

Proceedings of the Seventh Congress
of the European Society for Research
in Mathematics Education

Editors

Marta Pytlak, Tim Rowland, Ewa Swoboda

University of Rzeszów, Poland

Editors

Marta Pytlak, University of Rzeszów, Poland

Tim Rowland, University of Cambridge, UK

Ewa Swoboda University of Rzeszów, Poland

Editorial Board

Paul Andrews, Carmen Batanero, Claire Berg, Rolf Biehler, Angelika Bikner-Ahsbals, Laurinda Brown, María C. Cañadas, Susana Carreira, Maria Luiza Cestari, Sarah Crafter, Thérèse Dooley, Viviane Durand-Guerrier, Andreas Eichler, Ingvald Erfjord, Pier Luigi Ferrari, Anne Berit Fuglestad, Athanasios Gagatsis, Uwe Gellert, Alejandro S. González-Martin, Núria Gorgorió, Sava Grozdev, Ghislaine Gueudet, Kirsti Hemmi, Marja van den Heuvel-Panhuizen, Jeremy Hodgen, Paola Iannone, Eva Jablonka, Niels Jahnke, Uffe Thomas Jankvist, Gabriele Kaiser, Ivy Kidron, Götz Krummheuer, Alain Kuzniak, Jan van Maanen, Kate Mackrell, Mirko Maracci, Pietro Di Martino, Snezana Lawrence, Roza Leikin, Thomas Lingefjärd, Nicolina Malara, Emma Mamede, Carlo Marchini, Maria Meletiou-Mavrotheris, Alain Mercier, John Monaghan, Elena Nardi, Reinhard Oldenburg, Alexandre Pais, Marilena Pantziara, Efi Papanistodemou, Bettina Pedemonte, Richard Philippe, Demetra Pitta-Pantazi, Despina Potari, Dave Pratt, Susanne Prediger, Luis Radford, Leonor Santos, Wolfgang Schloeglmann, Gérard Sensevy, Florence Mihaela Singer, Nad'a Stehlikova, Andreas Ulovec, Paola Valero, Konstantinos Tatsis, Joke Torbeyns, Jana Trgalová, Constantinos Tzanakis, Fay Turner, Geoff Wake, Kjersti Wæge, Hans-Georg Weigand, Carl Winsløw.

The proceedings are published by University of Rzeszów, Poland
on behalf of the European Society for Research in Mathematics

TABLE OF CONTENTS

<u>General Introduction</u>	1
<i>Ferdinando Arzarello, Tim Rowland</i>	
<u>Editotrial Introduction</u>	5
<i>Tim Rowland, Ewa Swoboda, Marta Pytlak</i>	
PLENARY LECTURES	
Plenary lecture 1	
<u>Research into Pre-service elementary teacher education courses</u>	9
<i>Anna Sierpińska</i>	
Plenary lecture 2	
<u>The structure and dynamics of affect in mathematical thinking and learning</u>	34
<i>Markku S. Hanula</i>	
Plenary lecture 3	
<u>Proving and proof as an educational task</u>	61
<i>Maria Alessandra Mariotti</i>	
RESEARCH PAPERS	
WORKING GROUP 1	
<u>Introduction to the papers of WG 1: Argumentation and proof</u>	93
<i>Viviane Durand-Guerrier, Kirsti Hemmi, Niels Jahnke, Bettina Pedemonte</i>	
<u>Meta-cognitive unity in indirect proofs</u>	99
<i>Ferdinando Arzarello, Cristina Sabena</i>	
<u>Abduction in generating conjectures in dynamic geometry through maintaining dragging</u>	110
<i>Anna Baccaglioni-Frank</i>	
<u>Argumentation and proof: discussing a “successful” classroom discussion</u>	120
<i>Paolo Boero</i>	
<u>Mathematical proving on secondary school level I: supporting student understanding through different types of proof. A video analysis</u>	131
<i>Esther Brunner, Kurt Reusser, Christine Pauli</i>	
<u>Everyday argumentation and knowlegde construction in mathematical tasks</u>	141
<i>Julia Cramer</i>	
<u>Analyzing the proving activity of a group of three students</u>	151
<i>Patricia Perry, Óscar Molina, Leonor Camargo, Carmen Samper</i>	
<u>On the role of looking back at proving processes in school mathematics: focusing on argumentation</u>	161
<i>Yosuke Tsujiyama</i>	

<u>Making the discovery function of proof visible for upper secondary school students</u>	172
<i>Kirsti Hemmi, Clas Löfwall</i>	
<u>Conjecturing and proving in AINuset</u>	181
<i>Bettina Pedemonte</i>	
<u>A schema to analyse students' Proof evaluations</u>	192
<i>Kirsten Pfeiffer</i>	
<u>The appearance of algorithms in curricula a new opportunity to deal with proof?</u>	202
<i>Modeste Simon, Ouvrier-Buffer Cécile</i>	
<u>Proof: a game for pedants?</u>	213
<i>Joanna Mamona-Downs, Martin Downs</i>	
<u>Two beautiful proofs of Pick's theorem</u>	223
<i>Manya Raman, Lars-Daniel Öhman</i>	
<u>Multimodal derivation and proof in algebra</u>	233
<i>Reinert A. Rinvold, Andreas Lorange</i>	
<u>The view of mathematics and argumentation</u>	243
<i>Antti Viholainen</i>	
<u>Upper secondary school teachers' views of proof and the relevance of proof in teaching mathematics</u>	253
<i>Emelie Reuterswärd, Kirsti Hemmi</i>	
<u>Development of beginning skills in proving and proof-writing by elementary school students</u>	263
<i>Stéphane Cyr</i>	
<u>Designing interconnecting problems that support development of concepts and reasoning</u>	273
<i>Margo Kondratieva</i>	
WORKING GROUP 2	
<u>Introduction to the Papers of WG 2: Teaching and learning of number system and arithmetics</u>	283
<i>Susanne Prediger, Nad'a Stehlikova, Joke Torbeyns, Marja van den Heuvel-Panhuizen</i>	
<u>Cognitive styles and their relation to number sense and algebraic reasoning</u>	287
<i>Marilena Chrysostomou, Chara Tsingi, Eleni Cleanthous</i>	
<u>Danish number names and number concepts</u>	297
<i>Lisser Rye Ejersbo, Morten Mistfeld</i>	
<u>Strategies and procedures: what relationship with the development of number sense of students?</u>	307
<i>Elvira Ferreira, Lurdes Serrazina</i>	
<u>Preschool children's understanding of equality: opting for a narrow or a broad interpretation?</u>	316
<i>Anatoli Kouropatov, Dina Tirosh</i>	
<u>Using the double number line to model multiplication</u>	326
<i>Dietmar Küchemann, Margaret Brown, Jeremy Hodgen</i>	

<u>Proportion in mathematics textbooks in upper secondary school</u>	336
<i>Anna Lundberg</i>	
<u>Teaching arithmetic for the needs of the society</u>	346
<i>Hartwig Meissner</i>	
<u>Analysing children’s learning in arithmetic through collaborative group work</u>	356
<i>Carol Murphy</i>	
<u>A theoretical model for understanding fractions at elementary school</u>	366
<i>Aristkolis Nikolaou, Demetra Pitta-Pantazi</i>	
<u>Between algebra and geometry: the dual nature of the number line</u>	376
<i>Ildikó Pelczer, Cristian Voica, Florence Mihaela Singer</i>	
<u>Special education students’ ability in solving subtraction problems up to 100 by addition</u>	386
<i>Marjolijn Peltenburg, Marja van den Heuvel Panhuizen</i>	
<u>Mental calculation strategies for addition and subtraction in the set of rational numbers</u>	396
<i>Sebastian Rezat</i>	
 WORKING GROUP 3	
<u>Introduction to the papers of WG 3: Algebraic thinking</u>	406
<i>María C. Cañadas, Thérèse Dooley, Jeremy Hodgen, Reinhard Oldenburg</i>	
<u>Can they “see” the equality?</u>	410
<i>Vassiliki Alexandrou-Leonidou and George N. Philippou</i>	
<u>Patterning problems: sixth graders’ ability to generalize</u>	420
<i>Ana Barbosa</i>	
<u>The role of technology in developing principles of symbolical algebra</u>	429
<i>Giampaolo Chiappini</i>	
<u>Secondary school students’ perception of best help generalising strategies</u>	440
<i>Boon Liang Chua, Celia</i>	
<u>Using epistemic actions to trace the development of algebraic reasoning in a primary classroom</u>	450
<i>Thérèse Dooley</i>	
<u>Graphical representation and generalization in sequences problems</u>	460
<i>María C. Cañadas, Encarnación Castro, Enrique Castro</i>	
<u>The entrance to algebraic discourse: informal meta-arithmetic as the first step toward formal school algebra</u>	470
<i>Shai Caspi, Anna Sfard</i>	
<u>Students’ reasoning in quadratic equations with one unknown</u>	479
<i>M. Gözde Didiş, Sinem Baş, A. Kürşat Erbaş</i>	
<u>Investigating the influence of student’s previous knowledge on their concept of variables - an analysis tool considering teaching reality</u>	490
<i>Sandra Gerhard</i>	
<u>What is algebraic activity? Consideration of 9-10 year olds learning to solve linear equations</u>	500
<i>Dave Hewitt</i>	

<u>The role of discursive artefacts in making the structure of an algebraic expression emerge</u>	511
<i>Laura Maffei, Maria Alessandra Mariotti</i>	
<u>Algebraic thinking of grade 8 students in solving word problems with a spreadsheet</u>	521
<i>Sandra Nobre, Nélia Amado, Susana Carreira, João Pedro da Ponte</i>	
<u>Algebraic reasonings among primary school 4th grade pupils</u>	532
<i>Marta Pytlak</i>	
WORKING GROUP 4	
<u>Introduction to the papers of WG 4: Geometry teaching and learning</u>	542
<i>Philippe Richard, Athanasios Gagatsis, Sava Grozdev</i>	
<u>Innovative early teaching of isometries</u>	547
<i>Carlo Marchini, Paola Vighi</i>	
<u>Static and dynamic approach to forming: the concept of rotation</u>	558
<i>Edyta Jagoda, Ewa Swoboda</i>	
<u>Elementary students' transformational geometry abilities and cognitive style</u>	568
<i>Xenia Xistouri, Demetra Pitta-Pantazi</i>	
<u>Geometrical transformations as viewed by prospective teachers</u>	578
<i>Xhevdet Thaqi, Joaquin Giménez, Nuria Rosich</i>	
<u>Preservice teachers and the learning of geometry</u>	588
<i>Lina Fonseca, Elisabete Cunha</i>	
<u>Towards a comprehensive theoretical model of students' geometrical figure understanding and its relation with proof</u>	598
<i>Eleni Deliyianni, Athanasios Gagatsis, Annita Monoyiou, Paraskevi Michael, Panayiota Kalogirou, Alain Kuzniak</i>	
<u>Secondary Students behavior in proof tasks: understanding and the influence of the geometrical figure</u>	608
<i>Athanasios Gagatsis, Paraskevi Michael, Eleni Deliyianni, Annita Monoyiou, Alain Kuzniak</i>	
<u>Relations between geometrical paradigms and van Hiele levels</u>	618
<i>Annette Braconne-Michoux</i>	
<u>Geometry as propaedeutic to model building – a reflection on secondary school teachers' beliefs</u>	628
<i>Boris Girnat</i>	
<u>Geometric work at the end of compulsory education</u>	638
<i>Alain Kuzniak</i>	
<u>Language in the geometry classroom</u>	649
<i>Caroline Bulf, Anne-Cécile Mathé, Joris Mithalal</i>	
<u>Proofs and refutations in lower secondary school geometry</u>	660
<i>Taro Fujita, Keith Jones, Susumu Kunimune, Hiroyuki Kumakura, Shinichiro Matsumoto</i>	

<u>Identifying the structure of regular and semiregular solids – a comparative study between different forms of representation</u>	670
<i>Jürgen Steinwandl and Matthias Ludwig</i>	
<u>Generating shapes in a dynamic environment</u>	681
<i>Sue Forsythe</i>	
<u>Integrating number, algebra, and geometry with interactive geometry software</u>	691
<i>Kate Mackrell</i>	
WORKING GROUP 5	
<u>Introduction to the papers of WG 5: Stochastic thinking</u>	701
<i>Dave Pratt</i>	
<u>Designing pedagogic opportunities for statistical thinking within inquiry based science</u>	705
<i>Janet Ainley, Tina Jarvis and Frankie McKeon</i>	
<u>Preservice primary school teachers’ intuitive use of representations in uncertain situations</u>	715
<i>Chiara Andrà</i>	
<u>Relating graph semiotic complexity to graph comprehension in statistical graphs produced by prospective teachers</u>	725
<i>Pedro Arteaga, Carmen Batanero</i>	
<u>The challenges of teaching statistics in secondary vocational education</u>	735
<i>Arthur Bakker, Monica Wijer, Sanne Akkerman</i>	
<u>Children’s emergent inferential reasoning about samples in an inquiry-based environment</u>	745
<i>Dani Ben-Zvi, Katie Makar, Arthur Bakker, Keren Aridor</i>	
<u>Investigating relative likelihood comparisons of multinomial, contextual sequences</u>	755
<i>Egan J Chernoff</i>	
<u>Prospective teachers’ common and specialized knowledge in a probability task</u>	766
<i>J. Miguel Contreras, Carmen Batanero, Carmen Díaz, José A. Fernandes</i>	
<u>Investigating secondary teachers’ statistical understandings</u>	776
<i>Helen M. Doerr, Bridgette Jacob</i>	
<u>Mental models of basic statistical concepts</u>	787
<i>Andreas Eichler, Markus Vogel</i>	
<u>Instructional representations in the teaching of statistical graphs</u>	797
<i>Maria Teresa González Astudillo, Jesús Enrique Pinto Sosa</i>	
<u>Assessing difficulties of conditional probability problems</u>	807
<i>M. Pedro Huerta, Fernando Cerdán, M^a Ángeles Lonjedo, Patricia Edo</i>	
<u>Using a rasc partial credit model to analyze the responses of Brazilian undergraduate students to a statistics questionnaire</u>	818
<i>Verônica Y. Kataoka, Claudia Borim da Silva, Claudette Vendramini, Irene Cazorla</i>	
<u>Attitudes of teachers towards statistics: a preliminary study with Portuguese teachers</u>	828
<i>José Alexandre Martins, Maria Manuel Nascimento, Assumpta Estrada</i>	
<u>Developing an online community of teaching practitioners: a case study</u>	838
<i>Maria Meletiou-Mavrotheris, Efi Pappastodemou</i>	

<u>Risk taking and probabilistic thinking in preschoolers</u>	848
<i>Zoi Nikiforidou, Jenny Pange</i>	
<u>Influential aspects in middle school students' understanding of statistics variation</u>	853
<i>Antonio Orta, Ernesto Sánchez</i>	
<u>Carrying out, modelling and simulating random experiments in the classroom</u>	864
<i>Michel Henry, Bernard Parzysz</i>	
<u>Risk-based decision-making by mathematics and science teachers</u>	875
<i>Dave Pratt, Ralph Levinson, Phillip Ken, Cristina Yogui</i>	
<u>Individual pathways in the development of students' conceptions of patterns of chance</u>	885
<i>Susanne Predige, Susanne Schnell</i>	
<u>The role of relevant knowledge and cognitive ability in gambler fallacy</u>	896
<i>Caterina Primi & Francesca Chiesi</i>	
<u>Connecting experimental and theoretical perspectives</u>	905
<i>Theodosia Prodromou</i>	
<u>Implementing a more coherent statistics curriculum</u>	915
<i>Anneke Verschut and Arthur Bakker</i>	
WORKING GROUP 6	
<u>Introduction to the papers of WG 6: Application and modelling</u>	925
<i>Gabriele Kaiser, Susana Carreira, Thomas Lingefjärd, Geoff Wake</i>	
<u>Are integrated thinkers better able to intervene adaptively? – a case study in a mathematical modelling environment</u>	927
<i>Rita Borromeo Ferri and Werner Blum</i>	
<u>A modelling approach to developing an understanding of average rate of change</u>	937
<i>Helen M. Doerr and AnnMarie H. O'Neil</i>	
<u>An investigation of mathematical modelling in the Swedish national course test⁴⁷ in mathematics</u>	947
<i>Peter Frejd</i>	
<u>Modelling problems and digital tools in German centralised examinations</u>	957
<i>Gilbert Greefrath</i>	
<u>Analysis of the problem solving process and the use of representations while handling complex mathematical story problems in primary school</u>	964
<i>Johannes Groß, Katharina Hohn, Siebel Tellil, Renate Rasch, Wolfgang Schnotz</i>	
<u>Application and the identity of mathematics</u>	973
<i>Kasper Bjerling Søby Jensen</i>	
<u>Students constructing modelling tasks to peers</u>	982
<i>Thomas Lingefjärd</i>	
<u>Modelling as a big idea in mathematics with significance for classroom instruction – how do pre-service teachers see it?</u>	990
<i>Hans-Stefan Siller, Sebastian Kuntze, Stephen Lerman, Christiane Vogl</i>	

<u>Modelling in an integrated mathematics and science curriculum: bridging the divide</u>	1000
<i>Geoff Wake</i>	
<u>Exploring the solving process of groups solving realistic Fermi problem from the perspective of the anthropological theory of didactics</u>	1010
<i>Jonas Bergman Ärlebäck</i>	
<u>Hypotheses and assumptions by modeling – a case study</u>	1020
<i>Roxana Grigoraş</i>	
 WORKING GROUP 7	
<u>Introduction to the papers of WG 7: Mathematical potential, creativity and talent</u>	1030
<i>Roza Leikin, Demetra Pitta-Pantazi, Florence Mihaela Singer, Andreas Ulovec</i>	
<u>Integrating theories in the promotion of critical thinking in mathematics classrooms</u>	1034
<i>Einav Aizikovitsh-Udi, Miriam Amit</i>	
<u>High attaining versus (highly) gifted pupils in mathematics: a theoretical concept and an empirical survey</u>	1044
<i>Matthias Brandl</i>	
<u>Does mathematical creativity differentiate mathematical ability?</u>	1056
<i>Maria Kattou, Katerina Kontoyianni, Demetra Pitta-Pantazi, Constantinos Christou</i>	
<u>Unraveling mathematical giftedness</u>	1066
<i>Katerina Kontoyianni, Maria Kattou, Demetra Pitta-Pantazi, Constantinos Christou</i>	
<u>Questioning assumptions that limit the learning of fractions: The story of two fifth graders</u>	1075
<i>Andreas O. Kyriakides</i>	
<u>Mathematical creativity of 8th and 10th grade students.</u>	1084
<i>Roza Leikin, Yona Kloss</i>	
<u>Employing multiple-solution-tasks for the development of mathematical creativity: two comparative studies</u>	1094
<i>Roza Leikin, Anat Levav-Waynberg, Raisa Guberman</i>	
<u>Mathematical creativity in elementary school: Is it individual or collective?</u>	1104
<i>Esther Levenson</i>	
<u>Developing creative mathematical activities: method transfer and hypotheses' formulation</u>	1115
<i>Božena Maj</i>	
<u>Didactical vs. mathematical modelling of the notion competence in mathematics education: case of 9-10-year old pupils' problem solving</u>	1125
<i>Bernard Sarrazy, Jarmila Novotná</i>	
<u>Problem posing and modification as a criterion of mathematical creativity</u>	1133
<i>Florence Mihaela Singer, Ildikó Pelczer, Cristian Voica</i>	
<u>Creativity in three-dimensional geometry: How can an interactive 3d-geometry software environment enhance it?</u>	1143
<i>Paraskevi Sophocleous, Demetra Pitta-Pantazi</i>	
<u>Mathematical challenging tasks in elementary grades</u>	1154
<i>Isabel Vale, Teresa Pimentel</i>	

WORKING GROUP 8

- [Introduction to the papers of WG 8: Affect and mathematical thinking](#) 1165
Marilena Pantziara, Pietro Di Martino, Kjersti Wæge, Wolfgang Schloeglmann
- [Self – about using representations while solving geometrical problems](#) 1167
Areti Panaoura, Eleni Deliyianni, Athanasios Gagatsis and Iliada Elia
- [A comparative study of Norwegian and English secondary students' attitude towards mathematics](#) 1179
Birgit Pepin
- [The pupils' voice in creating a mathematically resilient community of learners](#) 1189
Clare Lee, Sue Johnston-Wilder
- ["You understand him, yet you don't understand me?!" – On learning mathematics as an interplay of mathematizing and identifying](#) 1199
Einat Heyd-Metzuyanin, Anna Sfard
- [An intervention on students' problem-solving beliefs](#) 1209
Gabriel Stylianides, Andreas Stylianides
- [A reversal theory perspective on disaffection using two examples](#) 1219
Gareth Lewis
- [Students' dispositions to study further mathematics in higher education: the effect of students' mathematics self-efficacy](#) 1229
Irene Kleanthous, Julian Williams
- [An examination of the connections between self discrepancies' and effort, enjoyment and grades in mathematics](#) 1239
Laura Tuohilampi
- [The impact of context and culture on the construction of personal meaning](#) 1249
Maïke Vollstedt
- [The effect of a teacher education program on affect: the case of Teresa and PFCM](#) 1259
Maria Pezzia and Pietro Di Martino
- [Fear of failure in mathematics. What are the sources?](#) 1269
Marilena Pantziara and George Philippou

WORKING GROUP 9

- [Introduction to the papers of WG 9: Language and mathematics](#) 1279
Maria Luiza Cestari
- [Infinite and unbounded sets: a pragmatic perspective](#) 1282
Cristina Bardelle
- [Mathematical joint construction at elementary grade – a reconstruction of collaborative problem solving in dyads](#) 1292
Birgit Brandt, Gyde Höck
- [The concept of equivalence in a socially constructed language in a primary school class](#) 1302
Cristina Coppola, Monica Mollo, Tiziana Pacelli

<u>Contention in mathematical discourse in small Groups in elementary school teaching</u>	1313
<i>Andrea Gellert</i>	
<u>Turn-taking in the mathematics classroom</u>	1325
<i>Jenni Ingram, Mary Briggs and Peter Johnston-Wilder</i>	
<u>Communicating experience of 3D space: Mathematical and Everyday Discourse</u>	1335
<i>Candia Morgan, Jehad Alshwaikh</i>	
<u>A working model for Improving Mathematics teaching and learning for bilingual students</u>	1346
<i>Máire Ní Ríordáin</i>	
<u>Revoicing in processes of collective mathematical argumentation among students</u>	1356
<i>Núria Planas, Laura Morera</i>	
<u>Epistemological and semiotic issues related to the concept of symmetry</u>	1366
<i>Frode Rønning</i>	
<u>Language as a shaping identity tool: The case of in-service Greek teachers</u>	1376
<i>Konstantinos Tatsis</i>	

WORKING GROUP 10

<u>Introduction to the papers of WG 10:</u>	
<u>Discussing diversity in mathematics education from social, cultural and political perspectives</u>	1386
<i>Paola Valero, Sarah Crafter, Uwe Gellert, Núria Gorgorió</i>	
<u>Agency in mathematics education</u>	1389
<i>Annica Andersson, Eva Norén</i>	
<u>Interplays between context and students' achievement of agency</u>	1399
<i>Annica Andersson</i>	
<u>Climate change and mathematics education: making the invisible visible</u>	1409
<i>Richard Barwell, Christine Suurtamm</i>	
<u>Teachers discussions about parental use of implicit and explicit mathematics in the home</u>	1419
<i>Sarah Crafte, Guida de Abreu</i>	
<u>Students perceptions about the relevance of mathematics in an Ethiopian preparatory school</u>	1430
<i>Anduaem Tamiru Gebremichael, Simon Goodchild and Olav Nygaard</i>	
<u>Differential access to vertical discourse</u>	
<u>– Managing diversity in a secondary mathematics classroom</u>	1440
<i>Uwe Gellert, Hauke Straehler-Pohl</i>	
<u>Mathematics teachers' social representations and identities made available to immigrant students</u>	1450
<i>Núria Gorgorió, Montserrat Prat</i>	
<u>Social functions of school mathematics</u>	1460
<i>David Kollosche</i>	
<u>Becoming disadvantaged: public discourse around national testing</u>	1470
<i>Troels Lange, Tamsin Meaney</i>	

<u>Parent-child interactions on primary school-related mathematics</u>	1481
<i>Richard Newton, Guida de Abreu</i>	
<u>Socio-cultural roots of the attribution process in family mathematics education</u>	1491
<i>Javier Díez-Palomar, Sandra Torras Ortin</i>	
<u>Between school and company: a field of tension?</u>	1501
<i>Toril Eskeland Rangnes</i>	
<u>Ethnomathematics in European Context</u>	1511
<i>Charoula Stathopoulou, Karen Françoi, Darlinda Moreira</i>	
<u>Doctoral programs in mathematics education: current status and future pathways for Turkey</u>	1521
<i>Behiye Ubuz, Erdinç Çakıroğlu, Ayhan Kürşat Erbaş</i>	
<u>Connecting the notion of foreground in critical mathematics education with the theory of habitus</u>	1531
<i>Tine Wedege</i>	
 WORKING GROUP 11	
<u>Introduction to the papers of WG 11: Comparative studies in mathematics education</u>	1541
<i>Eva Jablonka, Paul Andrews</i>	
<u>The case of calculus: Comparative look at task representation in textbooks</u>	1545
<i>Emmanuel Adu-tutu Bofah, Markku Hannula</i>	
<u>The teaching of linear equations: Comparing effective teachers from three high achieving European countries</u>	1555
<i>Paul Andrews</i>	
<u>Exploratory data analysis of a european teacher training course on modelling</u>	1565
<i>Richard Cabassut, Jean-Paul Villette</i>	
<u>Comparison of item performance in a Norwegian study using U.S. developed mathematical knowledge for teaching measures</u>	1575
<i>Arne Jakobsen, Janne Fauskanger, Reidar Mosvold and Raymond Bjuland</i>	
<u>Belgian and Turkish pre-service primary school mathematics teachers' metaphorical thinking about mathematics</u>	1585
<i>Çiğdem Kiliç</i>	
<u>Problem solving and open problems in teachers' training in the French and Mexican modes</u>	1594
<i>Alain Kuzniak, Bernard Parzysz, Manuel Santos-Trigo, Laurent Vivier</i>	
<u>What kind of teaching in different types of classes?</u>	1605
<i>Céline Maréchal</i>	
<u>Comparing the construction of mathematical knowledge between low-achieving and high-achieving students – a case study</u>	1614
<i>Ingolf Schäfer, Alexandra Winkler</i>	
<u>Conceptual metaphors and “grundvorstellungen”: a case of convergence?</u>	1625
<i>Jorge Soto-Andrade, Pamela Reyes-Santander</i>	

WORKING GROUP 12

<u>Introduction to the papers of WG 12: History in mathematics education</u>	1636
<i>Uffe Thomas Jankvist, Snezana Lawrence, Constantinos Tzanakis, Jan van Maanen</i>	
<u>Uses of history in mathematics education: development of learning strategies and historical awareness</u>	1640
<i>Tinne Hoff Kjeldsen</i>	
<u>Classifying the arguments and methodological schemes for integrating history in mathematics education</u>	1650
<i>Constantinos Tzanakis, Yannis Thomaidis</i>	
<u>The development of attitudes and beliefs questionnaire towards using history of mathematics in mathematics education</u>	1660
<i>Mustafa Alpaslan, Mine Isiksal, Cigdem Haser</i>	
<u>Implementing ‘modern math’ in iceland –Informing parents and the public</u>	1670
<i>Kristín Bjarnadóttir</i>	
<u>Voices from the field: incorporating history of mathematics in Teaching</u>	1680
<i>Kathleen M. Clark</i>	
<u>Designing teaching modules on the history, application, and philosophy of mathematics</u>	1690
<i>Uffe Thomas Jankvist</i>	
<u>Uses of history in mathematics education: development of learning strategies and historical awareness</u>	1700
<i>Tinne Hoff Kjeldsen</i>	
<u>Establishing the ‘meter’ as citizens of French National assembly during French Revolution</u>	1710
<i>Panayota Kotarinou, Charoula Stathopoulou, Anna Chronaki</i>	
<u>Lessons from early 17th century for current mathematics curriculum design</u>	1720
<i>Jenneke Krüger</i>	
<u>How much meaning can we construct around geometric constructions?</u>	1730
<i>Snezana Lawrence and Peter Ransom</i>	
<u>Identity of mathematics educators. The Portuguese case (1981 - 1990)</u>	1740
<i>José Manuel Matos</i>	
<u>The Teaching of Mathematics in Portugal in the 18th century – The creation of the 1st faculty of Mathematics in the world</u>	1750
<i>Catarina Motaa, Maria Elfrida Ralhab, Maria Fernanda Estrada</i>	
<u>Using students’ journals to explore their affective engagement in a module on the history of mathematics</u>	1760
<i>Maurice OReilly</i>	
<u>A cross-curricular approach using history in the mathematics classroom with students aged 11-16</u>	1770
<i>Peter Ransom</i>	

WORKING GROUP 13

<u>Introduction to the papers of WG 13: Early years mathematics</u>	1780
<i>Ingvald_Erfjord, Ema Mamede, Götz Krummheuer</i>	
<u>Issues on children's ideas of fractions when quotient interpretation is used</u>	1782
<i>Ema Mamede, Manuela Oliveira</i>	
<u>Finger-symbol-sets and multi-touch for a better understanding of numbers and operations</u>	1792
<i>Silke Ladel, Ulrich Kortenkamp</i>	
<u>Similar but different - investigating the use of MKT in a Norwegian kindergarten setting</u>	1802
<i>Reidar Mosvold, Raymond Bjuland, Janne Fauskanger, Arne Jakobsen</i>	
<u>Kindergartners' perspective taking abilities</u>	1812
<i>Aaltje Berendina Aaten, Marja van den Heuvel-Panhuizen, Iliada Elia</i>	
<u>The linguistic coding of Mathematical Supports</u>	1822
<i>Anna-Marietha Hümmer</i>	
<u>Analysis of mathematical solutions of 7 year old pupils when solving an arithmetic problem on distribution</u>	1832
<i>Edelmira Badillo, Vicenç Font, Mequè Edo, Núria Planas</i>	
<u>Kindergartners' use of gestures in the generation and communication of spatial thinking</u>	1842
<i>Iliada Elia, Athanasios Gagatsis, Paraskevi Michael, Alexia Georgiou, Marja van den Heuvel-Panhuizen</i>	
<u>How do children's classification appear in free play? A case study</u>	1852
<i>Vigdis Flottorp</i>	
<u>ERSTMAL-Fast (early Steps in Mathematics Learning - Family Study)</u>	1861
<i>Ergi Acar</i>	
<u>Changing mathematical practice of kindergarten teachers.</u>	
<u>Co-learning in a developmental research project</u>	1872
<i>Per Sigurd Hundeland, Martin Carlsen and Ingvald Erfjord</i>	
<u>"Looking for tricks": a natural strategy, early forerunner of algebraic thinking</u>	1882
<i>Maria Mellone</i>	
<u>Can you take half? Kindergarten children's responses</u>	1891
<i>Dina Tirosh, Pessia Tsamir, Michal Tabach, Esther Levenson, and Ruthi Barkai</i>	
<u>Investigating geometric knowledge and self-efficacy among abused and neglected kindergarten children</u>	1902
<i>Pessia Tsamir, Dina Tirosh, Esther Levenson, Michal Tabach, and Ruthi Barkai</i>	
<u>Playing and learning in early mathematics education – Modelling a Complex relationship</u>	1912
<i>Stephanie Schuler</i>	

WORKING GROUP 14

<u>Introduction to the papers of WG 14: University mathematics education</u>	1923
<i>Elena Nardi, Alejandro S. González-Martin, Ghislaine Gueudet, Paola Iannone, Carl Winsløw</i>	
<u>Why abstract algebra for pre-service primary school teachers</u>	1928
<i>Eleni Agathocleous</i>	
<u>‘Applicationism’ as the dominant epistemology at university level</u>	1938
<i>Berta Barquero, Marianna Bosch, Josep Gascón</i>	
<u>Designing alternative undergraduate delivery: oil and massage</u>	1949
<i>Bill Barton</i>	
<u>Why do Students go to Lectures?</u>	1960
<i>Christer Bergsten</i>	
<u>Designing and evaluating blended learning bridging courses in mathematics</u>	1971
<i>Biehler, R.; Fischer, P.R.; Hochmuth, R.; Wassong, Th.</i>

PROCEEDINGS OF THE SEVENTH CONGRESS OF THE EUROPEAN SOCIETY FOR RESEARCH IN MATHEMATICS EDUCATION: GENERAL INTRODUCTION

This volume contains the Proceedings of the Seventh Congress of the European Society for Research in Mathematics Education (ERME), which took place 9-13 February 2011, at Rzeszów in Poland. ERME came into being at its first congress in Osnabrueck, Germany, in 1998. Thereafter, CERME congresses have taken place every two years since CERME2 in 2001.

CERME places great emphasis on promoting participation by all who attend the congress, with a deliberate shift from the succession of parallel research report presentations that characterise most international scientific conferences. Thus, the vast majority of CERME time is devoted to discussion and debate within thematic Working Groups (WGs), facilitated by a team of leaders for each WG.

These leaders give a great deal of their time in organising the peer review for their WG before the congress, the working sessions at the congress itself, and in coordinating and editing those parts of these proceedings related to their WG. CERME participants must commit themselves to membership of just one such Group, and to 6 or 7 sessions of 90-120 minutes *working* with the Group.

The number of WGs increased to 17 at CERME7, and the number of participants in each was around 25-30 on average, including about 4 WG leaders. The WG themes were as follows:

- WG1: argumentation and proof;
- WG2: teaching and learning of number systems and arithmetic;
- WG3: algebraic thinking;
- WG4: geometry teaching and learning;
- WG5: stochastic thinking;
- WG6: applications and modelling;
- WG7: mathematical potential, creativity and talent;
- WG8: affect and mathematical thinking;
- WG9: mathematics and language;
- WG10: diversity and mathematics education;
- WG11: comparative studies in mathematics education;
- WG12: history in mathematics education;
- WG13: early years mathematics;
- WG14: university mathematics education;

Introduction

WG15: technologies and resources in mathematics education;

WG16: different theoretical perspectives and approaches in research in mathematics education;

WG17: from a study of teaching practices to issues in teacher education.

Research paper and poster proposals were submitted to a *Group*, and were then subject to peer review within the WG and a decision about acceptance by the WG leaders. This structure results in significantly devolved and distributed responsibility for the organisation of the congress, and – hopefully – a sense of belonging to their chosen WG, for all participants. All accepted papers were posted on the CERME website before the congress, and each participant was expected to read all of those related to their WG – typically 15 or more – *in advance* of the congress.

At the congress itself, it was then possible to devote *all* of the time allotted to each paper to discussion, rather than the usual monologue-presentation. In this way, opportunities for interaction and participation are maximised. Following the congress, the authors of the accepted papers had the opportunity to make further revisions in response to the feedback and discussion within their WG. The form in which they appear in these proceedings reflects this continuous process of improvement, assisted by critical support within the WG.

The success of the ERME movement can be measured, in part, by the numbers of participants and presentations at recent meetings. In Rzeszów, 453 participants came from 50 countries, and were involved in 17 Working groups, coordinated by 75 leaders. 293 research papers were accepted for presentation and discussion at the congress, as well as 69 posters. Taken to the next stage, 279 papers and 49 poster-communications appear in these proceedings. Interest in CERME continues to grow, with participants coming from 17 countries beyond Europe (such as Canada, US, Brazil, Singapore, Australia ...) this time.

The ERME ‘spirit’ of communication, cooperation and collaboration is explicitly enshrined in its aims and vision. *Inclusion* is central to its ethos, and the way that the WGs organise their activity. At the same time, ERME must promote and support scientific *Quality* if it is to be useful to its members and credible on the international stage. At times the two goals, inclusion and quality, seem to pull in different directions, creating tension and sometimes dissatisfaction when, for example, a research paper is not accepted for presentation, despite formative feedback and revision, and the author is then unable to access funds to attend the congress. Thus, by upholding a notion of necessary ‘standards’ of scientific quality, someone is effectively denied participation in the congress.

This tension has recently been addressed in collaborative research by Barbara Jaworski (UK), João Pedro da Ponte (Portugal) and Maria Alessandra Mariotti (Italy), which is reported in Jaworski et al. (2011). A paper related to this research was made available to CERME7 participants in advance of the congress.

Introduction

In addition to the WG activities, the sense of belonging to the *whole* congress was fostered in a number of plenary scientific activities, and in a varied social and cultural program. The opening ceremony, held in the splendid surroundings of the Rzeszów Philharmonic Concert Hall, included a plenary address by Anna Sierpiska, on her recent research into elementary mathematics methods courses in preservice teacher education. Sierpiska maintains close links with mathematicians and mathematics educators in her native Poland. Two other plenary talks later in the conference recognised the work of two CERME WGs across several congresses, and were given by researchers who had led these WGs until recently. Thus, the address of Markku Hannula (Finland) was on the Structure and Dynamics of Affect in Mathematical Thinking and Learning; Maria Alessandra Mariotti's title was Proof as an Educational Task.

Three papers corresponding to these plenary addresses are published later in these proceedings. Another notable event in the plenary program was a session introducing the current work of the Education Committee of the European Mathematical Society, in particular the project to itemise 'solid findings' in mathematics education. This session included fruitful discussion about the nature and warrants of such findings, and their relationship to the work of ERME and its members.

The vision and ethos of ERME is also distinctive in its support for 'young' researchers in the field of mathematics education, notably those undertaking doctoral research or in post-doctoral positions. Every CERME conference is preceded by two half-days of YERME ('young-ERME') discussion groups and workshops.

At CERME7 these were led by professors Paolo Boero, Pessia Tsamir, Dina Tirosh, Barbara Jaworski, João Pedro da Ponte and Heinz Steinbring. The Society is fortunate to have such experts willing to give freely of their time for the benefit of the future leaders of ERME.

We extend sincere thanks to Ewa Swoboda and all the local organisers for their hard work, and to the University of Rzeszów for making us so welcome at the first CERME to be held in Eastern Europe. The next CERME will take place in February 2013, in Antalya, Turkey.

PROCEEDINGS OF THE SEVENTH CONGRESS OF THE EUROPEAN SOCIETY FOR RESEARCH IN MATHEMATICS EDUCATION: EDITORIAL INTRODUCTION

In this brief introduction to these proceedings of the Seventh Congress of the European Society for Research in Mathematics Education (CERME7), we set out to explain the nature and the organisation of the contents. Individual contributions can be accessed directly from hyperlinks on the contents page.

Following the general introduction by the ERME President and the CERME7 Chair, the first section-proper of the CERME7 Proceedings consists of three major papers, by Anna Sierpinska, Markku Hannula and Maria Alessandra Mariotti. These three distinguished scholars were invited by the scientific program committee to give **plenary addresses** to the congress. Each of them responded to the request for a written paper, recording and elaborating on the content of their presentations. Following discussions with the editorial panel, these papers are published here.

The second section of the proceedings is the written record of the activity which lies at the heart of every CERME congress. It is in 17 parts, corresponding to the 17 **Working Groups** (WGs) at CERME7. Each part begins with an introduction, an overview of the work of the WG by the team that led it, followed by those papers accepted for presentation *and* publication by the WG leaders, following peer review before and discussion during the congress. The papers are ordered alphabetically, by first author, although thematic groupings are sometimes suggested in the WG-leaders' introductions. We extend our thanks to, and acknowledge the editorial contribution of, the leaders of each WG in their scrutiny of the papers accepted for publication from their Group.

The third section of the proceedings is an innovation in the dissemination of the content of posters accepted for presentation and discussion at CERME. In response to a request from some WG leaders, the ERME Board agreed that posters accepted for CERME7 could be 'published' in the proceedings. This was realised by inviting the relevant poster-authors to submit a two-page communication of the content of their poster. These **poster-communications**, also grouped by Working Group, appear in this final section.

Since CERME3 in 2003, Proceedings of CERME congresses have been produced electronically, usually in CD format. They can be also be accessed online from <http://www.erne.unito.it/>

Editors, Proceedings of CERME7.

Introduction

Plenary lectures

RESEARCH INTO PRE-SERVICE ELEMENTARY TEACHER EDUCATION COURSES

Anna Sierpinska
Concordia University, Montreal, Canada

Considerable effort has been put into mathematics education research towards the development of knowledge that could serve as a basis for a professionalization of the work of mathematics teachers. In recent years, a similar effort has been expended with regard to the work of the mathematics teacher educator. Three years ago, I joined this current by engaging in a research project on the “Teaching Mathematics” (TM) courses for future elementary school teachers with Helena P. Osana, a researcher in educational psychology and an experienced elementary mathematics teacher educator. The goal of this research, ultimately, is to make public, communicable and open to critical analysis the personal experience of university professors teaching such courses. The more modest and immediate goal of our small project is to describe and make sense of TM courses in six Canadian universities, three Francophone and three Anglophone. We observed classes, studied course descriptions, and conducted long interviews with instructors; we also interviewed students. In the talk, I present some results of our research so far, focusing on a framework for analysing the TM courses that we have started developing in our research. This framework might be useful for other researchers wishing to contribute to professionalization of elementary mathematics teacher educators’ work.

HOW IT STARTED

It all started with a meeting of two singularities: Helena P. Osana, the single mathematics educator in the Education Department, and myself, one of two mathematics educators in the Mathematics & Statistics department of our university. We started talking about possibilities of collaboration, such as teaching courses in the other department, and doing research together. Helen could certainly teach a course in educational psychology in the *Master in the Teaching of Mathematics* program in the math department. But what could I teach? The Education Department has only two courses in mathematics education, both in the undergraduate program leading to certification of elementary school teachers. Moreover, Helen’s research has been in the area of elementary education, whereas my research so far, was on secondary or tertiary mathematics teaching and learning. So, if I wanted to engage in collaboration with Helen – and I did – I had to learn something about her area of practice and research.

I was curious about her elementary mathematics teacher preparation courses, thinking that I could maybe teach one in the future. There were plans, in fact, to add one more course on mathematics teaching to the two already in place in the

Plenary lecture

elementary teacher preparation program. To prepare, I started reading about mathematics teacher education. There was no shortage of sources. This is a huge area. There is a specialized journal, *Journal of Mathematics Teacher Education*, and one of the recent ICMI Studies was devoted to the area (Even & Ball, 2009). I was finding interesting ideas for activities for teachers and information about teacher education programs around the world. All this was, however, not enough for me to make decisions in designing a whole course for future teachers. Of course, I could just start by teaching one of the courses already in place by taking Helen's course outline and her lecture notes and materials and teach according to those. But I don't think I would be able to do that properly without seeing her course as a result of a rational choice. To understand it as a result of a choice, I had to see alternative ways of conceiving such course. I wanted to see what other instructors of elementary mathematics teacher preparation courses in Canada are doing. And this is how I embarked, with Helen, on the research of which I will be showing some snapshots in this talk.

THE DATA

We visited elementary mathematics teacher preparation courses in six universities in three Canadian provinces: Québec, Nova Scotia and New Brunswick. Three universities were Francophone and three Anglophone. We labelled the French universities FU1, FU1, FU3; AU1, AU2, AU3 are labels for the English universities. I will call all these courses "Teaching Mathematics" courses (TM), although they had different names in different universities. The courses we visited were part of 120 credit Bachelor of Education programs (Elementary Education option). At all the English language universities, 6 of the 120 credits had to be obtained in two 3-credit TM courses, each lasting about 13 weeks. FU1 and FU3 had four 3-credit compulsory TM courses. At FU2, located in New Brunswick, beside the two 3-credit TM courses, students preparing to teach in grades 5-8 had to take four mathematics courses, including one-variable Calculus. In New Brunswick, elementary education counts 8 grades, not 6 as in other provinces. There were no compulsory mathematics courses for elementary teachers at the other universities, although at FU1, there was a mathematics "placement test", and students who failed it had to take a remedial mathematics course based on secondary school material.

We interviewed instructors and students, observed classes, collected various documents such as course outlines, lecture notes, assignments, tests and examinations. We labelled the instructor of the course at AU1 "Professor Aone"; similarly, Atwo, Athree, Efune, Efdeux, Eftrois were labels for instructors of courses at the other universities. "Professor" marks the fact that these instructors were full time faculty members in charge of these courses. For the sake of brevity, I will omit the title "Professor" when referring to the instructors. Most of them designed their courses from scratch and had been developing them for several years. An exception was Atwo who was in her second year of teaching at the time we met her, and she

Plenary lecture

was teaching her course along a design inherited from her predecessor, who was retiring. There was also a somewhat exceptional situation at AU3, where, at the time of our visit, Athree did not teach the TM course, and was replaced by “Ms. West”. Ms. West was a part-time instructor at the university, and a pedagogical consultant for mathematics teaching on the Elementary School Board in the area. She did not use Athree’s course design but developed her own. We interviewed both Ms. West and Athree about the way they designed and ran the TM course, but could visit only Ms. West’s class.

FOCAL ASPECTS OF THE STUDY

As we collected and analysed data, we tried to identify, in each course: the content structure; the tasks given to students; the formats of teacher-student interaction (see Bruner, 1985; Sierpinska, 1997); the instructor’s reasons for his or her choices about the previous three aspects; and students’ perceptions of the course. Based on our analysis of these aspects, we attempted a description of the *nature of knowledge* that was emerging in the course.

SOME SNAPSHOTS OF THE RESULTS SO FAR

This is a study in progress, so what I can offer is only a glimpse of partial results obtained so far. I will talk about the following aspects of the TM courses: (a) course content components, (b) differences in course content and the weighting of course components, (c) our analysis of tasks in TM courses and in particular, the epistemic actions they are designed to generate, (d) the formats of interaction between TM instructors and students as another way to capture the nature of epistemic actions emerging from TM courses, and (e) student perceptions of the TM courses.

Content Components

The content of the courses seemed to have the following components, in various proportions:

- Mathematical Knowledge for Teaching (MKT)
- Psychology of Mathematics Learning (PML)
- Teacher’s Didactic Actions (TDA)
- Reflection on teacher preparation (R)
- Ideology (I)

The name *Mathematical Knowledge for Teaching* sounds like Ball’s MKT model of a knowledge base for mathematics teaching (Ball, Thames, & Phelps, 2008), but it refers to only a subset of this model, namely *Common Content Knowledge* and *Specialized Content Knowledge*. Ball’s MKT encompasses our MKT, PML and TDA combined. Our PML is close to Ball’s *Knowledge of Content and Students*, and TDA, to Ball’s *Knowledge of Content and Teaching*. We chose to separate MKT

Plenary lecture

from PML and TDA because syllabi of the TM courses sometimes do that too. At AU2, the first TM course focuses on MKT only: it is intended to be a review of elementary school mathematics.

Our MKT, PML, and TDA categories are different from Ball's model in that they refer not to what teachers *should* know but to what TM instructors *choose to teach* in their courses. PML may contain any content related to how elementary school children learn mathematics (e.g. Piagetian theories of learning mathematics, the van Hiele model, or "principles" of learning mathematics advanced by mathematics educators), and TDA – any content related to teacher's didactic actions (planning a lesson; designing an assessment, etc.). I will not discuss the PML and TDA components in general terms; some examples of PML and TDA content will be given later in this talk. Here, I will dwell a bit more on MKT, focusing on the aspect that has been stressed also in Ball's model, namely that mathematical knowledge for teaching is very different from the mathematician's mathematics.

As Freudenthal stressed long ago (1986), MKT for elementary school is neither a part nor a "didactic transposition" of scholarly mathematics (Chevallard, 1985). One immediately obvious difference is the kind of quantities they work with: mostly abstract numbers for the mathematician, and mostly (concrete) quantities of units (of lengths, areas, time, weight, money) in the elementary school, and abstract numbers figure as "multipliers" (or scalars) that can scale the quantities (e.g., one can double a quantity, or halve it). Vergnaud's notion of "measure spaces" models rather well the quantitative structures of MKT (Vergnaud, 1983).

The mathematician conceives of operations on numbers as functions; in MKT, an arithmetic operation is conceived of via problem situations that call for this operation. For example, in a recent textbook for elementary school teachers (Sowder, Sowder, & Nickerson, 2010), the chapter on "Understanding Whole Number Operations" has a list of "Problem situations that call for multiplication" (p. 63). The "problem situations" in the list are named and described as "ways of thinking about", "views," or "models" of multiplication or division. The categories are labelled as: 1. Repeated addition; 2. Area/array model; 3. Operator view, and 4. Fundamental counting principle. A mathematician may be baffled by the categories because some sentences in their descriptions look like definitions, some like computational procedures, and others like statements of problems. Some conditions appear unnecessary and some categories, redundant. This confusion is one of the consequences of a different understanding of the notion of "model" by the two parties. An expression such as "models of multiplication" used in reference to a "context that calls for multiplication" is surprising for the mathematician who would find it more natural to say, "multiplication is a (mathematical) model for this context" than "this context is a model for multiplication." The mathematician looks at a problem situation and tries to find or construct a mathematical theory that would represent it. MKT works in the opposite direction: Given a piece of mathematical

Plenary lecture

theory (e.g., the operation of multiplication), look for situations that could be described using this piece of theory, so that, in teaching, the theory acquires some sense for the students, and which can be used to practice the theory and assess students' knowledge of it. MKT contains a categorization of situations that can be described using the piece of theory. The categorization then serves to design exercises, curricula, and textbooks.

The existence of different “models” for multiplication in MKT leads to more differences with the mathematician's mathematics. In particular, while for the mathematician, multiplication in real numbers is commutative, for MKT, it is not necessarily. It depends on the model of multiplication the class is presently working on. In the repeated addition model of multiplication, which applies to “problem situations”, where one has to find “the sum when a whole number of like quantities is combined” (Sowder et al., 2010, p. 59), in the US textbooks for children, an expression such as 2×3 means $3 + 3$, and not $2 + 2 + 2$. The first number is understood as the multiplier; the second – as the quantity multiplied. From the point of view of this model, the expression 2.5×3 “cannot be interpreted” (ibid.)

The *Reflection on teacher preparation* component has no counterparts in Ball's model, but we had to add it to the aspects we looked at in the courses because it played an important part in some of them. When Aone and Athree were starting to develop their courses, *Reflection* could take the form of only an informal classroom discussion, but, over the years, it would gradually occupy a larger space. For about 3-4 years now, Athree has not been preparing a detailed course syllabus before the course starts. He begins his course by developing the syllabus together with his students. He also designs the assignment and assessment techniques for the course with them. Athree claims that by devolving part of the responsibility for the course content to his students, they understand better the goals of the course and what is expected of them in the assignments. This was Athree's solution to the recurrent problem he faced in his courses of students asking him “Why do we need to know all that?” and not producing what he expected in the assignments, despite increasingly detailed and lengthy instructions and explanations. Aone has not turned to such radical solutions, but she believes her students need a preview of the kind of knowledge she is going to give them a glimpse of in her TM course and that they will be responsible for developing later in their professional careers in schools. Thus for quite some years now, she would start her course with one long written assignment, where students are asked to reflect on what they think an elementary mathematics teacher should know, and then revisit their thoughts after reading an article on teacher knowledge (usually Ball, Hill, & Bass, 2005).

We use the word *Ideology* in the sense of “visionary theorizing” (see Endnote 1). Some instructors promote a “vision” of mathematics learning and teaching. This vision may or may not be explicitly linked to a theory, but it is not a theory. In a theory, statements about teaching and learning are hypotheses or results of empirical

Plenary lecture

research. An ideology makes statements about how teaching and learning *should be*. Thus, a theoretical statement such as, “a child learns by adapting her cognitive structures to deal with problems arising in her own environment” may be turned, in an ideology, into “an invitation to teach mathematics from a problem-solving perspective” (promoted, in particular, by the NCTM Standards), and “placing the child in the centre”, as in a textbook used, at the beginning of his work as a TM course instructor, by Athree:

The vision of mathematics learning presented in this book places the student at its centre. The living context of each student is important to the learning scene and it is out of that culture that ideas for proposing mathematical problems should emerge. (Cathcart, Pothier, Vance, & Bezuk, 2000, p. xi)

At the beginning of his career, Athree was strongly promoting “constructivism” as the preferred vision of learning for teaching. In his second year of teaching, for example, students’ responses to a task of planning a take-home mathematics teaching activity were evaluated based on, among a few other aspects, “the extent to which your planning reflects consideration of constructivist learning theory” (Athree, Course Outline 2000). Now, he leaves his students the choice of the learning theory on which they want to build their own visions of teaching and learning, and even according to which they want to be assessed in the course. He expects them, however, to be conscious of the choice they make and aware of its consequences, and suggests relevant articles to read. However, there can be no escape from ideology in a TM course. If it is not explicit, it is conveyed by the instructor’s choice of classroom activities and comments, however neutral he or she may try to appear. Education, in general, is value-laden.

Course Differences: Weights and Content of Course Components

Courses differ in the weight they assign to the content components. When we examined the evolution of a course developed by an instructor over a longer period of time, changes in the weight assigned to different components were one of the more salient observations. In the case of AU1 and AU3, we noticed a drastic change in the weight of MKT from very small in the first year to quite large in the second year. This was the result of the realization, by both instructors, that future elementary teachers know even less mathematics than they had been warned to expect, and TM instructors must review with them the most basic ideas.

We measured the weight of a content component by analysing a sample of tasks instructors assigned the students: we looked at the content area of the knowledge each task called for and counted the relative frequency of tasks corresponding to the given content area. An example of such analysis will be given later. We considered this measure to adequately represent the weights of the components because there was usually very little lecturing in the courses. Classes were organized around “activities”, which we were able to decompose into tasks.

Plenary lecture

With respect to course content components, the categories of MKT, TDA, PML, etc. are quite broad and their detailed content varies widely from one TM course to another. Even using the same textbook for elementary mathematics teachers, such as the quite popular textbook by Van de Walle (1998), does not guarantee many commonalities in the content of the courses. Some instructors choose to “cover” all fundamental elementary mathematics topics; others pick only a few. Some insist on knowing the precise mathematical terminology and definitions for mathematical concepts; others are much more relaxed about it. Ms. West at AU3, in particular, would correct any student’s departure from the conventional mathematical terminology. In the class we observed, a student called a regular hexagon, an “equilateral hexagon”. She laughed at the expression, and corrected it: “regular!”. Professor Athree said that he would not correct this expression since it is quite logical: a generalization of the term “equilateral triangle” to a hexagon with all sides equal.

Some instructors insist also on knowing terminologies developed in mathematics education, educational psychology or cognitive psychology in relation with chosen theories and models of teaching and/or learning. We started calling these theories and models “structuring frameworks”. One of the frameworks is a repertoire of problem-solving strategies, included in all textbooks for elementary teachers we had a chance to look at. The textbook used by Professor Athree in the first few years of his teaching the TM course, for example, presented strategies such as “Draw a picture or a diagram”; “Find a pattern”; “Solve a simpler problem”, etc. (Cathcart, Pothier, Vance, & Bezuk, 2000). Professor Athree, however, did not require his students to know and use the exact names of these strategies. Professor Aone, on the other hand, does, and she tests her students on this knowledge. On a test, students may be given a solution of a problem and the question would be, “Name the strategy used in solving the problem”. At FU2 (and only at this university), the Piagetian theory of developmental stages was an important structuring framework. One of major assignments in the course was to design and implement a diagnostic interview with children between 4 and 12 years of age to assess their developmental stage in relation to a particular mathematical concept (number, chance, space). To prepare for this task, students had to read Copeland (1984, 1974) and Kamii (1985, 1989).

The course at AU1 appeared to be the strictest in the use of structuring frameworks. In fact, at AU1, in the first TM course, there was at least one explicit structuring framework for each content area, and students had to know the categories well since they were used and required on tests and the written final examination. The MKT component of the first of the two TM courses contained the following structuring frameworks (and only those):

- Mathematical principles of counting, based on Ginsburg (1989), e.g. “One-to-one Principle” (each member of the set must be counted once and only once)
- Place value and numeration systems, based on a chapter from Burriss (2005)

Plenary lecture

- Arithmetic operations on whole numbers and their properties (Burris, 2005)
- Types of problems involving each of the four arithmetic operations, based on Carpenter et al. (1999) – written from the perspective of Cognitively Guided Instruction (CGI).

Structuring frameworks for the PML component were:

- Psychological principles of counting, based on Ginsburg (1989); e.g. different results after having counted a set twice do not usually bother pre-schoolers; most pre-schoolers have difficulty touching each thing in a set once and only once when counting
- General problem solving strategies, based on Reys et al. (2008)
- Children's problem solving strategies, based on the CGI book by Carpenter et al. (1999)

For TDA, the frameworks were:

- Teaching counting based on mathematical and psychological counting principles (Ginsburg, 1989)
- Flexible interviewing techniques, based on Ginsburg, Jacobs and Lopez (1998)
- Effective learning environments, based on Hiebert et al. (1997).

Hiebert et al. (1997) provided also a structuring framework for the Ideology component, and, as already mentioned, a structuring framework for the Reflection component was Ball et al.'s (2005) model of mathematical knowledge for teaching.

Tasks for future elementary mathematics teachers

Tasks in mathematics teacher education have been at the centre of attention in the area for some years now. In 2007, the *Journal of Mathematics Teacher Education* produced a Special Issue on tasks in 2007 (Jaworski, 2007). A recent ICMI Study on mathematics teacher education was also interested in tasks (Clarke, Grevholm, & Millman, 2009). The question of such tasks has puzzled me for years, long before I embarked on this research, and the hope of getting some insight into those tasks was a great incentive to engage in it. What can future teachers be asked to do in a course besides solving mathematical problems? How can we ask them to do problems about the teaching of mathematics if they have never taught before, and particularly because TM courses are often given before they have their practicum? Aren't the problems of teaching mathematics always very deeply situated in the actual, day-to-day practice of teaching?

What can the TM instructor do to engage his or her students in tasks that are meaningful for teachers' work in the absence of real life elementary classroom experience?

We saw several ways that instructors deal with this issue in the courses we observed:

Plenary lecture

- organizing *authentic* educational interactions with real children, with future teachers in the role of educators; e.g. tutors, animators of an extra-curricular activity, researchers;
- *simulating* an elementary mathematics classroom with future teachers in the role of elementary school-children and the TM instructor as the teacher, or some TM students in the role of teachers and others in the role of their students;
- engaging future teachers in a teacher's "*private*" tasks, i.e. tasks that are mostly done outside of the classroom.

We saw the "*authentic*" technique applied at AU2 and FU2. One of the assignments at AU2 was for future teachers to do at least two weeks of volunteer tutoring in math in a community centre, where children came after school to get some help with their homework. Future teachers had to write a report about their experience as part of their coursework. Interviewing the future teachers after their volunteer tutoring, we were amazed at how enthusiastic they were about the tutoring experience, even those who were extremely critical about the TM course in all our previous interviews. Those future teachers, who up to that point had talked only of how miserable and unsure they were about being able to pass the exam in the TM course, suddenly started talking from the position of teachers concerned about children's difficulties in math and the challenge of helping them. This was difficult for them, and yet they were saying they "had a wonderful time".

At FU2, future teachers had to interact with real children in two assignments. One of the assignments was the Piagetian diagnostic interview task already mentioned above. The other, was an "enrichment project". Students had to invent problems for a "math trail" activity to be run in one of the buildings of the university, and then actually organize the event in collaboration with a school and animate it, accompanying the children along the trail. The math problems had to deal with objects actually found in the building. They were therefore intended to be "situational" or contextual problems, whose importance is stressed in Canadian mathematics curricula at both the elementary and secondary levels (see, e.g. Ministère de l'Éducation, des Loisirs et du Sport, Gouvernement de Québec, n.d., or New Brunswick, Department of Education, Curriculum Development Branch, 2011).

All the activities mentioned here as examples of the "*authentic*" technique are authentic teaching tasks only in the sense that they involve real children. They do not belong to an ordinary teacher's day-to-day practice.

The "simulation" technique with future teachers playing the part of elementary school children solving mathematical problems was used to some extent in all courses. In particular, in the first TM course at AU2, future teachers spent most of the time in a "lab", solving, in small groups, problems that could be given to elementary school children (although they were perhaps more "fun" and involved the use of a much greater variety of manipulatives and hands-on activities than is

Plenary lecture

common in most schools). The lab was intended to provide future teachers with an experience of a model learning environment for teaching mathematics in elementary school. There was no instructor-guided reflection on those activities from the point of view of a teacher at AU2, however. Such reflection was attempted in all the other courses, with greater or lesser use of the structuring frameworks. I give an example from Ms. West's class at AU3.

In one of the activities we observed in Ms. West's class, students were given a bagful of shapes, cut out by Ms. West herself, from a plastic foam sheet. The shapes were of a large variety of kinds, not only those with known names such as circles, squares, triangles and rectangles; some looked like apples, others like eyes; there were concave shapes, convex shapes, rectilinear shapes, curvilinear shapes, etc. The task for students was the following: "The group chooses one shape and places it at the centre of the table. One person chooses a shape that is like the shape in the centre, and explains how it is alike. The rest of the people at the table must choose shapes that have the same properties." The task's name was "The sorting task". After 15 minutes, Ms. West asked the students: "What is the purpose of this activity?" Students would venture some one-word responses, sounding tentative. I overheard, "Categories?" This was obviously not what Ms. West expected; so, without making any comments about these responses, she asked a question that indicated better her expectations: "What does it tell me about the children?" I hear a student responding, again with hesitation in her voice: "How they think?" Now Ms. West looked more satisfied, but she felt obliged to make explicit her expected answer herself: "It is an informal assessment of their van Hiele level of understanding. At Level 0, a student would say, 'it is a triangle because it looks like a triangle'. At level 1, the student would say, 'it is a triangle because it has three sides'." In Ms. West's class, the simulation phase of an activity always dealt with the MKT content area (students were learning elementary school mathematics); the reflection phase, in this example, brought up PML content: the van Hiele model of understanding in geometry.

This technique was also used by Athree, who, in a discussion about Ms. West's class, said:

Something I would do exactly the same [as Ms. West], I think, is this operating on two levels simultaneously. I am teaching mathematics and I am teaching elementary school mathematics because they don't know it. And I am trying to teach it that way that I would like for them to be teaching it because I think that that is the most effective way to be teaching it. And that I can simultaneously comment on that as I go along. Whether that shifting of levels is in fact something the students are comfortable with and can follow, whether they can reflect on their activity while they are engaged in that activity, is ... Somebody could do some research on that. (Athree, interview)

In yet another type of simulation, Athree engaged his students in co-teaching with him. The technique was also used by Efune. Athree used it for several years in his

Plenary lecture

TM courses in a task called “Teachers of the week”. The task was formulated as follows:

You and your teaching group will share responsibility (with the instructor) for the teaching of one component of one class. Prior to the class you will meet with the instructor to plan the lesson for that week.... All classes will conclude with a 20 minute discussion of the class: how it was taught, usefulness of the content, etc....

The “lesson” would consist of an activity to be done in small groups. Members of the teachers of the week group would present the activity, distribute any handouts, if needed, and then circulate among the tables, interacting with students, giving hints or prompts to reflect; the lesson would close with a plenary discussion of the results of the activity. Athree used this technique for a couple of years and then abandoned it. He said it was taking up a lot of his and his students’ time, and it was not obvious the students were gaining much from this experience for their future teaching in schools.

Tasks related to the teacher’s “private” activities were common in the courses.

In particular, at AU1, there were no other tasks. The closest the future teachers were brought into contact with the reality of teaching was through watching and analyzing videos of teachers in the classroom and children solving problems [examples of videos used at AU1 can be viewed at the website of Annenberg Media (1997, 2000); videos of children solving problems were taken from the DVD accompanying the CGI publication by Carpenter et al. (1999)].

The private tasks technique might seem a rather poor substitute for real life experience of teaching. Yet the following tasks on which Ball’s (2008) model of mathematical knowledge for teaching is built could be, in principle, engaged with outside of direct interactions with children: 1. do the mathematical work that the teacher assigns to students; 2. plan the teaching of a thematic unit and each of its lessons; 3. explain a mathematical idea, concept or procedure in a manner appropriate to a given educational level and curricular context; 4. design questions, exercises and problems for various purposes; 5. design own teaching materials, which involves choosing or developing appropriate representations; 6. evaluate teaching materials designed by others (in particular, textbook materials); 7. assess students’ learning and understanding of mathematics not only in terms of correct/incorrect but also in terms of identifying mathematical sources of students’ errors (as opposed to psychological sources, such as lack of attention); 8. find a way to help a student to correct an error he or she does in a systematic way; 9. find some “strategic examples” and /or representations to highlight a feature misunderstood by the student.

Therefore, the private tasks seem important to mathematics teacher educators, not as a substitute for real teaching, but on their own merits. Future teachers do not always appreciate the relevance of these tasks for teaching practice, however. We heard criticisms pointing in this direction from students in all universities. Admittedly, if

Plenary lecture

done outside of the school context, tasks 1-9 are not *authentic*. Instructors only take students through a “dry run” of such tasks, without the prospect of implementing the results of the private work in the public arena of classroom teaching. The tasks are imposed by the instructor of the TM course rather than arising naturally from interactions with children and colleagues.

If TM courses cannot engage students with knowledge that a practitioner actually uses in teaching, with what kind of knowledge do future teachers engage in those courses?

To obtain a deeper insight into the ‘epistemic nature’ of knowledge that tasks in the TM courses called for, we needed to analyze them in more detail. The idea was to select a sample of tasks in a TM course, examine the actions related to mathematical or teaching practices that were involved in solving each task, and then calculate the distribution of the actions. This method is similar to that used by Sánchez and García (2009) in their analysis of tasks in TM courses. These authors used a grid of analysis that identified elements related to, on the one hand, “mathematical practices” (defining, justifying, modelling, symbolizing, etc.), and, on the other, “mathematics teacher’s systems of activity” (e.g., the organization of the mathematical content for teaching; management of the mathematical contents and discourse in the classroom; analysis and interpretation of students’ mathematical thinking, which correspond to some of the private teacher tasks we enumerated above).

To derive some information about the nature of actions involved in solving each task, we needed a way to analyze each task in detail. We decided to use the *praxeology framework* developed by Chevallard in his *Anthropological Theory of the Didactic* (1999). Praxeology models a practice by the tasks it sets out to accomplish; the techniques normally used to accomplish the tasks; and two levels of discourse, one developed to objectify, communicate, and justify the techniques (“technology”), and the other, to justify the choice of the technology as one theoretical choice among others (“theory”). Based on this framework, we used a *grid of analysis* made of the following rubrics: Task, Content Area addressed in the task (MKT, PML, TDA, etc.); Technique; Technology; Theory; Type of Action (epistemic, pragmatic, mathematical, didactic, sub-type of such action, etc.). We also identified the institutional status of the task (e.g., small group activity in class; quiz question; midterm examination question; final examination question; take-home project). Below are a few examples of tasks, and Table 1 illustrates how these tasks were coded.

Task 1. (AU1, Quiz question) True or false? Justify. Statement: “Children must grasp the One-to-one Principle before they can effectively apply the Stable Order Principle”

Task 2. (AU1, Final examination question) Name the problem type: “Martha has 12 Polly dolls. She has 5 more Polly dolls than Sam. How many dolls Sam has?” (Expected answer: Addition-subtraction problem / Compare problem / Compared set unknown)

Plenary lecture

Task 3. (AU1, Final examination question) “When we use the standard algorithm to compute 454×3 , we write the following [3 is written below 454; a horizontal line below 3, sign of multiplication on the left of 3, 1362 below the line; small 1 above the leftmost 4 and small 1 above the 5 in 454]. Show how you would model this computation with Base 10 blocks. Make sure to be careful to explicitly point out the connection between the little ‘1’s in the algorithm and your manipulations with the blocks.”

Task 4. (AU3, Mrs. West, in-class activity) “Van Hiele Guided exploration of a square”. Envelopes with squares of different sizes are distributed, one envelope per table. Each student takes one square. Ms. West: “Jot on a piece of paper everything you know about a square”. When students finished writing, Ms. West gives further instructions, and asks consecutive questions to guide students in their exploration; she either repeats a student’s answer that she approves of, or states the expected answer herself: “Draw a line underneath your writing. (...) We are now going to be generating a vocabulary. (...) Fold your square on one diagonal. Underline ‘diagonal’. What do you get? (...) What happens when you fold the square along a diagonal? The diagonal is...? (...) The diagonal’s a line of symmetry (...) We are building our knowledge about the square. What does the diagonal do to the angle? (...) What’s the word for it? Bisects. The diagonal is bisecting the angle. Now fold the square on the other diagonal. Measure your diagonals with a ruler. (...)”. At the end of the activity, students are asked to fill out a table with names of shapes (Square, Rectangle, Rhombus, Parallelogram, Trapezoid, Kite) as headings of the columns, and a selection of properties as headings of the rows: Number of pairs of congruent sides; Number of pairs of parallel sides; Diagonals are congruent (Y/N); Diagonals bisect each other (Y/N); Has half-turn symmetry (Y/N); Number of lines of reflective symmetry.

Task	Content area	Technique	Technology	Theory	Type of action
Task 1, True/False, Justify, statement about counting principles (AU1, Quiz)	PML	Recall the meaning of technical terms, figure out relations between them	Mathematical and Psychological Counting Principles; empirical cases of children’s behaviour (Ginsburg)	No theory: Ginsburg’s “Psychological Counting Principles” treated as facts, not theoretical and hence hypothetical knowledge.	Epistemic actions: Reason based on recalled definitions of technical terms and knowledge of empirical facts
Task 2, Name the type of problem (AU1, Final exam)	MKT	Recall the list of categories of types of problems; identify the category that fits the example	Classification of addition / subtraction problems according to Carpenter et al. (CGI)	No theory: CGI categories treated as facts, not theoretical knowledge	Epistemic action: Identify an object (i.e. recognize it and name)
Task 3, Explain a standard algorithm (AU1, Final exam)	TDA	Use Base 10 blocs to model regrouping	Base 10 blocs, the notion of regrouping in positional numeration systems	No formal theory	Epistemic action: Represent a mathematical operation using material objects
Task 4, Van Hiele Guided	MKT	Recall and recognize properties	Properties of polygons; concepts of	No theory. Euclidean	Epistemic actions: identify

Plenary lecture

exploration (AU3, Ms. West)		of the square and other polygons	diagonal, angle, bisecting segments, perpendicular, parallel, half-turn symmetry, reflective symmetry	geometry treated as empirical knowledge about idealization of material objects	properties of classes of shapes (functioning at the van Hiele level of “Analysis”)
--------------------------------	--	-------------------------------------	--	--	---

Table 1. Examples of our coding of tasks used in the TM courses.

Some examples of results of our detailed analysis of tasks

In Ms. West’s 3-hour class on geometry, future teachers were engaged in 23 tasks in the first 2 hours of the class. Of these, 13 tasks focused on MKT; 4 tasks (short questions asked by Ms. West in the ‘reflection’ phase of each activity) focused on TDA only; 2 tasks on PML only; and 4 tasks included both a TDA and PML reflection. In the MKT tasks, the techniques expected and/or hinted at were to represent a mathematical situation with material objects; observe; experiment; state one’s observations; and use known mathematical ‘facts’ to derive new information about the properties of the studied objects. The ‘technology’ part of the praxeology consisted of mathematical terminology (restricted in this class to names of geometric shapes); properties such as ‘the sum of angles in a triangle is 180 degrees’, or ‘angles at vertices in a regular polygon are congruent’. These properties were treated as ‘facts’, not as hypothetical, theoretical activities. The level of geometric thinking expected of students did not go beyond the van Hiele level of “Analysis” and never touched upon the levels of Abstraction, Deduction and Rigor. In tasks related to TDA and/or PML, the techniques consisted mostly in recalling didactic or psychological principles and guessing which one the teacher had intended to illustrate with the mathematical activity she proposed in the simulation phase. Technology in both TDA and PML areas was restricted to a loose collection of ‘principles’ such as, in TDA, “always relate the math to the real world”; “use varied examples so as not to instructionally disable the children”, or, in PML, “children build categories based on typical examples, not definitions”; “recognizing is easier than naming”. The van Hiele model was expected to be known to the future teachers, but, in the class, they were only expected to recognize its application in Ms. West’s organization of the activities. They might, if they chose to, use it themselves in planning a geometric activity intended for children, when doing the homework assignment titled ‘Unit plan’. There were no written limited-time tests or examinations in the TM courses at AU3.

There were such tests in all other universities. In the first of Aone’s two TM courses, there was a 30-minute Quiz, a 2-hour midterm test, and a 3-hour final examination. We analyzed the 51 tasks involved in all these three examinations and the “Reflection” assignment given at the beginning of the course, where students had to read Ball et al.’s paper on mathematical knowledge for teaching. In the Fall 2010 version of the course, the distribution of the tasks among the content areas of MKT,

Plenary lecture

PML, TDA and Reflection was 17, 17, 11 and 6 respectively. In the first year of Aone's teaching, MKT tasks held a much smaller weight.

The techniques expected to be used in these tasks (but not explicitly taught) could be described as: use a checklist; recall a definition; apply principles or properties; and use common sense to find relations. The technology made available to students was very elaborate: it was made of the many structuring frameworks mentioned above. The frameworks were not presented as results of theoretical choices, rather, they started from explicit assumptions about mathematics, didactics and psychology of mathematical learning.

Examining the actions involved in tasks belonging to each content area, we could identify the following types:

MKT: Produce, discuss, assess a representation of a number; Assess the use of a standard algorithm; Identify the property of an operation used in solving a problem; Identify the type of problem; Identify the category of a mathematical object; Solve an elementary school mathematics problem.

PML: Identify the child's strategy in solving a problem; Name the advantages of a strategy used in the solution of a problem; Produce an example of use of a strategy; Model and assess a child's solution in a more formal mathematical symbolism; Find relations among the principles of counting and research findings; Discuss the relative difficulty of one problem over another.

TDA: Identify the didactic objective of a task; Produce a problem of a given type; Describe a didactic action of a given type; Explain a standard algorithm to (hypothetical) children of a given age; Assess a teacher's didactic actions (observed in a video or described in words); Assess the counting skills of a child (observed in a video or described in words).

Reflection: Express your beliefs about (a) the reasons why knowing mathematics is important for an elementary mathematics teacher; (b) ways a good teacher uses mathematics in the classroom; Read a research article; Identify a new kind of knowledge, namely the mathematical knowledge for teaching, and distinguish it from the 'plain old math'.

In 18 out of the 51 tasks (7 in MKT, 7 in PML, 2 in TDA and 2 in Reflection tasks), students were required to justify their answers. Taking this into account, abstracting from the content areas and generalizing the actions involved in the types of tasks, we found the following distribution of actions among the 51 tasks: Justify (18 tasks); Identify the type of an object (17); Produce an example of a type of object (9); Discuss / reflect on (8); Assess correctness of (7); Model child's work (3); Solve a mathematical problem (2); Find relations among mathematical statements (2); Explain something to a hypothetical child (2); Explain the sources of a mistake (1).

Solving a mathematical problem was given little weight in Aone's written tests: only two out of the 51 tasks required this action. Problem solving was given more space

Plenary lecture

in the class sessions, where students sometimes spent almost 2 hours on solving mathematical problems, e.g. an “Adventures of Jasper Woodbury” series problem (Cognition and Technology Group at Vanderbilt, 1997). Students were not tested on solving school mathematics problems, however. Aone believes that, if they were, most would probably fail the course.

As we can see from the distribution, the action of “Identifying” (i.e. recognizing and naming) was very frequently expected in the examination tasks in Aone’s course. This action is not usually ranked high on a ladder of levels of thinking. In particular, it belongs to the lowest level of “Visualization” in the van Hiele model. Ms. West also insisted on the action of identifying, mainly mathematical objects: in the geometry class, she expected future teachers to recognize geometric shapes and name them correctly. Athree, on the other hand, said he had no use for identify tasks in his courses. He would not insist on strict observation of institutionalized terminologies for mathematical objects and he did not teach classifications of types of problems or problem solving strategies. He said his students were free to communicate their reasoning using a mixture of “official” terms and ad hoc names and representations.

Athree insists on reasoning. So does Aone, with the stress on the action of justifying in her examination tasks. The justification is expected to be systemic, i.e. based on a system of concepts, properties and principles from the areas of MKT, TDA and PML. It was also written. The systemic and written character of Aone’s justification tasks contrasts with such tasks in Ms. West’s course, where students were asked to justify their claims, but they could do so only if they wanted (questions were asked to the whole class and only some students responded to them) and they could do so orally, without having to use complete sentences organized into a consistent discourse. Aone aims at teaching her students systemic knowledge. Ms. West is teaching her students that there exists a systemic knowledge out there, but she is not making it necessary for them to engage in using this knowledge in their own thinking.

Formats of interaction

Looking at *actions* involved in tasks was one source of our reflection on the epistemic nature of knowledge emerging in the TM courses. Modeling *formats of interaction* between the instructor and the future teachers were another. As mentioned, Ms. West interacted with future teachers on two levels: as a model elementary school teacher with her students (with future teachers in the role of students), and as a teacher educator. Each episode related to one mathematical problem concludes with a presentation of one or more solutions that Ms. West considers correct. We could say that there were three main formats of interaction in her classroom: the ‘Pretend-we-are-in-an-elementary-classroom’ format, the ‘Guided-reflection-on-the-math-activity’ format, and the ‘Here-are-the-correct-solutions’ format.

Plenary lecture

In Aone's class, we could identify two main formats: 'Make-a-mess-clean-it-up' used during the phase of small group work, and 'Interactive-lecture' used during the whole class discussion phase. In the 'Make-a-mess-clean-it-up' interactions, Aone provokes cognitive conflicts in her students to make them aware of what they don't know. She uses the structuring frameworks made explicit in her course to help students resolve the conflicts and learn more content, or see connections among pieces of content. She provokes her students to pose "why?" questions and uses this as an opportunity to teach the fundamental concepts of the structuring frameworks.

Based on the interview with Athree, we could infer that he was fond of what we labelled as 'Keep-thinking', and 'That's-an-interesting-question' formats. When, after a phase of small group work on a mathematical problem, a student asks him, "But what's the answer, sir?", Athree's answer is "Keep thinking". Athree collects, compares and discusses his students' solutions, but does not tell them whose answer is correct or what the correct answer is. In the interview, Athree said:

I have absolutely no problem with leaving a problem without an answer. ... Usually, the main reason why I am interested in the problem is to talk about the process. And usually you talk about the process without ever coming to an end. It's really not my goal in the course that they know the answer to a particular problem. (Athree, interview)

When he was asked, in the interview, if he would revisit the problem more formally later, he said, 'No'. When asked then, 'Suppose students are adding fractions by adding numerators, and adding the denominators? Would you still not react?', he said:

Well, in that case I would probably take it as an opportunity to say that there are several ways of adding fractions. They are appropriate in different contexts. It depends if you are adding parts of the same whole or parts of different wholes. (Athree, interview)

The 'That's-an-interesting-question' format was identified based on the following Athree's description of his seemingly disorganized way of teaching, which exasperated his students, and was one of the reasons why they liked Ms. West's way of teaching better:

Part of my teaching is that if an opportunity comes up, some abstraction in a weird and wonderful way, then, oh! Okay, the topic for today was supposed to be 3D geometry, but forget about that, we are doing fractions instead. (Athree, interview)

Based on this kind of analyses of the instructors' interactions with future teachers, and the actions involved in the tasks, we can say that there were at least these types of knowledge emerging in the TM courses:

Craft knowledge: knowing how to accomplish a type of task (Grimmett & MacKinnon, 1992); (Hiebert, Gallimore, & Stigler, 2002); in Chevallard's praxeology terms, this knowledge refers to the practical block: task + technique.

Plenary lecture

Téchnê, in Aristotle's sense of craft knowledge grounded in theoretical understanding [see *Metaphysics*, Book I, Part 1 (Aristotle, written 350 B.C.)]; in Chevallard's terms, this knowledge corresponds to task + technique + technology, or to knowing how to accomplish a task and knowing to justify the technique using a system of concepts and principles.

Craft knowledge with a theoretical attitude: knowing how to accomplish a type of task, knowing that there probably exist other ways, and that any justification of the solution is hypothetical, not certain. This type of knowledge is not easily described in terms of praxeology, although perhaps the closest would be: task + technique + theory-awareness.

Ms. West appeared to aim mainly at some limited *Craft* knowledge: knowing how to solve elementary mathematics problems and knowing how to set up a classroom activity to teach a given topic at a given grade level. This is, of course, a very limited portion of what teachers' craft knowledge may become after several years of practice (Grimmett & MacKinnon, 1992).

Aone aimed at *Téchnê*, also limited to certain teacher's "private" tasks: knowing how to choose tasks or sequences of tasks for different teaching and learning purposes and evaluate children's reactions to them, based on "structuring frameworks" such as knowledge of types of tasks, typical children's mistakes and strategies, or characteristics of effective learning environments.

Athree seemed to aim at *Craft knowledge with a theoretical attitude*. In Athree's course, no technology or theory was explicitly and systematically taught. However, mathematical concepts were not treated as facts but as theoretical, hypothetical entities. Didactic decisions were not justified by didactic or psychological principles accepted as true. They were based on experience and hypothetical thinking; e.g. 'If we choose to do X, what could be the consequences for achieving our assumed goals Y and Z, according to our past experience?' Future teachers were expected to gain this experience by planning lessons, implementing their plans in simulated teaching activities with their peers as students, reflecting on the implementation and having their teaching evaluated by others. Since 2008, Athree engaged his students in co-designing the whole TM course with him.

Interviews with students

As researchers and theoreticians we may value *Téchnê* and the *Craft* knowledge with theoretical attitude higher than *Craft* knowledge, especially if the latter is focused on only one component of the knowledge we think is absolutely necessary for teaching. But Ms. West's students were considerably more satisfied than Athree's students, and happier than Aone's students. Ms. West's students said in an interview:

She gives such ... great ideas and examples of how to get that across to students. (...) And her love of math really comes through, too. Which makes us want to love math, too.

Plenary lecture

(...) You go into every class excited. There's something new going on and there's always fun things to do and you don't realize that you actually are learning.

Athree had an explanation why future teachers like Ms. West better: "They like her better, because she is energetic, well-organized, and positive, while I am perceived as phlegmatic, disorganized and cynical".

Will Ms. West's students be happy also when they start teaching? They feel confident. They love math. They've seen a model of teaching that they find attractive, exciting even. They do not feel the pressure to be at the forefront of a "constructivist revolution" when they start teaching. Did Ms. West's students express any fears? Yes, they did. They were afraid of not being able to deal with the noisy reality of the elementary classroom; they were being acquainted with the "normal" curriculum, but not prepared to adapt it to special cases: e.g., to "special needs" children. But they voiced these fears only when prompted to say what they did not like about the course. And after responding, they still said, "Given the time allotted to the course, it is relatively perfect".

Yet, when we interviewed the other instructors, asking them, if this is what makes future teachers happy, whether they would teach like Ms. West, they all said *No*. A large variety of reasons was quoted, but the most common was that there was no guarantee that Ms. West was achieving even the limited Craft knowledge she was aiming at, since this knowledge was never debated, put to the test, or even confronted with alternative ways of knowing and doing things.

DISCUSSION AND CONCLUSIONS

The idea of constructing a knowledge base for teaching was advocated by Shulman (1986, 1987), and adapted for teaching mathematics by Ball (2008). In the Abstract, we suggested that the same idea could be applied to teaching future elementary school teachers, and that contribution to the construction of a knowledge base for teacher educators is the goal of our research on TM courses.

Not all researchers on teacher education would agree with this statement. The very idea of a "knowledge base for teaching" has been strongly criticized, particularly by researchers working in Schön's tradition of "the reflective practitioner" (Schön, 1987). It has been criticized for promoting the "theory-into-practice" approach to teacher education, based on the "epistemology of propositional knowledge... predicated on the assumption that teacher candidates are novice consumers, not expert producers, of knowledge" (Cochran-Smith & Lytle, 1999, quoted in Bullock, 2011, p. 26). Critics claim that "theory" in the "theory-into-practice" approach to teacher education refers to a mere "rhetoric of conclusions" (a phrase coined by Schwab, 1971, quoted by Clandinin & Connelly, 1995, p. 9), or "codified outcomes of inquiry" stripped of their origins in the inquiry process, and "packaged for teachers in textbooks, curriculum materials, and professional-development workshops" (ibid.).

Plenary lecture

This knowledge seems to correspond to the “technology” component in Chevallard’s praxeology model: it is technology without theory. Aone’s structuring frameworks such as “Effective learning environments”, “Psychological Principles of Counting” etc., presented in her course without the stories of the research processes that led to their formulation as plausible hypotheses based on explicit assumptions, would be examples of such “rhetoric of conclusions”. But Aone did not teach her students the technology only. She taught her students a praxeology of which the technology was one of the elements: she aimed at *téchnê*. Bullock’s description of teacher education programs based on “purely propositional approach to understanding how teacher candidates construct professional knowledge” which he claims is underlying Shulman’s model (2011, pp. 26-7) is a caricature that distorts and hides the complexity of the knowledge that emerges in Aone’s course, and probably in any TM course:

Teacher education programs usually require teacher candidates to complete a certain amount of coursework before having a practicum experience. The assumption underpinning this design is that coursework can begin to *transmit the knowledge base for teaching* to teacher candidates. The practicum experience is then an opportunity for teacher candidates to practice *applying the knowledge* gained from both undergraduate course work (subject matter knowledge) and professional studies courses (pedagogical content knowledge). (Bullock, 2011, pp. 26-7) (my emphasis)

The knowledge base for teaching TM courses need not be reduced to a technology abstracted from the praxeology within which it was constructed. Nor need it be transmitted by means of “rhetoric of conclusions” in a crash course for newly hired faculty expected to teach such courses at the university. There is no risk of this happening any time soon, anyway, because a body of “codified outcomes of inquiry” on TM courses does not exist. All we have, so far, are stories of individual TM instructors’ experience, and information about the various organizations of teacher preparation programs around the world. Stories of TM instructors’ professional experience, somewhat structured and interpreted using a network of metaphors or other tools for noticing, recognizing and naming phenomena in teaching/learning situations, would be a research outcome quite in line with Schön’s tradition, and would satisfy such vehement opponents of Shulman’s take on teacher education as Connelly and Clandinin (1995, 1996) or Bullock (2011).

That is what we could do in our research and stop there. I am not sure we would be satisfied with it, however. We think it would be useful for a TM instructor to know not only what choices other TM have made in designing their courses but also why and what consequences a given choice is likely to have for his or her goals in the course (e.g., the kind of knowledge he or she would like to see emerge in the course). We also believe that TM instructors have good reasons to ask themselves questions such as “What is known about effective teaching? What do teachers know? What knowledge is essential for teaching? Who produces knowledge about teaching?” TM

Plenary lecture

instructors ask these questions because they have a course to design and run, and the responsibility of assessing, at the end of it, that certified teachers coming out of the program will not have to be too ashamed of themselves in front of their students when they start teaching mathematics. Yet, these questions have been quoted by Clandinin and Connelly (1996, p. 24) as not the type of questions that they, working in the “narrative tradition of describing and interpreting teachers’ professional knowledge”, would ask to obtain “valid, reliable knowledge... making possible better educated teachers” (ibid.).

Thus our goals put us on an epistemological position that is contradictory with the narrative tradition. In Fernstermacher’s terms, our position is grounded in “the *epistemic status* sense of knowledge”, whereas the narrative tradition understands knowledge in the “*grouping* [categorical] sense”, meaning that the professional knowledge of teachers is produced “in the course of acting on experience... generat[ing] ideas, conceptions, images or perspectives when performing as teachers” (Fernstermacher, 1994, p. 31).

TM instructors appreciate the value of knowledge in the grouping sense, and we have seen how they have tried to provide future teachers with at least a substitute of the authentic teaching experience. Some of them would welcome the possibility of combining their courses with the practicum, thus getting a chance to engage future teachers more with experiential knowledge. But they have no influence over the organization of the teacher education programs of which TM courses constitute a minuscule part (6 to 12 credits out of 120). There is no guarantee that a teacher candidate will even have a chance to teach mathematics during the practicum, since they are being trained to be “generalists”, not mathematics specialists. All the instructor can do is engage future teachers in “reflection-BEFORE-action” (rather than “reflection-in-action”, (Schön, 1987)). I mentioned several techniques the instructors use in their courses to obtain this engagement, without putting students in real-life educational interactions with children. One was watching videos of classrooms and commenting or analyzing didactic and mathematical behaviors of the actors. There are other ways, of course. Videos of live teacher-student interactions in real classrooms can be replaced by animated movies of classroom interactions (Chazan & Herbst, 2011). Reading and reflecting on narratives of individuals’ practicum experience or practicing teachers’ narratives such as found in Clandinin and Connelly (1995) could be another technique.

In the just cited book, the narratives are analyzed and commented upon by the authors through the lens of a definite structuring framework – the framework of teachers’ *professional knowledge landscapes* – which, if used in a TM course, would probably be “transmitted” as a “technology without theory” condemned by Schwab (1971) as “rhetoric of conclusions”. Narrative approaches thus do not eliminate propositional knowledge. I don’t see how one could avoid presenting future teachers with unquestioned frameworks if one wants them to notice certain things in a

Plenary lecture

narrative. Future teachers have no personal experience of teaching with which these representations of practice could resonate. The instructor can only hint at the hypothetical character of the frameworks but may find it inappropriate to embed them in long-winded stories of processes of inquiry leading to them. TM instructors have varying reasons for avoiding narrative engagements, such as a lack of time or, like Aone, the fear of confusing future elementary teachers, who are notoriously very unsure about their knowledge (Marchand, 2010)).

Therefore, the landscape – to use Connelly and Clandinin’s metaphor – of TM instructors’ professional knowledge is constrained so that it is difficult, if not impossible, to totally avoid a transmission of propositional knowledge.

On the plane of research on TM’s instructors’ professional knowledge, therefore, it is also difficult to avoid asking how this knowledge addresses the four fundamental questions that the narrative tradition has issue with. As already mentioned, we do not think it would be enough to recount – as I have mostly done in this talk – individual TM instructors’ stories about their struggle with these questions, noticing similarities and differences and grouping tasks into types and epistemic actions. We would like to obtain more knowledge in the epistemic sense about TM instructors’ practices. This would require an effort of “instrumented synthesis” of individual instructors’ stories, but, at this point of our research, we do not know what the instrument we are looking for could look like. We don’t think there are any ready-made answers to our problem. We have to keep thinking.

ACKNOWLEDGEMENTS

1. The research reported in this paper was supported by a Social Sciences and Humanities Research Council of Canada grant no. 410-2008-28981.
2. I wish to thank all those – students and instructors – who kindly agreed to participate in the study, which was conducted under the leadership of Helena P. Osana.

THE STRUCTURE AND DYNAMICS OF AFFECT IN MATHEMATICAL THINKING AND LEARNING

Markku S. Hannula

University of Helsinki

In this paper, I will review the development of research on affect in mathematics education since 1990s and forecast some directions for future development. One trend of development has been the elaboration of the theoretical foundation for affect. I will suggest that a useful description of the affective domain can be based on distinctions on three dimensions: 1) cognitive, motivational and emotional aspects of the affect, 2) rapidly changing affective states vs. relatively stable affective traits, and 3) the social, the psychological and the physiological nature of affect. Another direction of development has been to explore the structural nature of affect empirically. I will review some instruments that have been developed to measure different dimensions of beliefs, motivation and emotional traits. Moreover, I will look at some empirical results concerning how the different dimensions are related to each other and how they develop over time.

INTRODUCTION

Mathematics is typically considered as the most objective and logical of academic disciplines. Yet, emotions, attitudes and motivation play an important role in contemporary research on mathematics education. From a practical perspective, mathematics-related attitudes and motivation are perhaps the most important determinants of mathematics attainment, because they determine how much people choose to study mathematics after it becomes optional. Compared with motivation to study mathematics, it is irrelevant how talented the student is for mathematics. Moving beyond the individual, there is consensus in educational policy in most countries that society has a need for mathematically educated persons in scientific and technical fields.

Affective issues are important in mathematics education also from a scientific perspective. When we investigate creativity, genuine problem solving, proofs and other higher-level cognitive processes, we see that cognition is intrinsically intertwined with emotions. However, we do not yet understand these processes well enough.

Research on mathematics-related affect has been a topic of interest at least since the 1970s. However, the reason for such interest has varied across decades and this has been also reflected in the variety of theoretical and methodological approaches to the topic. McLeod's (1992) review and reconceptualization of research has been extremely influential in this field of study. According to Harzing's 'Publish or Perish' software, (Harzing, 2011), it has received over 600 citations so far. The review provides an excellent overview of the state of art in the early 1990s.

Plenary lecture

Moreover, McLeod's conceptualization of the research area as well as his suggestions for future research have had a major influence on research on mathematics-related affect for the last two decades.

In this article, I will first review McLeod's seminal paper, then we will summarize the main criticisms of his approach and most important new ideas and findings since 1990s, with a special focus on work done within CERME.

As a synthesis of these reviews, this paper will suggest a new theoretical foundation for research on mathematics-related affect. The most important notions in this new framework are 1. a distinction between trait and state-aspects of affect; 2. perceiving emotions, cognition and motivation in a synergistic relationship; and 3. the identification of biological, psychological and social levels of affect.

Based on this conceptual framework, we will elaborate some structural properties of mathematics-related affect and review a number of instruments developed to measure affect towards mathematics. In a more speculative tone, we will use the theoretical framework and previous research to suggest some dynamic relationships between different dimensions of affect. Finally, the paper will look for some future venues for research on mathematics-related affect.

History pre 1990s

In this section of the article, I will provide an overview of the main conclusions that McLeod made in his article as a summary of research on mathematics-related affect prior to 1992. In the era of behaviourism, affect had been largely neglected, being considered an imaginary construct. As an exception, social psychology measured attitudes through a large number of quantitative survey studies. These studies had identified differences between countries and genders and an overall tendency for students' affective relation with mathematics to decline over the school years.

Within research on mathematical beliefs, McLeod had identified four main objects of these beliefs: mathematics as a discipline, self, mathematics teaching (and learning), and social context. In his conceptualization, beliefs about self were related to metacognition and self-regulation and included also motivation. As an important aspect of beliefs about context, McLeod had recognized Cobb, Yackel and Wood's (1989) work on social norms in the (mathematics) classroom.

One of McLeod's main concerns with respect to previous research was the lack of a decent theoretical framework. Research on mathematics-related affect was based on local theories, such as self-efficacy, mathematics anxiety, attribution theories, and aesthetics. However, from a holistic point of view, the local theories used confusing and ambiguous terminology.

McLeod identified cognitive science and cognitive psychology as promising new trends for mathematics-related affect in the 1990s. Cognitive science had accepted the importance of affect. More specifically, cognitive scientists had acknowledged

Plenary lecture

the significance of affect (interest, confidence) in metacognition. However, at that time, most cognitive scientists avoided affect in their theorizations in order to avoid some of the complexity.

According to McLeod, cognitive psychology emphasized more theoretical issues than cognitive science. Cognitive psychologists used qualitative methods in order to construct an empirically well-founded theoretical framework for the role of affect in mathematical thinking and learning. Their elaborations emphasized beliefs and emotions as central concepts.

As a summary for his review on the literature, McLeod (1992) suggested that research on mathematics related affect should use a “combination of techniques”, i.e. mixed methods. For a theoretical framework he suggested using Mandler’s (1989) theory, which provided not only a sufficient conceptualization for mathematics-related affect, but also for dynamics of affect in mathematical thinking and learning. In this framework beliefs were seen as an element that influenced the initiation of emotions. Moreover, repeated emotional reactions were seen as the origin of attitudes. Regarding the origin of beliefs, McLeod considered both social context (culture) and individual experiences to contribute to their formation.

Work that builds on McLeod’s paper

McLeod’s work has had a significant influence on later research and his foundation has proved to be fruitful for accumulating evidence. Much of the research has adopted a simplified version of McLeod’s framework where emotions, attitudes and beliefs are located on a continuum where beliefs are seen to be the most cognitive and stable, emotions as least cognitive and stable, and attitudes in the middle for both dimensions. Fewer studies have elaborated the dynamic nature between beliefs, emotions and attitudes.

One specific field of research on mathematics-related affect that has accumulated very strong evidence over the years is the role of gender. Studies have produced very consistent results that indicate that, across age and performance levels, female students tend to have lower self-confidence in mathematics than male students (e.g. Hannula, Maijala, Pehkonen & Nurmi, 2005; Leder, 1995). Lower self-confidence among female students has been found even at the level of individual tasks, in the case of both correct and incorrect answers (Hannula, Maijala, Pehkonen & Soro, 2002). Related to low self-confidence, female students also suffer mathematics anxiety more often than male students (Frost, Hyde & Fennema, 1994; Hembree, 1990). These results in affect provide an explanation to why female students usually choose not to study optional mathematics, especially when we consider that female students may have higher performance levels in arts and social sciences. Lower self-efficacy is also likely to explain why female students rely on school-taught solution methods and avoid non-standard or their own solution methods that include an element of risk.

Plenary lecture

There is no reason to believe that the low level of female students' self-efficacy beliefs is a natural and permanent characteristic of the female sex. The research has accumulated evidence for the hypothesis that female students' lack of confidence in mathematics is consistent with their teachers' beliefs (Li, 1999; Soro, 2002; Sumpter, 2009) and that teachers' typical interaction patterns with male and female students may thus attribute to the generation of gender differences. Mathematics teachers tend to believe that their male students often have hidden talent, but due to being lazy and careless they underperform, while female students tend to reach their performance due to diligence and hard work even if they are not very talented. Such teacher beliefs are assumed to lead to different feedback to male and female students and thus to contribute to the observed gender differences in self-efficacy beliefs.

A large number of studies have explored the relationship between mathematical affect and achievement. Ma and Kishor (Ma & Kishor, 1997a, b; Ma, 1999) have summarised much of that research in two meta-analyses. In one of these studies, they synthesised 113 survey studies of the relationship between attitude towards (=liking) mathematics and achievement in mathematics. The causal direction of the relationship was from attitude to achievement. Although the correlations were weak in the overall sample, they were stronger throughout grades 7 to 12, and in studies that had done separate analysis of male and female subjects. (Ma & Kishor, 1997a).

In another meta-analysis, Ma and Kishor (1997b) summarised 143 original studies on the effect of mathematics-related beliefs on achievement in mathematics. They found out that students' self-concept, family support and perception of mathematics as a male domain were positively related to their achievement in mathematics. Moreover, correlations between self-concept and achievement were stronger in studies that had done separate analysis of male and female subjects.

However, there has been criticism of studies that do not use a longitudinal design (see Ma & Xu, 2004). Minato and Kamada (1996) reviewed eight studies that had used a cross-lagged panel correlation technique (a longitudinal design) in order to synthesize findings on the causal relationship between attitude towards mathematics and achievement in mathematics. In most of the studies, there was no predominance of either attitude or achievement. However, in the few instances that predominance was found, the causal direction was from attitude to achievement. However, Ma and Xu (2004) found a contrasting result with a larger and more representative sample. According to their study, the dominant causal relationship is from achievement to attitude.

Research on mathematics-related emotions has been less active than research on attitudes and beliefs. However, several studies have confirmed that experts control their emotions better than novices (e.g. Allen & Garifio, 2007; Schoenfeld, 1985). There has been also some attempt to include physiological measures, e.g. heart rate (Isoda & Nakagoshi, 2000), skin conductivity, and muscle tension, to research on

emotions. In the case of anxiety, physiological measure and questionnaire data did not match (Gentry & Underhill, 1987; Dew, Galassi, & Galassi, 1984)

Main criticisms of McLeod's framework

Although McLeod's (1992) framework has dominated research in mathematics-related affect since 1990s, criticism has accumulated since then, regarding terminology, blind spots of the conceptual framework and the overall foundation of the framework. Regarding the terminology, researchers on mathematics-related affect had not succeeded in unifying their language. When Furinghetti and Pehkonen (2002) collected a virtual panel of these researchers to evaluate a number of definitions that these same researchers had suggested for the concepts *attitude*, *belief* and *conception* in their papers, the researchers could not agree on any of the their definitions.

The problem has been raised repeatedly over the years. For example, in the PME 2004 research forum on affect, Gerald Goldin (2004) said:

We do not now have a precise, shared language for describing the affective domain, within a theoretical framework that permits its systematic study (p. 109).

And this perspective has been repeated also more recently:

theories not yet well-developed, terminology used differently and ambiguously, and varying instruments, some untested, make the literature difficult to interpret, and leave researchers open to criticism. (Chretcheley, 2008, p. 147)

Probably the most problematic concept in McLeod's framework is attitudes. Within mathematics attitude research, attitudes have typically been defined as consisting of cognitive (beliefs), affective (emotions) and conative (behaviour) dimensions (e.g. Hart, 1989). If we try to combine the tripartite framework with McLeod's, we see that attitude is at the same time a parent and a sibling to emotions and beliefs.

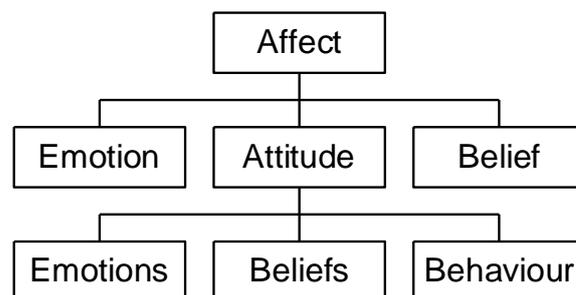

Figure 1. An unsuccessful attempt to combine McLeod's (1992) framework for affect with Hart's (1989) tripartite framework for attitude.

In fact, researchers have provided a variety of definitions of the concept 'attitude'. In addition to the tripartite definition above, some have used a bi-dimensional definition (emotions, beliefs) or simply identified attitude as positive or negative

Plenary lecture

degree of affect. Many researchers have given only an implicit definition through the instrument they have chosen to use. (Di Martino & Zan, 2010).

There are also more fundamental problems with the concept. Attitude is an **observer's** category which involves several psychological structures (Ruffel, Mason & Allen, 1998; Hannula, 2002a). Hence, it does not really help us to understand the inner world of the person, whose attitude we have observed. In fact, teachers often use the concept attitude as 'a claim of surrender', *i.e.* as an attribution to student's uncontrollable failure (Di Martino & Zan, 2009).

In McLeod's (1992) framework, emotions are considered to be unstable (at least less stable than beliefs or attitudes). This view has been criticized, because people can have very stable patterns for emotional arousal across similar situations (e.g. anxiety, frustration, Aha!) How would this differ from beliefs that appear only in appropriate context (e.g. self-efficacy beliefs in a test situation)? We shall return to this issue below, when we discuss the state and trait aspects of affect.

McLeod's framework did not pay enough attention to the variety of different emotions. Although McLeod (1992) had pointed out the importance of Buxton's (1981) study *Do you panic about maths* and Mason, Burton and Stacey's (1982) studies on the Aha!-experience, in his framework attitude was seen through positive/negative duality. This view misses important distinctions. For example, boredom, anger and shame are all negative emotions, but very different from each other. The three emotions appear in different situations and they have quite different impacts on behaviour. In similar way elation, pride and relief are very different positive emotions

Moreover, more recent research in mathematics education has highlighted affective concepts that are (or seem to be) missing from McLeod's conceptualization, such as values (DeBellis & Goldin, 1997, Bishop, 2001), motivation (Hannula, 2006b; Yates, 2000) and identity (Beijaard, Meijer & Verloop, 2004; Frade, Roesken & Hannula, 2010, Sfard & Prusak, 2005).

Also the 'social turn' in mathematics education (Lerman, 2000) has highlighted the problems of the primarily individual focus of McLeod's framework. Yackel and Cobb (1996) have elaborated the relationship between individual beliefs and the norms that are their social parallel. Moreover, the social view speaks about identity instead of beliefs or attitudes.

New findings and ideas since McLeod

Since McLeod published his paper in 1992, there have been important advances outside mathematics education research that have opened up new opportunities for research in mathematics-related affect.

Within educational psychology, motivation research has developed several theoretical approaches (for an overview see Murphy & Alexander, 2000). One of the

Plenary lecture

most influential is achievement goal theory (Pintrich & Schunk, 2002). It is a sociocognitive theory, which focuses on students' self-set goals in achievement situations, and is interested in the student's reasons for engage with learning tasks (Middleton, Kaplan, & Midgley, 2004). Different terminologies are used for two main goal orientations: A student who focuses on learning the task is said to have a mastery, task, or learning orientation, while students whose primary interest is to impress others with their performance are said to have a performance, ego, or ability orientation, but there are only nuanced differences between the different terminologies (Ames 1992; Järvelä, 1996; Pintrich & Schunk ,2002).

Different researchers have found rather comparable positive relationships between mastery goal orientation and achievement (Friedel, Cortina, Turner, & Midgley 2007; Midgley *et al.*, 1998). Results concerning performance goal orientation and achievement have been less consistent. Some have identified negative learning behaviour, while other results indicate performance orientation to lead to positive learning behaviour and achievement (Freeman, 2004; Midgley *et al.*, 1998). This has led to a need to differentiate between so-called performance-approach and performance-avoidance goal orientations (Elliot & Harackiewicz, 1996). More recent results have indicated that students may be influenced by several goal orientations simultaneously, and the emphasis of each orientation is influenced by the situation (e.g. Vollmeyer & Rheinberg, 2000).

Affect has also been given a significant role in elaborations of self-regulation. In mathematics education, the role of affect in self-regulation has been elaborated, for example, by Malmivuori (2001, 2006) and Hannula (2006b). Also the concept meta-affect (DeBellis & Goldin, 1997) relates to self-regulation.

The embodied view of cognition (e.g. Maturana, 1988; Brown & Reid, 2006; Núñez, 2006) and advances on the neurophysiology of affect (Damasio, 1994, LeDoux, 1998) have radically challenged the earlier view on human mind. Most notably this research has highlighted the indispensable role of emotions in human reason.

Increased computational capacity has allowed the use of more advanced quantitative methods, e.g. Meta-analysis and Structural Equation Models. These methods have made it possible to test more complex hypotheses with data from large scale surveys. For example, Williams and Williams (2009) used

...a structural equation model in which the mutual influence of self-efficacy and performance in mathematics is represented as a feedback loop. This model was estimated in each of 33 nations on the basis of data on the mathematics self-efficacy and mathematics achievement of 15-year-olds. The model was a good fit to the data in 30 nations and was supportive of reciprocal determinism in 24 of these, suggesting a fundamental psychological process that transcends national and cultural boundaries. (Williams & Williams, 2009, p. 453)

Issues raised in previous CERME meetings

Next, I will review the main issues of the Working Group (WG) on affect in CERME conferences 3, 4, 5, and 6, between 2003 and 2009) This review is very much also a personal journey, because I was a WG coordinator at CERME 3 (2003) and chair of the Affect WG for the three following CERME conferences. What I will present later in this article as a new (meta)theoretical framework for the study on affect is deeply influenced by the discussions in the CERME working group on affect.

Much of the discussions in the affect group in each of these CERME have focused on the conceptual framework and terminology. This has increased our awareness of being specific about the concepts that we use. We have realized that it is not sufficient to give definitions of the concepts that are being used in a particular study, but we have to explicate their relations to the other dimensions of affect research as well. A significant step forward was the graphic representation of the conceptual field that Peter Op 't Eynde drew for the final presentation session of the affect group at CERME 5 (Figure 2). Firstly, the figure identifies three main conceptual categories: cognition, motivation and affect, and their partial overlapping.

