successfully, then knowledge transfer has been completed. However, at this point the turtle idea is abandoned for the time being and will be picked up and further explored later.

The different way to start the activity indicates the two different frameworks that provide the springboard for discussion. Student M2 suggests using the turtle and expects the software to have similar functionality with the logo-based environment, while student M3 bases his reasoning [4] on the geometric object of the segment the construction of which he seems to know. This latter idea prevails for the time being and the students work on it.

Discussion of the rest of episodes

Then the group of boys work on the idea of student M3 for the construction of a random segment and try to give it the length of 11,3 cm with suitable manipulations. Their successful effort allows them to proceed with the same rationale to the construction of a closed line consisting of four consecutive variable segments, which resembles a rectangle that corresponds to a part of the schoolyard blueprint.

So, student M3 uses the artefact of the variable segment, a basic element of the work environment, and suggests stabilizing its length through trial and error dragging processes. His active involvement in both groups leads to the appropriation of his idea by the other students. In this way his idea becomes meaningful as it is transformed into an instrument through its collective use for the achievement of the common goal. However, two female students, M4 and M5, have not been involved in the debate so far, but carefully followed the discussion of their peers. The teacher moves a point that represents a corner of the schoolyard and the graph loses the shape of the rectangle. The students' surprise is coupled with the reminder that the goal is to design a dynamic plan that retains its geometric properties. "*But how are we going to do it, Sir? So much work to be wasted!*" student M1 reacts. The reminder of the dynamic floor plan is the cause for a new round of talks, which last for an hour. "*I found it, sir!*" student M3 enthusiastically cuts in. Going on to a different screen he displays the vertical axes of the software and thinking aloud or addressing the others he explains: "*I'll create the first dimension on the axis using the scale and I'll base all measurements on this length, here, when I change this point that other one changes too*".

Student's M3 idea incorporates both the preservation of the geometric properties of the shape and the potential for dynamic manipulation of the shape. The problem is that he does not know how exactly to put these specific points on the axis and demands that the dynamic geometry program provides a command corresponding to the logo-based environment. "*How do I say 'Set position [11.3, 0]' Sir?*", he asks. He had already used this Logo-based command in the first phase of the research when constructing a digital puzzle. At this point we intervened and provided information

for the resolution of the specific problem within the dynamic geometry environment. Here we can observe an instrumental jump made by student M3 during the process of instrumentation concerning the depiction of a point on a system of axis in order to achieve the goal of the dynamic blueprint. After that, student M3 makes point B of the plan, as shown in figure 1, correspond to point (0, 0) and works on his own with the tool "*plot points*" thus completing part of the schoolyard. On seeing that student's M3 request for an equivalent tool to depict points in the Sketchpad environment was satisfied student M2 repeats his earlier question: "*How can we move point A, 7.3 cm to the left, is there a command?*" [2]. At this point the idea of the turtle, which was earlier abandoned, is followed up by the group. This time we better evaluate the student's question and realize that, on the one hand, the simulation of the turtle movement command is possible while, on the other, such a simulation requires concepts relevant to geometric transformations. It is a pivotal point in the on-going process of instrumental orchestration as we experience a case of instrumental genesis. The Logo-based turtle movement command turns into a transformation instrument in the dynamic geometry environment. Then the discussion revolves around tools of parallel transfer transformation, which are embedded in the dynamic geometry environment.

The new tools appear to be also accepted by the two girls (M4, M5) slowly getting involved in the drawing of the plan. While the drawing is taking place for the third time, student M3, who has so far managed to draw a dynamic plan, addresses those who have worked with the tool of parallel transfer with the words: "*But yours doesn't zoom in and out! ha! ha!*" Indeed, the students have designed the school playground with accurate measurements and without moving the components affecting the plan. However, they have not given their plan a dynamic character. This idea opens new rounds of talks completed in two consecutive sessions. The focus is on minimizing the measurements as well as on trying to find proportional relations between the sides. "*Let's find all the other distances from segment 11,3*", student M2 characteristically says. Using paper, pencil and a calculator the rest of the students support student M2 and through discussions and individual actions they conclude to proportional relationships. Due to space constraints of the present paper these discussions are not presented here despite their interesting indications of how students perceive the proportional change in shape when they work with combined modeling tools. This area has been adequately illuminated by several other researchers (Noss & Hoyles, 1996; Psycharis & Kynigos, 2004).

Students' discussions and actions highlighted two new ways of working for the drawing of the dynamic plan. The first way adopted by student M2 required the proportional relationship between the sides. To construct the plan he used only one variable (variable-length segment) relating all the lengths to it. It should be noted that the specific student had worked on Microworlds pro in the first phase of the research in a group activity to design and present something that interested them.