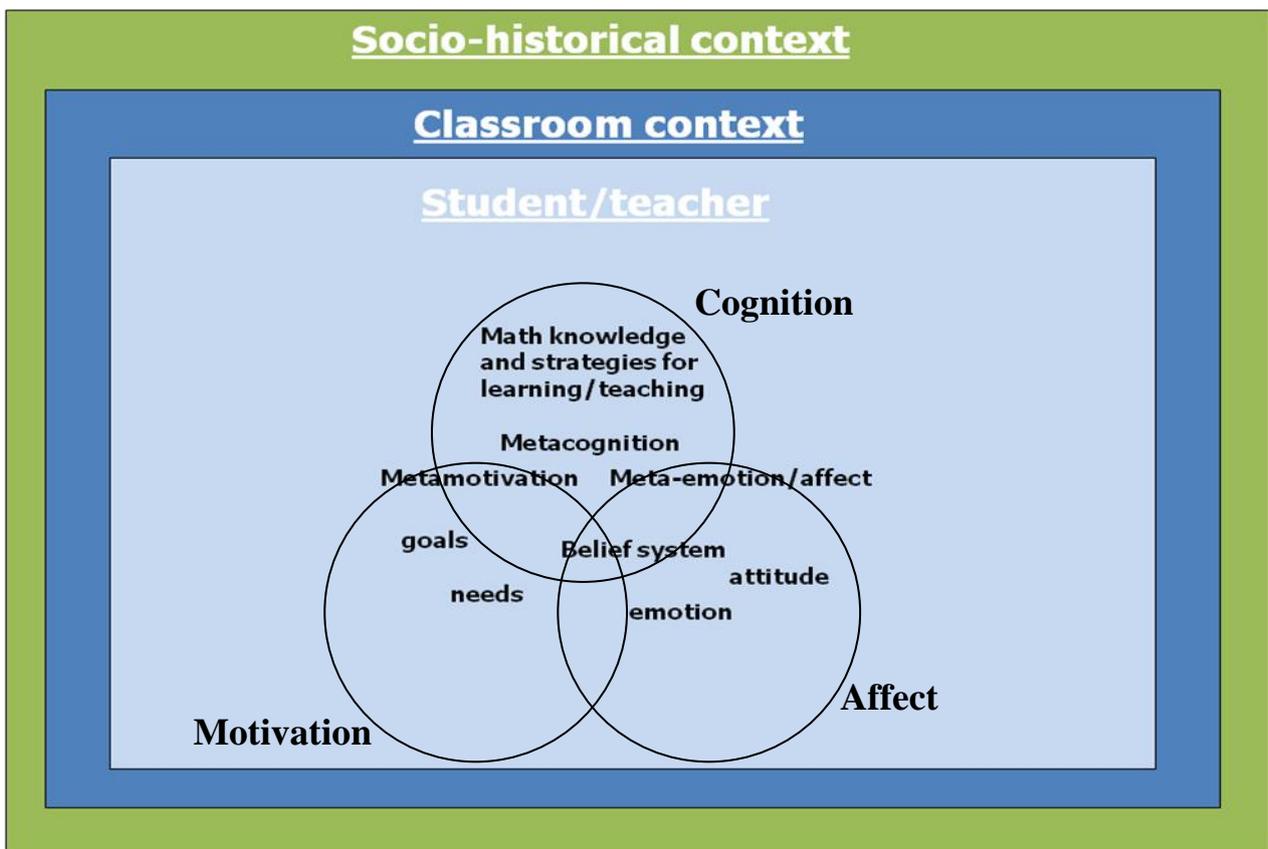

Figure 2. A graphic representation of the different dimensions of mathematics-related affect and their relationships, presented at CERME 5 (Hannula, Op 't Eynde, Schlöglmann & Wedege, 2007, p. 204).

Plenary lecture

The figure also positions several of the frequently-used concepts in relation to each other and in relation with the three overarching concepts cognition, motivation and affect. Thirdly, the figure identifies the local classroom context and the socio-historical context where the individual student's or teacher's affect is being formed and is developing. Since CERME 5 we have always returned to this figure as an overall framework where we locate individual studies and their relations.

The dynamic nature of affect is another recurrent issue through the history of CERME conferences. How do emotions and other less stable affects interact with cognitive processes? How are relatively stable affects (e.g. beliefs, attitudes and motivation) formed in the first place? How do they develop over time? How can we change these through interventions? As an example of the complexity of the dynamics of affect, let us consider the four different aspects of stability that we identified at CERME 6 (Hannula, M. S., Pantziara, M., Wæge, K., & Schlöglmann, 2009):

- 1) The *state* and *trait* aspects of affect. This will be discussed in more detail below.
- 2) Resistance to change. How strongly are individual beliefs and attitudes held? Which of them change 'naturally' over time? How difficult it is to influence them?
- 3) Robustness of constructs. Are the affective constructs held in a similar way across age levels? For example, some dimensions can not be reliably measured in younger populations. Does this suggest that these constructs are not developed until an older age? Would some of the constructs disappear in older populations? Are some affective constructs formed in a specific socio-historical context (e.g. the belief of mathematics as a male domain) and are they similar across the different cultures? Would some constructs that are relevant now disappear in the historical development of the society?
- 4) Relative stability in relation to other persons. Several studies have observed an overall decline in mathematics-related affect over the school years (e.g. Eccles, Adler, Futterman, Goff, Kaczala, Meece *et al.* 1985; Hannula, Maijala & Pehkonen, 2004). However, do those who have the most positive relationship with mathematics in the early years continue to have more positive relationship with mathematics than their peers who had a more negative affect to begin with?

The refinement of the conceptual framework and the focus on the dynamic nature of affect have highlighted the need to explore the structural properties of affect.

A third issue that we have discussed repeatedly in CERME is methodology. I will not go into detail here, but there has been a trend towards mixed methods that combine quantitative and qualitative methods, as well as a trend to adopt the more complex computational tools that have become available.

A NEW (META)THEORETICAL FOUNDATION

After this lengthy review of old theories, findings and their criticisms, we will finally begin our constructive efforts. The framework that I will construct below could be seen as a metatheoretical foundation for research in mathematics-related affect. Because of its broadness I do not expect this framework to be used as such in any single empirical study. However, this framework helps to identify similarities and differences between studies in this field, and it is probably useful for relating a variety of theories to each other. Moreover, this framework is likely to help in generating a shared language for researchers to communicate their findings and theories.

The framework will be based on distinctions on three dimensions: 1. cognitive, motivational and emotional aspects of the affect; 2. rapidly changing affective states vs. relatively stable affective traits; and 3. the social, the psychological and the physiological nature of affect.

The need to integrate cognition, motivation and emotion

Historically, psychologists have adopted three components to describe human learning: cognition, motivation, and emotion [...]. Yet, theorists and researchers have tended to study these processes separately, attempting to artificially untangle them rather than exploring their synergistic relations in the complexity of real life activities. (Meyer & Turner, 2002, p. 107)

My personal journey into mathematics-related affect started from beliefs research under the supervision of Erkki Pehkonen (Hannula, Malmivuori & Pehkonen, 1996). Trying to understand the formation of beliefs, I realized the importance of emotional experiences (Hannula, 2002a, 2003). When building an understanding of emotions, their relationship to personal goals became unavoidable (Hannula, 2002b, 2006b). Hence, my personal journey led me to attempt an integration of cognition, emotions and motivation. (Hannula, 2004, 2006a)

Of course, I have been influenced by the work of colleagues. If we accept values to be an aspect of motivation, all these three categories are present already in the tetrahedral framework of DeBellis and Goldin (1997), where the vertices are emotions, attitudes, beliefs and values. Another important influence has been Schoenfeld's framework for teacher decision making, where the key components are knowledge, goals and beliefs (Schoenfeld, 1998). In Schoenfeld's terminology, 'beliefs' is a broad category which includes also emotional aspects. Goals, on the other hand, are clearly a motivational concept.

In my framework, the *cognitive* domain includes knowledge, beliefs and memories, i.e. those mental representations to which it makes sense to attribute a truth value (cf. Goldin 2002). For example, "I have solved this task before", "Mathematics is useful" and "I can solve this task using an equation" belong in this category. With some hesitation I have also classified other cognitive schemata (e.g. scripts and

Plenary lecture

concepts) in this category as their applicability can be seen as a sort of truth value. In the category of *emotions* belong joy, pride, sadness, frustration, anxiety and other feelings, moods and emotional reactions. The third category, *motivation*, is perhaps the most difficult to define. The most important characteristic of this category is that motivation reflects personal preferences and explains choices. The distinction from the cognitive aspect is that preferences are subjective and it is not possible to attribute truth value or applicability to them. Motivation varies from very local preferences (“This would be a perfect moment for a cappuccino”) to a variety of different levels of goals (“I want to solve this task”, “I want my peers to think that I am clever”) and very global needs such as needs for nutrition and social belonging. Although the basic needs seem very universal, there are individual differences to how much importance they are given in different situations.

Some of the distinctions between the categories may seem arbitrary. However, in this integrative approach, the point is not simply to acknowledge all three aspects. The purpose is to go beyond that, and focus on the synergistic relations between the three. The distinctions between these categories make more sense when one focuses on their function in human thinking and behaviour. From the functional point of view, cognition codes the personal information about self and the environment (e.g. “I don’t believe that I can solve any of my homework”), motivation gives direction for behaviour through giving preference to some self-environment relationships over some others (e.g. “I want to show my parents that I at least try”). Success or failure in motivation-directed behaviour (e.g. solving a mathematics task) is reflected in emotions (e.g. relief). These emotions, in turn, can influence cognition through shifting the focus of attention (e.g. from ego to task), which may modify motivation (e.g. from showing effort to solving the task).

The state and trait of mathematics related affect

I was not successful in my effort to track down the origin of the distinction between trait and state aspects of psychological constructs. However, the first instance where I was able to find it (Bergmann 1955), considered the terms ‘state’ and ‘trait’ idiomatic. The distinction between trait and state (Spielberger, 1966) was an important step forward in anxiety research. More recently, Dweck (2002) has claimed that a similar distinction (traits and processes) is also relevant in motivational systems and that these are formed at an early age.

The state and trait aspects of affect towards mathematics have been implicitly present in most of the research done. However, these two temporal aspects have seldom been addressed explicitly. The rapidly changing affective state has typically been addressed as an element in problem solving. For example, the continuously fluctuating emotions and beliefs may influence the critical choices that determine whether the problem will be solved or not. These affects are situational and contextual. However, there is also a stable pattern in how an individual feels and thinks in these different contexts and situations, i.e. an affective trait. For example, in

Plenary lecture

any classroom situation high achievers are likely to have more positive expectations and affect than low achievers. This distinction has been reflected in different theoretical frameworks. In McLeod's (1992) conceptualisation, beliefs were considered more stable than attitudes, which were more stable than emotions. Also in Goldin's (2002) framework there is a distinction between local and global (more stable) affect. However, both McLeod and Goldin attribute stability to beliefs and rapid changes to emotions.

Unlike McLeod (1992) and Goldin (2002) I see that beliefs have both a state aspect and a trait aspect. While a student may have a belief trait that he is not very good with mathematical tasks, his belief state regarding a specific task evolves as he reads the task and begins to solve it. In a similar fashion, although the emotions of a student may fluctuate and change rapidly during problem solving, students also have very stable patterns of emotional reactions. By this we mean that each individual has typical emotional reactions to typical situations in the mathematics classroom. This is most clear in cases of mathematics anxiety, where worry and fear are typical reactions to many learning situations. This trait aspect of emotions can also be called emotional disposition, and it is also the core of different conceptualizations of attitude.

Also the third element in the present framework, motivation, has a state aspect and a trait aspect. The trait aspect of motivation is related to the overall values the person attributes to mathematics and to the general motivational orientations for learning. However, these traits are not sufficient to understand personal choices during problem solving or learning processes. During such processes one sets more local goals, that represent the motivational state at that time.

The trait and state aspects of cognition, motivation and emotion are summarized in Table 1.

	Cognition	Motivation	Emotion
State	Thoughts in mind	Active goals	Emotional state
Trait	Concepts, facts, scripts, etc.	Needs, values, desires, motivational orientations	Emotional dispositions (attitude)

Table 1. The state and trait aspects of cognition, motivation and emotion.

How about the social turn and the embodied cognition?

In order to guide you towards the social and biological dimensions of affect, I will now elaborate a little on emotions. Firstly, recall that we consider emotions here in their full spectrum. Joy, fear, sadness, curiosity, shame etc. have each their specific

Plenary lecture

characteristics in the dynamics of affect, and they can not be reduced on a single dimension.

Within theories of emotion we can distinguish three different traditions. The first tradition is the Darwinian tradition, which sees emotions as evolutionary functional means of body regulation and social coordination. This view highlights the biological basis of emotions but also acknowledges their social importance. The Freudian tradition conceptualises affects as derivatives of the instinctual drives and emphasizes the unconscious origin and regulation of emotions. (Taylor, Bagby & Parker 1997, p. 11 & p. 14)

The cognitive approach (e.g. Lazarus, 1991; Power & Dalgleish, 1997) argues that emotions are primarily psychological phenomena, generated and guided by cognitive appraisals. Nowadays, there is general agreement that emotions consist of three processes: physiological processes that regulate the body, subjective experience that regulates behaviour, and expressive processes that regulate social coordination (Buck, 1999; Power & Dalgleish, 1997; Schwarz & Skrunik, 2003; Taylor, Bagby & Parker, 1997).

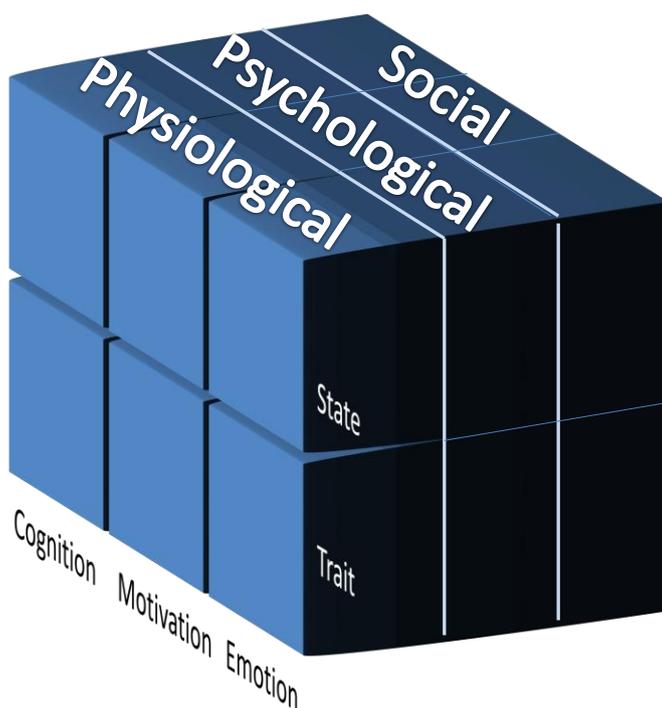

Figure 3. Identifying the social and psychological dimensions to state and trait of cognition, motivation and emotion.

Within the cognitive domain it is easy to identify similar distinctions between subjective experience and expressive behaviour (typically talking). Moreover, social theories of learning e.g. *social interactionism* (Bauersfeld, Krummheuer & Voigt, 1988), *emergent perspective* (Cobb & Yackel, 1996) and *didactic contract*,

Plenary lecture

(Brousseau, 1997) have highlighted the social construction of meaning. There is also a level of physio-cognitive processes, such as gestures as part of thinking (e.g. Núñez, 2006). With respect to motivation, it is possible to make a distinction between physiological, psychological and social needs (Nuttin 1984). On the other hand, the norms that social groups negotiate and form (Yackel & Cobb, 1996; Cobb & Yackel, 1996; Partanen, 2011) can be seen as shared goals, which are another social aspect of motivation.

It should be noted here that the social aspect can be further elaborated. There is the classroom microculture of teacher-student interactions, but also the more institutionalized school culture and broader socio-cultural situation where schooling takes place (Cobb & Yackel, 1996, Partanen 2011).

As a summary, we can add a third dimension to our framework on affect (Figure 3). Furthermore, we can identify the typical state and trait type constructs for psychological, psychological and social level of the affective domain (Table 2).

	Physiological	Psychological	Social
Affect as a state	Neural activation, physiological adaptation.	Feelings, emotions, thoughts, meanings, goals	Social interaction, communication, classroom 'weather'
Affect as a trait	Brain structure, neural connections.	Attitudes, values, beliefs, motivational orientations	Norms, social structures, classroom climate

Table 2. Physiological, psychological and social aspects of affective states and traits

The physiological trait refers, for example, to the structural properties of the brain that are slow to change. On the other hand, the physiological state refers to the dynamic activity in the brain and the hormonal adaptation of the body (e.g. adrenaline rush). With regard to the state and trait of the social dimension of affect, we can perceive the social traits as the overall social 'climate' of a group, which includes the norms and the discourse that the group has adapted to, and the social relationships that they have formed. Some of the norms and structures are institutionalized, e.g. the rules of a school and the educational legislation. The state aspect of this social dimension is the 'weather' in the class, which is constituted by the verbal and non-verbal communication in the group.

The structure of students' view of mathematics

The structural nature of affect has been emphasized repeatedly in mathematics education research. One of McLeod's (1992) recommendations for future research on

Plenary lecture

mathematics-related affect was to build a theoretical framework that would allow exploration of the relationships that explain the dynamics of affect. In one of the early elaborations of the systematic nature of affect, Green (1971) characterized beliefs systems in terms of three dimensions: quasi-logicalness (primary vs. derived beliefs), psychological centrality (core beliefs vs. peripheral beliefs), and cluster structure (beliefs are held in clusters around specific situations and contexts, more or less isolated from each other) (c.f. Furinghetti & Pehkonen, 2002).

Before delving deeper into the structural properties of affect, I now review a number of survey instruments. Each instrument's subscales have been classified into beliefs, attitudes (emotional traits) and motivations (including values) (Table 3).

Instru- ment	Beliefs (about)				Emotion trait	Motivation (including values)
	mathe- matics	sel f	teaching / learning	social context		
MAS		1	1	3	1	3
BMPS	0 - 1	1	1			1 -2
AtMI		1			1	2
MRBQr		1	4 -5	1	1	1 -2
VoM	1	2	1	1	1	1
PALS		2		11	1	6
MEW		2	2		1	6
AEQ-M					8	

Table 3. A review of the dimensions of mathematics-related affect measured by some instruments.

Key: MAS = Mathematics Attitude Scales (Fennema-Sherman, 1976), BMPS = Beliefs about Mathematical Problem Solving (Kloosterman & Stage, 1992), AtMI = Attitude towards Mathematics Inventory (Tapia & Marsh, 2004), MRBQr = Mathematics- Related Belief Questionnaire, refined (original by Op 't Eynde and De Corte, 2003, refined by Diego-Mantecón, Andrews and Peter Op 't Eynde, 2007), VoM = View of Mathematics (Hannula, Kaasila, Laine & Pehkonen, 2006; Roesken, Hannula & Pehkonen, 2011), PALS = Patterns of Adaptive Learning Systems (Midgley *et al.* 2000), MEW = The Motivation and Engagement Wheel (Martin, 2001), AEQ-M = the Academic Emotions Questionnaire-Mathematics (Pekrun, Goetz & Frenzel., 2005).

Such survey instruments focus typically on individual traits. However, some also provide a window on the social dimension. For example, PALS includes several measures on the respondent's perception of the motivational orientation emphasized by parents, and peers. Because of the incoherent use of language in this research domain, my classification is based on the original items of the scales. Attribution of

Plenary lecture

some of the components was problematic, and rather than emphasizing my subjective doubtful interpretation for those components, their classifications were left uncertain (e.g. BMPS has one component that could be interpreted either as a belief about mathematics or as a motivation for studying mathematics, see Table 3). If classification was very speculative, I omitted the scale from this table.

Most instruments have their specific focus. For example, MRBQr (Diego-Mantecón, Andrews & Op 't Eynde, 2007) has four to five scales on teaching and learning, while no other instrument has more than two scales in this category. In a similar way, PALS (Midgley *et al.* 2000) has a focus on social context and motivation, MEW (Martin, 2001) on motivation and AEQ-M (Pekrun, Goetz & Frenzel, 2005) on different dimensions of emotional traits. On the other hand, most instruments are fairly broad, covering several categories. However, broad instruments have only simplified measures on some of the categories. For example, while VoM (Hannula, Kaasila *et al.*, 2006; Roesken, Hannula & Pehkonen, 2011) has a subscale in each of the categories, it does not have more than two subscales in any of them.

Empirical research on mathematics-related beliefs has identified an overall pattern, where positive beliefs are related to each other and with positive emotions (e.g. Hannula, Kaasila *et al.*, 2006; Roesken *et al.*, 2011).

Although it is generally assumed that there is a relationship between mathematics-related motivation and beliefs, the theories about their relationships are fairly recent (Op 't Eynde, De Corte, & Verschaffel, 2006; Hannula, 2006b). Research has identified a positive relation between mastery orientation and attitudes, effort, competence beliefs (Seo, 2000, Hannula & Laakso, 2011; Kaldo & Hannula, manuscript) and positive emotions (Kumar, Gheen, & Kaplan, 2002; Midgely *et al.*, 1998; Pekrun, Elliot, & Maier, 2006).

The development and dynamics of affect

In this section, I will elaborate my personal understanding of the interplay of different aspects of affect through an example.

Let us consider a situation, where a teacher is about to meet a new class for the first time. Before entering the classroom, the teacher has his preconceptions about the class, based on his previous encounters with students of the same age in the same school. He is also in a certain physiological state, perhaps hungry or tired (this state is influenced by his physiological traits). The teacher's physiological state and preconceptions influence what kind of emotions, goals and expectations he has before entering the classroom. In a similar manner, the students in the class have their emotions, goals and expectations. Moreover, as a group, they have a set of social norms they adhere to (especially if they have studied together for a long time).

When the teacher enters the room, his state of mind will influence how he will interpret what he sees and hears. However, the environment (e.g. the lighting and acoustics, how is the entrance located in the class) will also influence his

Plenary lecture

impressions. When the teacher and the class begin to interact, they also negotiate the teacher role in this class. This negotiation is basically between the social norms of the class and the individual goals of the teacher, but it takes place through the communication between the teacher and his students. Through this communication the teacher and students influence each others' state of mind (emotions, thoughts, goals etc.) Moreover, they may end up changing the environment (e.g. seating of the students). This negotiation will influence the social norms of the class, the psychological traits of the teacher and to some extent also the negotiators' physiological traits.

After the lesson, both teacher and his students will engage in some reflection on the first lesson. This reflection is influenced by the cultural-historical background they are in and it may lead to further changes in the social norms of the class and the psychological and physiological traits of the teacher. The process will continue in their future lessons.

What I want to highlight here, is the interplay between the individual and the social and between the trait and state. Through the process of communication the individual state interacts with the social state. The individual is forming the social through communication and, through this very same communication, the social is forming the individual. The continuously dynamic psychological state of the individual is always influenced by three factors: the previous state, the traits and the situational information. The situational information and the previous state always determine which (if any) of the traits is activated. On the other hand, the activation and possible reflection of these different states is gradually changing the traits. The process is analogous for physiological and social traits.

POSSIBLE NEW DIRECTIONS

In the future, research on mathematics related affect is likely to make advances in the directions that have not yet been explored sufficiently. For example, quantitative studies on the structural and dynamic aspects of affect have so far relied on linear models. As an example of a study of non-linear relationships, Tuohilampi (2011) has explored how the discrepancy between ideal and real self (how we would like to be versus how we are) might be related to the student's enjoyment of mathematics. The preliminary analysis suggests that students enjoy mathematics most, when their real self is on a slightly lower level or on the same level as their ideal self.

Another future dimension for quantitative studies is to identify to what extent we can attribute variation of different affective measures to individual and social levels. The two origins of beliefs (individual experiences and cultural influences) were pointed out already by McLeod (1992). Researchers who emphasize the individual nature of affect tend to rely on psychological theories and in-depth interviews or surveys. On the other hand, those who emphasize the social construction of affect rely more on social theories and they focus on observing the emergence of affect in social

Plenary lecture

scenarios. Both of these approaches are valuable, but we should also evaluate the importance of these two origins for each affective variable. For example, is the lower self-efficacy of girls compared to males so culturally determined that teachers can have only a small effect on it? Or could this gender difference disappear in classes that have a gender sensitive teacher?

There are studies that attribute the origin of different affective variables on social and individual levels. For example, results from a Finnish high school indicate that students in the same class tend to have similar effort, enjoyment of mathematics and evaluation of the teacher, while their self-efficacy beliefs are more varied. One aspect of their self-efficacy beliefs is significantly influenced by gender while another aspect of it is mainly influenced by their achievement in mathematics (Hannula, 2009, 2010).

Another under-explored direction is the identification of different affective profiles for example through cluster analysis. In our study, we identified six affective clusters among teacher education students at the beginning of their mathematics education studies and we found this clustering to predict some of the differences in their progress in mathematics over the course (Hannula, Kaasila *et al.*, 2006).

Thirdly, there is shortage of good longitudinal studies. Due to the difficulties in longitudinal data collection, analysis is often based either on relatively small samples or a secondary analysis of data collected for another purpose. For example, Ma and Xu (2004) used data from another study and had to rely on only three items on mathematics usefulness as a measure of mathematics attitude in their attempt to analyse the causal ordering between attitude toward mathematics and achievement in mathematics. As the authors point out themselves, more reliable measures of confidence and enjoyment in mathematics might have produced different results.

Another direction that might produce interesting new results is the use of brain imaging techniques. For example, a recent study has identified that activity in the amygdala during an Aha! experience is a strong predictor of which solutions will remain in long-term memory (Ludmer, Dudai & Rubin, 2011).

The main purpose of this article has been to provide an overview of research on mathematics related affect that would enable bridging between existing theoretical frameworks. Empirical studies can well be based on local theories. However, if we wish to gain an overall understanding of human mathematical thinking and behaviour we need to engage into a dialogue across a number of local theories. I am well aware that my attempt at this synthesis is biased towards the individual level and psychological theories. People with a background in social theories might find different distinctions more relevant and useful for analysing and relating the variety of research in mathematics-related affect. I also expect and welcome other efforts at synthesising theories of affect.

PROVING AND PROOF AS AN EDUCATIONAL TASK

Maria Alessandra Mariotti
Università di Siena, Italy

Situated in the context of current research, my talk presents a point of view on proof as an educational issue. This point of view intends to combine three perspectives: epistemological, what we mean by proof; cognitive, which are the main difficulties that students meet; and didactical, what kind of didactic interventions can be proposed, among those that have been experimented and showed their effectiveness. The examples that will be presented are drawn from the current literature, but also from research studies which I have been directly involved in recently. In particular, I will discuss some results coming from long-term teaching experiments related to the use of computer-based artefacts as tools of semiotic mediation that teachers can exploit to develop the mathematical meaning of proof.

INTRODUCTION

It is for me a great honour and a great pleasure to give this lecture, and I thank the Program committee for their invitation.

The theme of my lecture has been that of one of the Working Groups at CERME since the very beginning, and it has been one of the themes of my research for many years. However, for a long time Proof and proving has been a theme of debate, not only in the community of mathematics educators, but also in the community of mathematicians (see for instance, Thurstone, 1994; Hanna, 1989)

Proof represents a very special case relative to other topics, like Geometry or Algebra. Debate among researchers has been very passionate, reflecting sometimes great divergences. This makes this theme fascinating but also shows its complexity, mainly with respect to the objective of outlining didactical implications that can be useful in school practice. In this respect, I found the contribution in the book by Reid and Knipping (2010) to be valuable, though I hardly recognize my work in their interpretation. However this is part of the complexity of the problem: often we take for granted that we share much more than we actually have in common, and only recently have we become aware of the need of making our epistemological assumptions (stance) explicit in our research work. Actually this is crucial in order to foster mutual understanding, but it is also needed in order to find a way of overcoming divergence of opinions, and to make our research results deliverable to an extended scientific community including teachers and curriculum developers.

Thus I will start with a brief introduction addressing some epistemological issues that I feel I must share with you, before entering into the core of my talk, when I will address the issue of proving and proof from a didactical perspective, and specifically I will present the analysis of different research studies concerning teaching approaches to proving and proof.

EPISTEMOLOGICAL ISSUES

I will start by posing a question:

Is there a shared meaning of ‘mathematical proof’ among researchers in mathematics education?

This question opens a recent paper by Nicolas Balacheff (2008) explicitly posing the issue of the existence of a shared meaning of the term ‘proof’ and consequently of any other term or expression related to it.

Currently the situation of our field of research is quite confusing, with profound differences in the ways to understand what is a mathematical proof within a teaching-learning *problématique* but differences which remain unstated. (Balacheff, 2008, p. 501)

As clearly argued by Balacheff in his paper, different epistemological positions affect mathematics education research on proof and in particular didactic /pedagogical approaches to proof at school. For this reason it is crucial to be aware of this problem and to make an effort to clarify one’s own different assumptions.

Though it may appear to be a simplification, I claim that when approaching the issue of proof there are two opposing positions that may be referred to two different epistemological, and maybe cultural, perspectives.

On the one hand proof is meant as an idiosyncratic issue, strictly dependent on the individual that produces it. In this respect a wide range of cases can be observed and described. An example of a study consistent with this perspective is offered by the research work developed by Harel & Sowder (1998), and the classification (taxonomy) provided by these authors is an exemplar of the results coming from these type of studies. Such a classification is very accurate, and differentiates a large number of students’ behaviours. However such different behaviours (proof schemes) share a common ‘definition’ of proof that is obviously quite general. The authors formulate an explicit definition of the process of proving, a process of which a proof can be considered a product.

Proving is the process employed by an individual [...] to remove or create doubts about the truth of an assertion. The process of proving includes two sub-processes: ascertaining and persuading. (Harel & Sowder, 1998, p. 241)

As the authors explain, ascertaining is the process an individual employs to remove her or his own doubts, whilst persuading is the process employed to remove others’ doubts.

According to this definition, the term *proof* is largely referred to any kind of argument, and “need not connote mathematical proof” (Harel & Sowder, 1996, p. 60)

On the other hand, other researchers take a completely different point of view and hold/claim that proof has a peculiarity of its own, and that such a peculiarity constitutes a key element of mathematics as a theoretical discipline. Proof is meant

Plenary lecture

as the product of the process of theoretical validation that is considered a specific and indispensable component of Mathematics. Taking such a perspective, that for good reasons we can call ‘formal’ (Arzarello, 2007), means to consider a proof independent on any interpretation and factual verification of the statement /statements that are involved. This is the stance, among others, of Raymond Duval (1991; 1992-93), who clearly states the specificity of proof, contrasting it with argumentation. Duval claims the need to clearly distinguish between argumentation and proof, stressing the epistemological and cognitive gap existing between these two processes, in spite of their similarities. The core of Duval’s argument concerns the difference between the semantic level, where the epistemic value of a statement is fundamental for its acceptability, and the theoretical level where the only matter is checking the theoretical validity of a statement: i.e., checking the validity of the logic dependence of a statement with respect to the axioms, definitions and theorems, without taking into account the epistemic value that can be attributed to any statement involved.

The epistemological and cognitive analysis carried out by Duval makes him warn us that the main issue from an educational perspective is exactly in the proximity of the two processes and in the danger of mistaking one for the other. Thus there is need of a careful distinction between them, stressing the theoretical nature of proof and recognising argumentation as a possible obstacle to the development of a sense of proof.

Of course this radical position leaves place for a wide range of intermediate possibilities and variations in conceiving the relationship between argumentation and proof. However it focuses on specific features of mathematical proof that characterize it, and for this very reason can hardly be neglected without serious/great loss for mathematics education. (Mariotti, 2006)

These same characteristics that inspired the following statement where the educational value of proof was clearly stated.

The concept of proof is one concerning which the pupil should have a growing and increasing understanding. It is a concept which not only pervades his work in mathematics but is also involved in all situations where conclusions are to be reached and decision to be made. Mathematics has the unique contribution to make in the development of this concept [...] (Fawcett, 1938, p.120, quoted by Reid & Knipping)

Coming back to the analysis carried out by Duval, we can remark that the distinction /opposition between argumentation and proof is based on the distinction between the semantic plane and the theoretical plane. While proof is confined on the theoretical plane and does not require any reference to the interpretation of any of the statements involved, it is on the semantic plane that an argumentation derives the epistemic value of the statement in focus. Based on the interpretation of the different statements and on their semantic relationships argumentation it is strictly connected

Plenary lecture

with the issue of understanding ‘why’ (Dreyfus & Hadas, 1996), in particular to an explication function that seems to be also a proper goal of proof (Hanna, 1989a) From this perspective the following question arises:

What is the role of theoretical derivation in respect to understanding? If we take a theoretical perspective, what about the explication function of proof ?

Different answers are possible, however it seems reasonable to agree on the fact that the sense of mathematical proof should include elements related to the semantic plane. This becomes more evident if we consider the process of proving not only in relation to the process of evaluating the acceptability of a proof of a given statement, but also in relation to the process of producing a new theorem; i.e. producing a conjecture and then its proof. Considering the practice of mathematicians, it seems difficult to conceive producing a conjecture, and in particular producing the links of logical implication between two statements, without referring to the meanings involved in the formulations of such statements and in the relationships between them.

to expose, or to find, a proof people certainly argue, in various ways, discursive or pictorial, possibly resorting to rhetorical expedients, with all the resources of conversation, but with a special aim ... that of letting the interlocutor see a certain pattern, a series of links connecting chunks of knowledge. (Lolli, 1999)

Meaning and epistemic values, given by the interlocutors to the statements involved, have no theoretical status, nevertheless it seems nearly impossible to think of a ‘practice of theorems’ –the mathematicians’ practice of producing theorems by formulating and proving conjectures - without any reference to meanings.

In this respect I do not see any conflict between the two perspectives presented above; rather I think that each perspective focuses on different aspects which are both fundamental for mathematics education. And taking the risk of oversimplification, I would summarize the didactic issue of proof in terms of resolving the potential conflict between the two main functions of proof, i.e. validating within a theory and explaining with respect to interlocutors’ conceptions. This means finding a way, a pedagogical/ didactical way, of developing the complex relationship between argumentation, with its goal of convincing, and proof, with its goal of theoretically validating. Finally, it means taking into account the differences between argumentation and proof, and exploiting their deep link rather than ignoring it.

Addressing the complexity of this issue sometimes requires the researcher to assume a position that may appear too rigid or oversimplified. Such simplifications might be reasonable for methodological reasons, but it remains necessary for the researcher (and the teacher) not to miss the complexity of the *problematique*.

In order to better clarify this point I will present two theoretical constructs that are consistent with the previous statement, and in my view can be of help to frame the design and the analysis of research studies on proof; at least, I would like to propose

them because I found them personally very useful in the research studies that I carried out recent years and are still in progress.

The first construct is the notion of Theorem that we introduced some years ago (Mariotti et al., 1997) At the beginning there was a need to provide a shared frame to describe commonalities between different research approaches to proof among some Italian research groups. Later, this notion has been used and further elaborated in other studies (see for instance its use in the analysis of the proof by contradiction (Antonini & Mariotti, 2008) The second construct is that of Cognitive Unity as developed by Pedemonte (2002), starting from the original definition introduced by Boero et al. (1996) In the following sections I am going to give a brief description of both such constructs.

A DEFINITION OF THEOREM

The definition of Theorem that we are going to introduce is motivated by the following remark. The current literature, but also textbooks, commonly refers to the educational issue of proof, and in so doing proof is considered in itself, without any reference to the other key elements without which the idea of proof evaporates. As a matter of fact, as briefly discussed above it is impossible to grasp the sense of a *mathematical proof*, specifically when we want to differentiate it from argumentation, without linking it to the two other elements involved: a *statement* and overall a *theory*.

In other words, we speak of a proof when there is a statement to which it provides a support for validity, but also when there is a theoretical frame within which such a support makes sense. Leaving statement and theory implicit is certainly comprehensible if we take the perspective of mathematics experts, but it may become a serious flaw if we take an educational perspective and we consider the students' point of view.

What may have become an automatic and unconscious implicit reference for experts, cannot be expected to be the same for novices. Grasping the sense of the mathematical proof in terms of *theoretical validation* may be difficult and not spontaneous. Certainly, where students are concerned, the peculiarity of such a way of thinking cannot be taken for granted and its complexity cannot be ignored. In particular, one may expect serious consequences from the confusion between an *absolute* and a *theoretically situated* truth, corresponding to the two main functions of proof - explication and validation - (for a full discussion see Mariotti, 2006)

Hence, taking an educational perspective and in order to express the contribution of each component involved, the following characterization of Mathematical Theorem was introduced, where a proof is conceived as part of a system of elements:

The existence of a reference theory as a system of shared principles and deduction rules is needed if we are to speak of proof in a mathematical sense. Principles and deduction rules

Plenary lecture

are so intimately interrelated so that what characterises a Mathematical Theorem is the system of statement, proof and theory. (Mariotti et al. 1997, 1, p. 182)

Traditionally in school practice, the reference to the Theory within which a proof makes sense is neglected, and, except for the case of Geometry, the theoretical context in which theorems are proved normally remains implicit. Consider, for instance, Calculus courses and textbooks: this is one of the few cases when proofs are provided, yet the axiomatic reference system is largely left implicit, and a careful analysis shows that most of the proofs would be better classified as argumentations.

Coming back to the definition of Mathematical Theorem, it is important to remark that what is shortly referred to as Theory, has a twofold component. On the one hand, Axioms, Definitions and already proved Theorems constitute the means of supporting the single steps of a proof; on the other hand, meta-theoretical rules assure the reliability of the specific way to accomplish this support - that is to say, how the Axioms and Theorems belonging to a Theory can be used to validate a new statement.

Actually, as clearly pointed out by Sierpinska, acting at a meta-theoretical level constitutes the very essence of a theoretical perspective

[T]heoretical thinking is not about techniques or procedure for well-defined actions, [...] theoretical thinking is reflective in that it does not take such techniques for granted but considers them always open to questioning and change. [...] Theoretical thinking asks not only, Is this statement true? but also What is the validity of our methods of verifying that it is true? Thus theoretical thinking always takes a distance towards its own results. [...] theoretical thinking is thinking where thought and its object belong to distinct planes of action. (Sierpinska, 2005, pp. 121-23)

In the school context, the complexity of this meta-theoretical level seems to be ignored. It is commonly taken for granted that students' ways of reasoning are spontaneously adaptable to the sophisticated functioning of a theoretical system. Thus not much is said about it, and in particular deduction rules and their functioning in the development of a Theory are rarely made explicit¹.

There are at least two aspects of acting at a meta level that need to be made explicit. One consists in the acceptability of some specific deductive means, the other in the fact that no other means, except those explicitly shared, is acceptable. If these two aspects are left implicit, it may happen that students have no access to any control on their arguments. In this case the control remains completely in the hands of the teacher, resulting for students in a general feeling of confusion, uncertainty and lack of understanding.

THE NOTION OF COGNITIVE UNITY

In the context of a long-term teaching experiment (Boero et al., 1995a), interesting results came to light concerning students' production of conjectures (Boero et al.,

Plenary lecture

1996; 2007) and the argumentation accompanying it. The teaching experiments were based on the solution of an open-ended problem, requiring both a conjecture and its proof. Clear evidence was found of different kinds of argumentative processes appearing in the solution. Further investigations demonstrated that when the phase of producing a conjecture had shown a rich production of arguments that aimed to support or reject a specific statement, it was possible to recognize an essential continuity between these arguments and the final proof; such continuity was referred to as Cognitive Unity.

During the production of the conjecture, the student progressively works out his/her statement through an intense argumentative activity functionally intermingling with the justification of the plausibility of his/her choices.

During the subsequent statement proving stage, the student links up with this process in a coherent way, organizing some of the previously produced arguments according to a logical chain. (Boero et al., 1996, p. 113)

If the first results supported a sort of “continuity” (as the authors called it), further investigation brought evidence of a possible gap between the arguments supporting the production of a conjecture and the proof validating it.

This construct has been widely used in analysing students’ solutions to different types of open problems. These studies led to a refinement of the construct and to the introduction of the distinction between *referential* and *structural* Cognitive Unity (Pedemonte, 2002) Further elaborations of this construct have been recently developed (Boero et al., 2010)

PROOF AS AN EDUCATIONAL TASK

Different research projects at different age levels in different countries have designed and implemented possible approaches to proof. Naturally, this has been done assuming different epistemological perspectives and different cultural contexts with respect to proof.

Results of survey studies and research work focused on students’ conceptions of proof, on difficulties that students may encounter, motivated and, at the same time, inspired the development of innovation projects aimed more or less directly at improving students learning about proof. There are two main types of such studies: first, those that more generally address the design of activities aimed at fostering students’ insight into what proof is for fostering their performances in proving tasks; and secondly, those that explicitly address the design of teaching sequences aimed at introducing students to proof, and developing a sense of proof not only for recognizing but also for producing a proof.

Because of the time limitations of this talk, I will deal only with the first types of studies, and focus on approaches to students’ first experiences of proof.

DESIGN OF TEACHING SEQUENCES TO INTRODUCE STUDENTS TO PROOF

In the light of the analysis carried out in the previous sections, we can synthetically summarize the educational issue concerning students' introduction to proof as follows:

teaching proofs and Theorems should have a double aim: on the one hand that of making students understand what mathematical proof is, and on the other hand that of making students capable of producing it.

Rephrasing what Balacheff (1982) wrote some year ago, proof should be considered both as an object, by which I mean a product that must fulfil the epistemic and communicative requirements of a mathematics community, and also as a process, that is to say the answer to a problem solving stance, intentionally aimed at producing a proof as product.

Consistent with this educational issue, the design of teaching sequences has taken the direction of searching for specific contexts to make possible:

1. fostering the emergence of a culture of explaining (a culture of Why questions); and
2. fostering the development of a theoretical perspective (a culture of Theorems)

In the following sections I will present examples of such contexts, trying to explain in what sense they may fulfil these two requirements.

Figure 1 Pupils experiencing sun shadows

Approaching Theorems in the field of experience of sun shadow

The first example concerns a research project aimed at analysing mental processes underlying the production and proof of conjectures in mathematics. The project was part of a long-term teaching experiment carried out by the research team directed by Paolo Boero, and involved several classes at different school levels (Boero et al., 1995a, 1995b, 2007) Within this project the idea of context is filtered by the notion of

'field of experience', explained as follows:

Field of experience: a system of three evolutive components: (external context, student's internal context and teacher's internal context) referred to a sector of human culture, which teacher and students can recognize and consider as unitary and homogeneous. (Boero et al., 1995a, pag.153)

Plenary lecture

The importance given in the project to the cultural value of Mathematics raised the issue of introducing pupils to theoretical thinking as well as that of developing pupils' competences in argumentation. Argumentative competences were considered a requirement for accessing theoretical thinking, in addition to their function as a means of control over mathematical techniques. But first and foremost, argumentative competences were considered a necessary condition for accessing a *cultural* discourse. (Boero et al. 1995a) In this respect it is important to highlight how the introduction to Theorems was part of a broader educational project aiming at developing concepts and ways of thinking belonging to mathematics, and generally speaking to our culture.

The field of experience of sun shadows was chosen in the project. This choice was motivated by the fact that it offers the possibility of producing, in open problem solving situations, conjectures which are meaningful from a space geometry point of view. Specific activities were designed for introducing students to a theoretical perspective, that is to introduce students to the culture of Theorems, as the designers express it, integrated in the teaching sequence concerning geometrical concepts emerging from making sense and produce conjectures in a real situation. The evolution of the field of experience is based on modelling shared experiences (see Figure 1) related to sun shadows. (Douek, 1999; Boero, 2002)

Conjectures are not immediate, and often there is a great variety of them; for this very reason, 'why' questions arise naturally. However, direct validation is mostly not possible, and any argument may be accompanied by drawings, although it can hardly be substituted by drawings. Because of the difficulties and the ambiguity in representing 3D spatial properties by drawing, drawings may not be convincing.

A first modelling approach leads the class to formulate a set of shared principles that constitute what we call a 'Germ Theory' (Bartolini Bussi et al. 1999)

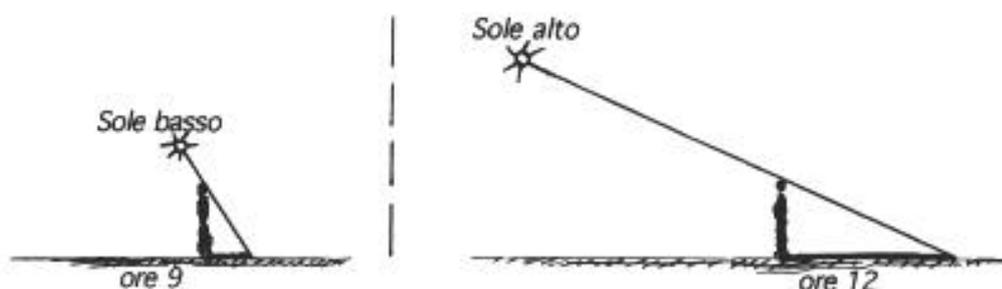

Figure 2 The triangle of shadow illustrating the first principle

This particular Germ Theory is constituted by the following two principles:

1. The length of the shadow depends on the height of the sun.
2. Two vertical sticks have parallel shadows.

The activities which then follow are characterized by posing open-ended problems concerning experiences with sun shadows. As already remarked, the context offers

Plenary lecture

rich possibilities of posing open problems where uncertainty, stressed by the difficulty and often the impossibility of a direct verification, is the main motivation triggering the production of arguments supporting one's own conjectures.

Thus, conjectures ask for supporting arguments, and the acceptability of such arguments is related to the shared principles. The aim is that of developing the sense of proof by connecting the construction of a theory to the production of arguments that make sense within it. In other words, according to the definition of Theorem given above, the educational aim consists in developing a sense of Theorems through relating three elements: a statement, a proof and a Theory within which the proof makes sense.

It is not surprising that in this experimental context the notion of Cognitive Unity, described above, emerged and became a designing principle. In the following section I briefly outline a specific example (for a full discussion see Boero et al., 2007)

The “two sticks” Theorem

Consider the following problem proposed to the class as individual work or work in pairs, as students prefer.

Problem. In recent years we observed that the shadows of two vertical sticks on the horizontal ground are always parallel. What can be said of the parallelism of shadows in the case of a vertical stick and an oblique stick? Can shadows be parallel? Sometimes? When? Always? Never? Formulate your conjecture as a general statement.

Some thin, long sticks and three polystyrene platforms were provided in order to support the dynamic exploration process of the problem situation.

The problem refers to a familiar situation – a stick standing and producing a certain shadow – it proposes to add a new element – the oblique stick – and asks students to analyse the effect of this variation. It is also explicitly asks students to formulate the conjecture as a ‘general statement’, while the initial reference to the parallelism of the shadows of vertical sticks implicitly frames the arguments supporting the conjectures, and eventually makes sense of asking for a ‘proof’. Let us consider the following text produced by one of the pupils involved in the teaching experiment.

Simone (8th grade)

If we took into consideration two sticks, of which one is vertical, the shadows will be parallel when the two sticks are seen parallel by the sun. If we suppose that the person is in the position of the sun and looks at the sticks, by going around the sticks we can observe that the sticks are parallel in a certain position and the shadows are also parallel since the difference in position of the two sticks cannot be seen from that position. Thinking about the shadow space we can say that the non-vertical stick seems to be within the shadow space. Let's imagine an imaginary vertical stick representing the oblique one, in line with the sun's rays and the same stick, the oblique one cannot be seen so it seems to be vertical, forming parallel shadows. The shadows can be parallel if the

Plenary lecture

sun is situated along the direction of the oblique stick [with a gesture he indicates the vertical plane containing the oblique stick].

This text is a good exemplar of the kinds of proofs that can be generated by students, in which the arguments are intermingled with subsequent different formulations of the conjecture statement. In spite of the reference to experience, and in particular to the fictive dynamic experience of “a person in the position of the sun”, the arguments also clearly show reference to the shared principles; thus it is possible to speak of a proof and then of a Theorem in a consistent way with respect to the definition given above.

However, it is clear that the interest and the care invested in developing such a theoretical perspective is deeply rooted in a semantic field: arguments are strictly related to their meanings in the context of sun shadow. They make sense in response to uncertainty, but base their acceptability on being elaborations (consequences) of the shared principles. It is clear, in this respect, how the aim of the Project designers is achieved: starting from an organization of the arguments based on their semantic content, to develop an organization consistent with the expectation and the requirements of the Theory, passing through the awareness of a shared need of communication and acceptability.

The specificity of the approach to Theorems presented above is highlighted by comparing it with others. In this respect we mention the distance between this approach and that of Duval (1991) The distance corresponds to that between two different epistemological perspectives. On the one hand an epistemological approach that recognizes a proof as primarily a derivation within a theory and aims at ‘realizing dissociation between content and operative status of propositions’ (op. cit., p. 223); on the other hand an epistemological approach that recognizes a proof as the construction of a validation in respect to a complex system of reasons, within which the reasons of the theory are only one part, and an epistemological and didactical approach that intends to maintain the priority of propositional content and reasoning with regard to such content.

This last claim is shared by other researchers, as the following passage shows.

In particular proof cannot be taught or learned without taking into consideration the relationships of mathematics to reality (Hanna and Janke 1996, p. 902)

Hence it is interesting to compare the Sun shadow Project approach with another approach that shares with it the choice of using the modelling of physical experience as a source of Geometry theory construction.

Modelling and theory: the approach of the theoretical physicist

When Geometry theory sprouts from a modelling process the relationship between Theorems and the verification of facts cannot be neglected. As we observed above, this problem was intentionally partially avoided in the activities proposed in the Sun

Plenary lecture

shadow Project. In fact, after an intense experience of sun shadow phenomena from which shared principles emerged, crucial activities were centred on the solution of problems where direct verification was impeded by specific circumstances (for instance, clouds hide the sun or students are asked to make a conjecture sitting in the classroom so that the situation at stake is out of their direct control) forcing the students to develop arguments based on stated principles to support conjectures.

Nevertheless the delicate issue concerning a the relationship between Geometry and reality can hardly be neglected. Starting from remarking how measuring and empirical verification have been discredited in common school practice, some authors (Hanna & Jahnke, 2007; Jahnke, 2007) claim the need to confront that issue, taking what they call the point of view of a *theoretical physicist*. From such a perspective Jahnke (op. cit., 2009) discusses the relationship between theory and practice, and in particular he discusses the status of geometrical problems and their solutions in respect to empirical verification, asking for consistency in treating empirical data in relation to Geometry and in relation to Physics. The didactical implication is the following.

Therefore, in teaching beginners an intellectually honest way is to take side by the physicist and to say that the angle sum theorem is true because of empirical measurements. Only at a later stage, one should expose the idea of a purely mathematical theory separated from reality. (Jahnke, 2005, p. 430)

There are similarities between the approach proposed by Jahnke and that proposed in the Sun shadow Project: both consider physical phenomena and their experience as a key element in posing meaningful problems that may generate uncertainty and consequently a culture of ‘why’ questions, and to produce conjectures and their validations according to stated hypotheses. However the issue of the relationship between argumentation and proof, specifically between empirical verification and theoretical validation is approached differently. In the Sun shadow Project, that issue is not explicitly addressed; rather, the implicit relationship between argumentation and proof is exploited, in an attempt to take advantage of spontaneous argumentation processes in order to make sense of mathematical proof. According to Jahnke’s approach the relationship between empirical an theoretical validation has to be explicitly taken into account. The need to state assumptions in relation to answering a ‘why’ question, and the need for a reasonable empirical base for these assumptions is part of the “theoretical physicist” approach that is held to be indispensable in the development of a sense of proof.

All this is related to a specific epistemological perspective that considers the assessment of a theory to be, in the end, a *pragmatic decision*. The ultimate reason for accepting a law is not of a logical, but of a *pragmatic nature*.

[...] a mathematical proof deriving a statement (natural law) of the theory does not provide absolute certainty to this statement, but it will considerably *enhance* its certainty

Plenary lecture

since the corroboration does not only come from an isolated set of direct measurements but from all measurements related to the theory. Such a theoretical network of statements and measurements connected by mathematical proofs is the safest form of knowledge at our disposal, though this does not change its, in principle, preliminary character. (op cit, p. 430)

Of course, the discussion on such a position is open. The ultimate autonomy of Mathematics might be claimed, nevertheless we must admit that the position of Jahnke is fairly reasonable in respect to the educational objective of introducing students to Theorems within the context of common physical experience.

LOOKING FOR CONTEXTS FOSTERING STUDENTS' INTRODUCTION TO PROOF

Looking for contexts for introducing students to proof, some authors pointed out the specificity of a Dynamic Geometry System (DGS) in offering powerful resources for designing situations for enhancing students' learning of proof (see for instance the Special Issue of ESM edited by Jones, Gutiérrez & Mariotti (2001) and specifically, Laborde's contribution to this Special Issue)

[...] the findings concerning the failure to teach proofs, the recognition of the multiple aspects of proving, and the existence of DG tools, lead naturally to the design of investigative situations in which DG tools may foster these multiple aspects. (Hadas et al., 2000, p. 130)

Open-ended problems are generally recognized as key elements, because of their potential in raising uncertainty and conflicts, and sometimes surprise - all ingredients that may trigger the need for explaining and validating, and eventually producing arguments. I will return to the specific issue of open-ended problems in the discussion of the last example. However other components have to be taken into account in the design; Hadas and colleagues outline a set of *design principles*, and the combination of these principles leads to designing tasks that afford "productive argumentative talk" (Hadas et al., 2000) In particular, besides promoting a collaborative situation, the need of "providing tools for raising and checking hypotheses" is suggested. In the case of a DGS, some of the negative aspects related to empirical verification may be overcome because of the specificity of the system of validation internal to the virtual environment. Such a validation system has a number of positive qualities: it can be explicitly shared in the classroom and it seems easily acceptable because it asks users to conform to the functioning of an artificial environment. Moreover validation by dragging is independent on the authority of the teacher and the aim of pleasing her, and it can be directly activated by any student, raising uncertainty, and sometimes curiosity. It is capable of triggering 'why' questions that open the way to producing arguments and explanations. For this reason, and other characteristics, to which we will return in the following, a DGS offers a rich potential for a didactical approach to proof.

FIELD OF EXPERIENCE CENTRED ON THE USE OF ARTEFACTS. THE CASE OF CABRI CONSTRUCTION

The second example that I present concerns a long-term teaching experiment centred on the use of a particular DGS, Cabri Géomètre, and aiming at introducing students to proof at the upper secondary level.

As mentioned above, the main objective was that of exploiting the didactical potential offered by a DGS, and in particular by the specific system of validation based on the use of dragging. An epistemological analysis of the use of Cabri highlighted the deep relationship between producing figures in Cabri that are stable under dragging, and solving Construction problems within Euclidean Geometry. On the base of this relationship we designed a sequence of activities which aimed to initiate and develop a culture of Theorems within what we can call the field of experience of Cabri Construction (Mariotti, 2000) In order to better explain the principles of the design, I need to clarify some elements of the theoretical framework within which the didactical potential of Cabri has been described, and its utilization in the classroom activities explained. The theoretical frame is that of the Theory of Semiotic Mediation (TSM) as it was elaborated in Bartolini Bussi & Mariotti (2008) Taking quite a broad perspective, TSM aims to describe the use of artefacts² as a means to foster the teaching-learning process.

The theory of semiotic mediation

The Theory of Semiotic Mediation (TSM) (Bartolini Bussi and Mariotti, 2008; Mariotti, 2009; Mariotti, 2010; Mariotti & Maracci, 2010) combines a semiotic and an educational perspective and elaborates on Vygotskij's notion of semiotic mediation (Vygotskij, 1978), considering the crucial role of *human mediation* (Kozulin, 2003, p.19) in the teaching-learning process.

Interpreting the teaching-learning process from a semiotic perspective means recognizing the central role of signs³ and describing the teaching-learning process as a process of evolution (transformation in a given direction) of signs. In particular, TSM focuses on the production of signs, as they originate in the use of an artefact, in relation to personal meanings emerging from it, and on the process of transformation of such signs through social interaction; such a transformation may be applied to specific mathematical knowledge and the signs related to it, thus the evolution of signs may be considered as an indication of a change in the relationship between the subject and mathematical knowledge, and eventually as an evidence of learning.

When using an artefact for accomplishing a task, students' personal meanings emerge. Such meanings can be related to mathematical meanings, but establishing such a relationship is not a spontaneous process for students. On the contrary it can be an explicit educational aim for the teacher, who can *intentionally* orient her/his own actions towards promoting the evolution from personal towards mathematical meanings. Evolution may occur through social interaction, so that in a mathematics

Plenary lecture

class context, signs⁴ produced by students and expressing the relationship between the artefact and the task in which it is used, can evolve into signs expressing the relationship between the artefact and mathematical knowledge (Figure 1)

The organization and fostering of this semiotic process has been the focus of our studies, based on long term teaching experiments (see for instance, Mariotti et al, 1997; Bartolini Bussi, 1996; Bartolini Bussi et al, 1998; Mariotti, 2000; Mariotti& Cerulli, 2001) from which the theoretical framework originated and developed, around two key elements: the notion of the semiotic potential of an artefact and the notion of a didactic cycle (for a full discussion see Bartolini Bussi & Mariotti, 2008)

As said above, the use of an artefact to accomplish a particular task may evoke (Hoyles, 1993) specific mathematical knowledge. In fact, going beyond the immediate sense of its use, experts – mathematicians, and in particular teachers – may recognize mathematical notions in solving a specific problem with the artefact. For example, positional notation and the polynomial notation of numbers may be evoked by an abacus and by its use in counting or addition; similarly, as we will see in the following, constructing a stable figure in a Dynamic Geometry System may evoke classic ‘ruler and compasses’ Geometry. In the TSM framework, the following definition aims to make explicit the twofold relation that may link an artefact to both the sphere of individuals and that of culture, to personal meanings and mathematical meanings. At the same time such a definition aims to draw attention to the need for a clear distinction between meanings related to the use of an artefact, in particular those related to the individual accomplishing a task, and meanings related to mathematical content as cultural attainment.

A double relationship may occur between an artefact and on the one hand the personal meanings emerging from its use to accomplish a task (instrumented activity), and on the other hand the mathematical meanings evoked by its use and recognizable as Mathematics by an expert.

We will call this double semiotic link the *semiotic potential* of an artefact. (Bartolini Bussi & Mariotti, 2008, p. 754)

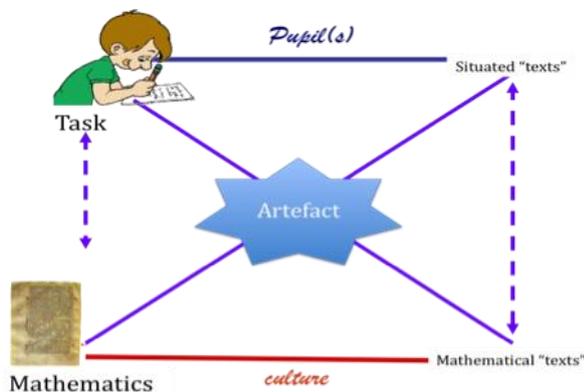

Figure 3 The TSM model for the teaching learning process

The notion of semiotic potential captures the idea that an artefact may be used not only by the student to accomplish a task but also as a vehicle for learning, in other words, it can be used by the teacher as *a tool of semiotic mediation*. Once its use is introduced in the classroom activities the teacher may exploit its semiotic potential to foster students’ mathematical learning. The analysis of the semiotic potential is to be considered an a priori phase that

Plenary lecture

constitutes the core of the teaching sequence design. In the case of classic ancient tools one can take advantage of history, finding there inspiration (Bartolini Bussi, 2001) As far as new technological tools are concerned, the instrumental approach (Rabardel, 1995) as developed by some authors (Trouche, 2005; Artigue, 2002; Lagrange, 2000) offers a good frame for an a priori analysis of the use of the artefact with different tasks and provides the basis for a cognitive and epistemological analysis that contributes to the identification of potential meanings that might emerge during students' activities and the related mathematical meanings.

Exploiting the semiotic potential of the artefact involves for the expert (for instance, the teacher) an awareness of its potential both in terms of evoked mathematical meanings and emergent personal meanings during the activity in the classroom. On the one hand, to the teacher must contrive didactic situations where students face tasks that are expected to mobilize specific schemes of utilization and consequently, situations in which they are expected to generate personal meanings. On the other hand, the teacher needs to orchestrate social interactions with the aim of making personal meanings, which have emerged during the artefact-centred activities, develop into the mathematical meanings that constitute the teaching objectives.

Within the frame of the TSM, I will describe how a DGS offers a good context for approaching proof, in particular how some of its elements may function in the hands of the teacher as tools of semiotic mediation to develop mathematical meanings related to proof: specifically, as discussed above, meanings related to the notion of Theorem as a system of statement, proof and theory.

Geometrical construction in a DGS

Let us start from the core of the analysis that lies in the relationship, immediately evoked in the mind of any mathematician, between Cabri figures and geometrical constructions. Such relationship can be elaborated from the point of view of semiotic mediation through both an epistemological and a cognitive analysis, leading to an outline of the semiotic potential of the artefact 'Cabri' with respect to the meaning of Theorem.

In Euclidean Geometry, traditionally referred to as 'ruler and compasses geometry', construction problems have a central position. The theoretical nature of a geometrical construction is clearly stated, and that is in spite of their apparent practical objective, i.e. the drawing which can be produced on a sheet of paper following the solution procedure (Mariotti, 2007) As Vinner clearly points out:

The ancient Greek undertook a challenge which in a way represents some of the most typical features of pure mathematics as an abstract discipline. It is not related to any practical need.(Vinner, 1999, p. 77)

Actually, the use of ruler and compasses generates a set of axioms defining the theoretical system of Euclid's Elements, thus any construction problem to be solved

Plenary lecture

within Euclidean Geometry – let's say a geometrical construction - leads to a Theorem that validates the construction procedure that solves it.

The appearance of DGSs has triggered a new revival in geometrical constructions. The use of virtual tools can simulate use of the ruler and compass of classic Geometry: lines and circles intersecting each other, over centuries drawn on sand, papyrus or paper, are now reproduced on a computer screen. Any DGS offers something new to the classic world of paper and pencil figures: screen drawings can be acted upon, using the 'dragging modality'. This modality allows the transformation of screen figures, changing the starting points of the construction, but maintaining all the properties defined by the constructing procedure. As a consequence, the stability of the characterizing properties of the drawn figure in respect to dragging, constitutes the natural/standard test of correctness for any construction task in a DGS .

Moreover, consider a DGS like Cabri (Laborde & Bellemain, 1995): the elements of any Cabri figure are related according to the hierarchy of properties determined by its construction procedure. Such a hierarchy of properties corresponds to a relationship of logical dependence between them, while a sub-set of the tools available in a Cabri Menu can be related to its correspondent set of construction tools in Euclidean Geometry (Laborde & Laborde, 1991) This correspondence allows control by "dragging" to be put into a relationship with "theorems and definition" within the system of Euclidean Geometry (Mariotti, 2000; Jones, 2000)⁵.

In summary, as far as the Cabri tools are concerned, a double relationship is recognizable. On the one hand, Cabri tools are related to the construction task that can be solved through their use, resulting in the appearance of a Cabri figure, and to the stability of such a figure by dragging; on the other hand, specific Cabri tools can be related to the geometrical axioms and theorems that can be used to validate the solution of the corresponding construction problem within the Geometry theory.

Hence, a semiotic potential of the Cabri environment is recognizable, residing in the twofold relation that it has with the meaning of the Cabri figure as it emerges from the use of its virtual drawing tools for solving construction problems controlled by the dragging test, and the theoretical meaning of geometrical construction as it is defined within Euclidean Geometry in relation to a given set of axioms.

Exploiting the semiotic potential of the artefact Cabri became the key pedagogical assumption inspiring the design of a teaching sequence that, according to the structure of a Didactic Cycle, consisted of activities involving the use of the artefact and semiotic activities aimed at individual and social elaboration of signs (for details see Mariotti, 2000; 2001)

The use of the artefact was centred on a *construction task* requiring students:

Plenary lecture

- to produce a specific Cabri figure that should be stable by dragging, and write the description of the procedure used to obtain it;
- to produce a validation of the ‘correctness’ of the construction realized.

The Construction task consisted of two requests, the first corresponding to acting with the artefact, the second to producing a written text referring to such actions. Note that producing a written text consists of both describing and commenting on the procedure carried out. The request of *validating* the solution made sense with respect to the Cabri environment, corresponding to the need for explaining and gaining insight into the reason why the figure on the screen passes the dragging test. The process which began in the students’ semiotic production proceeded through social interactions orchestrated by the teacher in true Mathematics Discussions (Bartolini Bussi, 1998; Mariotti, 2001) Whereas, at the very beginning, the term *construction* made sense only in relation to using particular Cabri tools and to passing the dragging test, later on the meaning slowly evolved, acquiring the theoretical meaning of Geometrical construction.

Such an evolution could be accomplished, under the guidance of the teacher exploiting the correspondence between Euclidean Axioms and specific Cabri tools and their modes of use. Starting from an empty menu, the choice of the appropriate tools to start with was discussed as well the correspondence with a set of *Construction axioms* constituting the first core of the Geometry Theory which any validation can refer to. Then, as long as new constructions were produced, the corresponding Theorems were validated and added to the theory. Students could experience and participate in two parallel processes of evolution: on the one hand, the enlargement of the Cabri menu, and on the other hand the corresponding development of a Geometry Theory. We can claim that students were introduced to the Theorems culture, because students not only produced new statements and their proofs, but they also had the opportunity of becoming aware of the theory within which proofs made sense, and of how such a theory was developing.

Results of several long-term teaching experiments attest the emergence of intermediate meanings, rooted in the semantic field of the artefact, and their evolution into mathematical meanings, consistent with Euclidean Geometry. In particular, the experience in the classroom highlighted how meanings emerging from the use of tools in the constrained world of Cabri were effective in developing and interlacing the sense of proof and the sense of theory. The use of any single tool mediates the meaning of the application of an axiom or a theorem, while the idea of the Cabri menu, that is the set of available tools, mediates the meaning of theory. Conventionality and the evolutionary nature of a theory clearly emerged during collective discussions where students experienced both establishing and developing a Geometry Theory through exploiting the possibility of personalizing the menu by selecting the tools to be used. I have written extensively in the past about these

experiments (Mariotti, 2000, 2001, 2007, 2009), and now I will move on to the last example.

More about the semiotic potential of a DGS: Dragging as a semiotic mediator of conditionality

For my last example I will elaborate a bit more on the potential offered by a DGS, and in particular on the semiotic potential of dragging modes in respect to the mathematical notion of conjecture. The significance of this discussion stems from a shared opinion, already mentioned above, about the fundamental role that open problems and conjecturing activities have in developing the sense of proof, fostering a productive relationship between ‘spontaneous’ argumentation processes and theoretical validation (Arsac & Mante, 1983; Arsac, 1992; Hadas et al. 2000; Pedemonte, 2002)

As I have already said, different contexts afford open-ended questions in different ways, offering different potentialities for both posing and solving open problems. What I want to discuss concerns a very peculiar aspect of Dynamic Geometry, and from this perspective I intend to compare the two contexts considered above, the sun shadow and the DGS contexts.

The studies carried out by Boero and his colleagues focused on different aspects of experiencing sun shadows, highlighting the crucial role played by the dynamic character of the phenomena under investigation. In the case of open problems, when it is requested to produce a conjecture, dynamicity seemed to foster transformational mental processes (Simon, 1996; Harel & Sawder, 1998) providing key elements to produce conditional statements. The conditional statement seemed to emerge as “crystallization” of a dynamic exploration. This crystallization isolates a specific moment, and a position, when the occurrence of one fact has the occurrence of another fact as consequence. In Mathematics, the formulation of a conjecture expresses such a crystallization in a conditional statement (Boero et al., 1999; Boero et al., 2007) Because of the dynamic nature of experiences in a DGS it seems reasonable to address the issue of the role of dragging modes in conjecture production.

Thus, in the broader perspective of the solution of open-ended problems, let us consider the specific request of formulating a conjecture concerning a specific configuration in a DGS. Actually, the term open-ended problem has often been used in the mathematics education literature (see for instance Arsac & Mante, 1983; Silver, 1995) Usually, it refers to a task that asks a question without revealing or suggesting the expected answer. In the specific case when the solver is explicitly requested to formulate a conjecture, we speak of conjecture open problems. This is a very common case in Geometry, when within a specific situation, corresponding to a well-defined geometrical configuration, the solver is asked to make a conjecture that usually assumes the form of a conditional statement between possible properties of

the given configuration. When the solution is sought within a DGS, like Cabri, the solver is expected to explore the configuration dynamically. This means that the solver has to interpret perceptual data coming from observing the screen whilst dragging the figure, and to transform them into a geometrical statement. In other words, the process of exploration is productive if the solver is able to *transform perceptual data into a conditional relationship between geometrical properties*

The seminal work of Arzarello, Olivero and colleagues (Arzarello et al., 1998, 2002; Olivero, 2001, 2002) as well that of other researchers (Hölzl, 1996; Leung & Lopez-Real, 2002 2006; Leung, 2008; Healy 2000), has shown the potentialities of different dragging modalities in supporting the conjecturing process. Starting from their results, I want to discuss the potential offered by a DGS not only in supporting the conjecturing processes but also in mediating the mathematical meaning of *conjecture* and specifically of *conditional statement* in the Geometry context. Specifically, in the frame of the TSM, I will outline the semiotic potential of particular modalities of dragging with respect to the notion of conjecture as a conditional statement. Dragging modalities can be considered as specific artefacts used to solve an open problem, and meanings emerging from this use may be related to the mathematical meanings of conditional statements that express the logical dependency between a *premise* and a *conclusion*.

Exploring in a DGS: invariants by dragging

When dragging is activated on a specific figure obtained by a construction, it provokes a phenomenon usually described as the movement of the figure. Such a movement is perceived because of the contrast between what is changing and what is not changing, because some properties of the figure are maintained by dragging and others are not. The notion of *invariant* by dragging naturally emerges as a property, or a set of properties, that are preserved during a dragging action, but for our discussion, it is useful to look more carefully at this phenomenon.

When a figure is acted upon, the properties stated by the primitives used in the construction are maintained, but it happens that other properties will appear as invariant too, specifically all those properties that are a consequence of the construction properties within the theory of Euclidean Geometry (Laborde & Sträßer, 1990) Take for instance the following configuration:

ABCD is a quadrilateral in which D is chosen on the line parallel to AB through C, and the perpendicular bisectors of AB and CD are constructed.

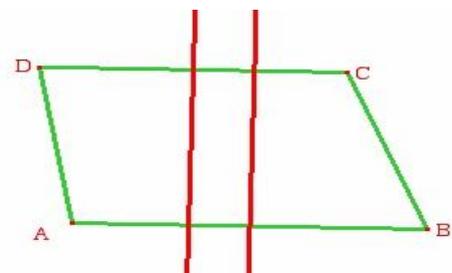

Figure 4: The result of the construction described in the example above.

By dragging the Cabri figure, the constructed properties are preserved - the parallelism between AB and CD, the perpendicularity between the

Plenary lecture

each side and its bisector – but also the parallelism between the two bisectors clearly emerges as invariant. This can lead us to formulate the following conjecture: “if two sides of the quadrilateral are parallel, then the corresponding perpendicular bisectors are parallel.”

Actually, the fact that a specific relationship between invariants is preserved corresponds to the general validity of a logical implication between properties of a geometrical figure. Because of their simultaneity it may be difficult to control the hierarchy induced on the different invariants by the construction. Nevertheless, the asymmetry between the two kinds of invariants has a counterpart in an asymmetry in the movement of different elements of the figure. Actually, only basic points – those from which the construction originates - can be selected and dragged, thus two different types of movement occur that it is worth distinguishing and analysing carefully for our purpose.

Direct motion, that is the variation of an element in the plane under the direct control of the mouse, and *indirect motion*, that is the variation of any other element as a consequence of direct motion.

During a dynamical exploration, the possibility of discriminating between the two movements allows one to ‘feel’ motion dependency. Hence, the solver can distinguish between *direct invariants* and *indirect invariants* and interpret their dynamic relationship in terms of logical consequences between geometrical properties, eventually expressing it as a conditional statement between a premise and a conclusion.

The distinction between direct and indirect movement leads us to reconsider the results coming from previous studies on conjecturing in a DGS, and in particular to reconsider one specific modality of dragging, previously described as *Dummy locus dragging* (or *Lieu muet dragging*) (Arzarello et al. 1998, 2002; Olivero, 2002) This involves acting on the mouse with the intention of maintaining a specific property, i.e. realizing a constrained movement of the original figure *in order* to make a specific property become ‘invariant’. Such a new type of invariant that we can call an ***Indirectly Induced Invariant*** will correspond to a consequence of all the properties given by the construction plus the new hypothesis corresponding to the constrained dragging. In other words, exploring via this modality that we call Maintaining Dragging (MD) (Baccaglioni-Frank, 2010) corresponds to what mathematicians would describe as exploring “under which condition ... a certain property occurs”.

According to the previous analysis using MD to solve a conjecture problem, it is possible to clearly distinguish between the premise and the conclusion of the conditional statement that is the outcome of the exploration as the student can carry it out. The student can directly and intentionally control such a distinction during the exploration: the conclusion will be the property that the solver decides to maintain, the premise will be the property corresponding to the constrained movement.

Plenary lecture

In summary, as far as dragging and conjecturing is concerned there are two main modalities characterized by the intention with which the solver selects and searches different types of invariants:

- free dragging: looking for indirect invariants as consequences of the direct invariants; and
- constrained dragging: looking for possible construction invariants that may cause a specific indirect intentional invariant to happen.

The simultaneity of invariants combined with the control of the different status of each kind of invariant is the counterpart of the logical dependency between a premise, corresponding to the direct invariants, and a conclusion, corresponding to the indirect invariants (induced either intentionally or unintentionally)

Taking the perspective of semiotic mediation, we claim that the different dragging modalities, together with the different types of invariants that originate from their use in solving a conjecture-production task, offer a rich semiotic potential in respect of the notion of conjecture as a conditional statement between a premise and a conclusion. The semiotic potential is recognizable in the following relationships between:

- *direct and indirect invariants and respectively premise and conclusion of a conditional statement; and*
- *the dynamic sensation of dependence between the two types of invariants and the geometrical meaning of logical dependence between premise and conclusion.*

The analysis of process of exploration that can be expected when using the MD has been the focus of a recent study carried out at the upper secondary level (Baccaglioni-Frank, 2010) The experiment consisted of a teaching phase in which students were introduced to the different modalities of dragging and an observation phase in which students were interviewed in pairs during the solution of conjecture open problems.

Results from the study show how different meanings related to the notion of conjecture may emerge. The different kinds of invariant can be characterized by reference to their specific status in the activity of exploration; their specific characteristics make them clearly recognizable by the students and can be used by the teacher to exploit the semiotic potential of dragging and specifically of MD. Such results, and in particular a model of the process of conjecture-generation based on the use of MD, has been presented and discussed in several papers to which I refer for a detailed discussion (Baccaglioni-Frank, 2010, in press; Baccaglioni-Frank & Mariotti, 2009, 2010; Baccaglioni-Frank et al., 2009)

CONCLUSIONS

We started with some considerations about different epistemological approaches to proving and proof, aiming at clarifying their impact on didactical approaches to proof in the classroom. The educational aim was summarized as resolving the potential conflict between the two main functions of proof, i.e. validating within a theory and explaining with respect to interlocutors' conceptions. This means finding a way, a pedagogical/ didactical way, of developing the complex relationship between argumentation, with its goal of convincing, and proof, with its goal of theoretically validating. Finally, it means taking into account the differences between argumentation and proof, and exploiting their deep link rather than ignoring it.

The approaches to proof that were discussed above can be considered consistent with that aim, though the way they were implemented in the classroom present differences; in particular, differences in the choice of context and the way its potential was exploited.

Differences can be referred to specific theoretical frameworks that inspire the design of the scenario of classroom activities. This is for instance the case of the choice of a DGS in the examples given above. In that case the potential of Cabri, as generally acknowledged in current literature, is elaborated via the filter of the TSM and described in terms of semiotic potential giving a clear explanation of the specific links between acting in Cabri and the meanings that may emerge in such use, and the mathematical meanings that may be recognized and may constitute the educational goal of the instructional intervention.

The complexity of the educational aim certainly requires long term interventions, and this requires long term teaching experiments and research projects that are very demanding, both from the point of view of the methodological design and the implementation in the classroom. Nevertheless, further research is needed, and I hope that this contribution will offer a stimulus in this direction.

NOTES

1. An exception is that of mathematical induction, which is explicitly treated, and to which a specific training is devoted. But, very rarely, is mathematical induction presented in comparison to other modalities of proving, which are commonly considered natural and spontaneous ways of reasoning.
2. Following the distinction introduced by Rabardel (1995) we use the term artefact in order to distinguish between the tool itself and the specific way of using that tool in order to accomplish a specific task.
3. According to the semiotic approach developed by other researchers (Radford, 2003; Arzarello, 2006) and inspired by Pierce, we use the term sign consistently with the idea of the indissoluble relationship between signified and signifier, and the idea that meaning originate in the intricate interplay of signs (Bartolini Bussi and Mariotti, 2008); for a thoughtful discussion see also (Sfard, 2000, p. 42 and following)
4. The distinction between personal meanings and mathematical meanings may remind of Brousseau's distinction between knowing (*connaissance*) and knowledge (*savoir*) (1997) Even if they are not in antithesis the two perspectives

Plenary lecture

cannot be reduced one to the other: the former stresses the semiotic dimension of the teaching-learning processes which is in the shadow in the latter.

5. Actually a DGS provides a larger set of tools, including for instance "measure of an angle", "rotation of an angle" and the like. That implies that the whole set of possible constructions do not coincide with that attainable only with ruler and compass, see (Stylianides & Stylianides, 2005) for a full discussion.

Working Groups: Research Papers

INTRODUCTION TO THE PAPERS OF WG01: ARGUMENTATION AND PROOF

Viviane DURAND-GUERRIER, Université Montpellier 2, France

Kirsti HEMMI, Mälardalen University, Sweden

Niels JAHNKE, Universität Duisburg-Essen, Deutschland

Bettina PEDEMONTE, Istituto per le Tecnologie Didattiche - CNR Genova, Italy

This chapter collects the contributions discussed during the working sessions by the thirty-one participants from fourteen countries of the WG1 «Argumentation and proof» at CERME7 in Rzeszow (Poland). Eighteen papers from eleven countries have been presented and discussed. Each presentation was followed by a reaction from a participant presenting the key issues and posing questions to the author(s). The papers are presented under five themes: epistemological and cognitive issues, means for analysing proving activities, transparency, educational implication of views on mathematics, on the relevance of proof on teaching mathematics.. We will conclude this introduction by some challenging perspectives emerging from our discussion.

EPISTEMOLOGICAL AND COGNITIVE ISSUES

Cognitive and meta-cognitive issues were specifically developed in three papers by the Italian participants, in line and deepening the research in this area since 1980.

The paper by Paolo Boero and the one by Ferdinando Arzarello and Cristina Sabena draw explicitly on the integration of the models of Toulmin and Habermas that was presented in CERME 6. Boero presents some tools for analyzing a « successful » classroom discussion at a university course in primary school teacher education, with the aim of developing awareness about the « rules » of argumentation and proof. Arzarello and Sabena consider the construction of “meta-cognitive unity” in order to give reason of success and difficulties in indirect proofs, using Peirce's account of abduction for their description of the cognitive processes involved in indirect proofs. The paper by Anna Baccaglioni-Frank focuses on an elaboration of conjectures in dynamic systems. The author emphasises two different types of abduction associated to two different ways of generating conjectures that arise using a particular modality of dragging in dynamic geometry. The hypothesis of the author is that conjectures suggested by the use of the dragging function will lead to cognitive rupture, while conjectures suggested by mathematical considerations will lead to cognitive unity.

MEANS FOR ANALYSING PROVING ACTIVITIES

An important issue in the research on proof and proving is the possibility to have access to the process in which students are involved when they elaborate a proof. The four papers in this section focus on this aspect, in various manners and with

Working Group 1

different populations. Esther Brunner, Kurt Reusser and Christine Pauli present an analysis instrument developed to describe content-related aspects of the proving process. This instrument has been used to analyse videos concerning a mathematical problem solving session in 32 classes of the 8th or 9th year of the three school types in Germany and Switzerland. The main result of this study is the dominance of formal deductive proof among the classes whatever the type of school, while experimental or generic proof could be relevant for the proposed problem. In his paper, Yosuke Tsujiyama focuses on the role of looking-back at proof-planning processes in students' proving activity, that are not explicit in proof as a product. This is illustrated with an example in geometry with Japanese 8th grade students. Patricia Perry, Óscar Molina, Leonor Camargo, and Carmen Samper analyse the proving activity of a group of three university students solving a geometrical problem in a dynamic geometric system. Solving the problem requires formulation of a conjecture and justification in a theoretical system. For their analyses, the authors refer to the integration of Toulmin's and Habermas' models mentioned above to elaborate components of a successful performance. The activities of the students were video taped and transcribed. Their analyses indicate that students' proving activities are close to the considered components. Julia Cramer develops a methodology combining Toulmin's scheme and a collection of topical schemes, and an epistemic action model in order to shed light on the relations between argumentation and knowledge construction. In her paper she presents some preliminary results obtained from the work of grade 10 German students and grade 11 Israeli students who were submitted three tasks in the frame of a research project on "effective knowledge construction in interest-dense situations". In the presented cases, everyday argumentation was the starting point to develop mathematical conjectures.

TRANSPARENCY

Through the notion of "transparency" the three papers presented in this section show the importance to make more or less invisible for students some important aspects concerning proof.

Kirsti Hemmi and Clas Löfwall present an ongoing research aiming to develop and test some tasks that could enhance students' understanding of the discovery function of proof. The authors consider proof as an essential artefact (i.e. tools that mediate knowledge between the social and the individual) in mathematical practice. The students seemed to catch the idea of the function of discovery, although they did not manage to construct the proof. The paper provides evidence of the interest of exploring these questions in further research. Kirsten Pfeiffer presents a scheme that she has developed to describe and explore students' proof evaluation performance; following Hemmi, she considers proof as an intellectual artefact in mathematical practice. The author uses this scheme for analysing an experiment consisting of interviews with eight first year university students. Students were asked to evaluate

Working Group 1

six different proofs of the same statement in a familiar domain. The results suggest the relevance of this scheme to investigate students' knowledge and skill in proof and proving. In her paper, Bettina Pedemonte explores the development of algebraic proof in a dynamic system (AINuSet). The main hypothesis of the author is that activities in this environment favour the “transparency” of the proof, due to the fact that in this system, the transformation of an expression is not the result of a calculation, but is carried out by explicit algebraic rules and axioms.

EDUCATIONAL IMPLICATION OF VIEWS ON MATHEMATICS

In their paper, Simon Modeste and Cecile Ouvrier-Bufferet consider the opportunity offered by the appearance of algorithms in the curricula in France to study the links between algorithms and proof. They have developed an epistemological analysis and a study of “how researchers know the algorithms” through interviews, taking into account both tool and object aspects. Their results support the relevance of algorithms for studying proof, but the authors point out that little is known about algorithms as objects. The authors intend to use this epistemological model of analysis in further research with students. Joanna Mamona-Downs and Martin Downs discuss in which respect mathematicians as teachers at tertiary level are able to convey the interest of proof. Relying on the difference between a credited argument and a proof, they hypothesise that in certain circumstances the insistence on proof could appear to students as a game for pedants. The examples that are provided concern examples where mathematical modelling takes place. Considering that beauty should take a place in curricula, which is the case in some countries, but not in others, Manya Raman and Lars-Daniel Öhman investigate in what ways mathematical proofs could be perceived as beautiful by working mathematicians and discuss possible educational implications on insight into the nature of beauty in mathematics. Their analysis relies on two proofs of Picks' theorem that gives a simple formula for calculating the area of a lattice polygon. Relying on the work of Etchmendy concerning Hyperproof, and on the legitimacy of visual or diagrammatic proof through possible formalisation in ω -logic, Reinert A. Rinvold and Andreas Lorange investigate the interest of developing multimodal proof, including actions and gestures in mathematics education, with a case study conducted with pairs of teacher training students, involving number patterns represented by visual and physical figures. The authors conclude that this kind of activity has a potential for learning proof. Antti Viholainen examines the effects of the view of mathematics on how the role of argumentation and proof is seen. He considers mainly two opposite views: if mathematics is seen as an axiomatic system, formal argument will be required, while if mathematics is seen as a thinking and learning process, informal arguments play an important role.

ON THE RELEVANCE OF PROOF ON TEACHING MATHEMATICS

In this session papers analyse the role of proof in teaching mathematics Emelie

Working Group 1

Reuterswärd and Kirsti Hemmi report some results from a case study on five Swedish upper secondary school teachers concerning their view on proof, particularly concerning the role and relevance of proof in teaching mathematics. The data consist of interview transcripts and protocols of observation of lessons. Two main different views appear: "proof as something for all students" and "proof as not necessarily for all students". This study was motivated by the appearance in the new Swedish curriculum of a more explicit focus on proof. The results open for the necessity of studying how these reforms are implemented and what effect they have on different student groups. In some countries like Canada, France or Italy, the relevance of teaching proof at secondary school level is well admitted, and the possibility of developing reasoning skills at elementary school is considered. The paper from Stephan Cyr presents the results of an experiment with elementary school students aged 11-12 showing the possibility of developing ability to reason deductively and validate geometric statements by using geometrical properties rather than measurement, which is an important issue for students in order to become aware of the difference between practical and theoretical geometry. Margo Kondratieva takes into account that development of reasoning skills and formation of concepts is a life-long process, considering that at each level of concept development, reasoning behaviour and degree of rigor depends on the level of concept maturity. In her paper, she illustrates the process of designing interconnecting problems on an example from Euclidian geometry, claiming that the course of formalisation of reasoning affects the conceptualisation process related to the object of the problem.

CHALLENGING PERSPECTIVES

During this session, we discussed on challenging perspectives about argumentation and proof. A first issue concerns the use, evolution, elaboration or integration of theoretical constructs introduced at the previous CERME (e.g. cognitive unity; Toulmin's model, transparency background), and discussion of new theoretical frames (e.g. Habermas model for rational behaviour in proving). Closely related are the epistemological and cognitive issues concerning different varieties of indirect proof, and the specificity of proof in accordance with different mathematical fields, in particular according with the prominence or not of axiomatisation, and the effect on the nature of proof of the use of technological environment. Another important issue concerns the cognitive development with three main topics that were discussed during the session and for which further research are needed: the effect on teaching and learning proof, on students' performance in mathematics - the way students really prove and learn to prove - the designing activity fostering argumentation and proof skills along the curriculum from kindergarten to university. We also discussed the logical aspects of proof, the way of taking into account everyday logic competencies in class and of considering the role of semantics aspects and the place for logical matters in the teaching and learning of proof and proving. The implication for teaching is a crucial question addressed to researchers and mathematics educators; it

Working Group 1

appears necessary to share relevant problems for fostering the learning of proof all along the curriculum, and on the way to prepare prospective teachers to teach proof and to work with teachers to implement design relying on research results, taking into account the difference of cultural contexts and curricula in the different countries. This may constitute a program for our next up-coming meeting in CERME8.

META-COGNITIVE UNITY IN INDIRECT PROOFS

Ferdinando Arzarello, Cristina Sabena

Dipartimento di Matematica, Università di Torino, Italia

In this paper we focus on the cognitive aspects of indirect argumentation and proving processes. Drawing on the Habermas model of rational behaviour in three components (epistemic, teleological, and communicative) and on the notion of cognitive unity as developed by Boero and his collaborators, we distinguish between two levels of argumentation, a 'ground level' and a 'meta-level'. On the base of a case study in early Calculus context (secondary school), we introduce the notion of 'meta-cognitive unity', which may give reason of success and difficulties in indirect proving processes. Furthermore, we use Peirce's account of abduction to shed light into some cognitive processes behind the production of indirect proofs.

Key-words: indirect proof, meta-cognitive unity, argumentation processes, diagrammatic reasoning, abduction.

INTRODUCTION AND THEORETICAL FRAMEWORK

Proving is one of the main activities in mathematics, and the investigation on proving processes has been one of the major subjects of research in mathematics education for thirty years at least (Balacheff, 1987; Hanna, 1989; Duval, 1991; Mariotti & Antonini, 2008; Boero, Douek, Morselli, & Pedemonte, 2010).

Many of these studies have focused on the nature of the relationships between conjecturing and proving, and have put forward different perspectives. Some of them point out the differences between argumentation and proving processes (Balacheff, 1987; Duval, 1991). According to others, "in order to bring about a smooth approach to theorems in school, it is necessary to consider the connections between conjecturing and proving, in spite of the undeniable differences between the two processes" (Garuti, Boero, Lemut, & Mariotti, 1996, p. 113). The possibility of a cognitive continuity between the phases of conjecture production and proof construction has been analysed with the notion of *cognitive unity* (*ibid.*). Within this perspective, Pedemonte (2007) has further distinguished between

- "the *referential system*, made up of the representation system (the language, heuristics, and drawings) and the knowledge system (conceptions and theorems) of argumentation and proof (Pedemonte, 2005). The analysis of *cognitive unity* takes into account the referential system.
- the *structure* intended to allow logical cognitive connection between statements (deduction, abduction, and induction structures) (Pedemonte, 2007).

There is continuity in the referential system between argumentation and proof if some expressions, drawings, or theorems used in the proof have been used in the argumentation supporting the conjecture. There is structural continuity between argumentation and proof

Working Group 1

when inferences in argumentation and proof are connected through the same structure (abduction, induction, or deduction).”

(Boero, Douek, Morselli, & Pedemonte, 2010, p. 183, emphasis as in the original).

Recently Boero and his collaborators (Boero, Douek, Morselli, & Pedemonte, 2010) have integrated the cognitive unity analysis with Habermas’ elaboration of *rational behaviour in discursive practices*. Adapting the three components of rational behaviour according to Habermas (teleologic, epistemic, and communicative) to the discursive practice of proving, they have identified:

“A) an **epistemic aspect**, consisting in the conscious validation of statements according to shared premises and legitimate ways of reasoning (cf. the definition of “theorem” by Mariotti & al. (1997) as the system consisting of a statement, a proof, derived according to shared inference rules from axioms and other theorems, and a reference theory);

B) a **teleological aspect**, inherent in the problem-solving character of proving, and the conscious choices to be made in order to obtain the desired product;

C) a **communicative aspect**, consisting in the conscious adhering to rules that ensure both the possibility of communicating steps of reasoning and the conformity of the products (proofs) to standards in a given mathematical culture.”

(*ibid.*, p. 188)

In this model, the expert’s behaviour in proving processes can be described in terms of (more or less) conscious constraints upon the three components of rationality: “constraints of epistemic validity, efficiency related to the goal to achieve, and communication according to shared rules” (*ibid.*, p. 192). As the authors point out, such constraints work at *two levels* of argumentation:

- a level (that we call *ground-level*) inherent in the specific nature of the three components of rational behaviour in proving;
- a *meta-level*, “inherent in the awareness of the constraints on the three components” (*ibid.*, p. 192).

In our research, we focus on the cognitive aspects involved in argumentation and proving processes, and use a Peircean *semiotic lens* to analyse them (see for instance Arzarello & Sabena, in print). Considering the description given by Peirce (Peirce, 1931-1958) of *diagrammatic reasoning* as a three-step process—constructing a representation, experimenting with it, observing the results—we can observe that the three components of Habermas and of Peirce have deep analogies (though not a one-to-one correspondence): the construction of a representation may be guided mainly by a teleological rationality, whereas the experimentation and observation with it assume an epistemic value.

In this paper we present the first results of an ongoing study on particular cases of argumentation and proving processes, i.e. those related to *indirect proofs*, namely proofs by contraposition or proof by contradiction.

Analysing indirect proofs and argumentations both from a mathematical and a cognitive point of view, Antonini and Mariotti (2008) provide a model to interpret students' difficulties. Essentially, the model splits any indirect proof of a sentence S (principal statement) in a pair (s,m) , where s is a direct proof (within a theory T , for example Euclidean Geometry) of a secondary statement S^* and m is a meta-proof (within a meta-theory MT , generally coinciding with classical logic) of the statement $S^* \rightarrow S$. An example given by the authors is the following. Consider the (principal) statement S : 'Let a and b be two real numbers. If $ab = 0$ then $a = 0$ or $b = 0$ '; and the following indirect proof: 'Assume that $ab = 0$, $a \neq 0$, and $b \neq 0$. Since $a \neq 0$ and $b \neq 0$ one can divide both sides of the equality $ab = 0$ by a and by b , obtaining $1 = 0$ '. In this proof, the secondary statement S^* is: 'let a and b be two real numbers; if $ab = 0$, $a \neq 0$, and $b \neq 0$ then $1 = 0$ '. A direct proof is given. The hypothesis of this new statement is the negation of the original statement and the thesis is a false proposition (" $1 = 0$ ").

Through this model, Antonini and Mariotti point out that the main difficulties for students who face indirect proofs consist in switching from s to m . On the contrary the difficulties seem less strong for statements that require a proof by contraposition, that is to prove $\neg B \rightarrow \neg A$ (secondary statement) in order to prove $A \rightarrow B$ (principal statement).

Let us observe that the meta-proof m does not coincide with the meta-level we considered above; rather, it is at the meta-mathematical level (based on logic). Integrating the two models, we can say that switching from s to m requires a well-established epistemic and teleological rationality in the students. To better disentangle this issue, we make the hypothesis regarding the importance of a *meta-cognitive unity* in argumentation and proving processes.

META-COGNITIVE UNITY

The distinction between the ground level and the meta-level drawn from the Boero *et al.* (2010) model may be very useful to investigate the proving processes related to indirect proof. Basing on such a distinction, we introduce the notion of *meta-cognitive unity*, as a *cognitive unity between the two levels of argumentation described above, specifically between the teleological component at the meta-level and the epistemic component at the ground-level.*

Differently from the structural and referential cognitive unity, which focuses on two diachronic moments in the discursive activities of students (namely the argumentation and the proving phases), the meta-cognitive unity refers to a *synchronic integration between ground- and meta- levels of argumentations.*

Our hypothesis is that the existence of such a meta-cognitive unity is an important condition for producing indirect proofs. In other words, a missing integration between the two levels of argumentations can block the students' proving processes, or produce cognitive breaks as those described in the literature on cognitive unity mentioned above. Furthermore, our ongoing data analysis suggests that meta-cognitive unity may entail also some kind of cognitive unity at the ground level (e.g. structural or referential).

We shall illustrate our claims through an emblematic example, in which meta-cognitive unity is accompanied by structural-cognitive unity, and develops through what we call the *logic of not* (see also Arzarello & Sabena, in print).

AN EXAMPLE

To illustrate the meta-cognitive unity and the logic of not, we discuss the case of Simone, related to the following Calculus problem in the graphical register.

The drawing [reported in Fig. 1] shows the graphs of: a function f , its derivative, one of its antiderivatives. Identify the graph of each function, and justify your answer.

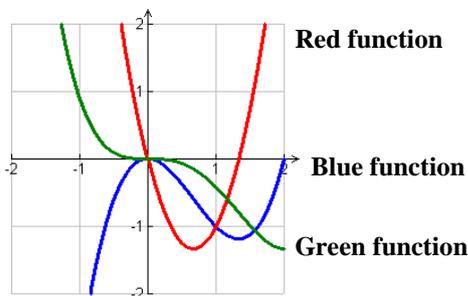

Fig. 1 The graphs of the problem

4) FACENDO UNA FUNZIONE "ROSSA"
 HO CERCATO TRA LE ALTRE CHE
 UNA SUA POSSIBILE PRIMITIVA;
 HO NOTATO CHE NEGLI ASCISSE $x=0$ LA FUNZIONE
 "ROSSA" TOCCA IL PIANO DELLE ASCISSE, QUINDI HA ORDINATA
 0, E PERCIÒ UNA SUA PRIMITIVA DOVREBBE AVERE IN $x=0$
 PENDENZA NULLA, MA SIA LA FUNZIONE "VERDE" SIA QUELLA "BLU"
 HANNO PENDENZA $\neq 0$, QUINDI HO VISTO CHE LA FUNZIONE
 ROSSA HA UN PUNTO DI MINIMA, QUINDI HO CERCATO TRA LE
 ALTRE DUE FUNZIONI QUELLA CHE PRESENTAVA UN PUNTO DI TANGENTE
 E C'È SOLO LA FUNZIONE "BLU" CHE L'HA; PER
 ACCENTRARMI HO VISTO CHE QUANDO LA FUNZIONE
 "ROSSA" TORNA A TOCCARE IL PIANO DELLE ASCISSE SOLO
 LA FUNZIONE "BLU" HA $p=0$ PER CUI LA FUNZIONE "ROSSA" È UNA
 DERIVATA DELLA FUNZIONE "BLU". ADDESSO HO CONFRONTATO LA
 FUNZIONE "ROSSA" CON QUELLA "VERDE": MA, LA FUNZIONE "VERDE"
 NON PUÒ ESSERE UNA DERIVATA DI QUELLA "ROSSA", PERCHÉ
 NELLA PRIMA PARTE, DOVE LA FUNZIONE "ROSSA" DECRESCe, UNA
 SUA DERIVATA DOVREBBE AVERE SEGNO NEGATIVO, MA LA FUNZIONE
 "VERDE" HA SEGNO POSITIVO, PERCIÒ LA FUNZIONE "ROSSA" È
 SICURAMENTE $f'(x)$ E DI CONSEGUENZA LA SUA PRIMITIVA (E
 QUELLA "BLU") È $f(x)$ E LA FUNZIONE "VERDE" È LA PRIMITIVA
 DI $f(x)$, QUINDI $F(x)$.

Fig. 2 Simone's protocol

The problem was given to grade 9 students in a scientifically oriented school (5 hours of mathematics per week). It worked as an assessment task at the end of a teaching sequence on the relationships between a function graph and the graphs of its derivative and of one of its primitives (introduced as 'antiderivatives', i.e. the function graphs whose derivative is the given graph). Though it may appear of simple combinatorial nature, the task indeed shows to be difficult for the students, who by "didactic contract" are asked to provide articulated arguments for their answers. A main source of difficulty consists in involving both direct and inverse problems mixed together. The antiderivative function has in fact been introduced as the inverse of the derivative function.

Working Group 1

Simone solves the problem correctly, as we can see from his written production (shown in Fig. 2, and translated below). In doing so, he is able to develop a strategy that may be compared to the one of a chemist, who in the laboratory has to detect the nature of some substance. He knows that the substance must be of three different categories (a, b, c) and uses suitable reagents to accomplish his task. For example, he knows that if a substance reacts in a certain way to a certain reagent, it may be of type a or b but *not* c, and so on. This kind of strategy may be referred to the notion of *abduction* (for a discussion of abduction in mathematics education, see for instance Arzarello et al., 1998; and Hoffmann, 2005). According to Peirce (1931-1958, 2.623) abduction is a form of reasoning in which a *Case* is drawn from a *Rule* and a *Result*. It is well known his example about beans:

Rule: All the beans from this bag are white
Result: These beans are white
Case: These beans are from this bag

As such, abduction is different from deduction, which would have the form: the Result is drawn from the Rule and the Case; and it is obviously different from an induction, which has the form: a Rule is drawn from a Case and many Results. Of course the conclusion of an abduction holds only with a certain probability; in fact Polya (1954) calls *heuristic syllogism* this form of reasoning. In our example of the chemist: if, as a *Rule*, the substance S makes blue the reagent r and if the *Result* of the experiment shows that the unknown substance X makes blue the reagent r, the *Case* of the abduction is that $X=S$.

Let us see how Simone develops abductive arguments in order to solve the task. We report the translation in English of the protocol shown in Fig. 2, parcelled and numbered for the sake of analysis:

- 0: Starting from the “red” function
- 1: I looked for a possible primitive among the other two:
- 2: I noticed that in the point $x = 0$ the “red” function touches the plane of abscissas, so it has ordinate = 0;
- 3: and therefore any of its primitives should have in $x = 0$ null slope,
- 4: but both the “green” function and the “blue” function have slope = 0;
- 5: so I saw that the red function has a point of minimum,
- 6: and I looked among the other two functions for the one with a point of inflection
- 7: and only the “blue” function has it;
- 8: to check [this] I saw that
- 9: when the “red” function comes to touch the plane of abscissas again,
- 10: only the “blue” function has $s[\text{slope}]=0$,

Working Group 1

11: therefore the “red” function is a derivative of the “blue” function.

Simone first describes two phases of his inquiry (Part A: lines 1-4; Part B: lines 5-8). In both parts he develops what we could call an abductive attitude, namely how he has been looking for Results that allow him to state a Case because of a Rule. More precisely, Simone starts with $f = \text{red function}$ (line 0), probably because it is the simplest graph, and wonders whether he can apply an abductive argument to the blue or to the green function. In both Parts the Rule is: “any primitive of f has property Q ”; the Result is: “a specific function h has property Q ”; the Case is “ h is a primitive of f ”.

In Part A, the Rule is in line 3, the Result is in lines 2 and 4, while the Case is contained implicitly in line 5, which states that the first inquiry has not been successful and starts a new inquiry. In Part B we have a new abductive process with a new Rule (implicitly contained in lines 5 and 6), a new Result (line 7), a judgment about the validity of the abduction (line 7) and a Case, which is not made explicit, but is implicitly stated in line 7.

Afterwards Simone checks his hypothesis (Part C: lines 8-11): he is successful with a fresh abductive argument. Recalling the metaphor with the chemist experiment, Simone has been able first to find a reagent that discriminates between the substances he is analysing, and then to confirm his hypothesis with a further discriminating experiment; that is, within the abductive frame, he has been able first to produce an hypothesis through an abduction and then to corroborate the hypothesis through a further abduction. The experiments of the chemists are here the practices with the graphs of functions. Such practices with graphs are examples of diagrammatic reasoning, according to the definition of Peirce: “by experimenting upon the diagram and observing the results thereof, it is possible to discover unnoticed and hidden relations among the parts” (Peirce, 1931-58, 3.363: quoted in Hoffmann, 2005, p. 48). Hence in Parts A-B-C Simone has produced and checked the Case of line 11.

Using Habermas model, some of Simone’s sentences can be considered *teleological* and at the *meta-level*, since they address the successive actions of Simone and his control of what is happening. On the other hand, other sentences show an *epistemic* character at *ground-level*, since they regard the specific mathematical notions and representations involved in the task. Coding the sentences of the protocol as $a \Rightarrow b$ to indicate that the sentence a is at the meta-level and controls the sentence b at the ground-level, it appears that the teleological component at the meta-level *intertwines* with the epistemic component at the ground level:

0, 1, 3 \Rightarrow 2, 4, 5

6, 8 \Rightarrow 7, 9, 10, 11

Working Group 1

We interpret such intertwining as an index of *meta-cognitive unity* in Simone's argumentation process. Besides, the presence of a meta-cognitive unity is signalled by the fact that the epistemic sentences can be understood only at the light of the teleological ones guiding them, and vice-versa. Even more than this: the sentences at the ground level have an epistemic component, e.g. they are logically linked each other, *because* of the influence of those at the meta-level. Let now see how this complex form of cognitive unity allows Simone to manage the problem using an argument by contraposition. It is the form of reasoning that logicians call "modus tollens" (from "A implies B" to "not B implies not A"). We have called such a process "the logic of not" (see also Arzarello & Sabena, in print). Let us explain it through what is written in Part D (lines 12-15):

12: Then I compared the "red" with the "green" function:

13: but, the "green" function cannot be a derivative of the "red" one,

14. a: because in the first part,

b: when the "red" function is decreasing,

c: its derivative should have a negative sign,

15: but the "green" function has a positive sign.

Here the structure of the sentence is more complex than before: Simone is thinking to a possible abductive argument, like the ones used before:

- (a) Rule: "any derivative of a decreasing function is negative" (lines 14)
 - (b) Result: "the function h is negative";
 - (c) Case: "the function h is the derivative of f"
- } (ARG. 1)

But the argument is a refutation of this virtual abduction (line 13); namely it has the form of the following syllogism:

- (a) Major premise:
"any derivative of a decreasing function is negative" (lines 14)
 - (b') Minor premise: "the "green" function has a positive sign" (line 15)
 - (c') Consequence: "the "green" function cannot be a derivative of
an increasing function" (line 13).
- } (ARG. 2)

In terms of the structure of the virtual abduction ARG 1, it has the form: *(a) and not (b); hence not (c)*. It is crucial here to observe that also the refutation of the usual Deduction (Rule, Case; hence Result) has the same structure, because of the contrapositive of an implication ("A implies B" is equivalent to "not B implies not A"); namely: *(a) and not (b); hence not (c)* is the same as *(a') and (b'); hence (c')*. In other words, the refutation of a virtual argument drawn through an abduction coincides with the refutation of a virtual argument drawn through a deduction. Simone produces in a very natural way this form of deductive argument within an

Working Group 1

abductive modality. This is remarkable from an epistemological point of view: whereas the abductive approach appears very natural for students in conjecturing phases (Arzarello et al., 1998), there is often a cognitive break with the deductive approach of the proving phase (Pedemonte, 2007 analyses it in terms of “structural discontinuity”). In fact, the transition from an abductive to a deductive modality requires a sort of “somersault”, namely an inversion in the way things are seen and structured in the argument (the Case- and the Result-functions in the argument are exchanged). Such an inversion is not present in case of refutation of an abduction, insofar it coincides with the refutation of a deduction (expressed in a syllogistic form). Of course a greater cognitive load is required to manage the refutation of an abduction compared with that required to develop a simple direct abduction. But the coincidence between abduction and deduction in case they are refuted allows avoiding the somersault. In our case study, Simone has been able to lighten the cognitive load of the task through a transition to a new epistemological status of his statements.

Moreover, Simone is doing mental experiments with the graphs and observing their results. The ground level at which Simone epistemic arguments are drawn is very concrete; possibly this makes it possible for him to develop at the meta-level the teleological arguments we have underlined above, which support him in producing a correct proof by contraposition. Lines 16-18 below show the conclusion of Simone’s argument:

16: Therefore the “red” function is surely $f'(x)$

17: and consequently its primitive (the blue one) is $f(x)$

18: and the “green” function is the primitive of $f(x)$, thus $F(x)$.

We shall now consider an example from the literature, in which the indirect argumentation process does not lead to a correct proof by contraposition. The example shows a typical difficulty, in which the students do not realise any meta-cognitive unity and shift from the problems they should solve to another problem, which allows them to skip the difficulties of the indirect proof. It is taken from Antonini & Mariotti (2008). A well known problem is considered in pencil and paper environment: “*Can two bisectors in a triangle form an angle of 90° ?*”. The students “formulate the conjecture that the angle...cannot be a right angle...*The argumentation produced can be summarized as follows: if the angle is right then the sum of two angles of the triangles is 180° , then the triangle becomes a quadrilateral.* After this argumentation, no proofs are generated by the students” (*ibid.*, p. 410). As stated in the paper, the shift to the quadrilateral can be considered an antidote to an “absurd world”: “the theory is changed according to the validity of the theorems he [the student] knows” (*ibid.*).

Here are the excerpts of the interview taken from that paper:

Working Group 1

61 P: As far as 90° , it would be necessary that both K and H are 90° , then $K/2 = 45$, $H/2 = 45 \dots 180^\circ - 90^\circ$ and 90° .

62 I: In fact, it is sufficient that the sum is 90° , that $K/2 + H/2$ is 90° .

63 R: Yes, but it cannot be.

64 P: Yes, but it would mean that $K + H$ is ... a square [...]

65 R: It surely should be a square, or a parallelogram

66 P: $(K - H)/2$ would mean that [...] $K + H$ is $180^\circ \dots$

67 R: It would be impossible. Exactly, I would have with these two angles already 180° , that surely it is not a triangle. [...]

71 R: We can exclude that [the angle] is $\square/2$ [right] because it would become a quadrilateral.

The excerpts show that no teleological aspects are present in the students at the meta-level: on the contrary they are completely embedded in the situation at the ground (epistemic) level and their geometrical knowledge pushes them to shift from a triangle to a quadrilateral (# 64, 67, 71).

DISCUSSION

We presented an illustrative example of how a *meta-cognitive unity* (i.e. a unity between a teleological control at meta-level and an epistemic knowledge at ground level) may contribute to the production of indirect arguments and proofs.

In the example, the graphical component is the core of the tasks, and it allows the student a visual approach to the problem, what in Peirce's words can be called 'diagrammatic reasoning'. This "concrete" component possibly lightens the cognitive load of the task, and facilitates the integration between the two levels to produce a meta-cognitive unity. Referring to the protocol, we see that the student is able to reduce the different cases to simple pass/not-pass 'experiments', like a chemist who checks the nature of an unknown substance, and we interpret his ability as an outcome of his meta-cognitive unity, which integrates the teleological meta-level control and the ground-level knowledge. As a consequence, the situation becomes a 'heuristic device' similar to cognitive mechanisms used naturally in everyday life, as pointed out by Freudenthal (1973, p. 629). The meta-cognitive unity construct brings about a unitary analysis of many students' difficulties as pointed out in the literature. We have also given a short example in which the absence of a teleological rationality at meta-level prevents the students from correctly carry out an indirect proof.

As far as concerns didactic consequences, our approach suggests a possible way for teaching indirect proofs, namely in making explicit the teleological dimension that can be developed in any reasoning made by the students. In particular it should be important to cultivate the idea of the rationality of impossible worlds related to the indirect arguments discussing with the students the intertwining between the

Working Group 1

teleological control and the epistemic knowledge starting from concrete examples produced by the same students. In a sense this was already suggested by Freudenthal, who wrote: “If the teacher would tell the student what is an indirect proof, he is advised not to contrive examples but to catch a student performing an indirect proof and let him understand consciously what he did unconsciously” (*ibid.*).

In fact in the teaching of both indirect and direct proofs, generally there is more attention to the communicative and possibly to the epistemic component, while the teleological one is not made explicit. This can start a sort of comedy of errors with students, who think that the communicative component is the more relevant and produce what Harel (2007) calls ‘ritual schemes’, which are not useful for understanding and possibly produce proofs, especially indirect ones.

ABDUCTION IN GENERATING CONJECTURES IN DYNAMIC GEOMETRY THROUGH *MAINTAINING DRAGGING*

Anna Baccaglini-Frank

University of Siena (Italy)

This paper introduces two types of abduction associated to two different ways of generating conjectures that arise from using a particular dragging modality in dynamic geometry. We refer to such dragging modality as maintaining dragging (MD). A first use of MD relies on physical dragging-support and it seems to lead the solver “automatically” to the formulation of a conjecture. In this case the abductive reasoning seems to occur at a meta-level and to be concealed within the MD-instrument. On the other hand, some of our data shed light onto a different way of generating conjectures which is rooted in use of MD but is “freed” from the physical dragging-support. In this case abductive reasoning seems to occur at the level of the dynamic exploration.

Key words: abduction, conjecture-generation, dragging, dynamic geometry, instrument, instrumented abduction, maintaining dragging (MD), psychological tool

INTRODUCTION

This paper reports on some findings of a study on conjecture-generation in a dynamic geometry system (DGS). The study¹ blossomed from results of Italian research that provided a classification of various dragging modalities used by solvers during explorations of open problem activities (Arzarello, Olivero, Paola, Robutti, 2002). This classification describes different ways of dragging points on the screen as a conjecture is elaborated and tested, and the solver’s control shifts from “ascending” to “descending” (Arzarello et al., 1998). Such transition was described as occurring in correspondence to use of *dummy locus dragging*, that is moving a base-point so that the drawing *keeps* a discovered property, and as being promoted by abduction. Our study aimed at unravelling the relationship between abduction and the use of particular dragging modalities.

Since according to the literature (Olivero, 2002), spontaneous use of dummy locus dragging does not seem to occur frequently, first, we explicitly introduced the participants of the study to four dragging modalities, elaborated from Arzarello et al.’s classification, during two in-class lessons. The modality elaborated from *dummy locus dragging* that we introduced is what we refer to as *maintaining dragging* (MD), and it consists in dragging a base-point of the dynamic figure on the screen trying to maintain some geometrical property of the figure. In other words, performing MD consists in identifying a property that the figure can have and in trying to induce such property as a *soft*³ *invariant* during dragging.

Working Group 1

In order to unravel the relationship between abduction and the use of MD during a process of conjecture-generation, we constructed a model (Baccaglini-Frank, 2010; Baccaglini-Frank & Mariotti, 2010) that provides a cognitive description of the process, as a sequence of (implicit) tasks that the solver seems to address. During the study we tested, refined, and tested again the model, which was used as a tool of analysis in the final round of data analysis. We proceeded through two rounds of 90-minute clinical interviews² with pairs of students, each round with different students who had participated to the introductory lessons on dragging. Data was collected in the form of screenshots with audio, video recording, students' Cabri files and work on paper, transcriptions and subtitled videos. The students (a total of 31), between the ages of 15 and 18, were from three Italian high schools and had been using Cabri in the classroom for at least one year prior to their interviews.

A few theoretical background notions

The study made use of the notions of *abduction* and *instrument* as follows.

Abduction. Peirce was the first to introduce the notion of abduction as follows:

...abduction looks at facts and looks for a theory to explain them, but it can only say a “might be”, because it has a probabilistic nature. The general form of an abduction is: a fact A is observed; if C was true, then A would certainly be true; so, it is reasonable to assume C is true (Peirce, 1960, p. 372).

Recently, there has been renewed interest in the concept of abduction, with a number of studies focused on its various uses in mathematics education (see for example Baccaglini-Frank, 2010, chapter 2). For this paper we will refer to the definition introduced above and to Magnani's description of abduction as an *explanatory hypothesis* (2001, pp. 17-18).

Instrument. The study considers “dragging” in a DGS after the instrumentation approach (Vérillon & Rabardel, 1995; Rabardel & Samurçay, 2001; Rabardel, 2002), as has been done fruitfully by other researchers (for example, Lopez-Real & Leung, 2006; Leung, 2008; Strässer, 2009). A particular way of dragging, in our case MD, may be considered an *artifact* that can be used to solve a particular *task* (in our case that of formulating a conjecture). When the user has developed particular *utilization schemes* for the artifact, we say that it has become an *instrument* for the user. We will call the utilization schemes developed by the user in relation to particular ways of dragging, “dragging schemes”. In this sense the model we developed can be interpreted as the description of a utilization scheme for MD, with respect to the task of generating a conjecture. From now on we will refer to our model as the *MD-conjecturing model*.

INSTRUMENTED ABDUCTION

The successive analyses of our data led to the development of a new notion, that of *instrumented abduction*, through which we describe the place and role of abduction

Working Group 1

in the process of conjecture-generation we have studied (Baccaglini-Frank & Mariotti, 2010; Baccaglini-Frank, 2010). We introduce this notion by providing excerpts of two solvers' exploration that constitute a paradigmatic example of how MD can be used in the process of conjecture-generation and how the MD-conjecturing model can be used as a tool of analysis.

James and Simon were given the following open-problem activity:

Construct three points A , B , and C on the screen, the line through A and B , and the line through A and C . Then construct the parallel line l to AB through C , and the perpendicular line to l through B . Call the point of intersection of these last two lines D . Consider the quadrilateral $ABCD$. Make conjectures on the kinds of quadrilaterals can it become, trying to describe all the ways it can become a particular kind of quadrilateral.

The solvers followed the steps that led to the construction of $ABCD$ (Fig. 1) and soon noticed that it could become a rectangle. Simon was holding the mouse (this is shown in the excerpts below by his name being in bold letters), and followed James' suggestion to use MD to "see what happens" when trying to maintain the property $ABCD$ *rectangle* while dragging the base-point A . The solvers have accomplished Task 1 of our model (Baccaglini-Frank & Mariotti, 2010): determining a configuration to be explored by inducing it as a (soft) invariant. In such situation we refer to the selected property

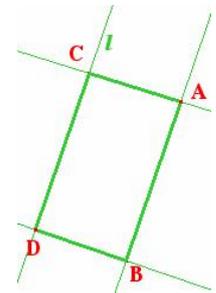

Figure 1

$ABCD$ *rectangle*, as *intentionally induced invariant*. As Simon was focused on performing MD, James' attention seemed to shift to the movement of the dragged-base-point, and he proposed to "do trace" in order to "see if ...[A moves along a "pretty precise curve"]." James seemed to be looking for something that A can be dragged along in order for $ABCD$ to remain a rectangle, thus addressing Task 2 of our model (searching for a condition, through MD, that makes the intentionally induced invariant be visually verified, and recognizing a condition in the movement of dragged-base-point along a *path*). This intention seems to indicate that James has conceived an object along which dragging the base point A will guarantee that the intentionally induced invariant is visually verified. This is what we call a *path*. In order to "understand" what such path might be he suggests activating the trace on A as Simon performs MD (Fig. 2).

Excerpt 1

- | | | |
|----|---------------|---|
| 1 | I: | and you, James what are you looking at? |
| 2 | James: | That it seems to be a circle... |
| 3 | Simon: | I'm not sure if it is a circle... |
| 4 | James: | It's an arc of a circle, I think the curvature suggests that. (...)... |
| 10 | James: | Ok, do half and then more or less you understand it, where it goes through. |
| 11 | Simon: | But C is staying there, so it could be that BC is...is |

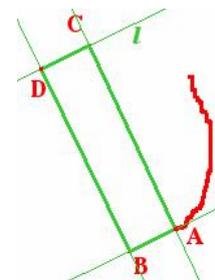

Figure 2

Working Group 1

12 James: right! because considering BC a diameter of a circle...

[They construct the circle and drag A along it, and then they write the conjecture: “ $ABCD$ is a rectangle when A is on the circle with diameter BC .”]

In this Excerpt there seems to be the intention of looking for something that leads the solvers to a *geometric description of the path* as “a circle” ([2], [4]) “considering BC a diameter” ([12]). Recognizing and describing the path can lead to a second invariant, that we call the *invariant observed during dragging*, as a regular movement of the dragged-base-point along such path (in this case “ A on the circle with diameter BC ”). Both invariants are perceived within the phenomenological domain of the DGS, where a relationship of “causality” may also be perceived between them. Of course such relationship can be formulated within the domain of Euclidean Geometry as a *conditional link* between geometrical properties corresponding to the invariants, provided that the solver gives an appropriate geometrical interpretation. This can be expressed through a conjecture and checked (Task 3: checking the conditional link between the invariants and verifying it through the dragging test).

Solvers like Simon and James who use MD effectively for generating a conjecture seem to withhold the key for making sense of their findings. This consists in conceiving, within the phenomenology of the DGS, the invariant observed during dragging as a “cause” of the intentionally induced invariant, and then, within the domain of Euclidean geometry, in interpreting such cause as a geometrical “condition” for the intentionally induced invariant, a geometrical property of the figure, to be verified. In other words, the solvers establish a causal relationship between the two invariants generating – as Magnani says (2001) – an *explanatory hypothesis* for the observed phenomenon.

From the data analyzed another characteristic of behaviors like that of Simon and James is the use of MD in an “automatic” way. That is, the solver proceeds through steps that lead *smoothly* to the discovery of invariants and consequently to the generation of a conjecture, with *no apparent abductive ruptures* in the process. So where is abduction when conjecture-generation occurs as described by the MD-conjecturing model? Abduction can be recognized in the expert’s *interpretation of the invariant observed during dragging as a cause for the intentionally induced invariant to be visually verified*. Thus, automatic use of MD does not seem to produce explicit abductive arguments during the exploration leading to a conjecture; instead it seems to *condense and subsume* the abductive process. We introduce the new notion of *instrumented abduction* to refer to an abductive inference *supported* by an instrument, like in this case. Here the instrument is the combination of MD (artifact) with the MD scheme (utilization scheme) described in the MD-conjecturing model.

USE OF MAINTAINING DRAGGING AS A PSYCHOLOGICAL TOOL

Our study was primarily aimed at developing and subsequently testing the MD-conjecturing model. Our final data analyses seemed to confirm the model, however one case opened a window onto a fundamentally different way of generating a conjecture that seems to have roots in use of MD even though no dragging is actually performed. Below we summarize the exploration in which we found such evidence and present an excerpt from it. The solvers, Francesco and Gianni, were given the following task:

Draw a point P and a line r through P . Construct the perpendicular line l to r through P , construct a point C on it, and construct the circle with center in C and radius CP . Construct the symmetric point of C with respect to P and call it A . Draw a point D on the semi-plane defined by r that contains A , and construct the line through D and P . Let B be the second intersection with the circle and the line through P and D . Consider the quadrilateral $ABCD$. Make conjectures on the kinds of quadrilaterals can it become, trying to describe all the ways it can become a particular kind of quadrilateral.

Francesco and Gianni had effectively used MD to generate conjectures in previous explorations. In this particular exploration they had noticed the potential property $ABCD$ *parallelogram*. Thus Francesco had chosen a base-point to drag while trying to maintain such property. However Francesco and Gianni seemed to conceive a geometric description of the path that did not coincide with their interpretation of the trace mark left on the screen as Francesco performed MD. This led the solvers to reject the original description and search for a new condition for maintaining $ABCD$ *parallelogram*. The solvers were not able to reach such condition using MD and they interrupted all forms of dragging. After a moment of silence Gianni started speaking about constructing a circle to drag along, as shown in the following excerpt.

Excerpt 2

- 1 Gianni: eh, since this is a chord, it's a to, it means equal chord my opinion because I a circle with
- 2 Francesco: A, you say...
- 3 Gianni: symmetric with respect to this make it with one, you have to center A .
- 4 Francesco: uh huh
- 5 Gianni: Do it!
- 6 Francesco: with center A and radius AP ?

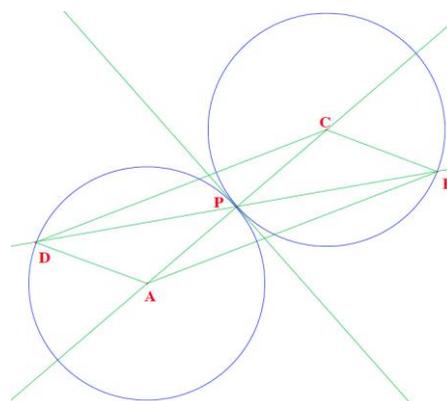

Figure 3

Working Group 1

7 Gianni: with center A and radius AP . I, I think...

Gianni appears to be trying to solve the problem of finding a way to drag D in order to maintain the property $ABCD$ *parallelogram* as if he had to perform MD. However the solvers' inability to perform MD successfully, led to the argumentation above in which the following abductive inference (in Pierce's terms) is evident:

- fact: $DP=PB$ (recognized as chords [1])
- rule: given symmetric circles with DP and PB symmetric chords ([1], [3]), then $DP=PB$ (as observed)
- abductive hypothesis: there exists a symmetric circle with center in A and radius AP ([3]-[7]).

Without further hesitation the solvers formulate their conjecture (Fig.3): " D belongs to the circle centered in A with radius AP implies $ABCD$ parallelogram." We highlight how Gianni applies a way of reasoning, that has roots in his knowledge of the MD scheme, to a substantially different situation. Gianni is trying to find a condition for $ABCD$ to be a parallelogram, but instead of focusing on the movement of a *point* (D) as would have occurred during use of MD, Gianni notices *chords* (BP and PD , which he interprets as a chord) and visualizes their symmetric behavior, which leads him to produce an *explicit* abductive argument. In particular now the "rule" *appears*, while in the case of instrumented abduction such rule would have remained implicit in the movement of the dragged base-point and/or the trace mark on the screen.

Taking a Vygotskian perspective (Vygotsky, 1978, p. 52 ff.), the process that was external, supported by the MD-instrument in the case of instrumented abduction, now can be seen as "transformed" into an *internal* process. We can say that the MD-instrument has been *internalized* and it can now be used as a *psychological tool* (Kozulin, 1998) to solve a conjecture-generation problem. Moreover, now we can underline how the intention of searching for a cause that solvers who have appropriated the MD scheme exhibit, resides at a different level, a meta-level (Gollwitzer & Schaal, 1998), with respect to each specific investigation the solvers engage in. Thus, instrumented abduction resides at such meta-level, while the abductive inference in the second case resides at the level of the dynamic exploration.

A HYPOTHESIS ON PROOF

If we consider conjectures generated in the two different ways described above, the differences between them are not in the *product* of the dynamic exploration, the statement of the conjecture, but in the elements that emerge during the *process* of the exploration. When MD is used "automatically" as in the conjecture-generation process characterized by instrumented abduction, the premise and the conclusion of the statement of the final conjecture seem to be "distant". That is, these conjectures seem to exhibit a "gap" between the premise and the conclusion, because no bridging

Working Group 1

arguments tend to emerge from the exploration. On the other hand, it seems that when MD is internalized and used as a psychological tool, the produced conjectures are accompanied by arguments that can be used to bridge the premise and the conclusion. To support this hypothesis, we now provide an excerpt (Excerpt 3) containing an oral proof produced by Francesco and Gianni after having reached their conjecture (Excerpt 2).

Excerpt 3

Francesco: ah, no! but wait! we know a lot of things here, excuse me, if DA is equal to AP which is equal to PC which is equal to CB , DAP and PCB are isosceles.

Gianni: yes... And so the angles, right!

Francesco: Wait, and so this [pointing to the angle ADP]...

Gianni: the angles over there and down there are..

Francesco: so, let's say ADP is equal to APD , which is equal to

Gianni: we know that these, these are also opposite at the vertex and so they are *all* equal those angles there. (...)

Francesco: but, excuse me, if this... if the angles at the base, are equal, also, obviously, the angle at the vertex, uhm, the angle DAP is equal to PCB necessarily because of the sum of angles.

Gianni: Yes, right.

Francesco: Because it is 180° minus equal angles

Gianni: okay, so this way we understood that the two triangles are equal.

Francesco: Exactly.

Gianni: And so also PD and PB are equal.

Francesco: Okay, so the diagonals divide each other in their midpoints, and therefore $ABCD$ is a parallelogram.

Gianni: Yes, right. [Smiling]

In the analysis of the Excerpt 2 we described how Gianni focuses on the two segments PB and PD , and interprets them as chords of symmetric circles. This constitutes the key idea (Raman, 2003) in their oral proof summarized as follows:

- the circles are symmetric so AD is congruent to AP which is congruent to PD and to therefore to BC ;
- the isosceles triangles APD and PBC are congruent because they have congruent angles, since the angle DPA is opposite at its vertex to CPB ;
- therefore PD is congruent to PB ,
- so $ABCD$ has diagonals that intersect at their midpoints and therefore it is a parallelogram.

Working Group 1

The geometrical properties that emerged during the production of the conjecture, now become fundamental ingredients of the solvers' proof. In other words, these geometrical properties seem to help bridge the gap between premise and conclusion of the conjecture. At this point, if we consider conjectures as both the *product* (the statement of the conjecture) and the *process* (the exploration leading to the statement of the conjecture), we can characterize conjectures as those *with a gap* that emerge through automatic use of MD as opposed to those *with bridging elements* that emerge as a product of an internalization of MD. This characterization helps express our hypothesis as follows.

Hypothesis on proof. Automatic use of MD seems to generate conjectures with a gap, while use of MD as a psychological tool seems to generate conjectures with bridging elements. Therefore use of MD as a psychological tool may foster the solver's construction of a proof of the statement of his/her conjecture.

CONCLUDING REMARKS

Through our study we were able to identify two distinct forms of abductive reasoning related to two different ways of generating conjectures that arise from using a particular dragging modality in dynamic geometry. When MD is used automatically through physical dragging, the abductive reasoning seems to reside at a meta-level with respect to the dynamic exploration. This idea is condensed in the notion of instrumented abduction that we introduced. On the other hand, when MD seems to be "freed" from the physical support, and internalized, the abduction seems to occur at the level of the exploration. In this case the conjecture-generation process seems to have the advantage of involving arguments that can be reinvested in a successive proof, like in the case of Francesco and Gianni.

We hypothesize that conjectures generated "automatically" through physical use of MD, that is *conjectures with a gap*, will present *cognitive rupture* with respect to a potential proof since the solver will have no arguments emerging from the conjecturing-process to base his/her proof upon. This seems to be the case because the process of conjecture-generation is supported by the DGS and mostly concealed within it, as is the abductive inference that we refer to as *instrumented abduction*. On the other hand, we hypothesize that if solvers who have appropriated the MD-instrument *also internalize it* transforming it into a psychological tool, or a fruitful "mathematical habit of mind" (Cuoco, 2008) that may be exploited in various mathematical explorations leading to the generation of conjectures, a greater cognitive unity (Pedemonte, 2007) might be fostered. In other words, it may be the case that when the MD-instrument is used as a psychological tool the conjecturing phase is characterized by the emergence of arguments that the solver can set in chain in a deductive way when constructing a proof (Boero et al., 1996). In particular we think this may occur if, as in the case of Francesco and Gianni, abduction in which the rules are taken from the domain of the Theory of Euclidean Geometry is used

Working Group 1

during the process of conjecture-generation. An abduction of this sort seems to expose key ideas that can be reinvested in the proof.

The relatively small amount of data analyzed in our study does not allow us to make general statements about the hypothesis on proof we illustrated above. Moreover our study was not focused on investigating internalization of the MD-instrument and its transformation into a psychological tool: the case of Gianni and Francesco was an unexpected isolated instance that suggested new potential insight into how a DGS can be used (or not) in the context of argumentation and proof, opening an alley for future research. For example, as some colleagues have suggested, it would be interesting to investigate *what it takes*, both from learning and teaching perspectives, for the solver to make the cognitive shift we describe, transforming the MD-instrument into a psychological tool.

NOTES

1. Research study partly funded by PRIN 2007B2M4EK (Instruments and representations in the teaching and learning of mathematics: theory and practice).
2. The activities proposed were open-ended tasks. The interviewer would typically ask the solver to explain an action, to describe what s/he was looking at or trying to accomplish, or to provide clarification or elaboration of a statement s/he made.
3. We use the terminology “soft” and “robust” as introduced by Healy (2000).

ARGUMENTATION AND PROOF: DISCUSSING A "SUCCESSFUL" CLASSROOM DISCUSSION

Paolo Boero

Dipartimento di Matematica, Università di Genova

This paper concerns a discussion in a university course of primary school teacher education. The discussion was aimed at developing awareness about the condition of "equally likely possible cases" in the classical definition of probability. During the discussion students engaged several times in reflections about validity of statements, validity of inferences, etc. The aim of this paper is to present some tools to analyze the discussion and hypothesize possible follow-ups, related to the performed analysis and the aim of developing awareness about the "rules" of argumentation and proof.

Keywords: argumentation; mathematical proof; rationality; meta-mathematics

INTRODUCTION

The development of students' awareness about the "rules" of argumentation and proof in mathematics is one of the main challenges for mathematics education. This statement expresses a conviction largely shared among mathematics educators in the last three decades, in spite of different positions concerning *when* to develop such awareness, *which elements* should awareness consist of, and *how* to deal with them in the classroom (cf Balacheff, 1987; Duval, 1991; Harel, 2008).

Concerning the *how*, we think that the rules of argumentation and proof cannot be taught as a separate subject in the phase of approach to them (obviously it can become a subject for specialized courses in more advanced education). For us the best didactical choice is to exploit *suitable mathematical activities* of argumentation and proof, and develop awareness of the rules according to the *occasions* offered by those activities. But what mathematical activities are *suitable* to offer the expected *occasions*? And *how* to exploit those occasions?

In this paper we will deal only with the *occasions* and the *how* question. After a description of the educational context in which the discussion reported in this paper took place, we will try to frame the analysis of the discussion in order to identify the *occasions* offered in it. We will also discuss *how* to exploit those *occasions*.

THE DOCUMENT IN ITS EDUCATIONAL CONTEXT

In Italy, since 1999 prospective primary school teachers must follow a four-year university preparation, including courses, laboratories and teaching stages (in the future a fifth year will be added). At present, students must follow at least four courses of 30 hours each in the mathematical area, which should integrate the revision of basic mathematical subjects together with didactic considerations, with

Working Group 1

an eye to national indications for primary school curricula. At the Genova University our courses are strictly co-ordinated. Teaching is organized according to a cyclic structure. In most cases, the starting point of each cycle is an individual problem solving activity; it exploits knowledge supposed as shared by students (sometimes recapitulated by the teacher), and/or new knowledge introduced by the teacher, and/or a document coming from primary school classes. A collective discussion led by the teacher follows; it concerns students' individual productions, selected by the teacher. Discussion results in a synthesis, which can provide elements for a further cycle - or constitute an end point for the subject at stake. Some contributions of the teacher during and after the discussions concern the historical origin of the mathematical content dealt with in that moment, and reflections on the relationships mathematics - "reality" and on the ways of reasoning in mathematics. Students' interventions and questions on the above issues are encouraged. Traces of the effects of these choices are in the document.

Students attending our courses come from different kinds of high school; the majority comes from a socio-pedagogical high school, with few hours of mathematics (3 or 2 hours each week, according to the grades); some students come from scientific high school (3-5 weekly hours of mathematics) or technical high school (3-4 hours of mathematics, but no mathematics in the last year). In the year 2004/05 49 students attended the fourth course of 30 hours (I was the teacher); 12 hours were dedicated to a technical and didactical introduction to elementary probability theory. 45 students took part in the activity described below. 15 of them (P-students) had already met elementary probability theory in the high school. Like every year, the starting point of the activity on probability was the following individual problem:

"If we cast two dice and sum the digits on their superior faces, is it more convenient to bet even, odd, or is it indifferent?"

Four solutions were considered for further discussion:

A) - it is more convenient to bet even, because the possible results are eleven (2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12) and 6 results out of 11 are even (14 answers similar to this, 6 of them are by students who studied elements of probability in the high school: P-students);

B) - it is more convenient to bet even, because $\text{even} + \text{even} = \text{even}$, $\text{odd} + \text{odd} = \text{even}$, $\text{even} + \text{odd} = \text{odd}$, thus in two cases out of three the result is even (7 answers, 1 from a P-student)

C) - it is indifferent because $\text{even} + \text{even} = \text{even}$, $\text{odd} + \text{odd} = \text{even}$, $\text{even} + \text{odd} = \text{odd}$, $\text{odd} + \text{even} = \text{odd}$, therefore two results out of four are odd and two results are even (11 answers, 3 from P-students);

D) - it is indifferent because if I take an even digit of the first dice, like 2, the sums with the digits of the other dice ($2+1$, $2+2$, $2+3$, $2+4$, $2+5$, $2+6$) are even in three cases and odd

Working Group 1

in three cases, and the same happens if I take an odd digit of the first dice (8 answers, 3 from P- students).

5 other students had produced other kinds of texts: "(...) I do not remember the solution"- a P-student; "It should be indifferent but I cannot explain why"; "Half of the numbers of each dice are even" (two answers, 1 from a P-student).

The knowledge at stake concerns the classical definition of probability (as the ratio between the number of favorable cases and the number of all possible cases, provided that they are equally likely), particularly the crucial condition of "equally likely cases". Usual approaches to probability in high school (when required in the programs) do not focus enough on this condition; exercises and examples on most texts concern only equally likely cases (without putting this aspect into evidence).

Individual solutions were written on a sheet of paper and distributed to all students; a discussion followed. *The translation has "smoothed" some students' expressions, due to difficulties of finding equivalent English expressions. Only main steps are reported below. The whole texts in Italian and English will be available for discussion.*

Some supporters of solution B quickly recognized to have considered only one of the two possibilities and abandoned it; but we will see that some doubts about this issue still emerged during the discussion. Then:

- 1-S1: I have studied probability at the high school, I have applied the definition of probability as the ratio between the number of favorable cases and the number all possible cases... The possible cases are 11, the even cases are 6, the odd cases are 5, thus the probability of an even sum is $6/11$, bigger than $5/11$.
- 2-S2: but this is not compatible with the precise reasoning of D. (...)
- 5-S5: we could make an experiment... to cast the dice a lot of times, one hundred, two hundreds, and see which solution is correct!
- 6- S2: we are making a discussion concerning mathematics, we must reach a conclusion by reasoning, not by experiments! Like in geometry, where measurements are not accepted to validate statements! (...)
- 10- S3: the dice are concrete! And if we cast two dice a lot of times we can see who is right (even or indifferent).
- 11- S7: but we are reasoning in our head, by considering different possibilities and reasoning about them. (...)
- 13- T: let us try to see if we can get a shared conclusion by reasoning!
- 14 -S9: I would like to come back to solution C. For me it provides a good justification for the "indifferent" hypothesis
- 15-S10: For me C is too abstract. I prefer the justification D.
- 16-S2: In C do not have the possible cases, we have general, abstract cases... I am convinced that "indifferent" is the correct answer, but (...)

Working Group 1

- 18-S12: A fits very well what I have studied in the high school: probability of an event is the ratio between the number of favorable cases and the number of all possible cases!
- 19-T: Are you sure? Imagine that you win if the sum is equal to 2. Let us consider the following possible cases: sum 2; and sum different from 2. They are two possible cases, the favorable case is the first one, thus probability of winning is $\frac{1}{2}$. Would you accept to bet an important amount of money on 2?
- 20-S11: But in this situation it is evident that the two cases are not.... They are not balanced, the case "different from 2" contains many numbers (like 3, 4, 5, 6, ...), we cannot divide one favorable case by those two unbalanced cases! (...)
- 23-S13: The example provided by the professor is like a counter-example for the use of our definition...
- 24-S2: but what does it happen in our situation? Perhaps, the sums 2, 3, 4, 5, 6 are not well balanced cases!
- 25-S6: There is a contradiction: if we follow A, it is more convenient to bet even; if we follow D, it is indifferent to bet even or odd. Thus some of the premises for A or for D are wrong. (...)
- 28-T: what are the premises? (...)
- 30-S6: If the conclusions are contradictory, it means that the premises are not compatible among them! We discussed it several times!
- 31-S11: I agree with you that one of the premises is right, the other is wrong
- 32-T: Are you sure that one of the two premises is necessarily right?
- 33-S3: Yes
- 34-S6: Not, both premises (though different) might be wrong!
- 35-T: Try to go in depth in the analysis of the premises!
- 36-S2: the most sure premise is in the solution D: the idea is to consider all the sums... (...)
- 40-S4: wait! Now I understand: 2 can be the sum in only one case (1+1), while 3 can be the sum in two cases (1+2 and 2+1)... They are not balanced!
- 41-S1: but I do not agree that 1+2 and 2+1 are different cases... (...)
- 44-S4: now I understand! A is wrong, because the cases (the sums 2, 3, 4, ...) are not well balanced! (*some voices of consensus*)
- 45-T: So, what conclusion can we derive from the above considerations?
- 46-S3: That A is wrong
- 47-S2: That D is right
- 48-S6: I agree that A is wrong, but this does not imply that D is right!
- 49-T: Try to explain why!
- 50-S6: I am still convinced that it is better to bet even, though I have understood that the motivation A is not right.
- 51-S3: But if a A is wrong and D is right, then what follows from D is right!
- 52-S6: We have not yet proved that D is right!

Working Group 1

- 53-S2: D is the opposite of A... A is wrong, thus D is right!
- 54-S6: No, D is another thing. It is like if I say that Milan is the capital of Italy, and you say that Naples is the capital of Italy: if I prove that Milan is not the capital of Italy, this does not mean that Naples is the capital of Italy! (...)
- 56-T: does D consider all possible cases? (...)
- 60-S9: yes, six cases for each number, it makes 36 cases - all possible cases!
- 61-S2: I see: we could represent it by a 6x6 table
- 62-T: draw it on the blackboard! (*S9 constructs the 6x6 table*)
- 63-S4: now I start to understand - not only D is right, but this allows to get the conclusion that it is indifferent to bet even or odd, (...)
- 65-T: is it OK for everybody? (*consensus*)
- 66-T: what about C? Does it prove that it is the same to bet even or odd? (...)
- 69-T: Can we avoid considering specific couples, like in D? (...)
- 71-T: are you sure that C ensures that all cases are balanced without considering couples? (*long silence*)
- 72-S6: If a dice would have 5 faces...
- 73-S3: But a dice has 6 faces! (...)
- 76-S2: D implies C, D is a justification for C!
- 77-S?: C allows to get the conclusion "indifferent" but is also necessary...
- 78-S?: to get D, C is a consequence of D,
- 79-S?: thus a longer road to prove that it is indifferent to bet even or odd!
- 80-T: Are you sure that C is not an independent way to get the conclusion "indifferent" ?
- 81-S3: It is independent, because a 5-faces dice does not exist!
- 82-S?: In the reality... But we could imagine it!
- 83-S4: C is an independent way to get the conclusion "indifferent" if we can prove in general that the four cases even+odd, odd+even, even+even, odd+odd are balanced...
- 84-T: How we could disprove it?
- 85-S2: To disprove it, it would be necessary to find a counter-example...
- 86-T: Everybody agrees on it? (*silence*)
- 87-T: To invalidate a statement is it necessary to find a counter-example?
- 88-S4: No, it is sufficient
- 89-T: Why sufficient and not necessary?
- 90-S4: Because to invalidate a statement we can also make a reasoning ... find a contradiction... without finding counter-examples!
- 91-T: Let us search for a counter-example. Have you any ideas?
- 92-S6: The five-faces dice...
- 93-S3: But it does not exist, and I cannot imagine it
- 94-T: Is it really important to have dice? What is relevant in the reasoning C? Where digits come from, or...
- 95-S2: The fact that half of digits are odd, and half are even!

Working Group 1

- 97-S6: Thus we could imagine another source of digits...
- 99- S4: For instance, digits taken from two boxes.. each box could contain 5 tickets!
- 100-S2: Let us see with the table:
(the 5x5 table is constructed; counting results in 13 even sums and 12 odd sums)
- 101-S6: But then it would be easier to imagine boxes with 3 tickets!
(the 3x3 table is constructed; counting results in 5 even sums and 4 odd sums)

In the economy of the course, if we consider the aim of introducing students into elementary probability theory, the reported discussion can be considered successful not only because crucial aspects of the concept of probability have been focused and clarified, but especially because the subsequent activities put into evidence that the most important "content" knowledge had been learnt by most students. Indeed the individual task "*How to explain to a student that was not there how we got the solution*" was accomplished by 36 students out of 45 with correct and enough precise justifications of the solution "indifferent" (34 students preferred to take the solution D and complete it). More interestingly, after the discussion of some unsatisfactory individual texts another individual task was proposed (the request was to identify in which random situations of a list it was possible to calculate the probability by applying the definition to the given set of cases, and to explain why): 42 students out of 45 were able to identify all the 3 appropriate situations out of the 5 proposed to them, with exhaustive specific justifications for the rejection of the others.

Thus, the "content" aim was achieved. But later I realized (reconsidering the reported discussion) that the potential inherent in some of its "segments" had not been exploited. With the exception of two students (S2 and S6) no trace of the epistemological, logical and meta-mathematical considerations was reported in the individual texts after the discussion. It was like if the attention had shifted from what was required in the task, to the usual presentation of a learned proof (according to the prevailing activity in high school). I must add that during the discussion, the teacher (myself) was aware of the importance of some interventions of the students (this was the reason that induced me to keep the audio-recording till now); what was lacking was not only the time needed to exploit the offered occasions, but also a broad perspective where to situate both "content", and "epistemological", "logical" and "meta-mathematical" aims (elaboration not yet available at that time).

DISCUSSION OF THE DOCUMENT

In this section I will present some tools to frame the reported discussion, and I will use them to analyze the discussion and prepare possible follow-ups.

The culture of theorems

By this synthetic expression I will mean both the knowledge needed to master conjecturing and proving and the capacity to use it, with reference to the construct of theorem (Mariotti & al, 1997) as the triad that consists of: the statement of the

Working Group 1

theorem; the theory, which the theorem belongs to; and the proof of the theorem, performed within the theory (according to the inference rules and by exploiting the reference knowledge provided by the theory). Knowledge inherent in the culture of theorems concerns the rules of the game of conjecturing and proving. It includes meta-mathematical knowledge about the nature of the acceptable references for the validation of a statement, the role of counter-examples, the logical and textual requirement of a statement and a proof, etc. It includes also more general (logical) rules of arguing. As to the capacity of using knowledge, I will elaborate on it in the following subsections.

This description makes evident the fact that the culture of theorems is part of what we could call "the culture of argumentation". The interest for prospective primary school teachers of the discussion reported in the enclosed document depends on the fact that the development of skills related to argumentation belongs to teachers' professional duties (explicitly stated in the present national programs and national curricula of several states, including Italy). The occasions offered by the document concern in some cases specific requirements of proof, in other cases more general requirements of argumentation; thus prospective teachers can relate reflections on the rules of argumentation to specific issues concerning further mathematics education.

The content of this paper could be rephrased now by saying that it deals with the problem of passing over to students the culture of theorems and of argumentation.

Framing argumentation and proof: Toulmin's and Habermas' models at work

B. Pedemonte in her thesis (2003) and then in Pedemonte (2007) proposed the use of Toulmin's model to study the relationships between argumentation and proof. In Toulmin's model an argument consists of three elements:

(*claim*): the statement of the speaker; (*data*): data justifying claim, (*warrant*): the inference rule, which allows data to be connected to the claim.

In any argument, the first step is expressed by a viewpoint (an assertion, an opinion). In Toulmin's terminology the standpoint is called the claim. The second step consists of providing data to support the claim. The warrant provides the justification for using the data as a support for the claim. The warrant, which can be expressed as a principle or a rule, acts as a bridge between the data and the claim. Three other elements that describe an argument can be taken into account: (*backing*) the support of the rule; (*qualifier*) the strength of the argument; (*rebuttal*) the exception to the rule. The force of the warrant would be weakened if there were exceptions to the rule: in that case conditions of exceptions or rebuttal should be inserted. The claim must then be weakened by means of a qualifier. Backing is required if the authority of the warrant is not accepted straight away.

Following Pedemonte (2007) we can apply this model to analyze specific points of the discussion; for instance, in the first intervention the student's claim (it is more

Working Group 1

convenient to bet even) is related to data (the possible sums) through a warrant (the way of evaluating probability as the ratio between the number of favorable cases and the number of all possible cases) that will be weakened by the remark that another reasoning brings to a conclusion different from the claim.

Habermas (2003, ch.2) distinguishes three interrelated components of rational behaviour: the epistemic component (**epistemic rationality**) inherent in the control of the propositions and their chaining, the teleological component (**teleological rationality**) inherent in the conscious choice of tools to achieve the goal of the activity, and the communicative component (**communicational rationality**) inherent in the conscious choice of suitable means of communication within a given community). With an eye to Habermas' elaboration, in the discursive practice of proving we can identify (see Boero & al, 2010): an epistemic aspect, consisting in the conscious validation of statements according to shared premises and legitimate ways of reasoning (cf. the definition of "theorem" by Mariotti & al., 1997); a teleological aspect, inherent in the problem-solving character of proving, and the conscious choices to be made in order to achieve the aim; and a communicative aspect, consisting in the conscious adhering to rules that ensure both the possibility of communicating steps of reasoning and the conformity of the products (proofs) to standards in a given mathematical culture.

Our adapted Habermas model allows to consider some pieces of the transcript under the perspective of rational behavior: for instance, in the last 10 interventions, once students realize that (C) might not stand by itself as a proof that it is indifferent to bet "even" or "odd" without considering (D), the search for an example in which the four cases of (C) are not equally likely is guided by the teacher and performed according to teleological rationality, in dialectic relationship with epistemic rationality.

The complexity of the discussion can be described rather well if we consider the nature of the claims, data, and warrants used by the teacher and the students during the discussion: we could qualify them with the adjectives "mathematical" (like in the case §1), "meta-mathematical" (like in the case §94), "logical" (like in the case §53 - §54), "epistemological" (like in the case §6).

The integrated use of Habermas' and Toulmin's models proposed in Boero & al. (2010) allows us to analyse the reported discussion according to a broader, unified perspective. The discussion can be considered from two points of view: the point of view of the teacher and the point of view of the students. The teacher's intention is to bring students to realize why the condition of equally likely possible cases is necessary to get a way of evaluating probability that makes sense. Thus his teleological rationality consists of interventions that address the students' attention towards data (produced by the students, or provided by him -see §19) that could weaken or confirm their warrants; while his epistemic rationality allows him to take under control the evolution of the argumentation from the point of view of logical

Working Group 1

and mathematical validity (see §87), and communicational rationality results in the formulation of interventions that are suitable to reach the students.

From the students' point of view, their teleological rationality is exercised in few occasions and only locally (according to short term aims - see for instance §101) during the discussion, while the path towards the global achievement of the final aim and several steps to approach it are in the hands of the teacher. On the contrary, the students' epistemic rationality is locally at work in an autonomous way in several occasions, both at the mathematical level and at the metamathematical, logical and epistemological level. The task "*How to explain to a student that was not there how we got the solution*" fulfils the aim of re-constructing a mathematical, unitary solution of the problem. Did it allow the students to exercise rationality on the global level in all of its components? The lack of reflexive traces in almost all the texts prevents to answer. It is probable that several students wrote down what they were accustomed to do since the secondary school - a well written presentation of the solution of a task, without exercising awareness of the epistemic and teleological requirements of proving. Thus the task does not fulfill the aims of letting the students recompose the rationality of the guided construction of the solution, and of making them aware of the components of the rational behavior at the epistemological, meta-mathematical and logical level. The students' experience in our previous courses allowed some of them (less than 10 out of 45) to raise or deal with epistemological, meta-mathematical and logical issues during the discussion. Those issues remained as concerns for the students who introduced or discussed them, and in most cases were even lost in their individual texts.

The follow-ups

The analysis of the transcript has put into evidence some important elements of the culture of theorems (and, more generally, of the culture of argumentation), which some students have brought to the fore with their interventions. In order that those elements become shared and conscious acquisition for all students, it is necessary to design suitable didactical situations. Epistemological and meta-mathematical concepts cannot be introduced through definitions (specially when young students are concerned). Thus it is necessary to exploit the *occasions* offered by the discussion to approach those concepts through meaningful examples and situations (that will become "reference situations" for them). Various solutions can be worked out.

In a situation like the reported one, the analysis of the main *motive* of the discussion for the teacher (and the students as well) brings us to exclude the introduction of systematic reflections on epistemological and meta-mathematical issues during the discussion. It would mean to distract the students' (and the teacher's) attention from its important "content" goal. Thus it is necessary to design a-posteriori didactical situations based on the use of the transcript of the discussion. The transcript can play

Working Group 1

the role of a permanent mediation tool, useful for addressing attention to elements that remain available to all students for reflection.

According to experiments performed in similar circumstances (see Douek, 2009 and Boero & al, 2010, second part), I think that a possibility might be to choose the final text by S6 (the most rich on the logical and epistemological ground, even if far from being exhaustive!) and ask students to compare it with another "poor" (but satisfactory from the mathematical point of view) text in order to identify the differences, then ask to identify further aspects of the discussion concerning *similar* (epistemological and logical, according to our terminology) aspects.

Another idea might be to present a complete, reasoned re-construction of the problem (where explicit epistemological, logical and meta-mathematical considerations inform and guide the sequence of steps of reasoning needed to achieve the solution), and ask students to identify if, how and when in the transcript (and eventually in students' individual productions) those considerations emerged.

A third idea might be to analyze the first part of the transcript with students, putting into evidence the relevant logical and meta-mathematical aspects, then ask them to complete the analysis of the transcript according to the same categories.

The three proposals are based on the exploitation of written texts; the first two imply a comparison of at least two texts. This choice provides all students with permanent tools for reflection on the issues at stake.

All the proposals need to be followed by a whole class discussion, orchestrated by the teacher, about (some of the) individual productions. According to the students' maturity and the aims of the activity, during the discussion or after it the teacher might introduce some technical terms and explicit logical and meta-mathematical concepts in order to bring students from an initial, informal awareness of the issues at stake to a more mature take in charge of elements of the culture of theorems (and of the culture of argumentation). More importantly, during the discussion the teacher could drive the students' attention towards a re-construction of the whole elaboration of the solution, in order to make them aware of his intentions and the aims of his interventions. A way to contribute to pass over to the students his rationality.

MATHEMATICAL PROVING ON SECONDARY SCHOOL LEVEL I: SUPPORTING STUDENT UNDERSTANDING THROUGH DIFFERENT TYPES OF PROOF. A VIDEO ANALYSIS

Esther Brunner, Kurt Reusser, Christine Pauli

University of Teacher Education Thurgau, Kreuzlingen CH, University of Zurich, CH

Within the framework of the Swiss-German study “Instructional Quality, Learning Behaviour and Mathematical Understanding” [1] (Klieme, Pauli & Reusser, 2006, 2009) and by using the example of a purely mathematical problem, it was examined in 32 classes how teachers support the process of proving in classroom instruction from a subject-based and a communicative point of view. For this purpose, an analysis instrument was developed which describes content-related aspects of the problem-solving process as well as the students’ participation. The results clearly indicate that the individual teachers differ in terms of their choice and application of specific types of proof. A special group, however, is constituted by those teachers who prove in multiple ways.

Keywords: Mathematical proving, Mathematics instruction, Secondary school level I, Support of the students, Video analysis

INTRODUCTION

In the context of educational standards (cf. Blum et al., 2006; EDK, 2010; NCTM, 2000), learning to prove and argue has gained new significance and experiences a real renaissance. This change was particularly furthered after the criticism of formal proof and its strictness could be neutralized with respect to public school instruction and was complemented by other concepts like, for example, pre-formal (or operative) proving (e.g. Krauthausen, 2001).

Since mathematical proving is a demanding activity, it requires teachers to support their students in a way which is close to contents and understanding-oriented. And since a mathematical proof is accepted or rejected by the community, argumentation takes place within a discourse. For these reasons, two aspects are crucial to the support of proving: content-related support as well as participation in subject specific discourse. This paper is focused on content-related, subject specific support.

Various empirical studies have shown that rather few students are able to give mathematical reasons for or to prove a given fact (cf. Healy & Hoyles, 1998; Reiss, Klieme & Heinze, 2001). As regards geometrical proofs, Reiss and collaborators (Reiss, Hellmich & Thomas, 2002) found that the varying capabilities of students in terms of proving can be substantially explained by class membership. Against this background it is surprising that only relatively few studies focus on the part of the teacher and his or her support behaviour while proving.

THEORETICAL FOUNDATIONS

Proving as an Important and Demanding Mathematical Core Activity

The debate around proving in mathematics instruction is multi-faceted and extensive. Besides questions about the strictness of a proof (cf. Hanna, 1997; Jahnke, 1978) or its significance (cf. Heintz, 2000), there is an interest in the different functions of a proof (cf. Hanna & Jahnke, 1996; Hersh, 1993; de Villiers, 1990), or in the role of communication and the community in proving. The distinctions between process and product, or proof and proving as an activity are likewise objects of the debate. In a genetic conception of learning, the process of proving is important especially to mathematics instruction. It is for this reason that Jahnke (1978), by reverting to Freudenthal's proposition of "local ordering" (1977), recommends that students should also be offered an understanding of sufficient reasons while problem-solving. It is not the completed proof alone or its re-enactment that should dominate mathematics instruction. Various didactic models of teaching proving processes are based on this assumption (cf. Boero, 1999; Reiss, 2002). By starting out by a (constructed) need for proving (cf. Hefendehl-Hebeker & Hussmann, 2003; Reusser, 1984), these models suggest different steps of how to get from a "why"-question to argumentatively supported reasoning. This reasoning, however, must turn out to be conclusive enough also for other persons, and it must be possible to validate it. Owing to this validity claim and external validation, a proof obtains a communicative function as well. Correspondingly, didactic communication and together with it orality are of high importance in classroom instruction.

Types of Proof

As various authors highlight the importance of sufficient reasons in connection with the strictness of a proof, it becomes clear that in mathematics instruction not only proof in the mathematically strict sense but also its action- and thought-psychological precursors in the sense of more or less "strong" reasoning should be permitted.

There are numerous different classifications of proofs (cf. Balancheff, 1988; Blum & Kirsch, 1989; Leiss & Blum, 2006). The classification of Wittmann and Müller (1988) constitutes the basis for this study. It differentiates three fundamentally different types of proof: 1) formal-deductive proof, 2) experimental proof and 3) content-related illustrative proof.

Formal-deductive proofs are based on the logical deduction of a statement which follows from another statement step by step. They are related to conciseness of formulation which is manifested in as brief a form as possible, i.e. the mathematic formula or the formal language. Because of this, formal-deductive proofs require not only a particular way of thinking but also a particular procedure backed by a specific technical terminology.

Working Group 1

In contrast to formal-deductive proofs, experimental proofs do not yield conclusive certainty but remain tied to the respective examples. Yet working directly with examples is fruitful especially for younger and less competent students, and it facilitates argumentations which are bound to examples. Moreover, experimental approaches are suitable for generating a subjective need for proving.

As far as content-related illustrative proofs are concerned, formalism is only of limited significance as well, though in addition to that reasons should not solely be derived by showing plausible examples as this is the case with experimental proofs. Content-related illustrative proofs are rather based on constructions and operations which render it intuitively discernible that they are applicable to a whole class of examples, and that certain conclusions can be drawn (cf. Wittman & Müller, 1988, p. 249). It must be possible to generalise content-related illustrative proofs directly from the given example. This process of generalisation should be as intuitively discernible as possible which is facilitated by making the mathematical structure transparent, mostly on the enactive or iconic level.

These three types of proof each make different demands on the students' competences, and at the same time they offer different approaches – and as a consequence specific, content-related support – depending on the current level of knowledge of the class. A genetic procedure might start out by an experimental or content-related illustrative proof and then advance to a formal-deductive proof, thus inducing an increasing degree of abstraction and symbolization.

Research Questions and Aims of the Study

The aim of the current analysis is to describe teachers' support in phases of mathematical proving in secondary school level I instruction as extensively as possible and to analyse it comparatively. The following two research questions are guiding the study presented below:

- Which types of proof can be observed while the proving and reasoning problem is being worked on?
- Is it possible to distinguish special groups of teachers whose support in proving phases differs clearly from the support of the majority?

METHOD

In order to compare instructional processes and the teachers' acting on the micro-level, it is important to standardise contents. This is realised by the video-based study of mathematics instruction in secondary school level I classes from Germany and Switzerland named "Unterrichtsqualität, Lernverhalten und mathematisches Verständnis" ["Instructional Quality, Learning Behaviour and Mathematical Understanding"] (Klieme, Pauli & Reusser, 2006, 2009) which was jointly conducted by the German Institute for International Educational Research (Deutsches Institut für Pädagogische Forschung, DIPF) and the Institute for

Working Group 1

Educational Science of the University of Zurich. The aim of the project is to examine components of instructional quality. It ran from 2000 to 2006, and was structured into three phases each of which lasted two years. These three phases had different research focuses: The first phase involved a representative survey of teachers regarding instruction-related, self-related and school environment-related cognitions. The second phase of the project consisted in the video-based recording of two different instructional modules in 20 German classes of the 9th and 19 Swiss classes of the 8th school year. In the third project phase, an internet-based training programme for the participating teachers was organized.

In total, 5 lessons per teacher on a standardised content were video-taped. Two thematic units, both representing typical learning situations, were recorded as objects of the investigation: on the one hand a unit on the introduction to the Pythagorean Theorem, and on the other hand a unit on solving mathematical word problems picked from a given set. One of these problems was a purely mathematical proving and reasoning task. This paper refers to the implementation of this task in its purely mathematical context with the teachers' support of the students while reasoning and proving being at the centre of the analyses.

Data Set

The sample consisted of 32 teachers and their classes of the 8th or 9th school year from the highest track ("Gymnasium") and from the middle track ("Realschule"/"Sekundarschule") of the three school types in Germany and Switzerland.

In order to enable as representative an insight as possible into the everyday working on a reasoning problem, the teachers were not specifically prepared. Several days before the arranged double lesson, they were sent a set of word problems which had to occur in the instructional unit. Apart from that, the teachers were free in their methodological-didactic arrangement.

For the analysis presented in the following, the provided proving and reasoning task was selected. The object of the analysis is the complete tackling of the problem. This was realised in classroom discourse but also in the form of learning support in phases of group work and silent work.

Mathematical Problem

The task in question is a purely mathematical proving and reasoning problem which opens up different procedural options.

The sum $13 + 15 + 17 + 19$ is divisible by 8. Does this hold for any sum of four ensuing uneven numbers?

The given fact can be both elucidated by means of a numerical example (experimental and/or content-related illustrative proof) and worked out through a formal-deductive procedure. As the formal-deductive procedure is not too

Working Group 1

demanding for the age group in focus, the students can actively participate in the line of argument when they are appropriately supported.

Instrument

To be able to describe proving phases with respect to content-connected tackling and understanding-oriented support as well as with respect to opportunities for participation in classroom discourse in a differentiated manner, in a first step a subject-based analysis instrument was developed by means of which the 32 cases were coded. In total, 117 different features of the way of working on the problem were captured per case. These features constituted the starting point for further analyses.

The instrument, specially developed for this analysis, captures features both on the surface structure and on the deep structure of instruction (cf. Reusser, 2005). The three big domains of the instrument refer to 1) the context of working on the problem, 2) the communicative dimension and 3) the content-related dimension. The context of working on the problem captures, among others, the duration and the arrangement pattern of working on the problem. The communicative dimension captures features like the conceptual level, communication of meta-rules and meta-commentaries, and others, as well as the type of didactic communication and the students' participation for every content-related feature. The content-related dimension captures the type of proof chosen by the teacher, the heuristics made use of, the elements of comprehension as actual content-related kernel of the problem, as well as rather peripheral features of working on the problem.

The current paper is restricted to the presentation of results referring to the type of proof chosen by the teacher.

Video Analyses

The 32 instructional units were coded with the help of the analysis instrument (inter-rater reliability: 88–100%). The thus yielded data could then be further processed by means of statistical analyses. The first results, presented below, are based on descriptive statistics, on group comparisons, and on correlative connections between the individual supportive features.

RESULTS

Type of Proof

All of the three different categories of proof occurred, though in a quite varying distribution. Formal-deductive proofs could be found in 65.5% of all cases (21 classes), experimental proofs in 12.5% of the cases (4 classes), and content-related illustrative proofs in 37.5% of the cases (12 classes). Consequently, there are classes in which several categories of proof could be observed. This was true for 9 classes.

Working Group 1

In 4 classes, however, no proof at all was (conclusively) completed. The choice of the type of proof does not bear any connection with the type of school.

Multiple Proving – A Special Group

In total, 9 classes could be determined in which two of the three types of proof were implemented. These classes can be described as a special group because the use of different types of proof can be regarded as an elaborated line of argument.

That these classes constitute a special group can be inferred from statistically significant differences. These teachers clearly made more use of heuristic aids in their classes ($M = 2.33$; $SD = .86$; $N = 9$) than those teachers who only realised one type of proof ($M = 1.53$; $SD = .96$; $N = 19$). This difference in the mean is statistically significant ($t = 2.13$; $df = 26$; $p < .05$), and it displays a very strong effect ($ES_d = .86$).

Statistically significant differences between the group of teachers who carry through several types of proof ($n_1 = 9$), the group of teachers who make use of one type of proof ($n_2 = 19$), and the group of teachers who do not implement any proof ($n_3 = 4$) can also be detected with respect to other supportive features in the reasoning process, for example concerning the formal-deductive procedure ($\chi^2 = 9.55$; $df = 2$; $p < .01$), the content-related illustrative procedure ($\chi^2 = 9.34$; $df = 2$; $p < .01$), the criterial assessment of a proof ($\chi^2 = 10.38$; $df = 2$; $p < .01$), and others more which cannot be set out any further here. All differences appear in favour of the group which implements several proofs – i.e. in this group, the supportive aids mentioned above (heuristics) are made use of more often than in the other two groups. The group of teachers who carry through two different types of proof can therefore be characterised as a special group also on the level of individual features of the solving process.

Since the choice of the two different types of proof differs quite obviously within this group, further sub-groups can be differentiated.

Group A: Experimental and formal-deductive: Two classes of the middle track (“Sekundarschule”/“Realschule”) belong to this group. Both teachers first carry through an experimental proof and discuss its limits with the class. Afterwards, a formal-deductive proof is worked out in a questioning-developing classroom dialogue. Both cases can be regarded as genetic procedures, because a formal-deductive approach is developed out of an experimental approach and the determination of its weaknesses.

Group B: Content-related illustrative and formal-deductive: In six classes there is first a content-related illustrative proof and then a formal-deductive proof. Five of these classes are of the highest track (“Gymnasium”), one is of the middle track (“Sekundarschule”). In one class, the teacher initially asks his students to work out a proving procedure themselves in groups during quite a long period of time.

Working Group 1

Thereafter, students from two different groups present two different types of proof – first a content-related illustrative proof and then a formal-deductive one – as results of their independent work. Subsequently, these results are discussed and deepened in a classroom dialogue. The other five teachers make use of short phases of independent student work, but they work out the line of argument together with their students by way of a classroom dialogue. The content-related illustrative proof occurs in all classes before the formal-deductive one. In the five classes without presentation of the students' own solutions, the content-related illustrative proof is raised on the next level of generalisation in a further step and the formal-deductive proof is developed. Also this case can be considered as a genetic procedure. It is, however, more structured and more systematic than in group A. In group B, it is not only the weakness of the procedure which is demonstrated by means of the content-related illustrative proof. Moreover, a way of preparatory thinking and a didactic guidance to formal-deductive proving on the basis of the now transparent and understood inherent structure is presented.

Group C: Experimental and content-related illustrative: In one class of the highest track (“Gymnasium”) an experimental and a content-related illustrative proof occur. This class works out the two types of proof in a questioning-developing classroom dialogue with the teacher collecting the students' suggestions regarding the procedure. In doing so, he first carries through an experimental proof together with his class and then demonstrates that this proof is limited in its validity claim. Afterwards, he applies a content-related illustrative proof to a concrete example. Also in this case we are dealing with a genetic procedure, though in a different way. The experimental approach is discussed with regard to its weaknesses, and thereafter it is complemented by a content-related illustrative proof.

DISCUSSION

It is not very surprising that in the vast majority of classes a formal-deductive proof is implemented. This can be put down to the fact that strictness of a proof is characteristic of mathematics seen as a science. What is more astonishing, on the other hand, is the fact that the choice of one of the types of proof does not depend on the type of school. Formal-deductive proofs do not occur more often in classes of the highest track (“Gymnasium”) than in classes of the middle track (“Sekundarschule”/“Realschule”). This dominance of formal-deductive proof in both types of school indicates that teachers think that proving is necessarily tied up with a strictly formal-deductive procedure. For this reason, the potential of the different types of proof with regard to specific, content-related support is still underused to a great extent.

It is interesting that a special group of teachers can be characterised who differ from the other teachers in their use of multiple proving and thus in various supportive features. As far as this group is concerned, it can be assumed that the instruction with

Working Group 1

respect to proving and reasoning displays a clearly higher quality than in the other groups. The reason for this assumption is that different approaches to a given fact are opened up, and that the focus is not one-sidedly on formal-deductive proving, thus preventing a hasty reference to the strictness of the proof. Rather, we are dealing with a genetic procedure which implies a real guidance to formal-deductive proving by means of a supportive arrangement of the argumentation. This is why in the training of mathematics teachers it should be carefully made sure that they do not only know about the strictness of a proof, but also, at the same time, that they are able to regard this formal strictness as an aim of instruction and not as a prerequisite for the implementation of a proof.

However, the chosen type of proof alone does not state anything about the quality of the understanding-oriented support. Rather, it solely describes a predominant practice. In order to investigate the quality of the understanding-oriented support and of the fostering of argumentation there is need for further in-depth analyses which are currently undertaken. It is examined, among other things, whether and under which circumstances the choice of a certain type of proof is functional, to what extent this choice has effects on the students, and which impact the teachers' beliefs have in this respect. Moreover, further content-connected aids by means of which teachers support their students in understanding and arguing are of interest. Finally there is an interest in the way of student participation while arguing and proving. These analyses are under way as well.

EVERYDAY ARGUMENTATION AND KNOWLEDGE CONSTRUCTION IN MATHEMATICAL TASKS

Julia Cramer

University of Bremen

The aim of this study is to gain insights into relations between knowledge construction and argumentation. This paper presents a case study showing an analysis that combines different tools: the Toulmin's scheme to reconstruct the argumentation structure, a collection of topical schemes to characterize different types of inferences including everyday inferences and an epistemic action model to describe processes of knowledge construction. Some preliminary results of this case study will illustrate how the combination of these different tools can shed light on relations between argumentation and knowledge construction.

Key words: Everyday argumentation, knowledge construction, topical schemes.

INTRODUCTION

The aim of my research is to gain insights into relations between knowledge construction and argumentation. Arguing is an important learning goal for two reasons. Schwarz (2009) distinguishes between learning to argue and argue to learn. Referring to Andriessen et al. he clarifies this distinction:

„Learning to argue' involves the acquisition of general skills such as justifying, challenging, counterchallenging, or conceding. In contrast 'Arguing to learn' often fits a specific goal fulfilled through argumentation, and in an educational framework, the (implicit) goal is to understand or to construct specific knowledge.” (Schwarz 2009, 92)

Some researchers like Krummheuer & Brandt (2001) even assume a constitutive function of arguing for learning mathematics in school: Students learn mathematics by participating in argumentation that means practicing argumentation within social interaction as a collective activity. In addition, learning to argue is stated as a goal in many curricula all over the world (e.g. see NCTM 2000). Nevertheless, students have difficulties to learn how to reason in a deductive way. Research shows that everyday argumentation predetermines their way of reasoning in mathematics. For example, many students infer general rules from just some examples (Martin & Harel 1989), just like they would do in everyday situations, without feeling the need to prove their inference. Furthermore, Galbraith (1981) has shown that students often do not realize that one counterexample disproves a mathematical statement because in everyday life an exception does not mean that a rule is not valid. These findings show that students bring experiences of everyday argumentation with them into math classes interfering with the learning of mathematical reasoning. The question is how to use these everyday experiences as a foundation for mathematical reasoning. Efforts in this direction are complicated by the fact that we do not exactly know how mathematical

Working Group 1

argumentation emerges out of everyday argumentation and how this is connected to knowledge construction. This is exactly the point on which I will focus in my study. The leading questions are:

- What elements of everyday argumentation do students use when solving mathematical problems and how does this lead to mathematical argumentation?
- How is knowledge constructed through argumentation? How can the epistemic function of arguing be described?
- How can we describe the relation between argumentation and knowledge construction?
- What components of argumentation processes foster or hinder processes of knowledge construction?

ARGUMENTATION

Schwarz et al. (2003) state that

“constructing knowledge is a never-ending process of marshalling evidence that the chosen belief is (a) supported by the available evidence and (b) more warranted than plausible rival beliefs” (Schwarz et al. 2003, 222).

Following this statement, I assume that arguing is an epistemic action, i.e. an intentional action to gain knowledge. The construction of new knowledge arises from reasoning or checking the validity of claims. Therefore, arguing has two epistemic functions: Constructing new knowledge and/or convincing others of the validity of one’s own hypothesis. The epistemic function of convincing others means: The more people one can convince, the more likely one’s own hypothesis will be. In this sense, an argument is a statement that makes a hypothesis more or less likely.

The Toulmin’s scheme is an appropriate tool to reconstruct the structure and depth of argumentation processes (Krummheuer 1995, Knipping 2004) or to characterize abductive and deductive types of arguments (Pedemonte 2002). But how can we grasp the students’ more intuitive methods of concluding? Looking at philosophy and at rhetoric is worthwhile. A collection of topical schemes has the potential to identify the starting point of how mathematical inferences develop. These two tools, the Toulmin’s scheme and a collection of topical schemes, will be presented in the following paragraphs.

The Toulmin’s scheme

To analyze processes of argumentation, Toulmin (1958) developed a scheme that classifies elements of an argumentation with regard to their function into data, conclusion, warrant, backing and qualifier. The conclusion is the statement that has

Working Group 1

to be reasoned. Data are unquestioned facts the conclusion is led back to. Data and conclusion are part of every argumentation. The step of inferring from data to conclusion can be explained by a warrant that sometimes is implicit. To ensure the practicability of a warrant, the warrant can be backed up by additional statements. Qualifiers or exceptions specify the validity of a conclusion.

In processes of argumentation with more than one step, conclusions that are already accepted by (most of) the other participants of the process can turn into new data. If backings, warrants or data are questioned, these elements have to be reasoned in a separate process of argumentation before they can be used in the primal argumentation. In complex processes of argumentation, Krummheuer & Brandt (2001) name these separate processes of argumentation as lines of argumentation.

A collection of topical schemes

Topical thinking means that someone has access to some basic ideas for generating arguments. These basic ideas for concluding methods are called topical schemes. In this sense, topical schemes are facilities to create steps of an argumentation or to ensure persuasively the power of argumentation steps. Ottmers (2007) presents a collection of topical schemes that is divided into two prime classes: everyday logical schemes and convention-based schemes. The everyday logical schemes contain five types: causal-based, comparison-based, contrast-based, classification-based and example-based conclusions. The first four types conclude from general to special statements (schemes of inferential nature), the last type concludes from special cases to general statements (schemes of inductive nature). Everyday logical schemes are redolent of formal logical rules. Causal-based conclusions use causal relations to ensure plausibility. Causal relations are those between cause and effect, between reason and consequence of human activities or between means and end. Comparison-based conclusions relate different parameters. They refer to equality, diversity, or more or less probable cases. Contrast-based conclusions refer to relevance between contrasts. These contrasts can be absolute, relative, or alternative. Classification-based conclusions use relations between parts and the whole issue, between species and genus, or between definition and the defined issue. To come to example-based conclusions, either a set of examples or just a single example is used as a (model/prototype/as evidence) of a general rule. A general example that is appropriate for reasoning in the direction of generalization is called an inductive example. An example that just shows that a rule is valid in this case is called an illustrative example.

Convention-based conclusions do not use any kind of logical structures but concluding methods that are established within a group. Therefore it is not possible to present a complete collection of convention-based concluding schemes. Ottmers presents two topical schemes as examples for this prime class: authority-based conclusions and metaphor-based conclusions. Authority-based concluding means referring to another person (a special group/special institution/etc.) that is accepted

as an authority in the relevant field. Metaphor-based conclusions are similar to example-based or comparison-based conclusions. They relate the conclusion to other similar cases for plausibility. There are two important differences between these concluding methods. Metaphor-based conclusions refer to one example. In contrast, example- or comparison-based conclusions regard an amount of similar cases or examples. Furthermore, the similar cases in this concluding method stem from another field and explain the conclusion in a more metaphorical way [1].

Knowledge construction

Bikner-Ahsbabs (2005) developed an epistemic action model to analyze the epistemic process in interest-dense situations in comparison to other learning situations [2]. This model consists of three epistemic actions that shape epistemic processes. These epistemic actions are gathering mathematical meanings, connecting mathematical meanings and structure-seeing. Gathering means assembling similar mathematical entities; connecting means linking a limited amount of these to other entities; structure-seeing means constructing or reconstructing a mathematical structure that refers to an unlimited number of mathematical entities.

METHODOLOGY AND METHODS

This study is embedded into the research project “*Effective knowledge construction in interest-dense situations*” that investigates processes of in-depth knowledge construction and its background conditions by linking two theories of constructing mathematical knowledge. This project is a joint study between two research teams from Israel and one team from Germany and it is supported by the German-Israeli Foundation for Scientific Research and Development (Grant 946-357.4/2006). Within this project, three different tasks have been developed that offer an opportunity to construct mathematical knowledge. In each country, three pairs of students (grade 10 in Germany, grade 11 in Israel) are video- and audiotaped when solving these tasks in a varying order. There is no teacher, however, in some instances an interviewer takes over the role of a teacher. The audio- and videodata are transcribed and translated into English to exchange them between the research teams. Including some transcripts of the project’s pilot phase, there are currently 11 German transcripts and 12 translated transcripts at my disposal.

The transcripts will be analysed interpretatively in turn-by-turn-analyses and in several steps according to the leading questions above. The kind of student’s involvement and the epistemic process is reconstructed through interpretation on three levels: the locutionary, the illocutionary and the perlocutionary level. The locutionary level consists of what is said. On this level, the construction of mathematical knowledge is reconstructable. The illocutionary level consists of what is said through an utterance (the underlying subtext) and the perlocutionary level contains the people’s intentions and the impact of utterances (Davis 1980).

Working Group 1

Reconstructing the illocutionary and the perlocutionary level shows how mathematical knowledge is constructed socially (Arzarello et al. 2009).

The analyses of the argumentation processes and of the epistemic processes will be done in separate steps. First, the epistemic processes will be reconstructed by identifying the epistemic actions gathering, connecting and structure-seeing and some social actions like asking for an explanation, valuing, initiating and contrasting. A diagram will illustrate the processes of knowledge construction as well as the social processes in a nutshell. Secondly, the structure of the argumentation is reconstructed with the aid of Toulmin's scheme, and the kind of warrants the students use is characterized by means of Ottmer's collection of topical schemes. The results will be shown in a diagram as well. In a last step, these diagrams will be compared and contrasted (Prediger, Bikner-Ahsbahr & Arzarello 2008). The comparison of the results of the different analyses will shed light on relations between argumentation and knowledge construction. However, the problem to compare a diagram showing a process (the epistemic actions) with a diagram showing products (argumentation) is not solved yet. Hence, some elements of the diagrams will be developed and modified in the study.

PRELIMINARY RESULTS

Two high-achieving students (grade 10 of a German Gymnasium), Tim and Matthias, solve a task asking them to interpret the continued fraction $1 + \frac{2}{1 + \frac{2}{1 + \frac{2}{1 + \frac{2}{\dots}}}}$. The task is

structured into two parts. In the first part, the students are asked to find the first 7 elements of the sequence, reflect on how they computed them, extend the computation to 20 elements and write them as simple as well as decimal fractions. In the second part, the students are asked to make a conjecture on the sequence from the first part and justify their conjecture.

In the case of Tim and Matthias, the transcript can be divided into main three parts according to the task. The first main part of the transcript corresponds with the first part of the task (line 31 – 718). In this part, Tim and Matthias compute the elements of the sequence very accurately always checking that they made no miscalculation. Their accurate and precautious way of solving the task becomes apparent in the following parts as well. In the second main part, Tim and Matthias make conjectures on the sequence (line 719 – 1465); in the third main part (line 1466 – 2630) they try to justify their conjectures with the interviewer directing the students' focus on some aspects. This paper presents the analysis of the second main part of the transcript that can illustrate some interesting relations between argumentation and knowledge construction.

Working Group 1

When Tim and Matthias are asked to make conjectures on the sequence, they focus on the decimal places. They look at the elements of the sequence from $f(7)$ on and observe that the amount of same decimal places increases.

729 Matthias: [...] ,wait here were only three zeros (points at the following on the sheet) ,then three nines ,then three zeros again ,then four nines ,then four zeros ,then four nines again ,so always after [...]

731 /Matthias: always after- ,always after three. ,it becomes ,it becomes one more.

Matthias gathers information of their previous work (three zeros, three nines ...). This information is unquestioned and can be used as data later on. When gathering the information, Matthias uses words like “only”, “then” and “again”. This is a hint that he already connects these data in order to make a conjecture. Matthias infers example-based that after every third element of the sequence the amount of nines respectively zeros behind the decimal point increases by one. Tim starts counting the amount of nines respectively zeros behind the decimal point from the first element of the sequence on. He realizes that the results are not in line with Matthias’ conjecture. But instead of abandoning this conjecture now, they first check if they have made any mistake. They find that they did no miscalculation, and therefore they change the conjecture a bit:

744 Tim: yes at least ,one notices that always (.) ,always three nines ,three zeros ,the amount of nines and zeros is identical ,and then it always switches after three or four.

The whole second main part of the transcript (line 719 – 1465, approximately 30 minutes) consists of making conjectures on the sequence and sharpening the formulation of these conjectures. All the conjectures are associated. They do not contradict, but deal with different aspects of the sequence. For lack of space it is not possible to show all diagrams of the second main part. Some selected parts are presented to illustrate important observations. Figure 1 shows how Tim and Matthias develop a new aspect concerning their conjecture.

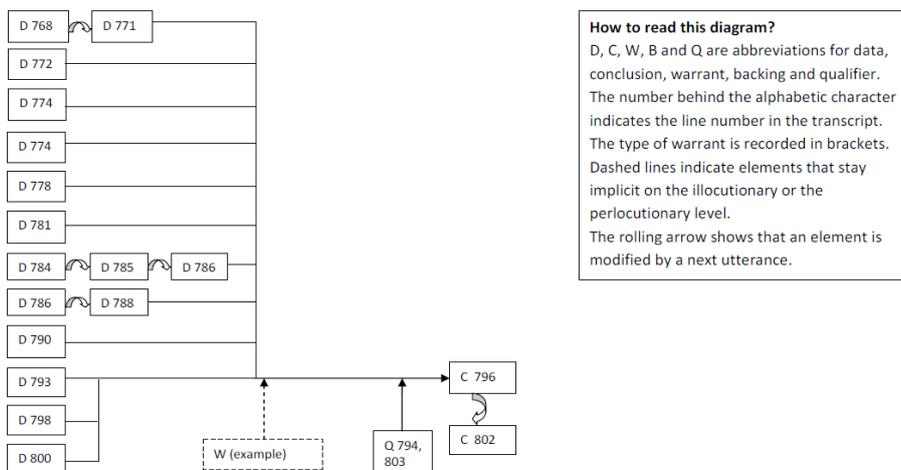

Figure 1: diagram of line 768 - 803

Working Group 1

Tim and Matthias start gathering a lot of data. Some data is modified. They connect the data immediately what is shown by words like “then”, “here again”, etc. They realize that $f(8)$ till $f(10)$ have two nines or zeros behind the decimal point, $f(11)$ till $f(13)$ have three nines or zeros and $f(14)$ till $f(17)$ have five nines or zeros behind the decimal point. $f(8)$ till $f(10)$ and $f(11)$ till $f(14)$ are rows of three elements with the same amount of nines or zeros behind the decimal point. $f(14)$ till $f(17)$ is a row of four elements with the same amount of nines or zeros behind the decimal point [3]. From these data, they infer example-based.

796 Tim: I would say ,ohm- ,as soon as it is a row of three four five whatever ,ohm- ,lets just say a row of five ,o- or no ,lets say a row of four ,and twenty-five is inside of it ,so five squared ,from then on ,are ,five nines ,five times

They sharpen their formulations and even create a new term in order to specify what they mean. The term “space of places” describes a space (some following elements of the sequence) where the amount of nines or zeros behind the decimal point is the same. For instance, $f(4)$ till $f(7)$ is a space of places as there is one nine respectively one zero behind the decimal point. $f(8)$ till $f(10)$ is the following space of places. With the aid of this term, they develop and clarify their conjectures.

During the whole second main part of the transcript, Tim and Matthias write down their conjectures in a very accurate and careful manner. They always discuss their formulation and do not note it down until both agree on it. Here is what they wrote down as their conjectures:

“The amount of zeros or nines behind the decimal point is the same in a particular space of places. If you go from one to another space of places, the amount of nines or zeros increases by another nine or zero. If there are nines or zeros behind the decimal point, depends on the x -value. If the x -value is even, there are nines behind the decimal point and a one in front of it. If the x -value is odd, there are zeros behind the decimal point and a two in front of it. The length of the space of places changes to c as soon as the space of places contains c^2 .”

All of these conjectures are inferred example-based. Before a new aspect of a conjecture arises, Tim and Matthias gather a lot of data. In the following, they sharpen and modify this conjecture. A characteristic argumentation line during this part is shown in figure 2.

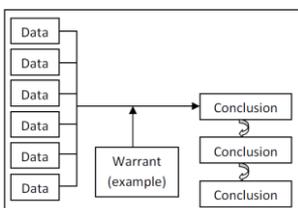

Figure 2: characteristic argumentation line in part 2 of the transcript

Working Group 1

Obviously, several data in the form of examples are necessary for example-based inferences. However, such argumentation lines with a high concentration of data do not seem to be characteristic only for example-based inferences. In another case study (see Cramer 2010), the first argumentation lines contained a lot of data as well. The conclusions in this case were inferred causal-based. This could be a hint, that in general a high concentration of data is characteristic for argumentation lines in the beginning. This result corresponds with the finding of interest-dense situations, that gathering phases until a certain saturation level are necessary to provide a basis for further increases of knowledge.

The fact that conjectures arise example-based is obvious as well. It is a heuristic strategy stemming from everyday life and the way how discovery learning works. The question is how to encourage students to justify their conjecture in a mathematical way. Tim and Matthias insist several times that their conclusions are conjectures. They believe that they are valid, but they are not sure. The way they become more and more sure in the second part of the transcript stems from everyday life as well. When they observe that nines and zeros behind the decimal point alternate as well as one and two in front of the decimal point, they take the alternation as an argument for the validity of their conjecture.

1000 Tim: Yes ,that always switches ,thats why it is logical

The implicit argument is based on previous experiences. The students are asked to look for patterns and regularities. Something alternating is a pattern, therefore it is more likely that their conjecture is true. Ottmers does not mention experience-based conclusions. It could be a type of example-based conclusions in the sense that previous experiences are kind of examples. But the related examples are not mentioned explicitly. Therefore it is not possible to check the relevance of these experiences, and for this reason I would describe it as a convention-based scheme. Another example of this concluding scheme appears later on. Tim and Matthias realizes that the space of places from $f(4)$ till $f(7)$ has a length of four. This is not in line with their conjecture that the length of the space of places changes to c as soon as the space of places contains c^2 . Tim would like to solve the problem in this way:

1345 Tim: Yes exc- ,exception ,or then write exceptions prove the rule next to it

This is an everyday proverb that even contradicts with mathematical argumentation. This finding shows that, on the one hand, Tim and Matthias are influenced by everyday argumentation; but on the other hand they show that they are aware of the fact that mathematical argumentation works differently by insisting that their rule has the status of a conjecture. A little episode of the third part of the transcript illustrates this awareness. At the end of the second part they mentioned that the sequence tends towards two. They are now working on a justification. Matthias remembered that $0,\bar{9} = 1$ and justified this fact authority-based referring to his teacher.

1446 Matthias: So one found out that ohm- ,on(e)- one say ,our teacher told us that ohm- ,one point nine period equals two.

Working Group 1

Such a convention-based conclusion seems to be insufficient or unsatisfactory, therefore Matthias justifies it classification-based.

1449 Tim: [...] ,because one plus nine ninth is precisely two ,but nine ,one ninth ,is zero point one one one one one

Tim and Matthias use convention-based schemes seldomly. However, when they use these schemes, they give up these argumentations lines quickly. This is a hint that they regard these concluding methods as insufficient or unsatisfactory as convention-based schemes do not lead to deeper understanding why a conclusion is valid.

CONCLUSIONS

The combination of the Toulmin's scheme and a collection of topical schemes turned out to be an appropriate tool to describe argumentation and to identify elements of everyday argumentation. In this case, everyday argumentation was the starting point to develop mathematical conjectures. Everyday logical schemes can turn into strategies to come to conjectures and to create ideas of how to justify them. The analysis of the episode presented in this paper focuses on this aspect. To find out more about typical argumentation structures and relations between knowledge construction and argumentation, analyses of different episodes have to be compared. A first hint concerning relations between knowledge construction and argumentation is that argumentation lines with a high concentration of data prevail in the beginning of epistemic processes. This corresponds to phases of gathering and combining in terms of the epistemic action model. In structure-seeing phases, argumentation lines occur where warrants and backings are formulated and sharpened. In the future, several case studies will be compared to deliver deeper insights into relations between argumentation and knowledge construction.

NOTES

1. Ottmers calls these metaphor-based conclusions analogy-based ones. His example for such an analogy-based conclusion makes clear that these analogies are metaphorical. As analogy is understood in a different way in mathematics, I decided to call these conclusions metaphor-based ones.
2. In this study, Bikner-Ahsbahs' epistemic action model is used to describe processes of knowledge construction. The emergence of interest-dense situations will not be analysed. Therefore, I do not enlarge upon this term here. For further information about the theory of interest-dense situations see Bikner-Ahsbahs 2004.
3. To follow the excerpts of the transcript, here are the elements of the sequence presented as decimal fractions:

	Decimal fraction		Decimal fraction		Decimal fraction		Decimal fraction		Decimal fraction

ANALYZING THE PROVING ACTIVITY OF A GROUP OF THREE STUDENTS

Patricia Perry, Óscar Molina, Leonor Camargo and Carmen Samper

Universidad Pedagógica Nacional, Bogotá, COLOMBIA

We present an analysis and outline an evaluation of the proving activity of a group of three university level students when solving a geometrical problem whose solution required the formulation of a conjecture and its justification within a specific theoretical system. To carry out the analysis, we used the model presented by Boero, Douek, Morselli and Pedemonte (2010) that centers on the arguments and rational behavior. Our analysis indicates that the student's proving activity is close to the one we used as a reference.

Key words: evaluation, proving activity, rational behavior, type of argument

INTRODUCTION

Producing and reading proofs are complex mathematical practices because they require being able to articulate many and diverse, not necessarily routine, actions; therefore mastering them is not an easy or direct process. Understanding this has recently impelled research and reflection of a didactic character of the different methodological approaches used to teach proof and proving in the tertiary level, and to subsequent innovations which could lead to satisfactory results in students' learning (see Selden, 2010).

In this regard, since 2004, we have been engaged in consolidating and implementing a curricular innovation whose primary scenario is the Euclidian geometry course that takes place in the second semester of a pre-service teacher program at Universidad Pedagógica Nacional (Colombia). The innovation aims to deliberately support students' learning to prove and seeks to have students conform an ample idea of what proving activity consists of (Perry, Samper, Camargo, Echeverry, & Molina, 2008). Presently, we are interested in finding different types of evidence that will permit us to evaluate, in a long term, the effectiveness of the curriculum design and development achieved with the innovation. We start by undertaking the evaluation of the students' performance in specific tasks that were assigned in the third semester geometry course.

The purpose of this paper is to analyze and evaluate some excerpts of the proving activity displayed by a group of three students when they solve a given problem without the teacher's intervention. In the task, a conjecture must be found, based on a dynamic geometry exploration, and justified deductively. In order to analyze the students' proving activity, we shall use the integrated model presented in Boero et al. (2010). To evaluate the analyzed activity, we shall consider a list of key actions, that we designed in the light of the model, which we consider conform a successful

performance; naturally, the actions are coherent with the learning goals set in the innovation and the learning experiences promoted by it. Thus, we first contextualize the study indicating what we mean by proving activity and by learning to prove, and we mention three key characteristics of the methodological approach to teaching used in the course. Secondly, we expose our interpretation of Boero and his colleagues' model which will guide our analysis. Thirdly, we describe aspects of the experimental design; we include information about the course the students belonged to, state the problem we proposed, present some components of a successful performance to which we compare the students' proving activity, and give details of the data treatment for the analysis. Fourthly, we analyze the evidence that provides elements to evaluate their proving activity. Finally, we expose the evaluation.

STUDY CONTEXTUALIZATION

The purpose of our innovation is to support learning to prove. Thus we promote student participation in *proving activity* that is carried out as a means to develop the geometric course content. For us, *proving activity* includes two processes, not necessarily independent or separate. The first process consists of actions that support the production of a conjecture; these actions generally begin with the computer-based exploration of a geometric situation to seek regularities, followed by the formulation of conjectures and the respective verification that the geometric fact enounced is true. Hereafter, the actions of the second process are concentrated on the search and organization of ideas that will become a *proof*. This last term refers to an argument of deductive nature based on a reference theoretical system in which the proven statement can be a theorem (Mariotti, 1997). *Learning to prove* is a process through which students gradually become more able to participate in proving activity in a genuine (i.e., voluntarily assuming their role in achieving the enterprise set in the course), autonomous (i.e., activating their resources to justify their own interventions and to understand those given by other members of the class community), and relevant form (i.e., making related contributions that are useful even if erroneous).

Three characteristics of our methodological approach to teach proof and proving are the key roles of: (i) the student *geometrical problem solutions* as a means to provide elements that contribute to the development of the course content; (ii) the *interaction* between teacher and students or among students to develop the course content and to support individual learning; (iii) the use of a *software of dynamic geometry* (e.g., Cabri) in the feasibility of an autonomous, genuine and relevant student participation; this resource provides them with an environment in which actions such as empirical exploration, communication and validation of statements are propitiated.

ANALYTICAL TOOL

Boero's et al. (2010) integration of the Toulmin argumentation model and the Habermas rational behavior model highlights some of the elements that must be articulated to face the complexity of proof; we therefore find it useful for our purpose. In what follows, we present our interpretation of their proposal.

Type of argument: Accepting that proving activity involves arguments of different nature, describing it requires focusing on the different types of arguments (i.e. inductive, deductive, abductive) that students formulate during the problem solving process. Every argument, according to Toulmin, has three basic components¹: a statement whose validity is argued by someone (claim), premises that motivate concluding the claim (data) and the statement considered as valid that connects data to claim (warrant). More precisely, the analysis is centered on how the three components are connected, that is, what the structure of the argument is, because our methodological approach induces it and requires it.

Teleological aspect: Considering proving activity as a special case of problem solving, an important part of it is focusing on the goal which must be reached, so that the different actions carried out have a clear purpose. Also included in this aspect are the formulation of a plan to reach the goal, the determination of the strategies that can contribute to following it and reaching the goal, and the control of the latter.

Epistemic aspect: Considering proof as an object that must satisfy epistemic requirements established by the community of mathematical discourse in which it is being constructed or presented, when describing it and evaluating it, the focus is on if there is or not conscious validation of the statements, taking into account shared premises and legitimate forms of reasoning.

Communicative aspect: Considering proving activity as a sociocultural practice, it is natural to take into account the care students have in the way they communicate their arguments, and how conscious they are of the elements, associated to proof, that affect communication.

EXPERIMENTAL DESIGN

The problem proposed to the students

In a one and a half hour class session, the students, in groups of three, worked collaboratively on the following problem. As usual, they were asked to hand in a group document that reports: details of the Cabri construction and exploration, the conjecture formulated as the result of empirical exploration, and its proof.

With Cabri, construct a circle with center C and a fixed point P in its interior. For which chord AB of the circle, that contains point P , is the product $AP \times PB$ maximum?

Working Group 1

The teacher informed the students that they had to work without his intervention. The teacher and the members of the research group acted as non participative observers in some of the student groups, with the intention of registering in video the solution process and intervening, only if necessary, to favor the exposition of ideas by students and thus obtain as complete information of the process as possible.

The students and the course content

The students were registered in the third course of the geometry trend of the pre-service program. They had participated of our methodological approach since their first semester. With respect to the geometrical content covered up to the moment of the proposed task, congruency of triangles, parallelism of lines, and quadrilaterals were given a thorough treatment. With respect to similarity of triangles, the definition, the criteria to determine it, and theorems such as Ceva and Menelao were established. The students had experience in proving properties that are deduced from the similarity of two triangles, and in using the similarity to prove other geometrical properties. The existence of chords, diameters and secant lines was discussed from a theoretical point of view. The *Theorem of the interior point of a circle*, which establishes that a line which contains a point in the circle's interior, intersects it in two points, was proved. The special relations between angles and circles had not been studied. Precisely, with the proposed problem these were expected to be introduced. In this article, we concentrate on the analysis of the activity of just one group (henceforth NAF) that, for the purpose of this research, had no special characteristics with respect to the other groups.

Components of a successful performance

The students perform relevant intentional actions towards the final goal or the recognizable sub-goals throughout the solution process (teleological aspect), such as: modeling the situation in Cabri appropriately; exploring by dragging and measuring; detecting the regularity; producing different and relevant types of arguments (inductive, abductive, deductive) in the different phases of the solution process; enriching the figure with an auxiliary construction, if necessary, to favor a search process of key ideas for the proof. Specifically, to solve the proposed problem, the students construct another chord containing point P to verify that the result obtained with the first chord is also true for the second one or as a mechanism to prove the thesis. They use the two chords to determine two triangles, visualize or conjecture their similarity, establish a path to obtain the equality of the two products involved, and justify such invariance within the theory of similar triangles. They also carry out empirical explorations with Cabri to identify the corresponding angles that are congruent, and to discover the theorem that establishes that inscribed angles that subtend the same arc are congruent, that can be used provisionally as a justification since it is not yet part of their theoretical system.

Working Group 1

The students perform general actions associated with the requirements of the mathematical discourse of proof related to the production of appropriate arguments in the different phases of the solution process (epistemic aspect): every statement that is part of the arguments must be justified; every justification must come from the theoretical system in which they are working; the representation system used provides information only based on the conventions previously established in class; a warrant can be used to obtain a conclusion only if the conditions required in its antecedent have been established before; in a deductive chain the premises change their operative status (i.e., a premise obtained as a conclusion, in one step, can be data in a posterior step); between two deductive chains that lead from the same premises to the same conclusion, the one that presents a simpler path is preferred. Specifically, they look for possible warrants to validate the congruency between at least two pairs of angles, and recognize that in the theory available to them they can only show the congruency of the vertical angles.

The students communicate their ideas carefully: formulating the conjecture as a conditional statement; reformulating the conjecture, if needed, to facilitate the construction of the proof; using the terminology established in the classroom appropriately; and using the format established in class to expose their final proof.

Data treatment for the analysis

The video of the group's work was transcribed, and the observer's figures and notes were included in the margins, so that reading the transcript permitted following the students' detailed activity comprehensively. The transcription was divided in phases, each one covering an important sub-activity of the complete process. The different types of arguments were identified, typified and outlined, and the interventions analyzed to determine signs of the other three aspects of the integrated model. Due to space limitations, we shall present emblematic episodes that well represent the activity we are evaluating.

It is necessary to make two comments. Firstly, when the data for the study was collected, using the model to analyze the activity was not part of the plan; therefore, no questions were designed to promote student allusions to the epistemic and teleological aspects. Secondly, we are not analyzing finished reports made retrospectively, but student conversation when carrying out the task. Thus the arguments are mostly a collective construction, although, occasionally, the observer's questions impel one of the group members to synthesize the discussion and thus assume the responsibility of exposing the co-constructed argument. This is why we evaluate the group's proving activity and not that of individuals.

EVIDENCE TO EVALUATE NAF'S PROVING ACTIVITY**NAF detects that the product is constant, writes the conjecture and sketches a way to prove it**

Alejandro reports the result of their first exploration: "I am measuring \overline{AP} and \overline{PB} to multiply them and check if the maximum is when it is a diameter, or if it is in some other place [...] The product remains the same always [...] even if the measure of the chords change; the product will be the same rotate it wherever we rotate it."

In this fragment, we see signs of an inductive argument. The students, using Cabri, generate innumerable positions of chord \overline{AB} together with the respective products $AP \times PB$ and thereof detect the invariance. The premises that provide evidence (data) to affirm that the product is constant (claim) come from the conditions found in the problem statement and of the numerous cases that are offered by dragging the chord. The warrant is the conjecture that suggests that for any chord that contains P , the product is constant. On the other hand, in Alejandro's verbalization we find an initial plan to answer the question asked in the problem, plan that he carries out in Cabri as he talks, and that is evidence of the presence of the teleological aspect.

The students become involved in writing the conjecture as a conditional statement. To start with they mention the if-then format as the proper one to express the conjecture. With Fabian's intervention: "Shall we put given or must we construct it?" they evaluate if they can assume the existence of chord AB as given or if they must include, in their proof, statements and justifications that theoretically validate the construction of the chord. Afterwards, they agree on a first statement: "*Given a circle with center C , a fixed point P which belongs to the interior and a given chord AB which contains P , then the product $AP \times BP$ is constant.*" However, Nancy manifests inconformity: "No, look, you know what? ... It's better, given a circle with center C and a fixed point P such that P belongs to the interior of the circle, for **any** chord AB of circle C such that P belongs to AB , then the product such and such." Alejandro points out that the purpose of changing the word is to bring out the generality of the fact: "...we had said **one**, only one chord; then, it was saying that only one chord AB exists; now we are saying that for any chord that passes through point P , then it's going to be constant."

The epistemic aspect appears when they ask themselves if they must justify the existence of chord AB ; this suggests that they see the difference between a chord that exists, because it is given in the statement's premises, and a chord whose existence is justified theoretically; they are obeying the class norm of justifying the existence of the geometric objects that are being used. We also see the communicative aspect when they write their conjecture; on the one hand, because they know they have to formulate it as a conditional and, on the other hand, because they note that their first formulation is incorrect since it does not express the detected generality, reason why they include the universal quantifier.

Working Group 1

When they are rewriting the conjecture, Alejandro asks: “In the proof we can construct another chord, right? To have similar triangles.” and explains, “...because what we need to prove is a ratio.” When the observer asks him the reason for the auxiliary construction, he answers “Because we see that the product will always be the same, right? Then another chord can give us similarity or ratio between this side, the segment that we would create new and this...” Nancy amplifies Alejandro’s idea: “We would have that the ratio of... or that by ratios we get that AP times BP is going to be the same for both chords. That way we would confirm that it would be for **any** chord... not only the given one but also the one we compare it with.”

NAF has set the goal: proving that the product is constant for any chord. This leads them to construct two chords that contain P with the purpose of obtaining similar triangles, to thereof work with ratios that will lead to equal products. This goal motivates an auxiliary construction without which, as we know, it is practically impossible to prove the conjecture. We recognize the teleological aspect in the conversation because they sketch a plan to reach their goal and propose an auxiliary construction as a tool to obtain it.

NAF examines how to justify the existence of another chord

As they start writing the proof, they consider how to justify theoretically the existence of both chords that contain P , which they have represented in Cabri. They establish that the first chord is given and that they only have to justify the existence of the other chord. Alejandro points out that they must guarantee the existence of a line through P , maybe motivated by the construction done in Cabri. Nancy mentions that the line must also contain a point of the circle. Fabián says: “To create the line we need the Line Postulate² and it requires the two points. What shall we do?”

In the summarized interchange, the existence of the other chord containing P can be seen as the claim of a possible abductive argument that does not take shape because the warrant is not explicit (i.e., the chord is a subset of the line). In contrast, the existence of the line containing P (and not the given chord) becomes the claim of an abductive argument when Nancy indicates the necessity of having two points (data) and Fabián completes it by mentioning the Line Postulate (warrant). The goal they establish, due to this argument, is to justify the existence of the two points; it guides their next actions. Thus the teleological aspect is present. With respect to the epistemic aspect, it is worth noting that in the first case the warrant is not mentioned while in the second it is.

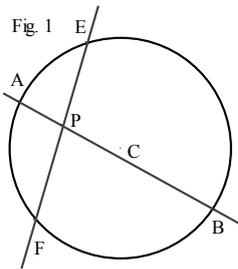

Trying to justify the existence of two points that determine the line whose existence they want to show, Nancy suggests using the Interior Point of a Circle Theorem, and, due to Alejandro’s petition, she says: “if we have a circle and a point of it and a line, ah! no, but we need a line anyway, that is we have to construct it.” When Nancy discards this possibility, Alejandro proposes a plan: “The best would be to construct

Working Group 1

a line by the Line theorem [Postulate] and then we can say that the points intersect the circle.” NAF eventually realizes that neither way is useful for their purpose.

The claim of the argument in the conversation is the existence of two points, P and a point on the circle; the failed warrants are the Interior Point of a Circle Theorem and the Line Postulate together with its intersection with the circle. The data required is the existence of a line that intersects the circumference in two points. The epistemic aspect is evidenced when Nancy realizes that they do not have the elements of the hypothesis of the theorem they want to use, and that, therefore, they must discard it.

NAF discards the established path to validate the existence of a pair of congruent angles

The students have two chords that contain P (Fig. 1). Alejandro declares the congruency of $\angle FPB$ and $\angle APE$ because they are vertical angles. Nancy questions: “And, from there, where are we going?” As an answer, Fabián proposes the following plan: “We construct the triangles and then we talk about the angles to talk about similarity.” Alejandro adds that with the Angle-Angle Criteria they would already have similarity. Nancy objects:

“And, where is the other [pair] angle? Okay, we already have these two angles, and the others, where are we going to get them? We need another one.” Once they have the triangles, Fabián discards parallelism as a way to reach their goal: “There are no parallels. Because if we had them, this would facilitate finding alternate interior angles, and we already have the other angle and similarity would be the result.”

We find two abductive arguments. In the first one, the claim is the existence of similar triangles, the warrant the Angle-Angle Similarity Criteria, and the data required the congruency of two pairs of angles, of which one is already guaranteed. In the second one, the claim is the existence of another pair of congruent angles, the warrant is the theorem that guarantees that alternate interior angles between parallel lines are congruent, and the data required is assuring that two lines are parallel.

We point out three issues. Firstly, we can see the control Nancy exerts over the trend of the activity they are developing, sign that she is conscious, on the one hand, of the necessity of not losing sight of what they want to justify and, on the other hand, of the class norm of justifying every statement in the context of the situation they are studying. Nancy’s interventions —the first one of teleological nature and the second of epistemic nature— lead them to formulate a plan or discard a possible path. Secondly, Fabián’s argument, with which he discards parallelism as useful to reach their goal, makes us think that he tacitly assumes that the congruent angles are $\angle EBA$ and $\angle FAB$ or $\angle BEF$ and $\angle AFE$, which is not correct. Thirdly, we are surprised that, during a good part of their activity, NAF refers to similar triangles without explicitly establishing the correspondence for the similarity. Maybe they could have established it much sooner than when they actually did if they had allowed

themselves to explore the situation numerically with Cabri (angle measurements, calculating the proportion) as Fabián suggested: “The only thing we can do is measure this one with..., the ones that are going to determine, form similarity and see whether that proportionality remains in the three [angles] and then, with that we can then determine that they [the triangles] are similar.” Nancy responds: “[...] we find measures and that, but how do we find it here... geometrically?”, and Fabián accepts the veiled objection: “With the postulates and that.”

NAF determines the proportionality of the measurements of the sides and the congruent angles

After various failures in trying to find the way to validate the congruency of two angles, without indicating exactly which pair they are referring to, Alejandro turns to the observer: “Help us. How do we relate another angle?” She responds: “Are you sure that the triangles are similar?” Nancy explains why they are similar: “[...] they are similar, not because of the angles but... because we have this angle [referring to the vertical angles] and as Alejandro showed, having AP times PB is equal to EP times PF [she writes $AP \times PB = EP \times PF$] we can make our proportion [...] Then AP is to PF as EP is to PB [writes $\frac{AP}{PF} = \frac{EP}{PB}$] and that way we have it.” Fabián asks surprised: “ EP to PB ? ... This segment is to this segment ... which triangles are you talking about?” Nancy responds: “Of triangles FPB and APE because as you superimpose [moves hand] let’s say this one [signals $\triangle APE$] over this one [signals $\triangle FPB$] we have that this [shows \overline{PE}] is to this one [points to \overline{PB}] as this [shows \overline{AP}] is to this [points to \overline{PF}].” Alejandro adds: “In the calculator I looked at angle PAE [...] and angle PFB and they are congruent.”

To explain why the triangles are in fact similar (claim), Nancy recurs to the Side-Angle-Side Similarity Criteria (warrant) which she does not mention. She takes into account the empirically found fact when exploring the situation: the constant product of the measures of the segments determined by point P on each chord of the circle (data). Using that fact, she obtains the proportionality of the measurements (intermediate claim). Thus we see that with the purpose of justifying the similarity of triangles FPB and APE , Nancy carries out a deductive argument. It must be noted that the students are conscious that such reasoning is not the adequate one for the situation they are tackling because they use what they want to prove.

CONCLUSIONS

As we compare the description of NAF’s activity with the components established for a successful performance, we recognize that NAF sets four sub-goals that lead them to the expected goal: detect regularity; formulate a conjecture in the terms used by the class community; justify the auxiliary construction of a chord; and prove the congruency of two pairs of corresponding angles. Intentional actions to reach the sub-goals are evidenced although proving that the triangles are similar is not

Working Group 1

proposed with the precision required and desired. Only after more than an hour, does NAF discover which are the corresponding angles that guarantee the similarity, and they never find the relation between the angles and the circle which would permit justifying their congruency. Maybe with this deficiency in their proving activity, many of their actions to search for the justification could be considered as not relevant. Related to the former is the fact that NAF prefers using the theory as resource more than the empirically obtained information; this shows an undesired unbalance between exploratory actions and justification actions. Yet, the abductive arguments that arise show that NAF has enough knowledge of the theme to allow them to make connections that are not incongruent with the situation they are studying; these arguments impulse and guide their actions. Although in the whole process we evidence skill in handling the teleological, epistemic and communicative aspects, they still lack the mastery needed to perform as an expert. Or maybe we cannot expect the students to act as if they were already writing a report of successful arguments, in the course of the proving activity process.

NOTES

1 In fact, Toulmin's model presents six components of an argument: claim, data, warrant, backing, qualifier and rebuttal.

2 The Line Postulate states that given two points there exists a unique line containing them.

ON THE ROLE OF LOOKING BACK AT PROVING PROCESSES IN SCHOOL MATHEMATICS: FOCUSING ON ARGUMENTATION

Yosuke Tsujiyama

Graduate School of Comprehensive Human Sciences, University of Tsukuba, Japan

The purpose of this paper is to theoretically examine the role of looking back at proof-planning processes in school mathematics from the perspective of argumentation. Various research studies have elaborated the significance of proof and proving in school mathematics. A particular focus of this paper is on what students can gain by looking back at proving processes that do not appear explicitly in the presentation of proof. Examples of hypothetical proof-planning processes are chosen to illustrate that two kinds of ideas can occur by looking back at the processes. In particular, the ideas are related to how to identify why the statement is true and how to prove the initial statement and another related statement.

Keywords: proving, looking back, proof-planning, argumentation, changing condition

INTRODUCTION

Proof and proving should be central to students' school mathematical experience (Yackel & Hanna, 2003). Many research studies have addressed to the question: what students can/should gain through proof and proving. Several studies among them focus on various functions of proof from a theoretical perspective (de Villiers, 1990; Hanna, 1990) or using empirical evidence (Miyazaki, 2000). In addition to the issue of verification of truth of a statement, these studies have pointed out the need to investigate what roles proof can/should play, and how we can apply such functions.

On the other hand, more recently, Hanna & Barbeau (2008) have focused on another role of proof, inspired by Rav's (1999) philosophical work, as a way to convey mathematical methods, tools, strategies and concepts. Their discussion is based on what has been underestimated in the mathematics education literature when this literature "seem to have dealt primarily with the logical aspects of proof and with the problems encountered in having students follow deductive arguments" (Hanna and Barbeau, 2008, p.347).

As to the discussion on the functions, Hanna & Barbeau emphasize the role of proving as a process, over the role of proof as a product. For example, Hanna and Barbeau describe how students can obtain the technique of 'completing the square' by illustrating how it can appear in proving the formula for the solution of a quadratic equation. Then they mention that this technique "does not stem logically from a previous statement or axiom" but "is a topic-specific move" and useful for their on-going mathematical learning (ibid, p.349).

This study focuses on the educational significance of proving processes. Moreover, the motive of this study is to design teaching material to promote improvement in students' proving abilities and habits and to encourage further mathematical inquiry from the side of the students by reflecting on past proving processes. For example, students will try out various approaches in a process of proving. If they are promoted to reflect the past process to see how well each approach worked or not, they can be expected to obtain typical ways of proving which are useful not only for the statement at hand but also for many other statements which they will meet in the future. Since many students have difficulties in reaching ideas concerning how to establish a proof, acquisition of such ways can be considered valuable. However, the value of promoting students' reflection on the past processes to extract general ways of proving has been underestimated in the existing related literature. Therefore, it is necessary to answer the question: what can students gain through proving processes? This paper examines this question theoretically as a platform for future empirical studies.

LOOKING BACK AT PROOF-PLANNING PROCESSES

Literature review and research questions

To gain something through proving processes, students need at least to reflect and clarify what they have done in the processes. In relation to these activities, Polya (1957/2004) refers to the act of "looking back", which involves not only checking errors or the insufficiency of one's own activities or their outcomes, but also finding new problems or ideas based on the activities or outcomes (pp.14-16).

About the aspects of looking back, checking errors and identifying insufficiency are discussed in Heinze et al. (2008) in terms of "coordination". In addition, the studies on the roles and functions of proof (e.g., de Villiers, 1990; Hanna, 1990) discuss finding new problems or ideas based on a product of proof, although they do not use the term of looking back. Tsujiyama (2010) also analyses how mathematicians from the ancient Greek era and beyond could find, by examining proposed proofs, not only aspects of insufficiency in the proofs but also ideas which were applicable to other related proofs.

These studies focus on the part of proving processes related to a product. In contrast, Hanna & Barbeau (2008) focus on obtaining general ideas based on processes of proving rather than products. To reconcile the perspectives appearing in the literature, this paper focuses on looking back at processes that are not evident in a product.

Among other aspects, this paper especially focuses on proof-planning processes. Polya (1957/2004) listed the following four phases of proving: understanding a problem; devising a plan to establish a proof (this paper refers to this as "proof-planning"); constructing a proof; and looking back. Shimizu (1994) proposed, through a hypothetical process, that proof-planning in particular involves important

ideas that are not apparent from a product. Further, Thurston (1994) states that informal elements occur even when professional mathematicians are engaged in producing a proof and these elements promote their understanding of proof and their on-going work.

Therefore, this paper proposes to examine the following research questions: “by looking back at proof-planning processes, what kinds of new problems or ideas can students obtain?”; “what is the significance of the problems or ideas?”

Ways of proof-planning

Proof-planning is to find deductive connections between the statement and other known theorems, in order to establish a proof of the statement. Nevertheless, in processes of proof-planning, even mathematicians do not necessarily think only in a formal or deductive way. In order to capture students’ activities, we need to widen our awareness of different ways of proof-planning. This paper takes a wide perspective in analysing ways of proof-planning by distinguishing three components: order (i.e. how to proceed from the premise to the conclusion); objective (i.e. the statement to be proved); and manner (e.g. formality).

First, about order, it is extensively pointed out in the literature that not only forward reasoning but also backward reasoning are useful in proof-planning. In recent years, Heinze et al. (2008) have analysed complex processes of constructing multi-step proof from the logical point of view. They focus on how to deal with intermediary conditions/conclusions obtained by backward/forward reasoning; then they point out an essential aspect of proof competence that they call “coordination” (p.445). According to their study, this kind of looking back during a proof-planning process plays a role in choosing the most propitious deduction available.

For the second component, Polya also suggests that changing the statement can be useful in proof-planning. When backward and forward reasoning do not work well, it is important to find special, general or analogous problems and “try to solve first some related problem” (Polya, 1957/2004, p.10) by changing the initial statement. Proof-planning by changing the condition is important for the following two reasons. First, especially in geometry, students tend to spontaneously consider only special cases. For example, when students prove the statement: “diagonals in any parallelogram intersect at their midpoints”, they usually draw diagrams and judge if the statement seems to be true or not. Intentionally or not, through such activities, they may consider special cases such as a rhombus, rectangle or square.

Another reason to consider changing the condition is that it is an effective way to find a useful problem for solving the initial problem in mathematics. Particularly, in regard to specialization, Polya (1954) refers to using “a leading special case”: restricting the initial problem to a simpler case; after, utilizing a solution of the simpler case in order to solve the initial problem (p.25). This kind of proof-planning

is seen in several articles but its value has been underestimated in mathematics education literature.

For example, Hanna and Barbeau (2008), note that students can extract the technique often referred to as ‘completing the square’ through considering how to obtain the formula for the solution of the quadratic equation $ax^2 + bx + c = 0$. In the discussion, they refer to an instance where students restrict their attention to an easy case of the equation, $x^2 = k$ where k is positive. Then the students consider why it is easy to solve $x^2 = k$ and realize that the key lies in the absence of the linear term (pp.348-349). Starting with this illustration, Hanna and Barbeau argue that the technique of completing the square that students possibly can obtain through the above process “does not stem logically from a previous statement or axiom” (ibid, p.349). From the focus of this paper, it is remarkable that neither the equation $x^2 = k$ nor its solution appears explicitly in the presentation of proof. Moreover, in the discussion, Hanna and Barbeau do not analyse or even mention the role of the specialization to $x^2 = k$.

The third component deals with ‘manner’. In contrast to a formal manner towards a product of proof, processes of proof-planning have informal aspects. Especially in geometry, students can use a diagram for proof-planning. For example, Douek (1999) considers the references used in proof and proving as involving not only mathematical theory but also diagrams or visual evidence and other kinds of representation. Using empirical evidence she points out that semantically routed arguments including diagrams or numerical examples play an important role in proving.

Thus, this paper focuses on the following three ways of proof-planning: backward/forward reasoning; changing the condition; referring to diagrams.

PROOF-PLANNING PROCESSES BASED ON ARGUMENTATION

Since students do not know how the product of proof should be, they may make errors in directing their proof-planning processes. Thus, in analysing proof-planning processes, it is necessary to consider that the processes may have plausibility. That means, an intermediary condition/conclusion obtained by backward/forward reasoning is not necessarily used in the proof; reasoning obtained under the changed condition is not necessarily applicable for the initial condition; an idea found based on diagrams does not necessarily work generally. Therefore, this paper focuses on the concept of argumentation, that is, a process of making arguments that may include plausibility and of examining already made arguments. An argument is logically connected (but not necessarily deductive or formal) reasoning (Douek, 1999).

In this section, first, we briefly summarize the literature on proof/proving and argumentation. Second, we characterize proof-planning processes according to the nature of argumentation. Third, based on the characterization, we illustrate two kinds

of hypothetical proof-planning processes. This illustration is used to discuss the role of looking back at proving processes in the next section.