Working Group 15

When his turn came he said: *"I will not show you something but I'll tell you one way I found to make one and the same shape bigger or smaller without having to write a new program"*. His presentation was, in fact, the structure of a parametric process, which he passionately believed he had invented himself. The reference to this fact is to indicate that the student had learned how to minimize the variables of a parametric shape in a logo-based environment and functionally transferred this knowledge to the environment of dynamic geometry software. The second mode supported by the students M4, M5 involved the multiplicative relationship between each measurement and a number corresponding to the scale factor. The probing questions showed that this method of the female students stemmed from their engagement with the concept of scale in the geography lesson. At this point they could choose one of following three ways to work: based on a scale or on a proportion or on co-ordinations. Students M4 and M5 cooperated to a sufficient extent in the design of the floor plan of the school, but student M5 was the one who completed the plan after a week. Figure 2 shows the final draft of student M5 in which point M on the top left represents the slider of the rescaling. Students M2 and M3 worked at different workstations, each one developing his plan for a while but soon abandoned the task finding it rather tedious to repeat something that they already knew. Careful study of the students' M4 and M5 blueprint produced by the use of the tool "object properties" that is provided by the software as well as the probing questions that followed showed us that the draft floor plan was drawn with a mixed approach. They based their design on the transformations tool but they also used Euclidean geometric constructions whenever they thought they would proceed faster.

There is particular interest in student's M5 effort to name places on the blueprint in a dynamic way. *"Sir, I would like the names of places on the plan to change size along with the plan. Look I wrote Schoolyard and when the size of the plan grows the word remains the same"*, she explains. We were impressed by the fact that although she had repeated the same scale structure to construct the plan components dozens of times she seemed not in need of it in this case. With more profound questions we realized that she firmly believed that if the word was in a closed-dynamic shape it should also zoom in and zoom out along with the plan. She mentioned that the word was on *"a bordered area"*, implying the restricted area of the schoolyard. This restrictive view of the student derived from the instrumental jump she attempted based on her knowledge of the use of *select* and *zoom* buttons available in widely used software.

CONCLUSION

In the two groups which we could monitor very closely during the set meetings while intervening when we saw fit, we observed the interweaving of different mental schemes, technical knowledge and specific mathematical knowledge, which determined the progress of task completion. These mental schemes became an object of negotiation. The different types of tools we chose gave the students an opportunity

Working Group 15

to mentally jump from one instrumental environment to another thus shaping both individual and collective actions. These mental passages led to the creation of mixed instrumental approaches. The knowledge and the utilization schemes transferred from one micro-context to the other were informed both by the inherent features of the former environment and the characteristics of the later environment. This combination resulted in the creation of hybrid tools. Knowledge transfer was achieved in some cases while in others it was hindered, as shown by the brief presentation of the episodes. The conditions under which it is possible to transfer mathematical knowledge from one micro-context of practice to another as well as the role of social interaction are considered attractive research topics that deserve further investigation.

NOTES

1. The idea comes from the title of the book *Transitions between contexts of mathematical practices* by DeAbreu, Bishop, and Presmeg (2002).

FUNCTION CONCEPT AND TRANSFORMATIONS OF FUNCTIONS: THE ROLE OF THE GRAPHIC CALCULATOR [1]

Madalena Consciência

Hélia Oliveira

Escola Sec. Dr. Ginestal Machado Instituto de Educação da Univ. de Lisboa

This communication focuses on the activity of two secondary school students in a task involving the concept of function and transformations of functions of the type $p(x)+k$ and $p(x+h)$, and analyses the role of the graphic calculator. The results suggest that students are beginning to have an object-oriented view of function. Concerning the transformation $p(x)+k$ they have already established the operational invariants, and it seems that the graphic calculator played an important role in that.

Keywords: Function concept, Transformations of functions, Graphic calculator, Instrumental genesis, Operational invariants

INTRODUCTION

This communication originates from a study in which the main objective is to understand how secondary school students integrate the graphic calculator in their mathematical activity, and the role it plays in learning of functions, along the 10th and 11th grades. Here we focus our analysis on the following research question: How do students understand the concept of function and of transformations of functions in a particular task, and what role does the graphic calculator play in this?

THEORETICAL FRAMEWORK

The process of instrumental genesis

The availability of a tool does not automatically turn it into an instrument in the student activity. Rabardel (2002) stresses the difference between artefact and instrument: he considers that an artefact only becomes an instrument when the user is able to appropriate it and integrate it into his activity. An instrument is thus a mixed entity, constituted by the artefact and utilization schemes.

The process through which the artefact becomes an instrument is called Instrumental Genesis. It concerns the two poles of the mixed entity (the artefact and the utilization schemes), and integrates two dimensions and orientations: Instrumentalization, directed towards the artefact, is related with the emergence and evolution of the artefact components of the instrument – selection, regrouping, production and attribution of functions, deviations, catachreses, and transformation; and Instrumentation, directed towards the user, is related with the emergence and evolution of utilization schemes (Rabardel, 2002). According to Vergnaud (1998), a scheme always involves: (i) one or more goals, sub-goals and its anticipation; (ii) rules of action, information seeking, and control; (iii) operational invariants –

theorems-in-action (propositions taken as true), which are the means to infer the objectives and the rules to adapt the activity to situations, and concepts-in-action which are central in the schemes organization; and (iv) possibilities of inference. To Rabardel (2002), the analysis of the operational invariants is important from the instrumental point of view, since it allows identifying the situations' characteristics which users take into account.