Proof/proving and argumentation

Based on mathematicians' accounts of informal elements as made by Lakatos (1976) or Thurston (1994), studies on proof/proving and argumentation mainly analyse how students can (or cannot) construct a proof by utilizing argumentative activities. Several studies point out connections between argumentation and proof (e.g. Douek, 1999), while other studies point out the gap between them (e.g. Balacheff, 1991). Prompted by the findings of these studies, Pedemonte (2007) focuses not only on "content" but also on "structure" and introduces Toulmin's (1958/2003) "layout of arguments" for a methodological tool to analyse relationships between them.

These studies focus not only on processes of making arguments that may include plausible content or structure, but also on processes that can remove the original plausibility. In addition, for the aims of this paper, we need to focus on reasoning that does not necessarily appear in a product, for example reasoning that students use in order to obtain an idea of proof but do not use in order to present a proof. Therefore, this paper re-examines the nature of argumentation and, by synthesizing findings in the above literature, it characterizes proof-planning processes.

Characteristics of proof-planning from the viewpoint of argumentation

Making an argument based on observations concerning the conclusion

The studies on proof/proving and argumentation mainly analyse contents (e.g. reference to diagrams) and structures (e.g. abductive reasoning) (Pedemonte, 2007). What is common to both is an emphasis on observations concerning a conjecture. For example, Pedemonte mentions the role of "abductive argumentation", which "allows the construction of a claim starting from an observed fact" (Pedemonte, 2007, p.29), and some difficulties related to it. Toulmin (1958/2003) also emphasizes such observations and regards that an assertion that is going to be claimed comes first. Thus, one aspect of argumentation is to make an argument based on observations concerning the conclusion. Even if the proposed statement might be false in general, the foci of the literature are on the processes of justifying a conjectured "fact". Therefore, this aspect of argumentation is only suitable for the case when the conclusion holds.

Thus, the first characteristic of proof-planning processes is: (i) to make an argument for which a claim holds based on observations.

Uncertainty

Toulmin's "layout of arguments" consists of six related components of an argument: three elements "Data", "Warrant" and "Claim" which have similar functions to minor premise, major premise and conclusion in syllogism; and three more elements "Rebuttal", and "modal Qualifier" which are used for ordinary arguments (Figure 1

uses abbreviations by their initials). Since the framework can capture logical and plausible aspects at the same time, it is an effective tool for the aim of this paper. In particular modal qualifier functions to show uncertainty of an argument. This element is necessary since we sometimes have to make an argument by limited data or warrants (Toulmin, 1958/2003, pp.93-94).

Thus, the second characteristic is: (ii) to make an argument which may include uncertainty.

Adding the condition

Rebuttals represent “conditions of exception” and are used when one notices exceptional cases or conditions under which the data and the warrant cannot implicate

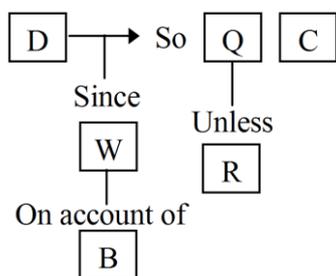

Figure 1 Layout of arguments
(Toulmin, 1958/2003)

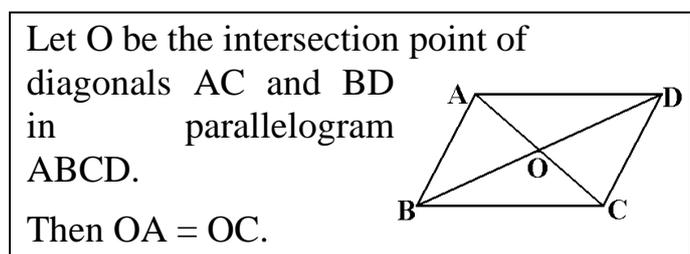

Figure 2 Statement α'

the claim (ibid, p.93). Since such cases are special cases, one needs to consider several cases and check if the claim holds or not for each case. This consideration is necessary because even having certain data and warrant sometimes cannot implicate a claim without a suitable connection between them.

Thus, the third characteristic is: (iii) based on checking special cases or conditions under which a claim does not hold, to make an argument that takes in consideration exceptional cases or conditions. In this paper, “unless” in Figure 1 is replaced by “under the condition”, in order to allow usage also in an affirmative form.

Hypothetical proof-planning processes

To illustrate hypothetical proof-planning processes based on the characteristics (i)-(iii) above, we consider Statement α , “diagonals in any parallelogram intersect at their midpoint”. We neglect possible issues in understanding the statement and assume that students ‘translated’ Statement α to Statement α' with the diagram shown in Figure 2 leaving the demonstration that $OB = OD$ for later.

In Japan, 8th graders are expected to be able to tackle proving Statement α . Students have already proved several statements such as “opposite sides in any parallelogram are equal” or “opposite angles in any parallelogram are equal” based on properties concerning parallel lines, alternate angles and triangle congruency. The key idea in proof-planning of Statement α' is to find an appropriate pair of congruent triangles.

Working Group 1

If students use backward/forward reasoning successfully, they can find a pair of triangles ADO and CBO or ABO and CDO. However, many of the students seem to have difficulties in processing the reasoning. These difficulties seem to be related to the lack of students' experience of working with such complex diagrams.

Thus, we assume that students could not find an appropriate pair of triangles; instead they refer to the diagram and try to change the condition. Students will consider several cases, for example rhombus, rectangle, square, trapezoid and so on. The conclusion holds for some cases, but it does not for other cases.

On examining cases for which the conclusion holds

In the case of a rhombus, students can easily see many pairs of triangles that seem congruent by referring to a diagram. If they focus on a pair of triangles ABO and CDO (or ABO and ADO and so on), they can verify that the triangles are congruent by the

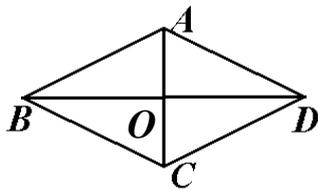

Figure 3 Diagram in the case of a rhombus

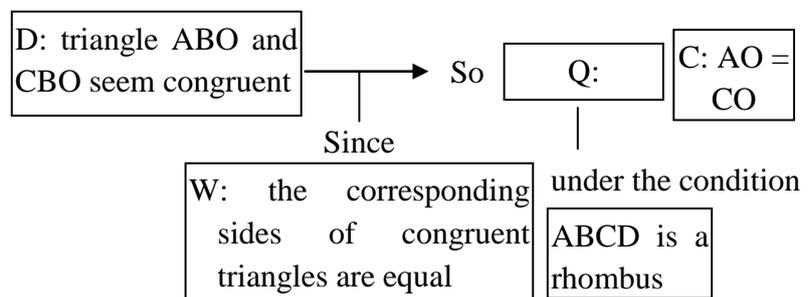

Figure 4 Argument in the case of a rhombus

ASA congruency condition by backward/forward reasoning. On the other hand, if they focus on a pair of triangles ABO and CBO (or ADO and CDO), they will find that none of the congruency conditions SAS, ASA and SSS can be applied.

In the latter case, students do not have enough information to make a deduction to show the property “triangles ABO and CBO are congruent” (i.e. they only know that $AB = CB$). At this time, students would be uncertain whether they can deduce the property. However, if they consider based on observations that the property ‘probably’ holds, they can make an argument as shown in Figure 4, due to the characteristics (i) and (ii) of proof-planning.

By changing the condition back to the general case of a parallelogram, students can check whether this argument holds for the case of parallelogram. Then they will confirm that neither triangle ABO and CBO nor ABO and ADO are generally congruent, but they will also feel that triangle ADO and CBO seem to be congruent. Thus they arrive at the key idea in proof-planning of Statement α' .

On examining cases for which the conclusion does not hold

If students consider a trapezoid, they can easily find, by referring to a diagram, that the conclusion does not generally hold. However, due to the characteristic (iii) of

proof-planning, they can look for an additional condition which makes the conclusion “ $OA = OC$ ” hold. If they consider “ $AB \parallel CD$ ” as such a condition, they will find that this idea does not help. On the other hand, if students notice the definition of a trapezoid and the relationship between parallel lines and alternate angles, they can argue “angle $DAC = ACB$ ”, as well as “angle $ADB = DBC$ ” (Figure 5).

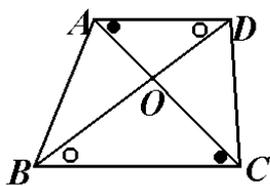

Figure 5 Diagram in the case of a trapezoid

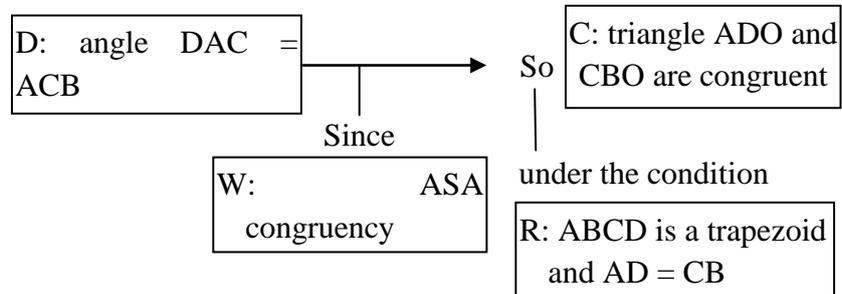

Figure 6 Argument in the case of a trapezoid

In the latter case, they have found out that two angles of the triangles ADO and CBO are equal. By backward reasoning, they would find out that, if the condition “ $AD = CB$ ” is added, the conclusion “ $OA = OC$ ” holds by ASA. Due to the characteristic (iii) of proof planning, they can make an argument on the lines indicated in Figure 6.

By changing the condition back to the case of a parallelogram, students will notice that “ $AD = CB$ ” holds by the known proposition “opposite sides in any parallelogram are equal”. Thus, they can deduce that triangle ADO and CBO are congruent.

THE ROLE OF LOOKING BACK AT PROOF-PLANNING PROCESSES

Even if students manage to construct a proof of the initial Statement α , the presentation of the proof will not show the practices concerning the above processes (e.g. Figure 4 or 6) but only show a sequence of deductive reasoning from the premise to the conclusion of Statement α . Supposing that students reach a proof by going through one of the above processes, we discuss what kinds of new problems or ideas could occur by looking back at the process that does not shown in the presentation of the proof.

The sufficient condition of the conclusion

Let us take the case of a trapezoid, for which the conclusion does not hold. By looking back at the proof-planning process related to Figure 5 and 6, students can compare the case of considering a parallelogram to the case of considering a

trapezoid, that is, cases where the conclusion holds and where it does not. Hence, they can discover a sufficient condition that ensures that the conclusion holds, as follows.

The process related to Figure 6 shows that a key condition to implicate the conclusion “ $OA = OC$ ” is “ $AD = CB$ ”. In detail, in addition to “angle $DAC = ACB$ ” and “angle $ADB = DBC$ ” (which hold in the case of a trapezoid as well), “ $AD = CB$ ” holds in the case of a parallelogram (which does not hold in the case of trapezoid).

The value of this sufficient condition is that students can obtain an answer to the mathematically important question: “why do diagonals intersect at their midpoints for parallelograms but not for trapezoids?”. By looking back at the above process, students can answer: “because for parallelograms, not only opposite sides are parallel but also these sides have equal length”.

What has just been said was made to illustrate the explanatory role of proving processes, inspired by the explanatory role of proof as a product discussed in the literature. To utilize the explanatory role of proof, students have to identify the crucial elements raised from all the deductive connections that appear in the proof. This seems difficult for many 8th graders who are not attuned to mathematical logic. In contrast, the process illustrated above develops only for the purpose of proving Statement α . To utilize the explanatory role of proving, students only have to look back at the process.

A statement which was not proved

We now take the case of a rhombus, for which the conclusion holds. By looking back at the process related to Figure 4, students are able to prove Statement β , i.e. “in any rhombus $ABCD$ triangles ABO and CBO are congruent”, which they considered to be ‘probably’ true but they were not able to deductively show at that time. After proving Statement α , by using it they can easily prove Statement β .

The value of isolating and proving Statement β lies not only in posing new problems (cf. the discovery function of proof) but also in obtaining ideas of how to change the condition. In the above process, students obtained ideas how to prove Statement α (that concerns parallelograms) by considering rhombi instead. Reversely, in looking back at the process, they can obtain ideas for proving a new situation concerning rhombi (i.e. Statement β) by considering parallelograms. From both experiences, students will appreciate that changing the condition is a useful way for proof-planning for both the initial statement and changed statement.

CONCLUDING REMARKS

The analysis made in this paper suggest that there are other roles of looking back at proving processes than those that appear in the related literature such as Hanna and Barbeau (2008) or studies on functions of proof. However, the analysis is not based on actual students’ practices but based on hypothetical illustration. Considering the

fact that many students have difficulties in constructing proof or looking back at a proof, it would be a great effort for them to look back at proving processes. Therefore, there is an especial need for empirical studies on how teachers can promote students' practices of looking back, and on designing situations for which students can appreciate the practice. The analysis also suggests that it can be useful to give students opportunities to compare different eventualities that can occur in proving the same statement.

ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to Dr. Martin Downs (University of Patras) for his very detailed and significant suggestions on earlier version of this paper. I also would like to thank Dr. Viviane Durand-Guerrier (Université Montpellier 2) and Dr. Joanna Mamona-Downs (University of Patras) for their arrangements and considerations for my situation as well as the reviewers and participants in the WG for their valuable comments on my presentation. This study is supported by research grants from the Japan Society for the Promotion of Science as a Research Fellow.

MAKING THE DISCOVERY FUNCTION OF PROOF VISIBLE FOR UPPER SECONDARY SCHOOL STUDENTS

Kirsti Hemmi

Clas Löfwall

Mälardalen University, Sweden

Stockholm University, Sweden

This paper presents an analysis of a teaching experiment with seven high achieving upper secondary school students in Sweden focusing on the de Villiers' discovery function of proof. The aim of the experiment was to test if it is possible for students to get insights to, and use, this function. The data consists of a tape recorded introductory pass, students' group work and the final discussion together with the students. The results show that the students did get some insights about the function. However, it was difficult for the students to construct the original proofs in order to use them to discover new results. The paper also shows that the function of discovery needs to be explored and clarified, as there are different interpretations of it in our field.

Key words: mathematical proof, discovery function, transparency, upper secondary school mathematics

INTRODUCTION

Many mathematics educators have explored and discussed the functions of proof in mathematics as science (e.g. conviction, explanation, intellectual challenge) and their relevance for the teaching and learning of proof (e.g. Bell, 1976; de Villiers, 1990; 1999; Hanna 2000; Weber, 2002) Several studies also apply these functions in empirical studies (e.g. Knuth, 2002; Hemmi & Löfwall, 2009). The discovery function was first presented by de Villiers 1990. With this function he refers to discovery/invention of new results by purely deductive manner exploring and analysing a proof.

To the working mathematician proof is therefore not merely a means of a *posteriori* verification, but often also a means of exploration, analysis, discovery and invention. (de Villiers, 1990, p. 21)

New results in his examples often refer to generalisation of the initial statement. The function of discovery as de Villiers defined it has not been so much in the focus of empirical research. Miyazaki (2000) conducted a teaching experiment with tasks specifically designed for students' engagement with activities connected to the discovery function. However, his concept of the function is wider than the one that de Villiers (1990; 1999) presents.

The functions of proof are sometimes interpreted in different ways by researchers. There is also some confusion about the difference between the concept of *function of proof* on the one hand and *approach to proof* on the other hand (i.e. how we work with proofs and proving and how we present mathematics) (c.f. Hemmi, 2010). For

Working Group 1

example, Knuth (2002), although referring to de Villiers, connects the function of discovery, not to finding new truths by deductions, but quite the opposite, to inductive ways of finding patterns and making conjectures that may be followed by deductive proofs. Hence, there seems to be a need to scrutinise and clarify also the concept of function in order not to create confusion between different research results and, in the end, their consequences to the teaching practice.

De Villiers (2007) discusses the recent focus on the investigative working manners for example in the mathematics textbooks and points out that they do not promote students' understanding of and skills in using the function of discovery but leads rather to the need for verification, the function that has traditionally been in focus in mathematics education. We do not question that "new" ways to approach proof (investigations-conjectures-proofs) may enhance students' understanding and appreciation of the verification function in another way than just confronting them with complete proofs constructed and verified by others. We also agree with de Villiers (2007) when he points out the importance of the balance between experimentation and deductive thought.

The aim of our ongoing explorative study is to develop and test some tasks that could enhance students' understanding of the discovery function as defined by de Villiers (1990). We also take as our starting point that proof sometimes provides valuable insights into why something is true and that looking back and reflecting on it can enable one to generalise or vary the results in different ways (c.f. de Villiers, 2007). We delimit to look at the function of discovery more narrowly than Miyazaki (2000) in order to be able to scrutiny some details in this function as well as students' learning and understanding of it. The earlier studies have mainly focused on geometrical problems. In our study, we explore this function and students' encounter with it within both algebraic and geometrical contexts.

THEORETICAL STANDPOINTS

We look at our experiment from the perspective of social practice theory applied to proof and proving in mathematical practice (Hemmi, 2008) and consider proof as an essential *artefact* in mathematical practice. Artefacts are tools that mediate knowledge between the social and the individual. According to the theory there is a balance between how much to focus on artefacts and how much to work with them without a focus on them, called the *condition of transparency*, and a lot of research in our field illuminates this balance in different ways (c.f. Hemmi, 2008). According to the social practice theory, an important part of learning is experiencing meaning in the practice (Wenger, 1998). Understanding the role and functions of proof in mathematical practice could enhance students' experience of meaning in both scrutinising and reflecting on complete proofs and trying to construct their own proofs. Teaching is seen to only offer possibilities for learning and we want to study

what aspects of the object of learning become visible for the students (c.f. Marton & Booth, 1997).

What we mean by the discovery function

The example that de Villiers (1990; 1999) gives in order to enlighten the function of discovery is about a kite where the midpoints of the sides form a rectangle. The perpendicularity of the diagonals is the essential step in the proof and the property of equal adjacent sides is not required. Hence, it was possible to generalise the result to any quadrilateral with perpendicular diagonals. Recently, de Villiers (2007) presents another problem that further enlightens the function of discovery. Miyazaki (2000) extends the meaning of the discovery function to concern not only the generalisations of the original results by using the proof but also finding tacit assumptions, making new mathematical concepts and so on (Miyazaki, 2000, p. 5).

This is a very wide conception about the discovery function and some of the aspects Miyazaki includes in the function (e.g. finding tacit assumptions) have been connected to the function of systematisation for example by de Villiers (1990; 1999).

The aim of our study is to make visible certain aspects of the discovery function for upper secondary students in order to enhance their understanding of them and at the same time enhance their appreciation of proof as a useful tool in mathematical activities. Therefore, we created some special problems the proofs of which could be used for finding new results.

Miyazaki (2000) first let students work with a proving task and analyse the logical structure of their individual proofs carefully. Then, the students received an additional problem where they would study the conditions of the initial problem and find out generalisations. The Swedish students are not as familiar with proving tasks as the Japanese students seem to be according to the results of Miyazaki's study. We also wanted to control the experiment by holding some variables fixed in order to be able to look at more limited aspects of the function than Miyazaki did. Therefore, we focused on the investigations of the initial proofs in order to find out more general statements that the same proof would work for. In Miyazaki's experiment, new proofs were sometimes needed in order to solve the additional problem. In our examples, this is not the case.

The following examples illustrate our view of the discovery function and were used when introducing the students to the topic. We also carefully present the proofs of the examples in order to show the possibilities of using the function in different ways.

Statement 1

In a rectangle the midpoints of the sides are connected. Then one obtains a parallelogram.

Proof

Draw the diagonal in the rectangle. We will use the following theorem in Euclidean geometry:

Let P be a point on the line AB and Q a point on the line AC. Then PQ is parallel to BC if and only if $AP:PB = AQ:QC$.

It follows that the line connecting the two midpoints on the same side of the diagonal is parallel to the diagonal:

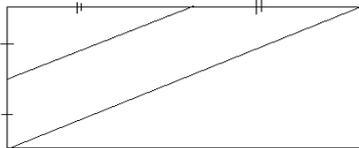

Figure 1

The same is true for the side on the other side of the diagonal. Hence these two lines are parallel. Also, we find that the other two lines are parallel, by considering the second diagonal.

QED

Analysing this proof, we see that we have not used the fact that the quadrilateral is a rectangle. The proof goes through as it stands for any quadrilateral. Hence, we get a new true statement:

Connecting the four midpoints of the sides of an arbitrary quadrilateral, yields a parallelogram.

In this way we have got a more general result, by realising that the proof for the original statement is valid under weaker assumptions.

It is also possible to obtain new results, by realising that the proof in fact proves more than the original statement. In the next example we will see an application of this. One can combine these two ways to find new truths by both making the assumptions weaker and the conclusion stronger. Formally, this may be illustrated in the following way:

$$A \Rightarrow C \Rightarrow D \Rightarrow B$$

Here $A \Rightarrow B$ is the original statement and $C \Rightarrow D$ is the newly discovered statement.

Another way to create new statements is by “generalisation”. The proof is perhaps a special case of a more general proof. In the above example we see that the proof uses a theorem in the special situation where the proportion is 1:1. The proof works equally well if we instead divide the sides outgoing from two opposite corners in the

Working Group 1

same proportion. Hence, we get the following generalisation of the original statement:

In a quadrilateral the two sides outgoing from a corner are divided in the same proportion. The same proportion is also used to divide the two sides outgoing from the opposite corner. Connecting these four points gives a parallelogram.

Next, we illustrate what we mean by the discovery function with an algebraic example.

Statement 2

If two prime numbers greater than 2 are added, then the result is not a prime number.

Proof

A prime number greater than 2 cannot be divisible by 2. Hence it is 1 greater than an even positive number. If two such numbers are added, the result is a number which is 2 more than an even positive number. This number is greater than 2 and divisible by 2 and hence it is not a prime number.

QED

Analysing the proof, we see the following structure:

x, y prime numbers $> 2 \Rightarrow x, y$ odd $> 1 \Rightarrow x+y$ even $> 2 \Rightarrow x+y$ not prime

We may hence discover a new truth by both weaken the assumptions and draw a stronger conclusion:

$$x, y \text{ odd } > 1 \Rightarrow x+y \text{ even } > 2$$

Compare with the general picture above, $A \Rightarrow B$ is replaced by . Finally, we remove the assumption, $x, y > 1$, and weaken the conclusion to, $x+y$ even, to obtain a more aesthetic statement. Hence, we have discovered the following truth by examining the proof.

The sum of two odd numbers is even.

Is it possible to find generalisations?

Here is one possible generalisation (with the same proof):

If the integers a and b , when dividing them with the integer k , have the rests r and s and $r+s$ is divisible by k then also $a+b$ is divisible by k .

The following two problems were left to the students to work with, in two groups during about one and a half hour.

Problem 1

Let n be an integer which is not divisible by 3. Prove that $n^3 - n$ is divisible by 3.

Problem 2

Working Group 1

Two circles intersect at the origin of an orthogonal coordinate system. The centre of one of the circles is on the x-axis, while the centre of the other circle is on the y-axis. The circles intersect at one more point. Prove that they intersect there under right angle.

METHODOLOGY

This is the first explorative study where we focus on the function of discovery. We introduced this function to a group of high-achieving upper secondary school students, two girls and five boys. The students were to finish their secondary level studies during the time of the experiment. We chose these students because they had taken some special courses in mathematics, for example in geometry, so we could be sure that they were familiar also with geometrical proofs. In Sweden, not much time is usually spent on geometry in ordinary upper secondary school classes.

During the introduction, we presented the examples above. Clas led the session and engaged also the students in the presentation with appropriate questions. The students did not need to take notes because we handed out the written presentation to them after the introduction. Also their mathematics teacher took part of this session together with the students. Kirsti observed the session and she also videotaped the presentation. The presentation took about 30 minutes.

After the presentation we divided the students into two small groups according to the recommendations of their teacher and they obtained the written introduction with the two tasks that they would work with. We asked the students to read the tasks individually and then together discuss and try to solve them. They could come and ask for help if needed and Clas visited the groups twice during the session in order to offer his help. The group work was tape-recorded.

After the groups had struggled with both problems about one and a half hour we gathered the students together again and asked them to tell us how they had solved the problems. This discussion was also tape-recorded. We kept also the notes that the individual students had made during the group work session in order to use them as a complementary data. We decided to meet after one week and the students could read the material we handed out to them and think about two additional tasks.

During the last meeting we asked the students to tell us if they had obtained some new insights concerning the use of proof and proving. Finally, Clas showed the solution of one of the tasks they had been thinking about at home. This session was tape-recorded as well.

Data analysis

We watched and listened the videotaped session to find out students insights during the presentation. Then, we listened the tape-recorded group work sessions several times and identified the parts that in various ways enlightened the students' insights concerning the discovery function. We transcribed the relevant parts of the

Working Group 1

discussions. In parallel, we also studied the notes that the individual students made during the group session.

Ethical aspects

We carefully informed the students and the teacher about the background and the aim of our study and that it was optional to take part of it. We informed also what we would do with the data and that the data would be handled in a way that would protect their anonymity.

RESULTS OF THE TEACHING EXPERIMENT

In the presentation of the Statement 1 above, some students nicely pointed out that one even obtains a rhombus and proved that the sides are equal using the Pythagorean Theorem. However, to be able to use the discovery function, Clas showed them the proof given above. Concerning the algebraic example, one of the students seemed to catch the idea of discovery already and suggested a generalisation of the statement.

The analysis of the group sessions shows that students in both groups seemed to realize that it was a question about finding new results. Group 1 started their work enthusiastically encouraging each other:

S1: Now, let's find new truths!

They also show that they have understood that it is important to first find a solution to the original problem first.

S2: First, we have to show that we have a solution.

However, they did not manage to find a proof for the initial statement which was a prerequisite for exploring and deriving deductively new results. Instead, they started to discuss the possibilities of proving something more general.

S1: Is it possible to take away some demands in some way?

S3: I wonder if it works for all odd integers.

The second group managed to prove the statement by expressing the number n with $t+1$ and $t+2$ where t was divisible with three. During the proving process they also noticed that the expression is always even. However, they did not succeed to put their results together and extend the divisibility result from 3 to 6. They did neither notice that they could omit the prerequisite that n is not divisible by three. In the similar manner as the first group they started to make and test conjectures about possible generalizations without reflecting on their proof.

S4: But the point is that this is a correct proof and we have to go on, and what was it we would do, we would generalise or specify... why not just put $n^x - n$ divided by x ?

Working Group 1

Then they tested the generality of the statement and arrived at a conjecture that $n^x - n$ is divisible by x if x is a prime. Hence, they did not reflect on the proof they had constructed but went on inductively testing new conjectures inspired by the initial statement.

Some students suggested a proof by induction for the first problem and also worked a bit with it. However, they did not seem to understand the idea of mathematical induction properly.

S5: The proof by induction, would it work here?

S4: We can always do it.

S6: But I don't remember proof by induction.

S4: But exactly like we have started now (testing with the conjecture) we start by the basic... and then, you know, one first proves that it holds for n and then that it works for $n + 1$.

S7: Exactly.

One student also suggested a proof by contradiction and here also we noticed that the student did not really grasp the idea from the logical point of view.

S4: Shall we do this classical that we assume the opposite that n is divisible by three and then look how it works?

Regarding the geometry task, both groups managed to prove the initial statement and also to generalize the statement (the angles are equal in both intersection points).

When we met the students after one week and posed a question about what they had learned the students answered:

S5: Mm, yes, the key word is I think 'generalise' in these proofs and then it is we have learned, or any way I have learned, I think in another way and it is that if one can extend the proof and use it and if it works with other assumptions.

S4: The way in which I understood this was that one either generalises or specifies that one, as you (Clas) expressed it, strengthens the prerequisites of this proof or that one opens it to see what more cases hold.

Hence, these students state they had got insights in the aspects of discovery function that we aimed with our experiment. Yet, the second extract shows that the student has difficulties to distinguish between assumptions and conclusions. We also noticed that the two problems they would think about at home were too difficult in the light of the analysis of the group work.

CONCLUSIONS AND DISCUSSION

The students in our study showed in several ways that they caught the idea of the discovery function. However, they had great difficulties to construct and analyse

Working Group 1

their own proofs in a way the students in Miyazaki's (2000) study did. Miyazaki stresses that it is important for the teacher to let students first themselves prove the initial statement, in order to successfully apply the function in the teaching of lower secondary school mathematics. Concerning the Swedish students we found out that it could be better to also work with complete proofs in order to engage the students in exploring the very deductions in searching for further discoveries. One of the hindrances for the groups concerning the first problem was the construction of the initial proof.

Our focus was not on the very construction of the proof of the initial statement but on the use of it in order to enlighten the discovery function. If the teacher has designed a situation that aims to enhance students' understanding of certain aspects of proof, it can be better to hold some other aspects constant and vary the ones that are the object of learning (c.f. Marton & Booth, 1997; Hemmi, 2008). Recent international comparisons and national evaluations show that Swedish students are not very strong in algebra (e.g. The Swedish National Agency of Education, 2009; Brandell et al, 2008). This is confirmed by our study. Although the students were considered as high-achieving they had difficulties with some elementary algebra, e.g., finding the factorisation $n^3 - n = n(n+1)(n-1)$. The students in our study had also difficulties to cope with some logical aspects involved in proving. Hemmi's (2008) study shows that many university students still struggle with them.

Our aim is to go on conducting a new teaching experiment where we will modify the design of it according to the results from this study. The present study shows that there are a lot of interesting aspects to explore concerning the function of discovery, both theoretically and in applying it in the teaching of mathematics at different levels.

CONJECTURING AND PROVING IN ALNUSET

Bettina Pedemonte

DiDiMa srl., Istituto per le Tecnologie Didattiche – CNR Genova

This report proposes an approach to algebraic proof. It is based on the use of the AlNuSet system, a dynamic, interactive system to enhance the teaching and learning of algebra, numerical sets and functions in secondary school. This work wishes to show in which way AlNuSet can be used in the educational practice to enhance the teaching and learning of algebraic proof. The research hypothesis is that educational activities performed in AlNuSet favour the combination of the aspects of visibility and invisibility in the approach to proof, making it “transparent”.

Key words: Algebra, AlNuSet, transparency, conjecturing and proving

PROOF IN ELEMENTARY ALGEBRA

Bibliography on the theme of algebraic proof at secondary school level is sporadic (Healy & Hoyles, 2000). A possible reason is that in the secondary school curricula of many countries, the approach to proof is still taught in the context of traditional geometry (Hanna & Jahnke, 1993). Nevertheless, rigorous proof is generally considered as a sequence of formulae within a given system, each formula being either an axiom or derivable from an earlier formula by a rule of the system. This kind of proof clearly reveals the influence of algebra (Hanna & Jahnke, 1993).

Furthermore, some recent studies (Pedemonte, 2008) show that Algebra seems to be a good domain to introduce proof. In fact, unlike the geometrical case, in Algebra some difficulties students have in the construction of proof seem not to be present. This has been observed when students solve open problems requiring the construction of a conjecture and the production of a proof. Some Italian researchers (Boero, Garuti, Mariotti 1996, Garuti e al. 1998, Mariotti 2001) showed that open problems are suitable for proof learning because *cognitive unity* between argumentation supporting the conjecture and the construction of the proof can be realised. According to *cognitive unity* hypothesis, the argumentation used to construct a conjecture can be used by students in the construction of proof by organising some of the previously produced arguments in a logical chain. This continuity supports the construction of a proof. However, another kind of continuity, the *structural continuity*, exists between argumentation supporting a conjecture and proof (Pedemonte, 2007). This kind of continuity occurs when argumentation and proof have the same structure (abductive, inductive, deductive). Pedemonte (2007) observed that this continuity can be an obstacle for the construction of a geometrical proof: some students do not construct a proof because they are unable to transform abductive steps of argumentation into deductive ones in the proof. When constructing algebraic proof this obstacle seems not to be present (Pedemonte, 2008). Since algebraic proof is characterised by a strong deductive structure, abductive

Working Group 1

steps in the argumentation activity can be useful in linking the meaning of the letters used in the algebraic proof with numbers used in the argumentation. Thus, the approach to proof in Algebraic domain could be more effective than in Geometry.

In school practice, however, algebra is not usually considered as a way of seeing and expressing relationships but as a body of rules and procedures for manipulating symbols. Normally, students can develop manipulations but are not aware of axioms and theorems they are using in performing it. Thus, algebra is taught and learned as a language and emphasis is given to its syntactical aspects. The actual “vision” of Algebra should be modified to introduce it as a domain for proof - algebra should be considered as a theoretical system where techniques used to make manipulation derive from mathematical axioms and rules.

This paper proposes an approach to algebraic proof. It is based on the use of the AlNuSet system which can be used to propose specific tasks requiring the construction of a conjecture and the production of an algebraic proof. AlNuSet was developed in the context of ReMath (IST - 4 - 26751) EC project for students of lower and upper secondary school (years 12-13 to 16-17). It is constituted by three integrated environments: the *Algebraic Line*, the *Algebraic Manipulator*, and the *Functions*. In this paper we consider two of them: the Algebraic Line (AL) and the Algebraic Manipulator (AM). The AL is an explorative environment to construct conjectures through a motor perceptive approach; the AM is a symbolic calculation environment to produce algebraic proof. The aim of this report is to show how this system can be used to support the teaching and learning of algebraic proof, making proof “transparent”.

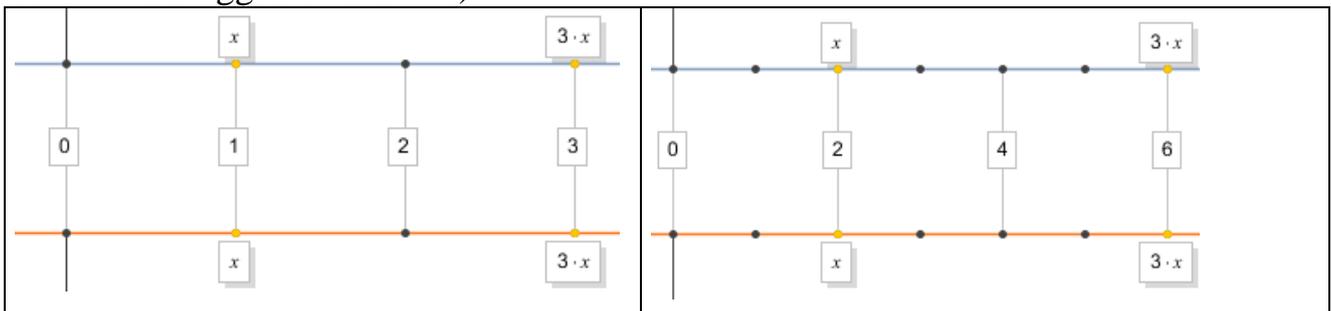

PROOF HAS TO BE “TRANSPARENT”

The role of the proof in the educational practice is not well defined and very often difficulties emerge because some aspects of proof are not explicit for students and they are not well explained by teachers (Hemmi, 2008). Through the notion of “transparency”, in her report Hemmi contributes to solve the dilemma to make more or less invisible for students some important aspects concerning proof. The concept of transparency (Lave and Wenger, 1991) combines two characteristics: visibility and invisibility. Visibility concerns the ways that focus on the significance of proof (construction of the proof, logical structure of proof, its function, etc.). Invisibility is the form of “unproblematic interpretation and integration to the activity” (Hemmi, 2008, p. 414). It concerns the proof as a justification of the solution of a problem without thinking it as a proof. It has been underlined that “*Proof as an artifact needs to be both seen (to be visible) and used and seen through (to be invisible) in order to provide access to mathematical learning*” (Hemmi, p. 425). The lack of visibility in the teaching of proof regards the lack of knowledge about proofs techniques, key ideas and proof strategies.

The hypothesis of this study is that AlNuSet can be used in teaching and learning algebraic proofs to make proof more “transparent”. The AL can be used to make “visible” some important mathematical concepts that are usually implicit in the algebraic manipulation (the variable, the dependence of an expression from the variable, the meaning of equation, etc.). The AM of AlNuSet can be used in teaching and learning algebraic proofs to make rules and axioms used “visible” in proof processes and to let theoretical aspects usually implicit in algebraic manipulation emerge. The AL and the AM are briefly presented in the following. A more detailed presentation can be found in other reports (Chiappini, Pedemonte, Robotti, 2008; Pedemonte, Chiappini, 2008).

THE ALGEBRAIC LINE OF ALNUSET

The AL of AlNuSet is constituted by two lines¹ where it is possible to insert letters and mathematical expressions involving numbers and letters. These expressions can be inserted (or constructed) and represented as points on the line depending on the mobile point of the variable contained in such expressions. Once an expression has been inserted, dragging the x mobile point, the expression(s) that depend on it move accordingly (i.e. in the figure below the expression $3x$ moves when x is dragged on the line).

This dynamic characteristic is very important to allow students experience important algebraic concepts - the dependence of the expression from a variable, the meaning of denotation for an expression, the equivalence among expressions, etc. These aspects are detailed in the following.

THE ALGEBRAIC MANIPULATOR OF ALNUSET

The AM of AlNuSet is a structured symbolic calculation environment for the manipulation of algebraic expressions and for the solution of equations and inequalities. Its operative features are based on pattern matching techniques. In the Algebraic Manipulator pattern matching is based on a structured set of basic rules that correspond to the basic properties of operations, to the equality and inequality properties between algebraic expressions, to basic operations among propositions and sets. These rules are explicit for students. They appear as commands on the

¹ The two lines are used to construct expressions through a geometrical model. It is not possible here to explain in which way they work. In this report we use these lines as a unique line.

Working Group 1

interface and made active only if they can be applied to the part of expression previously selected. An expression is transformed into another through this set of commands that corresponds to axioms and rules. Students can see the transformation of an expression as the result of the application of a rule on it.

TEACHING EXPERIMENT

In this section student's resolution processes of some tasks involving the production of a conjecture and the construction of proof in AlNuSet are analysed. They are taken from a set of data collected from an experiment carried out in a class of 22 students of the Second year of Lower Secondary School (12-13 years old). Empirical data were both qualitative and quantitative and were collected according to different methodologies: written tests, observations and recording of students dialogs. Data were transcribed and translated from Italian into English. The main aim of this experiment was to analyse the role of AlNuSet in a teaching experiment centred on algebraic expressions and propositions. The experiment lasted 6 weeks, with sessions of two hours per week. The first session of the teaching experiment focused on algebraic expressions. In this report we present results of this session. Students worked in pairs with AlNuSet under the supervision of the teacher and the researcher. Students had not used AlNuSet previously. The teacher presents the software showing some specific technical features. Then she distributes a paper containing the tasks.

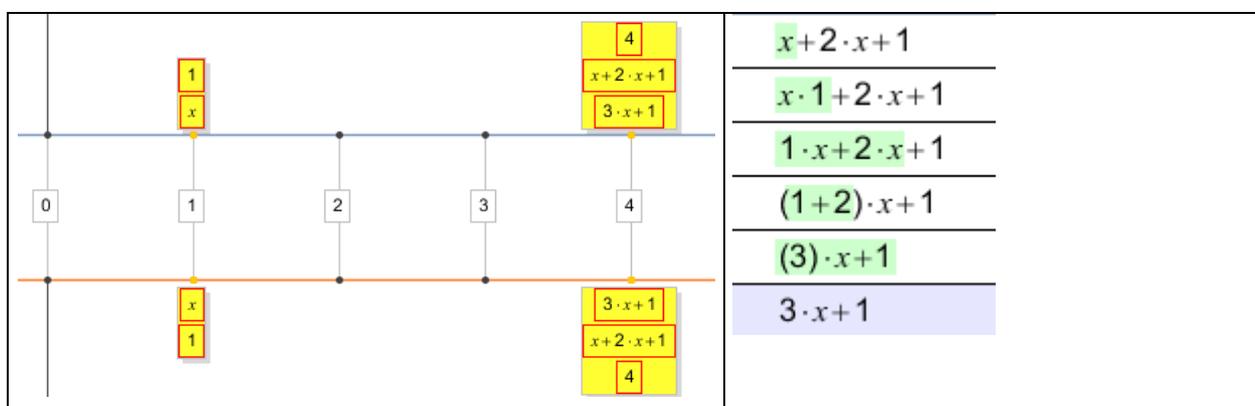

Tasks

- a) Let x be an integer number. Write an expression for the triple of x .
Represent this expression on the AL. Is your answer correct? Why?
Write an expression for the consecutive of the triple of x . Represent it on the AL and verify your answer.
Consider the expression $x+2x+1$. Compare this expression with the previous one.
Check your answer using the AL and AM of AlNuSet.
- b) Let x be an integer number. Write an expression that represents the quadruple of x increased by 3.
Is there any value of x such that this expression is 27?
- c) The teacher asks a student to carry out the following computation:
Think a number, double it, add 6, divide the result by two, and subtract from it the number that you thought initially.
The teacher says:
The result is 3
The teacher proposes the exercise to two other students changing the number to add.
At the end she proposes the following exercise:
If x is the initial number, and a is the number to add, write an expression to translate the described computation.
Represent the expression on the AL.
What can you observe when you move x ? What can you observe when you move a ?
What is the result of the expression? Represent the result on the AL and check your hypothesis.

Working Group 1

Tasks a) requires to construct the expression $3x$ in the AL and verify that this expression represents the triple of x . Moving x on the line the expression $3x$ moves accordingly. Through a perceptive approach students can see that the point associated to the expression $3x$ assumes values that are multiples of 3. In this way, what the expression $3x$ denotes is made more explicit. Furthermore, only moving the variable x it is possible to move $3x$ allowing students to experience the expression's dependence from the variable x .

The second part of the task requires to construct the consecutive of the triple of x and to compare it with the expression $x+2x+1$. The aim of this second question is to point out the equivalence between the two expressions from a perceptive point of view and not from a formal one. In the AL the equivalence among expressions is represented by a post-it (see figure below). The two expressions $3x+1$ and $x+2x+1$ belong to a same post-it for each value the variable x assumes on the line.

Students can “experience” the equivalence of the two expressions and then they can prove the equivalence in the AM. In the AL, students make visible the equivalence between the two expressions. The focus here is not to prove the equivalence but to experience it. In the AM proof is made explicit - students are obliged to explicit the rules necessary to transform the first expression into the other. This is not obvious because this transformation in a paper and pen environment is usually not treated as a proof; here proof is in general invisible to students.

Analysis of tasks a) results

All students are able to answer the first question: they write the expression $3x$. However it is interesting to observe that students are not able to justify why $3x$ is the triple of x .

Some students construct a table, other students tell the 3 times table. Only when they can move the expression on the AL they are able to explicit that the expression $3x$ denotes the triple of x because “*the expression assumes only values that are multiples of 3... it probably takes all multiple of 3*” (Sara).

Another interesting aspect that emerged during the exploration was the dependence of the expression $3x$ from the variable x . When students have to move the expression $3x$, they fail because they move directly the expression and not the variable x . Here

Working Group 1

an example of two students who are not able to move $3x$.

Francesca: $3x$ does not move

Danilo: We are not able to move $3x$

Teacher: Why isn't it moving?

Francesca: we are trying but with no results...

Teacher: Why are you moving directly $3x$?

Francesca: Because I want to move the expression $3x$

Teacher: You should not move directly $3x$ because this expression is dependent on the variable x

Silence

Teacher: In which way can you move $3x$?

Silence

Teacher: you have to move x

Danilo: x ??

Danilo moves x

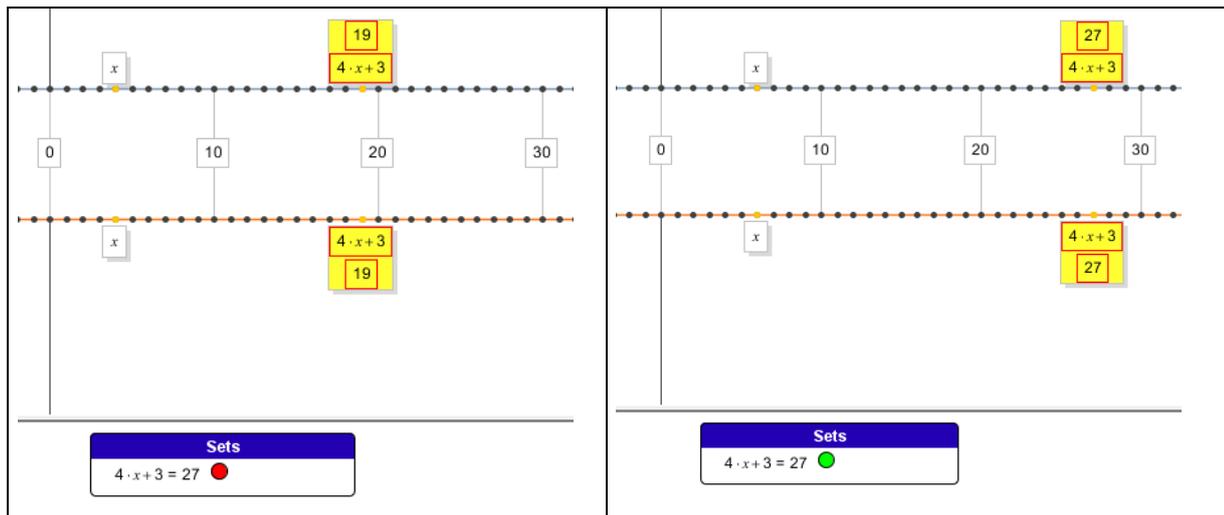

Danilo: Ahh... $3x$ is dependent on x

Francesca: Ahhh... it was really too difficult for us...

All students write the expression $3x+1$ and they insert it on the line. Once more some students try to move the expression directly on the line. The intervention of the teacher is necessary to overcome this obstacle. All students are aware that the two expressions $x+2x+1$ and $3x+1$ are equal because a calculus rule ($x+2x$ is equal to $3x$). Proof is invisible here. On the contrary, in AM, the transformation of an expression into the other becomes visible: many students feel frustrated when they have to prove their calculations with AM. The teacher has to guide them specifying properties they are using (distributive property, insertion of the neutral element, etc.). In AM proof is not spontaneous for students. As highlighted by Hemmy, visibility and invisibility of proof interact in the process of learning and both are needed. It was unexpected for the teacher that after the teaching experiment and during the usual lessons students could explicit these properties also in a paper and pen environment or on the blackboard and when not required. For example, they used to say “*we are applying distributive property*” to replace the usual statement “*we are performing a calculation*”. Moreover, the work with AL was important for students to make visible the relation between the value of a variable and the value of an algebraic expression or proposition. The following statement was written by a student “*An expression is dependent from a variable, from the letter that is contained in it. If in the expression there are only numbers, then the expression is not dependent from the variable*” (Carlo).

Tasks b) is an implicit requirement to solve an equation. In AlNuSet (as shown in the next figure) it is possible to solve the equation dragging x to move the expression $4x+3$ in the point 27. When x is situated on the point 6, the expression $4x+3$ is on the point 27 and the little ball associated to the equation is green. On the contrary, when x is moved on the other values, the little ball is red to show that other points are not a solution for the equation. As a consequence, AL makes available functionalities to solve equations in a non formal way.

Working Group 1

This feature helps understand the meaning of equation. Students are usually able to solve the equation through the manipulation rules but they cannot say that the solution makes it true if replaced in the equation.

Analysis of tasks b) results

All students are able to solve this task, and a pair of them recognises that they are solving an equation. However, it is interesting to observe that many solve the equation on the paper before the exploration on the line. Proof is invisible in the paper. In the AL some important mathematical concepts useful to understand the proof may become visible. Students are not able to move directly x on point 6 to obtain the solution. They try to move directly the expression on point 27, and then they make an exploration moving x . When they see that the expression $4x+3$ is situated on point 27 only if the variable x assumes number 6 as values, they seem to understand that they are solving the equation in a completely different way. The insertion of the equation $4x+3=27$ and the different color assumed by the corresponding little balls moving the variable on the line, is really effective to construct a justification: “6 is the solution of the equation, for this reason when x is on point 6 the expression $4x+3$ is on point 27 and the little ball here is green... when x is situated on the other values the little ball is red and not green!” (Martina).

The AL is really important to make visible the relationship between the variable and the equation. The teacher observed that some students, even after the end of this teaching experiment, in spontaneous way, replaced in the equation the value of its solution to see if the solving process was correct.

The proof in AM is constructed on the screen by the teacher supported by students.

Tasks c)

Task c) is a real effective task to understand the different meaning between variable and parameter. Observe that the expression $\frac{2 \cdot x + a}{2} - x$ is equivalent to the expression $\frac{a}{2}$.

Working Group 1

As consequence, the teacher may always guess the result of the expression because it is not dependent on the value thought by the student.

In AL, the expression $\frac{2 \cdot x + a}{2} - x$ does not move dragging the variable x . In this way, students can experience that this expression is not dependent on x . Students may also observe that the value of this expression is always the half of the value of a (which is the value that the teacher requested to add). This explains why the teacher can always know the value thought by the students. After the production of this conjecture, students have to prove it.

$\frac{(2 \cdot x + a)}{2} - x$ <hr/> $(2 \cdot x + a) \cdot \frac{1}{2} - x$ <hr/> $2 \cdot x \cdot \frac{1}{2} + a \cdot \frac{1}{2} - x$ <hr/> $x \cdot 2 \cdot \frac{1}{2} + a \cdot \frac{1}{2} - x$ <hr/> $x \cdot 1 + a \cdot \frac{1}{2} - x$ <hr/> $x + a \cdot \frac{1}{2} - x$ <hr/> $x + \frac{a}{2} - x$ <hr/> $\frac{a}{2} + x - x$ <hr/> $\frac{a}{2} + x + -x$ <hr/> $\frac{a}{2} + 0$ <hr/> $\frac{a}{2}$	<p>On the left the required proof.</p> <p>The proof in the AM is more complex than in a paper and pen environment.</p> <p>Even if a lot of effort is required by students to prove the equivalence between these two expressions, the system can make visible the rules and procedures of manipulation supporting the comprehension of proof as part of a theoretical system.</p>
--	---

Analysis of tasks c) results

When the teacher asks to carry out the following computation, all students are really surprised when she guesses the results of the calculations “*Think a number, double it, add 6, divide the result by two, and subtract from it the number that you thought initially*”. The teacher proposes the same task modifying the number to be added to two other students. She asks to add 4 and then 8.

The students are not able to explain why the teacher is able to guess always the result. The teacher asks to write an expression to translate the computation.

Two pairs of students write the expression $\frac{2 \cdot x + a}{2 - x}$ but the others write the correct expression.

The teacher asks to insert the correct expression on the AL and move alternatively a and x to observe the behaviour of the expression.

In the following a part of the discussion developed in the class.

Teacher: What does it happen when you move x ?

Alberto: the expression does not move!

Fabrizio: nothing happens!

Working Group 1

Teacher: are you surprised?

A lot of students: yesss

They continue to move x

Teacher: and when you move **a**?

Fabrizio: there are some values that are ok...

Giuseppe: but not all values... sometimes the expression disappears

Students speak among them to try to explain why sometimes the expression disappears

Sara: the expression is dependent only on **a**

Teacher: This is an important point! We have seen that if we move **x** this expression does not move accordingly. This expression does not depend on **x**. On the contrary, we have seen that moving **a** the expression has a particular behaviour. Who can account for this behaviour?

Carlo: wait... if **a** is an even number then I can see the expression, but if **a** is an odd number, the expression disappears! I cannot see it!!?

Dylan: The expression is exactly the half of **a**

Teacher: are you sure that it is always the half of **a**?

Federico: yes it is true, it is the half of **a**

Sara: this is why you guessed the results of the expression... It is always the half of the number you required to add..

A lot of students: yess! It is true!!!

Teacher: but why, in your opinion, the expression disappears when **a** is an odd number?

Carlo: because an odd number divided by 2 is a decimal number

Alberto: it is a decimal number

Carlo: You asked to add only even numbers...otherwise it wouldn't have been possible to divide by two

Teacher: Perfect! In a previous case, in the computational task I asked to add 6, then 4 and then 8. They are even numbers. I can calculate the half of an even number. This is why I could guess the result. Is it clear to all?... But what happens if we change the domain?

Danilo: the expression does not disappear

Alberto: it is always the half of **a**, we cannot see it in the Integer numbers because the integers are not decimal numbers!

Teacher: So the expression is always equal to...

All students: the half of **a**

Teacher: so we can write

$$\frac{2 * x + a}{2} - x = \frac{a}{2}$$

The teacher writes on the blackboard

Teacher: can you prove it? Try to prove it in the manipulator.

Only three pairs of students were able to complete the proof by themselves. The intervention of the teacher was required for the other students. However, the constructed proof obliged them to be aware of axioms and rules that are used step by step during the transformation of an expression into another. Only at the end of the teaching experiment students are able to use the AM by themselves effectively.

CONCLUSIONS

In this report we have presented AlNuSet to introduce proof in algebraic domain. The recent paper (Pedemonte, 2009) it was already shown how the AM of AlNuSet makes proof “visible”. In AM the transformation of an expression into another one is not the result of a calculation, but it is carried out by the applications of “explicit” algebraic axioms and rules. Likewise, AL can be used to make “visible” some mathematical concepts (the variable, the parameter, the equation, etc.) that have a crucial role in understanding an algebraic proof. As a consequence, AlNuSet maintains the balance between “visible” and “invisible” in the approach to proof in Algebra, where proof in the ordinary educational practice is usually “invisible”.

A SCHEMA TO ANALYSE STUDENTS' PROOF EVALUATIONS

Kirsten Pfeiffer

School of Mathematics, Statistics and Applied Mathematics, National University of Ireland, Galway

Abstract. In this exploratory study I investigate first year mathematics undergraduates' practice of proof evaluation of alternative mathematical proofs. This paper describes the theoretical background which I chose as a basis for developing a schema to describe and explore students' proof evaluation performances. This schema is illustrated on students' evaluations on one particular example proof. Further I demonstrate insights arising from this study about to what degree the nature and purposes of proofs are visible to the participating students.

Key words: proof, proof evaluation, proof validation, artefacts, purposes of proofs.

INTRODUCTION

Interested particularly in the students' transition from school to university, I explore first year students' behaviour and knowledge when validating and evaluating mathematical proofs. Students' proof validation performances have been discussed in the research literature, for example by Selden & Selden (2003) and Alcock & Weber (2005). With Selden and Selden, I call the readings and considerations to determine the correctness of mathematical proofs and the mental processes associated with them *validations of proof*. In a mathematical community the process of accepting a proof involves more than its validation. Validation, the determination of the correctness of an argument, is a significant part of the process of accepting a proof, followed by a more extensive and open-ended process that involves a search for understanding as well as correctness, a desire for clarity and an alertness to the possibility of adaptation or extension. Seeing learning as assessing and participating in the practices of a community, I suggest to widen the context from *proof validation* to the notion of *proof evaluation*. With *proof evaluation* I mean two things: determining whether a proof is correct and establishes the truth of a statement (validation) and also how **good** it is regarding a wider range of features such as clarity, context, sufficiency without excess, insight, convincingness or enhancement of understanding. That is, *proof evaluation* includes assessment of the significance and merits of a proposed proof.

In her doctoral thesis, Hemmi (2006) developed a theoretical framework to describe how students encounter proof when studying mathematics at university level in Sweden. Her theoretical framework combines a sociocultural perspective with Lave and Wenger's (1991) and Wenger's (1998) social practice theories and with theories about proof obtained from the mathematical education research. In my study I adopt parts of Hemmi's theoretical framework and its terminology and combine it with some new ideas for investigating and describing how students validate and evaluate

mathematical arguments. A significant aim of my study is to develop and test a schema to describe and analyse students' proof evaluation skills and habits.

In this paper I present this schema and use it in the interpretation of some excerpts of interview transcripts. The first part of this paper introduces the theoretical framework. I describe Hemmi's view of proof as an artefact in a community of mathematical practice, then explain how I employed her ideas in my development of a schema to describe and explore how students evaluate mathematical proofs. The second part of this paper describes the experiment, in particular one of the tasks I used in interviews held in 2009 with eight first year students. The third part of this article describes the students' behaviour when evaluating one of the proofs proposed in the interviews, using the specialized schema mentioned above. Observations arising from this study provide opportunities for researchers to learn about the students' views of mathematical proofs. In the final part of this paper I outline some of those findings and discuss the value of the suggested framework.

THEORETICAL BACKGROUND

1 Students as newcomers in a community of mathematical practice

Influenced by Vygotsky's theories, Lave and Wenger (1991) established their notion of *legitimate peripheral participation*, a situated learning theory that argues that knowledge is distributed throughout a *community of practice* and can only be understood with the 'interpretive support' provided by participation in the community of practice itself. I consider the mathematical community, as Hemmi does, as a *community of mathematical practice* and the students as its *newcomers*. A fundamental concept of sociocultural theory is that mental activity is organized through culturally constructed *artefacts*. Becoming knowledgeable or *learning* means increasing membership in the practice which includes the ability to use and understand its artefacts. They provide learners with opportunities to enter a community.

Motivated by Adler (1999) and Hemmi (2006) I argue that proofs can be seen as intellectual *artefacts* in mathematical practice. Adler considers *talk* as an artefact in mathematical learning and Hemmi extends this idea to mathematical *proof*. Recognizing that validating and evaluating proofs are crucial activities in a mathematical community, I investigate novice students' habits when performing these activities. Considering Hilpinen's (2004) philosophical approach towards artefacts, I describe how artefacts can be evaluated in general and specialize this to the practice of proof evaluation throughout the mathematical community and by *newcomers* such as first year students. Observation of novice students' behaviour when validating and evaluating proofs will give us insights into their existing knowledge about the artefact proof.

2 Proof - an artefact in the mathematical practice

An *artefact* can be described as an object that has been intentionally made or produced for a certain purpose. The philosopher Hilpinen (2004) describes how artefacts can be evaluated. He distinguishes between the *intended character* of an artefact, its *actual character*, and its *purpose*, and evaluates on the basis of the relationships among those features. In the following sections I apply this philosophical approach to artefacts of the type *proof* and use it to describe how the interview participants evaluate proofs.

Figure 1 below describes how a *proof* can be evaluated, applying Hilpinen's description of evaluations of artefacts in general. A proof can be evaluated in relating the three features of an artefact, its *intended character*, its *actual character*, and its *purposes*.

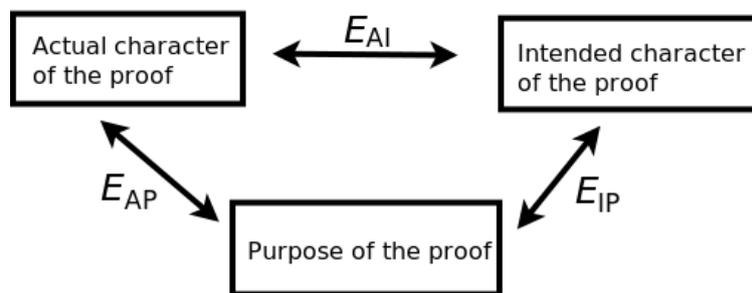

Fig1: Evaluation of the artefact proof

In this graphic the *actual character of the proof* means the actual realization of the author's intention, whereas the *intended character of the proof* designates this intention. *Purposes* (or functions) of proofs [1] have been widely discussed within the mathematical education literature in the last four decades, considering that a broader range of functions of proofs than that of establishing the truth of a statement should be recognised. De Villiers' (1999) suggested model for the functions of proof has been broadly accepted and applied within the mathematical education community. In his model functions of proofs include *verification* (concerned with the truth of a statement), *explanation* (providing insight into why it is true), *systematisation* (the organization of various results into a deductive system of axioms, major concepts and theorems), *discovery* (the discovery or invention of new results), *communication* (the transmission of mathematical knowledge) and *intellectual challenge* (the self-realization derived from constructing a proof). Expansions to this list of functions have been suggested. For example Hanna and Barbeau (2008) claim that the list “stopped short of stating that proof contains techniques and strategies useful for problem solving.” Acknowledging that those purposes of proofs weigh differently, depending on preferences of authors and readers and also on the circumstances of the presentation of a proof, I consider in the context of proof evaluation particular *proofs*, not *proof* in general. In **Figure 1** the

Working Group 1

an evaluation task in September 2008 as well, were invited to participate in a research project. They were chosen carefully in an effort to cover a wide spread of performances in the written experiment. All eight students who volunteered participated in the project. Each of the interviews took 30 to 45 minutes. Every interview was tape recorded and transcribed. The aim of the interviews was to get a deeper insight into students' opinions about valuable proofs, students' validation and evaluation processes and learning effects during the validation and evaluation processes. The students were presented with two mathematical statements and five or six proposed proofs of each statement and asked to evaluate and rank them. One proof of the first statement was purely visual, one consisted only of a fairly random assortment of examples, one was completely wrong but written in "algebraic" language, one was more general than required, another was written in text. [2] I will now present one of the proposed proofs and reflect on how an experienced reader might evaluate it. An interpretation of the students' evaluations and rankings of this proof during the interviews will demonstrate how the transcripts were used to learn about the students' evaluation habits and their knowledge about mathematical proofs. Finally I will outline the results of the analysis of the entire student evaluations of the six proposed proofs of *Statement I* [3].

Statement I. Consider the following statement. The squares of all even numbers are even, and the squares of all odd numbers are odd.

Anna's answer:

Even numbers end in 0,2,4,6 or 8.

$$0^2 = 0, 2^2 = 4, 4^2 = 16, 6^2 = 36, 8^2 = 64.$$

When you square them the answer will end in 0, 4 or 6 and is therefore even.

So it's true for even numbers.

Odd numbers end in 1,3,5,7 or 9.

$$1^2 = 1, 3^2 = 9, 5^2 = 25, 7^2 = 49, 9^2 = 81.$$

Squaring them leaves numbers ending with 1,5 or 9, which are also odd.

So it's true for odd numbers.

An experienced evaluator would probably identify that Anna's argument centres on her assertion that the last digit of the square of an integer is determined by the last digit of that integer itself. This assertion is correct. It certainly could be argued that the assertion needs some justification. If the evaluator is prepared to accept Anna's assertion, the actual character of this proof does coincide with the intention and therefore the argument does satisfy condition E_{AI} . However, Anna's argument does not provide an essential explanation of WHY squaring an integer preserves parity (i.e. oddness or evenness). There is no reason to construct a modulo 10 argument (based on the last digit - the remainder on division by 10) for a problem in modulo 2

Working Group 1

arithmetic (the problem is about remainders on division by 2). A reader may well complain that by using 10 cases where two would suffice, this proof misses the key point. The intended character of this proof, involving 10 different cases, is not a good fit to the purpose of explaining why squaring preserves parity. For that reason an experienced evaluator might regard Anna's proof not satisfactory concerning E_{IP} and E_{AP} .

3 Example: An Interpretation of some transcript excerpts

The coding table below (**Table 2**) provides an overview about the participants' evaluations of Anna's proof; the codes in the bottom line refer to how the students placed Anna's proof in the ranking of all six proposed proofs. The heading line refers to the codes for the students (*Students C and D* were interviewed together). **Table 1** describes the coding scheme.

Satisf	The student regards the answer as satisfying.
NotSatisf	The student regards the answer as not satisfying.
Proof?	The student is not sure whether the proposed approach is a sufficient proof of the statement or not.
NoProof	The student does not regard the answer as proof of the statement.
NotGeneral	The student criticises that the proposed approach is not applicable in general.

Table 1: Coding Scheme

<i>A</i>	<i>BC/D</i>	<i>EF</i>	<i>G</i>	<i>H</i>
Proof?	Satisf NotSatisf NoProof NotGeneral NotGeneral	NotSatisfNotSatisf NotGeneral NotGeneral	Satisf Proof? NotGeneral	Satisf NoProof
first	fourththird	fourthfourth (jointly) (jointly)	fifth	second

Table 2: Coding Table: Students' evaluation of Anna's proof

The coding table refers to three groups of comments.

- **Satisf/NoProof:** The student is happy with Anna's answer and considers approvingly that Anna is using examples. The student considers that Anna's answer is not a proof of the statement. “*It's not a proof, but it works*” or “*It's a good answer. (...) There is no kind of proof (...)*” are responses assigned to this group.

Working Group 1

- **Satisf/Proof?:** The student likes Anna's answer because Anna “*gives examples*” or the answer “*is different*”. It is not clear from the interview conversation whether the student regards Anna's answer as a sufficient proof of the statement.
- **NotSatisf/NotGeneral:** The student does not accept the answer as a proof of the statement because it “is not general”.

With the research questions listed in the above diagram (**Fig2**) in mind I suggest an interpretation of the students' evaluations of Anna's proof, occasionally using short transcript exemplars to advance certain claims.

4 How do the student evaluators relate the three features of Anna's proof?

Two of the five students whose opinions belong to (Satisf/NoProof) or (Satisf/Proof?) do not seem to focus on relations E_{IP} or E_{AP} as there is no evidence to suggest that they are considering the purposes of mathematical proof. Even though the other three of those students (Satisf/NoProof) express the opinion that Anna's answer is not a valid proof of the statement and in particular that the argument is not applicable in general they acknowledge the unusual approach and the internal correctness and rank Anna's proof relatively highly (second or third out of six). Their responses to Anna's answer suggest that E_{AI} may be more important to them than the relations E_{IP} or E_{AP} : “*It's not a proof, but it works.*”(C/D) or “*There is no kind of proof, it's just ---. But it does make sense*”(H). Internal correctness seems to be considered more important by this group of students than the purpose of establishing the general truth of the statement.

The three (NotSatisf/NotGeneral)-students do relate the actual proof not only with the author's intention but with its purposes and therefore do consider relations E_{IP} and E_{AP} as well as E_{AI} . They consider at least one purpose of proof, namely its general applicability, criticize the poor relation between the actual or intended proof and its purposes, and therefore regard Anna's proof as unsatisfactory, which is indicated by their ranking of this proof. These three students seem to regard relations E_{IP} and/or E_{AP} as being at least as important as E_{AI} .

5 Do the student evaluations of Anna's proof indicate what the students consider purposes of proofs?

Five students criticize a lack of general applicability in Anna's proof, which indicates that they consider this as one purpose of mathematical proof. One of the (NotSatisf/NotGeneral)-students (E) finds the level of justification insufficient “*She doesn't prove that 'When you square, the answer will end in 0,4,6...' If she'd proved that, it would be ok.*” Certainly for this student justification of intermediate steps is a necessary ingredient of mathematical proof. This student seems to see Anna's answer as an attempt at a general argument about the last digit that could be improved to a proof. This is similar to how an experienced evaluator is likely to see it, namely as more than a collection of examples. In an experienced evaluator's view the examples that are included in Anna's proof are not intended as examples but as items in an

exhaustive list that covers all cases. The other students who complain that Anna's answer is not general and consists of “*just examples*” interpret this in a different way: *Student F* for example seems to see it as basically the same as another proposed proof which consists of a collection of examples, just “*up to ten numbers*”. *Student B* like *student F* considers Anna's answer as just a selection of examples: “*She took the numbers from 1 to 9, but what about all the other numbers? (...) Nice example, but that's about it.*”

6 Do the student evaluations of Anna's proof indicate a learning process? Do nature or purposes of mathematical proof become *visible* to the student evaluator?

Student G's reaction indicates that a learning process is initiated by the task. Her first reaction (“*Very cool*”, “*different*”) indicates that she admires the unusual approach (“*I could never think of anything like that, (...) the way she writes it down (...)*”). After careful prompting by the interviewer a reflection process is initiated and the student is getting more and more unsure, until at some point she almost decides that this is not a proof, but is never really sure about this. *Student G's* comments do not show clearly what she considers as a valid or valuable proof, but she certainly thinks about it.

The second proposed proof (*Benny's answer*) consists of a collection of ten examples. Interestingly seven of the eight students commented in the interviews on how they compare Benny's answer to Anna's, even though they weren't asked to do so. Four students regard the answers as very similar. Two students approve the fact that Benny includes examples of negative integers in his answer. Five students, all agreeing that neither answer proves the statement sufficiently, mention that Anna's answer is more like a proof than Benny's. They identify two aspects of proof more present in Anna's than in Benny's answer:

- the description of general patterns: “*She has this --- with the endings*” (C/D), “*In [Anna's answer] there is more thinking in it. She saw this fact, if you square an even number, that there is a 0,2,4,6,8 at the end of each one.*” (E)
- Anna's answer includes some attempts to explain **why** the statement is true. “*She says why the squares are odd, because they end in that. He [Benny] just presumes that they are odd numbers.*” (F)

Considering Benny's answer in comparison to Anna's, some of the students who have interpreted Anna's proof as list of randomly chosen examples when discussing Anna's answer now identify some potential in Anna's answer to provide a general proof: *Student F* states that “*Anna's is more of a proof [than Benny's]. She says why the squares are odd, because they end in that*”. Likewise *Student B* regards Benny's answer as “*more example than proof than Anna's was*”. These changes in some of the students' opinions about Anna's proof indicate a learning effect about proofs

through the comparing process. It seems that some purposes of mathematical proof became *visible* to these students.

SUMMARY AND FURTHER OBSERVATIONS

Consideration of the interview data with the relationships E_{AI} , E_{IP} and E_{AP} among the actual and intended character and the purposes of a proof in mind led to the following observations. The students' evaluations of all six proposed proofs of *Statement I* indicate which purposes of proofs they consider relevant. In *Student A's* evaluation the most relevant consideration is how the statement's plausibility is verified and demonstrated by the proposed answer. Consequently she favours answers consisting of examples. Generality of a proof is an important evaluation criterion to most of the students. Five students mention at some point during the interviews that they appreciate considerations and explanations about *why* the statement is true in certain proposed answers. Some of the students take into account whether the proposed proof emphasizes some mathematical contents or general patterns. Some students consider sufficiency without excess in their proof evaluations. Some students appreciate a didactical value in a proof, which includes how well a reader's interest is stimulated or how well both statement and proof are being explained to the reader. The proof idea or method does not seem to play a significant role in the students' evaluations of proofs of the first statement, which is indicated by three observed phenomena. Firstly, a proposed visual approach is liked least considering the ranking of all eight students together. The intrinsic idea behind this approach seems unimportant to the students. Secondly the fact that one of the proposed arguments proves a more general fact than the facts of *Statement I*, is rarely being recognized and not appreciated by the students. The third surprising fact indicating poor appreciation of proof ideas or methods is the relatively high ranking score of an irredeemably wrong approach. While some of the students noticed errors in this proof, none questioned the basic strategy.

Interpretations of oral and written proof evaluation exercises so far suggest that the developed conceptual framework and schema to interpret student-evaluations are beneficial to gain some understanding about students' knowledge and skills about proofs and proving. The schema appears to be in particular useful to identify students' criteria to accept or value a mathematical proof and also to what extent and how first year students consider purposes of mathematical proofs. *Proof evaluation* as an important activity in mathematical practice might carry some potential to provide students with opportunities to enter the practice. The suggested schema to interpret student-evaluations is appropriate to determine whether that is the case, i.e. to what degree *proof evaluation* performances support learning effects. However, the suggested method seems to be less effectual regarding observations about students' proof reading habits. I did not gain a lot of noteworthy information about how the students try to understand a proposed proof.

Working Group 1

Overall, results of this study indicate that, considering importance and challenges in the teaching and learning of mathematical proof, exploration and practice of incoming students' proof evaluation skills and habits are worthy of further attention.

NOTES

1. By *function* of proof I mean with De Villiers(1999) “meaning, purpose and usefulness” of proof.
2. Hilpinen (2004) introduced the notation $(E1) - (E3)$ for the relationships of the three features of artefacts, relating to three aspects of evaluations, where 'E' symbolizes 'Evaluation'.
3. Detailed descriptions of the tasks, interview questions and transcripts can be found in my forthcoming PhD Thesis.

THE APPEARANCE OF ALGORITHMS IN CURRICULA A NEW OPPORTUNITY TO DEAL WITH PROOF?

Modeste Simon, Institut Fourier, Université Joseph Fourier, Grenoble.

Ouvrier-Bufferet Cécile, UPEC & Laboratoire André Revuz, Université Paris 7.

We deal with the concept of algorithm which is taking importance in curricula in many countries. In particular, we develop an epistemological analysis of this concept and discuss its place in the mathematical science and the link it has with proof. This analysis is enriched by the study of “how researchers know the algorithm”. We conclude with implications of the changes in curricula on proof learning.

Keywords: algorithm, proof learning, interview of researchers, epistemological study.

Discrete mathematics represents a mathematical field which takes a growing importance in our society. In particular, the accessibility of the concepts of this field brings new tracks to teach and learn proof (e.g. Grenier & Payan, 1999; ZDM, 2004). This paper will deal with one of the concept of this field: the algorithm. Indeed, with the omnipresence of computers and technologies in our society, it seems that algorithm will take more and more importance in curricula and it raises questions that impacts on the teaching of mathematics. Moreover, new types of proofs involving computations appear, and with them, algorithmic proofs for instance and the philosophical and epistemological questions of the use of computers to create and/or validate proofs (Hanna, 2007). The 1998 Yearbook of the National Council of Teachers of Mathematics was entirely dedicated to the questions of algorithms and was “an attempt to answer many of [the questions provoked about the place of algorithms in today curricula] and to stimulate other questions that all of us in mathematical education need to consider as we continually adapt school mathematics for the twenty-first century” (NCTM, 1998, p. vii). Recently, the studying of algorithms got into the class of mathematics in the French curriculum of the secondary school. The appearance of the concept “algorithm” in the mathematical curriculum questions the role in mathematics of an object which seems, at first look, to belong more to computer science. Actually, algorithm is first of all, from historical and epistemological points of view, a mathematical concept.

The links between algorithm and proof are not easy to describe and have not been much studied epistemologically. The goals of our study (started in Modeste, Ouvrier-Bufferet & Gravier (2010)) are here twofold: from a mathematically-centered perspective, we want to bring an epistemological analysis of the algorithm which emphasizes its interplay with proof. The way researchers in mathematics and computer science know the concept of algorithm allows a validation of the epistemological model we develop in this paper. From a didactical perspective, we ask how the concept of algorithm can enhance the curriculum, focusing on links

between algorithm and proof (avoiding the ubiquitous computer aspect). We ultimately want to build Research Situations for the Classroom (RSC) (Grenier & Payan, 1998, 1999; Godot & Grenier, 2004) involving algorithm and proof processes. In particular, the design of such situations implies to rely on an epistemological analysis and a study of the practises of researchers (see Knoll & Ouvrier-Bufferet, 2006). Then the concluding session highlights the links between the concept of algorithm and the proving process and brings new research tracks in order to design and to analyze situations for the classroom.

EPISTEMOLOGICAL ASPECTS OF THE CONCEPT OF ALGORITHM

A common definition

The usual definition of algorithm is presented by Knuth who takes algorithm as an object of study (and also questions the differences between mathematical thinking and algorithmic thinking):

“(...) an algorithm is a set of rules or directions for getting a **specific output** [1] from a **specific input**. The distinguishing feature of an algorithm is that **all vagueness must be eliminated**; the rules must describe operations that are so simple and so well defined that they can be **executed by a machine**. Furthermore, an algorithm must always terminate after a **finite number of steps**.” (Knuth, 1996, p. 59)

This implies that an algorithm solves a specific *problem* P by returning in the *output* the answer corresponding to the instance of P given in the *input*. It is important to remember that the input and output information are coded and “algorithms deal primarily with the manipulation of symbols that need not represent numbers.” (Knuth, 1996, p. 61)

The previous definition also shows the *effective aspect* of algorithm: no ambiguity must exist in the instructions so that any *operator* – most of the time a computer, and in this case the algorithm can be described by a *program* – gets the same output with the same steps. The *finiteness* cannot be dissociated from the notion of algorithm, as Chabert notes it in his book on the history of the algorithm:

“Today, principally because of the influence of computing, the idea of **finiteness** [1] has entered into the meaning of algorithm as an essential element, distinguishing it from vaguer notions such as process, method or technique. [...] Here we have a finite number of operations, a finite number of input values, but also a finite number of solution procedures, that is that each step should be able to be carried out by a finite process – something which is not possible, for example, in determining the quotient of two incommensurable real numbers. We also refer to an **effective** procedure, that is one that will effectively achieve a result (in a finite time).” (Chabert et al., 1999, p. 2-3)

This finiteness raises questions regarding *complexity*: given an input, how many steps does the algorithm take to answer? How much space does it need to store the involved information? These questions respectively deal with *time complexity* and

space complexity. This complexity depends on the size of the input and can be studied from two points of view: the *worst-case complexity*, the maximum complexity of the algorithm for an input of size n and the *average-case complexity*, the average of the complexity for an input of size n (usually, the inputs of size n are considered to have the same probability). Since Knuth, complexity is a specific and fundamental aspect of the algorithm which is absent from the other fields of mathematics. He says (about Bishop's mathematics [2]) that “[it] is constructive, but it does not have all the ingredients of an algorithm because it ignores the “cost” of the constructions” (Knuth, 1996, p. 110). Here, we have detailed three important aspects of algorithm: the link with **problems**, the **effectivity** and the **complexity**.

Ambiguity of this definition

As examples of algorithms, authors often give Euclid's algorithm for gcd, arithmetic operations on integers, algorithms for sorting or algorithms for shortest paths in a graph... Among all these examples, one strikes us: the method to find the roots of the quadratic equation $ax^2 + bx + c = 0$ using the discriminant $b^2 - 4ac$.

With more details, the algorithm is the following:

Input: a, b, c
 $\Delta = b^2 - 4ac$
if $\Delta > 0$ **then** return $\frac{-b+\sqrt{\Delta}}{2a}$, $\frac{-b-\sqrt{\Delta}}{2a}$
else if $\Delta < 0$ **then** return $\frac{-b+i\sqrt{-\Delta}}{2a}$, $\frac{-b-i\sqrt{-\Delta}}{2a}$
else return $\frac{-b}{2a}$

Judging by the definition we gave above, we could say that it is an algorithm. But we find it surprising that such a method was chosen as an illustration of the concept “algorithm”. Indeed, in each case, the algorithm is just a formula. Moreover, from the point of view of the “complexity”, such an algorithm is not interesting, as the complexity is independent of the size of the input (we are not speaking here about the complexity of the arithmetic operations involved in the discriminant, which are for us better examples of algorithms). This example raises the question of the border between algorithmic and non-algorithmic areas and the “usual” definition is ambiguous about this. For our study, for a didactical purpose, it would be useful to distinguish this kind of formula with “real” algorithms.

A more theoretical definition

In the beginning of the 20th century, the quest of foundations for mathematics caused mathematicians to give a more theoretical definition of algorithm.

“The works of Gödel inspired the research of Alonso Church, Stephen Kleene, Alan Turing and Emil Post. These mathematicians attacked Hilbert's Entscheidungsproblem and showed that there were, indeed, undecidable problems, that is mathematical statements for which no procedure exists by which it can be decided if the statement is

Working Group 1

true or false. To do this, each of them defined a concept of computability, that is a concept of algorithm.” (Chabert et al., 1999, p. 457)

Two of these concepts should be quoted: the *Turing machine* and the *recursive functions*. This theoretical work leads to a classification of problems depending on whether there exists an algorithm to solve them or not (*undecidable* and *decidable problems*) and if they are “easy” or “hard” problems, which means if they can be solved by a polynomial algorithm or not (we refer here to *P* and *NP-hard problems* [3]). This point of view will constitute a fundamental aspect of algorithm, the **theoretical models**.

Algorithm and proof

Algorithm and proof interplay in many ways, it will be another important aspect for us. First, an algorithm has to be proved; more precisely, it is necessary to prove its *correctness* (i.e. it gives the expected answer) and its *termination* (i.e. it always stops after a finite number of steps). And, once it is proved, an algorithm can be used as a *step in another proof*. Actually, all the aspects raised previously have a link with proof. In particular, correctness and termination correspond respectively with *problem solving* and *effectivity*. The *complexity aspect* involves proof too, and studying the complexity of an algorithm often needs substantial mathematics. The same is true of *theoretical models*, which only make sense in a proof process. Just like any mathematical object, the algorithm raises questions involving proof. But some of them are specific and only the algorithm raises the mathematical questions previously mentioned. Moreover, the algorithm is not only linked with proof on that way. An algorithm can also be a *tool for proving* a property, and for a given problem, an algorithm will give a *constructive proof* of its resolution (e.g. Euclid's algorithm provides a proof of the existence of the gcd of two integers and an effective way to compute it). Conversely, an algorithm often lies under a constructive proof and it can be interesting to formulate this algorithm clearly. For instance, from any *proof by induction* follow a recursive algorithm.

Algorithms, seen as proofs, allow to deal with two kinds of problems: *existence problems* and *testing a property*.

Recently, a link has been pointed out between proof and algorithm, with the computer-assisted proofs, that is the use of algorithms to build proofs which are much too long to be verified by a human being. For instance the four-color theorem has been proved this way. However, the algorithm has to be proved in order to validate the mathematical result. This new kind of demonstration asks philosophical and epistemological questions about the nature of proof.

Tool-Object

The aspects of algorithms underlined above can be divided into two parts since they refer to algorithm as a tool or as an object. Looking at the algorithm as an object means studying questions of validity, of complexity and description of algorithms.

Working Group 1

Looking at the algorithm as a tool is focusing on the use of algorithms to solve problems. Among the aspects discussed here, the **effective aspect** and **problem aspect** refer to the algorithm as a **tool** whereas the **complexity aspect**, the **theoretical models** and the **link with proof** refer to the algorithm as an **object**.

MATHEMATICIANS' POINT OF VIEW ON ALGORITHM

This analysis of the algorithm concept is mainly theoretical and it would be interesting to compare it with the reality of mathematics, that is the ongoing research.

- Are mathematicians' representations in accordance with our epistemological study of algorithm?
- How do algorithms interplay in their practice of research?
- Which aspects of algorithm are involved in mathematical research and which ones are not?
- Do researchers refer mostly to the algorithm as a tool or as an object?
- Do these questions depend on their field of research?

Actually, the main point which interests us is the following: validating our epistemological analysis when comparing the descriptions of mathematicians of coming to use and to know algorithm and our epistemological model (in the same way that Burton did). Here, the form of our interviews does not permit to describe the whole conceptions of the researchers in a specific theoretical model. Right now, the trends in our results are enough to use this analysis as a preliminary work in order to build Research Situations for the Classroom (RSC).

Interviewing researchers

To answer the previous questions, we chose to interview researchers both in applied and fundamental mathematics. We also interviewed researchers from fields at the intersection of mathematics and computer science, like operational research, combinatorics, computational geometry... These researchers have a mathematical activity too, that is a proof activity, but should have a rich and different vision on the algorithm, provided by the links they have with computer science. We interviewed 22 researchers. From their point of view, they belong to the following fields:

	Fundamental	Applied
Mathematics	10	7
Computer Science	5	5

Table 1: Distribution of the researchers [4]

In fact, in order to study the practice and the representations of mathematicians, the tool of interview seemed to be the most convenient possibility (in the same way as Burton, 2004). We have met the researchers face-to-face and the interviews were

Working Group 1

audio taped. The researchers received a brief questionnaire to provide personal information (name, gender, function, discipline (mathematics, computer science; fundamental and applied mathematics [5]), research subjects, teaching level at university), and an excerpt of the new French curriculum with the appearance of algorithms [6]. We followed a list of questions (see above) in conversational style. These interviews last between 20 and 30 minutes and the part which interest us here makes up around half of this time.

The interviews

In the interviews, we chose to bring up three points:

- 1) What is an algorithm, how can one define it and recognize it, and what examples can be given?
- 2) How is it used in mathematics and in the field of the researcher?
- 3) The place and the role of algorithms in the researchers' work.

The questions were the following:

Q1: How would you define what an algorithm is?

Q2: How can one recognize an algorithm?

Q3: Give examples of algorithms, of non-algorithms. Is the discriminant (presented like above) an algorithm? Where is the border between algorithmic and non-algorithmic areas?

Q4: What are algorithms useful for? What are their roles in your field?

Q5: Are there algorithms in your personal research? Where?

The first three questions aim at making the researcher talk about the definition(s) of algorithm. Giving examples, counterexamples and thinking about the discriminant should make the researchers question their own definition of "algorithm". The last two questions aim at making them evoke the role and place of algorithms and more particularly in their field. All the questions were reformulated if necessary, so that there was no misunderstanding. And as it was an open discussion, these points were not been necessarily mentioned in this order.

Analysis of the interviews

In order to study the transcriptions of the interviews, we built an analysis grid based on our epistemological study. The goal was to find in the interviews which aspects were present. The difficulty was to give the grid a good granularity: the purpose was to associate each idea of the researcher to one or more precise aspect of algorithm, but many aspects were often vaguely mentioned. For example, as far as complexity is concerned, most of the time, the researchers just spoke about its importance but did not give details about the different kinds of complexities or about the question of optimality. After different draft versions of an analysis grid, we finally decided on the following:

Working Group 1

TOOL						OBJECT								
Problem		Effectivity				Complexity		Theoretical models			Proof			
Solve a problem	Input/Output	Any operator and non-ambiguity	Computer or Program	Finiteness	Complexity (Space/Time)	Optimality	Turing Machine and other models	(Un)decidables	problems	P/NP	Correctness	Termination	Tool for proving	Induction

Table2: The analysis grid

Results

Validation of the epistemological analysis

In the interviews, all the aspects we expected researchers to speak about were mentioned by them. Obviously the researchers did not all talk about every aspect and they did not always give many details. But each aspect has been mentioned enough to confirm our study. We will discuss in details how each aspect has been brought up.

Domination of the algorithm as a tool

The “effective” aspect and the “problem” aspect were mentioned by all the researchers. That means that the “tool” aspect is very important in their representation of the algorithm. The “effectivity” and “problem” aspects mainly appear in the definitions of algorithm researchers gave. The “effectivity” aspect is often linked with the use of computer, and many researchers pointed out the importance of computers for algorithms (and some of them made the confusion between algorithms and programs).

Definition of the algorithm

As the definitions researchers gave very often involve the effective aspect of the algorithm, we can say that their definitions are very close to the “usual definition” we mentioned at the beginning. To illustrate this, here are some definitions of “algorithm” given by the researchers:

“A sequence of instructions which enable from an input to produce an output.”

“A finite chain of steps which can be described, and which allows to compute or find the solution of a given problem.”

“An effective process which allows to achieve a calculus or an automatic deductive task.”

“An automatic method to solve a problem which does not need any human intervention, and which is workable for a machine.”

About the discriminant, most of the researchers answered that, according to their definition, it was an algorithm. Some others felt embarrassed that their definition

Working Group 1

encompassed the discriminant and explained that it was an algorithm but had no interest:

“It is not a very rich algorithm, not a good example.”

“We can compute it explicitly. It is just applying a formula.”

“We are between the “method” and the “algorithm”. There is no real process. If any time we have a formula we consider it as an algorithm, it reduces the meaning of algorithm.”

“The problem has a set size... for me, in the idea of algorithm, there is an aspect of variable size, there is the complexity behind...”

The problem of the ambiguity of the definition we underlined seems to be shared by some researchers. The “complexity” aspect seems to be closely related to this problem. Most of the researchers must not have noticed this because, as we will see below, the notion of complexity is not of a big importance for them.

Presence of the “proof” aspect

The “proof” aspect, which is for us the most important when looking at the algorithm from a mathematical point of view, has been brought up by about half of the researchers (12 among 22). There is a link with their field of research: indeed, most of the researchers who brought up the proof consider themselves as fundamental researchers (in maths or computer science) whereas the majority of the others consider themselves as applied mathematicians or computer scientists. We can say that the importance of proof activity has a link with fundamental questions. Moreover, among all the parts of the “proof” aspect, the most quoted is that an algorithm is a tool of proof, that is to say that the algorithm is associated with the notion of constructive proof. The notion of proof of an algorithm (correctness or termination) has not been mentioned much, and more precisely it is always the correctness which was quoted.

The “complexity” aspect

The “complexity” aspect was not mentioned by all the researchers, only 11 of them spoke about it. In this case, it seems to be linked with the computer science field of research: among the 10 (self declared) computer scientists, 8 raised the questions regarding the complexity involved by the algorithm. We can infer that the complexity is not really important from the mathematicians' point of view (as the quotation of Knuth about Bishop's mathematics let us think).

The theoretical models

Theoretical models were mentioned by only 8 researchers, not only from fundamental research but mainly from fields at the intersection of mathematics and computer science (computational geometry and topology, operational research, combinatorial optimization, graph theory or cryptology). In fact, theoretical models for algorithms have a very important role in these fields. That must be the reason

Working Group 1

why those researchers mentioned them. However, it should be noted that very few researchers from other fields (only two) brought up those theoretical models. It seems that this “recent” aspect of the algorithm (but older than the link with computers!) is not known by the researchers or does not seem important to them. The first possibility is, according to us, the most plausible. As an interviewed mathematician underscored:

“As far as I’m concerned, I’m aware of these questions [about algorithm and theoretical models] because my husband is a computer scientist. But this is not in mathematicians’ culture...”

CONCLUSION AND PERSPECTIVES

Our epistemological analysis has been validated by the interviews. Hence, we can ask ourselves what this study implies for the teaching of algorithm and the teaching of proof. These questions have their importance at the moment in France, but also widely impact on mathematical education. We saw that if one does not want to teach algorithm as a tool only, but also as an object, it cannot be separated from the “proof” or “complexity” aspects. Learning algorithm seems to be a good way to learn proof, judging by the connections there exists between these two concepts.

Learning from these interviews, it seems that researchers in mathematics and in fields which link mathematics and computer science, do not have a wide view of the algorithm concept. We can say that little is known about this concept. We could explain this by the recent development of the study of algorithm, but this still seems pretty worrying. We can assume that this lack of knowledge about algorithm is shared by teachers of mathematics (at least in France) and their training curriculum has to be questioned.

This study of the algorithm in mathematics should allow us to study curricula and textbooks of mathematics of the secondary in order to know if the “tool” and “object” aspects are involved.

We would also like to study how the algorithm can be handled as an object by pupils and how it can make them enter in a proof process. We already made experimentations about this, at the beginning of university and in the training of primary teachers, and we obtained promising results (the students and pre-service teacher training were able to build several algorithms and their proof, see Modeste, Ouvrier-Bufferet, Gravier, 2010). Our goal is to carry on these kinds of experiments in the secondary level. Schuster (2004) has studied combinatorial optimization problems in the secondary and has obtained very positive results about pupils' skills in manipulating algorithms and proving. We could work on the “Konigsberg's bridges problem” studied by (Cartier, Moncel, 2008) or on other problems studied by the “Maths à Modeler” team, but from an algorithmic point of view. The analysis of the way one can deal with algorithms and proof in the classroom and the results of

Working Group 1

such experiments will be the object of a new article, based upon the epistemological model developed in this paper.

NOTES

1. Bold types added.
2. In this article, Knuth studied books from many mathematicians and notice that, for him, Bishop's mathematics were the most close to the algorithmic thinking. However, even in Bishop's mathematics, Knuth noted that the notion of complexity was absent.
3. The definitions of P and NP-hard problems are not exactly these ones. For more details about theoretical models, one can read: Hopcroft, J.E., Motwani, R., & Ulmann, J.D. (2007). *Introduction to Automata Theory, Languages, and Computation*. Pearson Education.
4. The total number is not 22 because some researchers consider that they have 2 fields of research.
5. The choice of the researcher is not necessary dichotomous. Indeed, the presentation for their choice of the discipline was the following:

Mathematics Computer science
Fundamental Research Applied research

6. The analysis of this excerpt by the researchers and their answers to questions about teaching the algorithm will not be discussed here.

PROOF: A GAME FOR PEDANTS?

JOANNA MAMONA-DOWNS* & MARTIN DOWNS

*University of Patras, Greece

In this paper, we propose to examine the types of argument that are deemed acceptable at tertiary level mathematics and under which circumstances, and why the expectancy that a proof is required is sometimes relaxed. We specialise on the status of proof in cases where mathematical modelling takes place, and on tasks whose informal resolution rests on two or more mathematical milieu. On occasion, can the insistence on a proof be regarded as pedantry?

Key words: Proof, Credited Argument, Definitional Tautness, Mathematization, Modelling.

INTRODUCTION

Students attending Mathematics courses at the tertiary level often have difficulty to understand the status of proof (Jones, 2000). Further there is evidence that students find the standards applied to proof production somehow arbitrary (Gondek et al, 2009). What is the line between a mere argument and a proof? For this question, some would consider a spectrum might be more appropriate rather than a demarcation line. However, such a viewpoint leaves students in the dark as to when their work should end, or whether their final product qualifies as a proof. It is useful for the researcher to distinguish a proof itself from an argument where basically all the essential ideas behind the proof have been collated but are not articulated in terms of ratified mathematical systems. We shall call such an argument a credited argument; we will discuss our choice of wording in the next section, contrasting it with similar notions employed by other educators. Also we shall give our position of what a proof is in the context of this paper.

If we acknowledge the notion of a credited argument as well as proof, fairly natural educational issues arise, including the following:

- In what circumstances is credited argument acceptable as a final output? The answer to this question might explain why lecturers can be perceived inconsistent in the level of strictness in argumentation they use.
- We do not say that all proof productions necessarily go through a preliminary stage corresponding to a credited argument. However, for those that do, the backing of the credited argument can give support for the student to formulate the proof, and to appreciate what the proof gives beyond the credited argument.
- One reason that argumentation may end as a credited argument is that translating it into a proof can be deemed not worth the effort. Reasons for this

Working Group 1

could be that the undertaking would be messy and/or lacking in giving additional insight. Insisting on the proof in such circumstances might be considered as pedantry. However the lecturer might have good reasons to persist; these reasons, however, may not be immediately appreciated by the students.

- A task may invite a mathematical treatment whereas the context is not strictly ‘mathematical’ itself. Sometimes, the situation can be resolved at the level of a credited argument, where the reasoning retains references to the extra-mathematical context. Because of this, it is not a proof. However, if the task is modelled into another format within a recognized mathematical framework, a proof of the model may be available. Is such a proof, though, to be considered as a proof of the original version of the task?
- The solution of a task may ‘import’ tools from another mathematical perspective from the one that is most natural to assume. The fitting together of different mathematical perspectives sometimes can be made at a perceptual level and as a result aspects of argumentation can be glossed over. In such a case, we have a credited argument but not a proof.

The aims of the paper are rather wide and illustrative in character. The main part consists of descriptions of three tasks that demonstrate the difference between a credited argument and a proof, and the particular issues raised above. In particular, we discuss whether a ‘translation’ from a credited argument to a proof is always merited. Before doing this, we include a more theoretical section where our terminology is put on a firmer basis, with reference to other related research.

BACKGROUND DISCUSSION

This section will define and situate the notion of credited argument that we introduce in this paper. To do this we first consider the notion of ‘truth status’ vis-à-vis proof.

There are many perspectives put forward in the literature concerning how different types of (mathematical) argumentation could be contrasted to proof, or (on the other side) identified with proof. We do not have the space or the expertise to be expansive here. We specialize straight away to consider models of argumentation that are not considered as proofs but in a sense embrace all the central ideas on which a proof would be based. There is a sense of certainty but a lack of usage of the requisite mathematical tools in order to present a proof. Hence, the argumentation attains a ‘truth status’ but is not completely verified as a proof. Intuition can play a large part in the truth status; Fischbein (1987) says that ‘the concept of intuition ...expresses a fundamental, very consistent tendency in the human mind: the quest for certitude’. In the past, an argument that carried conviction both personally and for others was taken as a qualification for proof (Hersh, 1993), or at least conviction is often a prerequisite for seeking a proof (De Villiers, 1990); today, a consensus on conviction could be accepted as an indication

Working Group 1

of truth but not necessarily of proof (c.f., Segal, 2000). Another notion that educators employ is a warrant. According to Rodd (2000), a warrant is a justification / rationale *for the belief* in mathematical propositions; a warrant acts ‘as the lever for (mathematical) knowledge’, where ‘knowledge generally entails “truth”’. Durand-Guerrier (2008) considers the difference of truth and validity via logical aspects in mathematical proof. In particular, she quotes Tarski: “the truth of a proposition lies in its agreement (or correspondence) with reality; or a proposition is true if it designates an existent state of things”.

All the models or positions mentioned above are attributive (rather than operative); they characterize argumentation in terms of a completed output of thought. In this paper, we stress the possibility that argumentation that promotes confidence in the truth status also can be a basis to form a proof. In this case, care is required both in specifying what argumentation conveys ‘truth’ and in one’s stance of what proof is. We consider proof first. We take a line similar to Thurston (1995) purporting that proof production takes place in the milieu of a certain mathematical language; its’ vocabulary is technical but also allows a generous allowance of informal expression in using technical terms. It is difficult for students to attain this language, and ‘the language is not alive except to those who use it’. The technical vocabulary is based on explicit mathematical definitions (Section 2.1, Mamona-Downs & Downs, 2005). If an argument in the mathematical language is challenged, then one always has the recourse to argue more rigorously in terms of first - principle definitions and their known logical consequences. We characterize an argument as a proof if it has this recourse; we then say that the argument has ‘definitional tautness’.

Now we consider the situation of having a line of reasoning lacking definitional tautness but satisfactorily conveys the truth status; we shall call this a credited argument. This begs the question how we regard the truth status in this context. We find difficulties in confronting this issue directly. The direction we take is to imagine an expert to examine the argument and recognise channels that would allow it to be translated into the mathematical language. This stance has unsatisfying aspects; in particular, one would like to say that an individual can feel certainty in his or her argument without exterior authority. However, the reference to a proof clearly is the most reliable source to merit the truth status of an argument. A student, then, might believe that his/her reasoning determines the truth; but this belief must be justified itself, perhaps requiring external ratification. The word ‘credited’ carries allusions to both ‘confidence felt in the veracity in a body’ and endorsement, explaining our choice in wording of the term credited argument.

The forming of a credited argument always indicates a lack in the usage of relevant mathematical tools. Sometimes the tools are not available simply because the student has not been introduced to a requisite mathematical theory. This has led some researchers to make a distinction between what is called ‘disciplinary proof’ (i.e., proof as viewed by professional mathematicians) and ‘developmental proof’ referring

Working Group 1

to the stages of learning where different types of tools pertinent to proof making are realized. (See ICMI Study 19, discussion document.) The interest of this paper, though, is when the students are familiar with the tools needed; this means that potentially the student is equipped to ‘convert’ a credited argument into a proof. This suggests a two-stage process in producing a proof, leading to the issues mentioned in the introduction. (There are other models for which two stages are identified in forming a proof; for example, ‘pre-conjecture’ and ‘post-conjecture’ stages are discussed in Pedemonte, 2007, but conjectures are not stressed in this paper. Other papers, such as Mamona-Downs & Downs, 2009, and Zazkis, 2000, consider students’ ability to convert mental argumentation into a proof presentation.)

One of the issues brought up in the introduction was modelling; this might need some clarification. A credited argument might be available within the context (i.e., prior to modelling), whilst the proof only verifies the model (and arguably not the actual act of modelling). Another term that is often used by educators is ‘mathematization’, that seems to convey the same kind of purpose of rendering a non-mathematical situation into a controlled mathematical environment. However, we regard that an act of mathematization retains a closer reference to the intuitive reasoning available in the context (compared to an act of modelling), so it is easier to accept that a credited argument can act as a ‘template’ for the proof. This point will be illustrated later in the paper.

EXPOSITIONAL EXAMPLES

Here we illustrate some issues concerning the difference between credited argument and proof, as raised in the introduction.

The first task is widely known, but we go further in its solution than is usual. The task is:

For a unit square 8×8 array, the bottom-left square and the top-right square are removed. Show that the resultant figure cannot be covered by rectangular tiles all of dimension 1×2 .

The usual way to demonstrate this is as follows. Suppose that for the 8×8 array, the squares are painted white or black like a chessboard. Then there are 32 squares painted white, the other 32 squares black. Now the opposite corner squares removed will have the same colour, white say. Hence the resultant configuration has 30 squares painted white, 32 black. But each tile must cover one white square and one black. So for a tiling, a necessary condition is that there are an equal number of white tiles as they are black. Hence a tiling cannot exist.

The argument is highly contextual, however carries a strong sense of conviction. What is remarkable is the assertive character it has. Every claim made reads like a fiat; ‘it is so’. There could be an objection in that its declarative manner rests much

Working Group 1

on perception and in this way seems to be at odds to deductive reasoning. At the same time, it seems difficult to get around this. How can you introduce 'definitional tautness' in such a physical situation? This problem seems to be compounded when in the argument itself the notion of colours is brought in; even in the process of solving the problem, another undefined notion is introduced.

Despite this, we believe that many mathematicians would accept the solution as being a valid answer. However, if one were to ask whether it constitutes a proof, the response likely would not be so unanimous. If you gave them time, some probably would say that the problem lies in the task rather than the method: "the task, if you want a fully grounded argumentation, should have been...". Below, we suggest a plausible candidate for such an alternative form of the task:

Let $S := \{1, 2, \dots, 8\}$.

Let $T := S^2 \setminus \{(1, 1), (8, 8)\}$.

Let W be the set of subsets of T of two elements of the form:

$\{(u, v), (u + 1, v)\}$ or $\{(u, v), (u, v + 1)\}$.

Prove that there cannot be a subset R of W satisfying both

r_1, r_2 are different elements of $R \Rightarrow r_1 \cap r_2 = \emptyset$

and

$\{t \in T : t \in r \text{ for some element } r \text{ of } R\} = T$.

At first sight, the second task might seem radically different to the original. In a way, indeed it is; where are the objects and actions understood on a physical level that motivated the exercise in the first place? Moreover, if you were presented the second task independently, it would seem highly contrived; which eccentric would dream up such a convoluted seeming creature? No, there is no motivation unless the tasks are regarded as a pair, and it is not so difficult to see how the two are (isomorphically) connected. The sets and the conditions that appear abstractly in the second task are readily 'lifted' to the environment of the first with contextual meaning. Hence, the set T represents the depleted array, W the potential positions in the array that one tile can take, R a tiling of T : the two conditions explain what we mean by a tiling in the set theoretical setting. To prove the proposition, one constructs the sets:

$T_1 := \{(u, v) \in T : u + v \text{ is odd}\}$

$T_2 := \{(u, v) \in T : u + v \text{ is even}\}$

that accounts for the colouring. By showing that $|T_1| \neq |T_2|$, one proves that R cannot exist. The details here are left to the reader.

Working Group 1

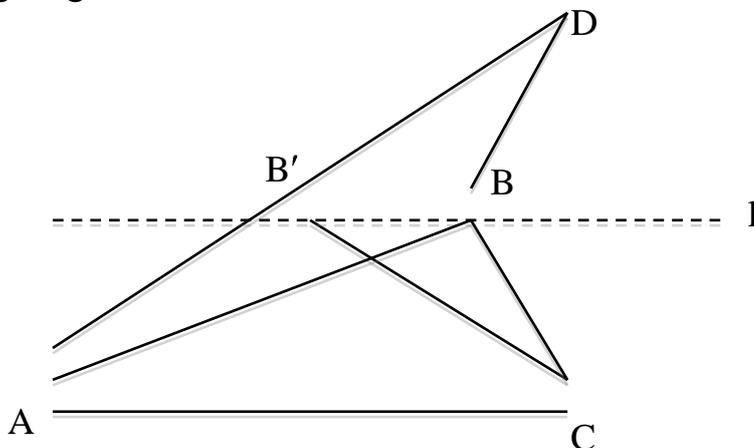

Psychologically, one can either 'identify' the two tasks regarding them essentially the same, or separate the two whilst acknowledging they have completely consonant structure. In the first case, one might say that an act of 'mathematization' has taken place, whilst for the second an act of modelling. By the word mathematization the second version of the task would be regarded as a channel to give the appropriate tools to prove the first task, whereas the modelling viewpoint would suggest that the proof status holds only for the second task. As a central construction transfers in the *solution* (i.e., the notion of colouring to the sets T_1 and T_2) we regard that here mathematization is the more appropriate term to use of the two, as insight is given why the original contextual argument works.

Suppose that a teacher presented the original task; after expounding the credited argument, what would be the pedagogical advantages in converting it into a form that permits a proof? Well, the decision whether to stop at the more intuitive and contextual level or to go further depends on the teachers' own aims. By continuing, though, students have an opportunity to judge whether an argument is a proof or not, and to see that problem solving is not only for obtaining results but also has a role in the forming of mathematization or mathematical modelling. (Obtaining the phrasing of the second task is the result of considerable reflection.) Further, a sense of structural commonality is conveyed, as is the recourse to fundamental mathematical ideas such as a set. Finally, aspects of the modelling or mathematization used in one task could be emulated in other tasks (for example, other problems involving 'arrays' could be susceptible to treatments involving Cartesian products).

Let us now proceed to another example:

Let A, C be points of the plane. Let l be any line parallel to AC . Let S be the set of triangles ABC where B is a point on l . Show that the triangle of S that has the least perimeter is isosceles.

This task is conducive to conventional calculus tools for optimization of functions. However we discuss a solution that retains its basis in geometry. We consider the following diagram:

What prompted us to make this diagram? Well, B' is a point on l such that the triangle $AB'C$ is isosceles. The triangle ABC is drawn as a generic object satisfying the conditions. As the two triangles share the same basis, the problem reduces to show that:

$$2|AB'| < |AB| + |BC| \quad \text{for all } B \neq B' \text{ on the line } l.$$

To show this, we construct the triangle $B'DB$ that represents the reflection of triangle $B'BC$ in the line l . As a reflection preserves lengths, we have from the resultant triangle ADB :

$$|AD| = 2|AB'| < |AB| + |BD| = |AB| + |BC|. \quad (1)$$

This argument is certainly persuasive, however there are points of awkwardness in it. It rests mostly on Euclidean geometry, for which the recourse to reflection is made mostly on a perceptive level; for instance the fact that the points A , B' and D are co-linear is assumed or regarded obvious in the argument. The reflection is not treated according to definitional tautness.

A little shift in how to read the constructive elements of the diagram removes these difficulties. Now we suppose that D is the point for which B' is the mid-point of AD . Consider the triangles $B'DB$ and $B'CB$. The lengths of two sides are shared as the angle between, so they are congruent. This means that $|BC| = |BD|$ and we are in the position to state the inequality (1) on a firmer ground.

Hence we have demonstrated the proposition via procedures that are in common currency in Euclidean Geometry, and thus we have crafted a proof. We succeeded to circumvent the problem of introducing a reflection. But we have paid a price in doing this. The first argument involving a reflection is more influential in forming the diagram; the second just exploits it.

This example, we contend, illustrates an almost universal phenomenon in formulating a proof; there are 'opposite forces' in basing an argument conceptually against concerns about means of full explication. When elements are introduced that are 'foreign' to the mathematical field in which the task environment is set, either these elements have to be assimilated or have to be sidestepped as in the example above. Obviously it is preferable to have a proof that seems transparent once it has been exposed, and this sentiment has been passed on by many mathematicians as well as educators. The phrase "A good proof is one that makes you wiser", accredited to the eminent mathematician Yu. I. Manin, has become almost a maxim. However, the situation in reality is more complicated. The advantage in distinguishing a credited argument from a proof is that a teacher or student can gauge which of the two 'makes you wiser'.

AN EXAMPLE THAT SHOWS ASPECTS OF STUDENTS' BEHAVIOUR

The example recounted here concerns a student activity. The eight students are, at the time of writing, participants of a master's program in Didactics of Mathematics; all the students had recently graduated from a Mathematics department. For the activity, a task with a 'realistic' context, an informal argument and a mathematical model is the material given to the students; what was left for them to do was to produce an argument in terms of the model. (The example serves as an indicator of issues rather than an empirical analysis, so details of methodology are omitted.)

The givens:

Task: Let $g(n,k)$ denotes the number of ways of placing k indistinguishable lions in n cages (in a row) such that no cage contains more than one lion and no two lions are put in consecutive cages. Show that $g(n,k) = \binom{n-k+1}{k}$ (i.e., the number of ways we can choose k things out $n-k+1$).

An informal argument: Suppose that we have a legal positioning of the lions. Then, except possibly for the k^{th} lion, there is an empty cage to the immediate right to each cage containing a lion. Imagine removing these $k-1$ cages. Then we have $n-(k-1)$ cages remaining and k lions, but now lions can be put into adjacent cages. Hence we are free to place the k lions wherever we want into the $n-k+1$.

Mathematical modeling of the task: Let $S = \{0, 1\}$. Let $S_{n,k}$ be the subset of the Cartesian product S^n where an element of $S_{n,k}$ has exactly k of its components taking the value 1. Suppose that $T_{n,k} \subset S_{n,k}$ is defined by:

$$(x_1, x_2, \dots, x_n) \in T_{n,k} \Leftrightarrow \forall i \in \{2, 3, \dots, n-1\}, \text{ if } a_i=1 \text{ then } a_{i-1}=0 \text{ and } a_{i+1}=0; \text{ if } a_1=1, \text{ then } a_2=0; \text{ if } a_n=1, \text{ then } a_{n-1}=0.$$

What the students were asked to do was to prove that $|T_{n,k}|$ equals $|S_{n-k+1, k}|$.

There are two options for a student to approach this assignment. The first is to translate the sets of the model back to the contextual families of objects and properties (e. g. lions, cages, in a row...) found in the original task environment. Then the set theoretical task is treated through the less precise but more semantic setting of its 'isomorphic' realistic-like task. The disadvantage is not only that you shift from a situation that avails the tools allowing proof to one that does not, but you also have the problem to explicitly express the grounds of the transfer itself. The second option is to keep your work within the set theoretical setting, using the contextual version rather like a 'template' to guide the argument but keeping its influence implicit in the exposition. In this case, the direction would be to construct a bijection between that $|T_{n,k}|$ and $|S_{n-k+1, k}|$. The advantage here is that you are in a

Working Group 1

position to give a direct proof; a disadvantage is that what seems immediate in the other task can transfer to messy constructions mathematically.

Of the eight students that participated, seven students clearly took the first option with various degrees of success in expounding the consonant structure between the two tasks. Their reasoning was in terms of the physically understood objects that appear in the description of the original task. Just one student adopted the second option; in his work, clearly the sets were the central actors, with just a few aside references to the context of the first task.

What is the significance of this in educational terms? The authors designed the assignment wishing to test the students' ability to argue in the environment of a model or a system arising from an act of mathematization. The aim was to push forward students' working from a credited argument to a proof via a structurally isomorphic setting. This aim backfired in the way described above. In fact this was anticipated by the teacher (one of the authors); the assignment was set as homework, and the next class was devoted to open debate about the differences between credited argument and proof, and in what circumstances is it useful to try to render a credited argument into a proof. (Such a class debate was possible because it took place within a course, on problem solving and proof, which was part of a master's program in Didactics of Mathematics.) We do not have the space to describe the dialogue that took place, but the overall opinion was that the process of bringing up the mathematical model, or mathematization, was over pedantic. But in forming this opinion, we would have to accept that, in some cases, argumentation without the definitional tautness to qualify it as a proof can give an acceptable mathematical result, even at the tertiary level.

CONCLUSION

Mathematics students at university are often confused about the nature of proof, and worry whether what they write for a solution is in an acceptable form from the point of view of their teacher. Such confusion is natural because teachers can be inconsistent in what they accept. (For example, the notion of diagrammatic proof is accepted by some mathematicians, not by others.) Subtle hints of the level of deductive reasoning expected can be conveyed; for example, if the directive of a task is in the form 'show that', rather than 'prove that', there is an expectancy that a more relaxed argumentation is allowed. There is a lot of 'etiquette of standards' that students are supposed to pick up by themselves: this clearly pertains to the notion of didactical contract, due to Brousseau (1984). In reality, perhaps mathematicians on their own are not equipped to convey to their students what standards are demanded for different circumstances; educators should take the initiative to assist.

In this paper, we aimed to explain why for certain types of tasks an argument naturally ends even when its form falls below the level expected for a proof. Here we did not insist on formal proof, which we regard as an ideal that in practice is

Working Group 1

rarely respected. However, we did insist that a proof is put on a firm mathematical basis where all objects and actions concerned can be explicitly defined. We pointed out and illustrated some situations where the need for a proof is debatable. In particular, we considered problems that are far from being trivial but are conducive to mental argumentation embracing perceptual elements; also we considered cases where the most natural approach involves more than one mathematical tradition or theory. Are we obliged to model in the first case, and alter the argument such that it fits within a consistent mathematical setting in the latter? We leave this question as an open issue, but we stress that, for students, there is a danger of seeming to be engaged in a game that only a pedant would be interested in. This problem is aggravated in the case where we model one task by another; are we proving the model or the original? In this respect, we raised the issue of the relative meanings of the terms ‘mathematical modelling’ and ‘mathematization’ that deserves more research inquiry.

TWO BEAUTIFUL PROOFS OF PICK'S THEOREM

Manya Raman, Lars-Daniel Öhman

Umeå University

We present two different proofs of Pick's theorem commonly held to be beautiful and attempt to identify features that give rise to the sensation of beauty. In particular, we discuss two concepts, generality and specificity, that appear to contribute to beauty in different ways. We also discuss possible implications of this work for the teaching of mathematics, especially in countries in which discussions of beauty and aesthetics are notably absent from curricular documents.

Keywords: Beauty, Aesthetics, Proof, Pick's theorem, Motivation

INTRODUCTION

The claim that mathematics contains elements of deep beauty seems uncontroversial. The literature abounds with references to this beauty and characterizations of it. For instance Chandrasekhar, a Nobel prize winning physicist, once wrote that “a discovery motivated by a search after the beautiful in mathematics should find its exact replica in Nature persuades me to say that beauty is that to which the human mind responds at its deepest and most profound” (Chandrasekhar, 1987). And Hardy, in his so-called apology for mathematics, asserted, “The mathematician's patterns, like the painter's or the poet's, must be beautiful; the ideas, like the colors or the words, must fit together in a harmonious way” (Hardy, 1940). We even see references to the beauty of mathematics in poetry, such as Edna St. Millay's famous line, “Euclid alone has looked at beauty bare” (Millay, 1941).

What it is less clear is why mathematics appears to us as beautiful. Hardy claimed that the sense of beauty comes, at least in part, from a sense of surprise (Hardy, 1940). Rota refutes this view. He gives an example of Morley's theorem which states that adjacent angle trisectors of an arbitrary triangle meet in an equilateral triangle (see Figure 1), claiming that this theorem while surprising is not beautiful (Rota, 1997). Rota suggests instead that what characterizes beauty is enlightenment, an admittedly fuzzy concept which he claims mathematicians do their best to avoid (Rota, 1997).

Another answer to the question of why mathematics appears as beautiful comes from Scarry, a professor of English at Harvard, whose work has recently gathered attention even in mathematical circles. In her book “On Beauty and Being Just,” she claims that beauty is, in essence, compelling. It draws us to itself. This claim resonates with Poincaré who said, “The scientist does not study nature because it is useful to do so. He studies it because he takes pleasure in it; and he takes pleasure in it because it is beautiful” (Poincaré, 1908). The strong claim is that beauty has some

Working Group 1

sort of allure, similar to that of pollen to the bee, which draws people's interest, allows it to replicate, and secures its future.

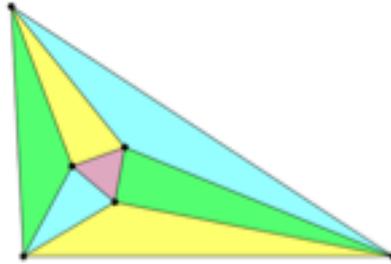

Figure 1: Morley's theorem

PREVIOUS RESEARCH AND MOTIVATION

If beauty is compelling, then it seems natural to ask whether it can play a motivational role in the teaching of mathematics. However, there has been surprisingly little research about this question, and related questions, in the area of mathematics education (ESM, 2002). Most of the work done on this area falls under the broader, related notion of aesthetics, which involves a host of affective components in addition to the experience of beauty, such as the experience of pleasure. One recent example comes from Sinclair (2002) who created a model to describe three important functions that aesthetics play in the working lives of mathematicians: generative, motivational, and evaluative¹. Burton (2004) used this framework to study the aesthetic judgements of mathematicians, looking at the connections between affective experiences of mathematics and intuitions and/or insight that the pursuit of mathematics often provides. Other examples, both from philosophy and mathematics education, include Mack (2006), Tymoczko (1993), and Wang (2001).

This study differs from the previously mentioned in that it specifically investigates the notion of beauty; we are not concerned in this paper with the affective responses, or in fact any other psychological processes related to the aesthetic experience. Another feature of the current study that differs from those previously mentioned is that the main source of data is the mathematics itself, though we draw on pilot data from an interview with one mathematician to help support our analysis, and in a future study will look more closely at interview data. We do not depart from a particular theoretical position, but rather hope to build such a position through a systematic examination of the mathematics, as demonstrated in the analysis below.

A brief look at how beauty is treated in curricular documents in different countries provides some motivation for the eventual outcomes of this project². In some countries, such as China, the aesthetic nature of mathematics is actively researched and explicitly mentioned in the curriculum (e.g. Fu, 2004; Li, 2003; Ministry of China, 2008)³. However, in other countries, such as the United States, Sweden, and

Working Group 1

Finland, there is little or no mention of beauty. In Sweden, there is some explicit mention of beauty at the compulsory level, but not at the high school level (Skolverket, 2000). Moreover, little or no information is given about how beauty should appear in details such as task selection or teaching practices. In the United States, beauty is not listed among the five content and process strands that affect all K-12 levels (NCTM, 2000). Similarly, we found no mention of beauty in the Finnish curriculum (which does stress many affective qualities, such as "courage" in solving problems)⁴. The kind of work done here could eventually serve a purpose both in raising awareness of beauty in countries that do not currently emphasize it and in articulating some of the features of beauty that could be operationalized in curricular documents.

CURRENT PROJECT

The research described here is in its initial stages. The ultimate goal, similar to that described in Burton (2004), is to develop a theoretical model for beauty against which we can compare the views held by working mathematicians. To begin creating this model, we have proceeded fairly simple-mindedly. We looked through the literature to find proofs that are commonly held to be beautiful (e.g. Aigner et al., 2010; Wells, 1990). We wanted to choose theorems that would be fairly uncontroversial but not overly discussed (such as a proof of $e^{\pi i} = -1$). We chose to focus on the beauty found in the proofs, not in the theorems themselves (though the two are often linked). We also asked mathematicians to suggest proofs that they consider beautiful, and now have a small collection of these.

One theorem that appeared both in our literature search and as a suggestion from a mathematician was Pick's theorem, which provides a simple formula for finding the area of a lattice polygon. This theorem is simple enough to be understood and verified by middle schools students, while the statement and proofs of the theorem have relevance for research mathematicians⁵. This feature makes the theorem particularly useful for our study, since on the one hand it is challenging enough to present to mathematicians to obtain data, but on the other hand it is accessible enough to allow us to investigate whether school age children appreciate beauty (or have capacity to appreciate beauty) in similar ways.

Below we will examine two proofs of the theorem, the first suggested by a mathematician in our pilot study, and the second found in Aigner et al., 2010⁶. These two particular proofs were chosen because they are similar in many respects, except for one which we would like to highlight, namely a respect that potentially gives rise to a sense of beauty. The two features of beauty that we will highlight (among many more that could be chosen, with other proofs, or even considering different parts of these proofs, such as the lemmas that support them) are those of *generality* and *specificity*. We suspect that these are two features that appear in many instances of

mathematical beauty and that they will show up as important features when we interview mathematicians about their judgements of these two particular proofs⁷.

PICK'S THEOREM

Pick's theorem gives a simple formula for calculating the area of a lattice polygon, which is a polygon constructed on a grid of evenly spaced points.

Theorem: Let A be the area of a lattice polygon, let I be the number of interior lattice points, and let B be the number of boundary lattice points, including vertices. Pick's theorem says that $A = I + B/2 - 1$.

For example, in the lattice polygon given in Figure 2a there are 16 boundary points and 1 interior point, so the area is $1 + 16/2 - 1 = 8$. (One can confirm this is correct by counting the number of squares and triangles inside the polygon.)

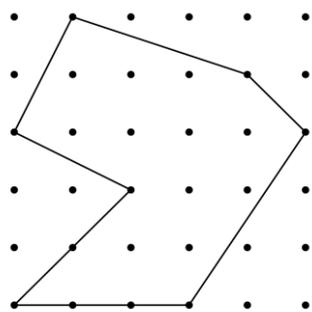

Figure 2a: Lattice Polygon

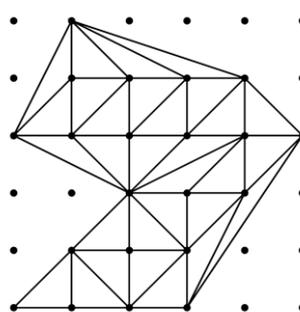

Figure 2b: Triangulated Lattice Polygon

Below we give two different proofs of Pick's theorem, which we claim are beautiful in different ways. Both proofs use a method of double counting based on a triangulation of the polygon (see Figure 2b). In the first proof, we count the angles inside the triangles in two different ways. In the second proof we interpret the figure as a graph and count the number of edges, using Euler's formula to relate the numbers of edges, faces, and vertices of the figure. We will draw on the following three lemmas, which we state here without proof.

Lemma 1: Any lattice polygon can be triangulated by elementary triangles.

Lemma 2: The area of any elementary triangle in the lattice Z^2 is $1/2$.

Lemma 3: Let f be the number of faces, e be the number of edges and v the number of vertices in a connected plane graph. Then $v - e + f = 2$.

Proof 1 (using angles). We begin by partitioning the polygon into elementary triangles, which is possible by Lemma 1. (See Figure 2b.) We now sum up the internal angles of all these triangles in two different ways. On one hand, the angle sum of any triangle is π so the sum of all the angles is $S = N \pi$.

On the other hand, at each interior point i , the angles do not add up to π , but if we add the interior angles of the vertices, we get $k \cdot \pi - 2\pi$, where k is the number of

Working Group 1

vertices, since the sum of the exterior angles is 2π (see Figure 3). Let I be the number of interior points and B be the number of boundary points. In all, the sum of the angles at the boundary points is $B\cdot\pi - 2\pi$, and the sum of the angles at interior points is $I\cdot 2\pi$. Therefore, $S = I\cdot 2\pi + B\cdot\pi - 2\pi$.

We conclude that $N\cdot\pi = I\cdot 2\pi + B\cdot\pi - 2\pi$, so cancelling π we get $N = 2\cdot I + B - 2$. Since by Lemma 2 the area of any elementary triangle is $\frac{1}{2}$, we have $A = \frac{1}{2}\cdot N$ and thus $A = I + \frac{1}{2}B - 1$. \square

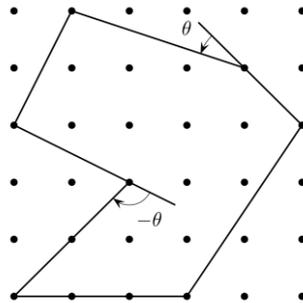

Figure 3: Polygon with one exterior angle marked

Proof 2 (using Euler's Formula). We begin by partitioning the polygon into elementary triangles, which is possible by Lemma 1. (See Figure 2b.) We then interpret the triangulation as a graph (network), where vertices in the graph are vertices of the triangulation, and edges in the graph are edges of the triangles in the triangulation. This graph subdivides the plane into f faces, one of which is the unbounded face (the area outside the polygon), and the remaining $f - 1$ of these are the triangles inside the polygon. By Lemma 2 the area of each triangle is $\frac{1}{2}$, and thus $A = \frac{1}{2}(f - 1)$. This of course proves nothing; it is a simple consequence of how we defined f .

An *interior* edge borders on two triangles (the blue edges marked in Figure 2b), and a *boundary* edge borders on a single triangle and forms part of the boundary of the polygon itself.

Let e_{int} be the number of interior edges, and e_{bd} be the number of boundary edges. Counting the number of edges in two different ways, we get

$$3(f - 1) = e_{int} + e_{bd} (*)$$

(Here we are overcounting to get the total number of edges of the collection of triangles. The left hand side counts these edges using the fact that each triangle has 3 edges. The right hand side counts them using the fact that each interior edge contributes to two triangles while each exterior edge contributes to one.)

We can also observe that the number of boundary edges is the same as the number of boundary vertices, $B = e_{bd}$ and that the number of vertices in the network is the sum of all the interior and boundary points, $v = I + B$.

Working Group 1

Using Euler's formula and substituting for v , we get that $(I + B) - e + f = 2$, or by rearranging, $e - f = (I + B) - 2$, where $e = e_{int} + e_{bd}$ is the total number of edges. With some clever algebraic rearrangements, starting with (*), we get

$$\begin{aligned} f &= -2f + 3 + 2e_{int} + e_{bd} \\ &= -2f + 3 + 2e - e_{bd} \\ &= 2(e - f) - e_{bd} + 3 \\ &= 2(I + B - 2) - B + 3 \\ &= 2I - B - 1. \end{aligned}$$

Thus we get $A = \frac{1}{2}(f - 1) = \frac{1}{2}((2I - B - 1) - 1) = I - \frac{1}{2}B - 1$. \square

ANALYSIS AND DISCUSSION

To what extent are each of these proofs beautiful? We begin with some data from a mathematician who thought the first proof was beautiful. One way in which the proof is beautiful to him is that it gives meaning to the terms I , $B/2$, and -1 . He explains, "In particular, I like that you can see that each boundary lattice point contributes half as much total angle as each interior lattice point." He also said that he likes proofs that get information by counting things in different ways. The particular choice of counting angle measures, though, both contributed and detracted from the sense of beauty in this proof. He says, "The fact that the proof involves angles is beautiful in the sense that it is unexpected, but also ugly in that it breaks some symmetry." Pick's theorem, as stated, holds for any lattice polygons, regardless of whether the lattice itself is transformed in a way that preserves area. However the argument involving angle measures does not. If you shear the triangle, the angle measures change. Thus the introduction of the new quantity does not have the same property as the figure itself, which this mathematician referred to as "unnatural."

In contrast, the second proof, using Euler's formula, uses only quantities that are invariant under transformation. What seems beautiful about it is that it turns out to be an application of Euler's formula. One gets a sense of "even here, this method can apply!" But whereas the second proof is more general than the first (we introduce no auxiliary concepts) it is much less intuitive. The first proof, besides the sophisticated application of double counting, is fairly elementary. Even a grade school child can count the angle measures in both ways described above. However, the second proof requires a bit more machinery to understand. First one must conceptualize the plane in such a way that Euler's formula applies (which includes the somewhat strange step of considering the complement of the polygon in the plane as a face in itself.) Also, in applying Euler's formula, one is resting on a result which by itself is not obvious. Even if one really believes Euler's formula and feels comfortable using it to get the result, one doesn't get a full understanding of the proof if one doesn't in turn

Working Group 1

understand why Euler's formula is true. This reliance on heavy theory seems to be an aspect which detracts from the beauty of the second proof.

We see then that in each of the proofs there is some feature that contributes to the beauty and some feature that detracts. It turns out in this case that the features are complementary. The feature that contributes to the beauty of the first proof is missing in the second and vice versa. For instance, in the second proof, what makes it beautiful is some sort of generality. This particular proof fits into a family of proofs all of which are instances of Euler's formula. In the first proof, what makes it beautiful is some sort of specificity. The surprising use of angle measures in the double counting introduces some unexpected element, which on the one hand breaks the harmony of the proof, but on the other hand— perhaps because of that breaking— becomes a compelling feature of the argument.

Both proofs appear to contain an element of surprise, but the nature of that surprise is almost opposite. In the first case the surprise arises from the specificity. We contend that the pleasure one gets from reading the proof is similar to the feeling of finding a specific tool, like the correct size hexagonal screwdriver for one particular screw. In the second case the surprise comes from the feeling of generality. The sense of fitting in arises from there being a set of objects that have a similar property. It is a wonderful, unexpected finding that this second proof is one of those kinds of proofs. To continue the tool analogy, Euler's formula is the monkey wrench, that is suitable for a great number of different situations.

CONCLUDING COMMENTS AND NEXT STEPS

To claim that generality and specificity contribute to the beauty of these proofs through some element of surprise, we must return to Rota's criticism that beauty arises out a feeling of enlightenment rather than surprise. His critique was grounded on the fact that there are proofs that are surprising, but nonetheless not beautiful. For now we leave this as an open question, with the possibility that surprise might be a necessary (or at least contributing) but not sufficient condition for beauty. We note, however, that what seems similar about surprise and enlightenment is some sort of allure, something that grabs the mind's interest. And it might be this allure, or "compelling"-ness referring back to Scarry again, that is the defining characteristic of beauty.

It seems fairly obvious to say that for a proof to be compelling, it must on the one hand be not too simple, and on the other hand not too complex for the mind to grasp. It might be that the features of generality and specificity are what keeps these two particular proofs appropriately compelling. The specificity of the first one makes the proof technically accessible. The generality of the second one imparts a certain status. Another striking characteristic of these two features is the fact that they play mirrored roles with each other— they are in a sense duals— and the way in which they

Working Group 1

mirror each other is that one contributes to beauty in exactly the way that the other detracts.

At first the fact that two seemingly opposite characteristics could both give rise to beauty might seem contradictory, but we offer another interpretation: that beauty arises from the interplay of a sort of access and restraint. A potentially beautiful object which was completely accessible might not appear beautiful, just as a potentially beautiful object that is completely hidden would never be able to be experienced as beautiful. The proof based on Euler's theorem brings out some sort of hidden structure; the proof based on angle measures provides a specific instantiation of an otherwise seemingly common sort of mathematical tool.

Generality and specificity might not be just two features of beauty— they might turn out to be *exactly* the aspects of mathematical expression which provide the needed tension to give rise to the sense of beauty. We do not rule out that there might be other features that give rise to beauty, but from our preliminary analysis, we are willing to commit that the fact that we found these two particular features here is not surprising, nor idiosyncratic.

This study was meant as a first step into a rather large inquiry domain. The goal was to make the pursuit of a study of beauty in mathematics tractable, both in terms of methods and potential results. This study gives rise to a few hypotheses that we would like to investigate (and invite others to investigate!) in future studies. These include:

- (i) The features of generality and specificity are not idiosyncratic. They appear in a wide number of proofs commonly held to be beautiful.
- (ii) There is consensus among mathematicians, not just about which proofs and/or theorems are beautiful, but also about what gives rise to the sense of beauty.
- (iii) The fact that generality and specificity are related, as duals, is also not a coincidence. If there are other features that give rise to beauty, they will also be related in a way that creates some sort of tension, and the sense of beauty that arises will be related to this tension.

NOTES

1. A description of these functions is given in Sinclair (2002): "The most recognized and public of the three roles of the aesthetic is the evaluative; it concerns the aesthetic nature of mathematical entities and is involved in judgments about the beauty, elegance, and significance of entities such as proofs and theorems. The generative role of the aesthetic is a guiding one and involves non-propositional modes of reasoning used in the process of inquiry. I use the term generative because it is described as being responsible for generating new ideas and insights that could not be derived by logical steps alone. Lastly, the motivational role refers to the aesthetic responses that attract mathematicians to certain problems and even to certain fields of mathematics."

Working Group 1

2. Thanks to the following people who provided information on statements about beauty and aesthetics in curricular documents: Antti Viholainen (Finland), Kirsti Hemmi (Sweden), Aihui Peng (China). We welcome examples from other countries, especially those that incorporate beauty in a meaningful way.
3. Some examples of curricular statements include "appreciate the aesthetic value of mathematics theorems and mathematics methods", "experience the flexibility, the elegance (similar to the beauty, but higher than beauty, and ingenuity of mathematical proof)", "experience the beauty of figure".
4. See http://www.oph.fi/english/publications/2009/national_core_curricula_for_basic_education.
5. See http://www.cut-the-knot.org/ctk/Pick_proof.shtml for a web application of a classic way of introducing the task to middle school students. And see Sally & Sally (2007) for a lovely exposition of how this task can be made relevant to people of all ages, from school children to research mathematicians, not just in terms of verifying the theorem, but in terms of really understanding the underlying ideas. Yet another proof of the theorem, using a heat model, can be found in Hanna & Jahnke (2007).
6. These two proofs correspond closely to the two proofs given in Sally & Sally (2007).
7. To be clear, our goal here is not to establish that these two features capture all aspects of mathematical beauty, but rather to suggest that they are two features that could give rise to the sensation. The argument presented in the paper is a sketch what a mature argument about beauty in mathematical proof might look like, using the mathematics itself (rather than psychological or sociological data) as our primary data source.

MULTIMODAL DERIVATION AND PROOF IN ALGEBRA

Reinert A. Rinvold

Hedmark University College, Norway

Andreas Lorange

NLA University College, Norway

This paper is a combination of a theoretical paper and a case study. The theoretical purpose is to introduce the concept of multimodal proof into the context of algebra in mathematics education. The case study follows two teacher training students conjecturing and proving results in an environment of visual and physical number patterns. The case study is used both to discuss what multimodal proof can be in this environment and to show some of the potential of such reasoning in the learning of proof.

Key words: multimodal proof, proof environment, algebra, physical number patterns.

INTRODUCTION

The interest in visual proof and visual reasoning has been increasing over the last decades. This is the case both inside mathematics and in mathematics education. Several references are given in Bardelle (2009). Barwise and Etchemendy (1994) has developed a computer based proof environment called Hyperproof. Logic students carry out proofs with this program that combines sentential formal logic rules with visual reasoning related to positions and sizes of boxes and pyramids. Barwise and Etchemendy (1996) use the phrase heterogeneous proof for this kind of proofs. This name points to the two distinct kinds of reasoning involved. Oberlander, Monaghan, Cox, Stenning and Tobin (1999) characterize hyperproofs as multimodal, because of the use of both graphical and sentential methods. We think that also other modalities are relevant for mathematical proof. In the context of mathematics education it is possible to involve students in proof like activities which not only uses the sentential and visual modality, but also the tactile, speech and motor action. We introduce a general concept of multimodal proof that intends to cover both formal proofs, visual proofs and proof like student activities. We are not claiming that multimodal proof should be seen as legitimate rigorous mathematical proof. The phrase “visual proof” is widely used even if many mathematicians do not accept such reasoning as part of rigorous proof. In the same way multimodal proof may be seen as a kind of intuitive proof.

This paper analyzes one empirical case study with teacher training students to show what multimodal argumentation and proof can mean. The learning of proof is difficult for students, especially if their background in formal mathematics is weak. Proving in the context of visual and physical number patterns gives meaning and allows for the students’ intuitive thinking. Seeing the conjecturing and arguing

process with number patterns as multimodal proof, makes clearer the potential this kind of activity has for proof learning. This uncovers structure in the students' thinking similar to traditional proof but in other modalities. Those similarities explain why we use the term “proof”, and not just multimodal argumentation.

THE CONCEPT OF MULTIMODAL PROOF

In traditional formal proof, the emphasis is on the modality of written symbols and sentential reasoning. A multimodal proof is a generalized proof which beside written symbols and sentential reasoning can also include the visual modality, speech, the tactile and motor action. Gestures are included in the latter. Multimodality means that more than one modality is involved. Barwise and Etchemendy (1996) make a point that visual and non-visual proofs are not separate worlds. Visual proof is, of course, highly dependent on the visual modality, but the mathematician looking at such proofs invokes both language and mathematical concepts in his thoughts. Moreover, proofs not mentioning any picture or diagram have visual aspects. The first argument is that written mathematical symbols by themselves are visual (Rinvold, 2007). Secondly, mathematicians almost always relate intuition to their proofs. This intuition is very often connected with visual ideas, for instance see Sfard (1994).

It is not the intention of this paper to give a precise definition of what a multimodal proof is. This has to be done in forthcoming papers. At the moment we make a first step. In order to increase precision, attention can be restricted to subclasses of the general concept. The concept of proof environment may be useful. The proof environment is the available and allowed resources, objects, operations and modalities. In a sense we have one concept of multimodal proof for each possible proof environment.

A formal proof can be seen as symbols on paper. Multimodal proofs can also be mediated by books, as for instance in Nelsen (1993, 2000). The inclusion of gestures, speech and motor action, means however, that multimodal proof has to be linked to human cognition. More specifically, we are talking about sensuous cognition, cf. Radford (2009). We adapt the semiotic-cultural perspective. “Thinking is considered a sensuous and sign-mediated reflective activity embodied in the corporeality of actions, gestures, and artifacts.” (p. XXXVI). In the environment of our case study, gestures, tactility and motor action is considered both to be genuine parts of cognition and multimodal derivation.

A difference between text based proof and multimodal proof is the non-linearity of the latter. In the “proofs without words” of Nelsen (1993, 2000), some proofs are given holistically by diagrams with limited guidance to the reader. Traditional proofs are given step by step. Numbering of formulas and names of applied theorems are ways to guide the reader. When the carriers of information are physical, gestures are an important way of directing the attention. More specifically, pointing gestures are

used for this. The research literature uses the name *deictic gestures*. According to Sabena (2008) “*deictic gestures*: indicate objects, events, or locations in the concrete world” (p. 21). Some words in written language or oral speech have a similar function. Radford (2009) gives the examples “top” and “bottom” (p. XLI). These kinds of words are called “spatial deictics”, (p. XLI). Other pointing phrases are “this one” and “that one”. Both linguistic and non-linguistic deictics are central to multimodal deduction. In classical proof we use mathematical deictics as “equation 25” or “theorem 4”, which means that neither this kind of deduction is completely linear.

ALGEBRAIC THINKING IN MATHEMATICS EDUCATION

In mathematics education the multimodal perspective has been used to analyze student thinking, especially in algebra and functions. Radford, Edwards and Arzarello (2009) introduce what they called “construction of mathematical meaning from the perspective of multimodality”:

... taking into account the range of cognitive, physical, and perceptual resources that people utilize when working with mathematical ideas. These resources of modalities include both oral and written symbolic communication as well as drawing, gesture, the manipulation of physical and electronic artefacts, and various kinds of bodily motion. (Radford, Edwards and Arzarello 2009, p. 91)

Our use of the word multimodal is inspired by and compatible with the perspective of those researchers. Radford (2009) have used a multimodal approach to the introduction of students to the elementary parts of algebra. We share the context of visual number patterns in algebra with Radford, but our focus on proof is new.

Radford classifies algebraic thinking into three forms, factual, contextual and symbolic. Following Radford, contextual thinking acknowledges a general figure through the concept of figure number, but “still supposes a spatially situated relationship between the individual and the object of knowledge...” (p. 9). The students’ reasoning depends on the particular context and perspective. When the students start to use symbols for variables, but still think contextually, Radford observed a phenomenon which he called iconic formulas or formulas as narratives. Formulas are not simplified, but divided into parts. Each part tells a story about the corresponding part of the pattern described by the formula. We identified both the use of contextual thinking and iconic formulas by the students in our case study. Contextual algebraic thinking is not necessarily a low level of thinking, but the students also need to master the symbolic form in order to use multimodal thinking in a mature way.

LEGITIMACY OF MULTIMODAL PROOF

In pure mathematics, visual proofs are still not widely accepted as legitimate part of rigorous proof. However, arguments have been put forward that may change this in

the future. Barwise and Etchemendy (1996) have done work in mathematical logic which argue for the legitimacy of some kinds of visual reasoning. In philosophy of mathematics Brown (2008) argues for the possible validity of pictures in proofs. Jamnik, Bundy and Green (1997) and other studies in the field of automated reasoning have also indirectly provided good arguments for the case of visual proof. They have shown that typical diagrammatic proofs can be formalized with recursive ω -logic and automated. This is an argument for the legitimacy of a wide class of visual proofs. These proofs are based on generic reasoning. In such proof the general is proved through special cases. One or two instances are used to describe how to carry out the proof for any instance. Recursive ω -logic is an alternative to the classical induction approach, but equally valid. In ω -logic a formula is proved if you have a proof for each instance of the formula. A recursive ω -proof also has an algorithm to find the proof of each given instance. The use of physical figures and number patterns in our case study are confined to generic reasoning. The validity of multimodal reasoning in these kinds of environments thus rests on the correctness of generic arguments.

Conditions for legitimate formal reasoning are well developed. Similar analyses of visual reasoning are still in an early phase. The work of Barwise and Etchemendy (1996) is relevant also for multimodal proof, but the possible legitimacy of multimodal proof is not yet analysed in depth. An idea of Barwise and Etchemendy (1996) that can be useful for such analysis is the concept of information. "Valid deductive inference is often described as the extraction of making explicit of information that is only implicit in information already obtained." (p. 4). Mathematical formulas and written text contain information. Classical proofs show how the information given by a theorem is already implicit in axioms and established mathematical results. Also pictures, diagrams and physical patterns contain information. A map, for instance, contain lots of information. If you know the use of a map and compass, you can deduce how to get from A to B. As in classical proof, some deductions are valid and others not. You do not get from A to B if you do not use the map and compass in legitimate ways.

METHODOLOGY

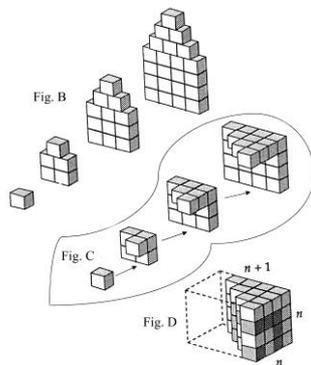

The paper uses one single successful case study with teacher training students to give examples and to discuss what multimodal argumentation and proving can mean. The students are in a problem solving process leading to derivation of formulas. We do not see a straight line of reasoning, but also some mistakes and dead ends. As such, the students are proving, not presenting a proof. The data gives examples of multimodal proving, but much of the argumentation could with some refinement be part of a multimodal proof. We thus see continuity between proving and multimodal proof. Within a traditional proof paradigm, more radical changes are needed to go from the students' argumentation to proof. However, we do not claim that this kind

Working Group 1

of continuity between argumentation and proof is always the case within the multimodal paradigm.

In the spring of 2009 five pairs of teacher training students took part in a study conducted at Hedmark University College and NLA University College. All of the students were following a course in number theory at one of the two colleges. The pairs were asked to investigate number patterns represented by visual and physical figures. Their work is immediately followed by an interview by one or both researchers. Both the student investigations and the interviews were videotaped. One episode from one of the pairs is chosen for analysis. The selected pair clearly was the most successful. We observed a complex interplay between the students and between visual diagrams, physical figures, speech, gestures and formulas.

THE START OF THE CASE STUDY

The students Erik and Jon are given a problem sheet with two equivalent visual number patterns B and C and asked to find out as much as possible about the sequence. Also included is a figure D. The latter figure results when the four figures in C are joined. In front of the students are physical versions of C and D built from plastic cubes. More cubes are available so that they may build their own figures. Each student also has a personal note sheet. Before we come into the story, the students have spent about 20 minutes. Among other things, they have derived an explicit formula for the sequence in B by decomposing each figure into a square and a triangle on top of it. They also observed that B and C give the same sequence.

THE FORMULA TO BE PROVED

We will follow the derivation of a recursive formula for the sequence in B. The students were not asked to prove such a formula. They discovered and proved the formula themselves. In the problem solving process the given recursive formula was the end product. They first wrote the square part of the formula and then added the triangle part. As can be seen, F_{n-1} was written at a later stage.

$$F_n = \underbrace{F_{n-1}^2}_{\square} + \underbrace{n-1}_{\triangle}$$

Working Group 1

F_n refers to the n 'th figural number from the left in B or C. The formula is a combination of standard mathematical symbols, curly brackets and drawn figures. The latter signify the square and triangle part of the formula. The formula to be proved is not part of standard notation. The drawn square and triangle link the formula to the multimodal context of the activity. Following Radford (2009), the formula could be seen as iconic or as telling a narrative. This means that the formula mirrors the division of each figure into a square part and a triangle part.

In the following analysis, we use the students' argumentation to show what a multimodal proof can be. Deictics has a central role. We also look for generality in the students' thinking. One example is the use of indices. It is not mature, but nonetheless they think generally through them.

THE BEGINNING OF THE DERIVATION

The start of the derivation is an oral description of the task:

105 Jon: We are going to find a formula to find the next one when we know this one.

Descriptions, definitions and reformulations are often the start of direct proof. No deictic gestures are used in 105. This may be interpreted as generality in the students' reasoning. Then they enter a journey outside the main path, but after a while Jon reformulates 105 with gestures and symbols on his note sheet. He has already written " $F_n = F_{n-1} +$ ".

139 Jon: To find F_n [pointing at the sign F_n on his note sheet] it's the last one [circular pointing gesture around F_{n-1}] plus something more [points to the right of +].

Both deictic gestures and deictic speech turn up already at this juncture when standard mathematical symbols appear. The last deictic gesture is abstract pointing. According to Sabena (2008), abstract pointing is "when there is no actual physical pointed object, rather the pointed empty space houses an introduced reference, ..." (p. 22). Then Jon introduces the visual B-pattern on the problem sheet. The second and third figure in this pattern are denoted $F_2(B)$ and $F_3(B)$.

141 Jon: It becomes this [circular pointing gesture around $F_2(B)$] plus something more [points in direction of $F_3(B)$].

The deictics shows the connection when 141 is derived from 139. Note the striking similarity between gestures linked to corresponding terms, for instance the circular pointing gestures used both for the sign F_{n-1} and the visual figure $F_2(B)$.

THE LEMMA

At this juncture both students start to manipulate the physical figures. Jon puts F_2 and F_3 together and then takes one of these figures in each of his hands. After a short period of silence Jon expands what he wrote in 139 to this formula:

146 Jon: $F_n = F_{n-1} + (K_n - K_{n-1}) + (T_n - T_{n-1})$

Working Group 1

K_n and T_n refer to the n 'th square numbers ('Kvadrattall' in Norwegian) and triangular numbers.

147 Jon: This one is nice [smiling]! But, is it correct?

The question about correctness means that 146 at this stage is a conjecture or a lemma to be proved. The lemma splits the problem of 105 into two parts. Jon's smile and description of formula 146 as "nice" may be an indication that this is the kind of answer which is expected in mathematics. But, we will see that the formula is used more as a vehicle of thought than in the standard way. Careful readers may have noticed that the indices for the triangular number part are wrong. The students, however, do not comment on this "mistake", but get it right when $T_n - T_{n-1}$ is replaced by $n - 1$. The indices n and $n - 1$ at this stage seem to have the operational meaning "the next one" and "this one". One argument for this is the complete similarity between Jon's derivations of the triangle part and the square part of 146. Because of this similarity we only show Jon's derivation of the square number part:

149 Jon: From this one [pointing to physical F_2] to this [pointing to F_3], this square number is added [lay his fingers down on F_3] minus the square number we had earlier [makes a circular pointing movement around the bottom of F_2]. $K-n$ minus $K-n$ minus one.

In fact, Jon uses 141, but he has replaced the visual B-patterns with the physical figures. 149 is the first time physical figures are explicitly used in the derivation. Deictic gestures now have a vital place in the derivation to show which part of the figures which is in focus. Note how the physical figures give possibilities for clearer and more precise gestures compared with the visual B- and C-figures.

THE FINAL PART OF THE DERIVATION

Now we come to a striking example of multimodal proving involving physical objects and gestures. The lemma (146) is proved, and the students return to the derivation of the recursive formula. They are going to replace each part of the lemma with a simplification.

152 Jon: [Laughs] I doubt the formula should look like this.

153 Jon: It isn't very nice, but [smiles and laughs] [silence]

154 Jon: Yes, gets right, yes, but probably has to be rewritten in one way or another.

At this moment Jon realizes that the lemma can be simplified and starts to think how. We will follow the simplification of the square number part. The reasoning for the triangle part is similar. Jon has changed his mind and does not find the formula

Working Group 1

“nice” anymore. Jon’s question is triggering Erik to make a contribution. He takes the physical F_3 and puts it on top of F_4 :

- 159 Erik: What is added then? It is the sides, the sides of the first quadrilateral number plus one. [He moves his finger along the side while talking.]
- 160 Erik: Like quadrilateral numbers...
- 161 Jon: n minus one then
- 162 Erik: Two times minus one plus one. [He writes a formula on his note sheet.]

$$F_n = F_{n-1} + 2(n-1) + 1$$

- 163 Erik: The corner is included. [He points to the corner between the mentioned sides.]

Erik locates the square numbers as the bottom part of the physical figures. He physically compares the bottom squares of F_4 and F_3 . The way the figures are relatively placed allows him to show one of the added sides with a sliding finger gesture. The plus one is explained by pointing to the corner below the triangular number part of the white physical F_4 .

This explanation by Erik is an example of reasoning which can be refined. His idea is good, but the triangular number on top of the bottom square obscures the reasoning. In fact, Jon does not understand, and Erik follows up by an improvement. Erik takes off the triangular parts of F_2 and F_3 and places K_2 on top of K_3 .

Then he shows a sliding finger movement along each of the two sides and points with a finger to the corner. Now it is obvious to Jon what is going on.

THE GENERALITY OF THE REASONING

The interview indicated that the concept of figure number was a safe ground which resolved potential dangers in general reasoning. Again, this corresponds to the contextual form of reasoning in the classification of Radford (2009).

- 341 Jon: We noticed by looking at the drawing that the square number equals the figure number.

Working Group 1

342 Researcher: Yes.

343 Jon: And the triangle number is one less.

Except for the non-standard use of indices in the lemma, they always related figure numbers correctly to symbolic variables. This indicates that the students were aware of the generality of their reasoning. Their switching between different values of n when relating to physical figures strengthens that conclusion. In “The final part of the derivation” Jon uses $n = 3$ and Erik $n = 4$, but they do not comment on the difference. Jon and Erik behave as if they are talking about the same thing. A few minutes later Erik repeats his sliding finger gesture argument with $n = 3$, also with no comments. Jon was convinced that the reasoning done for a particular value of n could be done for all other values as well. They have tested the formula in the theorem for $n = 4$, but not for $n = 5$. When the researcher asked for reasons to trust the formula, Jon repeated the derivation from the third and fourth physical figures. Then the following dialog ends the interview relating to the recursive formula:

428 Jon: You really see that it’s logical both from the figures and from the plastic cubes.

429 Researcher: Yes, you could have built something similar if we considered number five from four, for instance?

430 Jon: Yes! [Looking convinced]

CONCLUSION AND QUESTIONS FOR RESEARCH

Traditional proof has been thought to consist only of sentential reasoning. Visual proof in an active way uses visual information. Multimodal proof can also include the use of physical objects, the tactile, gesture and other kinds of motor action. Especially the latter modalities transcend the traditional concept of proof.

The analysis of data has shown that quite advanced multimodal proving is possible for students even if their form of algebraic thinking is partly contextual and only to some extent symbolic. There is a form of structure in their proving even if they are not trained in formal proof methods. A possible explanation is the resources of intuitive thinking which is opened by this approach. A conclusion is that this kind of proof activities has a potential in proof learning. The data analysis has also shown the important role of deictics in multimodal reasoning.

The concepts of multimodal proof and derivation need further clarification and development in order to discern valid proof from other kinds of activity and presentation. We think that the concepts of proof environment and extraction of information will be helpful in this. Further research is needed both to find conditions for valid reasoning and to investigate the role of deictics in multimodal proof. The latter may also be a key to better understanding of visual proof. In mathematics education more empirical studies are necessary, combined with development of better design and teaching approaches. A question of research is how to support the development of students reasoning to include a symbolic form of thinking.

THE VIEW OF MATHEMATICS AND ARGUMENTATION

Antti Viholainen

Umeå Mathematics Education Research Center

Umeå University

The view of mathematics affects how the role and function of argumentation is seen. If mathematics is considered as an axiomatic system, arguments have to be based on definitions, axioms and previously proven theorems, and the function of argumentation is mainly to verify and systematise a statement. On the other hand, if mathematics is seen as thinking and learning process, which requires conceptual and holistic understanding, then arguments based on more concrete representations are important. In this latter case, the function of argumentation is to engender understanding by explaining. These two types of argumentation provide a framework, which could also be applied in the design of teaching.

Key words: argumentation, formal and informal reasoning, mathematical views, representation.

INTRODUCTION

What kinds of arguments should be favoured in mathematics education? What kinds of arguments should students learn to understand, produce and present? These are important questions in design of teaching practices, teaching materials, assessment etc. In this paper some aspects to these questions will be presented on the basis of different views of mathematics and results of some earlier studies about mathematical reasoning.

Arguments can be seen both as elements and as products of a mathematical reasoning process. Often an aim of a reasoning process is to construct an argument. This process may include inductive, deductive or abductive reasoning, use of intuitions, making conjectures and testing of them etc. Both cognitive and affective factors influence this process (Furinghetti & Morselli, 2009). It may also include construction of sub-arguments, which are needed in other parts of reasoning. Also, different kinds of representations may be used in the reasoning process.

Toulmin's (2003) model of argumentation in mind, it can be said that the aim of argumentation is to construct an explanation (*a warrant*) for why the information concerning the initial state (*the data*) necessitates the statement which is argued (*the conclusion*). In some cases, a justification for the authority of the warrant (*backing*) is also needed. The same conclusion can often be argued by using different kind of arguments.

In order to answer to the question why *proofs* are needed in mathematics, the following functions are often presented: *verification, explanation, systematisation, discovery* and *communication* (Hanna, 2000; de Villiers 1999). Argumentation has a

broader meaning than the term proof, but it can be thought to have these same functions too. In the following, more specifically the functions of verification, explanation and systemisation are evaluated with respect to different views of mathematics.

DIFFERENT VIEWS ABOUT MATHEMATICS AND ARGUMENTATION

Mathematics can be considered either as *a toolbox*, as *a system* or as *a process* (Törner & Grigutsch, 1994). The toolbox-view means that mathematics is seen as a set of skills, the system-view means that mathematics is a logical and rigorous system and according to the process-view mathematics is a constructive problem solving process (Törner, 1998). Ernest (1989) has presented a corresponding division by defining *the instrumentalist view* to mean that mathematics is seen as “an accumulation of facts, rules and skills to be used in the pursuance of some external end” (p. 250), *the Platonist view* to mean that mathematics is “a static but unified body of certain knowledge” (p. 250), and the *problem solving view*, for one, to mean that mathematics is “a dynamic, continually expanding field of human creation and invention” (p. 250).

The toolbox/instrumentalist view and argumentation

The view of mathematics has an influence on how teaching and learning of mathematics are seen. On the basis of several studies, Beswick (2005) has connected the instrumentalist view to content-focused teaching in which emphasis is on performances and learning is seen as a passive reception of knowledge. At least, the toolbox/instrumentalist view alone is neither sufficient nor desirable, because deep understanding, knowledge construction and learners active role have been omitted from it, and mathematics as such is not seen interesting. Therefore, the role of argumentation is only to ensure the correctness of facts and rules, that is, only verification can be considered as a function of argumentation.

The system/Platonist view and argumentation

The Platonist view is often connected to an objectivistic worldview. According to Ernest, the Platonist view involves understanding mathematics as a consistent, connected and objective structure. Mathematical objects are seen to be real and exist independently of human (Brown, 2005). Mathematical statements are considered to be objectively true or false and their truth-values are also seen to be independent from human. In addition, mathematical knowledge is seen to be non-empirical. This kind of objectivistic view of knowledge implies easily that, in the classroom, the teacher is seen as an explainer and the learning is seen as a reception of knowledge. According to Beswick (ibid.), the Platonist view also implies content-focused teaching. However, the emphasis is on understanding: Learning is seen as an active construction of understanding, but through assimilation of received knowledge.

On the other hand, the view about mathematics as a system is so salient that it cannot be omitted. The building of an axiomatic system can be seen as an essential goal in mathematics [1]. *Systemisation* means that various known results are ordered into a deductive system, and it has usually been considered as one important function of proof and proving (Hanna, 2000; de Villiers, 1999). According to De Villiers (ibid.), systemisation is useful, because it “helps to identify inconsistencies, circular arguments and hidden or not explicitly stated assumptions” and because it “unifies and simplifies mathematical theories by integrating unrelated statements, theorems and concepts with one another, thus leading to an economical presentation of results” (p. 277). In addition, de Villiers mentions a global perspective and easiness in applications as benefits of systematisation.

Mathematics can yet be considered as a consisted and connected structure without any global or objective meaning. It may be seen either as a personal or socially shared construction, which works as a frame of reference in mathematical reasoning. It is not seen as an objective system, but the wideness in which the system is socially shared may vary. This kind of view is well compatible with the problem solving view, which is discussed in the next section.

If mathematics is considered as an axiomatic system, an important function of argumentation is to connect a statement to the system. Therefore, it is important that the argument is based on the elements of the existing system. By applying Toulmin’s model, the concept of *a formal argument* can be defined in the following way:

An argument is *formal*, if its warrants are based on definitions, axioms and previously proven theorems, i.e. the elements of an axiomatic system.

Usually formal arguments are rigorous and detailed, and, thus, they remove all doubts and uncertainty about the truth of a statement. Therefore, in addition to systemisation, verification is their important function too.

The process/problem solving view and argumentation

According to Beswick (ibid.), the problem solving view can be connected to learner-focused teaching, in which learning is seen as autonomous exploration of the learner’s own interests. Beswick sees the process/problem solving view to be in accordance with the principles of the constructivist learning views. If mathematics is looked from this point of view, it is important that the learners understand the content conceptually and holistically and that they can connect it to their earlier experiences, either inside or outside of the field of mathematics. In addition, invention of new creative ideas is important. According to de Villiers (ibid.), the aim of an explanation is to help an individual to understand the reasons, why a statement is true, in other words, to provide an insight into why the statement follows from the given data. This function of argumentation is crucial when mathematics is seen from the process/problem solving view.

Working Group 1

Weber and Alcock (2004) have presented a categorization for proof production, which contrasts the functions of verification and explanation. According to their categorization, *a syntactic proof production* refers to reasoning in which inferences are drawn using only symbolic manipulation in a logically permissible way and *a semantic proof production* means that different kind of internally meaningful representations or mental images (Weber and Alcock use the term instantiations) are used to guide the reasoning [2]. Weber and Alcock regard the semantic proof production primarily as a support for the syntactic proof production so that it guides the process of choosing proper facts and theorems to apply. By the semantic proof production an individual can in a meaningful way make sense of the claim, get suggestions about inferences that could be drawn and become convinced at an intuitive level about the truth of the claim.

A similar contrast between the functions of verification and explanation is observed in Raman's (2002; 2003) categorisation of arguments into private and public ones. According to her *a public argument* has to be sufficiently rigorous for a particular mathematical authority, like a teacher at school, and it has to reveal step-by-step the progress of inference and justifications for each step. Instead, *a private argument* is an argument engendering understanding and having an essential role in facilitating conceptual and holistic understanding of relationships between concepts. According to her, private arguments are often based on empirical or visual data.

Construction of mental images is important for understanding explanations but also to construct explanations. According to Presmeg (2006a), a mental imagery may occur in various modalities, such as sight, hearing, smell, taste or touch, but in mathematical thinking the visual modality is the most prevalent one. Therefore, it is understandable that the role of visual representations in learning of mathematics and in mathematical reasoning is an issue that has widely aroused interest and vivid discussion among mathematics educators (Presmeg, 2006b).

The following definition of *an informal argument* emphasises the need for explanations as a function of argumentation:

An argument is *informal*, if its warrants (cf. Toulmin's model) are based on concrete interpretations of mathematical concepts, which may be based on visual or other illustrative representations.

According to this definition, the characteristic of informal arguments is that mathematical concepts are interpreted by using illustrative representations. Perhaps, visual representations are the most important ones, but, in addition to them, mathematical concepts can be illustrated, for example, by relating them to some physical context. However, the illustrative effect of representations and the explanatory effect of arguments based on them may depend on personal experiences, situational factors and the field of mathematics. In the next section, an example concerning the concept of derivative is presented.

FORMAL AND INFORMAL ARGUMENTS

An example: Formal and informal reasoning concerning the concept of derivative

The formal definition of derivative in the case of a real-valued function of a single variable is based on the concepts of function, limit and real numbers. If these concepts have been defined earlier in teaching, then the aforementioned formal definition connects the concept of derivative to the axiomatic system. [3]

By using visual representations, the meaning of the derivative can be described by referring to the steepness of the graph of a function. It can be explained that the sign of the derivative reveals whether the graph is going up or down, and the absolute value describes how steep the uphill or downhill of the graph is. It can also be said that the derivative at a given point is the slope of a tangent line drawn to the graph at this point. For more dynamic visualisation the derivative can be illustrated by sliding a pencil along the graph from left to right so that the pencil always lies on the tangent line, and the nib of the pencil points in the direction of the movement (Hähkiöniemi, 2006).

An instantaneous rate of change can be regarded as a physical interpretation of derivative. For example, instantaneous speed is the derivative of the total distance travelled as a function of time, instantaneous acceleration is the derivative of the speed as a function of time, and the electric current is the derivative of the flowing electric charge through a surface.

Next the theorem stating that the derivative of a constant function is everywhere zero is considered. By implementing the formal definition of derivative, this theorem can be proven through a short calculation. Visually, the same result can be reasoned by explaining that because the graph of a constant function is a horizontal straight line, it does not have any uphill or downhill and, therefore, the tangent drawn to the graph is everywhere a horizontal straight line, whose slope is zero. Physically, the same thing can be reasoned by explaining that if a quantity is constant, its value does not change, and thus the rate of change is everywhere zero.

Relationship between formal and informal arguments

Previous examples illustrated how formal arguments usually serve for the functions of systematisation and verification, and how informal arguments often serve for the function of explanation. However, this categorization is not absolute: A formal argument may be explanative, but this requires that its overall central ideas are recognised. On the other hand, an informal argument may in some cases be general and rigorous enough so that it is sufficient to verify a statement. Especially, the role of visual arguments has occasionally raised vivid discussion among researchers of mathematics education (Presmeg, 2006b). Several researchers have proposed that

Working Group 1

visual arguments should be considered as an intended and accepted form of final arguments (Arcavi, 2003; Dreyfus, 1994; Rodd, 2000).

Construction of formal arguments often requires exact and detailed analytic reasoning based on symbolic representations and procedural skills to carry out calculations and other technical procedures. However, informal arguments may reveal holistic features and wider trends, which, yet, may also be very important in the construction process of the argument, by simplifying and concretising the problem situation. Experienced mathematicians are often able to utilize informal elements, like visualization, in an effective way in their reasoning. Stylianou (2002) noticed that mathematicians use visualization in a very systematic way, so that in their reasoning the visual and analytic steps were very closely connected and they interact with each other. Also Raman (2002; 2003) found that mathematicians considered visual and formal arguments closely connected so that the visual arguments in an essential way contributed to inventing ideas in construction of the formal argument. Mathematicians were able to use and construct heuristic/informal and procedural/formal ideas simultaneously so that both ideas clarified each other. Instead, students could not recognise connections between visual and formal arguments. Stylianou's and Silver's (2004) study revealed that mathematicians also saw a wide variety of problems where visualization could be used, whereas students considered visual representations useful mostly in geometrical problems.

The importance of formal and informal arguments is dependent on personal and institutional needs. As well, they may have different roles depending on the field of mathematics. Especially, students may have different tendencies with respect to formal and informal reasoning depending on the field of area. Weber and Alcock (ibid.) found that in the case of algebra students' reasoning was too much restricted around the formal definitions of the concepts, but in the case of analysis several studies have reported students' tendencies to use informal approaches without sufficient connections to the formal theory (Juter, 2005; Pinto, 1998; Viholainen, 2006; 2007; 2008; Vinner, 1991).

The use of the division of arguments into formal and informal ones

On the basis of the aforementioned definitions, it could be possible to categorize arguments into informal and formal ones. According to these definitions, the decisive difference between formal and informal arguments is in the natures of the warrants. It is not decisive, how much and what kinds of representations have been used in reasoning, when the arguments are constructed. For example, the use of visualization as an aid of thinking in reasoning does not make the argument informal. On the other hand, in construction of an informal argument, the applied visual or physical interpretations may be justified by using formal definitions, but this does not make the argument formal. In this latter case, the definitions work only as a backing (cf. Toulmin's model) for the used informal interpretations. Therefore, the categorisation of arguments based on these definitions has to be made on the basis of the final

forms of the arguments, not on the basis of the reasoning processes. In this way the categorisation presented in this paper differs in an essential way from Weber's and Alcock's and Raman's categorisations.

Weber and Alcock see the semantic proof production, as well as Raman sees the private arguments, as important element of a reasoning process, but not as a final goal. Instead, the definitions of formal and informal arguments make it possible to consider any of them as a final goal of argumentation. No mutual order between the types of arguments with respect to importance follows from the definitions. Therefore, this division provides a framework for design of teaching, especially, for design of argumentation tasks, in which both the need of systematisation and verification based on the view of mathematics as a system and the need of explanation based on the view of mathematics as a problem solving process are equally taken into account. Traditionally, only formal arguments are considered as intended and desirable in mathematics, but in order to consider the need of explanation in the design of teaching, opportunities to exercise both understanding and producing more explanative arguments should also be provided for the learners.

CONCLUSION

The presented division of arguments into formal and informal ones can be used as a starting framework in determining what kinds of arguments students should learn to understand and produce. However, this division does not cover all features of mathematical reasoning: It concerns mainly deductive arguments, but it does not cover, for example, inductive and abductive arguments and arguments, whose warrants are based on some authority. These kinds of arguments may have an important role in mathematical reasoning, especially, in the affective level. The broad variety of different forms of reasoning comes out, for example, in Harel's and Sowder's (1998) classification of proof schemes. It is possible to extend the presented framework on the basis of Harel's and Sowder's classifications.

In addition, it should be noted that the nature of mathematics as an axiomatic system is explicit mostly in the tertiary-level. As well, aforementioned studies about mathematical reasoning concern mainly the tertiary level. Therefore, more studies about applicability of this division into the lower levels of mathematics education are needed. In addition, the nature and the purpose of informal arguments may differ depending on the field of mathematics and this difference could be investigated further.

NOTES

1. In 1931, Gödel proved incompleteness theorems, which showed that it is impossible to construct a complete and consistent axiomatic system, in which all theorems concerning natural numbers could be proven. Due to that, an ambitious attempt to build a complete and consistent axiomatic system including all mathematics proved to be impossible.

Working Group 1

2. Alcock and English (2008; 2009) and Weber (2009) have later modified these definitions.
3. In practice, the concept of real numbers is rarely defined properly before presenting the definition for the concept of derivative.

UPPER SECONDARY SCHOOL TEACHERS' VIEWS OF PROOF AND THE RELEVANCE OF PROOF IN TEACHING MATHEMATICS

Emelie Reuterswård

Stockholm University, Sweden

Kirsti Hemmi

Mälardalen University,

Sweden

This paper reports some results from a case-study on five Swedish upper secondary school teachers' views of proof. We describe the teachers' views of what constitutes proof and focus particularly on their views on the role and relevance of proof in teaching mathematics. We identified two basically different ways of relating to the teaching of proof in our data that consists of interview transcripts and protocols of observations of lessons. We discuss these views from a socio-cultural perspective on learning and Wenger's concepts of community of practice, reification and participation.

Keywords: Mathematical proof, teachers' views, community of practice, reification, participation.

INTRODUCTION

The proposed new curriculum for upper secondary school mathematics in Sweden is manifesting a more explicit focus on proof and proving (Swedish National Agency for Education, 2010). The same trend is visible in curricula also in other countries. The guidelines from NCTM already in 2000 recommend that every student from pre-kindergarten through grade 12 experience proof and proving in different ways in their school mathematics (NCTM, 2000). Proof has also recently obtained a stronger status in curricula in Italy (Furinghetti & Morselli, 2010) and Estonia (Hemmi et al., 2010). Common to many of these curriculum reforms is the emphasis on the relevance of proof for all students. However, it is not clear to what extent this emphasis is coherent with teachers' views of proofs and the role of proof in teaching mathematics.

The American secondary school teachers in Knuth's qualitative interview study (2002) express the view that formal and less formal (Knuth's classification) proofs are not something beneficial for all students. Instead the teachers mainly find this kind of proof appropriate for students studying science or other mathematically intensive educations. This view is contrary to the visions put forth in NCTM 2000. Informal proof – i.e. explanations or empirically based arguments – is not considered as valid proofs but regarded by the teachers in Knuth's study as a vital part of the education for all students. The view that proof – in the traditional sense (c.f. Reid, 2005) – is not something for all students is also present in the teachers' responses in a multinational pilot study carried out in Sweden, Estonia and Finland (Hemmi et al., 2010). Although distinguishing several functions that proof can serve (c.f. de

Working Group 1

Villiers, 1990; Hanna, 2000; Hemmi, 2006), the teachers mainly consider proofs and proving relevant for students studying courses that prepare the students for university studies in programs that include mathematics, for example technology and natural science. Both studies actualise the question of what constitutes proof in upper secondary mathematics as well as what kind of proofs and proving activities are appropriate and relevant for different kinds of students.

Research suggests that the way that curricular guidelines are implemented in the classrooms is greatly influenced by the teachers' experience, views and conceptions (Corey & Gamoran, 2006; Remillard, 2005). This underlines the fact that school reforms are never launched into a vacuum. Rather they are introduced into a community of teachers with their own conceptions of proofs and about what role proofs can or should play in teaching mathematics. To understand how reforms are going to be implemented and, on a larger scale, what role proofs play in the teaching of mathematics, it is important to understand teachers' conceptions of proof and proving. This is not the least true in Sweden, where the national curriculum leaves substantial space for local interpretation and appliances.

In this paper we report parts of the results of a case-study about five Swedish upper secondary school teachers' conceptions of proof (Reuterswård, 2008). We discuss the teachers' views on what constitutes proof in upper secondary school mathematics and analyse the ways in which the teachers talk about the role and relevance of proof in their teaching.

We focus in particular on the following questions:

- What constitutes proof according to upper secondary school teachers?
- What are upper secondary school teachers' views on the role and relevance of proof in teaching mathematics?

Theoretical stances

The analysis is based on a socio-cultural perspective where learning is considered to take place through active participation in a community of practice. Proof is according to this perspective seen as an artifact that can mediate mathematical knowledge. Wenger's (1998) concepts negotiation of meaning, reification and participation are used as central tools of analysis to understand and discuss teachers' talk about proof (c.f. Hemmi, 2006; Reuterswård, 2008).

By a community of practice we mean people who share experiences and have a common goal or purpose of some kind. Both a group of teachers at an upper secondary school as well as a group of students studying mathematics fall under this definition. Every community of practice has its artifacts, or reifications; tools like a calculator, a mathematical formula or a proof, mediating mathematical knowledge. They create focus points around which teaching can be organized. But the symbol for pi (π) or the proof for the Pythagorean Theorem do not carry any meaning of their

Working Group 1

own. Without people participating in negotiating their meaning, they are mute, meaningless (c.f. Wenger, 1998, p 52-54). It is when people engage in a mathematical practice and participate in negotiating the meaning of proofs that they can be meaningful and convince, explain and communicate mathematics.

The meaning of reifications must be negotiated within the community of practice. Hence, proofs taken from a mathematical practice must be renegotiated, within upper secondary school. It is therefore not self-evident that proofs will play the same role in school as they do within the mathematical science. Pushing to extremes, the role of proof needs to be renegotiated within every single classroom. The aim of this paper is to shed light on how teachers renegotiate the meaning and role of proof within an upper secondary school context.

Method

The paper is based on a case-study aimed to describe what constitutes proof in upper secondary mathematics from a teachers' perspective (Reuterswård, 2008). The case-study had a phenomenographic approach and hence sought to qualitatively describe teachers' views and conceptions, believing that a concept can only be perceived in a number of qualitatively different ways. The study was conducted at one ordinary Swedish upper secondary school that includes the Social- and Natural Science Programs. Five teachers were chosen to participate in the study. They were of different ages, both genders, with different teaching background and at the moment of the data gathering teaching different groups of students. Such a heterogeneous selection of participants can represent qualitatively different views (Marton & Booth, 1997).

The data was collected using semi-structured interviews. In order to enhance the richness of the data the teachers were given an outline of what themes were going to be discussed during the interview. Hence, they had the chance to reflect on the questions beforehand. Several days before the interviews they also received a questionnaire with statements chosen from a questionnaire that was piloted by Hemmi during the time of the data gathering. By choosing a number 1-4 the teachers stated to what degree they agreed with the statements. Thus, we had written material to come back to during the interviews and thereby inconsistencies or uncertainties could be resolved. In the beginning of every interview the teachers were asked to describe how they defined a mathematical proof. The interview focused on the following themes: how the teachers perceived student attitudes toward proofs, how the teachers worked with proof and proving in their teaching and how they viewed proof in general. Every interview was tape recorded and transcribed. Unstructured observations of lessons, at least two with every teacher, were also used to further triangulate the method and validate the results.

RESULTS

Teachers' views of proof

There is a broad consensus among the teachers about what constitutes mathematical proof. Proof is something specific for mathematics that from certain premises, through logical argument, step by step, deduces the truth of a statement. Some of the teachers stress that the premises should be axioms or theorems that have previously been proved. The characteristics of proof are a mathematical language, an unassailable logic and a specific structure. The teachers hereby distinguish between proof and other types of arguments. Proofs for them are more formal:

Teacher: It [a proof] is that one, from certain premises, with given presuppositions, can strictly, step by step so to say, that is totally true, arrive at something that has to be general.

Teacher: If someone says proof you feel that it is a bit heavier piece, so to say.

Teacher: It follows that, hence, implies, is equivalent with. It's a bit of those things. You use some of those words that are associated with proofs. That's when I think it's a real proof.

Emphasizing that proof through logical derivation, structure and formal language deduces the truth of a statement, these teachers can be said to embrace a *traditional concept of proof* (c.f. Reid, 2005). This view of proof was also represented in Knuth's (2002) study by American teachers, referred to as *formal* or *less formal* proof.

Although the teachers see the formal mathematical language, structure and logic as distinguishing proofs from other types of arguments, there is some uncertainty as to where to draw the line. Tasks like "show that left hand side equals the right hand side" and using general methods to solve problems are examples of areas that the teachers mean "*are in the vicinity of proof*" but for which the term "proof" is not used. This view is coherent with the view that Knuth calls *less formal* proof: a general argument that lacks a rigorous mathematical structure.

One teacher also gives a slightly more informal definition of what proof can be in upper secondary school:

Teacher: Proof in the sense that they [the students] should understand that it's not arbitrary, then you do it most every day. To make them understand that mathematics is a logically built system, and it's not a coincidence that we have to do things in a certain way.

This can be compared to what Knuth calls *informal proof* i.e. justifying by explanations or examples. There is, however, no doubt that examples and empirical investigations are not considered valid proof, neither in Knuth's nor in Reuterswård's study, and the concept *informal proof* is therefore somewhat unfortunate.

Working Group 1

The difficulty to draw the line to what counts as proof is not a problem reserved to school. Instead it is a forever ongoing discussion for which different answers are given within separate mathematical disciplines and historical contexts (Hanna & Jahnke, 1993). In Wenger's (1998) terms we can say that the meaning of an artifact has to be negotiated within every practice.

The role of proof in the classroom

Common to all the teachers in this study is that they all think of proof as central to mathematical thinking, and that they distinguish several functions that proof can serve in teaching mathematics. They see proving as a desirable competence and as a suitable challenge for the well achieving students. They also agree that the role of proof in the classroom must be determined in relation to every single student group. Their views on how this valuation should be made, especially considering the low achieving students or students in the Social Science Program, are however different. Two separate views were distinguished in the study. This should not be understood in a way that the teachers can be said to solely support one view or the other. On the contrary, the teachers' ambivalence might be the most prominent feature of their views on the role of proof in teaching mathematics.

One view embraces the thesis that *proof is something for all students* and that it is important that the teacher takes the step from examples and informal reasoning to proof. The explanatory function of proof, in particular, motivates that proof is something for all students, even the low achieving ones.

Teacher: I don't really think that you should assert anything to students without in some way proving it. If it is sometimes easier to make a geometric proof or a purely theoretical proof... /.../ I definitely don't think you should just state it: now you do like this. Why should you do like that?

Teacher: With the students I've got I know that there are many who think that, if there is anything you should leave out, it's proof. And then I have to say that I don't quite agree because that could be what gets them back on track.

The underlying idea here is that understanding why something is the way it is in mathematics, is a vital condition for the students to experience mathematics as meaningful, and to be able to use it in the right way. As a teacher you therefore run the risk of losing students if you don't take the step to more formal arguments. The basic assumption is that students can and want to understand.

Furthermore, according to this view, proofs don't have to be difficult. There are abstract and concrete, easier and more difficult proofs, and according to this view it's up to the teacher to present them in a way that can appeal to every student.

The other view is characterized by the idea that *proof is not necessarily something for all students*. The teachers share the basic positive attitude towards proof, ("*I am pro proof, I really am.*") but mean that the students lack the necessary qualities to

Working Group 1

realize the meaning potential of proof in the classroom. The students lack sufficient mathematical knowledge or sufficient experience of proof:

Teacher: If you can hardly calculate the area of a triangle it's really hard to explain what it [proof] is.

Teacher: It will be really difficult because they've hardly done it at all before. They'll only scream when I do it.

Teacher: If they don't accept the proof it's because they have gaps in their [mathematical] knowledge. Then it's really hard to accept proofs.

According to this view, the students' insufficient previous knowledge makes it impossible for them to participate in negotiating the meaning of proof. The teachers mention, for example, that the students need to know the quadratic rule in order to understand the proof of the quadratic formula, and master similarity to understand one of the most common proofs of the Pythagorean Theorem. As a teacher you therefore run the risk of losing students if you conduct general or algebraic reasoning.

The basic assumption here is that proof generally is something advanced that only a few students have the ability to master. According to the teachers some students are also not interested in proof; they are content with examples and only want to know 'what to do'. Proof is not necessarily something that is relevant for all students, in many cases it's enough to explain through examples:

Teacher: These Social Science students for example, I don't know if they have any use of it later, when they graduate, because it's probably not too many of them who'll choose a mathematical education.

Reification, participation and negotiation of meaning

Some of the teachers' statements express that understanding mathematics makes the students more capable of using it correctly, more inclined to thinking math is fun and more apt to remembering what they have learned. In Wenger's terms: understanding mathematics enhances the students' inclination and ability to *participate* in the community of practice of mathematics as it is exercised in the classroom.

This is the leading idea in the view that we have called *proof is something for all students*. According to this view, understanding why something is the way it is in mathematics is a requirement if the students are to experience mathematics as meaningful and to be able to use it in the right way. As a teacher you therefore run the risk of losing students if you do not take the step towards such general arguments as proofs. In other words: Without *reifications* like proofs, the students may experience mathematics as meaningless or hard to understand. The reification offers a necessary structure, an abstraction to tie the knowledge to. The other view, which we have called *proof is not necessarily something for all students*, means instead that some students lack both the motivation and the knowledge to be able to participate in

Working Group 1

negotiating the meaning of proof. According to this line of thought, one runs the risk of losing the students if one *does* take the step towards such general arguments as proofs. Thus, the reasoning is turned over, and it is claimed that without possibility to participate – without previous knowledge or motivation – the reification is meaningless anyway. In line with this idea, Hanna and Jahnke (1993, p. 434) point out that the students need well-founded previous knowledge to be able to negotiate the meaning of proofs.

We can see that both views express the same main goal; to make the students understand mathematics. The different views can be described as different answers to the question of what proportion between reification and participation that is the most meaningful to the students. This can be compared to Wenger's (1998, p. 65) remark that the proportion between reification and participation always has to be negotiated, and that different proportions lead to different possibilities to create meaning. An abundance of mathematical artifacts such as symbols, formulas or proofs do not create any meaning without the possibility of participation. But in the same way participating without reifications can seem meaningless. The sole use of examples, empirical investigations and lots of time can be experienced as useless without mathematical reifications to focus the practice on; without concepts, symbols or formulas to structure the mathematical knowledge. It is in the tension between reifications and participation that meaning can be created in the community of practice.

All the teachers in this study express that proof and general arguments are something desirable. But like we have described above, some of them state that empirical investigations or examples can replace proof in groups where the students are not susceptible to formal reasoning. Even those teachers who in principle mean that proof is something for all students, point out that using informal methods is a good first step towards proof. Informal methods can include letting the students see examples, investigating certain cases (empirical investigation) and trying to find patterns. We can interpret these methods as strategies to increase the students' motivation and ability to take active part and engage in understanding reifications like proof.

Although the teachers express understanding as the main goal of their teaching, it is not self-evident that all students identify with the community's goal to understand. Above all, not all of them are interested in proof. "*Some students are only like "what to do?"*" as one of the teachers in this study put it. We can interpret it as if the students simply are not interested in identifying with the goal of the community of practice. Maybe they want to practice law and do not see any use in specifically mathematical reifications like proof. It is also possible that they want to understand, but that they through years of failure have developed an identity of non-participation (Wenger, 1998, p. 165) – 'I don't know mathematics'. That means that they have

developed an identity where they do not see themselves as participants in the community of practice.

The concept *community of practice* can also help us to see that the teachers have several different practices to consider when they value the role of proof in their teaching. Some teachers point out, for example, that one reason not to deal with more proofs is that “the students haven’t experienced them before, in compulsory school.” This is in turn probably related to the fact that proof is not at all mentioned in the Swedish steering documents for compulsory school (Swedish National Agency for Education, 2000). But also future practices play a role in the teachers’ views. Upper secondary school is meant to prepare for higher education and future professions. Which these are likely to be, matter to some teachers.

DISCUSSION

In this paper we have reported parts of the results of a case study of five Swedish upper secondary school teachers’ views of proof (Reuterswård, 2008). We have particularly focused on the teachers’ conceptions of proof and the role and relevance of proofs in the context of upper secondary school mathematics. In doing so we have presented two different views on the role of proof in upper secondary mathematics that we’ve called *proof is something for all students* and *proof is not necessarily something for all students*.

In the beginning of the paper we drew attention to the fact that many curricula around the world manifest a revaluation of the role of proofs in teaching mathematics. Common to the guidelines in the NCTM (2000), Italy (2003) and the proposed new curriculum for upper secondary school in Sweden² (2010), is the emphasis on the relevance of proofs for all students. This rhyme well with the view that we have called: *proof is something for all students*. But how will these reforms turn out in a community of teachers where one of the views is that *proof is not necessarily something for all students*? This question is not the least relevant considering that this view is expressed not only by the teachers in this study but also by American teachers (Knuth, 2002) and other Swedish teachers (Hemmi et.al, 2010). These results raise the need for these new curricula to be anchored in the community of teachers supposed to realize these visions.

We can only speculate as to what has been the driving force behind more focus on proof and proving in the curricula. We find it likely that it has something to do with the extensive functions – such as explanation, verification, communication and transfer (c.f. de Villiers, 1990, Hanna, 2000, Hemmi, 2006) – that proofs can serve in teaching mathematics. It is therefore important to notice that the teachers in Knuth’s (2002) study seem to regard proofs mostly as a topic to study, rather than using them

² Vocational programs not included.

Working Group 1

to teach mathematics. This view is not shared by the Swedish teachers in this study. They chiefly see proof as a tool that can mediate mathematics. This is probably partly due to the fact that proof is hardly mentioned in the present mathematics curriculum in Sweden. Yet, one can ask whether a sudden focus on proofs in the new curriculum has the effect that the teachers start viewing them first and foremost as a topic to teach, rather than a gateway to mathematics. Yet, both approaches are needed in the teaching of mathematics (c.f. Hemmi, 2008). This highlights once again the need for the curriculum reforms to be anchored in the community of teachers. This can be done by making the teachers aware of the arguments behind the new guidelines, and offering them the tools to introduce proofs also in groups of students lacking motivation or prior knowledge.

This being said one can wonder what the implications are if proofs become part of the mathematics education for all students. It is well documented that many students find it difficult to understand, conduct and value proofs (e.g. Healy & Hoyles, 1998; Selden & Selden, 2003). The teacher in this study who says “*If you can't calculate the area of a triangle, it's really hard to understand what a proof is.*” expresses a point not to be taken lightly. Introducing proofs to these students could possibly further their identity of nonparticipation in the mathematics classroom (c.f. Wenger, 1998). On the other hand, experiencing the derivation of the area formula for a triangle could help students to find proving as meaningful. One way to proceed might be to gradually formalize the use of justifications throughout the curriculum as is the case in the American guidelines from NCTM (2000). However, it certainly calls for research studies about how these reforms are being implemented and what effects the focus on proofs has in different student groups. It also underlines the need for research exploring different ways of teaching proofs to different kinds of students.

DEVELOPMENT OF BEGINNING SKILLS IN PROVING AND PROOF-WRITING BY ELEMENTARY SCHOOL STUDENTS

Stéphane Cyr

Université du Québec à Montréal, Canada

This paper presents the results of a study regarding the development of deductive reasoning among elementary school students. We have experienced a sequence of 8 teaching and learning lessons in order to develop their primary skills of writing proof in a geometrical context. This sequence, over a 4 months period, was tested with two classes of 26 students aged 11-12 from a single school in Quebec (Canada). Results showed an important increase in most of the students, between the beginning and the end of the sequence, in their ability to reason deductively and validate geometric statements by using theoretical properties rather than measurement.

Keywords: Proof, teaching, mathematics, primary school, geometry.

RESEARCH PROBLEM

It is now a well-established fact in research circles that teaching proof in secondary school is undeniably important. The significance of it may be explained particularly through the many roles that proof-writing plays in the mathematics education of students (Arsac & *al.*, 1992; Duval, 1990; Houdebine, 1990). Among other things, writing proofs, being explanatory by nature, fosters students' comprehension (Hanna, 1995) and helps them develop deductive reasoning (Reid, 1995), critical thinking as well as an ability to support lines of argumentation (Houdebine, 1990).

Key to children's education, proof-writing is also one of the most complex activities and one which secondary students experience the most difficulty with (Houdebine, 1990 ; senk, 1985). The difficulties encountered and the reasons for them are manifold. Amongst the problems observed, two seem to preoccupy experts in current mathematics education research.

The first one relates to the difficulty for students to fully understand the fundamental structure within deductive proof reasoning (Duval, 1991 ; Tanguay, 2005). When writing proofs, students often err in sequencing the inferences constitutive of their demonstration. All they see in it is a discourse, a line of argumentation where propositions are simply added and organized according to relevance only.

The second problem, in connection with the first one, lies in the way secondary school students perceive and use the representations of geometric shapes to write proofs. At the elementary school level, geometry is deemed *practical* (Perrin-Glorian, 2003), as it is linked to spatial sense, visual perception, and shape-building activities. Validating formal geometry statements implies empirical work on figures, whereas in secondary school it relies on theory and very specific axiomatic systems. Thus redefined, and as Muller (1994) mentions it, shapes constrain secondary school

students to reason through concepts rather than drawings; and this is an obstacle for them. Indeed, this alternative justification based on a deductive approach that excludes any conclusion drawn from measurements and observations of geometric figures, seems to generate a lot of difficulties for students. Research in various countries, including Canada, the United States, and France, supports that claim (Chazan, 1993 ; Muller, 1994 ; Paul, 1997). As for Balacheff (1987), he assessed that the switch from *practical* geometry to more *theoretical* geometry caused a breach in the didactic contract agreed upon by both teachers and students, which, he adds, is the main source of learning difficulties when students are introduced to proof-writing. This problem has raised an important question among many researchers: How can students be taught that a practical validating approach based on empirical observations may no longer be reliable when the time comes to write deductive proofs?

THEORETICAL FRAMEWORK

For Perrin-Glorian (2003), solving the problem could imply taking action before proof-writing is being taught in secondary school. She regards the end of the elementary curriculum and the beginning of the secondary cycle as the right time of transition from practical to theoretical geometry. According to her, carefully selected situations could facilitate the switch from one kind of geometry to the other. However, she observes that there is no consensus amongst researchers on how to include the relation between practical and theoretical geometry in the elementary curriculum. We consider that her recommendation seems worth looking into for the following two reasons:

1 – When students are introduced to proof-writing in secondary school, not only are they faced with a new and more rigorous validating procedure like proving, as well as with a new axiomatic system, but they must also learn deductive reasoning in a context of theoretical geometry. And yet, this context of proof-writing is already a problem in itself for students, for acquiring the previously-mentioned elements may not ideally prepare students for deductive reasoning nor to the switch to theoretical geometry. Rather, students should be learning deductive reasoning in more familiar everyday situations the way they do with geometric shapes in validation situations.

2 – Introducing deductive reasoning and more theoretical geometry in elementary school would reduce the breach in the didactic contract described by Balacheff (1987), which is the main source of difficulties for students when first coming to grips with proving. In addition to reducing this breach, a more gradual approach to those elements certainly allows for greater continuity between elementary and secondary school curricula in mathematics.

From practical to theoretical geometry: construction of abstraction

According to Parzysz (1991), geometry activates two types of space: physical space (surrounding space and concrete objects) and abstract space (idealized object). The

Working Group 1

first is associated with a more practical geometry while the second is developed through a more theoretical geometry. Objects in a physical space are concrete and they can be observed by the senses, while objects defined in an abstract space exist only in theory or in the form of ideas: they are a mental construct (figures whose existence is ensured by statements as definitions, properties or characteristics). So the transition from a practical geometry to a more theoretical geometry implies that students develop a degree of abstraction. Indeed, a close link exists between understanding of these properties and the use of mathematical abstraction, as pointed out by several authors.

According to Rosh (1978) abstraction may focus on the *properties* of perceived objects. Piaget, for his part, believes that abstraction can take several forms. He distinguishes in fact between construction of meaning through *empirical abstraction* (focusing on objects and their properties) and *pseudo-empirical abstraction* (focusing on actions on objects and the properties of the actions). He associated to these two kind of abstraction the idea of *reflective abstraction* which occurs through mental actions on mental concepts (Piaget, 1972, p. 70). Reflective abstraction is then seen as an activity applied to mental entities rather than physical objects. For Gray and Tall (2007), who also discuss the idea of abstraction, mathematical concepts are the result of a process of abstraction that takes place on a given situation. This abstraction may take the form of « a mental image of a perceived *object* (such as a triangle), a mental *process* becoming a concept (such as counting becoming number) and a formal system (such as a permutation group) based on its properties, with the concept constructed by logical deduction » (2007, p. 23).

If we accept that one of the main purpose of teaching geometry in primary school is to gradually bring students from a physical space to a more abstract space based on the properties of objects, then, we have to consider the importance of the development of abstraction in students and thus, the internalization of properties of mathematical objects and operations on them. This guidance also highlights the importance of taking into account the existence of different forms of geometric perspective, as called by Houdement and Kuzniak (2006): geometric paradigm.

Geometrical paradigms

Houdement and Kuzniak (2006) have defined three geometrical paradigms through which thinking patterns develop differently. Each paradigm is defined by the following components: objects, methods and problems, and therefore each is strongly link to a didactical contract (Houdement, 2007). Each of these paradigms reflects a sophisticated form of geometry and can thus define a specific geometric framework Kuzniak (2006, p.170). It should be noted that the three paradigms are not hierarchical in the sense that they all allow to solve geometry problems properly and efficiently. One is not better than the other, their use will depend on the context.

Working Group 1

- *Geometry I* or *Natural Geometry* is the first paradigm whose validation originates in the real, sensible world, according to Houdement and Kuzniak (2006), and where drawing plays a central role in validation. In this context, deduction is exercised primarily through the perception and the manipulation of objects.

- *Geometry II* or *Natural Axiomatic Geometry* is the second paradigm whose link to reality is not as strong as it is for the first one. It actually aims at understanding reality through axioms, and with the help of which tangible problems may be solved. However, axiomatization is not formal since syntax is not cut off from semantics, the latter referring to reality. In this regard, the source for validation is no longer the sensible, but indeed an hypothetico-deductive process in which intuition and experience still play a role, but to a lesser extent than deductive reasoning does.

- The *Geometry III* or *Formalist Axiomatic Geometry* paradigm is very different from the two previous ones, insofar as it is disconnected from reality. The source for validation is based on logical reasoning only, and not on the sensible world or perceptions.

Deductive reasoning in elementary school

Coppe, Dorier, and Moreau (2005) hold that in order for teachers to demonstrate that proving is meaningful and useful, they have to “force on students the transition to deductive reasoning” (p. 35). Indeed, elementary students are more likely to develop a proper ability for it if they can enjoy teacher’s support, even if that reasoning mode remains an integral part of the human procedural system (English, 1997). For English, textbooks and elementary school curricula must take reasoning processes into account and include informal deduction problems. Furthermore, current research shows that deductive reasoning could be within elementary students’ grasp (Braine and O’Brien, 1991; Daniel, 2005; English, 1997).

RESEARCH GOALS

With this research, we wish to encourage in students a more gradual approach to acquiring preparatory abilities when it comes to proof-writing. We believe that these abilities should be taught as early as elementary school in order to minimize the previously-mentioned breach-related problem. In this light we intend to:

1 – Encourage deductive reasoning in elementary students when dealing with mathematical situations.

2 – Building from their ability to reason deductively, encourage students to transition from practical geometry (Geometry I) to more theoretical geometry (Geometry II); also, gradually bring them to become aware of the limits of empirical validation for geometric figures and realize how effective more deductive reasoning (Geometry II)-based theoretical geometry can be.

Working Group 1

We expect the results of our research to be manifold: For one, it should facilitate the creation of activities for the elementary mathematics curriculum in order to later foster proof-writing skills in secondary students. In fact, no other study has ever looked closely into including basic proof-writing skills acquisition in the elementary curriculum so far. Finally, our research is in line with the general views of the MELS aimed at encouraging in students the gradual and ongoing acquisition of mathematical skills and knowledge between elementary and secondary school.

Hypothesis

We postulate that if we altered students' relation to figures as well as the role played by properties in the validation process, we would observe in students a spontaneous form of deductive reasoning. Indeed, the change of status for figures could induce new validation processes, no longer based on perceptions or measurements, but on theoretical properties which may only be resorted to through some sort of deductive reasoning. Note that the spontaneous use of deductive reasoning is based on the principle of accommodation in the sense of Piaget.

METHODOLOGY

To meet our objectives, we have opted for a design-based research methodology (Edelson, 2002). This method is cyclic in nature and each cycle consists of 5 stages: 1) Teaching sequence writing; 2) In-class testing of the sequence; 3) Retrospective analysis of experimental data; 4) In light of this analysis, reassessment of theoretical hypotheses, didactic choices, and anticipated learning paths; 5) As a result of reassessment, adjustments are made in the design of the teaching sequence and a new cycle may begin. Also, we have created activities based on works by Coppe and al. (2005), Perrin-Glorian (2003), and Houdement and Kuzniak (2006).

Participants

Two Montreal elementary classes of 25 sixth-graders (11-12 y.o.) were selected for this study prior to which none of the students had ever validated geometric propositions through deductive argumentation. When doing geometry activities, they would only validate geometric situations using measuring instruments.

Tasks

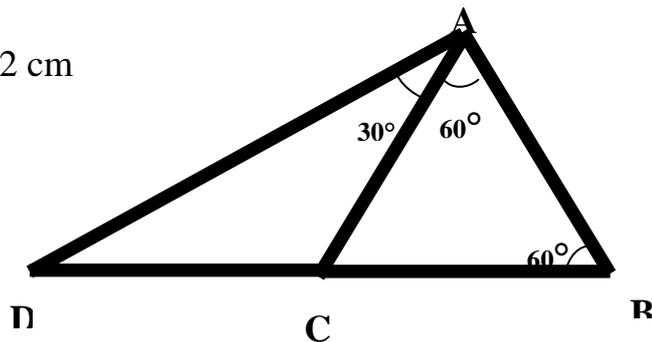

For the first stage of the design-based research methodology, we designed eight tasks that would elicit the spontaneous emergence of deductive reasoning in sixth-graders, as well as spur the transition from practical geometry (Geometry I) to theoretical geometry (Geometry II). The tasks focused on the essential knowledge as identified in the Quebec elementary education program literature, so that they would be easily merged into regular teaching planning and would not add new subject content.

Observation and measurement-based argumentation doubting procedure

The tasks were designed to cast doubt in students on their level of certitude they might reach observing and measuring figures and show them the limits of an argumentation based on that procedure. To this end, we first proceeded to use geometric shapes that made accurate measuring difficult, that is either drawn with exact measures yet in thick and bold lines, or free-hand thus yielding very approximate results. Students could use any chosen method to do each task. Then, they had to answer questions designed to have them process their results which they also had to compare with those of other peers. As an example, here are two questions asked to students:

Activity 1

Length of side AB = 6.2 cm

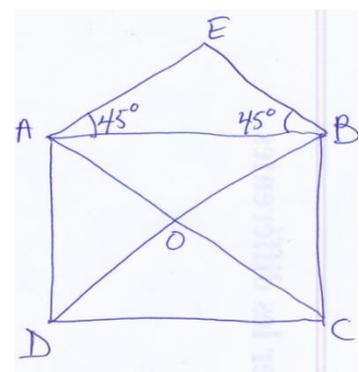

1. a) Measure angle D and segment CD. write down how you proceed and explain how you reason.
- b) Proceed differently to make up for missing measurements. Write down how you proceed and explain how you reason.
- c) Is there a discrepancy between results 1.a) and 1.b)? If yes, explain why.
2. Compare your results with those of another team.
 - a) Have you got the same results as the other team? If not, explain why.
 - b) Did you proceed as the other team did? If you proceeded differently, indicate which is the more appropriate procedure.

Activity 2

A student draws free-hand the figure below where ABCD is a square whose diagonals AC and BD intersect at O. Then, he draws a triangle ABE on top of the square. Finally, he claims that the quadrilateral AEBO is a square.

Note: The diagonals of a square always intersect in the middle and are perpendicular.

Is the student right? Explain your answer.

In the second step of the methodology (In-class testing of

Working Group 1

the sequence), we scheduled our experimentation to take place over a period of two months, one hour per week. We filmed the activities in progress so that we might later analyze how they were performed and how students reacted to them. Finally, students worked in pairs which aimed at prompting debate on validation procedure.

For the retrospective analysis of experimental data (methodological step 3), we observed the students' reactions to the tasks. We also analyzed their understanding of these tasks by using paper trail on written questionnaires, video of two teams in the tasks and the analysis of a logbook of our observations during the experiments. Our attention was also focused to the type of procedure used during the implementation of the tasks (use of measuring equipment or use of theoretical properties).

In the fourth step of our methodology, our objective was to evaluate both the type of geometric paradigm in which students could be located but also to assess how the task favored in the student the shift from paradigm 1 to paradigm 2. To support our analysis, we examined how students used the geometric figure which was provided to support their reasoning. For example, is that students based their answer and justification on intuition, observations or visual estimation, measures or geometric properties and deduction. The results of these tests have allowed us to edit questions, delete or add others to always promote the passage of natural geometry to a natural axiomatic geometry and thereby promote the use of geometric properties and use of deductive reasoning (methodological step 5). Since this experiment took place over a period of three years, we had the opportunity to repeat this sequence of activities on two other occasions with different student groups and thus make each time, adjustments to our work.

PARTIAL RESULTS

At first, more than three-quarters of the students (40 students out of 50) used measurement as the only method to work out missing data for this kind of problem (pré test where they have to find missing data on a geometrical figure with the strategy of their choice). Some used mixed strategies (6 students) whereas two teams (4 students) only spontaneously resorted to a deductive approach using theoretical properties. What we mean by mixed strategies is a crossover approach that uses measurement and theoretical properties. For instance for Activity 1 above, some students used theoretical properties in simple contexts like working out the measure of the 60 degree angle inside the triangle (they used the property of the sum of angles inside any triangle), yet they turned to measurement or visual perception for the more complex areas of the situation, such as working out the length of segment CD. Most students noted that triangle ACD was isosceles, relying on their perception, then concluded that segment AC was the same length as segment AB, that is 6.2 cm.

After the first four sessions, we noticed that students had clearly improved upon their justification procedures. In simple situations where they had to work out the missing measure of an angle in a triangle or a quadrilateral, 42 students out of 50

Working Group 1

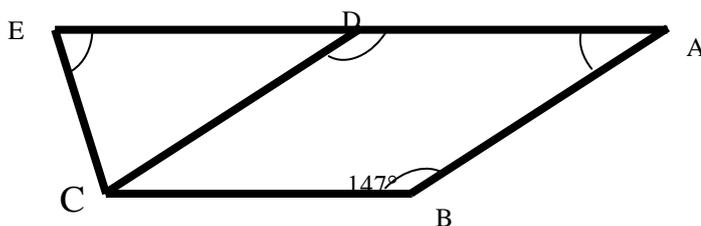

spontaneously turned to theoretical properties using a deductive approach. In more complex situations, we also observed some improvement when more than 50% of the students used a deductive approach appropriately. This improvement is partly due to the constraints imposed by the situations in which students were getting inaccurate results with measurements, thus forcing them to resort to mathematical properties and deduction to find the missing data. We also led the students to compare results between them and tried to explain the differences from one team to another. The students' comments were in line with the imprecision of the measure (which in our case was strengthened by the bold line that accentuates the vagueness on measure or the hand drawing figures).

At the end of our experimentation, all students were able to identify spontaneously the limits and lack of precision of a measurement and observation-based approach, as well as call on theoretical properties to validate simple geometry statements (problems where only one data is missing in a simple geometric figures). However, this result does not suggest that all students have acquired the ability to produce simple proofs or arguments based on properties using deductive reasoning appropriately. Besides, more complex situations remained difficult for some students leading them to use mixed strategies (measurement and deduction); and so did situations requiring validation, and where data were not provided. For example, in order to solve the problem below, students were able to use measurement as well as theoretical properties, which they knew well by then. However, the absence of numerical data significantly hampered task completion and caused students' strategies to revert to measurement and observation.

Let ABCD be a rhombus and let D be the midpoint of segment AE.

We know that the sum of the four angles of a rhombus is 360 degrees.

1. a) Find the measure of angles A, B, and E.

DISCUSSION

The eight sessions that we had scheduled over a period of two months allowed us to bring most students to switch from practical (G1) to theoretical geometry (G2) spontaneously. In doing so, we had set for students an environment conducive to the use of deductive reasoning in validation situations. And yet, our experimentation validated our initial hypothesis, that is deductive reasoning shows to be a demanding process that requires time and extensive experience to be exercised properly. In fact,

it had taken four sessions before students started showing some improvement in reasoning deductively. Yet, the students who improved the least were still able to grasp the geometry concepts and skills in the tasks given in the course of our experimentation. We believe that this type of activity can be very productive when it comes to teaching and learning the geometric properties of given figures; it could also apply with most geometric concepts covered in class during the school year.

DESIGNING INTERCONNECTING PROBLEMS THAT SUPPORT DEVELOPMENT OF CONCEPTS AND REASONING

Margo Kondratieva

Memorial University, Canada

In this paper I illustrate the process of designing a problem which can be repeatedly used by teachers in different mathematical courses and at various levels of complexity. The same problem can support reasoning appropriate for the context in which the problem is presented. Gradual increase of the requirements for rigor from one level to the next supports the learner's development within her natural sequence of learning modes from experimental to theoretical. The course of formalization of reasoning also affects the conceptualization process related to the object of the problem.

Keywords: multiple-solution problem, development of mathematical thinking, necessary and sufficient conditions, dynamic geometry software, geometry of isosceles triangle.

INTRODUCTION

Development of reasoning skills and formation of concepts is a life-long process. In particular, many mathematical concepts emerge from a child's earlier experiences in a primitive form and develop further as the child has a chance to perceive and act on physical objects, to form mental images and models, and eventually reflect, categorize, and hypothesize further properties expressed in a symbolic form. At each level of concept development, a child exhibits reasoning behaviour with the degree of rigor appropriate to the level of concept maturity. According to Bruner (1968) the sequence of learning modes, enactive-iconic-symbolic, characterizes not only grade school students but also an older learner. This idea is also consistent with van Hiele's theory of learning geometry by advancing through the stages from visualization to analysis, to informal or formal deduction and finally to rigor.

In mathematical instruction, one way to reflect this long-term continuous development of mathematical thinking is to consider the notion of an *interconnecting problem*. An interconnecting problem is characterized by the following properties (Kondratieva, 2011): (1) It allows simple formulation; (2) It allows various solutions at both elementary and advanced levels; (3) It may be solved by various mathematical tools from distinct mathematical branches, which leads to finding multiple solutions, (4) It is used in different grades and courses and can be discussed in various contexts.

It is proposed (Kondratieva, 2011) that a long-term study of a progression of mathematical ideas revolved around one interconnecting problem is useful for developing a perception of mathematics as a connected subject by all learners. Due

to the wide range of difficulty levels of its solutions, the same interconnecting problem may appear at the elementary school level, and then in progressive grades at the secondary or even tertiary level. The students, familiar with the problem from their prior hands-on experience, will use their intuition to support more elaborate techniques presented symbolically in the upper grades.

This article aims to discuss the process of creating an interconnecting problem with particular attention to the development of reasoning skills and the notion of proof. Here a Problem Designer is a mathematics teacher or mathematics curriculum developer who proceeds via the following stages: (A) choosing an initial question; (B) tailoring questions to elementary approaches; (C) upgrading to more advanced techniques; and (D) finding contexts suitable for the identified approaches and techniques within the overall curriculum.

The key point is that a problem becomes interconnecting as the Problem Designer herself experiments with the problem, identifies the types of reasoning emerging from her experiments, and starts to see different facets of its implementation in the classroom.

THERETICAL FRAMEWORK

Knowing and proving are synonyms in mathematics (Rav, 1999; Balacheff, 2010). On one hand, proof, as mean for validation, reinforces precise and highly logical way of thinking based on axioms, definitions, and statements, which link and describe the properties of mathematical objects. On the other hand, proofs include mathematical methods, concepts, and strategies also applicable in problem solving situations (Hanna & Barbeau, 2010). Despite their central role in mathematics, it was observed that proofs receive insufficient appreciation and epistemological understanding from grade school students (and even their teachers), who often rely on empirical evidence rather than on formal deductions of mathematical theorems (Coe & Ruthven, 1994). This situation identifies the needs for “problems and mathematical activities that could facilitate the learning of mathematical proof” and “designing the situations so that ... the theoretical posture demonstrates all its advantages.” “The challenge is to better understand the didactical characteristics of the situation and propose a reliable model for their design”(Balacheff, 2010, p. 133). One possible approach “is centred around the idea that inventing hypotheses and testing their consequences is more productive ... than forming elaborate chain of deductions”(Jahnke, 2007, p.79). The process of making conjectures and inventing hypotheses requires mathematical intuition, which develops through students’ experiences not only in formal logical manipulations but also in experimental explorations of objects and ideas (De Villiers, 1999). Thus collecting empirical evidence (e.g. constructing and measuring) is an important part of the mathematical education of students, and it should not be rejected as such. Instead, a productive way of incorporating experimentation and proving needs to be found so that “*proofs do not replace measurements but make*

Working Group 1

them more intelligent” (Jahnke, 2007, p. 83). The students should gradually move from everyday thinking in terms of “open general statements” (whose domains of validity are not completely specified) towards mathematical thinking where precision is achieved at the price of cutting ties to empirical reality. This move is possible due to several roles (besides validation statements) that proofs may play in mathematical thinking (Hanna, 2000; De Villiers, 1999). First, at the informal deduction stage, proof as explanation of empirical observations is most appropriate. Next, students “should build a small network of theorems based on empirical evidence” and become accustomed to “*hypothetico-deductive method* which is fundamental for scientific thinking” (Jahnke, 2007, p. 83). At this stage, the proof functions as a “*systematization* (the organization of various results into a deductive system of axioms, major concepts and theorems)” and “*construction* of an empirical theory”. These two stages prepare students to move towards rigorous proofs aiming at establishing truth by deduction or “*incorporation* of well-known facts into a new framework” (Hanna, 2000, p. 8).

The development of reasoning skills by the proposed scenario has an essential contribution in concept formation. As discussed in an upcoming publication (Tall et al), a child’s conceptual system evolves from the stage where several properties of an object occur simultaneously to the stage where these properties are linked by cause-effect relationship. This process results in developing *crystalline concepts* (e.g. platonic objects) with equivalent properties linked by mathematical proofs. Thus the process of maturation of reasoning skills both leads to and requires the use of more formal and structured conceptualizations of empirical objects.

From the perspective of this paper, two further ideas are of particular importance. First, learning to prove is a gradual process which requires years of mutually enhancing empirical and theoretical practices leading to concept formation as more properties, representations and relationships are being understood over time. If this structure is imposed on a learner in its final form, the effect of concept formation by the learner may not be achieved (Freudenthal, 1971). Second, teachers’ epistemological beliefs and their abilities to model the process of proving are decisive for students’ growth in this respect. Thus, teachers’ professional preparation, which facilitates them in transitioning from empirical arguments to proof, is essential (Stylianides & Stylianides, 2009). With this in mind, we now examine an example of designing an interconnecting problem.

AN EXAMPLE OF INTERCONNECTING PROBLEM DESIGN

In Euclidean geometry an isosceles triangle is often defined as a triangle which has two equal sides. It is well known that there are many equivalent characterizations of an isosceles triangle, such as “two angles are equal”, “an angular bisector is also a median”, “two altitudes are equal”, “two bisectors are equal”, each of which reflects the axial symmetry of the triangle. Proofs that the properties are pair-wise equivalent

Working Group 1

constitute problems of various levels of difficulty and contribute to building the conceptual understanding of the object by the learner.

Some properties of an isosceles triangle do not characterize it, however. It is an important exercise to recognize when this happens. For instance, think about the following **Problem**:

Observation: Consider any isosceles triangle ABC , where $AB = AC$. Let D be a point on BC such that AD is the angular bisector of BAC . Let M and N be midpoints of sides AB and AC respectively. Then $DM = DN$.

Question: In a triangle ABC with angular bisector AD and midpoints M and N of sides AB and AC , let the segments DM and DN have equal length. Does this property imply that ABC is isosceles?

In further subsections I discuss how to make this problem interconnecting in view of properties (1)-(4) and stages (A)-(D) of the design process outlined in the introduction.

A. The initial choice of problem

The choice of the problem may be justified by several factors such as how fundamental are the objects involved in the problem, the importance of the problem in the development of strands prescribed by the curriculum, or motivational aspects (e.g. surprising result).

For instance, our Problem was chosen by the Problem Designer because it deals with isosceles triangle, the object that appears in many problem-solving situations in geometry. The Problem poses a concrete question which prepares the learner to distinguish between equivalent statements and implications, and further between necessary and sufficient conditions in more abstract theorems. This problem calls for a proof involving construction of a counter-example. When such an example is constructed, it may surprise the students and produce a cognitive shift towards understanding the concept of isosceles triangle in a wider space of its examples and non-examples.

A problem must allow a simple formulation in order to become an interconnecting one. The students should understand the question and be able to specialize and exemplify the statement of the question (Mason et al 1982). For example, in our Problem we start with an Observation which can be justified by the symmetry argument or even by simply folding the paper triangle along its axis of symmetry. In order to answer the Question students may try other examples of triangles. They will quickly realize that they have to either find an example of non-isosceles triangle with given property or proof that such a triangle does not exist. It is clear what one has to do, but not obvious how one can approach this problem. A systematic search for an example needs to be initiated by the solver.

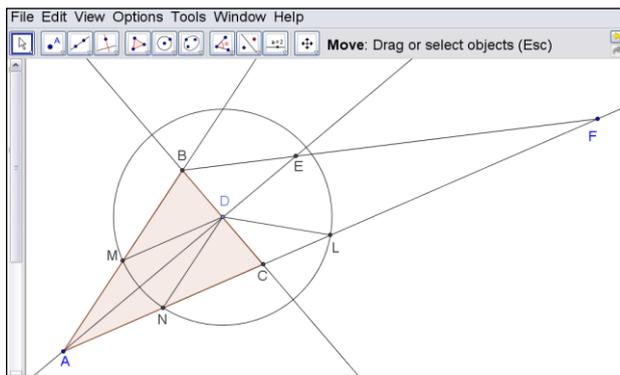

B. Making the problem Interconnecting: elementary level

First, the Problem Designer puts herself in the position of problem solver. She starts from thinking how she can approach the problem at the most elementary level. According to Bruner's classification, this corresponds to enactive representation of the problem and involves the use of real objects and manipulatives. For a modern learner equipped with a computer, thinking at the elementary level also involves the access to virtual manipulatives, and experimentations within dynamic geometry software (DGS) environments. Through the use of dragging function, the learner receives a visualization of her problem as continuum of options. The example she is looking for may be just one static picture in this continuum.

Construction of such a continuum requires understanding of many basic mathematical ingredients of the problem as well as the properties of the software tools. Here is a protocol from a problem designer's attempt to solve the problem.

First, I examined initial configuration. I have an isosceles triangle ABC , where $AB = AC$. Here M is the midpoint of AB , N is the midpoint of AC . Line AD is the angular bisector of angle BAC . We know that in this case $DM = DN$ due to symmetry argument. I draw this triangle on the screen (Fig. 1). Points M and N lie on the circle with centre at D . But this circle also intersects the extension of side AC at point L , which means that $DM = DL$. Aha, I have an idea: point L could be the midpoint of the side of the required non-isosceles triangle. Now I place point F on the extension of AC such that $AL = LF$ and look at the triangle ABF . Denote by E the intersection point of BF and the extension of angular bisector AD . If I could drag points and change the figure in such a way that D coincides with E then I will complete the task.

The Problem Designer experiments with this figure but unfortunately it does not seem to be possible to complete the task within this particular construction and she proclaims:

Maybe there is no such example at all. But then I have to explain why. Perhaps I should try to construct something else. Maybe I should not start with an isosceles triangle at all.

Figure 1: Unsuccessful attempt to build an example.

Meantime she also learned that the software has an option “reflect a point with respect to another point” which she uses to place a vertex, knowing the position of a midpoint. She continues to build her example. Finally, she succeeds in doing so, still employing the idea that the second point of intersection of the circle with the angle side is the key of the construction.

Working Group 1

I start with an arbitrary angle with vertex at A. I place two arbitrary points M and K one on of each of the sides (see Fig 2, left). Now I place point B on one side such that $AM = MB$ and place point C on the other side such that $AK = KC$. The intersection of BC with the angular bisector is called D. I draw the circle with centre at D and radius DM. This circle intersects side AC at points N and L. Now I want to make K coinciding with either N or L. I conjecture that the former case gives me an isosceles triangle and the latter, if this is possible, will produce the required example.

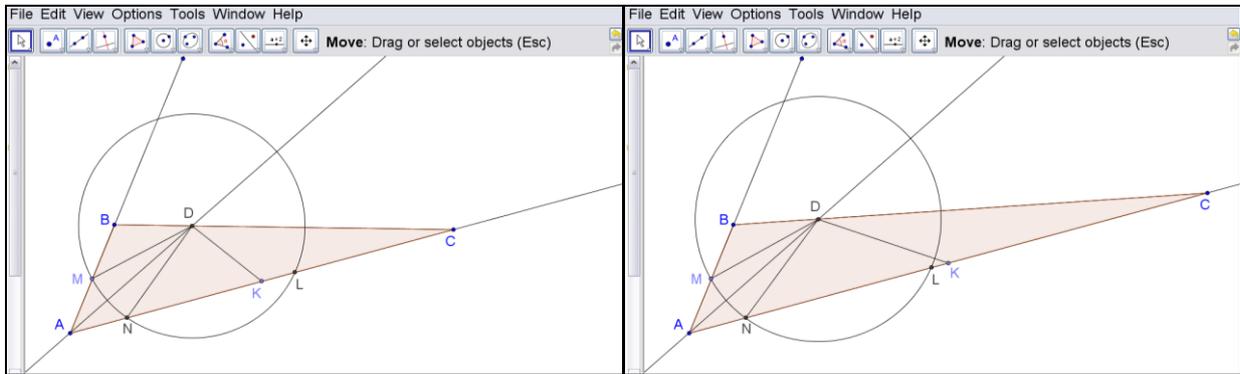

Figure 2: A successful attempt to build an example: dragging K along the side AC.

By dragging point K along the side AC I can interchange the positions of point K and L on the side of the triangle (see Figure 2, right). Thus, by dragging K along the side I achieve that points K and L coincide. (See Figure 3, left). And now I confirm that if K coincides with N then we indeed obtain an isosceles triangle (Figure 3, right).

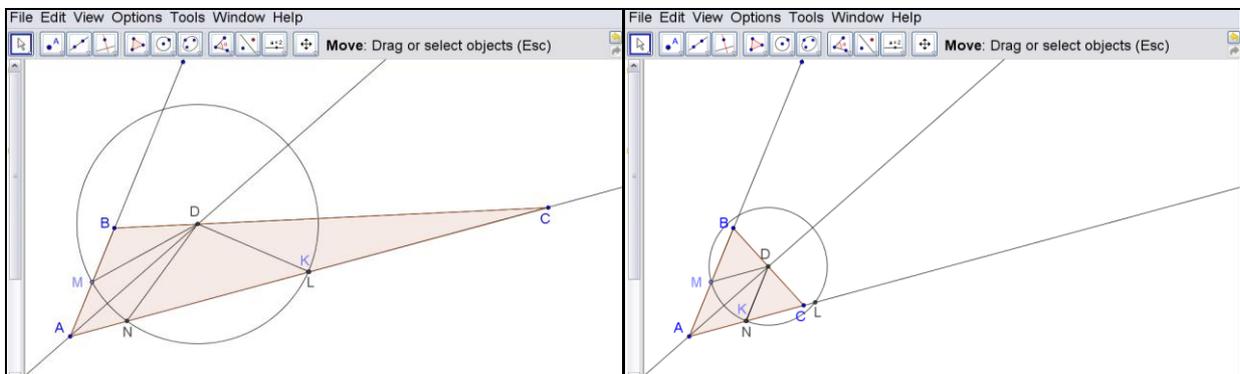

Figure 3: A successful attempt to build an example of a triangle where $DM = DN = DK$.