Several studies have shown that the process of instrumental genesis concerning symbolic calculators or graphing calculators is not trivial (Guin & Trouche, 1999; Drijvers, 2000), and that its integration with educational purposes requires some attention, since the technical and conceptual aspects are intertwined (Drijvers & Gravemeijer, 2005).

The learning of functions, representations and multiple representations

The concept of function is one of the most important concepts in mathematics, but is very difficult for many students (Sajka, 2003). One of the difficulties related with this concept comes from its dual nature. To Sfard (1991), the concept of function can be understood essentially in two ways: operationally, as a process, and structurally, as an object. These two visions should complement each other and form a coherent whole of the concept. The author claims that a mathematical concept is first acquired operationally and that the transition to its structural form is a process accomplished in three phases: internalization, condensation and reification. Gray and Tall (1994) also refer to the duality between processes and mathematical concepts. These authors claim that the mathematical notation involves a certain ambiguity, for example, $f(x) = x + 2$ may represent a process, i.e., a way to compute the value of the function for a particular value of x , or it may represent the object that covers the whole concept of function for a general x . In their opinion, the key to success in mathematics is to interpret the mathematical symbolism in a flexible way.

Slavit (1997) also stresses the importance of students moving from an action view of function to an object-oriented view. He considers that it is very difficult for a student to truly understand an action performed on a function, like the transformations of functions, if an object-oriented view has not yet been achieved. He proposes an approach to the reification of the concept of function based on functional properties, noting that students develop a property-oriented view when the study of functions includes, preferably, graphics and graphics technologies.

Mathematical concepts are closely linked with their representations. The concept of function can hardly be understood and acquired without the use of multiple representations, because each representation only provides information on some of its particular aspects (Gagatsis & Elia, 2005). The graphic calculator (GC) allows to combine multiple representations of functions (numeric, graphical, symbolic and physical), but as underlined by Dick and Edwards (2008), the fact that students have access to multiple representations of a mathematical object does not lead,

automatically, to a deeper conceptual understanding, nor does it lead to a flexibility to determine the most appropriate representation to a particular problem.

METHODOLOGY

In this paper we are analyzing the responses provided by two 10th grade students, in an individual interview with the first author, to Questions 1, 2 and 4 from the following task:

Consider the polynomial $p(x) = x^3 - 16x^2 - 2037x - 5940$.

1. Represent it graphically.
2. Indicate two possible values for k , with opposite signs, so that $p(x) + k$ has only one zero.
3. How many solutions does the equation $p(x) = -5940$ have? Determine them with an error less than one thousandth.
4. Determine the solution of the inequality $p(x+7) \cdot 100 - x^2 \geq 0$.

The interview was carried out one month after the topic Functions had been covered in the classroom. The task did not aim to enhance functions learning, but to create an opportunity to understand how students mobilize their knowledge about functions and how the GC is integrated in their activity, as they could freely use it during the interview. In the classroom, transformations of functions were explored in same tasks for the case of module and quadratic functions ($y = a|x+h|+k$; $y = a x+h^2+k$), by assigning values to parameters, and using the GC to observe the corresponding effects on the graphical representation. Students used a personal CG, under guidance of the teacher, essentially to solve equations and inequalities graphically. The two selected students, Helena and Diogo, are two of the four case studies, which take part in a broader study. Data collection is still ongoing and involves classroom observation in two consecutive academic years (10th and 11th grades); clinical interviews with students; and the collection of written documents produced by them in the classroom. The two students have different performances in mathematics and have followed different approaches to the task. Helena is an average student, with ratings around 12 values, in a scale of zero to 20, and Diogo is a student with ratings above average, around 16 values.

RESULTS

To represent the function graphically, both students used the GC, although Helena did not do it immediately. She represented the axis on her sheet of paper and said:

Helena: Well! I have no idea. [...] I don't know how to represent this graphically!

Researcher: And would the GC not help you in this issue?

Helena: But can we use the calculator? (And immediately picks up her calculator).

Working Group 15

The use of the GC was not an assumption made initially by the student, but it was suggested by the researcher.

Both students tried to find a proper display through trial and error, by changing the values directly in the window, without resorting to Zooms, and taking considerable time to achieve a reasonable viewing rectangle.

The students used the algebraic representation to decide whether they had an acceptable graphical representation of the function, however initially both of them had doubts about the degree of the polynomial function. They considered that the degree of the polynomial is given by the sum of the degrees of its terms. When this point was clarified, the degree of the polynomial was a fundamental criterion for them. The criterion used by Helena was based on the following theorem-in-action: *A third degree polynomial function has at most three zeros*. However, she denoted some difficulty in interpreting what she visualized on the screen, putting into question this very theorem-in-action:

Researcher: Are you already seeing the whole graphical representation?

Helena: (Pause) It doesn't have more than three zeros. [...] It has two, so it could be. [...] It has two, if it had... No, actually, it has four (looks closer at the screen). No, no, it has three. It has three zeros.

The criterion of Diogo draws on a theorem-in-action that is false: *A polynomial function of third degree changes its variation three times*.

Diogo: Now I know it should be this one [graphical representation], because if it is of third degree, changes three times, is increasing, then decreases, Ok, it is of third degree (laughs).