Once the problem is understood at the elementary level, the Problem Designer thinks how this can be used for introduction of more advanced techniques.

C. Connecting a problem to more advanced mathematics

Now, the Problem Designer aims to use intuition developed through the visualization of a solution for constructing a symbolic solution, which would correspond to the highest stage in Bruner's classification. In secondary school students learn equations of lines and circles. They also learn the idea that solving a system of two equations representing these curves gives the coordinates of the points of intersection of the curves. Thus to make the problem interconnecting one may try to represent

Working Group 1

previously obtained geometric solution algebraically. Here is what the Problem Designer does next.

I was looking at the Figures 2 and 3 and understood that to make an algebraic representation I need to introduce Cartesian coordinates. Let the side AC lie along the x -axis with A at the origin. Then point K has coordinates $(k,0)$. I introduce a general equation of the sides and the bisector; I fix coordinates of M and B and find how change of k affects the coordinates of D, C and L. I will set coordinates of L and K equal and find k from this equation. This is a plan. ... But its implementation becomes very cumbersome! I do not think that students will benefit from it.

Then she introduces another approach aimed at easier “algebraization”.

In a coordinate system I draw two rays starting from the origin and symmetric with respect to the x -axis (see Fig 4, left). I pick an arbitrary point M on the upper ray and point G on the x -axis. The circle with centre at G and radius GM intersects the lower ray at two points. I devote by N the one which is not symmetric to M with respect to x -axis. Now I place point B on the upper ray such that $AM=MB$, and point C on the lower ray such that $AN=NC$. The segment BC intersects x -axis at point D. I can drag point G along the x -axis in the position of point D and thus I obtain the example (see Fig. 4, right).

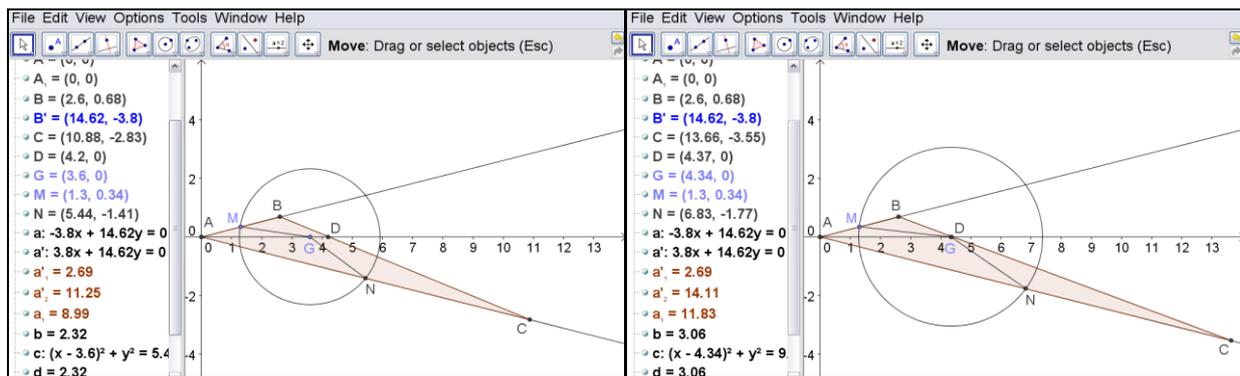

Figure 4: A successful attempt to build an example, which allows “algebraization”.

Now I construct an algebraic model. The two rays have linear equations in the form $y=mx$ and $y=-mx$, where the slope m can vary. Point G has coordinates $(g,0)$ and the circle has equation $(x-g)^2 + y^2 = r^2$, where $r=GM$. In order to find points of intersections of the ray and the circle we need to solve the quadratic equation $(x-g)^2 + (mx)^2 = r^2$, that is to express roots x_1, x_2 via g and r . Once I find the roots, I obtain coordinates of all points in terms of them: $M(x_1, mx_1)$, $B(2x_1, 2mx_1)$, $N(x_2, -mx_2)$, $C(2x_2, -2mx_2)$. Now, I want point G belong to the segment BC. Equating slopes of BC and BG gives the condition: $g = \frac{4x_1x_2}{x_1 + x_2}$. But from the quadratic equation I find that

$x_1x_2 = \frac{g^2 - r^2}{m^2 + 1}$ and $x_1 + x_2 = \frac{2g}{m^2 + 1}$, thus I obtain the relation between the radius and the coordinate of the centre of the circle $g = \sqrt{2}r$. From this relation I find integer coordinates for the vertices of a non-isosceles triangle for which the property $DM =$

Working Group 1

DN can be verified. For instance, if $A(0,0)$, $M(3,1)$, $B(6,2)$, $N(15,-5)$, $C(30,-10)$, $D(10,0)$ then $DM=DN=\sqrt{50}$.

D. Identifying levels and context suitable for problem

Once several approaches to solve our Problem are identified, the Problem Designer needs to summarize and identify all possible places in the curriculum where this problem potentially belongs. For example, the teacher may give students complete freedom in the choice of approaches to the question. Then the teacher may introduce a DGS and let students to try to build their examples from scratch. During this activity students rethink their task in view of tools available in the computerised environment. For example, the process of constructing angular bisector or a midpoint of a segment may be an automated part of a DGS, and then the major construction pertinent to the problem is conceptualized in terms of these operations.

Alternatively, the teacher may give the students an applet such as shown in Figures 2-3, which forces the students to explain already prefabricated construction. The students may be asked to state their observations about what constrains are preserved in the applet and how important they are for building the example, or what objects are introduced and what role in the solution they play. The students shall articulate their conjectures about observed relationships, for instance “What kinds of examples are possible (e.g. acute, obtuse, right angle)?” They also may be asked to explain why the example they construct with the applet is not just a visual illusion or an approximation; how do they know that the real example with all required characteristics exists. (The role of misleading diagrams in Geometry in relation to proofs is discussed in Kondratieva, 2009).

The problem may appear in the view of the students again when they study the coordinate approach. This time an applet from Figure 4 will be useful because the drawing explicitly reveals the coordinate system and equations on the side suggest a more general algebraic approach. Here the students may be asked to use concrete equations of the lines and circle and then generalize them and analyse the situation in an algebraic form, returning to concrete examples provided by the applet for a verification of their general course of reasoning. Consideration of various cases may be supported by the applet as well.

The problem may be recalled once again when the analysis of quadratic equations is discussed, and the existence of two real roots may be related to the existence of two points of intersection of the circle with the side of the angle. Since traditionally the number of real roots is said to be defined by the discriminant of a quadratic equation, the students may be asked to investigate the connection between the parameters of the figure (radius of the circle in Fig 4) and the resulting coefficients affecting the sign of the discriminant, and draw their conclusions with justification.

Finally, the problem can serve as an illustration in the study of conditional statements (implications) and their converses, inverses and contrapositives in formal

logic, as well as a study of proofs by counter-example. Now the emphasis can be made on the logical structure of the statements because the details of building the example are familiar to the students from previous encounters with the problem.

CONCLUSION.

In this paper, I illustrate the process of designing an interconnecting problem by using an example from Euclidean geometry. While making our Problem interconnecting, a variety of instances supporting the development of reasoning and proving skills has occurred. Being placed in the domain of mathematical activity the Problem deals with concrete objects, their properties and relationships. The experimentations with dynamic geometry software especially when the students interact with figures that are constrained to retain certain properties, forces the students to explain their actions and observations, to make and justify their conjectures. This activity accompanied by the requirement to systematise observed results pushes the learner towards the hypothetico-deductive stage of reasoning.

An algebraic approach is introduced after geometrical meaning of the model has been understood. While at this stage the focus is on setting and solving equations and development of algebraic thinking, the experience within DGS environments supports students' reasoning as they visualize the situation hidden behind variables and equations. These visualizations contribute into development of learners' intuition as well as in forming algebraic-geometric connections and perhaps a more holistic view on mathematics itself.

Behind concrete problems in mathematics often there is a more general and far-reaching agenda. For example, our Problem aims at grasping the general notion of a universally valid statement by making sense of the proclamation "For every isosceles triangle the segments DN and DM are equal." This statement has the same form as "For every isosceles triangle with $AB=AC$ the angles B and C are equal." However, the Question is posed to identify whether this property of an isosceles triangle necessarily defines an isosceles triangle. It invites students to realise that not every property of an object in fact defines the object. This fact should be brought to the students' attention forcing them to distinguish between equivalent conditions, such as "equal sides" and "equal angles", and those for which implication works only one way and not both ways. By solving this problem students not only advance their concept of an isosceles triangle, but also build their understanding of the statement's generality, the nature of implication, the notions of necessary versus sufficient conditions, and the idea of proof by counter-example. Thus, the design of an interconnecting problem discussed above aims at fostering reasoning skills at both visual-empirical and symbolic-theoretical levels within the same mathematical question in the background. Further research on teaching practices that involve adoption or design of interconnecting problems and their affect on students' reasoning abilities will show to what extent this would indeed be possible to achieve.

INTRODUCTION TO THE PAPERS OFWG 2

TEACHING AND LEARNING OF NUMBER SYSTEMS AND ARITHMETIC

Susanne Prediger¹, Nada Stehlikova²,
Joke Torbeyns³, Marja van den Heuvel-Panhuizen⁴

¹Dortmund University (Germany), ²Charles University Prague (Czech Republic),
³University of Leuven (Belgium), ⁴Freudenthal Institute (The Netherlands)

Working Group 2 has newly been formed for CERME 7 as a forum for presenting and discussing theoretical and empirical research on the teaching and learning of number systems and arithmetic (including models for operations in the number systems, ratio and proportion, rational numbers and number-theoretical aspects). The group intensively discussed on twelve papers and two posters addressing research for different ages, ranging from children of age 3-5 years up to pre-service teachers, with a focus on grade 2-6.

The thematic emphasis was put on

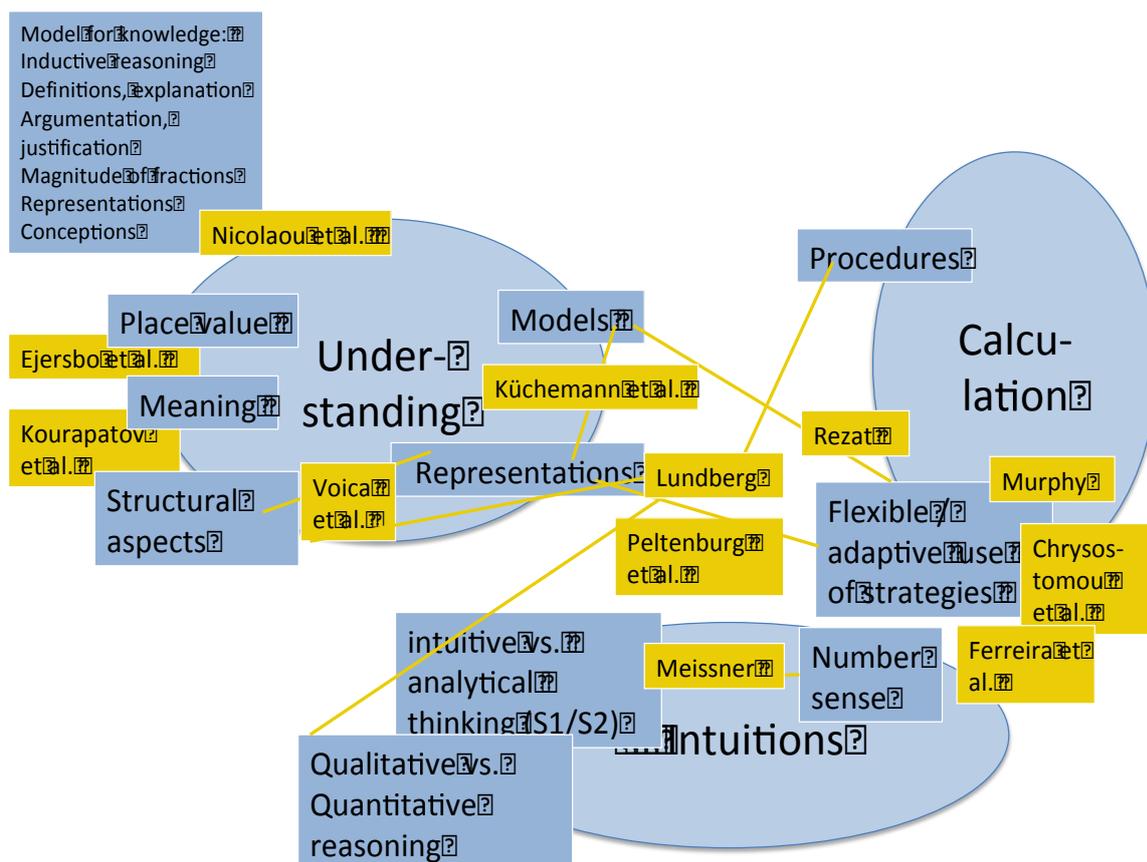

- 2 research-based specifications of domain-specific goals of what should and can be learned and in which priority;
- 3 analysis of learning processes and learning outcomes in domain-specific learning environments and classroom cultures;
- 4 new approaches to the design of meaningful and rich learning environments and assessments.

DIFFERENT CONSTRUCTS FOR CONCEPTUALIZING DOMAIN-SPECIFIC GOALS

The domain-specific goals comprised knowledge and competencies on numbers and operations in basically three areas: *intuition*, *understanding* and *calculation*. Whereas the participants of the working group agreed on the theoretical constructs to conceptualize competencies in *calculations* (procedures and flexible strategies), they used different constructs for conceptualizing *understanding* and *intuition*.

The figure attempts to give an idea on the landscape of different constructs that were used in the papers for conceptualizing different aspects of understanding, intuition and calculation. One intensively discussed example is the construct *number sense* that is widely used but conceptualized in different ways.

Working Group 2

DIFFERENT TYPES OF RESEARCH QUESTIONS

The research questions studied in the working group give an interesting insight into priorities of some of the current research in the domain of teaching and learning arithmetic. Most papers concerned research on students' thinking, but with a different focus.

Focus on *status quo* of students' thinking:

- describing selected phenomena, e.g.
 - Which strategies for subtracting do students apply? (Peltenburg & van den Heuvel-Panhuizen, Rezat)
 - Which typical difficulties appear, e.g., while solving problems? (Voica et al.)
- searching for internal connections, e.g.
 - How is students' use of strategies connected to their number sense? (Ferreira et al)
 - To which models do students refer for explaining their strategies? (Rezat)
 - How are different components of students' knowledge on fractions connected? (Nicolaou et al.)

Working Group 2

- searching for external connections, e.g.
 - How are students' strategies related to their preference to refer to structures in representations (spatial imagery)? (Chrysostomou et al.)

Focus on means for *supporting* students' thinking and its *development*:

- describing the development of students' thinking, e.g.
 - How does students' use of strategies develop over a certain time? (Ferreira et al., Murphy)
- specifying aspects or means that support or hinder students' thinking, e.g.
 - What mathematical / linguistic structures might hinder students in applying number concepts? (Ejersbo/Misfeldt)
 - What means (representations, models, ...) support the use of different strategies? (Peltenburg et al.)
- investigating means / conditions / contexts to support the development of students' thinking, e.g.
 - How can explorative talk in small group situations help students to develop their strategies? (Murphy)
 - How can the use of calculators contribute to developing number sense? (Meissner)
 - How do textbooks support or hinder the development of multi-faceted concepts of proportions? (Lundberg)
 - How can the double number line be used for developing multiplicative reasoning? (Kuechemann et al.)
 - Which activities helped kindergarten children to develop symmetric conceptions of equivalence? (Kourapatov et al.)

This wide spectrum of research questions reflects a large number of open points in the teaching and learning of number systems which need further research.

The discussion in the group raised some new awareness and questioned some positions that were taken for granted. Especially the following questions need further research:

- 5 What balance and what interplay between developing conceptual understanding and procedural skills for number operations can and should we aim at while designing learning environments? And in what order should we teach students understanding and procedural skills?
- 6 What does it mean to operate flexibly with numbers? What knowledge and skills are required to operate flexibly with numbers?

Working Group 2

- 7 What roles do models and teaching strategies play in operating with numbers flexibly?
- 8 What aspects of number theory should and can be taught in the primary school grades and how can these be taught?
- 9 How can long-term learning processes from grade 1 to grade 10 be supported and analysed?
- 10 What aspects of the number curriculum in the higher grades can support the transition to tertiary mathematics study?

These questions include so-called *what-questions* that are on the one hand crucial for didactical research and development, but, on the other hand, are often neglected in research papers because of a lack of established standards how to treat them scientifically. The working group will continue to search for ways of systematically tackling them, for example by math-didactical analysis (van den Heuvel-Panhuizen & Treffers, 2009), by referring to general educational goals (e.g. Heymann, 2003) and by specifying needs of the society (Meissner in this volume).

COGNITIVE STYLES AND THEIR RELATION TO NUMBER SENSE AND ALGEBRAIC REASONING

MarilenaChrysostomou, CharaTsingi, EleniCleanthous&Demetra Pitta-Pantazi

Department of Education, University of Cyprus

The purpose of the present study was to examine the relationship between individuals' cognitive style and their mathematical achievement and strategies used while solving number sense and algebraic reasoning tasks. A mathematical test on number sense and algebraic reasoning and a self-report cognitive style questionnaire were administrated to 83 prospective teachers. The results indicated that spatial imagery, in contrast to the object imagery and verbal cognitive styles, is related to the achievement in algebraic reasoning and number sense. The study also revealed that as prospective teachers' spatial imagery style increases, the use of conceptual strategies in solving the tasks also increases.

Keywords: cognitive styles, number sense, algebraic reasoning, procedural and conceptual strategies

INTRODUCTION

The relationship between various cognitive style dimensions and mathematical achievement attracted the attention of several researchers worldwide for many years (Pitta &Christou, 2009b; Presmeg, 1986a). A number of recent studies (Anderson, Casey, Thompson, Burrage, Pezaris&Kosslyn, 2008; Kozhevnikov, Hegarty& Mayer, 2002) examined the effects of students' cognitive styles on their mathematical learning, utilizing a new approach to the visual-verbaliser cognitive style dimension. These studies, supported the view that there exist three different cognitive style dimensions, a verbal style as well as two types of visual cognitive styles, the spatial imagery and the object imagery. Despite the fact that there have been suggestions for improvements concerning the cognitive style dimensions, research so far (Anderson et al., 2008; Pitta-Pantazi&Christou, 2009b), focused mainly on the investigation of the relationship between cognitive styles and achievement in geometry and measurement concepts. What is absent in mathematics research, is the investigation of a possible relationship between *cognitive styles*, *number sense* and *algebraic reasoning*. Consequently, the purpose of the present study was to examine the relationship between cognitive styles, achievement and strategies used while solving tasks that involve *number sense* and *algebraic reasoning*.

THEORETICAL FRAMEWORK AND RESEARCH GOALS

Cognitive styles

Cognitive style is an individual preferred and habitual approach to organizing and representing information, which subsequently affects the way in which one perceives

and responds to events and ideas (Riding and Rayner, 1998). A number of researchers have proposed a wide variety of cognitive style dimensions, such as visualisers-verbalizers (Paivio, 1971), impulsivity-reflectiveness (Kagan, 1965), field dependency-field independency (Witkin & Asch, 1948a). In the field of mathematics education, the verbaliser/imager distinction was the one that attracted most attention (Pitta & Christou, 2009). According to this view, visualisers rely primarily on imagery when attempting to perform cognitive tasks, whereas verbalizers rely primarily on verbal-analytical strategies. However, in a recent study, Blazhenkova and Kozhevnikov (2009) suggested that there exist two distinct imagery subsystems that help individual process information in different ways (Pitta & Christou, 2009), the object imagery system and the spatial imagery system. Therefore, research provides evidence for two types of visualisers, the object visualisers and the spatial visualisers. Object visualisers have low spatial ability and use imagery to construct vivid high-resolution images of individual objects, while spatial visualisers have high spatial ability and use imagery to represent and transform spatial relations.

Cognitive styles and mathematics

A number of studies have investigated the relationship between cognitive styles and mathematical achievement (e.g. Kozhevnikov et al., 2002; Presmeg, 1986a). However, their results are often conflicting. Some studies have shown that spatial imagery is an important factor of high mathematical achievement (Kozhevnikov et al. 2002) whereas other studies showed that students classified as visualisers do not tend to be among the most successful performers in mathematics (Presmeg, 1986a).

Moreover, findings from such studies revealed also certain areas of mathematics for which spatial imagery is important. For example, Kozhevnikov et al. (2002), conducted a study to compare the use of mental images by the two types of visualisers in solving problems with graphs of motion. Students with object imagery style interpreted the graphs as pictures while students with spatial imagery style constructed more schematic images and manipulated them spatially. In another study of Anderson et al. (2008), on geometry problems with geometry clues matched to cognitive styles, both spatial imagery and verbal cognitive styles were important for solving geometry problems, whereas object imagery was not.

Cognitive styles, number sense and algebraic reasoning

Some studies examined mental representations or *imagery* in arithmetic and revealed differences between high and low achievers (Pitta & Gray, 1996; Gray, Pitta & Tall, 1997). Low achievers had a tendency to highlight surface details and emphasized the concrete qualities within situations (focused to the descriptive qualities of numbers) and their responses to a range of addition and subtraction combinations involved mainly *counting procedures*. On the other hand, mathematically high achievers concentrated more on the relationships and abstract qualities of numbers (Pitta & Gray, 1996) and in the addition and subtraction combinations they seemed to have a

better sense of the concept that enabled them to *compress* the long sequences of procedures (Gray et al., 1997). According to Gray et al. (1997), different perceptions of the objects are at the heart of different cognitive styles that lead to success and failure in elementary arithmetic.

The aforementioned strategies used by high and low achievers refer to procedural and conceptual understanding, respectively. According to Hiebert and Carpenter (1992), procedural knowledge is a sequence of actions and conceptual understanding is the knowledge that is rich in relationships. In this study, the terms conceptual and procedural strategies emerge from these definitions and are used to describe the way that prospective teachers solved the tasks. Procedural strategies involve typical and time-consuming strategies, application of formulas and generally a “sequence of rote or senseless actions”. On the other hand conceptual strategies are those that reveal insightful “understanding” regarding the concepts that are studied and the ability of a person to make mathematical judgments and to use more flexible strategies. What must be noted, is that the term “cognitive style” was treated in an “informal” way in the abovementioned studies (Gray et al., 1997; Pitta & Gray, 1996), since no use of a tool for measuring the cognitive styles was evident. However, their suggestions about a possible relation between cognitive styles and arithmetic are in accord with some older studies’ results (Navarro, Aguilar, Alcalde & Howell, 1999; Blaha, 1982). Navarro et al. (1999), found that field independence style relates to achievement in arithmetic and the study conducted by Blaha (1982), showed that reflective cognitive style, relates to achievement in arithmetic problem solving. However, these studies, did not take into consideration an appropriate cognitive style questionnaire, that is rooted in more general theory of human information processing (Kozhevnikov et al., 2002).

Despite the fact that there has been a limited number of studies examining the relationship between cognitive styles and arithmetic operations, there is a lack of studies examining the relationship between cognitive styles, number sense and algebraic reasoning. Number sense refers to a person’s general understanding of number and operations along with the ability and inclination to use this understanding in flexible ways to make mathematical judgments and to develop useful strategies for handling numbers and operations (McIntosh, Reys & Reys, 1992). Algebraic reasoning is a process in which students generalize mathematical ideas from a set of particular instances, establish those generalizations through the discourse of argumentation, and express them in increasingly formal and age-appropriate ways (Kaput, 1999). The interrelation of number sense and algebraic reasoning is reported by several researchers (Carpenter, Levi, Berman & Pligge, 2005; Steffe, 2001). Moreover, number and algebra constitute together the strand “Number and Algebra” in the mathematics curriculums of many countries e.g. New Zealand, Singapore, Hong Kong. For these reasons, number sense and algebraic reasoning were jointly considered in this article and were not separated.

The development of both, number sense and algebraic reasoning is crucial for mathematics learning. However, results from some studies (e.g. Johnson, 1998), revealed that prospective teachers' general number sense is not sufficiently developed. For these reasons it is important to investigate whether some cognitive variables (such as cognitive styles) will enable us better to understand individual differences in solving problems and tasks that involve these concepts, something that is not evident in the mathematics literature review.

As a result, the purpose of the present study was to investigate whether mathematical achievement in number sense and algebraic reasoning tasks and strategies used for solving these tasks, are related to specific cognitive style. More specifically, we sought answers to the following questions: (a) Do cognitive styles (verbal, spatial and object-imagery) predict prospective teachers' achievement in number sense and algebraic reasoning tasks? (b) Does prospective teachers' achievement in the aforementioned tasks differentiate in accordance to their cognitive style profile? (here participants were grouped into eight different cognitive style profiles) (c) Is there a relation between prospective teachers' cognitive style and the strategies they adopt in solving algebraic reasoning and number sense tasks?

METHODOLOGY

Participants

The participants were 83 prospective elementary school teachers. All participants have taken mathematics lessons during their lower and upper secondary education. At the university level, they attended three mathematics courses where one of them was mathematics education. A mathematical test and a self-report cognitive style questionnaire were administered to participants during two sessions.

The mathematical test

The mathematical test on number sense and algebraic reasoning included 10 tasks. Examples of tasks are provided in Figure 1. A verbal and a pictorial task were employed to examine students' abilities in each content area (calculation-estimation, patterns, number divisibility, relations among numbers and problem solving with unknowns). Using two different representations (verbal and pictorial), we attempted to achieve a balanced test among the three cognitive styles that were examined in this study. Two codes were given to each answer. First, the answer was coded as correct (success=1) or incorrect (success=0). Then, a second code was given for the strategy used by the participant to complete the task. In the initial stage of the analysis many strategies were generated which were later grouped into two general categories. The first category (strategy=1) contained conceptual strategies (i.e. flexible strategies that revealed deep understanding of relationships among numbers and symbols) and the second category (strategy=2) included procedural strategies (i.e. strategies that followed step by step procedures or memorization of formulae and rules). For

Working Group 2

example, a prospective teacher gave the following answer when asked to solve task 1 “Yes, (there is there a number divisible by 7 between 12 358 and 12 368) because the difference between the two numbers is ten and there must be at least one number that is divisible by 7” (strategy=1). On the other hand, another participant answered as follows: “I believe that the numbers 12 357 and 12 363 can be divided by 7 because the numbers 57 and 63 can be divided by 7” (strategy=2).

<p>Task 1 (number sense) Is there a number divisible by 7 between 12 358 and 12 368? (Zazkis& Campbell, 1996)</p>	<p>Task 2 (algebraic reasoning)</p>  <p>Find the value of one star.</p>	<p>Task 3 (number sense) Calculate the sum of numbers between 1 and 100.</p>
---	---	--

Figure 1: Sample Tasks of the mathematical test

The cognitive style questionnaire

The cognitive style questionnaire that was a translation of the Object-Spatial Imagery and Verbal Questionnaire (Blazhenkova&Kozhevnikov, 2009) contained 45 statements and examined participants’ differences in spatial imagery (15 items, e.g. *My images are more schematic and they are not colourful*), object imagery (15 item, e.g. *My images are colourful and bright*) and verbal cognitive style (15 items, e.g. *My verbal skills are excellent*). These items were statements about qualitative characteristics of the images, special favours to specific types of visual images or verbal thinking, learning and habitual preferences, preferences to certain professions and individuals’ assessments of their skills in using spatial or object imagery or verbal processing. Participants rated the items on a 5-point Likert scale with 1 indicating total disagreement and 5 indicating total agreement. For each participant, the spatial imagery, the object imagery and the verbal scale scores were created by calculating the average score of the fifteen items of each cognitive style. The data were analysed using the statistical package SPSS and multiply methods of analysis were performed, including regression analysis, multivariate analysis of variance (MANOVA), pearson correlation and descriptive statistics. The results of this study are presented in two sections. The first section deals with the relationship between cognitive styles and achievement in number sense and algebraic reasoning, whereas the second is concerned with cognitive styles and their relationship to the strategies that prospective teachers adopt in solving the tasks.

Cognitive styles and achievement in number sense and algebraic reasoning

In order to answer research question 1 correlation and regression analyses were conducted. Firstly, to investigate the relationship between cognitive styles and achievement in number sense and algebraic reasoning, we examined the correlations between prospective teachers’ cognitive styles and their achievement, which are presented in Table 1. As it appears from Table 1, spatial imagery cognitive style significantly correlates with prospective teachers’ total achievement score, with their

Working Group 2

achievement in verbal tasks as well as with their achievement in pictorial tasks. However, the other cognitive styles (object and verbal) did not correlate with prospective teachers' achievement.

Cognitive styles	Total achievement	Achievement in verbal tasks	Achievement in Pictorial tasks
Spatial Imagery	.401*	.358*	.345*
Object Imagery	-.165	-.216	-.075
Verbal	-.176	-.190	-.118

*Correlation is significant at the 0.05 level (2-tailed).

Table 1: Correlations among achievement and spatial imagery, object imagery and verbal cognitive styles.

Then multiple regression analyses were conducted with criterion (dependent) variables the total achievement score, the achievement in verbal tasks and the achievement in pictorial tasks, and predictors (independent) the spatial imagery, object imagery and verbal cognitive styles. The results of the multiple regressions are presented in Table 2 and provide more information about the nature of the relationships between teachers' achievement and cognitive styles. It is obvious that only the spatial imagery cognitive style is a statistically significant predictor of prospective teachers' achievement in number sense and algebraic reasoning, regardless of the mode of representation of the tasks, and it explains a respectable proportion of variance (more than 20%) in achievement in number sense and algebraic reasoning. In other words, as prospective teachers' spatial imagery cognitive style increases, their total achievement in the test, and their achievement in verbal and pictorial tasks also increase. Moreover, in order to answer research question 2 and investigate possible differences between the different profiles of cognitive styles, participants were grouped in eight different groups with respect to their spatial imagery, object imagery and verbal cognitive styles as follows: high/low Spatial, high/low Object and high/low Verbal. The mean scores of each group with regard to their total achievement score are presented in Table 3. The highest mean score corresponds to prospective teachers with high preference in spatial visualization processing and low preference in object visualization and verbal processing (group 6).

Cognitive styles	Total achievement		Achievement in verbal tasks		Achievement in pictorial tasks	
	<i>b</i>	<i>p</i>	<i>b</i>	<i>p</i>	<i>b</i>	<i>p</i>
Spatial imagery	1.339	.001*	.660	.002*	.679	.003*
Object Imagery	-.495	.222	-.390	.093	-.106	.661
Verbal	-.199	.593	-.140	.510	-.059	.790

*Statistical significance $p < 0.05$

Table 2: Multiple regression analyses with dependent variables total achievement, achievement in verbal tasks and achievement in pictorial tasks, and independent variables spatial imagery, object imagery and verbal cognitive styles.

Also, prospective teachers with high preference in spatial processing (groups 1,3,4,6) have higher scores than those with low preference in spatial processing.

To further investigate the impact spatial imagery has on achievement, prospective teachers were assigned to high and low spatial imagery groups. A multivariate analysis of variance (MANOVA) was conducted with the achievement scores in verbal and pictorial tasks as dependent variables and the preference in spatial processing as independent one. The results of the multivariate analysis showed that there were significant differences between prospective teachers achievement according to their preference in spatial processing (Pillai's $E_{(1,81)} = 3,882$, $p < 0,05$). More specifically, prospective teachers with high spatial imagery have significantly better achievement scores on verbal and pictorial tasks than prospective teachers with low spatial preference.

Cognitive style profiles			N	\bar{x}	SD	Cognitive style profiles			N	\bar{x}	SD
S*	O*	V*				S*	O*	V*			
1. H	H	H**	18	3.89	1.78	5. L	H	H	13	3.08	1.80
2. L	L	L**	7	3.14	1.35	6. H	L	L	9	5.56	2.65
3. H	H	L	11	4.36	2.58	7. L	L	H	9	3.22	1.39
4. H	L	H	11	4.82	2.72	8. L	H	L	5	4.00	1.23

*S=Spatial, O=Object, V=Verbal, ** H= High, L=Low

Table 3: Means of achievement score for each cognitive style profile.

Cognitive styles and strategies used in solving the tasks

To answer research question 3, correlation and regression analyses were conducted. The correlations among prospective teachers' strategies and cognitive styles are shown in Table 4. It appears that the spatial imagery cognitive style significantly correlated with the use of conceptual strategies ($r=.310$, $p < 0.05$) and not procedural strategies, while the rest of the cognitive styles did not correlate with any type of strategies.

Cognitive styles	Conceptual strategies	Procedural strategies
Spatial imagery	.310*	-.021
Object Imagery	-.124	-.092
Verbal	-.152	-.101

*Correlation is significant at the 0.05 level (2-tailed).

Table 4: Correlations among strategies used in number sense and algebraic reasoning tasks and spatial imagery, object imagery and verbal cognitive styles.

To further investigate the nature of these correlations, we analysed our data using multiple regression analysis with criterion (dependent) variables the “conceptual strategies” and the “procedural strategies” and predictors (independent) variables the cognitive styles. The results are presented in Table 5. As it can be seen, the spatial imagery cognitive style is a statistically significant predictor of prospective teachers’ use of “conceptual strategies” for solving tasks with numbers concepts and algebraic reasoning and it explains the 20% of the variance in the adoption of strategies. We can conclude that as prospective teachers’ spatial imagery increases, the use of conceptual strategies in solving various tasks, also increases. On the other hand, none of the cognitive styles can predict the use of “procedural-conventional” strategies.

Cognitive styles	Conceptual strategies		Procedural strategies	
	<i>b</i>	<i>p</i>	<i>b</i>	<i>p</i>
Spatial imagery	.864	.009*	-.137	.681
Object Imagery	-.299	.402	-.299	.529
Verbal	-.184	.576	-.268	.424

*Statistical significance $p < 0.05$

Table 5: Multiple regression analyses with dependent variables the strategies prospective teachers use and independent variables spatial imagery, object imagery and verbal cognitive styles.

DISCUSSION

Several studies revealed the important role that spatial imagery cognitive style plays in mathematical creativity, geometry and problem solving (see e.g. Pitta & Christou 2009; Anderson et al., 2008; Kozhevnikov et al., 2002). The present study moves one step further and provides evidence that spatial and object imagery may have different effects on the achievement and on the strategies that children adopt for solving tasks that involve number sense and algebraic reasoning. The results indicated that spatial imagery is the only significant predictor of prospective teachers’ achievement in number sense and algebraic reasoning tasks and that teachers with high preference on spatial processing had significantly higher scores on both verbal and pictorial tasks, than the teachers with low preference on spatial processing. This finding is in line with other studies’ results that examined cognitive styles in relation to mathematical problem solving (Kozhevnikov et al., 2002) and mathematical creativity (Pitta-Pantazi & Christou, 2009).

The present study also revealed that spatial imagery is a significant predictor of prospective teachers’ “conceptual strategies” adoption. It appears that as prospective teachers’ preference to spatial processing increases, the adoption of conceptual strategies for solving the number sense and algebraic reasoning tasks also increases. We can say that prospective teachers with high spatial imagery tend to “see” relations between numbers that others do not and consequently they are “in favour”

in using quicker and conceptual strategies that involve “understanding” or “insight”. This is in accord with previous research by Gray et al., (1997), who suggested that individuals may approach mathematics tasks in different ways, depending on their cognitive styles. On the other hand, none of the cognitive styles could predict the use of procedural-conventional strategies that involve “rote” or “senseless” actions. The latter might indicate that the adoption of “procedural-conventional” strategies is more of a result of formal instruction in schools and prospective teachers, regardless of their cognitive style, adopt the aforementioned strategies only when they cannot efficiently use the “conceptual-short strategies”. However, from these results it cannot be generalised that spatial imagery is the only cognitive style that is beneficial for number sense and algebraic reasoning, since the sample was of limited size and from a certain age group. The replication of the present study with a different and larger sample is necessary in order to inform us whether the same pattern appears in younger students.

Concluding, an interesting proposal for future research could be the investigation of in-service teachers’ cognitive styles and their relation to the strategies they teach to students for solving several mathematical problems that involve different concepts. If a certain cognitive style (e.g. spatial imagery) relates to specific strategies, then possible growth of teachers’ spatial processing could improve teachers’ strategies, which in turn could enhance students’ conceptual understanding concerning several concepts.

DANISH NUMBER NAMES AND NUMBER CONCEPTS

Lisser Rye Ejersbo & Morten Misfeldt

Danish School of Education, Aarhus University

This paper raises some questions concerning the relation between Danish number names and digits in the canonical base 10 system. Our hypothesis is that in Danish, number names are more complicated than in other languages, and for this reason, Danish children have more difficulties learning and working with numbers. From this point of view, we make a theoretical investigation among different languages and how the names influence the conceptual understanding of numbers. We compare Danish, English and Japanese number names and show from semiotic and cognitive perspectives how the qualitative differences in how the first 100 numbers are named may give rise to linguistically determined differences in children's concept of numbers and in the cognitive load of arithmetic processes.

Keywords: Base-10 system, two-digit number names, semiotic, cognitive perspectives

INTRODUCTION

In this paper we investigate theoretically the Danish number names and their influence on how children may conceptualize numbers. We look at the interplay between the words we use to denote numbers and the way numbers are written in the canonical base-10 system (from here on base-10). In the Great Danish Encyclopedia, Danish number names are described as “Very old and reflecting a number concept that is primitive in relation to mathematical thinking” (Talord, 2009–2010/Our translation).

Danish number names are very complex, deriving from old number systems using base-12 and base-20. In our investigation, we are especially interested in how the Danish number names can help or hinder the development of a practical concept of numbers and arithmetic competence.

Denmark is one of the Scandinavian countries, and Danish is so similar to Swedish and Norwegian that the three languages are mutually intelligible— except for the number names. In both Swedish and Norwegian, the system for number names is similar to the English one.

Comparative investigations between different linguistic communities provide examples of how a preschool child's mother tongue influences his or her concept of numbers and understanding of place value (Miura et al., 1989; Miura et al., 1993; Miura et al., 1999). The focus of several investigations has been the connection between number names from 10–100 in different languages and the understanding of the place value in base-10. Denmark has never participated in such comparative studies.

Working Group 2

Our hypothesis is that the Danish names for the first 100 numbers are more complicated than those in other languages, and that for this reason Danish children have more difficulties learning and working with numbers. In this paper we test this hypothesis from three different types of theoretical perspectives: comparative perspectives involving the analysis of the number names in Danish, English and Japanese, semiotic perspectives, and cognitive perspectives.

COMPARING NUMBER NAMES

The following table contains number names in Danish, English and Japanese. The table shows how some Danish names for numbers use 20 as the base reference, while the numbers written with digits follow base-10.

	Danish	Explanation	English	Explanation	Japanese	Explanation
1	En	1	One	1	Ichi	1
2	To	2	Two	2	Ni	2
3	Tre	3	Three	3	San	3
4	Fire	4	Four	4	Shi	4
5	Fem	5	Five	5	Go	5
6	Seks	6	Six	6	Roku	6
7	Syv	7	Seven	7	Sichi	7
8	Otte	8	Eight	8	Hachi	8
9	Ni	9	Nine	9	Kyu	9
10	Ti	10	Ten	10	Juu	10
11	Elleve	11	Eleven	11	Juu-ichi	10 + 1
12	Tolv	12	Twelve	12	Juu-ni	10 + 2
13	Tretten	13	Thirteen	13	Juu-san	10 + 3
14	Fjorten	14	Fourteen	14	Juu-shi	10 + 4
15	Femten	15	Fifteen	15	Juu-go	10 + 5
16	Seksten	16	Sixteen	16	Juu-roku	10 + 6
17	Sytten	17	Seventeen	17	Juu-sichi	10 + 7

Table 1: Number names between 1 and 100 in Danish, English and Japanese, combined with the underlying calculation ‘explained’ through these names.

Working Group 2

In comparing Danish and English and Japanese, we look at two main issues:

1. The number of words that must be learned by rote in each language
2. The regularity of the spoken number system; that is, the degree to which the spoken number system corresponds to the written base 10 system

We can simply count the number of rote learning instances that are required to count to one hundred. The first 100 numbers of spoken Danish can be viewed as a system containing 28 basic signs, 1–9, 10–20, 30, 40, 50, 60, 70, 80, 90, 100, whereas the written base 10 contains 10 signs and a system. In that sense it takes 28 different words to count to 100 in Danish while in Japanese it only takes 11. In English, it is debatable whether there are 13, 20 or 28 different words to be learned by rote. If we accept that the three different forms often (ten, -teen and -ty) are the same, then there are only 13 words; if we accept only that -ty is equal to ten, then there are 20; and if we do not accept that -teen and -ty are the same as ten, then there are 28 words – as in Danish. In Danish, all the numbers from 13–19 end with a-ten, but the initial syllable does not sound like the numbers (from 3–9) that they refer to and we therefore count them as different words. The Danish decade number names from 20 to 90 are not directly connected to the numbers from 2–9 and must therefore be learned by rote without a system. Compared to English, the Danish number names are harder to systematize. In English, there is a system whereby all decades start with the number (e.g. twen-, thir-, four-, ...) and end with a -ty. In Japanese there is regularity in the oral counting system exactly as in base 10 and in addition, the names for numbers between 0–9 are very short.

Danish and English have the same regularity as base-10 starting with the number twenty (in Danish tyve): we start counting from 1–9 between each decade. In Japanese, this regularity starts already at 10, as in base-10. The English and Danish numbers between 10 and 20 follow another system. In both languages eleven (elleve in Danish) and twelve (tolv in Danish) do not follow the same system as the numbers between 13 and 19; in fact they are reminiscences of an old base-12 system. The numbers from 13 to 19 are combinations of an ordinal number with a -ten in Danish and a -teen in English. In both languages, the numbers between 13 and 19 are named in reverse order from the digits. This irregularity continues for the Danish numbers up to 100. For instance, the Danish name for 83 is “three and ‘fours’” or in Danish "tre-og-firs" where ‘tre’ is Danish for ‘three’, ‘og’ is Danish for ‘and’, and ‘fire’ is Danish for ‘four’ (the inflection ‘firs’ means eighty); in numbers: 3 + 80. In English, this irregularity in the sequence of the syllables constituting the number words only exists in the numbers from 13–19.

In summary, the Danish spoken number system is in reverse order from 10–100, the English spoken number system is reversed from 10–20 and regular from 20–100, while the Japanese system is regular from 10–100.

COMPARATIVE PERSPECTIVES

Several studies (Miura et al., 1989; Miura et al., 1993; Miura et al., 1999) comparing English-speaking American, Japanese, Chinese and Korean first graders' (aged on average 6–7 years) cognitive representation of and understanding of place value confirmed that the Asian language speakers showed a preference for using base 10 representations to construct numbers, whereas English speakers showed a preference for using a collection of units. Note that a significant difference between American and Asian number names appears between 11 and 19; exactly when the base-10 system starts to use two digits. In the investigation, children were asked to construct the numbers 11, 13, 28, 30 and 42 from sets of wooden blocks (ten blocks and unit blocks). The results showed that 91 % of the American first graders used unit blocks to represent the numbers on their first try. In contrast, about 80 % of the Asian children used ten-blocks when representing the numbers on their first try. These differences in cognitive representation were mainly ascribed to language (Miura et al., 1993). Still, the validity of this conclusion is challenged by the many other cultural and educational differences between Asian and Western children. Yet, children who share similar cultures and belong to similar school systems but have different mother tongues have also been investigated. For example, Dowker et al. (2008) compare English and Welsh students. These students have the same cultural conditions, but Welsh names for numbers are as regular as the Japanese. They conclude:

No statistically significant differences were found between schools or age groups on the scaled score on either test (arithmetic and number skills). [...] However, there were group differences in a specific area of arithmetical ability, notably, in ability to read and judge numbers pairs.

Because their investigation can more or less eliminate the cultural and educational differences we can conclude that the results indeed show an effect of linguistic differences:

Welsh-speaking children find it easier than English-speaking children to read and compare two-digit numbers, suggesting that they are better at using the principles of place value.

This raises the question of why and how different languages influence number concepts and perhaps even the ability to learn simple arithmetic.

SEMIOTIC PERSPECTIVES ON NUMBER NAMES

The empirical studies show that some languages seem to support the development of concepts of numbers better than other languages, and our initial comparison of Danish, English and Japanese shows that the differences maybe related to the degree to which the number names and the written numbers are 'alike'.

In order to view this case from a semiotic perspective we use the concept of iconicity (Stjernfelt, 2007), which describes the likeness of a sign to what it signifies, and the

epistemological triangle (Steinbring, 2006), a model describing the relation between mathematical signs and mathematical concepts.

Iconicity of the base-10 number system

In the case of an iconic sign, the token relates to the object by similarity. Signs with strong iconicity typically “look like” their objects in some sense. For example, the roman number *iii*, which represents *three*, is typically considered iconic, because the three *i*'s correspond to the cardinality of the number three.

In order to describe how the base-10 numbers can be considered iconic we use Stjernfelt's description of operational iconicity (Stjernfelt, 2007). The operational criterion for iconicity denotes the way a sign or a system of signs allows us to experiment and learn about what the sign signifies by extracting information from the sign that was not deliberately included by the producer of the sign. Base-10 has some qualities that make it reasonable to consider written numbers as partially iconic signs. In particular, it is possible to build any number in a position based system using only the number of different digits given by the base. It is one of the genius aspects of here the base-10, but this aspect is spoiled if the names don't follow the numbers. A base-10 number tells us how many of each power of 10 it contains. The system allows us to create increasingly larger numbers from the ten basic numbers; furthermore, the system allows us to easily decide which one of two given natural numbers is largest. Written base ten numbers fully reflect the system. Using the operational criterion of iconicity we can say that written numbers are iconic in the sense that it is easy to determine which one of two given (natural) numbers is largest; it is easy to create larger and larger numbers; and the written base-10 numbers support a range of arithmetic algorithms (addition, subtraction, multiplications etc.). There is in principle nothing to prevent spoken number names from resembling this kind of iconicity. As simple examples of iconic spoken numbers, the additive “bum bum bum” can represent “three” in the same way as the roman number *iii*, and saying “four times ten and 3” to represent 43 is iconic in the same way as writing “43” in base-10. As we have seen, this is the situation in Japanese and for some numbers in English, but not at all in Danish.

Epistemology and the signification of numbers

In order to understand how written numbers, spoken number names and concepts of numbers relate to each other we use the ‘epistemological triangle’, which connects conceptual entities to the signs that represent them and to mathematical objects in a reference context (Steinbring, 2006). Steinbring notes that there is in some cases exchangeability between the reference context and the sign/symbol, because the same sign can serve as a reference context for a mathematical concept (left side of the triangle) in some cases and as a representation of a mathematical concept (right side of the triangle) in other cases (Steinbring, 2006).

We can apply the epistemological triangle in order to understand how mother tongue influences number concepts, by viewing spoken words and written signs as reference contexts for each other. Taking point of departure in the epistemological triangle, we can represent the situation as shown below:

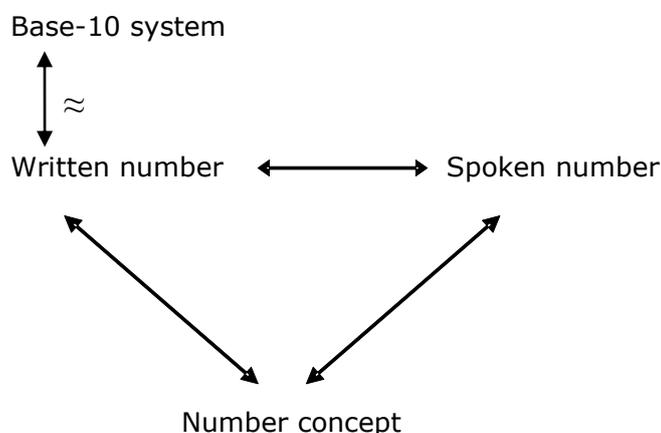

Figure 1: The influence of written and spoken numbers on the number concept. The written numbers reflect the base-10 system completely.

The epistemological triangle shows that the relations between the written number and the spoken number in terms of how the written number signifies the spoken number and how the spoken number signifies the written number, can influence the number concepts that individuals develop. Since these relations, as we have argued, differ from language to language, we should expect a difference in the number concepts arising from the different number names.

In English and especially in Danish, the signifying relations between spoken and written numbers are more complicated than in Japanese. The specific effect on the number concepts for English and Danish speaking children cannot be inferred from this analysis, but to hypothesize that this leads to more complicated concepts of numbers and possibly even to problems in learning numbers seems reasonable.

Using the concept of iconicity and the epistemological triangle for mathematical signs, we have seen that the written numbers resemble base-10, and using an operational criterion of iconicity, can be said to be iconic. We have also seen that different languages respect this iconicity in the spoken numbers to different degrees. What we have previously described as regularity between written base 10 numbers and spoken number names are cases in which the operational iconicity of the base 10 numbers are reflected in the spoken numbers as well.

Furthermore, we have applied the epistemological triangle to a situation in which written and spoken signs for numbers are considered as reference contexts for each other. We infer that these two representations of numbers affect the number concept

that pupils develop and hypothesize that this leads to more complicated number concepts for native speakers of languages in which the operational iconicity of the written numbers is less reflected in the spoken number names.

COGNITIVE PERSPECTIVES

Learning to count and understand base-10 are cognitive challenges involving many small steps. We have chosen to focus on the following three aspects:

1. Oral counting
2. The cardinal principle of combining a name with a cardinal value
3. The combination of words for a number, its cardinal value and the digit sign

Oral counting

Developing familiarity with the symbolic number system begins with oral counting. Children start oral counting quite early, and it is not clear if they understand what they are doing when they count. Counting appears to be learned first as a linguistic routine through which the number names are perceived as ‘sign systems’ or cultural semiotic systems that enable the symbolic representation of knowledge (Goswami, 2008).

We have seen that Japanese number names are brief and regular. English number names are somewhat longer and the regularity of the number system starts more or less at 20. In Danish, number names are generally even longer and the system has many irregular numbers. Studies of numbers and language (Sousa, 2008) show that a language with short number names loads the working memory (WM) less than a language with longer number names. There are no differences in the ability to count and numerate sets from 1 to 12 among Asian and American children, but from 13 to 100 Asian children are much better (Sousa, 2008). The development from being a novice to being an expert by gaining automaticity with numbers bigger than 12 seems to take longer if the language used has an irregular number system. Danish children have to learn many different and meaningless number words by rote, and we can now conclude that Danish number names load the children’s WM considerably when they are learning to count; in addition, there is clear evidence that syllables rated as more meaningful are easier to recall (Baddeley et al., 2009). A Danish investigation of children’s ability to count (N=140) at the age of 6 showed that more than 40 % of the children stopped counting at a number ending with 9 (Lyngsted & Knudsen, 2007). We suspect that this is due to the irregular Danish system for naming decade numbers.

The cardinal principle of combining a name with a cardinal value

At 3–5 years of age, children understand more or less the five counting principles at least until the set of 10, even when they err in their counting. The five counting principles are (Gelman and Gallistel, 1978, here Siegler, 2003):

Working Group 2

1. The *one-one principle*: Assign one and only one number word to each object.
2. The *stable order principle*: Always assign the numbers in the same order.
3. The *cardinal principle*: The last count indicates the number of objects in the set.
4. The *order irrelevance principle*: The order in which objects are counted is irrelevant.
5. The *abstraction principle*: The other principles apply to any set of objects.

Children typically learn the names of numbers as a long list of words and demonstrate knowledge of the stable order principle by almost always saying the number words in a constant order and saying the last number with emphasis (ibid). The names are developed as sounds connected to the number of objects in the sets.

The developmental shift to understanding the number name as a cardinal value requires a qualitative shift in children's representation of numbers. The cardinal principle requires an understanding of the logic behind counting (Goswami, 2008) and the ability to judge the size of a set. It relies on a representation of quantitative information in which the coding of smaller quantities is different from the coding of larger quantities (ibid). Children are born with the capacity to cognize magnitudes (Halberta et al., 2008) and distinct numerical difference in small number values, called subitization (Dehane 1997). This means that when comparing two different sets, children are for the most part capable of pointing out which set is biggest, depending on the size of the sets and the differences between them; but counting and telling the number in words seem to be harder, especially with bigger numbers.

Children's conceptual understanding of numeration depends on their being able to make a connection between a number name and its cardinal value, which they learn to do by grouping and quantifying sets of objects (Thomas et al., 2002). To group a set means to divide the set into smaller equal groups. Miura et al. (1993) showed how American, French and Swedish children used units instead of ten sticks representing two-digit numbers, and we know from our own experiences that Danish children do the same; it seems that certain languages facilitate grouping in tens whereas others do not.

The combination of words for a number, its cardinal value and the digit sign

Learning how to connect the number word, its cardinal value and the digit sign is another challenge. As discussed, two different systems must be combined with different representations. Becoming an expert at combining these two systems means developing rapid access to an automatic use of written numbers and at the same time being able to multitask to solve other problems in parallel. If the two systems are iconic and support each other, the difficulties the child encounters in learning this skill will be minimized, as is the case for Japanese-speaking children. If the two systems are irregular and therefore conflict with each other, the child will have

greater problems understanding and remembering the connection between the name, the cardinal value and the sign. Duval (2006) describes this situation as a conversion between registers, and observes that the conversions that seem to be easiest for students are the ones that are congruent, meaning that the representation in the starting register is transparent to the target register.

From preliminary observations of Danish first graders, we have seen that if the task is to say the name of a written number, say 63, children often repeat the ten, twenty, thirty-rhyme and use their fingers. The children stop when they get to their sixth finger and then they know the word. This may be seen as a kind of interfering process, which in cognitive terms means that two parallel processes are in conflict with each other. The semantic treatment demands too much attention, and therefore it is not possible to multitask and complete both processes at the same time (Baddeley, 2009). This interfering effect means that learning to combine spoken and written numbers takes Danish children much longer time to automate. The logic in the base-10 disappears in the Danish language, and therefore the combination of the names and the written digits has more or less to be learned by rote.

CONCLUSION

In this article we have theoretically investigated our hypothesis that Danish number names are more complicated than those of other languages, and therefore, that Danish children have more difficulties learning and working with numbers. We have shown through comparison of number names in different languages, combined with semiotic and cognitive arguments, how the differences in naming numbers may give rise to linguistically determined differences in how children learn number concepts as well as in the cognitive load of arithmetic processes.

We have argued that the Danish number names create comparatively great cognitive load in relation to number comparison, counting and basic arithmetic. Furthermore we have shown how number concepts are influenced by the names of numbers, and that number concepts are especially simple when the iconicity in the written base-10 numbers is also present in the words used to signify numbers. In Danish there are two main reasons that this iconicity is not present in the number names: (1) the order of digits is reversed in the numbers between 11-99, and (2) the names of the number decades do not correspond to the number of tens they represent.

We conclude from this first stage of our investigation that comparatively, Danish children find learning numbers difficult, due to the system of naming numbers in Danish. Our next step is to make empirical approaches where we intend to set up a comparative investigation of numeracy performance, comparing numbers written with digits and with words, a design research project about "School numbers" and finally investigate language reforms, with an example from the Norwegian numbers.

STRATEGIES AND PROCEDURES: WHAT RELATIONSHIP WITH THE DEVELOPMENT OF NUMBER SENSE OF STUDENTS?

Elvira Ferreira¹ and Lurdes Serrazina²

¹Higher School of Education of Torres Novas

²School of Education, Instituto Politécnico de Lisboa

This paper analyses the procedures and strategies used by Daniel, a second grader student, when solving a set of problems, using addition and subtraction of positive whole numbers, under a classroom teaching experiment. This is a qualitative and interpretative case study, with data collection through participant observation, interviews and documents, namely, reports of classroom episodes, tasks and student's involvement in classroom activities. The results suggest that Daniel's preference for certain mathematical procedures and strategies depended on the context of the problems, namely the types of situations and the size and the structure of numbers involved.

Keywords: procedures, strategies, number sense, addition and subtraction.

INTRODUCTION

During the last decade, the goals and content of elementary mathematics education have changed internationally (Kilpatrick, Swafford, & Findell, 2001; Verschaffel, Greer, & De Corte, 2007). The development of number sense is now an essential aspect of learning mathematics in the first school years, enabling students to solve problems involving addition and subtraction with positive whole numbers (McIntosh, Reys, & Reys, 1992). In the 21st century, “helping children develop number sense is being considered on a global scale as a key task in mathematics education” (Yang, Li, & Lin, 2008, p. 805).

This paper reports part of a study which main aim is to describe and analyse how students develop their number sense in a problem solving context using addition and subtraction of positive whole numbers, considering problems of real world addition and subtraction situations (Fuson, 1992). In particular, understanding the strategies and procedures they use in solving subtraction problems under a classroom teaching experiment. In this paper will be analysed the strategies and procedures used by Daniel, when compared with those described in the literature in the field.

THEORETICAL FRAMEWORK

What is number sense? This is a question which the answer is not easy to obtain. Greeno (1991) states that “number sense is a term that requires theoretical analysis rather than a definition” (p. 170) and he suggests that “it may be more fruitful to view number sense as a by-product of other learning than as a goal of direct instruction” (p. 173). Dolk (2009) considers that developing number sense in the

class setting “implies giving students the opportunity to think with numbers and operations, guiding them in the way they look at numbers, and helping them to construct an active network of number relationships” (p. 5). Developing number relations also implies that students see numbers as mathematical objects.

McIntosh et al. (1992) define number sense as “a person’s understanding of number and operations along with the ability and inclination to use this understanding in flexible ways to make mathematical judgements and develop useful strategies for handling numbers and operations. It reflects an inclination to use numbers and quantitative methods as a mean of communicating, processing and interpreting information” (p. 3). They propose three strands to number sense: (i) knowledge of and facility with numbers, (ii) knowledge of and facility with operations and (iii) applying knowledge of and facility with numbers and operations to computational settings. This definition encompasses the behaviour defined by other authors as strategy use, and on the belief that promote strategy flexibility is important for all children, including younger and mathematically weaker children (Kilpatrick et al., 2001; Verschaffel et al., 2007; Verschaffel, Greer & Torbeyns, 2006).

Thus, strategies are seen as embedded within number sense. Strategies for solving particular types of problems are often presented as procedures that are followed in response to the stimulus problem. For Beishuizen (1997) strategy is the “choice out of options related to problem structure” and procedure is “the execution of computational steps related to the numbers in the problem” (p. 127).

The discrepancy between formal and informal computation procedures is currently seen as an impediment to the initial learning and understanding of mathematics (Blöte, Klein, & Beishuizen, 2000) as well as a hindrance in the development of number sense and the use of flexible number operations at the end of primary school (McIntosh et al., 1992; Treffers, 1991). The study developed by Yang (2003) demonstrates that students’ number sense can be effectively developed “through establishing a classroom environment that encourages communication, exploration, discussion, thinking and reasoning” (p. 132).

Many of the studies of children’s strategies and procedures consider mental computation methods very important in solving addition and subtraction problems (Beishuizen, 1993; 1997; Blöte et al., 2000; Buys, 2001; Klein et al., 1998; Torbeyns, Verschaffel, & Gesquière, 2006; Verschaffel et al., 2007). Such problems can be solved by three types of procedures: one type is the split method (1010); the second is the jump method (N10) and the third type is called *varying, compensation* or *short jump*. In the 1010 procedure numbers are decomposed in tens and ones which are processed separately and then put back together. The 10s (1010 stepwise) is a 1010 procedure that conceptually can be located between the 1010 and the N10 procedure. The N10 computation procedure (also the variant of N10C) starts with counting by tens up or down from the first, unsplit number. The A10 (adding-on)

procedure also starts from the first, unsplit number and goes from there to the next ten. The *varying*, *compensation* or *short jump* refers to bridging the difference in subtraction problems, like “71 - 69” in one or two steps instead of subtraction the second number from the first one (Blöte et al., 2000, p. 222) or $86 - 25 = 85 - 25 + 1 = 60 + 1 = 61$ (Torbeyns et al., 2009, p. 80).

All these three procedures belong to “direct subtraction or indirect addition strategies” (Torbeyns et al., 2009, p. 80), when solving subtraction problems. Solving a subtraction problem by indirect addition means “that the problem is solved by adding on from the subtrahend” (Van den Heuvel-Panhuizen & Treffers, 2009, p. 108) and “direct subtraction means that the subtrahend is subtracted from the minuend (e.g., $71 - 29 = ?$)” (Torbeyns et al., 2009, p. 80).

Apart from the nature of the numbers, Van den Heuvel-Panhuizen & Treffers, (2009) consider that there is more reason to calculate subtraction as an addition and so make use of the complement principle. It is important to consider subtraction as *taking away* (direct subtraction) and as determining the difference (indirect addition). The same authors say that “in the subtraction problems the context opened up the indirect addition strategy” (p.109)

The relationship between subtraction and addition is a big idea that children need to develop. Eventually, it is important that children know either strategy can be used. “Children need to understand the connection between addition and subtraction. Furthermore, they need to understand that comparison and removal contexts can both involve subtraction” (Fosnot & Dolk, 2001, p. 90). Traditionally teachers have often told learners that subtraction means “take away”. This is a superficial, trivialized notion of subtraction, if not erroneous (Fosnot & Dolk, 2001).

When students exhibit number sense, they apply efficient mental strategies and they are able to manipulate numbers mentally (Heirdsfield & Cooper, 2004). Some research (Blöte et al., 2000; Kamii & Dominick, 1998) has contended that mental computation promotes number sense if students are encouraged to formulate their own mental computation strategies.

METHODOLOGY

The aim of the research is to understand how students develop their number sense in a problem solving context using addition and subtraction of positive whole numbers. In particular, to understand the strategies and procedures children use in solving addition and subtraction problems under a classroom teaching experiment. The aim of this classroom teaching experiment is to promote the development of the number sense in solving addition and subtraction problems involving different situations and different numbers. In this case, a sequence of instructional tasks was elaborated with the main goal of promoting children’s mathematics development

Working Group 2

In the selection of tasks, we focused on four aspects: (i) context problems; (ii) selection of problems with “good” numbers to promote the use of different strategies and procedures to facilitate the discussion and permit students to ask questions. Numbers that allow multiple combinations, whose structures go further beyond the level of calculation by counting; (iii) sequence of the problems; (iv) adaptation/modification of this sequence after the analysis of each observation. In addition instructional tasks, we also considered the classroom culture and proactive role of the teacher. In the classroom culture we accounted the nature of classroom norms, social and socio-mathematical norms (Yackel & Cobb 1996)

The object of this study is a group of four children in elementary school integrated in a second grade classroom. The data collection was done during the school year 2007/2008, with observations of nine classes, where the students resolved two problems, one of addition and other of subtraction. Data collection included (i) participant observation, with reports from several lessons, one or two each month, during the school year, concentrating on the way children solve addition and subtraction problems with different structures (the sequence of instructional tasks mentioned above). All the lessons mentioned were videotaped; (ii) interviews, conducted by the first author, with the four children three months after finishing the classroom teaching experiment, which were audiotaped and transcribed; (iii) written documents, namely, reports of classroom episodes, tasks and students’ involvement in classroom activities.

The principal source of data is participant observation with writing of researcher reports and collection of documents (Yin, 1989; Patton, 2002), by the first author of this paper, completed by the transcripts of video-taped classrooms. Each observation lasted at least two hours, and included observing children solving problems and listening to their explanations (Bogdan & Biklen, 1994; Erickson, 1986; Guba & Lincoln, 1994). According to the research plan, data analysis began simultaneously with data collection, in order to identify students’ strategies and procedures and how they were developing them. The videotaped of classroom lessons were an important source of data. The lessons were analysed according to the sequence of problems presented by the teacher, and for each one the strategies and procedures used and discussed by the students.

In this paper, we describe Daniel’s strategies and procedures for four subtraction problems during classroom teaching experiment.

RESULTS

During classroom teaching experiment Daniel solved several real world subtraction problems (*take away, complete, compare difference unknown* and *compare referent unknown*). In this section we present the resolutions of one subtraction problem *compare difference unknown* and three subtraction problems *compare referent unknown*.

Problem one (*compare referent unknown*). Stamps problem (figure 1)

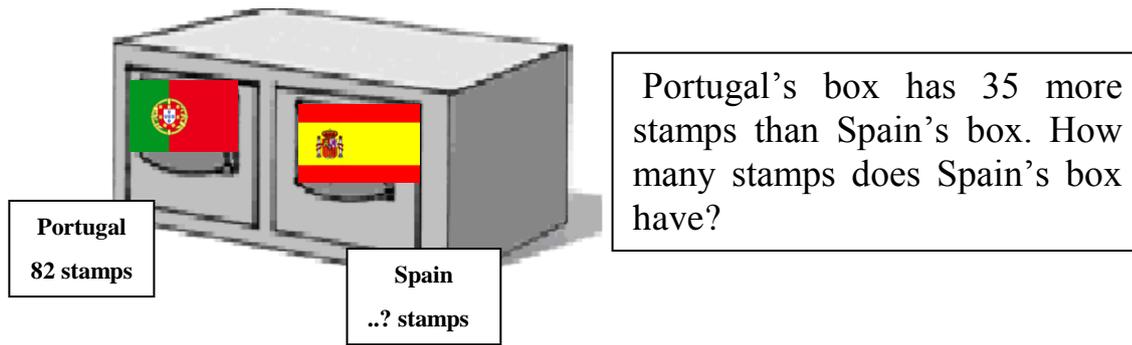

Figure 1: Stamps problem

This was the first problem *compare referent unknown* during classroom teaching experiment (3.rd observation). Daniel uses a direct subtraction strategy and he uses a mixed computation procedure, N10/A10. He starts from the first unsplit number and after he takes away 32 (figure 2)

Figure 2: The way Daniel solved problem two

First, he takes away 30 and he gets 52. Then $52 - 2$ (from decomposition 5 into 2 + 3), and, finally, he takes away 3 and he gets 47, the answer of the problem.

Problem two (*compare difference unknown*). In the cinema, Room 1 has 215 seats. Room 2 has 98 seats. How many more seats does Room 1 have compared to Room 2? (4.th observation).

Daniel uses a direct subtraction strategy and he uses A10 computation procedure. He starts from the first unsplit number and then he takes away 98 (figure 3):

Figure 3: The way

Daniel solved problem

one

Working Group 2

When he explains how he carried out the computations, he says:

Daniel: I did $215 - 15$ (from 98 decomposed into $15 + 80 + 3$) and I got 200. After, 200 minus 80 is 120. As I had taken away 95, there was still 3 missing so $120 - 3$ is 117.

Problem three (*compare referent unknown*). 303 students from Eleanor's school went to the cinema. These are 45 more students than from John's school. How many students from John's school went to the cinema? (8.th observation)

Daniel uses an indirect addition strategy and he uses a mixed computation procedure, N10/A10. He starts from the first unsplit number and after he adds 245 and he gets 290. He says "I already knew in my head that $45 + 45$ is 90" (a basic fact that he had already automated), and plus 200 is 290. After he adds ten and gets 300, a benchmark number (A10). Finally, he adds 3 and reaches 303 (figure 4).

The image shows handwritten mathematical work for Problem 3. At the top left, the number 158 is written. Below it, there are several lines of calculations: $45 + 245 = 290$, $290 + 10 = 300$, and $300 + 3 = 303$. A bracket connects the 158 to the 45 in the first equation. The final result 303 is written at the bottom right.

Figure 4: The way Daniel solved problem three

Problem four (*compare referent unknown*). For lunch, Peter ate a Big Mac which has 490 calories and Antonio ate a piece of salmon fish. The Big Mac has 295 more calories than the fish. How many calories does the fish that Antonio ate have? (9.th observation).

This is the last problem with this context during classroom teaching experiment. It is very interesting because first Daniel uses indirect addition strategy and a mixed computation procedure, N10/A10 and after he uses direct subtraction strategy and the same computation procedure (figure 5), that is, Daniel says that he can use both strategies for solving subtraction problem.

The image shows handwritten mathematical work for Problem 4. At the top left, there is a small drawing of a Big Mac with a label '295 cal.'. Below it, there are several lines of calculations: $490 - 90 = 400$, $400 - 200 = 200$, $200 - 5 = 195$, $295 + 100 = 395$, $395 + 5 = 400$, and $400 + 90 = 490$. A bracket connects the 295 to the 295 in the first equation. The final result 195 is written at the top right. At the bottom, there is a handwritten response: 'R: 195 cal. Antonio tem 195 cal.'

Figure 5: The way Daniel solved problem four

DISCUSSION

The results presented above show that Daniel is able to justify his computations using appropriate strategies and procedures. It seems that this is related to his mental computation ability, that is, to his flexibility with numbers and their manipulation. This seems to be related with the understanding of the meaning of numbers and operations, how he uses the reference numbers and how he recognises the reasonableness of the results. This understanding also enabled Daniel invent their own procedures. These findings are consistent with other studies (Heirsfield & Cooper, 2004; Blöte et al., 2000)

The findings of this study also indicate that Daniel used most frequently N10 e A10 procedures and this may be related to the way subtraction problems are solved. Another finding of this study indicates that there is a connection between the use of indirect addition and the context of the subtraction problems they have to solve. This seems to happen in problems of *complete*, *compare difference unknown* and *compare referent unknown*, as the context of these problems help Daniel, to understand the relationship between addition and subtraction and to use addition operation. The use of additive strategy also helped Daniel to use more efficient procedures, inventing his own procedures. Also there seems to be a relationship between the chosen strategy and effectiveness of procedures that Daniel was able to use.

Those findings also present empirical evidence, that the development of strategies and procedures on solving multi-digit addition and subtraction problems were influenced by social and socio-mathematical settings that Daniel were involved in a classroom environment that encourages communication, exploration, discussion, thinking and reasoning. These findings are consistent with other studies, namely, Kilpatrick et al. (2001), Verschaffel, et al. (2007) and Yang (2003).

PRESCHOOL CHILDREN'S UNDERSTANDING OF EQUALITY: OPTING FOR A NARROW OR A BROAD INTERPRETATION?

Anatoli Kouropatov

Dina Tirosh

Tel Aviv University

Mathematical concepts and symbols are often introduced at first in a narrow meaning. The harmful consequences of such initial presentation are widely reported in mathematics education. The present paper asks the following question: Is it essential to introduce the equal sign in a narrow meaning as an operation and not in its broader meaning as a relation? We found that preschool children are capable of addressing changes simultaneously made to two quantities (adding or subtracting the same or even a different number of elements to/from two groups of objects), a capability needed when handling relations. These findings call for looking more closely at the possibility of introducing the equal sign in its broader meaning, as a relation ("the same").

Keywords: preschool, quantities, models, equality, equivalence

EQUALITY AND SCHOOL MATHEMATICS

The meaning of a sign in mathematics is often determined by its context. This phenomenon is evident also in the mathematics studied in elementary and middle schools. For example, the minus sign has at least three uses: a negative number, a binary operator that indicates an operation of subtraction, and a unary operation, acting as a demand to replace the operand by its opposite.

The equal sign continues to attract considerable attention in elementary and middle school education (e.g., McNeil & Alibali, 2005; Vassiliki & Philippou, 2007; Mark-Zigdor & Tirosh, 2008; Molina & Ambrose, 2008; Molina, Castro & Castro, 2009). Consider the following expressions:

(a) $2 + 3 = 5$

(b) $2 + 3 = 4 + 1$

Various studies have reported that elementary school students tend to assign only the meaning of the expressions of type (a) to the equal sign, namely, "How many does it make together?" It has also been reported that children experience difficulty with expressions of type (b) (MacGregor & Stacey, 1999; Baroody & Benson, 2001; Keilpatrick, Swafford & Findell, 2001), which require calculating each side and verifying that the two sides are equal.

The equation of type (a) can be interpreted as a demand to perform an operation, whereas in type (b) the sign is interpreted as a relation between the two parts. The mathematical term "relation" is broader than the term "operation." Because operation is a special case of relation, viewing equality as a relation covers both situations. Nevertheless, instruction often starts with assigning a relatively narrow meaning to a

term, and the broader interpretations are introduced only later. For example, the term “number” is often introduced with reference to non-negative whole numbers, and only later to broader sets of numbers, such as rational, irrational, and real numbers.

Is it necessary to narrow the interpretation of the equal sign to that of an operation, or is it preferable to introduce the symbol in its broader meaning of a relation? This issue is of both theoretical and practical importance because the common pedagogic approach today is to initially introduce the equal sign only in the context of performing an arithmetic operation (Herscovics & Kieran, 1980; Saenz-Ludlow & Walgamuth, 1998; MacGregor & Stacey, 1999; Baroody & Benson, 2001; Keilpatrick, Swafford & Findell, 2001). Moreover, researchers have noted that the initial, narrow meaning assigned to the equal sign may have a long-lasting effect, and that children aged 5-12 tend to perceive the equal sign only as a request to calculate and not as a sign of relation (Herscovics & Kieran, 1980; Behr, Erlwanger & Nichols, 1980; Molina, Castro & Castro, 2009). The narrow interpretation of the equal sign dominates and often blocks other interpretations and references that are more general and are essential in various branches of mathematics (e.g., equations in algebra, identities in geometry and in trigonometry). There is some evidence that specific interventions can promote the interpretation of equality as a concept that expresses a relation among children aged 5-7 (McNeil & Alibali, 2005).

Two research questions arise naturally from the above description:

- 11 What is the understanding that children 3-5 years old have about equality before instruction? Specifically, do young children understand which manipulations can and cannot be performed on two quantities to maintain the equality relation?
- 12 What types of responses are evident when young children are presented with tasks that address the basic properties of an equivalence relation?

METHODOLOGY

Sample

Seventeen children from an upper-middle class neighbourhood in the central region of Israel participated in the study. The children were divided into two groups. Group 1 ("Older Children") included nine children aged 4-5, with an average age of 4 years and 8 months. Group 2 ("Younger Children") included eight children aged 3-4, with an average age of 3 years and 10 months. Ten boys and seven girls participated in the study.

Research tools

Interviews

We used task-based interviews (Goldin, 2000) as the primary research tool because they are well suited for the age of the participants. The interviews involved the

Working Group 2

interviewee, the interviewer, and the tasks. Interviews were pre-planned, but there was room for *ad hoc* changes initiated by the interviewer based on the interviewee's responses. This procedure allowed us to focus both on the correctness of the responses and on the thought processes involved (Steffe, Nesher, Cobb, Goldin & Greer, 1996). Each interview, conducted separately with each child by the authors of the paper, lasted about 50 minutes, in two sessions of approximately 25 minutes each. The duration matches the concentration span of most children of this age, although some children required additional sessions. The interviews took place in the children's preschool, in a separate room, in a calm and pleasant environment. All interviews were audio recorded and transcribed.

Tasks

Two sets of tasks were developed, each addressing one of the two research questions: manipulation of two quantities (research question 1) and properties of equality as an equivalence relation (research question 2). The majority of the tasks were developed based on the ideas of Morris (2003), with some necessary adaptations to the young age of the participants. Note that no written symbols were used in the design of the tasks and in the communication with the participants.

1. Manipulation of Two Quantities

We focused on two types of manipulations: reciprocal (manipulations that must be applied to both sides of the equation simultaneously), and non-reciprocal (manipulations that can be applied to one side of the equation).

Reciprocal manipulations

1a. *Equal Addition*. The researcher places two boxes on the table. In each box he inserts 5 marbles in a way that the child can see the marbles in the boxes. The child is asked to compare the quantities in the boxes. The researcher says, "Let's check what we have in our boxes. Do we have the same number of marbles, or does one of us have more?" After the child and the researcher agree that the quantities in the boxes are equal, the researcher takes the same number of marbles (3) into each hand from a pile of marbles. He shows the marbles to the child and inserts the marbles from one hand into one box and from the other hand into the other box. The researcher says, "I put these marbles in your box and these marbles in my box. What do you think? Do we have the same number of marbles in our boxes or does one of us have more?"

1b. *Different Addition*. The researcher places two boxes on the table. In each box he inserts 5 marbles in a way that the child can see the marbles in the boxes. The child is asked to compare the quantities in the boxes. The researcher says, "Let's check what we have in our boxes. Do we have the same number of marbles, or does one of us have more?" After the child and the researcher agree that the quantities in the boxes are equal, the researcher takes a different number of marbles from the pile of

Working Group 2

marbles in each hand (3 marbles in one hand and 2 marbles in the other). He shows the marbles to the child and inserts 3 marbles in the child's box and 2 marbles in his box. The researcher asks, "I put these marbles in your box and these marbles in my box. What do you think? Do we have the same number of marbles in our boxes or does one of us have more?"

1c. *Reverse of Different Addition*. Following the Different addition (1b) task, the researcher removes the amount of marbles that were added to each box, leaving equal quantities in each box. The child is asked to compare the quantities in the boxes. The researcher says: ", "Do we have the same number of marbles in our boxes, or does one of us have more?"

1d. *Equal Subtraction*. This task is identical to Equal addition (1a), but instead of adding marbles the researcher removes the same amount of marbles from the two boxes.

1e. *Different Subtraction*. This task is identical to Different addition (1b), but instead of adding a different number of marbles to the boxes the researcher removes a different number of marbles from the boxes (3 from the child's box, 2 from his box).

1f. *Reverse of Different Subtraction*. Following the Different subtraction (1e) task, the researcher returns the marbles that were removed and asks, "What is in the boxes now? Do we have the same number of marbles in our boxes, or does one of us have more?"

Non-reciprocal manipulations

1g. *Violation of Equality*. The researcher gives an equal number of marbles to the child and to himself and validates with the child that the amounts are equal. Additional marbles remain in a pile on the table. The researcher asks, "Can we do something so that we won't have the same number of marbles?"

1h. *Creation of Equality*. The researcher distributes a different number of marbles to the child and to himself (5 marbles to child, 3 to himself). Additional marbles remain in a pile on the table. The researcher asks, "What do you think, do we have the same number of marbles or does one of us have more? Is it possible to do something so that we will have the same the number of marbles? "

2. Properties of Equality as an Equivalence Relation

The equality relation is an equivalence relation. As such, it is reflexive, symmetrical, and transitive. Designing tasks to diagnose young children's comprehension of these properties (especially the reflexive property) is challenging. We developed the following three tasks to attempt to address these properties:

2a. *Reflexivity*. The researcher points to the marbles in his box and says, "I don't want these marbles in my box, but I don't want to have less or to have more. Please help me." The child is expected to substitute one or more marbles with the same

Working Group 2

amount of marbles, taken from the pile on the table. This task examines the substitution aspect of reflexivity. It appears that this aspect can be formulated in a meaningful way to young children. The task examines whether the child can ignore such factors as colour, shape, etc., and at the same time consider only the numerosity aspect and keep the same number of objects for both parties.

2b. *Symmetry*. The researcher places two boxes on the table and inserts 5 marbles in each box. He validates with the child that the boxes contain the same number of marbles and closes the boxes. The researcher then swaps the places of the boxes, without opening them. The researcher asks, "I showed this to two children: Guy and Shay. Shay said that the boxes still have the same number of marbles. Guy said that there are more marbles in one of the boxes. Who is right?"

2c. *Transitivity*. The researcher places two boxes on the table and inserts 4 marbles in each box. He validates with the child that the boxes contain the same amount of marbles, closes the boxes, takes one box, and gives the other box to the child. He then places a third box on the table and says, "Your box and my box contain the same number of marbles. Let's prepare a box for Sigal (a preschool teacher) with the same number of marbles that is in your box. What do you think, will Sigal and I have the same number of marbles or will one of us have more?"

The order of the presentation of the tasks was carefully planned to avoid creating a fixed pattern of responses that would accidentally lead to correct answers. For example, after several tasks for which the correct answers were "equal amounts," the child was presented with a task or a group of tasks for which the correct answer was "different amounts," and *vice versa*.

MAJOR FINDINGS

1. Manipulation of Two Quantities

Reciprocal Manipulations of Two Quantities

In two of the six tasks grouped under this category (Equal Addition (1a) and Equal Subtraction (1d)) the same changes (addition/subtraction) were carried out simultaneously on two equal quantities. Eight Older Children and 5 Younger Children solved the addition task correctly, and 9 Older Children and 7 Younger Children solved the subtraction task correctly. The explanations of all of the older children were based on the idea that "when you add the same thing to the same thing you get the same thing."

At first, 3 of the 5 Younger Children who provided correct responses to the Equal Addition (1a) task were mistaken in their judgement, but after reducing the initial amounts of marbles in both groups from 5 to 3, two more Younger Children provided correct answers and used the concept "when you add the same thing to the same thing you get the same thing" in their explanations. It is likely that the reduction of

quantities enabled the children to recognize the quantities. This behaviour may be related to subitizing (Dehaene, 1997).

In the Different Addition (1b) and Different Subtraction (1e) tasks, different numbers of marbles are added or subtracted simultaneously to/from equal quantities. Eight Older Children solved the Different Addition (1b) and 7 the Different Subtraction (1e) task correctly. The Younger Children, however, encountered difficulties especially with the Different Subtraction (1e) task: 6 solved the Different Addition (1b) and 2 the Different subtraction (1e) task correctly. Those who solved these tasks correctly used the concept: "If we add more to one side, this side gets more." Analysis of the interviews shows that 3 Younger Children mistakenly argued that "you took away more from me so now I have more." It is possible that for these children addition is a dominant prototype of an operation, and therefore the term "more," whether adding or taking away more, is conceived as resulting in a higher number.

In the four tasks discussed above, single changes were made on each of the quantities. The success rate of the children on these tasks was relatively high. But this was not the case for the Reverse of Different Addition (1c) and for the Reverse of Different Subtraction (1f) tasks. Only 8 children (4 in each group) succeeded in the Reverse of Different Addition (1c) task, and 6 children (5 Older Children and 1 Younger Child) succeeded in the Reverse of Different Subtraction (1f) task. The most common, incorrect response was: "If we add more to one side, this side gets more," referring only to the latter change. A possible explanation of the difficulties that children faced with these tasks is related to the sequence of actions being carried out. The children were asked to follow two-stage manipulations on both sides and/or to understand that the process of adding/subtracting the same amount to a set does not change its numerosity ($A=B, C<D \Rightarrow A \cup C < B \cup D \Rightarrow (A \cup C) \setminus C = (B \cup D) \setminus D$). It is likely that such tasks require a relatively advanced computational capacity, an ability to perceive quantities as partial sets and as wholes, and a capability to memorize the different steps that were carried out. Our findings suggest that children at this age have not yet developed these abilities, and consequently, in most cases they consider only one of the changes (the last one).

Non-reciprocal Manipulations of Two Quantities

Violation and Creation of Equality (1g/1h) are two facets of the same task. Nine of the older children and 7 of the younger ones succeeded in these tasks. The most common method used by the children to solve this task was to add marbles from the pile either to themselves or to the researcher. All but three children used the pile of marbles to create or violate the equality. Three children from the older group used another method: they transferred marbles from the researcher's box to their own or *vice versa*. Except for these three older children, the participants insisted on using the pile of marbles to create or violate the equality, and objected to attempts to form

or violate the equality without extra marbles. This resistance may be related to young children's tendency to conceive the quantities in each box as a “whole” from which parts are not to be taken away (e.g., Piaget & Szemirska, 1952).

2. Properties of Equality as an Equivalence Relation

Two of the three tasks included in this category were Symmetry and Transitivity. The Symmetry task was correctly solved by 8 Older Children and 6 Younger Children, and the Transitivity task by 8 Older Children and 5 Younger Children. The participants who succeeded in solving the Transitivity task used a strategy that may be represented schematically as follows: $A = 4$, $B = 4$, $C = 4$ and therefore $C = A$ (“The same number in all the boxes”), and not the classic transitive strategy of $A = B$, $B = C \Rightarrow A = C$.

To examine reflexivity we chose a “substitution” activity (the number of elements does not change if one or more elements are substituted by the same number of elements). Such a substitution may be considered reflexive. The distribution of responses to this task (3 Older Children and none of the younger ones solved the task correctly) and the nature of the accompanying explanations suggest that the majority of the children failed to understand the task. Common responses were: “If you don’t want these marbles, you can add others,” “Take more,” and “You can throw them away.” The children’s difficulty may have been the result of the phrasing of the task, but it seems that an inherent difficulty with reflexivity is the need to relate to equality within only one set. In their concrete world, the children find it challenging to relate to equality without the presence of at least two objects (how can one perceive that something is equal to itself if there is only one “thing” there).

This complexity manifests later in the difficulties that students often experience when asked to relate to equalities such as $5=5$ and $x=x$ (e.g., Herscovics & Kieran, 1980; Saenz-Ludlow & Walgamuth, 1998; Morris, 2003). It appears, however, that in the case of equality, the construction of meaning of symmetry, transitivity, and even reflexivity do not seem to indicate an inherent, epistemological obstacle.

DISCUSSION

The present study addressed two mathematical concepts that are unequivocally defined: equality and operation. Equality is defined as a relation (equivalence) and as an operation (in the context of this paper, a binary relation applied to a pair of natural numbers). Formally, the concept “operation” is a special case of the concept “relation.”

The formal terms can be translated into common language familiar to children using two well-known models. In the context of equality, the term “relation” may be interpreted as: “What can be said about two quantities (more than, less than, equal to, the same)?” (Model 1). The term “operation” may be introduced by asking: “How many are there together?” (Model 2). The study focused primarily on examining

young children's knowledge of Model 1. Two major considerations for focusing on Model 1 were that (a) Model 1 is more general (Model 2 is a special case of Model 1), and (b) in reports of difficulties that students encounter when facing situations in which Model 1 must be applied, the barriers are often attributed to the primacy effect of introducing Model 2 first and using it excessively in elementary schools, while almost neglecting the use of Model 1 (e.g., Fischbein, Deri, Nello & Marino, 1985).

In the present study we attempted to examine preschool children's capability to address various manipulations of two quantities ("two sides of the equal sign") and the properties of equivalence relation. Knowledge of young children's conceptions can assist educators in decisions about introducing Model 1 at an earlier age, possibly as the model to be presented first to young children. As noted above, many mathematical symbols and concepts carry several meanings, both narrow and broad. Often, a narrow interpretation of a concept is introduced first, assuming that it is easier to grasp (for example, multiplication is introduced only as "number of times"). Such narrow presentation often results in conceptual blockages that are widely reported in the research literature (e.g., Fischbein, 1993). A related question is: What information is needed to determine whether a concept should be presented in a narrow or in a broad meaning? In the present context, the question is: Are preschool children ready for the introduction of the concept of equality (and the equal sign) as an equivalence relation?

The findings of the current study suggest that preschool children are able to correctly solve tasks involving reciprocal and non-reciprocal manipulations of two quantities, and some tasks that draw upon the properties of equality as an equivalence relation. It seems that young children are capable of addressing some changes that are made simultaneously on two quantities (adding or subtracting the same or even a different number of elements to two groups of objects). This capability is necessary for handling relations. Our findings call for a closer examination of the effectiveness of introducing the concept of equality and the equal sign in its broader form, as a relation ("the same"). The findings of our study suggest that in the case of equality, many of the substantial properties of this concept are acquired at a very early age without any intentional intervention.

To summarize, the present study suggests that young children are capable of performing tasks involving comparison of quantities. The findings support the implementation of instructional sequences that attempt to present equality and the equal sign, from the earliest stages of instruction, in its broadest sense, as a relation and not only as an operator. In other words, the study calls for a re-examination of the common practice of introducing equality and the equal sign only as an operation ("How many are there together") and not as a relation ("What can be said about two quantities"). More research, on a larger sample of children, is needed to validate these findings. Additionally, some of the tasks that are included in the interview protocol should be modified (especially those that attempted to address reflexivity),

to critically examine the findings reported in this study and the feasibility of the approach that we propose.

USING THE DOUBLE NUMBER LINE TO MODEL MULTIPLICATION

Dietmar Küchemann, Jeremy Hodgen and Margaret Brown

King's College London, UK

As part of the research of the ICCAMS project, we have been exploring Year 8 students' (age 12–13 years) understanding of multiplicative structures and developing materials to enhance this understanding. In this paper we discuss some of our work related to the double number line and its use as a model for multiplication.

Keywords: models, multiplication, double number line

INTRODUCTION

Vergnaud (2009) argues that a concept's meaning arises from a variety of situations and puts forward the notion of a conceptual field, as a way of binding situations and concepts together. In the case of multiplicative structures, this conceptual field is extremely complex, as can be seen, for example, from the myriad of models put forward by the Rational Number Project (eg Behr et al, 1991), or from the intricate 'learning trajectories maps' woven by Confrey et al (2009). Anghileri and Johnson (1992) identify 6 key aspects of multiplication (and division), which they list as: equal grouping, allocation/rate, number line, array, scale factor, Cartesian product. They argue that "children will need to become familiar with the different situations that embody these aspects" (ibid, p170).

Davis (2010) describes how 'concept study' can be used to draw out and develop teachers' mathematical knowledge for teaching. He discusses how a group of teachers worked on the concept of multiplication. One of their activities was to produce a list of 'realisations of multiplication', which included these items:

grouping process; repeated addition; times-ing; expanding; scaling; repeated measures; making area; making arrays; proportional increase; splitting; skip counting; transformations; stretching/compressing a number line.

Of course, this list of realisations is in no sense definite and Davis makes the important point that the teachers' conceptions of multiplication (and how it might be engaged with in the classroom) was continually shifting over time. We would argue that the same will apply to school students, though depending on the extent to which they are allowed to engage with these ideas. In this regard, it is interesting to note the guidance on multiplication offered by the National Numeracy Strategy, which was set up by the UK government to offer advice on the teaching of mathematics. In the Strategy's Framework document for primary schools (DfEE, 1999), it is suggested that students as early as Year 2 (6–7 year olds) should understand multiplication in

terms of repeated addition and rectangular arrays. Similar advice is offered for Year 3 students, and it is suggested that the idea of scaling should also be introduced. Some advice on understanding multiplication is also given for older students, but this is subordinated to advice on performing calculations. Thus the use of models such as the array is not mentioned again in this document, nor in the Strategy's subsequent Framework document (DfEE, 2001) for early secondary school (Years 7, 8 and 9). One gets the impression that by the time students reach secondary school, multiplication is somehow meant to be 'understood' and no longer needs to be supported by models. So for example, it is stated that Year 7 students should understand that "multiplication is equivalent to and is more efficient than repeated addition" (ibid, Section 4, p82), but there is little indication of what 'multiplication' means here, ie in what situations it might be modeled or realised. Unfortunately, the paucity of models in the Framework documents is mirrored in most current secondary school mathematics textbooks in the UK.

Extensive work on the didactical use of models has been undertaken in Holland, from the perspective of RME (see eg Van den Heuvel-Panhuizen, 2002). This work makes an interesting distinction between 'models of' and 'models for', whereby the development of a more formal mathematical understanding is seen as a shift from the construction and use of the former to the latter.

THE DOUBLE NUMBER LINE

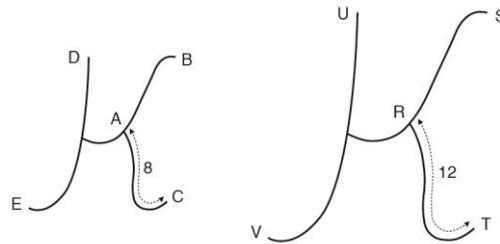

As part of the work of the ESRC-funded ICCAMS project¹ we have been exploring Year 8 students' (12–13 year olds) understanding of multiplicative structures, with the aim of developing teaching materials to enhance this understanding. From our work so far, including group interviews and short teaching sequences, but also the large-scale use of written tests, it is clear that many secondary school students have a very shaky understanding of multiplication, based in only a very limited way on models that could support and develop their understanding.

We think that one interesting and important *model for* multiplication is provided by the double number line, and it is this model that we focus on in this paper. The double number line also serves as a *model of* a variety of contexts that should be reasonably accessible to students (eg scales on a map; a one-way stretch; conversions, such as £ to €). An attraction of this model is that it offers a fairly gentle way of departing from an additive approach to multiplication. Repeated addition (perhaps modelled by skips along a number line) provides a salient and reliable (and quite efficient) model for the multiplication of (small) whole numbers (eg 3×7 can be thought of as 3 skips, each of 7 units, along the number line, starting at 0). However, even in situations that involve multiplication by simple rational numbers, eg $\times 1.5$, we have found that many students stick to an additive strategy (in this case, 'rated addition').

Working Group 2

Consider the item in Fig 1 (below), taken from the CSMS Ratio test (Hart, 1981). This was answered correctly by 14 % of a representative sample (N=309) of Year 8 students in 1976, and by a similar proportion (12%) of a representative sample (N=754) of Year 8 students in 2008. When we have interviewed students on this item, we have found that many students use an inappropriate ‘addition strategy’ (Karplus & Peterson, 1970) arguing along the lines of ‘ $8+4 = 12$, so $RS = 9+4 = 13$ ’. Those who do solve the task successfully tend to use an argument of this sort: ‘ $8 + \text{half of } 8 = 12$, so $RS = 9 + \text{half of } 9 = 9 + 4.5 = 13.5$ ’. Students tend not to go for the more direct approach of scaling by $\times 1.5$, along the lines of ‘ $12 = 8 \times 1.5$, so $RS = 9 \times 1.5 = 13.5$ ’. It is worth pointing out that this scaling approach is actually more *appropriate* here, since rated addition does not fit the geometric situation: one can’t really add a curved line of length 8 units to a smaller version of the line of length 4 units, and thereby make a larger version of the line of length 12 units! It is perhaps for this reason that the task is so difficult.

These 2 letters are the same shape. One is larger than the other.
AC is 8 units. RT is 12 units.

The curve AB is 9 units. How long is the curve RS ?

Fig 1: Curly Ks item (Hart, 1981)

Thus, in a study using items derived from Hart (1981) but with the numbers more closely matched, Küchemann (1989) found that while a Ks item was answered correctly by only 25% of students (N=153), a recipe item, where rated addition makes perfect sense, was answered correctly by 64% of students from a comparable sample (N=154).

The double number line provides a neat way of representing (or indeed embodying) multiplicative relations, such as $\times 1.5$. Consider the pair of lines A and B in Fig 2a, where 0 and 8 on line A are lined-up with 0 and 12 on line B.

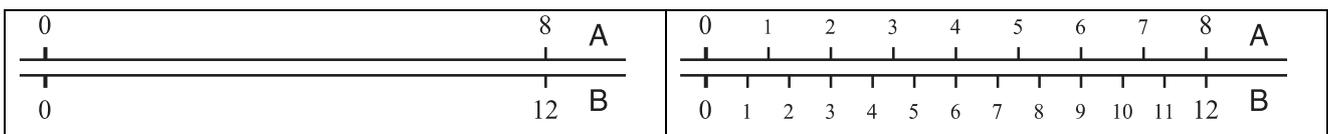

Fig 2a

Fig 2b

We know that 12 is 8×1.5 , and we can thus make the number lines represent the mapping $\times 1.5$ (or $x \rightarrow 1.5x$, or $y = 1.5x$, etc.) by drawing linear scales on each line (Fig 2b): any number on line A is now mapped onto a number positioned directly below it on line B that is 1.5 times its value. The great strength of this representation is that it is not just mapping 8 onto 12, but showing the mapping $\times 1.5$ regardless of any particular pair of numbers that we may be considering. Thus the operation $\times 1.5$ is brought to the fore. Of course, this may not be perceived in this way by all students. The diagram can, for example, be read as showing a move along a number line from 0 to 12, in 8 skips of 1.5 units (with line A representing the number of

Working Group 2

skips and line B the distance skipped); in other words the diagram can also be interpreted as showing repeated addition.

Scales on a map are well known examples of double number lines. One kind shows distances on the map (measured in cm, say) and corresponding distances on the object depicted by the map (measured in km, say). The ruler in Fig 3a is of this sort. Another kind shows how distances represented on a map can be read in different units (eg feet and metres). Fig 3b shows a scale of this sort used by Google Maps.

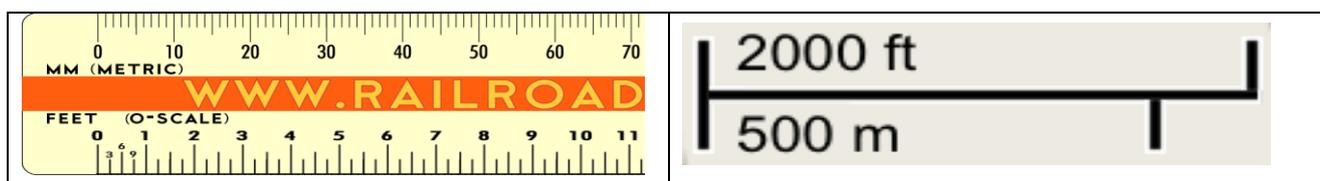

Fig 3a: A ruler for scaling feet to mm

Fig 3b: A scale used by Google Maps

A double number line can also be used to represent an enlargement, or more specifically, a one-way-stretch. An example is shown in Fig 4b, which shows the result of stretching scale A in Fig 4a by a factor $\times 1.5$. (Note the similarity to Fig 2b.)

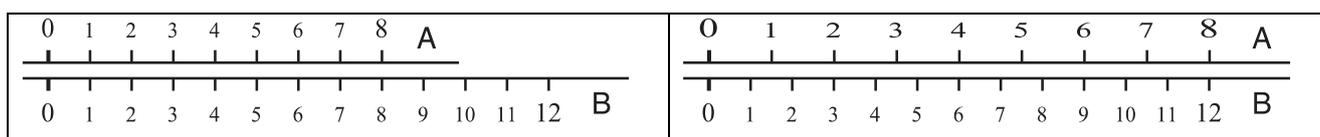

Fig 4a: Two identical scales, A and B

Fig 4b: A $\times 1.5$ stretch applied to scale A

RELATED WORK

Our approach to the didactical use of models is perhaps similar to the Dutch approach, as embodied by RME, though we would not be as strict about not handing ready-made models to students. Van den Heuvel-Panhuizen (2002), in describing RME, gives a nice illustration (ibid, Fig 11, p12) of how the number line can be used to support students' learning. She adds that

The number line begins in first grade as (A) a beaded necklace on which the students can practice (sic) all kind of counting activities. In higher grades, this chain of beads successively becomes (B) an empty number line for supporting additions and subtractions, (C) a double number line for supporting problems on ratios, and finally (D) a fraction/percentage bar for supporting working with fractions and percentages. (p12)

The fraction/percentage bar and, to a lesser extent, the double number line, feature strongly in materials developed by RME, as can be seen in the *TAL-project* materials in the Netherlands (eg, Van Galen et al, 2008) and in the *Mathematics in Context* materials in the USA (eg, Keijzer et al, 2006). The use of the double number line is not yet widespread in the UK, although the 'fraction wall', which has similarities to the fraction bar, has been around for a long time (eg, Watt et al, 1967, p103). However, since the introduction of the National Numeracy Strategy (DfEE, 1999) the

single number line has been used extensively in UK primary schools, which may partly explain the dramatic rise in facility of the CSMS Decimals item (Brown, 1981) shown in Fig 5. When we gave this to a representative sample ($N=294$) of Year 8 students in English schools in 1977, it had a facility of 37%, but with a similar sample ($N=767$) in 2008/2009 this had risen to 78%².

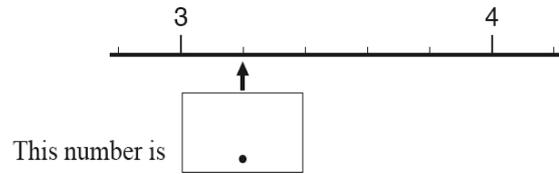

Fig 5: CSMS Decimals item 6e

TASKS AND FINDINGS

Our data on Year 8 students’ use of the double number line are still exploratory. However, we have sufficient data to give a sense of some of the affordances of the double number line and of some of the difficulties that students encounter. Put another way, our current data suggest that the development of classroom activities involving the double number line is worth pursuing for us, but that learning to construct and use the model may be far from trivial for students. We report informal data from three sets of tasks involving students from two classes. The first task asks students to use a double number line to represent equivalent fractions or to evaluate a percentage. The second task involves a one-way-stretch, while the third asks students to convert information on a map from metres to feet.

Fractions and percentage tasks

The task in Fig 6a gives some indication of whether students can, in certain circumstances, appreciate the *need* for a linear scale (although it clearly tests much more than this). The task in Fig 6b can be solved in a variety of ways. One approach is to see the double number line as representing a mapping, whose value (leaving aside the units, or in this case the %) is given by $\times 100 \div 40$, ie $\times 2.5$. We gave these tasks to an above-average attaining Year 8 class as a homework. The tasks were given cold, i.e. without any kind of introductory work.

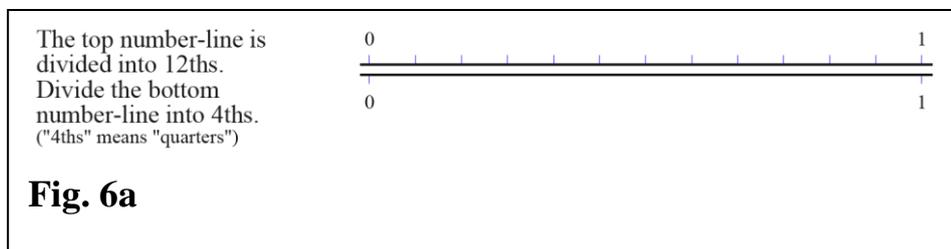

Fig. 6a

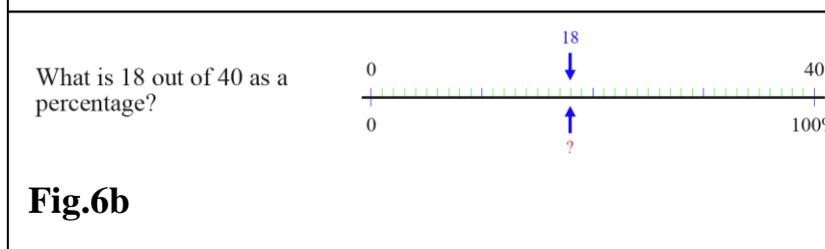

Fig.6b

For the task in Fig 6a, most students made effective use of the given scale (of 12ths) to mark off the required 4ths (as in Fig 7a). Some partitioned the line into 4 parts but seemed to ignore the given scale (Fig 7b), while a few

Working Group 2

come up with the correct value of 9cm, though there might of course have been others. Two had used rated addition ('The stretched strip is half as long again; $6\text{cm} + \text{half of } 6\text{cm} = 9\text{cm}$ ') while one student had used an argument based on the idea that if the strip was 10cm long the red mark would be 3cm from the end (this is quite a sophisticated argument since it would not be possible to enact this in practice).

Fig 10 shows a drawing that arose during an interview with 4 students (A, B, C and Z) from the previously mentioned above-average Year 8 class. The drawing of the 20cm strip and the 30cm stretched version was done by the interviewer. The vertical marks labelled A, Z, B, C, on the 30cm strip were drawn by the students. We started by considering the image of a line 5cm from the left hand end of the 20cm strip after the strip had been stretched to 30cm. Reading from the left, the first set of vertical lines (labelled A, Z, B and C) on the 30cm strip were students' estimates of the position of the image of the 5cm line. [The second set of lines labelled C, B, Z and A

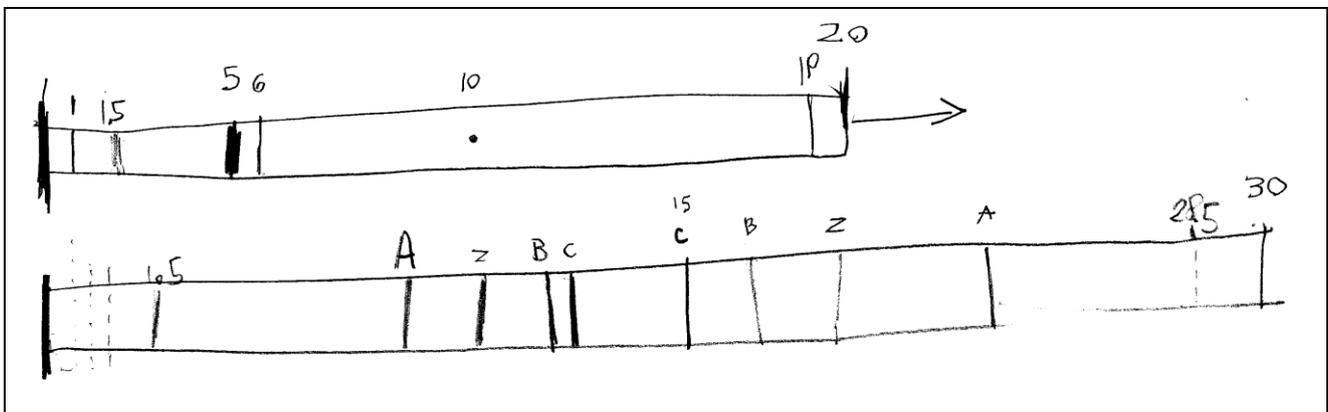

Fig 10: Interview responses to the elastic strip task

were their initial estimates for the image of the central dot drawn 10cm along the 20cm strip.] Student C justified his mark in terms of the addition strategy (ie the right hand end of the strip had moved 10cm, so the 5cm mark would move 10cm). Other students thought it would move a bit less than this (and hence drew their images to the left of C's image). However, initially their estimates were purely qualitative, though eventually, after considering the image of the midpoint, they adopted a successful rated-addition approach (the 5cm mark moves half this distance, ie 2.5cm, so it ends up 7.5cm from the left hand end).

A map task: Westgate Close

Our third task was based on a map of a short private road, Westgate Close. One version of the task is shown in Fig 11. As with the elastic strip task, we used this as a starter with some Year 8 classes. We would argue that it is more obvious in this task, than with the elastic strip, that the scales are linear (it would be very odd if for part of the road, a given number of feet matched a certain number of metres but that somewhere else on the road the same given number of feet matched a quite different number of metres!). Nonetheless, the addition strategy was still common here, with students calculating that the distance of El's house along Westgate Close was 107 ft

Working Group 2

from Roman Road ($50-15=35$, $35+72=107$, or $72-15=57$, $50+57=107$). However, the task also provoked an interesting variety of correct, or partially correct strategies. For example, several students in a low attaining Year 8 class, estimated the distance by marking-off 50 ft lengths.

Often this lead to quite good

Here is another map of Westgate Close and Roman Rd.
Di's house is 15 m, or 50 ft, along Westgate Close.
El's house is 72 m along Westgate Close, at the very end of the road.

- Estimate El's distance in feet.
- Calculate El's distance in feet (try to find *several* ways of calculating the answer).

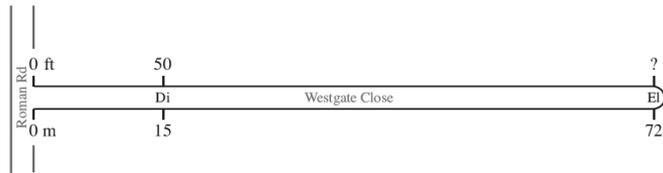

Fig 11: Westgate Close

estimates (Fig 12a), of between 200ft and 250ft (the actual answer is 240ft). Though these students simply ignored the information about the distances in metres, their estimates might stand them in good stead once they do try to calculate, especially if they use an inappropriate strategy.

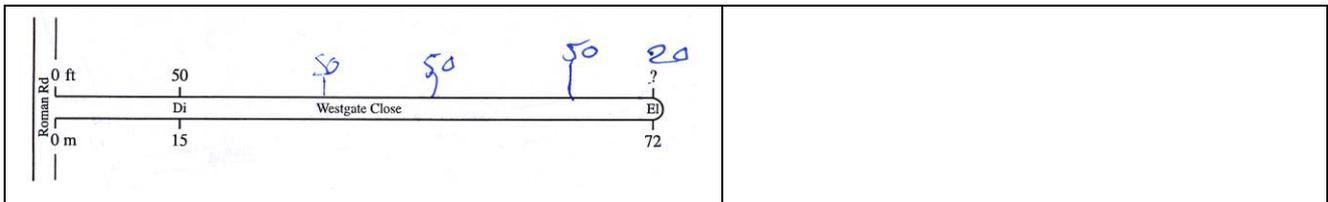

Fig 12a

Fig 12b

As with Elastic Strip, the task proved difficult for the average-attaining Year 8 class. One student (Fig 12b) used what might be called a 'function' approach to arrive at the multiplier 3.3 ($50 \approx 15 \times 3.3$), and used this to calculate 72×3.3 (but as can be seen, he made arithmetic and transcription errors to arrive at a widely-off answer of 91.87ft). Another student used an effective rated-addition strategy to move along the road in steps of 15m/50ft, to arrive at $75\text{m}=250\text{ft}$; however, having thus overshoot the 72m distance by 3m, she then subtracted 3 from 250 to arrive at 247ft.

In the above-average attaining Year 8 class, one pair of students used a 'scalar' approach; they determined that 72 is 4.8 times 15, and used this multiplier to calculate the distance of El's house in feet: $50\text{ft} \times 4.8 = 240\text{ft}$.

This pair also made use of a ratio table (Fig 13) which may well have helped them structure their work.

	m	f	
$4.8 \times$	15	50	$\times 4.8$
	72	240	

Fig 13: Ratio table

However, not all students in this class were immune from using the addition strategy, and one pair used a hybrid scalar/addition strategy to come up with an answer of 212ft, based on the observation that 72 can be expressed as $15 \times 4 + 12$ (leading to $50 \times 4 + 12 = 212$).

DISCUSSION

The findings reported above suggest that some students can make productive use of the double number line as a model of contexts that involve multiplication-as-scaling, even when they may have had little or no prior experience of using it in this way. But equally, there are students who do not readily see the multiplicative structure of the contexts (or of the model), which suggests that developing this insight is not a trivial matter. Nonetheless, we would argue that it is worth giving students experience of the model (both as a model *of* multiplication-as-scaling contexts, and as a model *for* multiplication-as-scaling concepts), since scaling is an important aspect of multiplication, and since it is important to be able to discern whether a context involves scaling. Also, the model is well suited to showing the contradictions inherent in the addition strategy when applied to scaling contexts (for example, in the case of a $\times 1.5$ stretch applied to a 20cm elastic strip fixed at one end, if students use the addition strategy to argue that points on the strip will move 10cm further from the fixed end, it is fairly easy to provoke a contradiction by asking what happens to the mid-point of the strip, or to a point very near the fixed end).

The double number line also links nicely to other powerful representations and we should help students develop these, in particular links with ratio tables, and with mapping diagrams and Cartesian graphs (the latter are also based on number lines, but in the case of Cartesian graphs the lines are orthogonal rather than parallel). At the same time the double number line may not always be the most appropriate model for representing and/or solving multiplication tasks, and we would argue that students, including those at secondary school, need extensive and ongoing experience of other models of multiplication, in particular arrays and the area model.

NOTES

1. ICCAMS (Increasing Student Competence and Confidence in Algebra and Multiplicative Structures) is a 4-year research project funded by the Economic and Social Research Council as part of a wider initiative aimed at identifying ways to participation in Science, Technology, Engineering and Mathematics (STEM) disciplines. Phase 1 of the project consists of a large-scale survey of 11-14 years olds' understandings of algebra and multiplicative reasoning in England. This is followed in Phase 2 by a collaborative research study with two teacher-researchers in each of four secondary schools. The aim is to examine how formative assessment can be used to improve attainment and attitudes, and finally how the work can be disseminated on a larger scale.

2. In 2008/2009, we re-administered three of the CSMS tests that had been developed in the 1970s - Algebra, Decimals, and Ratio. In general performance on the tests was very similar to the 1970s; the most notable exceptions were some Decimals items that related to measurement, where performance improved in 2008/2009.

PROPORTION IN MATHEMATICS TEXTBOOKS IN UPPER SECONDARY SCHOOL

Anna L. V. Lundberg

Linköping University, Sweden

Proportional reasoning and knowledge of proportion are prerequisites for success in higher studies in mathematics. The aim of this paper is to investigate what possibilities Swedish upper secondary school textbook tasks offer students to develop knowledge about proportion during the first course in mathematics. The three textbooks investigated in this paper show a variation in “know – how” of proportional reasoning but less variation regarding knowledge about proportion.

Keywords: Proportion, Textbooks, Upper secondary school, Anthropological Theory of Didactics.

BACKGROUND

To understand and use calculations with proportionality is one of the learning goals for grade nine in Swedish compulsory school (Skolverket, 2001). However, results from TIMSS 2007 show that 50% of the students in grade eight have difficulties solving tasks about proportionality (Mullis, 2008). But what about the students at upper secondary school? How are they managing proportions? International research also shows a predominance to use the linear model in solving proportion tasks in upper secondary school (De Bock, Verschaffel, & Janssens, 1998). My ongoing study attempts to shed light on various aspects of how proportion and proportional reasoning are exposed in textbooks at *upper secondary school* level in Sweden. According to several studies (e.g. Johansson, 2006), Swedish mathematics teachers rely on textbooks mainly in terms of exercises, making the textbook a critical factor in the classroom to study.

The aim of this paper is to present the first results from an investigation into what possibilities Swedish upper secondary school textbook tasks offer students to develop knowledge about proportion during the first course in mathematics.

THEORETICAL FRAMEWORK

This section will present the theoretical background from which the analytical tool used for this study was developed by first discussing how the notions of proportion and proportional reasoning were interpreted, then shortly outlining the theory linked to the tool, and finally presenting the tool as constituted by its four main parts.

Proportion and proportional reasoning

The term proportion is used when two quantities x and y are related by an equation $y=kx$, where k is a constant. Then y is said to be (directly) proportional to x , which may be written $y \propto x$ (The Concise Oxford Dictionary of Mathematics, 2009). It is

also common to use the term proportion for some specific relations such as *direct proportion* $y = k \cdot x$, *square proportion* $y = k \cdot x^2$, *inverse proportion* $y = \frac{k}{x}$, *inverse square proportion* $y = \frac{k}{x^2}$ and *inverse square root proportion* $y = \frac{k}{\sqrt{x}}$.

I am also investigating proportional reasoning tasks though it is difficult to set up a general definition of proportional reasoning, maybe because proportion is such a complex concept. I will here use the description of proportional reasoning found in Lamon (2007, p. 638).

According to Cramer and Post (1993) and several other studies there are three central types of problem situations in proportional reasoning: *numerical comparison*, *missing value*, and *qualitative prediction & comparison*. In numerical comparison problems, the answer does not call for a numerical value. The student compares two known complete rates, as in Noelling's (1980) well known orange juice problem. Lybeck (1986) among others, found that there exist two different main solution strategies: the A-form or the so-called Within Comparison, where quantities of the same unit are compared, and B-form, a Between Comparison across different units. In missing value problems three objects of numerical information in a proportion setting are specified with a fourth number to be discovered. A popular such task is the tall-man short-man problem (Karplus, Karplus, & Wollman, 1974). The third problem situation, qualitative prediction & comparison, does not demand memorized skill. These types of problems force the students to gain knowledge about the meaning of proportion with qualitative thinking (Cramer & Post, (1993).

Knowledge and know-how related to proportion tasks

As this study is focused on how a specific mathematical notion is treated in the school institution in terms of types of tasks and strategies, The Anthropological Theory of Didactics, ATD; (see e.g. Bosch & Gascon, 2006) offers a useful approach. The ATD postulates an institutional conception of mathematical activity, starting from the assumption that mathematics, like any other human activity, is produced, taught, learned and diffused in social institutions. Mathematical work can be described in terms of mathematical organisation. A mathematical organisation (MO) is constituted by two levels, the *know-how* (task & techniques) and the (discursive) *knowledge* (technology & theory) related to a given task (Chevallard, 2006). Task – different kinds of tasks to be studied, Techniques – how to solve tasks, Technology – justification and explanation of the techniques, Theory – founding technology and justification of technology. In this study, there are influences from two MO's, one where proportion is defined as a 'dynamic' notion MO₁ and one where proportion is defined as a 'static' notion MO₂ (see below).

In order to study a phenomenon a Reference Epistemological Model (REM) should be created by the researcher (Bosch & Gascón, 2006). Otherwise it is difficult to be

independent in relation to the educational institutions understudy and the result may be a model that is implicitly imposed by the educational institution. The REM is a corresponding body of mathematical knowledge that is continuously developed by the research community and connected to the different steps of the didactic transposition. The transposition process describes how the mathematical knowledge is transformed from the institution of knowledge production through the educational system to the classroom (Bosch & Gascón, 2006).

The knowledge of proportion

As a REM and theory category, the two MO's of describing proportion in textbooks was used. MO₁ was observed in a pilot textbook study (Lundberg & Hemmi, 2009), where it was found that a frequent way to present proportion is by the relationship $y = k \cdot x$, where y is dependent of x and k is a fixed constant. This has been named *adynamic notion of proportion* (Miyakawa & Winsløw, 2009), as we have different values of x as input producing specific outputs as y depending on the value of k .

Another way to describe proportion is *static* (Miyakawa & Winsløw, 2009). It is possible to identify this phenomenon in Euclid's definition of proportion (Euklides & Heath, 1956), where it is regarded as static in nature because it deals with pairs of "magnitudes" rather than numbers. A magnitude could be a length, like the diagonal of a square. For the Greeks it could not be measured in centimetres, but nevertheless multiplied in a geometric sense (e.g. enlargement). The static way of defining proportion is more general in comparison with the dynamic notion because it can be defined in n-tuples of real numbers and does not constrain proportion to pairs.

An example from a Swedish textbook (Gennow, Gustafsson, Johansson, & Silborn, 2003, p. 314) will serve as an illustration of static and dynamic definition:

"An electric radiator influences by power P (the thermal energy emitted per second) of voltage the U that the radiator has been connected to. The table shows some values of U and P that belong together. Check if there is a relation between P and U represented by $P = k \cdot U^2$ and if so calculate k . The power has the unit Watt (W) and the voltage Volt (V).

U (V)	120	160	200	240
P (W)	144	256	400	576

Solution: To investigate $k = \frac{P}{U^2}$ we put a new row in the table.

P/U^2 (W/V ²)	0,010	0,010	0,010	0,010
-----------------------------	-------	-------	-------	-------

We obtain the same result for all pairs. This implies that the relation can be written as $P = k \cdot U^2$ and $k = 1,0 \cdot 10^{-2} \text{ W/V}^2$. In electricity the unit W/V^2 is denoted S (Siemens). The relation can be also be written $P = \frac{U^2}{R}$ where $k = \frac{1}{R}$ and R has the unit Ω (Ohm)."

Auth transl.

In the beginning of the example the static definition is found in the table where the given data are n-tuples of U and P . In the solution it is necessary to switch to a dynamic definition because it is eligible to calculate k in order to check if there is a proportionality that can be expressed by the general formula $P = k \cdot U^2$.

The know-how in calculating proportional tasks

To investigate solution techniques for proportion tasks a study by Hersant (2005) was used because it had a lot of similarities with this study. She found six different types of techniques in her analysis of solved proportion examples in French textbooks. To show the differences between these categories of solution techniques (1-6 below, *Auth. transl.*) I will use the following task provided by Hersant:

If 18 meters of fabric costs 189 francs, how much will 13 meters cost?

1 Reduction by unit

If 18 meters cost 189 francs, 1 meter will cost 18 times less or $\frac{189}{18}$, and 13 meters will cost 13 times more than one meter or $\frac{189}{18} \cdot 13$ where $x = \frac{189 \cdot 13}{18}$. The answer will be 136.50 francs. In the context of the theory of proportionalities, it will be justified by the characteristic of the property proportion expressed here as part of quantities. Two quantities U and V are proportional so when U is multiplied by 2, 3, 4... λ (and λ real), V is multiplied by 2, 3, 4,... λ .

2 Multiplication by a relationship

Now consider the following solution: If 18 meters cost 189 francs, then 13 meters will cost $\frac{13}{18} \cdot 189$. Pay attention to that neither ratio nor proportion are used here. The technique of within measures proportion is used.

3 Use of proportion

If we let the price for 13 meters of fabric be x francs then the price should be in proportion to the length of the fabric $\frac{189}{18} = \frac{x}{13}$ so, $189 \cdot 13 = 18 \cdot x$ and $x = \frac{189 \cdot 13}{18}$. This technique differs from the earlier two when the proportion involves two different measures, length and price (between measures proportion).

4 Cross multiplication

Now consider the resolution that follows: Let x be the price of 13 meters of fabric. (1) $\frac{189}{18} = \frac{x}{13}$ then (2) $189 \cdot 13 = 18 \cdot x$ and $x = \frac{189 \cdot 13}{18}$ that can be summarized as follows in a table:

So $189 \cdot 13 = 18 \cdot x$ and $x = \frac{189 \cdot 13}{18}$. In the spirit of this technique, the equality (1) does not match proportion but more rather a technique with a formal setting of the magnitudes and detached from the theories of proportions.

Table 1: Cross product table

189	x
18	13

5 Use of coefficient

Another way of arguing is as follows: The fabric costs $\frac{189}{18}$ francs/meters, so 13 meters of fabric cost $13 \cdot \frac{189}{18}$ francs. Here again a reduction technique to unit is used but with no connection to proportion.

6 Other possible techniques

It is also possible to solve the task with a graphical solution method. However, if only one value is calculated it seems to be a waste of energy to use graphical technique unless you don't have access to a graphic calculator then it is very easy to sketch a graph.

RESEARCH METHODOLOGY

To investigate what possibilities textbooks offer upper secondary students in Sweden to develop knowledge about proportion during the first course in mathematics, the following research questions were set up (in terms of the ATD): What types of textbook tasks involve proportion? What techniques are used in the given solutions of proportion tasks? What explanations and justifications (technologies/theory) are presented in the proportion tasks? To answer these questions, an analytic tool was developed to investigate a selection of textbooks.

In a study about proportion in textbooks, da Ponte and Marques (2007) used the Pisa Assessment Framework as an analysing tool. In the pilot study (Lundberg & Hemmi, 2009) this tool was evaluated but for my purpose the categorisation at a cognitive level was problematic, so there was a need to develop an analytic tool better suited for text analysis.

The textbooks selected for this paper are from the A-course at the Swedish upper secondary school. The A-course is a special case because it is mandatory for all students at upper secondary school (Skolverket, 2001), selected here because it is the beginners' course for all further studies at both the theoretical and the vocational programs of upper secondary school. In Sweden there is an open market for textbooks without regulations from the authorities. There are several textbooks on the market for this course, among which I have selected the three most commonly used in my region (three municipals). The book chapters analysed were those where proportion was expected to be one of the key notions: arithmetic, geometry and functions. There was also a limitation in the geometry chapter. Only tasks about

similarity, scale and trigonometry in the geometry chapter were analysed. The textbooks were investigated concerning both the knowledge and the “know-how” of proportion. The textbooks were analysed to determine what type of tasks were given (missing value, numerical comparison and qualitative prediction & comparison) and what kinds of proportion were used (direct proportion, inverse proportion, square proportion, and square root proportion). Finally, solution techniques presented in the textbooks and the knowledge of proportion (theories and technologies) related to the tasks found were investigated. Thus, in terms of the ATD, the analytic tool used for this study was comprised by the following categories: *Task* – missing value, numerical comparison, qualitative prediction and comparison, static or dynamic proportion, direct proportion, square proportion, inverse proportion, inverse square proportion, and inverse square root proportion. *Technique* – how to solve tasks, the six categories by Hersant are used here. *Technology* – justification and explanation of the techniques. *Theory* – the two definitions of proportion static and dynamic are used as categories here.

FIRST RESULTS

The study is still ongoing but this paper will report some first results from the textbooks that have been analysed. In this section, the first most significant observations are presented, quoting selectively from the textbooks to illustrate the main findings. In all the textbooks, the definitions of the notions are introduced by solved examples and the examples presented in this section will therefore be structured by taking the technique used as the overarching categorisation principle, before type of task and knowledge (justification) are identified.

The number of examined tasks in total for all three textbooks were 3073 (1157, 1093 and 823). 24% (757) tasks were classified as proportion tasks. The preliminary data indicate that missing value tasks (43%) occur three times as much as numerical comparison (14%) and qualitative prediction & comparison tasks (12%). The static definition was used most often in the geometry chapter (32%) and the dynamic definition of proportion was predominant in the chapters about arithmetic (81%) and functions (72%). There were only a few justifications found in the textbooks in the geometry section. The most prevalent type of proportion was direct proportion but some examples about other kind were mentioned in the textbooks. However, all types of techniques described above were found, as shown by the following illustrative examples.

1 Reduction by unit

In Swedish textbooks this solution strategy is easy to find in the chapter about arithmetic. The following example is taken from Alfredsson et al, (2007, p. 45):

In a municipality the number of citizens is increasing by 8% over one year to 70 200. How many citizens were there in the municipality before the increase?

Working Group 2

108% is equivalent to 70 200.

1% is equivalent to $\frac{70200}{108}$.

100 % is equivalent to $\frac{100 \cdot 70200}{108} = 65000$ *Auth. Transl.*

This type of example is found in two of the textbooks(5%) and missing in the third book. The task is categorized as a proportional reasoning task called missing value and is also in favour for this solution technique. The MO represented is dynamic (MO₁) and direct proportion. This technique is missing in the function chapter in all three textbooks.

2 Multiplication by a relationship

This solution technique is found in the chapter about arithmetic in several Swedish textbooks, here Liber Pyramid (Wallin, Lithner, Wiklund, & Jacobsson, 2000, p. 43):

Anna has a salary of 17 250 SEK. She got a rise in salary with 4 %. How much is her new salary?
The new salary is 100% of the old salary and the salary rise of 4 % of the same salary. The new salary will be: 104% of 17 250 SEK and that will be $1,04 \cdot 17250$ SEK = 17940 SEK *Auth Transl.*

This is a very typical kind of example in all three textbooks (18%). I interpret this solution technique to use the same technique as in Hersant's example but here different data is used. The tasks is categorized as a missing value task and the notion of proportion is dynamic (MO₁) and direct proportion.

3 Use of proportion

This special solution technique is to be found in general in the geometry chapter. An example from a Swedish textbook (Wallin et al., 2000, p. 122):

The pentagon $ABCDE$ is similar to the pentagon $FGHJK$.

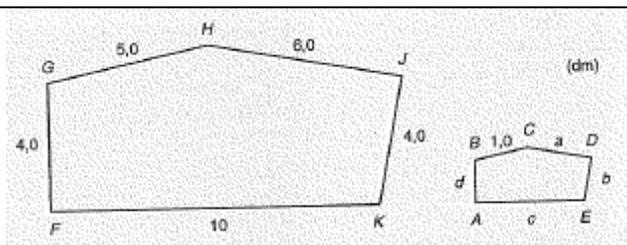

Calculate the length of the sides a , b , c , and d .

From the similarity it follows,

$\frac{a}{6} = \frac{b}{4} = \frac{c}{10} = \frac{d}{4} = \frac{1}{5}$ From the first and last

equality we get $\frac{a}{6} = \frac{1}{5}$, $a = \frac{6}{5} = 1,2$. In the same way we get $b = 0,8$, $c = 2,0$ and $d = 0,8$.

Auth. Transl.

This is the most frequently used technique overall (34%) and found in all three books. The example is analysed as a missing value task and the notion of proportion is static (MO₂) and direct proportion.

4 Cross multiplication

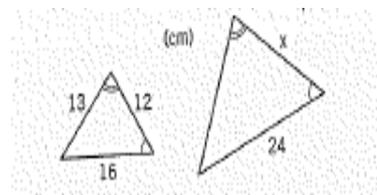

This particular solution technique is found in the chapter about geometry (Alfredsson, et al., 2008, p. 153):

In the figure the angles are marked with the same sign if they are in the same size. Calculate the length of x . The triangles are equal in two angles then they are similar and the ratio between two sides is equal.

Auth. Transl

$$\frac{x}{12} = \frac{24}{16}$$

$$x = 18$$

This is a very unusual solution strategy (2%) and it is only found in one textbook in the geometry chapter and static proportion. The task is analysed as a missing value task and the notion is represented as a static notion (MO₂) and direct proportion.

5 Use of coefficient

This category can be found in the function chapter (Gennow et al., 2003, p. 301):

In an experiment in physics, the students were measuring mass and volume for different amounts of aluminium tacks. First, the students weighed the tacks and then they poured them into a graduated measuring glass with water. The findings from one group were:

Volume (cm³) (V) 12 17 22 29 38

Mass (g) (m) 32 46 59 78 103

Determine the density (i.e. mass/volume) of aluminium if it is in proportion.

For this proportion to be valid k have to be $k = \frac{m}{V}$. We chose a pair of numbers far away from the origin of coordinates to increase the accuracy, draw lines to x and y axis.

Reading gives

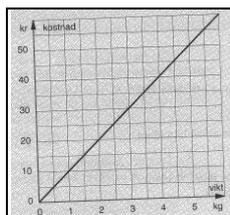

$$V = 40 \text{ cm}^3, m = 108 \text{ g}, k = \frac{108 \text{ g}}{40 \text{ cm}^3} = 2,7 \text{ g/cm}^3 \text{ Auth. Transl.}$$

This category is found in all the textbooks and is the next most frequent technique (26%) used especially used in the arithmetic chapter. The task is categorized as a missing value task and the notion is static (MO₂) and direct proportion.

6 Other possible techniques

An example of this solution technique comes from the chapter about functions (Wallin et al., 2000, p. 164):

Working Group 2

The graph is showing how the cost of apples depends on the weight. The graph is a ray with its origin in zero. This means that we have a proportion. How much for: a) 1kg? b) 2kg? Answer: a)10kr b)20kr. *Auth. Transl.*

This type of solution is found in all analysed textbooks (15%) and usually used in the function chapter with dynamic proportion. The example is categorized as a missing value task and the notion is dynamic (MO_1) and direct proportion.

DISCUSSION

The three textbooks investigated offer variations in types of tasks and techniques but the predominant task is missing value and some tasks could be exchanged for more qualitative tasks. Technique 1 and 4 are also missing completely in some of the textbooks so the techniques also have some limitations. The two notions of proportion (dynamic and static) are both represented but justifications are rare. Thus two MO 's are presented in different chapters (arithmetic, functions and geometry) with no link pointed out between them, which can be misleading for both teachers and students in their practice and might result in a predominance of the dynamic notion. It appears that the static notion is represented to a higher extent in the chapters about geometry and the dynamic notion more used in the chapter about arithmetic and functions. The theoretical description of proportion appears to be similar in all the textbooks and not presented in different approaches in parallel which is preferable. Proportion is also represented mainly as direct proportion with a few exceptions, which may be problematic as for example also inverse proportion is important for the further mathematics studies. Justifying technologies are very often missing. The explanation might be that justification is not a learning goal in the curriculum for this first basic course (Mathematics A). This study has also illustrated how the particular analytical tool developed for investigating tasks can be used as an instrument for what types of "knowledge" and "know-how" are represented in mathematics textbooks. This might be a benefit also for teachers in their practice by providing principles for the selection of tasks. However, if the students really use the techniques presented in the textbook is another research issue which will be investigated in a follow-up paper about students' solutions of proportion tasks.

ACKNOWLEDGEMENT:

This study is funded by The Swedish National Graduate School in Mathematics, Science and Technology Education.

TEACHING ARITHMETIC FOR THE NEEDS OF THE SOCIETY

Hartwig Meissner

Westf. Wilhelms-Univ. Muenster, Germany

In the newly formed Working Group 2 it may be allowed not only to discuss the research already done or the research in progress, but also to develop perspectives on the future needs of the society and how to approach these needs. This programmatic view into the future will not only summarize experiences from different research fields in learning arithmetic. It will also sketch necessary changes and suggest establishing a project within the European Union to face the common needs of arithmetic education in our technology based countries.

Keywords: Number sense, estimation, calculators, paper and pencil techniques.

INTRODUCTION

The author of this paper worked with calculators and computers in schools since the seventies. He was also a panelist at the ICME-3 Panel Discussion in 1976 on “What May Computers and Calculators Mean in Mathematical Education in the Future?”

Now, several decades later, it is interesting to see what really has happened in mathematics education in schools since the seventies. A state-of-the-art view is given in the 17th ICMI Study on *Mathematics Education and Technology – Rethinking the Terrain* (Hoyles & Lagrange 2010). But the experts at this ICMI Study discussed only briefly if the use of simple calculators had changed or if there were mental changes in the students’ computation abilities and skills. This paper will discuss some more aspects.

In 1984, after ICME-5 in Adelaide, 15 specialists from 10 countries from the Theme Group *The Role of Technology* summarized in their CALCULATOR REPORT:

- “Research investigations since 1980 have not produced dramatic new insights or results, they mainly confirm the findings of previous investigations.
- The overwhelming majority (greater than 95%) of investigations indicate that the use of calculators does not harm mathematics achievement in terms of the traditional curriculum and traditional tests.
- There are many countries with the ability rate of calculators to children of more than 80% where the school curricula ignore the existence of calculators or where the calculator use in mathematics education is not allowed for many grades” (Mohyla 1984, p. vii).

Since ICME-5 “simple *calculators* are no longer a central theme at congresses or conferences on mathematics education. *Computers* ... are the hits at the moment” (Mohyla 1984, p. 3). In the eighties investigations on the use of technology in mathematics education changed their focus. A shift can be observed from simple

Working Group 2

calculators via scientific calculators and programmable calculators to computers. This shift also includes a shift in the age groups, from investigations related to all grades to investigations related to upper secondary grades.

But what has happened in primary schools since then? We cite some of the questions from Karlsruhe (see Athen & Kunle 1977, p. 291 ff) and sketch the answers:

ICME-3 Questions (Karlsruhe 1975)	Answers in 2010 for Primary Schools (not only in Germany)
What to do with calculators today?	In most of the European countries there are no systematic curricula for using calculators.
How will calculators ... influence teaching mathematics?	Regarding the reality in schools till now there is almost no influence calculators have on teaching mathematics in primary grades.
Is there a danger that numeracy will suffer if such calculators are introduced, ...	YES – in the eyes of parents, teachers, and school administrations NO – according to almost every research report
... or may numeracy be improved by using simple calculators?	YES – according to many project groups, but <u>a large scale investigation is necessary</u> to convince parents, teachers, and school administrations for implementing appropriate curricula.

PAPER AND PENCIL TECHNIQUES

Which will be the future of paper & pencil algorithms for the four basic operations in the primary school curriculum? Already in the seventies Hans Freudenthal was warning: "We will run into a catastrophe when we today teach topics which one or two decades later will be done by calculators³." Nevertheless still in 1998 Schipper summarized that "sometimes up to 50% of the time from mathematics lessons in grades 3 and 4 is used to introduce and to train paper & pencil algorithms⁴." And Kaput (2002) continued warning: „The importance of the ability to serve as a poor imitation of a \$4.95 calculator is rapidly declining⁵." In daily life situations and for business purposes everybody uses a calculator. Simple calculators for the four basic operations are cheap and exist everywhere, they dominate our calculations in daily

³ The text originally in German: "Wenn unser Unterricht heute darin besteht, dass wir Kindern Dinge eintrichtern, die in einem oder zwei Jahrzehnten besser von Rechenmaschinen erledigt werden, beschwoeren wir Katastrophen herauf" (Freudenthal 1973, p. 61).

⁴ The text originally in German: "... in den Klassen 3 und 4 ... [werden] manchmal bis zu 50% der gesamten Unterrichtszeit dem Einueben der Algorithmen gewidmet." (Schipper 1998, p. 10).

⁵ conference note

life. But in mathematics education in primary schools calculators are forbidden in almost every country, worldwide. Here we spend up to more than 100 hours in the classroom to teach and to train computing techniques as if there were no calculators. Why do we waste so much time of our children to teach them things which after primary school they will not need any longer?

We see an emotional dichotomy. Despite the research results from many research projects in many countries there is still the fear that the use of calculators in primary grades will harm mental arithmetic and estimation skills. To explain and to overcome that fear we will reflect the nature of number sense and of paper & pencil skills more carefully. We realize that the development of number sense is an intuitive and unconscious mental process while the ability to get an exact calculation result must be trained consciously. To overcome the above dichotomy we must solve the hidden dichotomy *number sense* versus *precise calculation result*. We need a new balance. Different types of examples will be given how we can further the development of number sense in a technology dominated curriculum.

DICHOTOMY NUMBER SENSE VERSUS ALGORITHMIC SKILLS

Specialists from many research projects know that the use of calculators in primary grades does not necessarily harm mental arithmetic and estimation skills. But these “logical” arguments do not count. There still remains an emotional component against the calculator use which cannot be eliminated logically. Thus it is too simple just to claim to replace paper & pencil skills through the calculator. We need more than the ability to get a quick and exact calculation result. To remain mentally independent from the calculator we also must concentrate on automatic mental arithmetic and estimation skills. How do these skills develop? And which changes will we get when we change from paper & pencil skills to calculators?

A more profound view of mathematics learning is necessary to identify the nature of number sense and of paper & pencil skills. Learning and understanding mathematics is based on two different types of mental processes, on logical and conscious arguments (cf. *precise calculation results*) as well as on intuitive and unconscious mental processes⁶ (cf. *number sense*). These two systems interfere.

1. Precise Calculation Results

There are three techniques to get precise calculation results: Paper & pencil techniques, using a calculator or computer, and mental arithmetic. Teaching and training of paper & pencil skills is time consuming and the results are less safe than

⁶ For example, Vygotsky (1978) talks about spontaneous and scientific concepts, Ginsburg (1977) compares informal work and written work, or Strauss (1982) discusses common sense knowledge vs. cultural knowledge. He especially has pointed out that these two types of knowledge are quite different by nature, that they develop quite differently, and that sometimes they interfere and conflict (“U-shaped” behavior).

via pressing the calculator keys. It is obvious why the calculator technique dominates outside from school.

2. Mental Arithmetic

Mental arithmetic is a challenge for teachers to “teach” and for students to “learn” because of the two mental modes which are involved. On the one hand the students should be able to explain *logically and analytically* how they get the result. But on the other hand we also expect that for specific problems they can *react immediately* in a stimulus response style (stimulus response knowledge for e.g. $1+1$ table and 1×1 table). Furthermore, we also expect such an *unconscious and intuitive* stimulus response reaction when the student gets confronted with computation mistakes. Either he/she spontaneously notices a conflict with his/her intuitive individual stimulus response knowledge or there is a spontaneous reaction like “this is too big” or “this is too small”. The latter describes a conflict between the computation result and the individual personal experiences.

3. Estimation Skills

Estimation is a challenging activity. Before starting computing we ask for the approximate result of a possible solution. Either the computation task is already given in the classical mathematical symbolic notation or we have to solve a word problem. For the first type of problems the estimation result can be found more easily. Here we must round the numbers and compute with rounded numbers. Estimation in this case is a special analytical and logical approximation technique (in German *Ueberschlagen*).

For word problems we usually first analyze the situation described. We then need a modeling process to get a “translation” of the word problem situation into a mathematical notation of a computation problem where we can get an estimation result via approximation. But there is an alternative strategy to estimate the result for a word problem.

Analyzing a word problem can and should stimulate also subjective domains of individual experiences related to the situation given (*Subjektive Erfahrungsbereiche*, cf. Bauersfeld 1983). Intuitively and spontaneously non-mathematical knowledge and personal experiences get stimulated, too. Estimation may then become a spontaneous and intuitive reaction like “Oh, this must be about”.

4. Estimation and Sachrechnen

To estimate spontaneously and intuitively an approximate result for a given word problem we need special experiences, environmental and daily life experiences and experiences in comparing and measuring objects. To develop these experiences the German arithmetic curricula include a special topic called *Sachrechnen* (aspects of environmental and domestic sciences). In *Sachrechnen* we *compare* objects according to their length, time, weight, etc. (*direkter / indirekter Vergleich* in

German) and we *measure* objects: Select a unit und try how often that unit fits into the object. Estimation in Sachrechnen is then quite a different mental activity, it is the internalized process of *comparing* or *measuring* (*Schaetzen* in German)⁷.

5. Concept of Numbers

In traditional German curricula for primary schools we introduce step by step the “number spaces” [0 - 20], [0 - 100], [0 - 1.000], and [0 - 1.000.000]. Thus also step by step, the “object number” gets reduced into a sequence of digits and the computation with big numbers gets reduced into manipulations with sequences of digits. Outside from school, numbers have a different meaning. Here a number is mainly a measurement number (*Groesse* in German) which describes the size (value, magnitude, ...) of an object. It consists of two parts, a *quantity number* and the appropriate *unit* like 345 km or 2 830 hours or 562 048 cents. The quantity number (*Masszahl* in German) tells us how many units we need to represent the size of that object.

6. Number Sense

We have summarized important aspects which are touched when we talk about number sense: “Number sense refers to an intuitive feeling for numbers and their various uses and interpretations; an appreciation for various levels of accuracy when figuring; the ability to detect arithmetical errors, and a common sense approach to using numbers. ... Above all, number sense is characterized by a desire to make sense of numerical situations” (Reys 1991).

Number sense not only refers to numbers but also to both, to conscious and to unconscious techniques to manipulate numbers, and it also includes a feeling about possible outcomes of these techniques. With a good number sense we can roughly predict the result of calculations, sometimes spontaneously (intuitively) and sometimes consciously (by approximating). Number sense also includes an intuitive feeling for additive and multiplicative structures. A central question for future curricula must be if we can develop a more effective number sense by the use of calculators than we momentarily do in our traditional curricula.

CALCULATORS AND ARITHMETIC LEARNING

One of the first major projects to integrate the calculator use into a primary school curriculum was the Calculator-Aware-Number Project (CAN) in 1986 – 1989 in England and Wales (Ruthven 1999). But “during the 1990's, [the] curriculum and assessment system [became] much more '*calculator beware*' as a result of criticism of calculator use by mathematicians and politicians” (Ruthven 2007 in a personal

⁷ Sachrechnen also includes the topic money and problem solving activities (problems from real life situations like shopping, planning an excursion, constructing a bird-cage, etc.).

Working Group 2

communication). Thus we will start our analysis here with a warning. An unreflecting use of calculators in primary schools may damage some of the traditional goals of arithmetic education. The uncontrolled use might provoke two problems:

- Pressing keys is so easy. Why shall I still learn mental arithmetic?
- Pressing keys is so safe. Why shall I still check my calculator result?

A calculator curriculum must face these problems. But in this paper we will not discuss the PROs and CONs of the use of calculators in primary schools and how paper & pencil techniques could be replaced by a calculator use. Here we will reflect how arithmetic teaching in primary schools may benefit from the use of calculators and how the use of calculators may help to further the traditional mathematical goals. Of course, the calculator is an excellent tool to get quick and safe calculation results. But besides this property it also may serve as a didactical tool to stimulate intuitive and spontaneous ideas and activities in the teaching and learning processes. The possibility to handle a big bunch of quick calculations without any efforts allows a new working style in the class room which was not possible without calculators or computers. We will summarize and analyze some activities (for detail see Meissner 2006).

7. Stimulus Response Learning

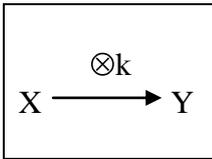

Calculators allow and facilitate stimulus response learning. This can be used in competitions to train mental arithmetic. The basic idea is to compute very quickly a given calculation problem to get an immediate feedback: *correct* or *wrong*. We developed several tasks starting with problems from the $1+1$ and 1×1 table:

- Individual worksheets, individual training: Type the problem into the calculator and calculate the result in your head. Then press the “=” and see if you were right. If YES write down the result, if NO do the next problem. Later on work on the still open problems.
- Competitions mental computation versus calculator, who is the first? At the beginning each student wanted to be in the calculator group, later on almost nobody wanted to be there because "I am quicker in my head".
- Each student gets a worksheet, the use of calculators is allowed. Who has finished the worksheet first? There may be different worksheets according to the students' abilities.

8. Operators

Simple calculators with a constant facility are very important for primary schools. They can be "programmed" to work as an operator " \otimes k" where \otimes stands for the four basic operations. Calculators with a constant facility allow for developing a feeling

for additive and multiplicative structures. We hide an operator \otimes_k and others must find out which operator we hid:

Select a value for X, press the calculator keys, and interpret Y. Guess what \otimes_k might be. If necessary select another value for X, etc. Finally select additional values for X and predict the results.

9. Calculator Games

There are several calculator games which use the constant facility to detect numbers and operations and to develop a feeling for additive or multiplicative structures. We will present an example with the calculator game *Hit the Target*.

Example:

A diagram showing a question mark followed by an arrow pointing to a bracketed interval [800,801], with a circled 'x 17' above the arrow.

<i>input</i>	<i>display</i>

Hit the Target: Find via guess and test a number z that $z \times 17$ is in the interval $[800,801]$. Write a protocol of your guesses.

More general: An interval $[a,b]$ is given and a factor k . Find a second number z via guess and test that the product " $z \times k$ " is in the interval $[a,b]$.

For primary schools we suggest to concentrate on integers $k, z < 100$.

More than 1000 guess-and-test protocols show that the students after a certain training develop excellent estimation skills. They guess a very good starting number and they develop an excellent proportional feeling. For more details on calculator games see Lange & Meissner (1980), Lange (1984), and Meissner (1987).

10. One-Way-Principle

Guess and test or trial and error are not considered to be a valuable mathematical behavior in mathematics education classrooms. But these components are necessary to develop spontaneous and intuitive ideas. Our experiences show that a systematic use of guess and test activities enriches creative and flexible thinking. So we developed a specific teaching method called One-Way-Principle (Meissner 2003). The One-Way-Principle is a method to use calculators or computers to explore intuitively and/or consciously many functional relationships of the type

$$X \xrightarrow{\sigma} Y \quad \text{or in case of the four basic operations } \otimes \quad X \xrightarrow{\otimes_k} Y.$$

The basic idea of the One-Way-Principle is to use not reverse functions or algebraic transformations but to experience the set of variables as a "unit", as a global entity, which gets explored via guess and test.

Concentrating on the four basic operations in primary schools we can explore with simple calculators additive or multiplicative structures of the type " $a \otimes b = c$ ". Here the One-Way-Principle implies not to switch from addition to subtraction (or vice

versa) or from multiplication to division (or vice versa). Instead we have to guess " a " (or " \otimes " or b or " $\otimes b$ ") to use again the originally given key stroke sequence. Regardless of which variables are given and which are wanted, there is only the ONE WAY to solve all problems: Always use the same simple key stroke sequence of your calculator. The goal for the learner in the guess and test work is to discover intuitively the hidden relations between the variables and to develop a feeling how to get a good first guess (estimation) and how to reach a given target with only a few more guesses (additive resp. proportional feeling). Thus applying the One-Way-Principle furthers some of the intuitive and unconscious skills described above in no. 2 and 3.

REDUCING PAPER & PENCIL TECHNIQUES

Again, in this paper we will not discuss how paper & pencil techniques could be replaced by calculators. We will reflect how the traditional teaching and training of paper & pencil skills could be reduced. We think the main question is not how to calculate all possible sequences of digits but to ask first for the importance of each technique.

11. Expanding Mental Arithmetic

Mental computations are usually done with small numbers. We suggest to expand the meaning of "small" and to concentrate the four basic operations " $a \otimes b =$ " on all a and b where a and b are one-digit- or two-digit-numbers. Adding and subtracting two-digit-numbers is already part of traditional curricula. For the multiplication of two-digit-numbers let the students themselves invent appropriate techniques. Paper and pencil should be allowed to write down results from intermediate steps.

12. Proportional Feeling

In parallel to the conscious techniques from no. 11 the students should also get an opportunity to develop an intuitive feeling for possible results. Playing Hit the Target would be an excellent addendum. The students can select themselves appropriate numbers for Hit the Target (small or big intervals $[a,b]$, no integer solution for z , ...).

13. "Large" Numbers

"Large" numbers in this paper are integers with at least 3 digits. Most of these multi digit numbers are unimportant in daily life because we prefer rounded numbers: Size of a swimming pool or a garbage container, distance between two cities or between the earth and the moon, weight of a lion, etc. Putting important rounded numbers on the number line we do not get an equidistant pattern. The larger the number space is the more unimportant numbers it will have. Do we still need for all these unimportant numbers the traditional paper & pencil techniques? We suggest concentrating only on calculating with "important" numbers.

14. Calculating with Rounded Numbers

Working Group 2

Rounded numbers are similar to measurement numbers (*Groessen*, see no. 4 and 5). They consist of two parts, a one or two digit quantity number (*Masszahl*) and a unit (“thousands”, “millions”, etc.). To calculate with rounded numbers we can separate the two parts. We can then calculate with one or two digit numbers and apply techniques about what to do with the units. This approach also furthers Sachrechnen goals:

- Changing the unit implies converting the related quantity number. Getting experiences in changing units also furthers the development of spontaneous and intuitive reactions as described in no. 3.
- For addition and subtraction both numbers must have the same “unit”.
- For multiplication and division there are easy rules how to compute with the units. The students themselves might discover these rules.

15. Number Spaces

Reflecting the topics above, we also should rethink the concept of introducing numbers. It is fine to start in the first grade with [0 - 20] and then [0 - 100]. But when we start using calculators the number space gets suddenly unlimited. We need a spiral approach in which the students themselves can discover numbers and number properties in individual own subjective domains of experiences and where they can discuss their experiences. A spiral approach would also help to develop a much broader number sense.

16. Decimal Numbers

When we introduce calculators in primary schools, we must be aware that the students will discover very soon decimal numbers in the display. But they already have a basic knowledge of writing decimals. According to our experiences they are just happy to learn that 23.5 can be interpreted as 23 cm and 5 mm, or 12.69 as 12 € and 69 ct or 3.125 as 3 km and 125 m. And when there are more digits behind the “point”? Usually the children accept the simple answer “just ignore those digits” which corresponds to the view from above to distinguish between important and unimportant numbers. Adding or subtracting decimal numbers also becomes easy with this view. With the decimal grid problem it is even possible to develop intuitive experience about the multiplication of decimals (Barbeau & Taylor 2009, p. 210f).

SUMMARY

There is a worldwide resistance in using calculators in primary schools, emotionally dominated by parents, teachers, and school administrations. And the experts in mathematics education are split. Teaching “only” arithmetic is in the domain of “educators”, while the use of technology is in the domain of “mathematicians” (cf. 17th ICMI Study). There is no real lobby for the needs of our primary school kids. To bridge this gap we need a new concept how to teach arithmetic in primary schools in a technology based country in the 21st century.

ANALYSING CHILDREN'S LEARNING IN ARITHMETIC THROUGH COLLABORATIVE GROUP WORK

Carol Murphy

University of Exeter

The paper presents an example of collaborative group work with three children aged 6-7 years old, as part of a project to promote cooperative learning situations in young children's arithmetic. The premise of the project is that participation in collaborative group work will support children's cognitive development in number. Process-object duality models and the notions of reification, encapsulation or 'procept' have provided a way of examining the use of processes and objects in learning mathematics. These notions are used in relation to participation in a mathematical activity. This entails the use of two different theoretical perspectives, neo-Piagetian and neo-Vygotskian, in examining the children's mathematical thinking within a social context.

Keywords: arithmetic, collaboration, participation, process-object duality

INTRODUCTION

Much research has been dedicated to the development of early arithmetic and children's progression in the use of calculation strategies (for example Gray, 1991). Such studies have indicated that there are 'milestones' that show progression from simple counting strategies ('count-all' and 'count-on' strategies) and the use of commutativity ('counting-on from the larger number') to the use of number facts (additive components) and place value. It has been suggested that lower attaining children rely on counting strategies in addition and subtraction (Gray, 1991) and that a reliance on such strategies could hinder children's progression to more sophisticated, flexible strategies. The use of flexible strategies requires that children have a conceptual understanding of number and their relations.

Several studies have looked at developing children's generic thinking skills through cooperative group learning. Key to these are studies that have taught children to talk together effectively (Mercer, Wegerif & Dawes, 1999). These have shown that explicit teaching of talk strategies or *exploratory talk* can increase performance in non-verbal IQ tests and in tests for academic subjects including mathematics (Mercer & Sams, 2006). This paper presents work from a project funded by the Esmee Fairbairn Foundation and carried out with colleagues at the University of Exeter. The project introduced strategies for effective talk to young lower attaining children (ages 6-7). Our premise was that such an intervention would support children's learning in arithmetic and our aim was to examine the mechanisms of talk in relation to children's conceptual understanding of number.

CONSTRUCTION OF MATHEMATICAL OBJECTS

Research has seen conceptual understanding of number as the cognitive construction of objects (such as number, relations and functions) and many researchers, including Dubinsky (1991); Sfard (1991); Gray & Tall (1994), have modelled this construction in terms of a process-object duality. Tall, Thomas, Davis, Gray & Simpson (2000) provided a thorough examination of the differences between these duality models but key to these is the notion of encapsulation (Dubinsky, 1991) or reification (Sfard, 1991).

In particular Gray and Tall's (1994) and Sfard's (1991) work points towards an initial focus on counting processes in children's learning in arithmetic. Sfard (1991) described a reliance on 'count all' where children count out each set. For example $3 + 4$ becomes 1,2,3 add 1,2,3,4. That is each number is seen as a process. This is distinct from a 'count-on' strategy, for example $3 + 4$ becomes 3 'count-on' 4,5,6,7. In this strategy three is seen as a cardinal number or object that can be 'counted-on' from. From Sfard's perspective, three is reified as an object. From Gray and Tall's perspective children see the symbol for an operation as both a process and a concept, or, in other words, as a *procept*.

It is proposed that, in order for children to progress in their use of calculations, they need to see this *dual nature*. This becomes key to children's development of flexible strategies beyond counting, and children's use of known facts to derive solutions to other calculations. This requires the knowledge of a small set of memorised facts that can be used flexibly. Gray and Tall distinguished between a *proceptual* known fact and a rote learned fact and how this knowledge is based on the notion of encapsulation or reification. In this way children will see the example $3 + 4$ not only as a process, but also as a known fact that can be used as a reified object to derive new facts.

Much of the work on process-object duality has been based on neo-Piagetian constructivist theories. These theories are concerned with "the building (of the notion) of a mathematical object as a cognitive process that involves the learner's construction of adequate cognitive structures" (Dorfler, 2002, p.340). The project that this paper refers to examined the introduction of a didactical tool based on exploratory talk and collaboration in mathematics tasks. Such an intervention is based on neo-Vygotskian socio-cultural theories and a participatory perspective of learning in mathematics (Sfard, 2001).

Within a constructivist perspective discourse is seen to describe mental images of objects. It is possible to "ascertain whether an individual has constructed a mental object" and how the use of language indicates if an individual is conceiving the object (Tall et al., 2000, p.230). Within a socio-cultural perspective the focus is on cognition as discourse rather than on the use of discourse to understand specific examples of cognition. Speech is not only seen as a window to the inner mind to

look at the representations stored there, but speech and thought are seen as inseparable (Sfard, 2001).

The examination of the use of collaborative group work as an appropriate didactical approach in mathematics would require the investigation of how an individual develops thinking within a social context. This suggests working between socio-cultural theories that relate to participation and neo-Piagetian theories that relate to the individual. Cobb proposed the notion of *bricolage*, adapted from Gravemeijer (Cobb, 2007), where ideas are used from different theoretical perspectives to study diversity in children's mathematical thinking within the social context of a collaborative activity. Such an approach would seem appropriate in this study.

THE STUDY

The project was based on a design experiment (Cobb, Confrey, diSessa, Lehrer & Schauble, 2003). It aimed to set up an intervention based on exploratory talk (Mercer et al, 1999) as a didactical tool with young children (ages 6-7) who were seen as low attainers in mathematics. Exploratory talk is typified by “a way of using language effectively for joint, explicit, collaborative reasoning” (Mercer et al., 1999, p. 97). Participants negotiate their understanding through constructive challenging discourse. It was anticipated that the use of exploratory talk would support children's participation in mathematics through collaborative reasoning and negotiated understanding.

Twelve teachers worked with the research team over two school terms to develop strategies to introduce exploratory talk and to trial mathematical tasks. Our aim was to analyse the group interactions and the learning of arithmetic that took place through the introduction of exploratory talk. The teachers were asked to select six focus children in each class and to engage the six children in talk and mathematics activities at least twice a week. This was managed in small groups of three children.

This paper presents excerpts from a group activity of one of the triads: Eric, Lydia and Amy. None of the children were recognised officially as bilingual learners but the teacher had identified them as lower attaining, with low confidence in their mathematics and poorer communication skills than other children in the class. Diagnostic tasks, based on those developed by the Shropshire Mathematics Centre (1996), were carried out with the focus children pre- and post-intervention. The pre- and post-tasks for addition carried out with the three children are shown in Table 1.

In the pre-tests Eric relied on ‘count-all’ strategies. Amy used a combination of ‘count-all’ and ‘count-on’ but also used an incorrect strategy. Lydia used ‘count-on’ strategies but did not always use these accurately. The post-tests indicated that the children still had a reliance on counting strategies but that there was some progression in accuracy and in the use of count on strategies and known facts. Lydia was more accurate in her use of strategies, she used known facts and made less

Working Group 2

errors. Eric used more efficient count-on strategies. Amy used a more efficient strategy of counting on from the larger number. There is no attempt to present these results as evidence that the use of talk has supported children in their calculation strategies in a general sense. We have to acknowledge that the teaching may have benefited the children even if the talk strategies had not been introduced. However it does indicate that the children made some progression and in this respect it is worth looking at the mechanisms involved in a cooperative group activity.

	Lydia pre-task	Lydia post-task	Eric pre-task	Eric post-task	Amy pre-task	Amy post-task
5+7	Count-on	Count-on	Known fact	Count-on	Count-all	Known fact
7+8	Count-on with error	Count-on	Count-all	Count-on	Count-all	Count-on from larger number
6+9	Count-on	Use of known fact	Count-all	Count-on	Count-on	Count-on from larger number
10+8	Count-on with error	Known fact	Count-all	Count-on	Count-on	Count-on
8+13	Count-on with error	Count-on with error	Count-all	Count-on	Incorrect strategy	Count-all
15+6	Count-on with error	Count-on with error	Not given	Count-on	Not given	Count-all

Table 1: Calculation strategies in pre- and post-intervention diagnostic tasks.

This paper presents an example of one group activity with the three children. The activity took place towards the end of one term's intervention. The task was to construct a rectangle of sixteen dominoes where each join gave a total of six. An example of a possible solution is shown in figure 1.

It had been found that tasks with little or no recording supported collaborative work better. The dominoes provide a set of manipulatives that could be used by the group to arrive at a solution together. The dominoes themselves present arrays of dots that can help children in using counting and patterning ability to develop conceptual subitising as a basis for addition (Clements, 1999). Through the familiar patterns numbers can be seen as both composite parts and as a whole. The arrangement of the dominoes in a rectangle also gave a geometric problem to solve. The children were given a worksheet with the outline

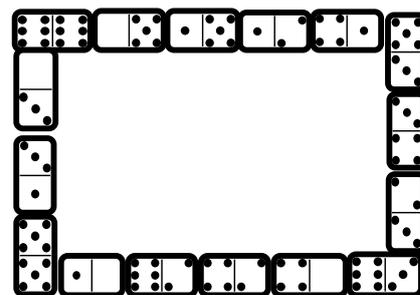

Figure 1: Domino activity.

Working Group 2

of blank dominoes and they used this as a template to help them organise the structure of the rectangle.

The transcript from the activity is presented in excerpts. Excerpt 1 shows the teacher modelling how to complete the task. The children are asked to agree on which domino to use next. Amy and Eric both predict a two, apparently without counting the dots and Amy selects a domino with a two. Lydia changes Amy's (correct) domino with her own. Amy then sits back from the task whilst Lydia places the next dominoes. Amy continues to observe the activity but does engage again later (see excerpt 4). Eric predicts the dominoes that are needed next. He states 'And four, there's four' and also 'Then we need a six'. Lydia expresses disagreement with a defiant 'No' or 'No, no, no...' It would seem she is checking the domino is correct by counting the dots. However, she counts all the dots on the dominoes and not just the joins. In the last line she realises the need to count the joining dots and agrees that the join makes six.

Transcript excerpt 1:

Teacher:	The next one you've got to put sideways like that. So the four needs a what to go with it? It's got to go down there but what will it need?	Teacher points to show position on the table
Amy:	Two.	
Eric:	A two.	
Teacher:	See if you agree then what one to put.	Amy places domino with a two.
Lydia:	No (Amy inaudible), two. Five and one more.	Lydia removes the domino and replaces it with another domino (two and five). Lydia places the next domino (one and two).
Eric:	And four, there's four.	Eric points to domino (four and zero). Lydia places the domino.
Eric:	Then we need a six	Eric refers to the next domino needed.
Lydia:	No, no, no, no ... I think 1,2,3,4,5,6,7. That's seven. Ah... 5,6...1,2,3,4,5,6. Yeah that's right.	Lydia counts the previous domino (one and two) with the four of the current domino. She then changes to count the two and the four.

In excerpt 2 Eric, again, predicts the next domino but Lydia ignores this and selects an incorrect domino. Eric challenges this by saying 'You think that is going to make a six with a zero?' and offers a correct domino. Eric does not justify his choice and Lydia does not appear to question the use of the six or count the dots to verify.

Working Group 2

Transcript excerpt 2

Eric:	We need a six, we need a six.	Eric refers to the next domino to go with the zero.
Lydia:	Another zero.	Lydia handles a domino but rejects it.
Eric:	That one I think.	Eric points to two different dominoes that have a six.
Lydia:	We need a one.	Lydia places a domino with a one next to the zero.
Eric:	You think that's going to make a six with a zero? (Lydia shakes head). Well get a six then, get a six like that.	Eric holds up a domino (six and five). Lydia places the domino.

In excerpt 3 this routine is almost repeated as Eric predicts the next domino, Lydia ignores this and selects an incorrect domino. Eric challenges this and presents Lydia with a correct domino. Again the error is when one addend is zero and we can only speculate that this causes confusion for Lydia. Lydia does not appear to verify that the six is correct by counting and accepts Eric's offer of a solution.

Transcript excerpt 3:

Eric:	One.	Lydia has placed domino (one and zero).
Eric:	Six.	Eric picks up domino with six but
Lydia:	Now we need a three.	Lydia places a domino with three.
Eric:	You mean that's going to make a six with a zero?	Eric holds up domino (six and four). Lydia removes domino with three and Eric places domino (six and four).
Lydia:	No. (Shakes head).	
Eric:	Two.	

In excerpt 4 Amy has rejoined the activity. She predicts the correct number of dots and checks by counting them. Eric also confirms the 'two and a four' but does not count these out. When Amy places the next domino this is challenged by Lydia using a similar question to Eric's. In this case her challenge is not supported by Eric or Amy.

Transcript excerpt 4:

Amy:	Ahhh, I know... two, four. 1,2,3,4,5,6	Amy picks up domino with four and counts the two dots and the four.
Eric:	Two, four. Two and a four.	Amy places domino (four and three).
Amy:	Ahhh, three	Amy places domino (three and zero).
Lydia:	You think that's going to make a six?	
Eric:	Yeah.	

Working Group 2

In excerpt 5 the children complete the rectangle. Lydia counts all the dots on both dominoes in trying to decide if the correct domino has been used and arrives at the total of 12. Eric then counts the dots that are joining and Lydia accepts this. As the children place the last domino in the rectangle Amy states that ‘the two is on there’. It may be that she is referring to the final join (a two has been placed next to a one). Eric points to the use of a two elsewhere to suggest that this is possible.

Transcript excerpt 5:

Eric:	We need a six again	Refers to the zero on the current domino. Eric points to domino (six and three). Lydia places domino.
Eric:	Now we need a three	Eric picks up domino with three and two.
Lydia:	That’s twelve.	Lydia counts all the dots on both dominoes.
Eric:	1,2,3...4,5,6.	Eric counts the two lots of three dots. Lydia places domino (three and two).
Amy:	But the two is on there.	
Eric:	Yeah but look.	Eric points to another domino in the rectangle that has a two.

ANALYSIS AND DISCUSSION

The use of discourse in analysing children’s mathematics presents problems in how to ‘read off’ or interpret what learners are thinking (Barwell, 2009). In the transcript from this study it is not entirely clear how the children have understood the task and if they are involved as the teacher intended. The task presented a geometric problem as well as arithmetic and at times it seems the focus of the discourse is on making the rectangle rather than finding the complements to six. The children miss the final join (although it is possible that Amy noticed this) so do not find a complete solution. However an assumption is made that the children follow the rule of making joins that add to six, at least up to the final join.

In analysing the transcript in relation to collaboration there are occasions that suggest lack of cooperation, for example when Lydia rejects Amy’s selection of domino in excerpt 1, but the children do work together to complete a rectangle following the rule. Analysis from a linguistic perspective does not indicate the children’s engagement with the characteristics of exploratory talk (cooperating, challenging and justifying) explicitly. For example, only the teacher uses the word ‘agree’ and there is little evidence of words indicating justification, for example the word ‘because’ is not used. However the children do appear to justify the use of dominoes by predicting or pointing to an example. At one point the phrase ‘Yeah but look’ is used alongside pointing. The children also verify the use of a domino by

counting the dots. The children do offer solutions and Eric is particularly proactive in this. He uses the term 'We need a six' and also 'That one I think'. There is evidence of children challenging ideas and Eric uses the terms 'You think' and 'You mean' when challenging Lydia's choice of domino.

Participation in a social context suggests the establishment of routines (Sfard, 2008). In the transcript we can see development of routines. For example, a problem is initiated 'So the four needs a what to go with it?' There is the offer of a possible solution 'A two', 'We need a six'. The children then select the appropriate domino. In some cases the selection is verified through counting, on other occasions the selection is challenged. In effect the challenging also becomes a routine and Lydia attempts to imitate this (albeit at an inappropriate point). It is noted that participation may not always involve active engagement in the discourse. Amy sits back from the task in excerpt 1 and does not rejoin until excerpt 4. However from the video data she can be observed watching the other children until she comes in with her prediction 'Ahhh, I know, two, four...'

How much can we see children working with numbers as processes and objects? In selecting the appropriate domino the children are finding an unknown number, the number that complements to make six. In this way the number is held as an object. This is modelled by the teacher as she asks 'So the four needs *a what* to go with it?' Here the teacher uses the indefinite article 'a' and refers to the unknown number as a noun. The term 'We need *a...*' (for example 'we need *a six*') is used frequently by the children, and maybe they are following the model of the teacher. Dorfler (2002) has suggested that the use of language provides means to express something as an object, such as the use of nouns. Dorfler also notes the use of actions on objects, such as the use of verbs. The children are often engaged in the action of counting and also use the phrase 'You think that is *going to make...*' suggesting that there is a use of actions on objects.

In determining the correct domino the children appear to use two strategies, either prediction, commonly used by Eric, or checking by counting, as used by Lydia. The dominoes allow the use of conceptual subitising as an early form of addition. It is possible that Eric, who is able to predict the next domino without counting, is using this strategy. Amy also shows some ability to predict but then counts to check. Lydia does not appear to use conceptual subitising as she does not predict any domino and relies on counting to verify any domino's correct use.

SUMMARY

It would seem that the use of exploratory talk as a didactical tool has enabled the three children to work together with a level of cooperation and that this cooperation leads to participation in mathematical routines. Collaboration and participation has engaged the children in solving a problem related to finding complements as an unknown number. This number is often referred to as a noun or object and the children use processes in determining and verifying the object. The familiar arrays represented on the dominoes can support the use of conceptual subitising and this is particularly evident with one child.

The premise of the study was that collaboration and participation in mathematical activities would support cognitive structures and in particular a proceptual knowledge. By reviewing the children's mathematics within the social context of the collaborative group work we have been able to consider the diversity of their approaches (Cobb, 2007). However this is not to say that each child's acquisition of the strategies can be determined from their participation. When a child used a process of counting it could be as a means of justification to others, not that they needed to count. The diagnostic pre- and post- tests aimed to acknowledge the children's diverse use of strategies. From these we can see how the children differ in their reliance on procedures in relation to concepts and this would seem to be reflected in the children's individual approaches. It may be too big a leap to suggest that such collaborative strategies have supported these changes but there is some initial evidence to show that the children were participating in arithmetic that involved both processes and objects and asked them to work with number in a proceptual way.

A THEORETICAL MODEL FOR UNDERSTANDING FRACTIONS AT ELEMENTARY SCHOOL

Aristoklis A. Nicolaou and Demetra Pitta-Pantazi

University of Cyprus

In the present study we propose a theoretical model for understanding a concept of elementary school mathematics. We selected fractions for examining our model. Our theoretical model consists of six factors: inductive reasoning, explanations, justifications, conception for the magnitude of fractions, representations and connections with other concepts. The fit of the model was tested in a sample of 344 fifth and sixth grade elementary school students using confirmatory factor analysis and it was found to have very good fit with the empirical data. The results suggest that the proposed model is much comprehensive of the factors suggested for understanding fractions at the elementary school.

Keywords: theoretical model, understanding fractions.

INTRODUCTION

Various theoretical models have been proposed for the learning and understanding of fractions (Kieren, 1976; Behr, Lesh, Post, & Silver, 1983; Lamon, 1999; Pirie, 1994; Mack, 1990). Kieren (1976) proposed a model with five interrelated subconstructs of fractions: part-whole, ratio, operator, quotient and measure. Later on Behr et al. (1983) further developed Kieren's ideas, proposing a theoretical model linking the different interpretations of fractions to operations on fractions, fraction equivalence and problem solving. Lamon (1999) also studied fraction understanding from the perspective of fraction subconstructs. Pirie and Kieren (1994) proposed a dynamic model with levels of understanding and described key features of the model they proposed. They then used the concept of fractions to justify and explain the levels they proposed. Mack (1990) in a similar manner proposed a "more general" model which stresses the importance of students' informal knowledge towards understanding mathematical concepts, and she then examined how students' informal knowledge can be used to give meaning to fractions symbols and procedures. What we attempt in this study resembles more to the work of Pirie and Kieren (1994) and Mack (1990), i.e. we first developed a model of what constitutes mathematical understanding at the elementary school and we then examined the proposed model specifically for the concept of fractions. For the purpose of this study, we consider the term "understanding" to include conceptual understanding as well as procedural understanding.

What this study *adds* to the existing research on fraction understanding is that it seeks of those *crucial factors* that constitute understanding of fractions. By the term crucial factors we refer to those competencies that students must possess in order to understand fractions. At the same time, we encompass in the proposed model a sufficient number of factors so that they explain *as much proportion* of mathematical

understanding as possible. It must be noted that the proposed model lays in the cognitive, epistemological and semiotics domains, therefore we seek of crucial factors in the context of those domains. Of course we admit that it is impossible to include all the factors that are required for mathematical understanding. The added value of the proposed model is also situated in that it encompasses factors of mathematical understanding that were considered important by the mathematics education research and were included in national curricula (e.g. NCTM, 2000). In the section that follows the rationale for formulating the proposed model and the selection of the specific factors is explained in more detail.

THEORETICAL BACKGROUND AND AIMS

The proposed theoretical model

We consider that the factors that constitute understanding of fractions are: inductive reasoning, definitions and mathematical explanations, argumentation and justification, students' conception about the magnitude of fractions, representations and connections of fractions with other concepts. There are two reasons for selecting those factors. The first reason is that researchers in the field of mathematics education stress the importance of factors such as inductive reasoning (de Koning, Hamers, Sijtsma, & Vermeer, 2002), mathematical explanations (Levenson, Tsamir, & Tirosh, 2007; Niemi, 1996), argumentation and justification (Duval, 1992/1993), conception about the magnitude of fractions (Clarke & Roche, 2009), representations (Newstead & Murray, 1998; Niemi, 1996; Gagatsis, Michaelidou, & Shiakalli, 2001; Lesh, Post, & Behr, 1987) and connections of fractions with other concepts (Sweeny & Quinn, 2000; Oppenheimer & Hunting, 1999) for fraction understanding. The second reason is that national curricula (e.g. NCTM, 2000) refer to processes such as reasoning, communication, representations, and connections with other concepts that students should acquire in order to understand mathematical concepts. It should also be noted that all the aforementioned factors refer to fraction understanding both conceptually and procedurally. For example, inductive reasoning refers to processes (finding similarity, dissimilarity and integration attributes) that students need to apply (procedural knowledge), but at the same time, students should know why they apply those processes (conceptual knowledge), and these processes should be meaningful to students (Hiebert & Lefevre, 1986).

In the space below, we provide description of each factor with special reference to its importance for fraction understanding.

1. Inductive reasoning

Inductive reasoning is defined as the process that permits the extraction of general conclusions or rules from specific cases (Demetriou, Doise, & van Lieshout, 1988). Consequently, via inductive reasoning generalization can take place, the role of which is essential for understanding mathematics and the world. Especially for

understanding fractions at the elementary school level, where students' thought is at the concrete level and they use a plethora of manipulatives and materials, inductive reasoning is essential, since it permits the extraction of general rules and conclusions from specific examples. For example, the equal partitioning of a piece of chocolate, of a surface or of a group of objects can lead to the identification of the concept of fraction (de Koning, et al., 2002).

2. Definitions and mathematical explanations

The ability of communication and use of language is very important according to NCTM Standards (NCTM, 2000) for understanding fractions. A lot of researchers have stressed the importance of definitions and mathematical explanations for learning and understanding mathematical concepts (Levenson, et al., 2007; Niemi, 1996). Literature review did not reveal any information as regards definitions of fractions by elementary school students. We will consider for the purpose of the present study that elementary school students can "define", but by defining we do not mean the formal definition that is required by elder students. We will consider that students can define fractions if they can express in their own words what is the meaning of the fraction, e.g. what a fraction is. Students can define either verbally or with the use of drawings, symbols and diagrams. Also, apart from those tasks that require definitions (e.g. what is a fraction), students might use more than one ways to explain other issues regarding fractions, e.g. when two fractions are equivalent.

3. Argumentation and justification

Reasoning and proof are considered important factors of what constitutes understanding mathematical concepts (NCTM, 2000). According to NCTM (2000), elementary school students should be able to develop and evaluate mathematical arguments and proofs and select various types of reasoning and methods of proof. Since formal proof cannot be the case for elementary school mathematics, argumentation and justification could "substitute" what we call formal proof in the upper level of education.

Argumentation can be defined as students' ability to recognize the truth or the falsehood of a mathematical statement (Duval, 1992/1993). At the same time, students have to justify their answer. Argumentation and justification are very important because they can reveal students' conceptions about fractions, their knowledge of fractions and their errors. For example, an argument referring to what happens to the size of a fraction when increasing or decreasing the numerator and the denominator could serve as an indicator of students' understanding of fractions. Students' answers in this case will show if they understand that a fraction is a relation and not see the nominator or the denominator as two different numbers having no connection between them. We will consider that for the purpose of the present study students can justify their answer by providing numerical examples or by means of a "more general rule". More sophisticated levels of justification would provide an insight into students' understanding of fractions.

4. Conception for the magnitude of fractions

Students' sense for the magnitude of fractions is crucial for understanding, since in the case a student cannot perceive that $\frac{1}{4}$ is smaller than $\frac{1}{3}$, then he/she probably does not understand the meaning of these fractional numbers and fractions in general. It is very common for some students to consider the nominator and the denominator of a fraction as two different numbers that do not constitute a unique entity, i.e. the fraction. Conception about the magnitude of fractions is essential for comparing and ordering. According to Clarke and Roche (2009), a number of researchers have highlighted the importance of students being able to give meaning to the size of a fraction and the many difficulties associated with doing so.

5. Representations

Representations are very important for understanding the concept of fraction (Lesh et al., 1987; Newstead & Murray, 1998; Gagatsis, et al., 2001). In the context of teaching fractions, children come across a great variety of representations. Further to the recognition and flexible use of various representational systems, a basic goal of teaching and learning fractions should be the development of ability to translate from one form of representation to another (Lesh, et al., 1987). Gagatsis et al. (2001) claimed that the ability to shift from one kind of representation to another is especially important for fraction understanding.

For the purpose of developing the proposed model, we consider that a student understands the concept of fraction if he/she is able to translate to iconic, symbolic and verbal representation and if he/she is able to construct drawings for fractions.

6. Connections of fractions with other concepts

Students face serious difficulties in connecting the various forms of rational numbers (Sweeny & Quinn, 2000). It is argued that students' ability to convert from one kind of rational number to the other is an indicator of understanding rational numbers (Oppenheimer & Hunting, 1999). Moreover, it seems that students' ability to see fractions as division of the numerator by the denominator is an indicator of understanding fractions (Newstead & Murray, 1998). Newstead and Murray (1998) have reported students' difficulties in doing so, thus their difficulties in understanding fractions.

For the purpose of this study, we consider a student to be adequate in connections, if he/she is able to link the concept of fraction with the concepts of decimal numbers, percentage and division of integers (division of the numerator by the denominator).

Aim

The aim of this study was to develop and empirically test the theoretical model for understanding a concept of elementary school mathematics described in the previous section. The concept of fractions was selected for testing the model in a sample of students at the upper level of elementary education (fifth and sixth grade students).

METHODOLOGY

A test was developed for measuring the six factors considered to constitute understanding of fractions. The test was broken into two parts, since 65 tasks were needed for measuring all the factors and students would need a large amount of time to solve all the tasks at one administration. All students solved the two parts of the test. In Table 1 below, we give an example of an item for each of the six factors.

Tasks 1-7 (task 4 had two sub-tasks 4a, 4b) were used to measure inductive reasoning and were similar to the tasks developed by Christou and Papageorgiou (2007) for finding similarity, dissimilarity and integration attributes and relations. Tasks 8-13 were used to measure definitions/mathematical explanations and some of them were used by Niemi (1996) for measuring explanations as regards the concept of fraction. In tasks 14-20 statements about fractions were presented to students and they had to judge them as right or wrong and explain their way of thinking. We considered that in this way students would provide an argument about their choice and justify their choice to judge the statement as right or wrong. Some of the tasks for argumentation/justification were similar to tasks proposed by Lamon (1999) while discussing reasoning with fractions and some other tasks were used by Niemi (1996). Tasks 21a-21f and task 22 were used to measure conception about the magnitude of fractions. Tasks 21a-21f referred to fraction comparison, whereas in task 22 students had to put four fractions in the right order starting from the smallest one. Similar tasks were used by Clarke and Roche (2009) for comparing and ordering fractions. Tasks 23, 25 and 26 were previously used by Niemi (1996) and involved recognizing fractions in iconic form. Tasks 24, 30, 32 and 33 referred to writing problems that have a fraction as an answer, from an equation or on the basis of a drawing (translating to verbal representation). Tasks 27, 31, 35 and 37 asked students to construct their own drawings to show a fraction, for an equation of adding fractions and for two problems involving fractions. Tasks 28a-28f asked students to select the right fraction that could be represented by pictures (translation to symbolic form, similar tasks were used by Niemi, 1996). In tasks 29a-29c number lines were presented to students and they had to select the right fraction for each. In tasks 34 and 36 students had to solve two problems of addition and multiplication of fractions and they had to write the equation for each. Finally, in tasks 38a-38f students were asked to convert fractions to decimals, in tasks 39a-39f they had to convert fractions to percentages, while tasks 40a-40c and 41 were about the relation of fractions with the division of integers.

The test was administered to 344 fifth and sixth grade students (119 fifth grade and 225 sixth grade) from 11 different schools in Cyprus (both urban and rural areas were represented). The time period for administration was the end of the school year, so that both fifth and sixth grade students had covered the notions included in the model. The test was administered by the classroom teachers who were requested to provide no further clarification and ask students to work on their own.

Table 1: Examples of items for each of the six factors

Inductive reasoning	<p>One of the following fractions differs from the others. Find that fraction and circle it.</p> $\frac{2}{7} \quad \frac{3}{2} \quad \frac{14}{49} \quad \frac{10}{35} \quad \frac{4}{14}$		
Definitions/mathematical explanations	<p>Imagine that your teacher asked you to explain to one of your classmates what a fraction is. Use as many different ways you can.</p>		
Argumentation/Justification	<p>If I double both the numerator and the denominator of a fraction, then the formed fraction has twice value compared to the initial one.</p> <p>Justify your answer: . <table border="1" style="display: inline-table; vertical-align: middle;"><tr><td style="padding: 2px 10px;">T</td><td style="padding: 2px 10px;">F</td></tr></table></p> <p>.....</p>	T	F
T	F		
Conception about the magnitude of fractions	<p>Put the fractions $\frac{1}{2}$, $\frac{4}{3}$, $\frac{2}{3}$, $\frac{1}{4}$ in order starting from the smallest one.</p>		
Representations	<p>Write a problem that could be solved by the equation $+\frac{1}{2} n \frac{1}{4}$</p>		
Connections of fractions with other concepts	<p>Convert the following fractions to decimals.</p> <p>a) $\frac{1}{4} =$ b) $\frac{2}{5} =$ c) $\frac{3}{10} =$ d) $\frac{1}{20} =$</p>		

The answers were coded on the basis of a coding scheme. Some tasks were marked either with 0 or 1 (categorical variables), whereas in other tasks the score could vary from 0 to 1.

For testing the fit of the proposed model, confirmatory factor analysis using MPLUS software was used with WLSMV estimator, since this kind of estimator is the most appropriate for categorical variables (Muthén & Muthén, 2004). More than one fit indices were used to evaluate the extent to which the data fit the theoretical model under investigation. More specifically, the fit indices and their optimal values were: (a) the ratio of chi-square to its degrees of freedom, which should be less than 1.96, since a significant chi-square indicates lack of satisfactory model fit, (b) the Comparative Fit Index (CFI), the values of which should be equal to or larger than 0.90, and (c) the Root Mean Square Error of Approximation (RMSEA), with acceptable values less than or equal to 0.06 (Muthén & Muthén, 2004). Moreover, confirmatory factor analysis was used to examine construct validation and “evaluate

the extent to which particular instruments actually measure one or more latent variables they are supposed to assess” (Marcoulides&Kyriakides, 2010, p. 279).

RESULTS

After subsequent model tests, the model shown in Figure 1 proved to have very good fit to the data ($\chi^2=338.478, df=198, \chi^2/df=1.71, CFI = 0.971, \text{ and } RMSEA = 0.045$)

From Figure 1, we verify that the factors we consider to constitute understanding of fractions do so very well (the fit indices are very good). Three of the factors and more specifically inductive reasoning, definitions/mathematical explanations and argumentation/justification seem to constitute a second order factor which contributes to understanding fractions. We will call this second order factor as “reasoning and informal proof” at the elementary level. Figure 1 also confirms that verbal, symbolic, iconic representations and students’ ability to construct their own drawings for fractions constitute the factor “representations” which in turn constitutes understanding fractions. In the same manner, connections of fractions with decimals, percentages and division constitute the factor “connections of fractions with other concepts” which also constitutes understanding of fractions.

Figure 1: The proposed model for understanding fractions

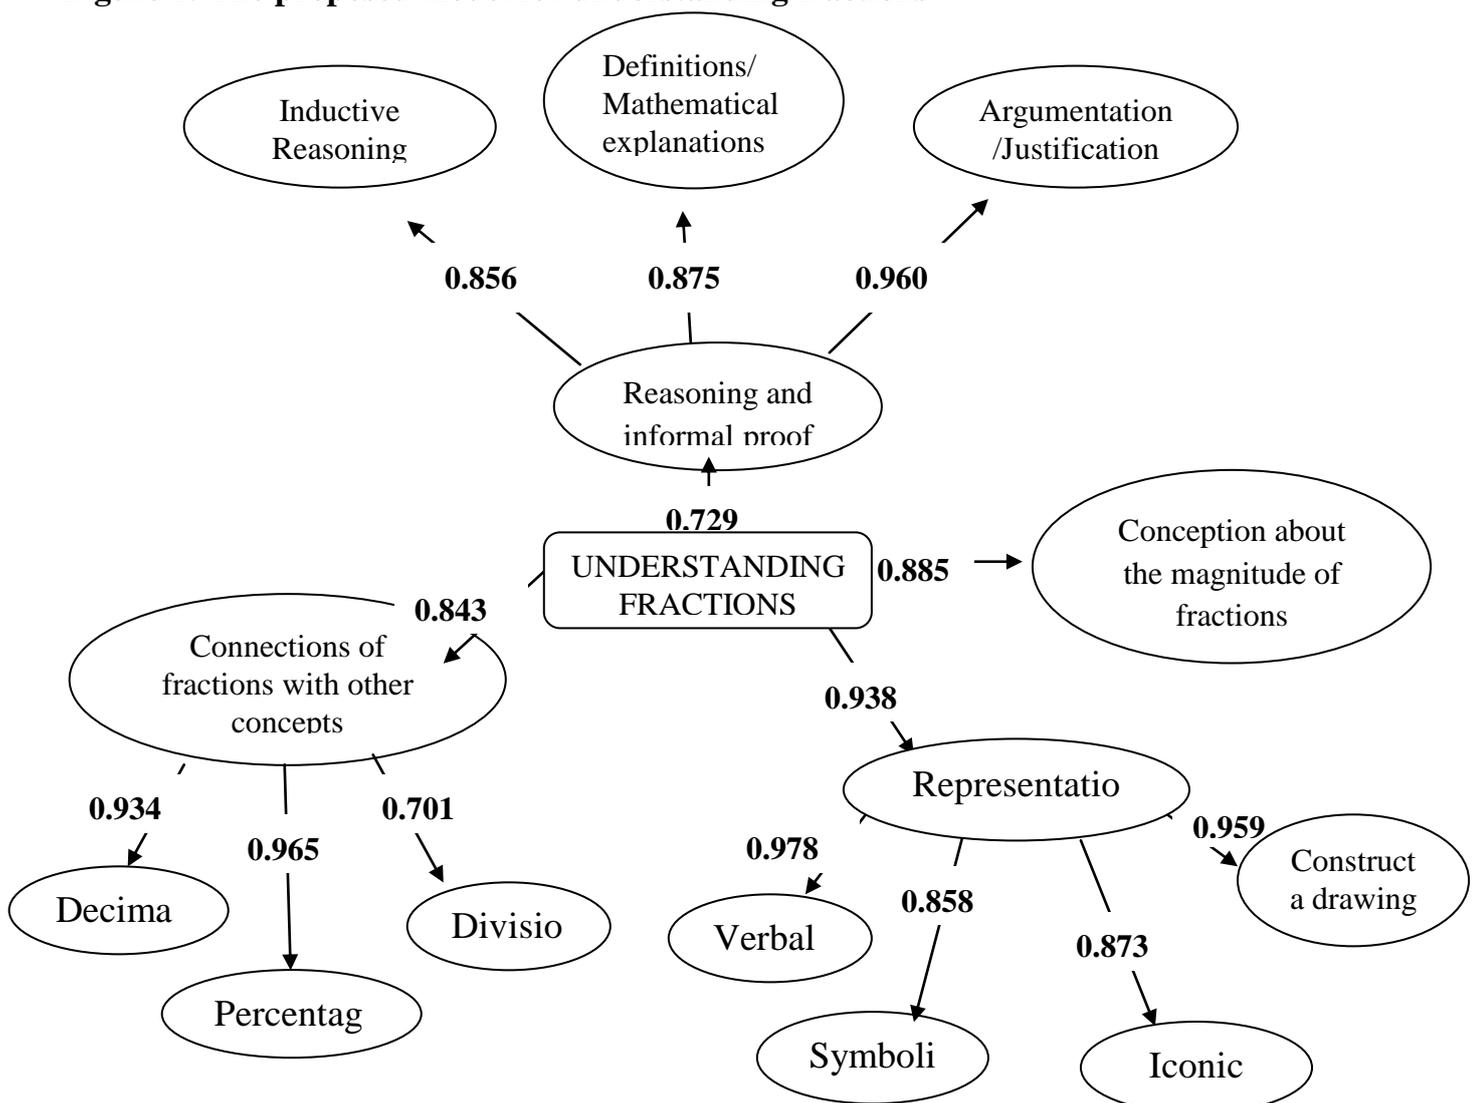

Figure 1 shows that representations have the highest contribution towards understanding fractions, followed by the conception about the magnitude of fractions, connections of fractions with other concepts and “reasoning and informal proof”. The coefficients could serve as an indicator of the importance of each factor for understanding fractions. Moreover, the square of the coefficient shows the percentage of variance of fraction understanding that is explained by the corresponding factor. For example, representations account for about 88% of the variance of fraction understanding. As regards the validity of the instrument used in the present study, this is ensured by the results of the confirmatory factor analysis, since all fit indices had optimal values ($\chi^2/df=1.71<1.96$, $CFI = 0.971>0.9$, and $RMSEA = 0.045<0.06$). The optimal values of the fit indices provide evidence that the instrument measures the latent variables it is supposed to measure and overall provides a means for assessing fraction understanding (Marcoulides&Kyriakides, 2010).

DISCUSSION

The results of the statistical analysis confirmed our theoretical model and suggested that the six factors constitute understanding of fractions. Moreover, three of these factors constitute a second order factor which we call “reasoning and informal proof” at the elementary school. Therefore, we claim that for a student to understand fractions he/she should be able to engage to “reasoning and informal proof” as regards fractions, he/she should possess a conception about the magnitude of fractions, he/she must be fluent in representations and the translation from one kind of representation to the other and he/she must be able to connect fractions with other concepts.

The contribution of the factors was high (all loadings were greater than 0.7) showing that all factors had a considerable contribution towards understanding fractions. However, the contribution of representations was the highest (0.938), showing the great importance of this factor for understanding fractions, as other researchers have also claimed (Lamon, 2001;Lesh et al., 1987). The second factor in importance was conception about the magnitude of fractions with also very high loading, followed by connections with other concepts with a little bit less contribution. Therefore, both factors are considered important for understanding fractions. “Reasoning and informal proof” had the lowest contribution among the factors but it was high enough to stress the importance of this factor as well.

The findings of the present study are also important for assessment purposes as we have developed a validated test for assessing fraction understanding. Moreover, the present study provides a way for assessing representations and connections of fractions with other concepts. As shown in Figure 1, translation to verbal, iconic, and symbolic representations and the ability to construct drawings to show fractions comprise representations. In a similar manner, Panaoura, Gagatsis, Deliyianni, and Elia (2009) developed a model for understanding fraction addition. As regards

connections of fractions with other concepts, it can be claimed that for the elementary level, this can be assessed by measuring students' ability to convert fractions to decimals and percentages and by the relation of fractions with the division of integers (division of the numerator by the denominator).

The results indicated that inductive reasoning, definitions/mathematical explanations and argumentation/justification are highly correlated forming a second order factor. The relation of definitions/mathematical explanations and argumentation/justification was expected since terms such as explanations and justification are used interchangeably for reasoning at the elementary school and a relation of the two has been reported from other studies (Niemi, 1996). Explanations and justification can also provide a kind of "informal proof" at the elementary school. The relation of inductive reasoning to the other two factors can be explained by the fact that inductive reasoning is also necessary for reasoning at the elementary school.

The importance of the present study is situated in that it proposes a theoretical framework with factors that constitute understanding a concept of elementary school mathematics. In this study, fractions were selected as the concept under study. The results of the present study support our claim that we have "decomposed" understanding in factors that can be directly measured. Additionally, we believe that we have provided a sufficient number of factors to describe understanding.

Although the sample is high enough, in future the proposed theoretical model could be tested again, enhancing the validity and the reliability of the results. Moreover, from a teaching perspective, an intervention could take place for improving students' ability in the factors found to constitute understanding of fractions. Finally, the proposed theoretical model can be tested for *other concepts* beyond fractions.

BETWEEN ALGEBRA AND GEOMETRY: THE DUAL NATURE OF THE NUMBER LINE

Ildikó Pelczer

We analyze the statistical distribution of the answers given by 2nd to 10th graders to a set of number line problems. To structure our analysis of students' misconceptions, we identified three clusters of problems related to the number line. Our analysis shows that neglecting one of the main features of the number line can be a potential cause for misconceptions. By further exploring the students' mistakes, we found that children ignore either the geometric or the algebraic nature of the number line, making inappropriate decisions within the problem context. The errors in the problems treated within this paper seem to originate from students' lack of understanding of the dual nature of the number line, and are persistent over time.

Keywords: number line, cardinal, distance, origin, direction.

INTRODUCTION

There is a large body of literature that discusses children's early capacity of learning the numbers (e.g. Griffin & Case, 1997; Karmiloff-Smith, 1992; Singer, 2007). Children have strong primary perceptions related to the number line (Singer & Voica, 2008). Another category of neuroscience studies seems to conclude that the human mind possesses analogical representation of quantities, more precisely: numbers are automatically associated with positions in space, thus supporting the metaphor of a spatially organized internal "number line" (Dehaene, 1992, 1997; Dehaene & Cohen, 1995; Gobet, Walsh & Rushworth, 2001). However, beyond some native predispositions, students of various ages show deep conceptual difficulties in understanding the number line properties.

Formally, the number line concept includes the "empty number line" (see e.g. Beishuizen, 1999), which is filled in by taking into account three essential elements: direction, origin and unit measure. These three elements emerge from the combined nature of the number line: on the one hand, the geometric nature of its representation; on the other hand, its algebraic properties connected with the order relation on \mathbf{R} .

Ordering and direction have intuitive support from everyday experience. We acquire a basic level of understanding them by polarized descriptions of the type: bigger – smaller; taller – shorter; up – down, etc. In contrast, the origin is a theoretical construct: it is the „nodal point” that allows the construction of a reference system, endowed with a measuring unit conventionally chosen. This allows associating a number („algebraic object”) to a segment („geometrical object”). Thus, by

introducing the distance function, the number line (a geometric representation) is algebrized.

Because the number line is a basic concept, some of its features are neglected in teaching, being considered obvious. However, Booth & Siegler (2006) concluded that individual difficulties in learning the number line are correlated with lower achievement in mathematics. Their result suggests that there might be a long-term impact of these difficulties.

This paper emerged from the following questions: To what extent does the neglect of one of the three elements of the number line determine children's misconceptions in problem solving? Do these misconceptions appear in different grades?

METHODOLOGY

The data reported in this study come from the statistical results of a large contest that takes place every year in Romania. At this contest, of multiple-choice type, there is a yearly participation rate of around 250,000 students from grades 2 to 12, in total.

The tests in this competition consist of a range of 24 to 40 problems, depending on the school grade. The tests cover the whole school curriculum and present students with a considerable variety of problems. In order to limit guessing, wrong answers are penalized. In this way, children who do not know the correct answer to a question are in advantage if they do not answer that question, since the no-answer choice is not scored at all. For this reason, we consider that the statistical analysis of the answers can be highly informative about children's reasoning during the test.

For our study, we have chosen problems related to the number line that have (relatively) similar text or are based on similar solving mechanisms, and grouped them in clusters. Given the focus of our first question, the clusters have been built from mathematical considerations. We thus identified three clusters of number line problems and we looked at the distribution of the students' answers to the distracters of these problems.

In the present paper, we analyze the statistical distribution of the answers given by 2nd to 10th graders to a set of number line problems. We have chosen this vertical extension of the analysis in order to see changes in misconceptions as function of age. This vertical analysis helps us to see if the errors are influenced by a certain instructional focus. Although the curriculum recommends the frequent use of the number line, it is not a common practice in the Romanian classrooms in primary grades. The classical use of the empty number line happens in grade 4, when a diagram segment is used for solving some word problems (that usually leads to the use of equations). Frequently, this is learned as an algorithm. The formal number line is used by the math teachers starting with the 5th grade.

RESULTS

Our primary interest was to understand the mathematical sources of the students' mistakes. We looked especially at the problems in which the errors related to the properties of the number line (eventually cumulated) were higher than the percentage of correct answers. In the next sections of the paper, we focus on these problems to structure our analysis of students' misconceptions.

The “cardinal cluster”

The first cluster contains problems that request the finding of the cardinal of an ordered set; we call it the cardinal cluster.

Problem 1.1. (Grade 2, 38,917 respondents): From my story book some pages are missing. Where pages are missing, I see number 12 on the left page and number 15 on the right page. How many pages are missing?

(A) 1; (B) 2; (C) 3; (D) 4; (E) 5.

Problem 1.2. (Grades 3-4, 124,641 respondents): Ana found an old book from which some pages are missing. At the place where the pages were missing, there was the number 24 on the left page; while, on the right was 45. How many pages were missing?

(A) 9; (B) 10; (C) 19; (D) 20; (E) 21.

Problem 1.3. (Grades 5-6, 42,439 respondents): How many integers are there between 19.03 and 2.009?

(A) 0; (B) 17; (C) -17; (D) 19; (E) 17,021.

Problem 1.4. (Grades 7-8, 26,827 respondents): Harry brings the mail on Long Street. He has to distribute a letter to each house having an odd number. The first house has number 15 and the last 53. To how many houses did Harry give the mail?

(A) 19; (B) 20; (C) 38; (D) 39; (E) 53.

The problems from this cluster are alike since they ask to find out the length of a finite arithmetic progression of ratio 1 (problems *1.1*, *1.2*, *1.3*), or of ratio 2 (problem *1.4*). We noticed that, for each of these problems, the most frequent chosen answer refers to the computation of a length. In problem *1.1*, answer (C) comes up as the difference between 15 and 12; similarly in problem *1.2*, the wrong answer with the highest percentage is the one obtained from $45 - 24$. In the same way, in problem *1.3*, the distracter with the highest percentage has been generated by performing a subtraction. A special discussion is worth for problem *1.4*. While answer C is obtained by computing $53 - 15$, some of the students observed that the ratio is 2 and, therefore, they divided the result, thus obtaining answer A. Consequently, the answer A is also based on a reasoning that relies on the difference between two numbers. For this reason, we refer to the total of A and C choices as belonging to the same type of mistake. The statistical results are presented in Diagram 1.

Working Group 2

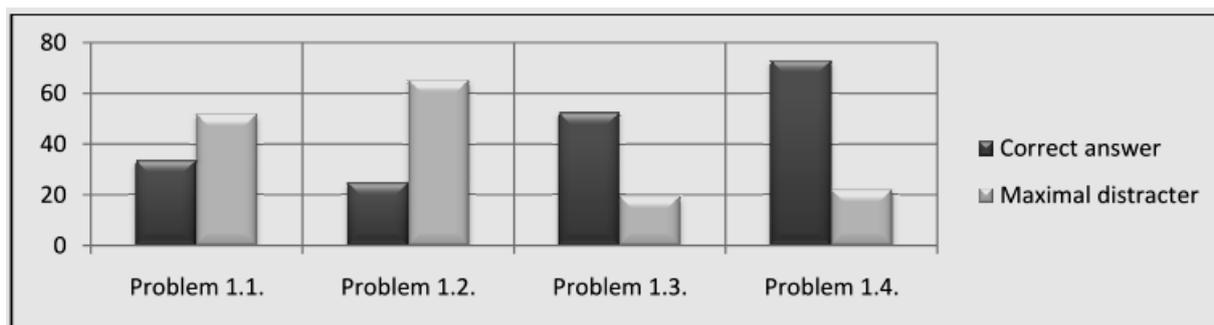

Diagram 1. Correct answers and maximal distracter for the cardinal cluster

Because students showed an obvious preference for the distracters based on subtraction, we wondered in what situations these subtractions are yet relevant to the problem solving process. In general, such operation leads to the determination of the distance between two points situated on an axis (that is, when the points are identified by their coordinates on the axis). Thus, for Cluster 1 problems, the unit measure becomes important: most of the students do not realize that they should work with a „discrete” unit (the number of integers) instead of a „continuous” measure (distance).

Consequently, we interpret these errors as due to the confusion children make between *cardinal* and *distance*. By further exploring the nature of this error, we concluded that the children’s mistake consists in adopting a *geometrical* solution (emphasized by the distance between the points) for a situation in which the answer is *algebraic* (based on “discrete” counting).

The “distance cluster”

To go deeply into this hypothesis, we focused on the second cluster, which we called the distance cluster. This second cluster contains problems in which one needs to find the distance between two points.

Problem 2.1. (Grades 3-4, 77,294 respondents): On the right side of an alley there are 9 street lamps. The distance between two neighbour street lamps is 8 m. John ran on the alley, from the first until the last street lamp. How many meters did John run?

(A) 48 m; (B) 56 m; (C) 64 m; (D) 72 m; (E) 80 m.

Problem 2.2. (Grades 5-6, 50,024 respondents): There are nine bus-stations, at equal distances, on a bus line. The distance between the first and the third bus-station is 600 m. What is the distance between the first and the last station?

(A) 1200 m; (B) 1500 m; (C) 1800 m; (D) 2400 m; (E) 2700 m.

Problem 2.3. (Grades 9-10, 19,327 respondents): The supermarket chariots are arranged in two lines. On the first line, 2.9 m long, there are 10 chariots, while on the second line, which is 4.9 m long, there are 20 chariots. What is the length of one chariot?

Working Group 2

(A) 0,26 m; (B) 0,9 m; (C) 1 m; (D) 1,1 m; (E) 1,4 m

(At the contest, the problem 2.3. had an illustration of the type seen above.)

The statistical results to the three above problems are presented in Diagram 2.

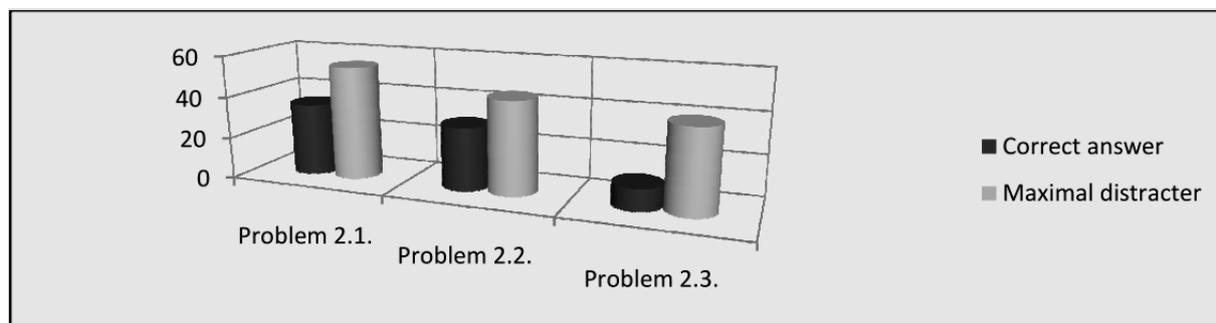

Diagram 2. Correct answers and maximal distractors for the distance cluster

The problems of this cluster are similar, each of them requiring the computation of a distance between two points of the number line. We can observe that in each of these cases, the most frequent error refers to the extrapolation of a proportionality relation between the discrete information (the ordinal of the „marking points” – street lamp/ bus stop) and data that are of a continuous nature (distance).

Because the proportionality-based reasoning was frequent in the sample population, we wondered in what situations this reasoning is certainly correct. The typical example for such situation would be the Thales' theorem, where one can transfer the ratio of segments situated on a line to segments situated on another line in conditions of homogeneity, meaning: the same unit of measure and, especially, the same origin (see figure 1).

$$\frac{OA}{OB} = \frac{OC}{OD}$$

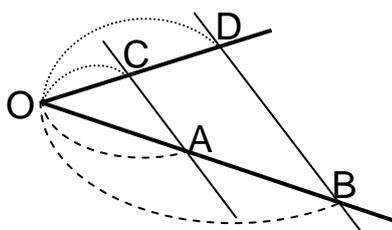

Fig. 1: A representation for the Thales' theorem

Obviously, in the cases of the analyzed problems, we work with different origins. Why the origin is so important? When computing the length of a segment situated on the number line, we choose an origin (usually one of the end of the segment) corresponding to 0. Therefore, when we position one of the segment's endpoint over 0, we perform a translation, which can be expressed through a single algebraic operation (i.e. subtraction). On the other hand, in order to find the cardinal of a (finite) set, we count its elements starting from 1; in other words, we chose the origin in 1. This positioning has no algebraic correspondent: if the reference points (initial and final) of the interval are a and b , then to position a in 1 means to change the coordinates of b into $b - a + 1$. Consequently, here we have two translations (first we

Working Group 2

take a to 0, then to 1), but children have difficulties in understanding how this succession of translations could be performed. The analysis of the second cluster shows that neglecting an essential element of the number line – namely the adequate positioning of the origin – can be a potential cause for misconceptions in algebra.

The “directions cluster”

What happens if children ignore another essential element of the axis? We look at the next cluster in order to find an answer. The third cluster was called the directions cluster given that the selected problems in this category require to handle two origins and, consequently, different directions for counting.

Problem 3.1. (Grades 3-4, 63,059 respondents): Radu and Maria went on a trip by train. Radu got his place in the 17th car from the beginning of the train; while, Maria got hers in the 14th car from the end of the train. They were surprised to see that they travel in the same car. How many cars did the train have?
(A) 28; (B) 29; (C) 30; (D) 31; (E) 32.

Problem 3.2. (Grades 5-6, 36,293 respondents): A staircase has 21 stairs. Mike and Nick count the stairs, the first from the bottom and the second from the top. They meet on the step that is the 10th for Mike. What is the number of this stair in Nick’s counting?
(A) 21; (B) 31; (C) 11; (D) 12; (E) 10.

Problem 3.3. (Grades 9-10, 16,692 respondents): Sally was in the 50th position on the list of the Kangaroo contest results when counting both in increasing and decreasing order. How many children participated in the contest?
(A) 50; (B) 75; (C) 99; (D) 100; (E) 101.

The statistical results of the three above problems are presented in Diagram 3.

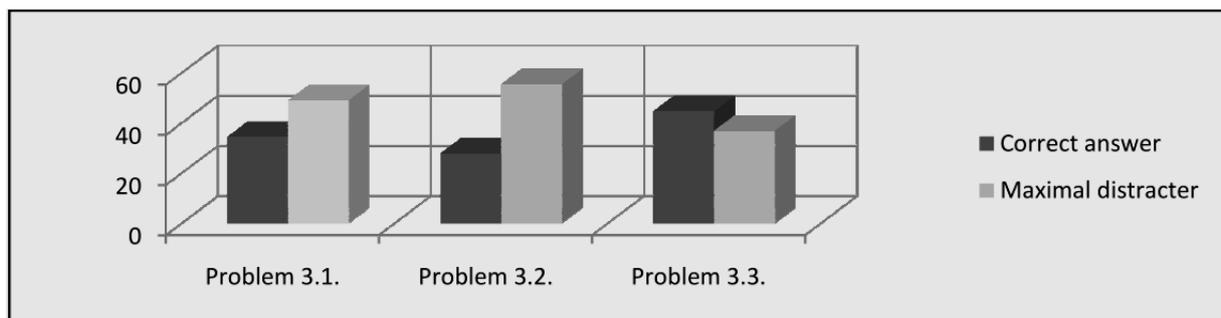

Diagram 3. Correct answers and maximal distracters for the directions cluster

These problems involve the relationship between the cardinality of a set and one of its subsets. From this perspective, the second problem is slightly different since we have the cardinality specified here and the task requests finding the number of elements when counting from two different origins. The typical error is given by performing a simple addition (or subtraction for the second problem) and it is linked to the idea that cardinality of a set can be obtained by summing up cardinalities of subsets. This type of reasoning is correct only for disjoint sets and children seem to

Working Group 2

forget that. Nevertheless, at a deeper level, their error is linked, once again, to the confusion between distance and the cardinal of the set of the marking points, thus to the geometrical and algebraic nature of the number line. When children sum up or subtract numbers, they work with distances on the number line, since the number is represented by its distance from the origin. But, in the above problems the questions focus on the marking points (in this sense, these problems are the opposite of the ones from Cluster 2) and play on the fact that one of the marking points is common to the two “countings”, therefore it does not define a new distance.

Most of the above tasks are of a special kind, which for many students can be understood as a trap. However, the pattern of wrong answers shows that the “trap” is not enough to explain the error. It is possible to consider that the trap invites the mistake, but actually the mistake is made by a misconception.

We conclude that, in general, the above problems cause difficulties to children because they request to see the dual nature of the number line, which is not explicitly highlighted by the information given in the texts. For example, in Cluster 2, the information is given by using “marking points”, which induces a mental image based on the geometrical interpretation of the line, but the question focuses on distances, which add an algebraic dimension. For the correct solution, one should be able to make a transfer, but for most of the children this is not evident. Therefore, they “continue” to reason in the frame that is induced by the problem text. We can see the same pattern of answers in Cluster 3: briefly, the source of errors consists in operating with distances and not with cardinals, therefore, in not being able to switch from algebraic to geometric properties.

NEW RELEVANT CASES

In order to get confirmation of the above assertions, we looked at two more problems where this switch between algebra and geometry is not necessary for the successful solution. The most common case for this is when an early algebraic transcription is possible or the problem needs to be treated algebraically. If the cause for the errors in these problems is geometry-algebra analogical transfer, then in problems that are similar to the ones discussed above, but, for some particular reason, do not require the interplay between algebra and geometry, we should have a different pattern of answers. We will analyze two such problems. The first discussed problem involves both distance and the cardinality of a set.

Problem 4. (Grades 7-8; 29,288 respondents): On both sides of a 20 m long alley, I planted roses. The distance between two neighbouring roses is 2 m long. How many roses did I plant?

(A) 22; (B) 20; (C) 12; (D) 11; (E) 10.

This problem is a „geometrical version” of problem 2.1. In both cases, we have a movement of length 2 and the computation of a cardinal. In opposition to the

Working Group 2

problem 2.1, in which 34.80 % of students answered correctly, the statistical results to this problem are the ones presented in Diagram 4.

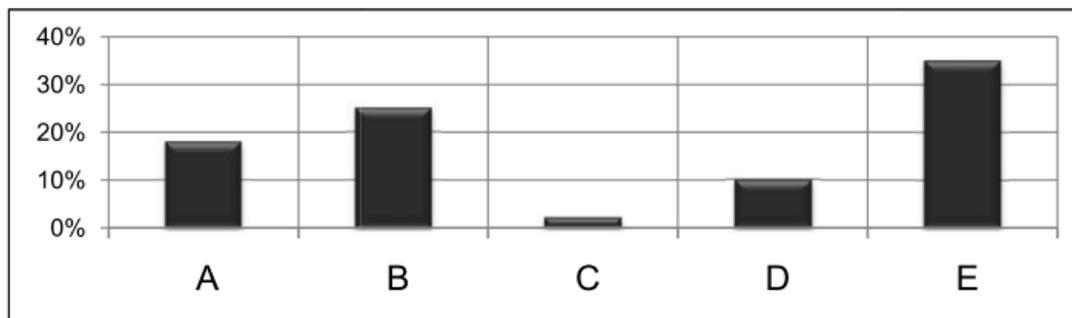

Diagram 4. Statistical results to Problem 4. (The correct answer is (A). The remaining percents correspond to non-answers.)

We can interpret answer D as „half correct”, with the mistake coming from neglecting a constraint of the problem’s text (that the roses are on the both sides of the alley). This is why we consider that the students who had chosen the answers (A) or (D) made a correct judgment. Similarly to the problems discussed above, we group answers B and E as belonging to the same category: here the errors come from the duality marking points – segment (distance). We can observe that we have a strong polarization here: almost 28% correct answers versus 60% typical error. We consider that the range of children’s answers to this problem can be explained by their different level of algebraic reasoning. More precisely, once the student manages to transfer from geometry to algebra, he/she can make use of both the number sets properties and an algorithmic thinking to solve the task. In order to check this hypothesis, we looked at the answers to the next problem.

Problem 5. (Grades 9-10; 17,620 respondents): 2 009 participants in a cross country race have arrived at the finish line. The number of persons behind John is three times bigger than the number of persons in front of John. In what position did John finish the race?
(A) 503; (B) 2009; (C) 1005; (D) 4; (E) 1507.

The statistical results to this problem are presented in Diagram 5.

The problem 5 is similar to problem 3.3. However, while for problem 3.3 the main distracter was chosen by 36.81 % of the respondents, here the maximal distracter (E) was chosen by only 14.98 % of the students. The percent of correct answers is relatively similar. What is the source of these differences? In the case of problem 5, one needs to transcribe the information into equations and the solution does not require switching between algebra and geometry. Once the equation is written, we can proceed in a purely, algebraic way. This can explain the differences in results.

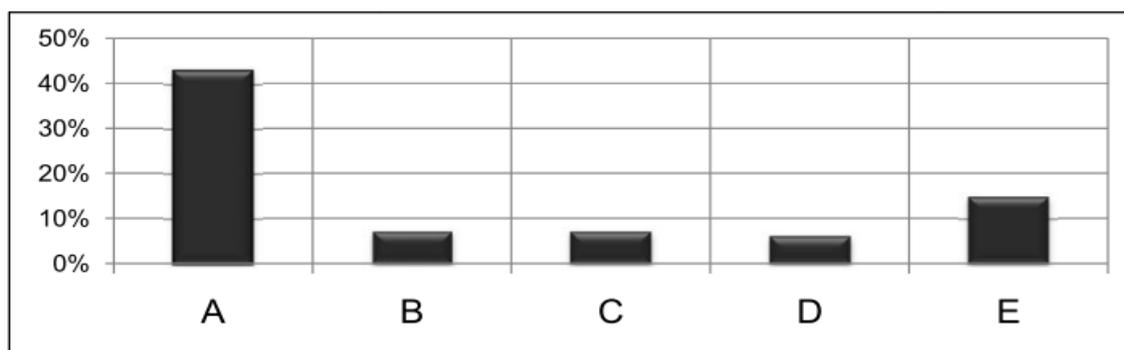

Diagram 5. Statistical results to Problem 5. (The correct answer is (A). The remaining percents correspond to non-answers.)

CONCLUSIONS

As a support-representation for the real numbers, the number line has a dual conceptual structure that consists of a geometrical component that allows visualization and an algebraic component, given by the introduction of distance. Consequently, in order to understand the number line with all its properties, we need a bi-directional transfer between geometric and algebraic viewpoints. Children seem tempted, even from the very beginning, to make this shift in an involuntary manner for problems that ask for length/ continuous measure (so, in which the origin “is situated” at 0) and cardinal/ discrete measure (in which the origin “is situated” at 1). The change of the origin seems to be more natural in the first case, given that there is a corresponding algebraic operation (subtraction). In the second case we have the composition of two translations; therefore, the algebraic correspondent is more complex. The problems in the third cluster belong to the first case mentioned here, but with an additional complexity related to the fact that the final results need to be „reinterpreted” through a switch between algebra and geometry. In conclusion, the answer to the first question of our study: “To what extent does the neglect of one of the three elements of the number line determine children’s misconceptions in problem solving?” becomes more complex. It seems that the problem is not only in neglecting one of the elements of the number line, but also in the quality of the connections made between various representations (algebraic or geometrical) of some abstract concepts.

We have seen that the errors in the problems treated above originate from the duality of the number line. Similar errors appear in different grades. One reason for this persistence over time can be the fact that school curriculum does not explicitly focus on the number line duality. In younger grades, children work, mostly, with the geometric interpretation of the number line, just using an intuitive algebraic structure. Once the algebraic structure is formally introduced, students are not

Working Group 2

reminded of the geometric aspects, and the structure remains, most often, in the realm of abstraction, lacking an intuitive interpretation.

This study is based on a statistical analysis. It allowed us to identify students' difficulties in solving number line problems and to launch some research hypotheses. Although these hypotheses were statistically validated, a qualitative study focused on these aspects could reveal more detail of students' thinking.

SPECIAL EDUCATION STUDENTS' ABILITY IN SOLVING SUBTRACTION PROBLEMS UP TO 100 BY ADDITION

Marjolijn Peltenburg & Marja van den Heuvel-Panhuizen

Freudenthal Institute for Science and Mathematics Education,

Utrecht University, the Netherlands

In this study we examined special education students' use of indirect addition for solving two-digit subtraction problems. Fifty-six students (8- to 12-year-olds), with a mathematical level of end Grade 2, did an ICT-based test on subtraction. Although most students had not been taught indirect addition they frequently applied this procedure spontaneously. For about two-thirds of the problems that have an adding-on context and for about half of all the problems with a small difference between the minuend and subtrahend indirect addition was used. The main prompt for using indirect addition were the item characteristics. Indirect addition was identified as a highly successful procedure for special education students and the best predictor of a correct answer was found in combination with a stringing strategy.

Keywords: special education, indirect addition, information and communication technology (ICT), assessment, empty number line

INTRODUCTION

At the end of primary school many special education (SE) students are considerably behind on the topic of subtraction with numbers up to 100 compared to their peers in regular education (Kraemer, Van der Schoot, & Van Rijn, 2009). To improve the achievements of SE students in solving subtraction problems, it is suggested to teach them one particular way of solving calculations (see e.g., Milo & Ruijsenaars, 2002; National Mathematics Advisory Panel, 2008).

There are several reasons for challenging this advice. Firstly, the idea of teaching only one method goes against the goal of developing numeracy in students. This goal implies that students should be able to choose a suitable strategy when solving number problems (see e.g., Van den Heuvel-Panhuizen, 2001; Warry, Galbraith, Carss, Grice, & Endean, 1992). Secondly, teaching one method implies that for solving particular problems students may have to follow an unnecessary long way to come to an answer (see e.g., Torbeyns, Ghesquière, & Verschaffel, 2009). Thirdly, using prescribed methods can lead to 'didactical ballast' (Van den Heuvel-Panhuizen, 1986) for students. This means that students have to become skilled at following the given recipes, which may not always be easy for them, because the ownership is completely on the side of the teacher or textbook author.

Despite these disadvantages, the idea of teaching students with mathematical difficulties one solution method is still often advocated nowadays. This plea results from the assumption that weak learners do not have the necessary

insights to choose an approach that suits a particular task (see e.g., Milo & Ruijsenaars, 2002; Timmermans & Van Lieshout, 2003). In the study reported in this paper the tenability of this claim is investigated by means of an Information and Communication Technology (ICT)-based assessment. The focus of the study is on using an *addition* procedure for solving *subtraction* problems up to 100.

Strategies and procedures for solving subtraction problems

For solving addition and subtraction problems with numbers up to 100 generally three different types of strategies can be distinguished: splitting, stringing, and varying (Van den Heuvel-Panhuizen, 2001). These idealized *strategies* of which examples are given in Figure 1 have in common that they describe *how we deal with the numbers involved* (in splitting both numbers are decomposed in tens and ones, in stringing one number is kept as a whole number, and in varying one or both numbers are changed in order to get an easier problem).

		Strategies Number perspective		
		Splitting	Stringing	Varying
Procedures Operation perspective	DS Direct Subtraction	$63-31 =$ $60 - 30 = 30$ $3 - 1 = 2$ $30 + 2 = 32$	$63-47 =$ 	
	IA Indirect addition	$64-52 =$ * 	$62-58 =$ 	
	IS Indirect Subtraction	$64-52 =$ * 	$62-58 =$ 	
	MO Multiple operations			$77-29 =$ or $(77+1) - (29+1) =$ $78 - 30 = 48$

* This way of solving this problem is not very common

Figure 1. Relation between procedures and strategies illustrated with problems

A different way of describing a calculation is by focusing on *how the operation is carried out*. From this perspective, two main *procedures* for solving subtraction problems can be distinguished: (1) direct subtraction (DS), which means taking away the subtrahend from the minuend (e.g., solving $62-58=_$ by $62-50=12$; $12-2=10$ and

finally $10-6=4$), and (2) indirect addition (IA), which means adding on from the subtrahend until the minuend is reached (e.g., solving $62-58=_$ by $58+2=60$ and $60+2=62$). Together the strategies and the procedures offer a complete framework for describing how students solve subtractions up to 100. See Figure 1. DS is likely to go together with splitting or stringing. For IA and IS, stringing is the most obvious strategy, although splitting can be applied as well. Finally, when a varying strategy is applied multiple operations are required.

Solving subtraction problems by indirect addition

In connection to the earlier mentioned chasm between opposing ideas about whether or not to teach one solution method to students who are weak in mathematics, there is also debate on whether SE students are able to flexibly solve subtraction problems up to 100 by applying an IA procedure. For example, a few recent intervention studies have revealed that even students in regular primary education have great difficulty to incorporate IA for solving subtraction problems up to 100 (De Smedt, Torbeyns, Stassens, Ghesquière, & Verschaffel, 2010; Torbeyns, De Smedt, Ghesquière, & Verschaffel, 2009).

However, these studies are contradicted by other intervention studies that do support the claim that already in the first grades of primary mathematics education, students of different ability levels in mathematics can learn to flexibly solve subtraction problems by applying IA (Blöte, Van der Burg, & Klein, 2001; Menne, 2001).

Factors influencing students' procedure use

Important factors that may influence students' procedure use when solving a subtraction problem are: (1) student characteristics, such as their general mathematics level, (see e.g., Torbeyns, De Smedt et al., 2009), (2) teaching characteristics, for example, whether or not students' have been taught a particular procedure (see e.g., Menne, 2001), and (3) problem characteristics. With respect to the latter, the influences of the following three features of a subtraction problem are discussed: (a) the numbers involved, (b) the problem format (context problems or bare number problems), and (c) the available auxiliary tools.

Influence of the numbers involved

Several studies (e.g., De Smedt et al., 2010; Torbeyns, De Smedt et al., 2009) have indicated that subtraction problems that require crossing the ten and have a small difference between the minuend and subtrahend may evoke the use of IA. However, IA may also be an efficient procedure in solving large-difference problems with a small difference around the tens and requiring crossing the ten. For example, $82-29=_$ may be easily solved by IA (i.e., $29+1=30$; $30+50=80$ and $80+2=82$, so $1+50+2=53$). Finally, research suggested that small-difference problems that do not require crossing the ten (e.g., $47-43=_$) may also evoke the use of IA (Gravemeijer et al., 1993).

Influence of the problem format

Two didactical phenomenological interpretations of subtraction are: (1) subtraction as taking away, and (2) as determining the difference. In the first interpretation, the matching operation is that of taking away the subtrahend from the minuend, whereas in the second interpretation bridging the difference between the subtrahend and minuend by adding on is also an option. Both interpretations need to be addressed if we want students to learn subtraction in a more complete way (Freudenthal, 1983; Van den Heuvel-Panhuizen & Treffers, 2009).

To contribute to this broad understanding of subtraction students should not only be presented bare number problems. Different studies (e.g., De Smedt et al., 2010; Torbeyns, De Smedt et al., 2009) revealed that bare number problems hardly evoke the use of IA. Context problems, on the contrary, have the possibility to open up both interpretations of subtraction (Van den Heuvel-Panhuizen, 2005).

Influence of the auxiliary tools

To support students in carrying out calculation problems up to 100, different models can be used. Basically, two main models can be distinguished: group models and line models (Van den Heuvel-Panhuizen, 2001). Group models, such as rods of ten and blocks of one, are particularly appropriate to represent a splitting strategy together with DS. Line models, such as the empty number line, are mostly suitable to support a stringing strategy in combination with either DS or IA. The empty number line thus has the possibility to represent both interpretations of subtraction: taking away by jumping backwards and adding on by jumping forwards.

The present study

The present study was set up to investigate whether and under which conditions SE students are able to use IA for solving subtraction problems up to 100, and whether they can solve subtraction problems correctly when applying this procedure. The purpose of the study was to clarify the role of the numbers involved, the format of the problem (context or bare number problems), the presence of a digital empty number line as an optional auxiliary tool, and the occurrence of prior instruction in IA. The study has two foci (I) students' spontaneous use of IA, i.e., applying IA without being asked to use this procedure, and (II) students' success rate when applying IA.

METHOD

Participants

In total, 56 students from fourteen second-grade classes in three Dutch SE schools participated in the study. The participating students (39 boys, 17 girls) were 8 to 12 years old, with a mean age of 10 years and 6 months (SD=10.4 months). All students

had a mathematical ability of level C or lower at the CITO Monitoring Test for Mathematics End Grade 2 (Janssen, Scheltens, & Kraemer, 2005).

Materials

ICT-based test on subtraction problems

An ICT-based test¹ was developed that contains a collection of items in which item characteristics are varied systematically. These characteristics include number characteristics and format characteristics.

The number characteristics refer to the size of the difference between the minuend and subtrahend (small means <7 and large means >11), whether or not the tens have to be crossed (e.g., $61-59=_$), and whether or not the minuend and the subtrahend are close to the ten (<3). The format characteristics refer to whether or not the items are presented as a bare number problem (BN) or as a context problem. The latter can describe a taking-away situation (ConTA) or an adding-on situation (ConAO). Figure 2 shows a screen shot of one of the context problems that reflects an adding on situation.).

Figure 2. Train ticket item; the read aloud instruction is: “A train ticket costs 41 euro. Father has already paid 29 euro. How many more Euros does he need to pay?”

The ICT-based test is divided into two parts. The first fifteen items do not feature the number line tool, whereas the last fifteen do. This digital empty number line operates by touch-screen technology. After a short introduction, the students worked individually on a touch-screen notebook. Students were told that they were completely free in choosing a particular solution method. As well as giving an

answer they had to report verbally how they solved the items. The students' on-screen work was recorded by means of Camtasia Studio software.

Online teacher questionnaire

To collect data about the students' prior instruction on subtraction problems an online teacher questionnaire was developed. The link for the questionnaire was sent by email to the fourteen teachers responsible for teaching mathematics to the students that participated in the study. All fourteen teachers filled in and submitted the questionnaire. The questionnaire contains two questions on the topic of 'subtraction up to 100' to collect data about (1) the models and materials the teachers have used for teaching subtraction up to 100, and (2) the procedures (DS and/or IA) they have taught their students for solving subtraction problems up to 100.

RESULTS

In the analysis of the data we included all the cases in which the students gave an answer to an item. Of the 1680 possible cases (56 students each doing all thirty items) 147 cases were missing. This resulted in 1533 cases to be analyzed. DS and IA were clearly the most frequently applied procedures. DS was applied in 64% of the total cases and went together almost equally often with a stringing and splitting strategy. IA was applied in 32% of the total cases; in almost 90% IA was applied in combination with a stringing strategy.

Different conditions and SE students' spontaneous IA use

Numbers involved

IA was most frequently applied in small-difference problems, i.e., in 50% of the 322 cases involving items with crossing the ten and in 43% of the 324 cases involving items without crossing the ten. DS was most frequently applied in large-difference problems, i.e., in 90% of the 282 cases involving items with crossing the ten, in 78% of the 306 cases involving items without crossing the ten, and in 66% of the 299 cases involving items with a small difference around the tens and requiring crossing the ten.

Problem format

We found that an adding-on context generally goes together with IA, whereas a taking-away context mostly resulted in a DS procedure. That is, IA was applied in 68% of the 509 cases involving an adding-on context and DS was applied in 75% of the 510 cases involving a taking-away context. When solving bare number problems the students also had a strong preference for DS. That is, in 91% of the 514 cases involving bare number problems, DS was

applied.

Prior instruction

The teachers' responses to the online questionnaire revealed that two different textbook series were used in the fourteen classes. Although these textbook series each contain some missing addend problems, they do not explicitly address the inverse relation between addition and subtraction. Because teachers might have given attention to IA without it being addressed in their textbooks we also asked them which procedures for solving subtraction problems they taught their students. Their answers made it clear that all teachers taught DS. Only three teachers responded that they have taught both DS and IA. This means that in total fifteen students were taught both procedures. These students applied IA in 32% of the total 419 cases they had solved; the students who were not taught IA applied this procedure in 32% of the total 1114 solved cases.

Use of the empty number line

According to the data that were retrieved from the online teacher questionnaire all students were familiar with the empty number line for doing subtraction. For fifteen out of the thirty items, the students had the optional digital empty number line for solving the subtraction problems available. The fifteen items resulted in 778 cases of processed items. In 131 of these cases the empty number line was actually used for finding an answer. The students used IA in 15% of these 131 cases. In the 647 cases in which the students saw the empty number line but did not use it, IA was applied in 33% of the cases.

Multilevel analysis with IA use as dependent variable

A cross-classified multilevel model was carried out with IA use as dependent variable. This analysis revealed, among other things, that the random item effect ($SD=2.41$) was quite large compared to the random student effect ($SD=.85$), indicating that IA use is mainly an item characteristic. This means that the application of IA is more strongly elicited by the nature of an item than by the specific preference of a student, which implies that students applied IA in a flexible, item specific way.

SE students' success rate in IA and DS use

In 70% of the 489 cases in which the students applied IA their answers were correct. In the 976 cases in which they applied DS their answers were correct in only 48% of the cases.

Different conditions and success rate in IA and DS use

Numbers involved

Small-difference subtraction problems were solved with the highest success rate when IA was applied. Of the 162 cases involving items that required crossing the

Working Group 2

tens, the students solved 86% correctly with IA and of the 139 cases that did not require crossing the tens, the students solved 88% correctly with IA. When students applied DS, the highest percentage of correct answers was found in small-difference subtraction problems without crossing the ten. Of the 176 cases involving such items, the students solved 67% correctly by DS.

Problem format

In all three problem formats (ConAO, ConTA and BN) the students solved more problems correctly than incorrectly when they applied IA. The highest percentage of correct answers was found in solving items that reflect taking away, i.e., 82% of the 108 cases involving taking-away items were solved correctly. When using DS, we found that in all three problems format the students solved about half of the items involved correctly. When not taking into account the procedure used and comparing the three problem formats, students appeared to be most successful in solving context problems that reflect adding on (ConAO) and least successful in solving bare number problems (BN).

Other conditions

The students who had received IA instruction correctly solved 76% of the 134 total cases they had solved by IA. The students who did not receive IA instruction correctly solved 68% of the 355 total cases they had solved by IA. Moreover, the IA-instructed students correctly solved 54% of the 270 total cases they had solved with DS. The students who did not receive IA instruction correctly solved 45% of the 706 total cases they had solved with DS.

Of the 778 cases in which the empty number line was available in the items IA was applied in 235 cases. In twenty cases the students actually used the number line and in 215 cases they did not. It appeared that the percentage of correct answers in both groups was about the same, namely 75% and 73% respectively.

Multilevel analysis with success rate as dependent variable

A cross-classified multilevel model was carried out with success rate use as dependent variable. This analysis was focused on revealing the influence of strategy use and procedure use on students' success rate in applying IA. It was found that only the use of a stringing strategy increased success rate significantly ($b=.52$, $SE=.19$, $p<.05$). The best predictor of a correct answer appeared to be the combination of a stringing strategy together with the IA procedure ($b=.96$, $SE=.37$, $p<.05$).

CONCLUSIONS

Our study was limited in scope, and therefore further research with more students covering more schools is needed. Moreover, we did not carry out a detailed inventory of the students' prior instruction in IA. Therefore, information on the

Working Group 2

quality of the instruction was missing. This might explain why we did not find any influence of prior instruction on the students' success rate in applying IA.

In general, more student characteristics and more details about their prior instruction should be taken into account to acquire a deeper understanding of SE students' potential in solving subtraction problems. Nevertheless, the present study has revealed three striking outcomes:

1. SE students are able to use IA spontaneously, i.e., without being asked to do so.
2. SE students are rather flexible in applying IA to solve subtraction problems.
3. SE students are quite successful when solving subtraction problems by IA.

We think these findings argue in favour of a reconsideration of the approach to mathematics education in SE which advocates only teaching the straightforward taking-away procedure. Such an approach clearly underestimates SE students' mathematical ability. Finally, this study has shown that solely focusing on strategies (splitting, stringing, and varying) or solely on procedures (DS and IA) is a too restricted way of investigating students' ability to solve number problems. Both should be taken into account, as our study showed that the best predictor of a correct answer is the combination of IA and stringing.

NOTE

¹ The ICT-based test was developed by the authors of this paper and programmed by Barrie Kersbergen, a software developer at the Freudenthal Institute.

MENTAL CALCULATION STRATEGIES FOR ADDITION AND SUBTRACTION IN THE SET OF RATIONAL NUMBERS

Sebastian Rezat

Justus-Liebig-University, Giessen

Studies on mental calculation strategies usually focus on elementary school students and accordingly on problems in the set of natural numbers. But, mental calculation is also an issue at secondary school in the context of other number sets. In the paper an exploratory study of eight eighth grade students' mental calculation strategies for addition and subtraction problems in the set of rational numbers is presented. The study focuses on the analysis of the used strategies and on students' adaptive expertise in the choice of the strategies.

Keywords: mental calculation strategies, adaptive expertise, rational numbers, didactical models of rational numbers

RATIONALE

A considerable body of research investigated issues related to mental calculation of elementary school students in the set of natural numbers. This body of research mainly focuses on three aspects: Firstly, strategies students are using are identified (Reys, Reys, Nohda, & Emori, 1995; Selter, 2001). Secondly, the issue of adaptive expertise, i.e. flexible and adaptive strategy use, is addressed (Blöte, Klein, & Beishuizen, 2000; Threlfall, 2002; Torbeyns, De Smedt, Ghesquière, & Verschaffel, 2009; Verschaffel, Luwel, Torbeyns, & Van Dooren, 2009). Finally, factors affecting different aspects of mental calculation, e.g. performance or adaptive expertise are analysed (Heinze, Marschick, & Lipowsky, 2009; Heirdsfield & Cooper, 2004).

The development of mental calculation strategies and their flexible and adaptive use by students in secondary school related to other number sets than the natural numbers has been rarely investigated so far. This is surprising, because on the one hand students in secondary school have had the opportunity to gain more experience in the number system. In Germany the set of natural numbers is extended to the integers, the rationals, and the real numbers in secondary school. Getting familiar with new numbers and their computation might possibly have positive effects on the development of number sense. Besides, metacognitive and affective factors number sense is regarded as one of the main influential factors on mental calculation performance and adaptive expertise (Heirdsfield & Cooper, 2004). On the other hand, mental calculation is a subject that is addressed in secondary school standards and national curricula. The NCTM-Standards expect that “In grades 6–8 all students should [...] select appropriate methods and tools for computing with fractions and decimals from among mental computation”. The call for mental calculation is continued in the upper grades: “In grades 9–12 all students should [...] develop fluency in operations with real numbers, vectors, and matrices, using mental

computation or paper-and-pencil calculations” (National Council of Teachers of Mathematics, 2000). Similar expectations can be found in the English National Curriculum (Qualifications and Curriculum Development Agency, 1999) and the German ‘Bildungsstandards’ (Ständige Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland, 2005).

In this paper an exploratory study of eight eighth grade students’ mental calculation strategies in the set of rational numbers is presented.

THEORETICAL FRAMEWORK

Mental calculation strategies

Research on mental calculation for addition and subtraction problems in the set of natural numbers has identified numerous strategies that can be divided into different groups. Threlfall (2009) firstly distinguishes “approach strategies” and “number-transformation strategies”. He defines an approach strategy in mental calculation as “the general form of mathematical cognition used for the problem—for example counting, or recall, or application of a learned method, or visualisation of a procedure, or exploiting known number relations” (Threlfall, 2009, p. 541). A number-transformation strategy in mental calculation is “the detailed way in which the numbers have been transformed to arrive at a solution” (Threlfall, 2009, p. 542). In the literature varying conceptualizations of these strategies can be found (see e.g. Threlfall, 2002 for an overview). In this paper Threlfall’s terminology is adopted. ‘Mental calculation strategy’ is used as an overarching term whenever it is referred to both, an approach and a number-transformation strategy.

In this section an a priori analysis of possible approach- and number-transformation strategies in the set of rational numbers is presented.

From a mathematical point of view an analysis of mental calculation strategies for addition and subtraction in the set of rational numbers might focus on different aspects:

13 Addition and subtraction with integers

14 Addition and subtraction with fractions

15 Addition and subtraction with decimals

Addition and subtraction with fractions (2) is carried out by treating the nominator and the denominator separately. Therefore, it is likely that the number-transformation strategies students use for solving addition and subtractions problems with fractions are the same as with natural numbers and integers. Furthermore, in everyday life mental calculation with fractions is hardly needed in contrast to mental calculation with integers and decimals (Profke, 1991). Therefore, the study reported in this paper focuses on mental calculation strategies related to integers (1) and decimals (3).

Working Group 2

Besides the occurrence of negative numbers a major novelty in calculating with integers is a zero-transition, i.e. crossing the zero-point in either direction – from positive to negative or vice versa – during the calculation process. In order to avoid the zero-transition, addition and subtraction of integers can be reduced to addition and subtraction of natural numbers either by definition or by proving the following rules: For any integers n, m

$(-n) + n = 0$	$0 - n = -n$
$(-n) + m = m - n, \text{ if } m > n$	$(-n) - 0 = -n$
$(-n) + m = -(n - m), \text{ if } n > m$	$0 - (-n) = n$
$(-n) + 0 = -n$	$(-n) - (-m) = (-n) + m$
$(-n) + (-m) = -(n + m)$	$(-n) - m = -(n+m)$
	$m - (-n) = n + m$

Therefore, mental addition and subtraction of integers can be approached by applying these definitions / rules combined with number-transformation strategies for natural numbers.

Another way of approaching mental addition and subtraction problems with integers is by referring to the mental image of the number line. In Germany a common way of introducing negative numbers is the extension of the number line. This geometrical model is sometimes derived from temperature, altitudinal, or monetary (bank-account-balance-model) contexts (Vollrath & Weigand, 2007). Table 1 summarizes the 5 different approach strategies that were identified in the a priori analysis:

<i>transformation</i>	<i>number line</i>	<i>bank-account-balance model (b-a-b-m)</i>	<i>temperature scale model</i>	<i>altitude model</i>
refers to an approach strategy where the original problem is transformed into an equivalent problem in the set of natural numbers according to the above stated rules	refers to an approach strategy where students solve the problem with reference to an internal image of the number line.	refers to an approach strategy where students solve the problem with reference to monetary contexts of deposit, withdrawal and depts.	refers to an approach strategy where students solve the problem with reference to a temperature context.	refers to an approach strategy where students solve the problem with reference to an altitude context.

Table 1: Idealized approach strategies for addition and subtraction problems in the set of rational numbers.

Decimals are introduced in Germany according to two major approaches: They are either regarded as a special kind of common fractions, e.g. $23,45 = 2345/100$, or they are introduced via an extension of the place-value-system (Padberg, 2009). In the former case, addition and subtraction of decimals is reduced to addition and subtraction of fractions, which is – as we have seen earlier – just a special case of addition and subtraction with integers. In the latter case, the number-transformation rules for decimals are traced back to the number-transformation rules of natural numbers.

In summary, all addition and subtraction problems with rational numbers can be approached by reducing them to equivalent problems with natural numbers. Therefore, it is likely that the actual transformation of numbers in order to arrive at a solution is carried out with number-transformation strategies for natural numbers.

In this paper I will refer to the conceptualization of idealized number-transformation strategies for addition and subtraction in the set of natural numbers that is put forward by Heinze et al. (2009), because it is appropriate for the German situation in the way that it comprises the strategies that are well known in German arithmetic literature. An overview of the different strategies is given in table 2.

<i>Stepwise strategy</i>	<i>Split strategy</i>	<i>Compensation strategy</i>	<i>Simplifying strategy</i>	<i>Indirect addition (ind. add.)</i>
$45 + 12 = 57$	$45 + 12 = 57$	$16 + 38 = 54$	$59 + 11 = 70$	$53 - 49 = 4$
$45 + 10 = 55$	$40 + 10 = 50$	$16 + 40 = 56$	$60 + 10 = 70$	$49 + 4 = 53$
$55 + 2 = 57$	$5 + 2 = 7$	$56 - 2 = 54$		
	$50 + 7 = 57$			

Table 2: Idealized number-transformation strategies for addition and subtraction according to Heinze et al. (2009).

Whereas the stepwise strategy, the split strategy, the compensation strategy, and indirect addition can be applied to integers and to decimals without any modification a variation of the simplifying strategy is specific to the set of integers: Problems like $-47+23$ can be solved by simplifying into $-(50-3) + (20+3) = -50+20+6$.

Flexible and adaptive strategy use

The use of the terms flexibility and adaptivity is not consistent in the literature (Selter, 2009). Based on a literature review Verschaffel et al. suggest that flexibility refers to “switching (smoothly) between different strategies” and adaptivity puts more emphasis on “selecting the most appropriate strategy” (Verschaffel, et al., 2009, p. 337). As a working definition they suggest that an adaptive choice of strategy is characterized by “the conscious or unconscious selection and use of the most appropriate solution strategy on a given mathematical item or problem, for a

given individual, in a given sociocultural context” (Verschaffel, et al., 2009, p. 343). This definition implies that strategies can be adaptive related to different aspects: they can adapt to task characteristics as well as to individual or sociocultural conditions. Furthermore, adaptivity seems to imply flexibility. This is even more evident in Selter’s slight variation of Verschaffel et al.’s definition: “Adaptivity is the ability to creatively develop or to flexibly select and use an appropriate solution strategy in a (un)conscious way on a given mathematical item or problem, for a given individual, in a given sociocultural context” (Selter, 2009, p. 624). Whereas flexibility might be operationalised by showing at least a certain number of different strategies, the question when a strategy is considered to be appropriate and which criteria are relevant to this are “critical and challenging [...] fundamental theoretical questions in this context (Heinze, Star, & Verschaffel, 2009, p. 536). Therefore, a normative perspective is usually taken in order to decide whether a strategy adapts to a given problem or not.

The findings of studies on students’ mental number-transformation strategies for addition and subtraction problems in the set of natural numbers indicate that elementary school students hardly choose among different strategies with respect to task characteristics, but favor one or two strategies that they apply to every problem (Selter, 2001; Torbeyns, et al., 2009; Torbeyns, Verschaffel, & Ghesquière, 2006).

Based on the discussion of mental calculation strategies and adaptive strategy use the following research questions are addressed in the study presented in this paper:

- Which approach and number-transformation strategies do students use for mental calculation in the set of rational numbers? Do students use strategies that are specific to the rational numbers or do they refer to strategies that they are familiar with from the set of natural numbers?
- Do students in secondary grade use mental calculation strategies adaptively according to tasks characteristics?

STUDY DESIGN AND METHODOLOGY

Data on students’ mental calculation strategies were collected in video recorded interviews. The tasks were read out loud to the students and the students were asked to solve the tasks mentally without using any notes. Afterwards the students were asked to explain the way they solved the task [1].

Eight eighth grade students from a German comprehensive school took part in the study. The school is located in a rural area in Germany. According to their grades in mathematics the students are considered to be medium-achieving students.

The problems posed in this study can be grouped into three different categories:

- Addition and subtraction problems with natural numbers (tab. 3: P1 – P4)

Working Group 2

- Addition and subtraction problems with integers (tab. 3: P5 – P8)
- Addition and subtraction problems with positive and negative decimals (tab.3: P9 – P14)

Whereas addition and subtraction problems with natural numbers (category 1) were included in order to get an idea which mental computation strategies students use in the set of natural numbers, problems of categories 2 and 3 relate directly to the main aims of the study. Since there are hardly any findings about students' mental calculation proficiencies with decimal numbers only numbers with one decimal were included in order to keep the numbers simple. Since a zero-transition is a major novelty when students are introduced to calculating with rational numbers two problems containing a zero-transition (P7, P14) were included.

In this study adaptivity is investigated related to task characteristics (research question 2). A normative perspective is taken in order to decide if a strategy adapts to a task or not. Therefore, problems suggesting the application of different number-transformation strategies were included. From a normative perspective the stepwise or the split strategy are most appropriate for problems P1, P2, P3, P9, P10, P11, P12. The compensation strategy is appropriate for problems P3, P7, P8, P13, P14. P13 is also suitable for applying the indirect addition strategy. P4 and P5 might be solved by a variation of the simplifying strategy, since e.g. $53-27=(50+3)-(30-3)=50-30+6$.

FINDINGS

Table 3 provides an overview of used approach and number-transformation strategies related to problems P1-P14.

The analysis of the eight students' approach strategies reveals that the main strategy applied to problems containing negative numbers was the transformation into equivalent problems with natural numbers using laws for addition and subtraction of integers, e.g. $-11 + 28 = 28 - 11$. Only the problems containing a zero-transition (P7 and P14) were approached by referring to a mental image of the number line or to the bank-account-balance-model. Student 1 approaches problem P4 through the number line model:

Interviewer: Minus 11 plus 28?⁸

Student 1: Plus 17!

Interviewer: Correct!

Student 1: I subtracted 11 from 28 so that I will be at 0 and then I added the rest.

Interviewer: And how exactly did you subtract?

Student 1: I took 28 minus 11 so that I am at 0, is 17, then 0 plus 17 is 17.

⁸ The language of the original interview data is German. All translations were carried out by the author.

Table 3: Approach and number-transformation strategies used by students S1-S8.

⁹ Whenever students use the approach strategy ,transformation⁶ the actual transformation will be specified in the table.

Working Group 2

Student 4 refers to the bank-account-balance-model in order to calculate the algebraic sign of the result of problem P14:

Interviewer: 0.8 minus 2.9?

Student 4: makes minus 2.1, right?

Interviewer: Yes!

[...]

Student 4: I subtracted 0.8 from 2, makes 1.2, then I add 9, 8 are missing up to 2, and I have got 9, makes 2.1, it's minus, because I am plus 0.8, when I have got 8 Cent deposit on my account and I make a withdrawal of 2.9 Euro, it's negative.

Regarding number-transformation strategies, the analysis reveals that all the problems were solved using familiar number-transformation strategies from the set of natural numbers. No strategies specifically related to rational numbers were observed. Six of the eight students solved problems with decimal numbers by applying either the *stepwise strategy* or the *split strategy*. Two of them (S1, S2) used the *stepwise strategy* for every problem, no matter if it was a problem with natural numbers, integers or decimals. S8 almost exclusively used the *split strategy*. Three students (S3, S4, S5) used the *stepwise* and the *split strategy*. Only two students (S7, S8) apply other strategies than the *stepwise* or the *split strategy*: S7 transformed some of the problems to problems with natural numbers by leaving the decimal point out and setting it correctly after the calculation. S6 also applied the indirect addition strategy once to a subtraction problem with decimals.

In terms of adaptive strategy use, the analysis of the used number-transformation strategies reveals that students do not apply a variety of strategies to the posed problems: Three of the eight students (S1, S2, and S8) use the same number-transformation strategy for almost all problems. The rest of the students use mainly two strategies. Although the compensation strategy would have been appropriate for problems P3, P7, P8, P12, P13, P14 none of the students used this strategy.

However, the three students using the *stepwise* and the *split strategy* (S3, S4, and S5) show the tendency to solve problems with integers using the *stepwise strategy* and problems with decimals according to the *split strategy*. This might be an indication for adaptive strategy use. But, the reasons for the strategy choice cannot be derived from the data.

DISCUSSION AND CONCLUSION

In the present study all problems from the set of rational numbers were solved according to number-transformation strategies that students are familiar with from the set of natural numbers. No strategies specific to the set of rational numbers were observed. Furthermore, no problems calculating with decimals were observed. This

Working Group 2

might be due to the fact that no problems containing numbers with a different number of decimal places were included, e.g. 1.23-2.5. This is a shortcoming of the present study and should be approached in further research.

The students in the present study hardly choose adaptively among different computation strategies with respect to task characteristics. In none of the cases where a compensation strategy would have been appropriate the students applied this strategy. Furthermore, students in the study favour the *stepwise* and the *split strategy*. Regarding the small scope of the study these results cannot be generalized. Further research is needed to support the findings from this study.

In terms of approach strategies, it is remarkable that students only refer to didactic models of negative numbers (number line, bank-account-balance-model) associated with problems that contain a zero-transition. This might indicate that problems with zero-transition present particular difficulties to students. This hypothesis could be approached in further research. Furthermore, the role of didactical models in mental calculation is an issue which has not been investigated very much so far.

The findings from the present study reflect results from previous studies on mental calculation in the set of natural numbers: students apply only one or two strategies to almost all problems without choosing strategies adaptively to task characteristics. To investigate factors affecting adaptive expertise in mental calculation is therefore not only an issue for further studies related to the set of natural numbers, but also related to the set of rational numbers.

NOTES

1. Data was collected by Jens Hubert in the context of his final thesis for earning a teaching degree in secondary school.

INTRODUCTION TO THE PAPERS OF WG 3: ALGEBRAIC THINKING

María C. Cañadas^a, Thérèse Dooley^b, Jeremy Hodgen^c, Reinhard Oldenburg^d

^aUniversity of Granada, ^bDublin City University,

^cKing's College London, ^dFrankfurt University

In CERME7, WG 3 “Algebraic thinking” continued the work carried out in previous CERME conferences (Ainley, Bagni, Hefendehl-Hebeker, & Lagrange, 2009).

The 13 papers were considered in four themes:

The transition to algebraic symbolisation

Caspi and Sfard investigate the discourse of 7th grade Israeli students as they move from informal meta-arithmetic toward formal algebra. By examining a historical example, they show how students' discourse, whilst informal and ambiguous, contains some algebra-like features, not normally found in everyday discourse. Dooley examines a group of primary pupils in Ireland aged 9-11 years. She uses the epistemic actions of recognising, building-with and constructing to analyse and describe the development of algebraic reasoning amongst the pupils. She argues that in some case the use of “vague” language facilitated this development. Drawing on a design science approach, Gerhard uses interviews with secondary students in Germany to exemplify the use of an analytic tool examining the transition from arithmetic to algebra. She argues that it is important to distinguish the transition from arithmetical to algebraic thinking and that from numbers to variables. Pytlak analyses a child's solution to a matchstick sequence task drawing on a wider study of primary children in Poland. She demonstrates how relatively sophisticated algebraic thinking can be achieved with geometric and numeric approaches but without the use of symbols.

Equations and symbolisation

In an intervention study of 135 primary children in Cyprus, Alexandrou-Leonidou and Philippou found that the children were capable of developing the dual meaning of the equal sign. This understanding, in turn, enabled the children to solve equations in multiple representation formats. By conducting a survey of 113 students in Turkey, Didiş, Baş and Erbaş examine students understandings and errors in relation to the solving quadratic equations. Their findings add further weight to the literature highlighting the ubiquity and problems of a purely instrumental, or procedural, understanding.

Technology

Drawing both on the historical development of mathematics and on examples of Italian students, Chiappini demonstrates how AlNuSet software can enable students to overcome crucial epistemological obstacles in the move from arithmetic to

Working Group 3

algebra, specifically negative numbers and the equivalence of different algebraic forms.

Hewitt discusses the work of a group of 9-10 year olds in England as they engaged with formal algebra for the first time using the software Grid Algebra. He outlines six perspectives from the literature on algebraic activity and uses these to analyse the students' activity in order to examine what constitutes algebraic activity.

Working in Italy, Maffei and Mariotti use Aplusix CAS to examine the interplay between different representations of algebra: standard (symbolic) representation, tree representation and natural language. They demonstrate that natural language has a dual role as a representation in itself and in describing the other representations. Nobre, Amado, Carreira and da Ponte show how a generic spreadsheet, Excel, can enable students to engage with algebraic structure without the need for algebraic symbolisation. Indeed, the three Grade 8 Portuguese students, were able to model and solve a complex problem involving simultaneous equalities and inequalities.

Generalisation

A. Barbosa reports on her analysis of the strategies used by 54 Portuguese students in 6th Grade working on generalization tasks as they participated in an intervention study. Students achieved better results with near generalisation than with far generalisation problems. Reporting on a survey of 359 Spanish Secondary students, Cañadas, Castro and Castro outline the different approaches to generalisation adopted. They find that students use graphical approaches infrequently and generally only when the problem was presented graphically. Chua and Hoyles discuss differences in the generalisation strategies used by 13 year old students in Singapore from the Express (higher attaining) course and from the Normal course. Express students were more flexible, adopting a numerical approach for a linear problem, but using a constructive approach for a quadratic problem.

GENERAL REFLECTIONS

Algebraic thinking is a “mature” domain within mathematics education research (Kieran, 2006). Indeed, alongside multiplicative reasoning, algebra is perhaps the most extensively researched area in mathematics education. The papers and posters reflect this and all the papers and posters drew on this body of research. Unsurprisingly given this research history, there were many aspects of consensus across the group, but there were also significant differences.

Points of consensus

In relation to the practice of teaching and learning algebraic thinking, there was general agreement that:

Working Group 3

- Doing algebraic thinking provides considerable insight into school mathematics, but translating these insights into general classroom practice is not straightforward.
- Classrooms around Europe and elsewhere tend to be dominated by procedures and manipulation. Skemp's (1976) seminal work is still of considerable relevance.
- The promise of technology has largely yet to be realised in most classrooms.
- There are many approaches to algebra and learners should acquire many ways to look at and work with algebra.

All participants agreed on the importance of multiple perspectives, of talk and discourse, of rich tasks and of children's existing and naïve (mis-)understandings [1].

Reflecting the three plenary lectures at CERME-7, key overarching issues in the group discussions included a recognition of the importance of the teacher (*Sierpinska*), the importance of pupils experiencing "surprise" (*Hannula*) and the relationship between arithmetic and algebra (*Mariotti*).

Points of difference

The issue of "early algebra" and the relationship to / transition from arithmetic continues to be a thorny one, which generated much debate. The question as to whether there is a clear cognitive gap between (generalised) arithmetic and algebra remains an open one. Similarly, there was disagreement on whether there exists one *best* or *ideal* learning trajectory or whether there are several *good-enough* learning trajectories or whether learning is inevitably somewhat idiosyncratic. An international conference inevitably (and usefully) highlights issues of language and meaning. Working Group 3 was no exception. For example, whilst all agreed on the importance of talk and discourse, some participants preferred the more general term of "talk" and others preferred the more specific and theory-laden "discourse". Related to this, theory was used differently by different participants. Some opted for a pragmatic use of theory to solve and illuminate research problems as and when they occurred. Others attempted to draw synergies between different theoretical approaches in order to inform research.

ISSUES FOR FUTURE RESEARCH

We have already noted the concern with early algebra. Whilst this concern in part reflects a current theme in the literature (Kaput, Carraher & Blanton, 2007), it also responds to the policy context in which some countries (such as Portugal) are introducing algebra earlier. This policy imperative highlights several important issues for Working Group 3 and CERME more generally. Re-contextualisation – the translation of "existing" knowledge into new settings and contexts - is a valid and important field of study and we note that the replication of existing research has been

Working Group 3

somewhat undervalued in mathematics education as a field generally. However, in re-contextualising or replicating existing work, researchers need to demonstrate the contribution they make to the field as a whole through stronger literature reviews.

The issue of translating research knowledge into practice in general was a concern for almost all participants. The mismatch between what can be achieved in experimental settings and the general practice in the majority of classrooms is a serious concern. So, for example, in considering how to realise the potential of technology, the group discussed how technology can help children do something that they would not otherwise do and then how teaching can enable children to understand “independent of” technology. Similarly, the group identified a need for further research into understanding group dynamics specific to algebraic thinking.

LOOKING FORWARD TO CERME-8

Finally, in looking forward to CERME-8, the group discussed ways of continuing and extending existing studies by:

- Identifying research collaborations with a view to replicating studies in different national / cultural contexts.
- Reporting follow-on studies to CERME-7 papers and posters.
- Examining the same research problem / dataset using different theoretical lenses and methodologies.

We hope that the majority of the participants will return the CERME-8.

NOTES

1. However, the issue of children’s understandings was conceptualised differently with some using the notion of misconceptions and others rejecting this as too cognitive.

CAN THEY “SEE” THE EQUALITY?

Vassiliki Alexandrou-Leonidou* & George N. Philippou**

*University of Cyprus **University of Nicosia

The concept of equality is basic and common in mathematics, but primary school students have limited understanding (operational meaning only) of the symbol used to represent it. The present study focuses on primary school students' abilities to recognize equality in different representation formats (iconic, verbal and symbolic) and reports on a teaching experiment that aimed at helping primary school students develop the dual meaning of the equal sign (operational and relational). Analysing data from 135 3rd to 6th grade Cypriot students who participated in the teaching experiment, we found that they are capable of developing the dual meaning of the equal sign and that this understanding has a significant effect on their ability to solve equations in multiple representation formats.

THEORETICAL FRAMEWORK AND RESEARCH GOALS

Deep understanding of the notion of equality is a necessary prerequisite for primary school students in order to proceed to upper school mathematics. Likewise, the equal sign ($=$), although is one of the most basic ones along with the numbers and the operation signs, it becomes a serious obstacle, if students do not understand it's meaning. However, research in developmental psychology and mathematics education over the last 20 years has indicated that many primary school students (ages 7 to 11) have an inadequate understanding of the equal sign (Behr, Erlwanger&Nichols, 1980; Carpenter, Franke&Levi, 2003; Jones, 2008; Kieran, 1981; McNeil &Alibali, 2005; Rittle-Johnson &Alibali, 1999). As has been documented, instead of interpreting it as a relational symbol of mathematical equivalence, most students interpret it as an operational symbol, meaning “find the total” or “put the answer”.

Linking multiple representations of the same concept may help students enhance their learning, as it helps them express generality, an asset that, according to Mason, Drury and Bills (2007), gives students powerful understanding of a concept. Radford (2003) argues that generalisation develops through three levels: factual, where the generalisation focus remains at the level of the material to be generalised; contextual, which is more abstract and descriptive and where explanations of generalisation are language driven; and symbolic, where algebraic notation (including letters) is used to describe the generalisation. Generalisation is a necessary objective of every mathematics lesson (Mason et al., 2007). Hence, the opportunities and the frequency that learners are given to express generalities through actions and words may facilitate their appreciation of what algebra can do for them.

As it has been stated a long time ago, every learner who arrives at school, walking and talking, has displayed the power to perceive and express generality (Whitehead,

1932;Gattegno, 1970). The critical issue is that the extent to which learners manage to use these powers depends on methods and the approaches adopted by the teacher in the mathematics classroom. Thus, the need for experimental intervention studies appears in order to practically improve the situation and document certain methodology and appropriate teaching approaches.

In this respect, the main goal of the present study was to describe primary school students' abilities to recognize equality in different representation formats (iconic, verbal and symbolic) and to develop and test a teaching experiment (TE) that aimed at helping learners understand the dual meaning of the equal sign (operational and relational), as a mean to foster their ability to recognize equality in different representation formats.

METHODOLOGY

The TE aimed at helping students understand the concept of equality and the structure of different representation formats of equality. It also aimed at developing students' understanding of the dual meaning of the equal sign, that is, its operational and its relational meaning. Practically, the TE was planned to give students the opportunity to work in activities involving multiple representations of the concept of equality. The effective involvement in such activities was expected to help them link the representations of this concept and proceed to generalize on the idea of equality.

Specifically, the planned activities involved working with objects (such as the number scale), with icons (such as with a picture of a scale with different weights), with words (such as with equivalent word expressions), and with symbols (such as with equivalent number sentences). Students were asked to complete missing weights or numbers on a scale to make it balance, to match and produce equivalent expressions in words and symbols and to identify and make equivalent vectors. They were also asked to match and produce verbal expressions of a symbolic expression and vice-versa, in order to link different representation formats. In addition, they were asked to use the equal sign to show equivalency of expressions in multiple representation formats, such as words, symbols and vectors. Students were given the opportunity to express general statements about the use of the equal sign, i.e. "it is used when we want to show that two things are equal" or "whatever exists on the left hand side of an equal sign should be equal to what there is on the right hand side".

Data were collected through two tests. Test 1 (T1) was designed to measure students' understanding of the equal sign and Test 2 (T2) was designed to measure ability to solve equations of similar structure, which were represented in different formats. T1 comprised of three parts and aimed to grasp the type of the students' understanding of the equal sign. The first part of T1 required students to write an informal definition of the equal sign in three contexts (the sign on its own, the sign at the end in a mathematical sentence and the sign between two equivalent mathematical sentences). These tasks were used in Knuth et al. (2006) study in a similar way. The

Working Group 3

second part of T1 required students to complete equalities of different structure, that is, different number of operations, with the equal sign and the unknown at different positions, i.e. $a + b = _ + d$, $a + b + c = a + _$. Only single digit numbers were used in the first and the second part of T1, to avoid students' difficulties with the operations' algorithms. The first four tasks in the third part required that students used the four operations and their own numbers to create a given result (These tasks were originally used by Saenz-Ludlow &Walgamuth (1998)). The remaining tasks in this part asked students to construct equalities with four numbers of their own, using all four operations, i.e. $_ + _ = _ + _$. (This task was originally used by Witherspoon (1999), while the rest were developed for the purposes of this research work (i.e. $_ \div _ = _ \times _$)).

T2 included equations in two different syntax, three different structures and six different representation formats. The two types of syntax used were the "start unknown" type (the unknown quantity was prior to the equal sign, i.e. $7 + x + 6 = 20$) and the "result unknown" type (the unknown quantity was after the equal sign, i.e. $26 - 9 - 7 = p$). The three structure types were $a + b + c =$, $a - b - c =$ and $a \times b + c =$. The six representation formats used were word descriptions (i.e. "When I add 5 to 8 and subtract 3, what is the answer?"), word problems (i.e. "Chris gathered 9 shells from the beach, he put them in his collection and he now has 17 altogether. How many shells did he have at the beginning?"), pictures (see Fig. 3 in Appendix), diagrams (see Fig. 4 in Appendix), symbolic equations with an unknown quantity shown with a shape (i.e. $21 - 6 - \diamond = 10$) and symbolic equations with a letter (i.e. $8 \times m - 6 = 18$).

Participants in the study were 135 students (66 male and 69 female) from two primary schools in Nicosia district in Cyprus, 30 were 3rd graders, 38 were 4th graders, 38 were 5th graders, and 29 were 6th graders. The TE lasted for four months. Students participated in a 40 minute lesson every week. All teaching was undertaken by the first author. The students completed T1 three times, at the beginning, in the middle and after the end of the TE. They also completed T2 twice, before and after the end of the TE.

Data were analyzed qualitatively and quantitatively. The definitions, provided by the students in the first part of T1, were analyzed qualitatively, as they were categorized according to the content of the definition. The definitions were coded as "relational", if students indicated that the equal sign represents a relationship of equivalence, and as "operational", if they indicated that it announces the result or it gives the direction to do the operations. No response or unclear responses were coded as "other". Data from the remaining tasks from T1 and from T2 were analyzed quantitatively. Correct responses to the tasks of T1 and T2 were coded as 1 and wrong responses were coded as 0. Each student's score for each representation format of the equations in T2 was estimated by the sum of correct responses to the four equations of each format.

Working Group 3

SPSS was used for descriptive and inferential statistical analysis of the data. Descriptive analysis was used to describe students' abilities to understand the double meaning of the equal sign and to handle algebraic tasks in different syntax, structure and representation format. Inferential analysis was used in order to evaluate the TE outcome, that is, whether it succeeded to help students develop relational understanding of the equal sign and whether it enhanced their ability to solve equations.

RESULTS

The number of students with relational understanding of the equal sign (when presented on its own/T1-Task 1) increased at the end of the TE (Fig. 1). A paired t-test for the whole student population showed a statistically significant difference $\{t(134)=-4,91, p=0,001\}$ between the first ($M=1,85, SD=0,69$) and the second ($M=2,26, SD=0,77$) measurement.

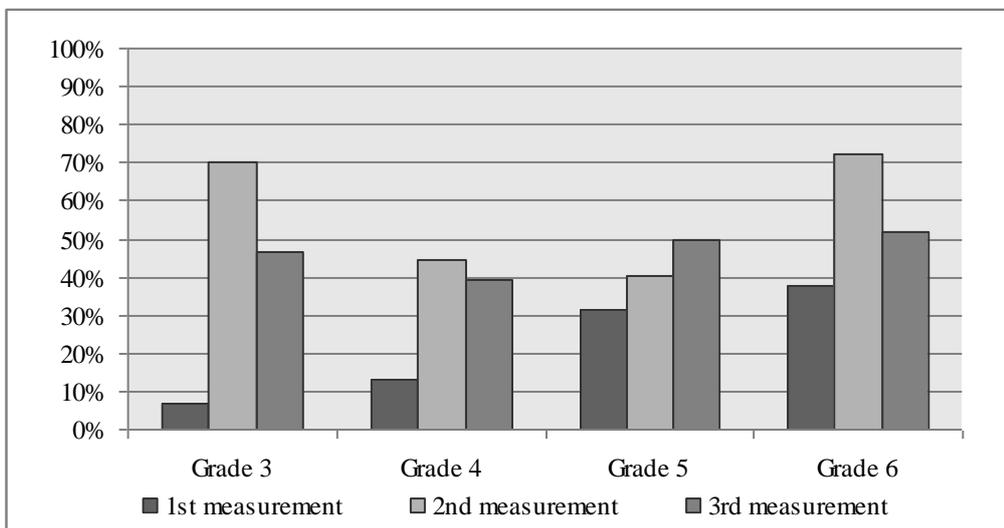

Figure 1. Percentage of students with relational understanding of the equal sign (T1-Task 1) by grade level

This indicates that on the total more students gave definitions indicating relational understanding at the second measurement (Fig. 1). Significant differences $\{t(134)=5,32, p=0,001\}$ were also observed between the second and third ($M=1,79, SD=0,81$) measurement. This outcome indicated that the number of students giving relational understanding decreased. As shown in Figure 1, more third and sixth graders kept the relational understanding at the end of the TE than fourth and fifth graders whose definitions with relational understanding were even more limited.

Kruskal-Wallis criterion revealed statistically significant differences in the students' Mean Rank by grade in the first ($K-W=19,78, df=3, p=0,001$) and the second ($K-W=18,04, df=3, p=0,001$) measurement of the level of understanding of the equal sign when it was presented on its own. Mean Rank increased from lower grades to

Working Group 3

higher ones, suggesting that the percentage of students with relational understanding increased the higher their grade was. There were no statistically significant differences between the Mean Rank in the third measurement. This can be explained by the fact that students from all four grades participated in the same TE and had developed analogous understanding for the equal sign.

The third task of T1 asked students to give a definition for the equal sign when it was presented in an equation. The context of this task, as opposed to the first one, was expected to lead students to the relational meaning of the symbol and to the structural characteristics of an equation. At the end of the TE, more students gave definitions of the equal sign as a relational symbol in this context (Fig. 2). A paired t-test between the first measurement ($M=1,85$, $SD=0,88$) and the second ($M=2,29$, $SD=0,93$) showed statistically significant difference [$t(134)=-4,72$, $p=0,001$]. The difference between the second and third measurement ($M=2,07$, $SD=1,07$) was also significant [$t(134)=2,05$, $p=0,042$]. It was also found that more students showed relational understanding of the equal sign in the middle of the TE than at the end of it.

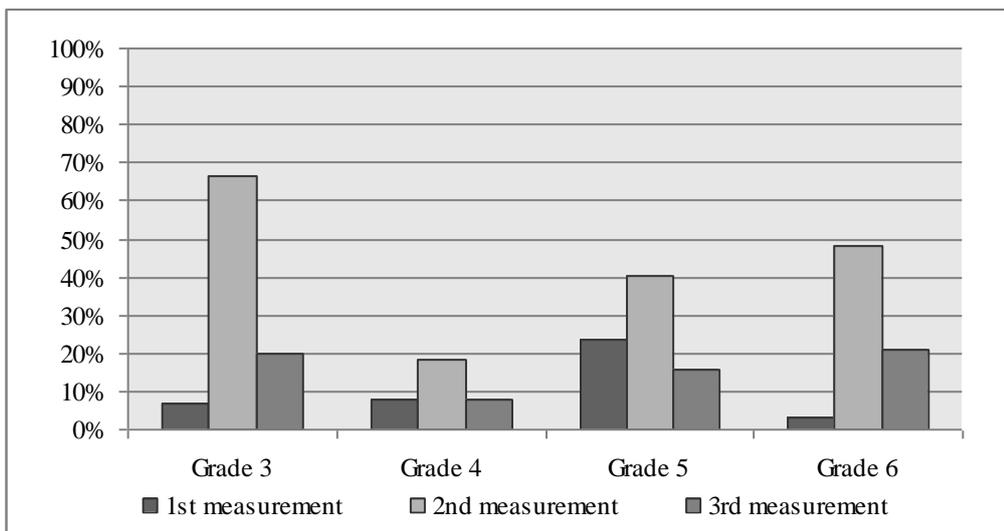

Figure 2. Percentage of students with relational understanding of the equal sign (T1-Task 3) by grade level

The Kruskal-Wallis criterion revealed statistically significant differences of the level of understanding of the equal sign when presented in an equation in the students' Mean Rank by grade in the first measurement ($K-W=8,65$, $df=3$, $p=0,034$). The Mean rank increased by grade, suggesting that the percentage of students understanding the equal sign relationally increases as according to their grade level (age). No statistically significant differences were found between understanding of the equal sign by grade level in the second and third measurement. This can be explained by the fact that all students, irrespective of grade, participated in the same TE and therefore had developed similar understanding of the equal sign.

Working Group 3

Multivariate analysis of variance has shown that there was statistically significant effect ($F_{3, 126} = 4,04, p=0,009$) of “time” and “grade level” on the students’ level of understanding of the equal sign among the three repetitive measurements [before TE ($M=46,81, SD=18,88$), in the middle ($M=56,73, SD=16,54$) and at the end ($M=57,87, SD=16,73$) of TE]. This can be due to the students’ exposure to the content of TE, although maturation may have played a role. Students’ ability to solve “result unknown” equations in different representation formats, different syntax and different structure was found to improve significantly [$t(134)=-5,98, p=0,001$] between the measurement before ($M=12,79, SD=4,56$) and after the TE ($M=14,94, SD=3,11$). Equations presented in pictorial and symbolic format were easier than word descriptions, word problems and diagrams, even after the end of the TE. Statistically significant differences were found in each one of the six different representation formats of the equations before and after TE, as shown in Table 1. Overall, the analysis has shown that the students’ performance in solving “result unknown” equations improved in all representation formats. The largest mean difference was observed in diagrams.

Representation format	M at the start	M at the end	t	df	p

Table 2: Comparison of mean performances at the “start unknown” equations (beginning and end of the TE) by representation format and overall

Working Group 3

Comparison of students' mean performance in solving "start unknown" equations before and after TE has shown statistically significant differences (before TE $M=10,83$, $SD=5,09$, after TE $M=13,23$, $SD=4,31$, $t(134)=-5,98$, $p=0,001$). Variation in the level of difficulty of the six different types of representation formats before and after TE was found. In particular, at the end of TE diagrams were found to be the second easiest types of equations after pictures, whereas at the beginning they were the most difficult.

Table 2 shows comparisons of students' mean performance before and after TE in solving "start unknown" equations in different representation formats. Results show that in each one of the six representation formats of the equations students' performance improved after TE, especially at diagrams and symbolic equations (with letter).

Independent Variable	β	p	F	df	R2
Gender	0,06	0,52	0,40	1,134	0,00
Grade level	0,32	0,00	15,50	1,134	0,10

Table 3: Regression coefficients of independent variables predicting students' ability to solve "start unknown" equations after the TE

In order to examine which variables could predict students' ability to solve "start unknown" equations at the end of TE, linear regression analysis was performed. Table 3 shows the values of each independent variable when it was examined separately. In the next step, in order to control multi collinearity, a linear regression analysis was performed stepwise with all independent variables together. In the final regression model ($F_{3, 130} = 45,4$, $p=0,001$, 51%) only three variables were included: Performance in T1 – 3rd measurement ($\beta = 0,50$, $p=0,001$), Grade level ($\beta = 0,22$, $p=0,001$) and Ability to construct equalities – 2nd measurement ($\beta = 0,23$, $p=0,001$).

Working Group 3

It is shown that improvement of students' ability to use the equal sign relationally to construct equalities helps their ability to solve "start unknown" equations. Also, it is suggested that their ability to solve such equations is improved by studying relevant subjects through their school years, since grade level has been found to play an important role. Finally, the values of the regression coefficients demonstrate that, when students develop relational understanding as opposed to operational understanding only, are more capable of solving "start unknown" equations.

Generally, results support the idea that equation solving ability can be improved through the development of the dual meaning of the equal sign. More specifically, it is suggested that a teaching program can help students understand that the equal sign represents a relation and subsequently improve their ability to solve equations in different structure, syntax and representation format.

DISCUSSION

Understanding the concept of equality is an important prerequisite for students' abilities to solve equations. As was documented by the outcome of the TE, when students are able to construct equalities with their own numbers using all four number operations, they are more successful at solving equations in multiple representations. Although primary school students' (grade 3-6) understanding of the equal sign is generally limited to its operational meaning, they are capable to develop its dual meaning when they are exposed to teaching that aims at developing the relational meaning of the symbol. Thus the concept of equality needs to be emphasized in primary school math curriculum, in order to help them build robust knowledge for further algebra study in later years.

The teaching of the relational meaning of the equal sign does not happen during the years of primary schooling and this omission of the mathematics curriculum leads students to a limited understanding of it. Besides, its pervasive use as an operational sign helps them build strong misunderstandings of its meaning. Consequently, the sooner in their school life students become aware that the equal symbol is both an operational and a relational symbol, the fewer misconceptions they will have. Limited understanding of the equal sign (that is, only operational meaning of the sign) may hamper the development of important algebraic ideas, such as the concept of equality and their ability to solve equations.

As it has been suggested by the outcome of the implementation of the teaching experiment discussed above, it is helpful for primary school students to both understand the dual meaning of the equal sign and use multiple representation formats for the concept of equality. The use of multiple representations of equivalent expressions gives students an insight of the concept of equality and helps them generalize. The order in which different representation formats of equality can be used seems to be an important issue for the teaching of the concept of equality. Pictures and symbolic expressions have been found to be easier for primary school

Working Group 3

students than verbal expressions and diagrams. Thus, a teaching program aiming at developing the concept of equality to students of these ages needs to be designed on the basis of students' abilities to handle certain representation formats.

Primary school students need to understand the concept of equality and to be able to use correctly the symbol that represents this relation, in order to be able to recognize equality during the process of equation solving. The process of generalization is an important element of a teaching program that may help them "see" the equality in multiple representation formats and use it to solve equations when they begin the study of formal algebra in high school.

PATTERNING PROBLEMS: SIXTH GRADERS' ABILITY TO GENERALIZE

Ana Barbosa, School of Education of Viana do Castelo, Portugal

This paper analyses the performance of fifty-four 6th grade students when solving visual patterning tasks. The main goal is to understand the following features: type of generalization strategies used; difficulties that emerged from students' work; and the role played by visualization on their reasoning. In this paper I will focus on the results related to the implementation of two particular tasks.

Keywords: Mathematics, problem solving, patterns, generalization.

INTRODUCTION

Since the 1980s problem solving has been recognised as a fundamental part of the teaching and learning process in mathematics (NCTM, 2000). This prerogative is still current in the recent curricular guidelines of several countries. However, international studies (SIAEP, TIMSS, PISA) show that Portuguese students perform badly problem solving (Amaro, Cardoso & Reis, 1994; OECD, 2004; Ramalho, 1994). These results along with similar difficulties observed in classroom experiences, are a matter of serious concern to the researchers and educators' community in Portugal. This study approaches problem solving through the exploration of visual patterning tasks: (1) pattern generalization may contribute to the development of abilities related to problem solving, through emphasising the analysis of particular cases, organizing data in a systematic way, conjecturing and generalizing. Working with numeric, geometric and pictorial patterns may be helpful in building a positive and meaningful image of mathematics and contribute to the development of several skills related to problem solving and algebraic thinking (NCTM, 2000; Vale, Barbosa, Barbosa, Borralho, Cabrita, Fonseca, et. al., 2009); (2) Geometry is considered a source that can help students to develop abilities such as visualization, reasoning and argumentation. Visualization is essential but its role has not always been emphasized in students' mathematical experiences (Healy & Hoyles, 1996; Presmeg, 2006). Portuguese teachers privilege numeric aspects over geometric ones in classrooms. This study aims to understand how 6th grade students (11-12 years old) solve problems involving visual patterns, addressing the following research questions: (a) how can we characterize students' generalization strategies? Which difficulties do 6th grade students have when solving pattern exploration tasks? (b) Which difficulties do 6th grade students have when solving pattern exploration tasks? (c) What is the role of visualization on students' reasoning?

THEORETICAL FRAMEWORK

The mathematics curricula of many countries include significant components related to patterns, including: searching for patterns in different contexts; using and understanding symbols and variables that represent patterns; and generalizing. Curricular guidelines reflect an enthusiastic view about the role of patterns in

Working Group 3

mathematics. Some mathematicians go even further to define mathematics as the science of patterns (Devlin, 2002; Steen, 1990), highlighting the centrality of this theme. The Portuguese curriculum considers the importance of developing abilities like searching and exploring numeric and geometric patterns, as well as solving problems, looking for regularities, conjecturing and generalizing (ME-DGIDC, 2007). Pattern generalization can be achieved through a given strategy, but different students may use diverse approaches to accomplish generalization. There are significant works concerning students' generalization strategies, from pre-kindergarten to secondary school. The revision of several researchers' frameworks (Lannin, 2005; Lannin, Barker & Townsend, 2006; Orton & Orton, 1999; Rivera & Becker, 2005; Stacey, 1989) led me to develop the categorization (Barbosa, 2010) shown in Table 1.

Strategy		Description
<i>Counting (C)</i>		Drawing a figure and counting the desired elements.
<i>Whole-object</i>	No adjustment (W_1)	Considering a term of the sequence as unit and using multiples of that unit.
	Numeric adjustment (W_2)	Considering a term of the sequence as unit and using multiples of that unit. A final adjustment is made based on numeric properties.
	Visual adjustment (W_3)	Considering a term of the sequence as unit and using multiples of that unit. A final adjustment is made based on the context of the problem.
<i>Difference</i>	Recursive (D_1)	Extending the sequence using the common difference, building on previous terms.
	Rate - no adjustment (D_2)	Using the common difference as a multiplying factor without proceeding to a final adjustment.
	Rate - adjustment (D_3)	Using the common difference as a multiplying factor and proceeding to an adjustment of the result.
<i>Explicit (E)</i>		Discovering a rule, based on the context of the problem, that allows the immediate calculation of any output value given the correspondent input value.
<i>Guess and check (GC)</i>		Guessing a rule by trying multiple input values to check its' validity.

Table 1: Generalization Strategies Framework

These categories will be clarified in this paper, through some examples.

Patterning activities can be developed in a variety of contexts (numeric, geometric, concrete, visual) and may promote the use of different approaches. Gardner (1993) claims that some individuals recognize regularities spatially or visually, while others notice them logically or analytically. This duality has caused much controversy. Many investigators stress the importance of visualization in problem solving (Presmeg, 2006; Shama & Dreyfus, 1994), while others claim that visualization should only be used as a complement to analytic reasoning (Goldenberg, 1996; Tall, 1991). Those perspectives reflect the importance of using and developing visual abilities, enhancing students' mathematical experiences. Nonetheless, teachers must consider that *seeing* an image can lead to different interpretations depending on the

individual. A figure can be apprehended perceptually when the image is interpreted as a whole, or discursively, if the individual identifies the spatial disposition of the elements that compose the figure (Duval, 1998). Considering patterning tasks and the generalization process, the discursive apprehension of a pattern can be of different nature. Either by seeing sets of disjoint visual cues that form the initial figure (constructive generalization) or by identifying overlaps, whose elements are counted more than once involving a subsequent subtraction (deconstructive generalization) (Rivera & Becker, 2008).

Depending on the type of task, some strategies may be more adequate than others and, on the other hand, can even lead students to difficulties or incorrect answers. It is fundamental that students understand the potential and limitations of each approach.

METHOD

I performed a qualitative approach (Erickson, 1986) with a case study design (Yin, 1989) with fifty four sixth-grade students (11-12 years old), from three different schools in the North of Portugal, over the course of a school year. These students solved seven tasks during six months, working in 27 pairs. Two pairs from each school were selected for clinical interviews. The tasks used in the study required near generalization (the order of the term allows the use of strategies like making a drawing or using a recursive method) and far generalization (the use of recursive methods is not adequate, implies the finding of a rule) and featured increasing and decreasing linear patterns as well as non linear ones. This paper reports results related to the application of two tasks.

RESULTS

Generalization strategies

The first task was *Pins and Cards*. It involves an increasing linear pattern, illustrated with a visual representation of the third element of the sequence. Table 2 shows the strategies used to solve the problem and its connection with the level of generalization. Following Table 1, the strategies were abbreviated. No answer or imperceptible strategy was categorized as NC. The first column of Table 2 summarizes the number of pairs of students that used a given strategy in each of the three questions of this task, based on the categories described in Table 1.

	C	W ₁	W ₂	W ₃	W	D ₁	D ₂	D ₃	D	E	GC	NC	Total
1.	16	8	-	1	9	1	1	-	2	-	-	-	27
2.	-	3	2	1	6	3	1	-	4	12	-	5	
3.	-	2	1	-	3	-	4	3	7	9	-	8	

Table 2: Summary of the strategies used by the 27 pairs of students

The first question of this task requires near generalization (students must find the 6th element of the sequence). It can be solved using recursive reasoning, either by making a drawing of the requested term of the sequence and counting its elements,

Working Group 3

using the *counting* strategy, or by extending the sequence through the identification of the common difference (recursive strategy). A counting strategy was the predominant approach in near generalization tasks and it always led to a correct answer. Figure 1a reflects one example of counting strategy.

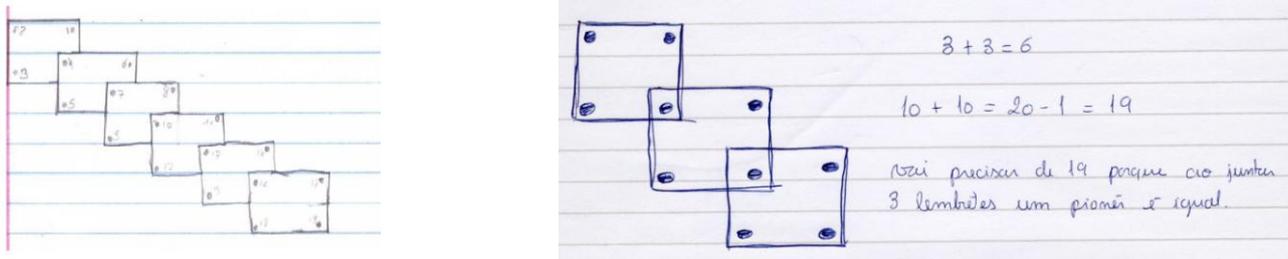

Figure 1a, 1b. Counting strategy and W_3 strategy to solve question 1

The *whole-object* strategy also emerged in some pairs of student. This approach is associated to direct proportion situations and the problem does not fit this model. For this strategy to be adequate, students had to make a final adjustment based on the context. Eight pairs of students used proportional reasoning, doubling the number of pins associated to the three cards. Only one pair adjusted the result obtained duplicating the number of pins of the three cards (see Figure 1b).

Only one pair of students extended the sequence using the common difference and achieves a correct answer. This is astonishing because this kind of task tends to promote *recursive* thinking (e. g. Orton & Orton, 1999; Stacey 1989), especially when near generalization is involved. We found another case in which the *difference* strategy was employed but in an incorrect way. These students used a multiple of the common difference, without adjusting the result. The *explicit* and *guess and check* strategies were not applied to solve this question.

Although both questions 2 and 3 require far generalization, the third question of task 1 involves reverse thinking. As expected, when approaching far generalization students revealed more difficulties and can be seen by the increasing number of NC answers in Table 2. We can also notice that students dropped the *counting* strategy when solving these two questions. Some pairs of students started using this strategy but gave it up, claiming that “there were too many cards”. As an alternative, *explicit* strategies prevailed. Those who relied on this approach, identifying an immediate relationship between the two variables, presented a high level of efficiency, making a discursive apprehension of the image. Some students *saw* that each card needed three pins and the last one four, deducing that the rule was $3(n-1)+4$ (n , number of cards). Other pairs of students *saw* the pattern differently, considering that each card had three pins adding one more at the end. The rule was $3n+1$ (n , number of cards). This fact reinforces that individuals might see the same pattern differently (Rivera & Becker, 2008), originating equivalent expressions. In spite of finding varied forms of representing the same pattern, these generalizations were all constructive. Two pairs of students performed this strategy inadequately in the last question, mixing pins and cards. The *whole-object* strategy remained in this question. Some students

Working Group 3

considered multiples of known terms of the sequence (Figure 2). Students used proportional reasoning to determine the number of pins and when adjusting the result, they neglected the problem context, and using only numeric properties, they obtained an incorrect answer.

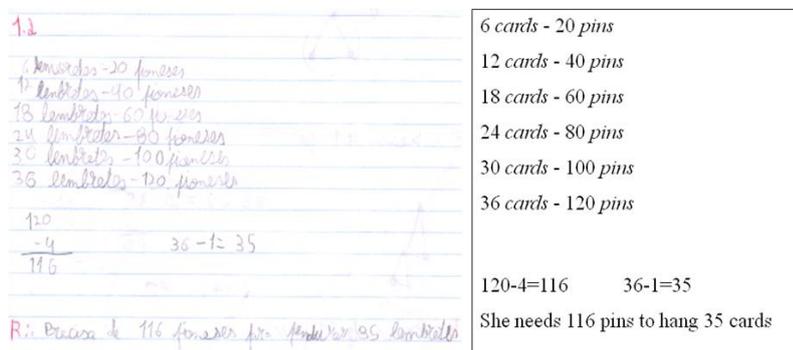

Figure 2: W₂ strategy used to solve question 2

Comparing the first question with the other questions the use of the *difference* strategy increases. Some students gave up *counting*, as the order of the term increased, and started by the common difference between terms. In the third question of the task, we noticed that three pairs of students applied a strategy that had not been used before (D₃). The difference between consecutive terms is three pins, so students used this fact to approach the number of pins. Knowing the structure of the pattern, they were able to criticize the result, adjusting it correctly.

It is important to note that nearly 25% of the responses to questions 2 and 3 of the first task were not categorized. This is because these two questions imply far generalization, involving a more abstract reasoning.

The *Sole Mio Pizzeria* task was solved four months later. This problem is very similar to the first one, exhibiting an increasing linear pattern and involving near generalization (question 1) and far generalization (questions 2 and 3), with a visual representation of the third and fourth terms of the sequence. The strategies used by the students are shown in Table 2, using the same structure of Table 1:

	C	W ₁	W ₂	W ₃	W	D ₁	D ₂	D ₃	D	E	GC	NC	Total
1.	21	-	-	-	-	4	-	-	4	2	-	-	27
2.	1	-	-	-	-	3	-	1	4	22	-	-	
3.	-	-	-	-	-	2	3	-	5	14	5	3	

Table 3: Summary of the strategies used by the 27 pairs of students

There was a lack of preference for the *whole-object* strategy in this problem. A linear pattern is involved but the use of proportional reasoning is not adequate, unless an adjustment is made based on the context. This adjustment is more complex in this problem than in the previous one. This might justify the absence of this approach. *Counting* was once again the predominant strategy in near generalization (question 1), leading to the students to a correct answer. It was applied by most of the students and this preference increased comparing to the previous task. Other

Working Group 3

strategies emerged in this first question but were used only by a minority of the students. Four pairs choose recursive reasoning to extend successfully the sequence to the 10th term and two pairs applied an explicit reasoning. We highlight that in the first task explicit strategies only appeared when students were dealing with far generalization so it is surprising that they used it at this stage, showing that they immediately discovered the structure of the pattern. As in the first task, when dealing with far generalization, students did not recognize the usefulness of *counting* and that is why it has no expression in Table 3, as they progress to far generalization. On the other hand, *explicit* reasoning prevailed being implemented by even more students in a successful way. All of them described the pattern as $2n+2$, n being the number of pizzas. They frequently referred that “in front of each pizza there are two people and one more at each end of the table”, describing the pattern in a constructive way. As an alternative, some students adopted a recursive approach, through the extension of the sequence using the common difference. Similarly to what happened in the first task, there were three pairs that considered multiples of the common difference but neglected to adjust the result, basing their work just on numeric relations. Table 3 also shows the use of the new strategy *guess and check* was only applied in far generalization, when reverse thinking was involved. Students identified the relation between the two variables and then tried some numbers until they achieved the intended result (Figure 3).

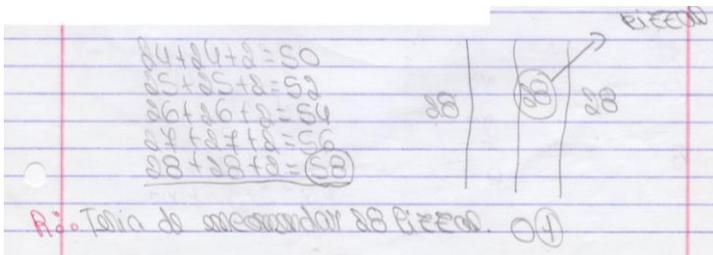

Figure 3: Guess and check strategy used to solve question 3

Difficulties emerging from students' work

When solving the first task some students struggled with cognitive difficulties that led to incorrect answers. In pairs of students who made false assumptions about the use of direct proportion, attention tended to focus only on numeric attributes with no appreciation of the sequence structure. The use of strategies based on recursive reasoning was not always adequate, particularly when far generalization questions were involved. The recursive approach through the use of D_2 lacked a final adjustment based on the context of the problem, because students only considered a multiple of the common difference. Also, when students used explicit strategies, the model was not always correctly applied. These errors might be linked to the extensive students' experience manipulating numbers without meaning, making no sense of what the coefficients in the linear pattern represent. Results from the second task show that the level of students' efficiency increased. They displayed a greater level of awareness in the selection of the proper strategies. For example, the

inadequate use of direct proportion was no longer observed. In spite of these differences, questions that involved reverse thinking provoked a shift on the type of approaches used by the students.

The role of visualization in students' reasoning

Presmeg (2006) states that a strategy is of visual nature if the image/drawing plays a central role in obtaining the answer, either directly or as a starting point for finding the rule. In this sense the following strategies are included in this group: *counting* (C), *whole-object with visual adjustment* (W_3), *difference with rate-adjustment* (D_3) and *explicit* (E). *Counting* was always a successful strategy but only useful in solving near generalization questions. Drawing a picture of a certain object and counting its elements was an action used in near generalization questions and does not lead to a generalized strategy. Strategy W_3 was only used by one pair of students, when solving the first task. They had only applied it correctly in near generalization. This type of reasoning involves a higher level of abstraction in visualization. In spite of not being one of the most frequent strategies, students who used D_3 always reached a correct answer. This fact enhances the relevance of understanding the context surrounding the problem. Finally, the application of an *explicit* strategy leads to a high level of efficacy. Students based their work on sequence structure, referring to the relation between the variables. Only a few pairs of students “disconnected” the sequence from the context and used a mix of different variables.

DISCUSSION AND CONCLUSION

In this study, patterning tasks were selected to set an environment to analyse students' generalization strategies, difficulties, as well as the impact of the use of visual strategies when solving this type of problems.

Concerning the research questions posed, some significant findings are: (a) a variety of strategies were identified, although the frequencies observed were different; (b) students achieved better results in near generalization questions than in far generalization questions and, even with some experience with patterning activities acquired along the study, reverse thinking was still complex for many of them; (c) some of the pairs worked exclusively on number contexts using inadequate strategies like the application of direct proportion, using multiples of the difference between consecutive terms without a final adjustment and mixing variables. As a result of the study, this tendency was gradually inverted as most students understood the limitations of some of those strategies; (d) in some cases, students revealed difficulties in finding a functional relation, frequently generalizing rules that were verified for particular cases or showing a fixation for a recursive strategy; (e) visualization proved to be a useful ability in different situations like making a drawing and counting its elements, to solve near generalization tasks, and “seeing” the structure of the pattern, finding an *explicit* strategy to solve far generalization tasks; (f) the application of visual strategies allowed students to find different

Working Group 3

expressions to represent the same pattern; (g) it was also evident that they privileged constructive generalizations, *seeing* the structure of the pattern as a set of disjoint elements.

To conclude, it is important to provide tasks which allow the application of a diversity of strategies and to encourage the students to use and understand the potential of visual strategies, establishing a relationship between the number context and the visual context to better understand the meaning of numbers and variables. The connection between parallel approaches and the exploration of the potentialities and limitations of each strategy can contribute to the development of a more flexible reasoning, essential to problem solving.

THE ROLE OF TECHNOLOGY IN DEVELOPING PRINCIPLES OF SYMBOLICAL ALGEBRA

Giampaolo Chiappini

Istituto per le Tecnologie Didattiche, Consiglio Nazionale delle Ricerche (CNR),
Genova, Italy

For a significant percentage of students, the current teaching of algebra is unable to develop skills, knowledge and forms of control that are necessary to fully master this domain of knowledge. This paper builds on Peacock argument that the difficulties of teaching and learning are due to epistemological obstacles rooted in the development of the Symbolical Algebra during the 19th century. The paper shows the role of AlNuSet system, particularly its two environments named Algebraic Line (AL) and Algebraic Manipulator (AM), in the conceptual development of Symbolical Algebra.

INTRODUCTION

Moving from arithmetic to algebra, students must overcome many obstacles that can be correlated with those that mathematicians have faced during the 18th century and the first half of the 19th century, with the development of Symbolical Algebra. In fact, the definitive overcoming of a vision of algebra as Universal Arithmetic, where the meaning of symbols is legitimated by the semantic references of numerical nature, dates back to that time. In 1830 Peacock distinguished between Symbolical Algebra and Arithmetical Algebra (Peacock, 2004a, 2004b). According to Peacock, Arithmetical Algebra differs from Arithmetic for the use of letters that allow operation on indeterminate quantities, namely on quantities whose value is not specified. In this algebra, however, the operations are those of Arithmetic, with the same natural limitations that they have in this knowledge domain, so that an expression like $a-b$ has a sense only for $b < a$ (Peacock, 2004a). With Symbolical Algebra, the meaning of symbols becomes operational, namely defined according to the operation (and its properties). In Symbolical Algebra, symbols can represent any kind of quantity that is incorporated into them through specific operations. The extension of the operational field, however, is not only the result of a process of generalization, but it marks a real change in terms of principles and culture of the discipline. Peacock established two principles from which the algebra becomes operational and deductive (Peacock, 2004b). The first principle states that the result of an operation that is impossible for arithmetic, as $a-b$ for $b > a$, can be regarded as a mathematical reality. The second principle is the principle of permanence of equivalent forms. It attests that the equivalence between two expressions can be deduced from the properties of operations that are combined in their form, and this guarantees the equality of the results of calculations of the two expressions, for each

value assigned to the variable. Peacock's work can be very useful for understanding and framing epistemological obstacles encountered in teaching algebra.

NATURE OF THE OBSTACLES IN LEARNING ALGEBRA

A reflection on the work of Peacock for educational purposes was performed by Menghini (1994). In this work the author stresses the importance of presenting algebra as a tool to quantitatively interpret real-world situations. She also highlights the need for an axiomatic approach to allow students to internalize the principles developed by Peacock, to understand the jump that takes place in the passage from arithmetic to algebra and to develop knowledge and meta-control skills that are specific of the Symbolical Algebra after Peacock. For example, moving from arithmetic to algebra, it is important to understand that algebraic symbols can represent not only the numbers used in arithmetic, but also other numbers, such as negative numbers. That is, it is important to understand that the operations of arithmetic are not only transferred into the new system of signs of algebra, but in the context of algebra their meaning and their operational field may be extended. It is also important to understand that if two expressions are equal to each other for any value of their variable, this can be demonstrated through the use of transformation rules that guarantee the preservation of equivalence in transformation. Note that, in building the described knowledge and skills, it is necessary that students learn to perform various forms of control, and more precisely: the control of an algebraic expression on the numeric level, i.e. the ability to control what the expression denotes when the value of the variable is modified (Arzarello et al, 2001); the control of the expression at a syntax level, i.e. the ability to transform it by applying rules which guarantee the equivalence in the transformation (see Kieran, 2006); the control of transformation of the expression at a theoretical level, i.e. the ability to justify the algebraic transformation of an expression as logical-deductive activity within an axiomatic framework (Cerulli & Mariotti, 2002; Pedemonte, 2010). Using the terminology of Peacock, the first control level is typical of the Arithmetical Algebra, while the other control levels are specific of the Symbolical Algebra.

NEED FOR A NEW TEACHING OF ALGEBRA

The current teaching of algebra is not able to promote the conceptual development described above with a significant percentage of students. The causes are certainly different. I believe that this development cannot be achieved through the mechanical and repetitive exercises of the traditional didactics of algebra. It is necessary to allow the students to make meaningful experiences of contents and algebraic concepts in a sort of Didactical Laboratory of Mathematics that only the use of appropriate tools can help to structure (Chiappini & Reggiani, 2003). In the following I shall refer to the system AlNuSet to highlight some practices centred on its use which can facilitate the development of the two principles developed by Peacock concerning Symbolical Algebra. AlNuSet is a system that was developed at ITD-CNR in the ReMath EU project to improve the teaching and learning of algebra (Chiappini & al,

2008; Pedemonte & Chiappini, 2008; Chiappini & Pedemonte, 2010). AlNuSet consists of three environments: the Algebraic Line (AL), the Algebraic Manipulator (AM), the Function Environment (FE).). In a previous paper presented at CERME 6 (Chiappini & Pedemonte, 2010) the main ideas underlying the development and design of these three components of AlNuSet have been presented and its design has been illustrated and justified theoretically within the anthropological framework. In that paper it has been shown that the instrumented techniques available in the three environments of AlNuSet structure a new phenomenological space where algebraic objects, relations and phenomena are reified by means of representative events that fall under the visual, spatial and motor perception of students and teachers. Moreover, it has been evidenced that in the phenomenological space determined by the use of the instrumented technique of AlNuSet, algebra can become a matter of investigation.

In this article I will present some teaching practices supported by the use of the AL and of the AM in the construction of knowledge, skills and abilities concerning the extension of the operational field of the subtraction (with the construction of different meanings that the sign "-" assumes in algebra) and the principle of equivalent forms (within the development of a deductive and axiomatic vision of algebra).

THE HISTORICAL ROOTS OF THE DIFFICULTIES REGARDING THE USE OF THE SIGN "-"

In the early development of algebra and the solution of equations with negative roots, a broad debate took place among mathematicians about the nature of negative numbers. The transformation of the negative number into a mathematical entity, well-founded at conceptual level, overcome considerable disagreements in the community of mathematicians. Many mathematicians of the 17th and 18th century referred to these numbers as "false" or "absurd" because they could not conceive a quantity that was "less than nothing" and therefore had great difficulty conceptualizing it as a number, namely as an ideal entity with specific properties. Indeed, for a long time, numbers as +4 and -4 were defined as a quantity respectively to add and to subtract, as an operational value and no predicative value was assigned to the signs "+" and "-". It took a long time to achieve consensus about validity of the different meanings to the sign "-" in writing as -4 or $a-b$ for $b > a$. The work of Peacock has played a crucial role in this development. The difficulties that students face extending subtraction to negative numbers reflect the difficulties that characterized the conceptualization of these numbers on the historical level. In fact, many students have difficulties interpreting the meaning of the sign "-" placed before a number, as in -3. It is not easy for the teacher to help them overcome these difficulties. Below I will highlight the role of mediation provided by the AlNuSet in developing these specific meanings.

THE EXPERIENCE OF THE EXTENSION OF THE OPERATIONAL FIELD OF SUBTRACTION

In AlNuSet, the Algebraic Line (AL) is a normal number line empowered with new operative and representative opportunities of algebraic nature through the exploitation of digital technology. The starting point of the transformation of the number line into the AL is the possibility to associate a letter to a point on the line. The figure below shows two states of the AL of AlNuSet after the editing of the letter x . In this environment the letter x becomes something very concrete and tangible - a mobile point on the line that can be dragged with the mouse. If the point is not moved, x assumes a definite value on the line. Dragging the point with the mouse, the value that x assumes on the line changes.

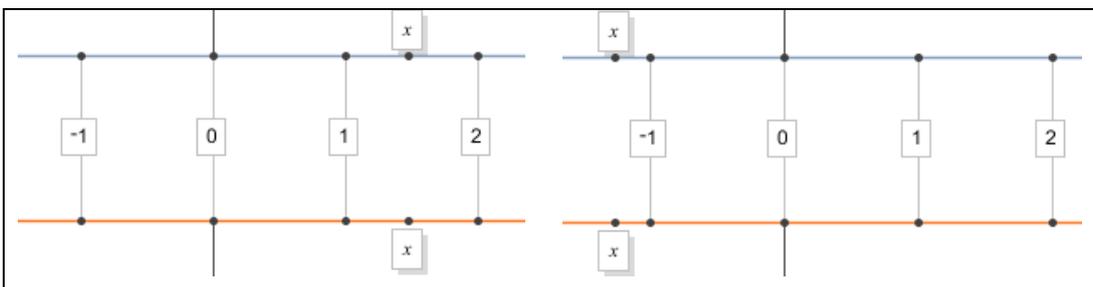

Fig 1: Two states of the Algebraic Line after the editing of the letter x

This environment offers different operative and representative possibilities of quantitative nature to operate with algebraic expressions, among these are the possibilities of :

- editing algebraic expressions that are automatically represented on the line associated with points that indicate the value of the expression according to the value assumed by their variables on the same line,
- dragging the mobile point corresponding to algebraic variables, whilst maintaining the relationship between points, expressions and values.

In addition, the AL can be instantiated in various numerical domains, including natural numbers, integers, rational numbers and real numbers. On the line only numbers and expressions that are compatible with the choice made are visible. These features have great importance at didactical level. Consider this didactical situation:

Working with natural numbers, associate the variables x and y with mobile points on the line, and edit the expressions $x+y$ and $x-y$ (first image of the Fig. 2). Drag the points x and y . Can you explain what happens? Repeat working with the integers.

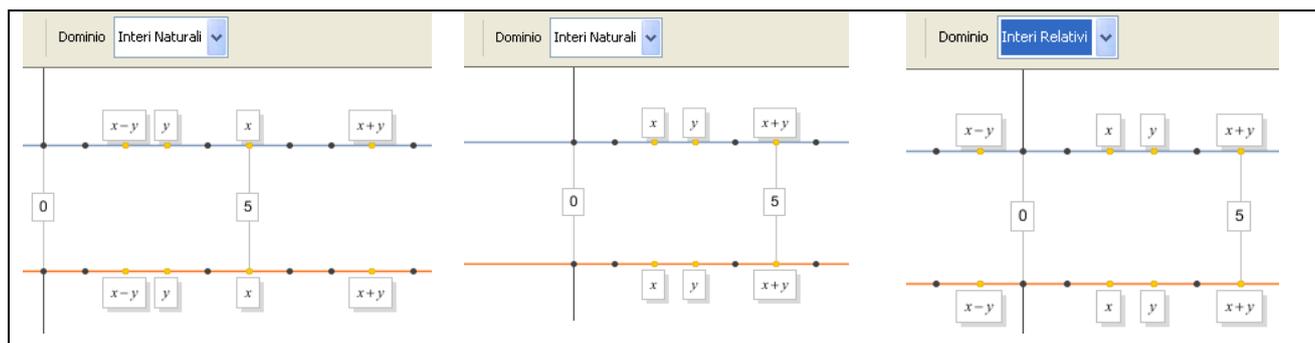

Fig 2: Three images highlighting crucial representative events of the didactical situation

Working with natural numbers, mobile points x and y can be dragged only to 0 or positive integers. By dragging points x and y , it is easy to verify that the expression $x+y$ is always represented on the line, whatever the value of x and y is, while when $y > x$, an important representative phenomenon occurs: the expression $x-y$ and the point associated to it disappear from the line (second image of Fig 2). This experience can be used to reflect on the domain in which an expression is defined, to investigate and clarify the conditions under which the subtraction is closed in N . When the domain is extended to include the integers, however, the expression is defined for any value of x and y (third image of Fig 2). In other words, it is possible to make a concrete experience of the principle of Peacock according to which the expression $x-y$ assumes a status of mathematical reality when $y > x$, through the extension of the operational domain of the subtraction to the relative integer. These features make the AL an important educational tool for learning to control the domain of existence of expressions through new types of activities such as:

Under what conditions will the following expressions will be represented on the AL if you select the domain of natural numbers: $6 \cdot x - y$; $2 \cdot x - 4 \cdot y$; $2 - x - 8 \cdot y$.

It is important to note that through tasks such as these, the AL becomes a kind of laboratory where it is possible to explore the domain of existence of an expression, to make conjectures on the conditions of its existence and to validate these *hypotheses*.

OPPOSITE AND EQUIVALENT EXPRESSIONS: THE EXPERIENCE WITH THE ALGEBRAIC LINE OF ALNUSET

Consider the following assertion: “The two expressions $-x$ and $-x^2$ considered in the domain of relative integers always represent a negative number”. What do you think about this statement? Justify your answer. Construct the two expressions on the AL and verify your answer using what is displayed on the AL during the interaction. Is there any difference among the following expressions: $-x^2$ and $(-x)^2$ and $-(-x)^2$?

Solving this task in an experimentation with AlNuSet, many students aged 15 answered that “ $-x$ is a negative number and $-x^2$ is always a positive number because the even power of a negative number is positive”. This answer shows that these students are not able to control either the use of the “-“ sign with the meaning of opposite and the connection of the algebraic notation with their referential objects.

Then these students represented the expression $-x$ and $-x^2$ and the other algebraic expressions indicated in the task on the algebraic line of AlNuSet (see Fig 3).

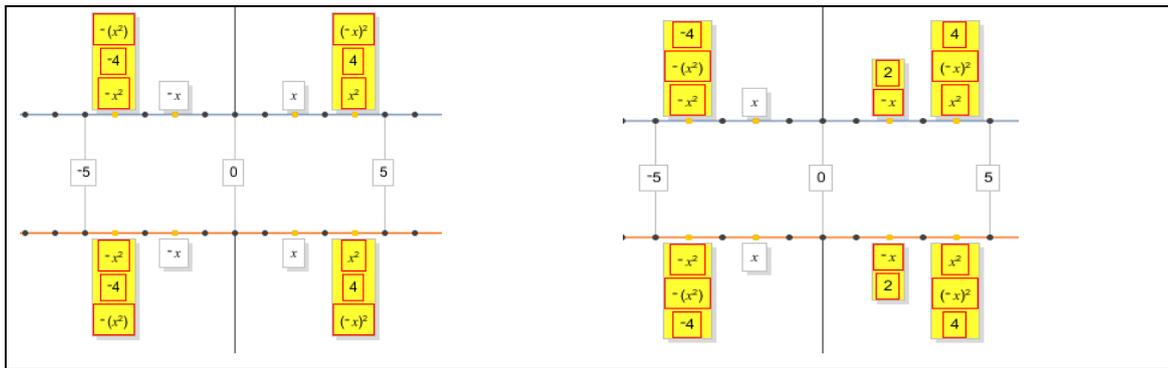

Fig. 3: Two images of the exploration of the didactical situation on the AL

They dragged the variable x and observed that the point corresponding to $-x^2$ on the algebraic line is always located on negative numbers while the point corresponding to $-x$ is positive when x is negative and vice-versa “We have verified with AlNuSet that what we have written is false, so the assertion reported in the text that $-x^2$ is always negative is true”. “With AlNuSet we have verified that $-x^2$ is a negative number, $(-x)^2$ is a positive number and $-(-x)^2$ is a negative number coincident with $-x^2$ ” Some students were quite amazed by these result. A pair of students wrote: “ $-x^2$ and $(-x)^2$ are the same thing because making the square you always obtain a positive number...” and after the verification with AlNuSet “...Ah, hence they are not the same thing, because in one expression the minus sign is inside the parenthesis while in the other it is not”.

The features of AlNuSet have been exploited both to destabilize students’ wrong conceptions regarding the connection of the algebraic rules used in a sign and its referential object and to develop new appropriate conceptions of this connection. “Through the observation of the line it emerges that, except at 0, x and $-x$ are opposite on the line. Moreover $-x^2$ and $(-x)^2$ are not the same thing, they are opposite while $-x^2$ is always equal to $-(-x)^2$ ”. The example shows the mediating role of two important features of the algebraic line, namely that:

- two expressions are opposite when their respective points on the line are *always* symmetric about the point 0,
- two expression are equivalent when they are *always* associated with the same point on the line.

These features have been exploited to mediate both the comprehension of the symbolic function of the sign “-“ and the development of the notions of equivalent and opposite expressions. Concerning the notion of equivalent expression, let me consider another task:

Explain what the expression $3 \cdot x + 1$ represents, considering x as natural number. Write an equivalent expression and use the Algebraic Line to verify their equivalence.

A pair of students wrote, “The expression $3 \cdot x + 1$ represents the triple of $x + 1$, and stated $3 \cdot (x + 1)$ to be an equivalent expression to $3 \cdot x + 1$. However, when they represented the two expressions on the AL, they observed that they are not equivalent because they do not refer to the same point on the line while dragging the variable x along the line. The emergence of a contradiction between the performed hypothesis and the results visualized on the algebraic line helped them reflect on the structure of the two expressions through the connection of the two expressions to their referential objects on the AL. “Using AlNuSet we have seen that the triple of $x + 1$ is $(x + 1) \cdot 3$ while $3x + 1$ is 3 times a natural number plus 1”. Successively they conjecture $2x \cdot x + 1$ to be equivalent to the expression $3 \cdot x + 1$. They verify with AlNuSet that also this hypothesis is wrong, they produce $2x + x + 1$ as equivalent expression, that successively transforms into $(2 + 1) \cdot x + 1$ and verify that this is equivalent to the given expression (see next paragraph). The two reported examples highlight the mediating role of AlNuSet in the appropriation of the algebraic symbolism through the comprehension of how algebraic operations characterize the expressions and determine what they denote. In particular the last example shows the construction of the notion of equivalent expressions through a quantitative approach. In the successive sections I will analyze the role of AlNuSet in the development of equivalent expressions through an operational approach coherent with the Peacock’s principle of permanence of equivalent forms.

DEVELOPMENT OF KNOWLEDGE, SKILLS AND ABILITIES TO CONTROL THE ALGEBRAIC MANIPULATION

Much of current algebraic educational practice is unable to promote the comprehension of the notion of equivalent expressions through an axiomatic and deductive vision of the algebraic transformation coherent with Peacock’s principle of permanence of equivalent forms. This is evidenced by the large number of students who, despite years of work with literal expressions, are not aware that the algebraic manipulation preserves the equivalence in the transformation, that equivalence between two expressions can be inferred from the properties of operations combined in their form, and that through the use of such properties more complex transformation rules can be proved. In this regard we note that in ordinary educational practice, the properties of operations are presented to students, but these properties are not used to perform algebraic transformations. The steps of transformation based explicitly on the properties of operations do need to be “condensed” into more powerful transformation rules. In ordinary educational practice, teachers tend to this too early in the students’ learning. This occurs because teachers consider the basic steps of transformation as “obvious”, and because the costs of their explicit use (in terms of cognitive effort, time, and even consumption of paper) are not considered compatible with the constraints of schooling. For these reasons, the approach to algebraic transformation, centred on a long-term use of the basic properties of operations, is not commonplace in ordinary teaching practice. To promote the development of appropriate skills in algebra, both at the operative level

(ability to follow the rules) and at the conceptual level, a transformation in the educational practice is necessary. I believe that a new educational approach should be based on the use of the properties of operations and should not be separated from a deductive, properly mediated axiomatic approach.

THE ALGEBRAIC MANIPULATOR OF ALNUSET

The AM of AlNuSet was designed to approach algebraic transformation according to the perspective outlined above. Figure 4 below shows the interface of this manipulator. It is divided into two distinct spaces: the space where symbolic manipulation commands available for the transformation activities are reported (in the figure only a part of the commands is visible); the space where the algebraic expression or proposition is inserted to be manipulated and where the transformation is realised (in the figure, an example of algebraic transformation).

In the interface Algebraic Manipulator (AM) (see Fig. 4) makes available commands for the algebraic transformation that correspond to the basic properties of operations, to the equality and inequality properties between algebraic expressions, to basic operations among propositions and sets. When a sub-expression is selected, only the commands of the interface that can be applied to it are automatically activated and highlighted to the user. This feature is very important from an educational standpoint because it allows students to explore the connection among the rules of transformation available in the interface, how they may be applied and the result that the application of a rule produces.

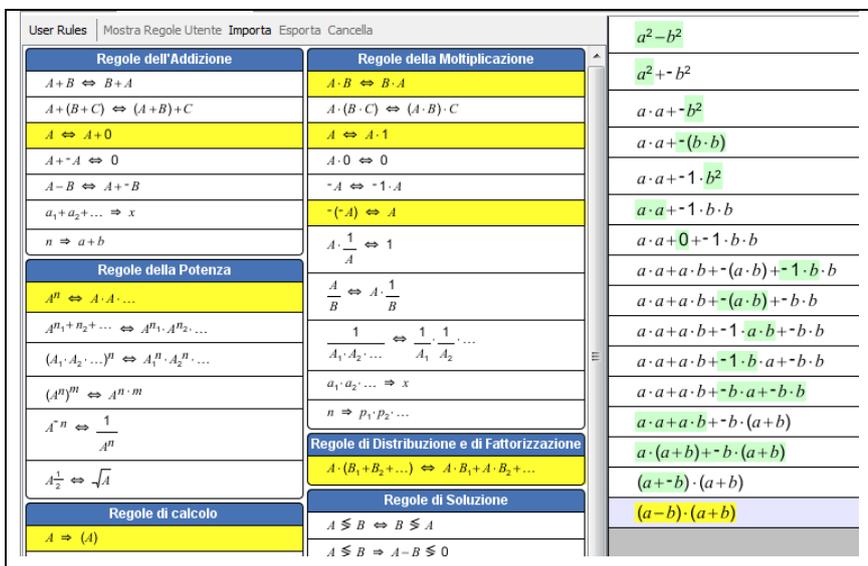

Fig 4: The interface of the Algebraic Manipulator of AlNuSet

Another feature of this AM allows students to create new transformation rules, once these have been demonstrated using the available commands. These new rules can be saved and included in the interface to be used in subsequent transformations. This feature is essential to mediate a didactic of algebraic transformation based on axiomatic and deductive approach, centred on the use of some basic axioms

Working Group 3

(properties of operations) and the demonstration of progressively more complex rules for the algebraic transformation (theorems).

EXAMPLES OF USE OF THE AM OF ALNUSET IN AN AXIOMATIC AND DEDUCTIVE FRAME OF ALGEBRAIC TRANSFORMATION

These are the commands concerning the operation of subtraction that are available in the interface of this AM.

$A+^{-}A \Leftrightarrow 0$	$A-B \Leftrightarrow A+^{-}B$	$^{-}A \Leftrightarrow ^{-}1 \cdot A$	$^{-}(\cdot A) \Leftrightarrow A$
-----------------------------	-------------------------------	---------------------------------------	-----------------------------------

These commands correspond to properties of the subtraction that students previously explored on the AL through the quantitative approach of this environment. In the Algebraic Manipulator these properties become operational tools to manipulate numerical and/or literal expressions, preserving the equivalence in the transformation.

In the following example, the commands used to perform the transformative steps are reported in the second column. These transformative steps are unlikely to emerge in the standard educational practice. On the contrary, this approach is important to learn to work consciously with the transformation rules of algebra. Often these rules are not entirely clear even to those who seem able to solve correctly. For example, several students who in the ordinary practice of algebra successfully transform $5 \cdot x - x$ into $4 \cdot x$, very often are not aware of the fact that behind their result there is the application of the neutral element of the product and the distributive property of product with respect to the sum. Not to mention those for which $5 \cdot x - x = 5$.

$5 \cdot x - x$	$A \Leftrightarrow A \cdot 1$	$(5+^{-}1) \cdot x$	$n \Rightarrow a+b$
$5 \cdot x - x \cdot 1$	$A \cdot B \Leftrightarrow B \cdot A$	$(4+1+^{-}1) \cdot x$	$A+^{-}A \Leftrightarrow 0$
$5 \cdot x - 1 \cdot x$	$A-B \Leftrightarrow A+^{-}B$	$(4+0) \cdot x$	$A \Leftrightarrow A+0$
$5 \cdot x + ^{-}(1 \cdot x)$	<i>Semplifica()</i>	$(4) \cdot x$	<i>Semplifica ()</i>
$5 \cdot x + ^{-}1 \cdot x$	$A \cdot (B_1+B_2+\dots) \Leftrightarrow A \cdot B_1 + A \cdot B_2 + \dots$	$4 \cdot x$	

The following examples concern the proof of the equivalence respectively between $-x^2$ and $-(-x)^2$ and between $3x+1$ and $2x+x+1$ after the activity performed on the Algebraic Line.

Working Group 3

$-(-x)^2$	$-A \Leftrightarrow -1 \cdot A$	$3 \cdot x + 1$	$n \Rightarrow a + b$
$-(-1 \cdot x)^2$	$(A_1 \cdot A_2 \cdot \dots)^n \Leftrightarrow A_1^n \cdot A_2^n \cdot \dots$	$(2+1) \cdot x + 1$	$A \cdot (B_1 + B_2 + \dots) \Leftrightarrow A \cdot B_1 + A \cdot B_2 + \dots$
$-((-1)^2 \cdot x^2)$	$A^n \Leftrightarrow A \cdot A \cdot \dots$	$2 \cdot x + 1 \cdot x + 1$	$A \Leftrightarrow A \cdot 1$
$-((-1) \cdot (-1) \cdot x^2)$	$1 \Leftrightarrow -1 \cdot -1$	$2 \cdot x + x + 1$	
$-(1 \cdot x^2)$	$A \Leftrightarrow A \cdot 1$		
$-(x^2)$	$-A \Leftrightarrow -1 \cdot A$		
$-1 \cdot (x^2)$	Semplifica ()		
$-1 \cdot x^2$	$-A \Leftrightarrow -1 \cdot A$		
$-x^2$			

The activity with the AM allows students to experience that the transformational algebraic activity is the demonstration of equivalence of different algebraic forms. The characteristics of the manipulator allow the teacher to introduce abstract notions in the algebraic activity such as those of proof, axiom, theorem, equivalent expressions exploiting what the system exhibits in the interaction to construct an idea of these notions.

CONCLUSIONS

In this article we have shown that when moving from arithmetic to algebra, technology can help to overcome some crucial epistemological obstacles. It has been shown that AlNuSet can be easily exploited to allow students to experiment with the two principles developed by Peacock and to grasp the axiomatic and deductive nature of symbolic Algebra. It has been highlighted that the two environments of AlNuSet allow students to interact with algebraic objects and concepts, of abstract and formal nature, in a concrete and tangible way. This is possible because digital technology allows to create phenomena related to algebraic concepts that can be controlled through a visual, spatial and motor experience. In this way, it is possible to have a direct and concrete experience with mathematical objects and concepts. This favours the construction of sense for these objects and concepts and the development of forms of control needed to master the language of algebra at the symbolic level.

SECONDARY SCHOOL STUDENTS' PERCEPTION OF BEST HELP GENERALISING STRATEGIES

Boon Liang Chua^a and Celia Hoyles^b

^aNational Institute of Education, Nanyang Technological University

^bLondon Knowledge Lab, University of London

This paper reports a study whose aim was to examine secondary school student choices of generalising strategy to determine what they would judge as the most helpful strategy for expressing generality. Data were collected from 45 Secondary One students through administering a questionnaire which contained one linear and one quadratic generalising tasks. The students had to select and justify the strategy that they believed would best help them to establish the rules. The data were analysed and revealed differences in the judgements of the more able and the less able students regarding the best-help strategy. The more able students' choices of best-help generalising strategy seemed to vary across the two different types of tasks whereas those of the less able students appeared to remain unchanged.

Keywords: Pattern generalisation, student beliefs, generalising strategy

BACKGROUND

Modelling mathematical problems as examples to demonstrate how the problems in question can be worked out is an important teaching activity that features strongly in most mathematics lessons. When illustrating examples, teachers tend to introduce their methods to show students the way to deal with these problems. They could have picked these methods based on their beliefs about what students are capable of understanding and how they will learn best (Chua & Hoyles, 2010b). All this is done with the good intention of wanting to help students experience some success. And students generally accept and follow the teachers' methods. But some teachers may go as far as to enforce their methods and get students to comply. So the big issue here is what students think of their teachers' methods. Do the teachers' methods help them understand the examples and learn mathematics better?

For generalisation of number pattern, the literature identified several kinds of generalising strategies used by students to establish a rule between the term and its position in the pattern (Drury, 2007; Lannin, 2005; Lee & Freiman, 2006; Rivera & Becker, 2008; Steele, 2008). In some of these recent studies, the students were even presented with different-looking rules that could be used to describe the same underpinning pattern and asked to justify how these rules could all be equivalent to one another (Drury, 2007; Lee & Freiman, 2006; Rivera & Becker, 2008). Such an activity challenges them to use different strategies to come up with multiple ways of seeing the same pattern. However, none of these studies went further to ask students for the kind of strategy that they believe will best help them to construct those rules. Thus the present study sought to fill in this gap by examining secondary school

student choices of generalising strategy to ascertain what they would judge as the most helpful strategy to establish the functional rule for deriving any term in the pattern. It is hoped that the findings of the present study could provide valuable insights for teachers, teacher educators and curriculum developers.

THEORETICAL FRAMEWORK

Pattern generalising tasks are a common feature of school mathematics in many countries. Generally, researchers concur that such tasks are a powerful vehicle not only for introducing the notion of variables (Mason, 1996) but also for developing two core aspects of algebraic thinking: the emphasis on relationships among quantities like the inputs and outputs (Radford, 2008) and the idea of expressing an explicit rule using letters to represent numerical values of the outputs (Kaput, 2008). Apart from these merits, pattern generalising tasks are also useful for developing the notion of equivalence of algebraic expressions as well. A typical generalising task involves facilities like identifying a numerical pattern, extending the pattern to make a near and far generalisation, and articulating the functional relationship underpinning the pattern using symbols.

There is a wealth of research that examines students' generalising strategies and reasoning when they deal with pattern generalising tasks. Students had been found to use a variety of strategies for constructing the functional rule underpinning the pattern depicted in the tasks. For instance, Rivera and Becker (2008) established three types of strategy that students employed: (1) *numerical*, which uses only cues established from any pattern that is listed as a sequence of numbers or tabulated in a table to derive the rule, (2) *figural*, which only applies in generalising tasks that depict the pattern using diagrams, and relies totally on visual cues established directly from the structure of the figures to derive the rule, and (3) a combination of both the numerical and figural approaches.

Different types of strategies do exist even within the *numerical* solutions. Bezuska and Kenney (2008) identified three such strategies that involve recursion: (1) *comparison*, where the terms in a given number sequence are compared with corresponding terms of another sequence whose rule is already known, (2) *repeated substitution*, where each subsequent term in a number sequence is expressed in terms of the immediate term preceding it, and (3) *the method of differences*, also known as finite differences in Mathematics, which is an algorithm for finding explicit formulae that are polynomial equations.

The *figural* solutions were further distinguished into two different categories by Rivera and Becker (2008): (1) *constructive generalisation*, which occurs when the diagram given in a generalising task is viewed as a composite diagram made up of non-overlapping components and the rule is directly expressed as a sum of the various sub-components, and (2) *deconstructive generalisation*, which happens when the diagram is visualised as being made up of components that overlap, and the rule

is expressed by separately counting each component of the diagram and then subtracting any parts that overlap.

Apart from these two kinds of *figural* strategy, Chua and Hoyles (2010a) introduced two other strategies into the existing classification scheme developed by Rivera and Becker (2008). One of them occurs when one or more components of the original diagram are rearranged into something more familiar. This newly reconfigured figure then unveiled the pattern structure and facilitated the construction of the functional rule. The other happens when the original diagram is viewed as part of a larger composite figure, from which the functional rule is generated by subtracting the sub-components from this composite figure.

To sum up, the literature review leads us to recognise the diverse ways of constructing the functional rule that represents the pattern in a generalising task. Hence this present study aims to add to the body of work on pattern generalisation by seeking to answer some of these questions: Which strategies would students believe would best help them to work out the rule? How would more able students' choices of best-help strategies compare with those of the less able students? If the rule underpinning the pattern were to change from a linear to a quadratic relationship, would the best-help strategies that students considered for the former case change to suit the latter?

METHODS

Student data were collected through a questionnaire administered to 45 Secondary One students (aged 13 years) from a secondary school. 29 of the students came from the Express course and 16 from the Normal (Academic) course. The students were placed in these courses based on their performance at a national examination taken at the end of their primary education when they were 12 years old. These students, 22 boys and 23 girls, were selected by the school according to their Mathematics grade in the national examination. Amongst the Express students who were considered academically more able than the Normal students, 15 scored an A or A* (high distinction) for Mathematics while the remaining 14 scored a B or C. All the 16 Normal (Academic) students scored a B or C because no one obtained A or A*.

These students had already learnt the topic of number patterns, which is part of the Singapore mathematics curriculum, before participating in this study. So they should be able to continue any pattern, whether presented as a sequence of either numbers or figures, for a few more terms, make a near and far generalisation and derive the functional rule in the form of an algebraic expression for predicting any term. Further, they should also be far more familiar in dealing with linear patterns than with non-linear ones, which are less common in their mathematics textbook.

Before administering the questionnaire, a worksheet comprising the two generalising tasks that were used in the questionnaire was distributed to every student. The two tasks, *High Chair* and *Christmas Party Decoration*, are presented in Figures 1 and 2

Working Group 3

respectively below. The first task involves a linear rule whereas the latter involves a quadratic rule. These two tasks differ from the typical textbook tasks in that they are less structured, thus allowing a greater scope for exploring the pattern structure. The students were asked to individually work out the functional rules in terms of the size number using any strategy that they were familiar with. The purpose was to prepare and familiarise them with these tasks so that they could better understand the questionnaire tasks that they had to do later.

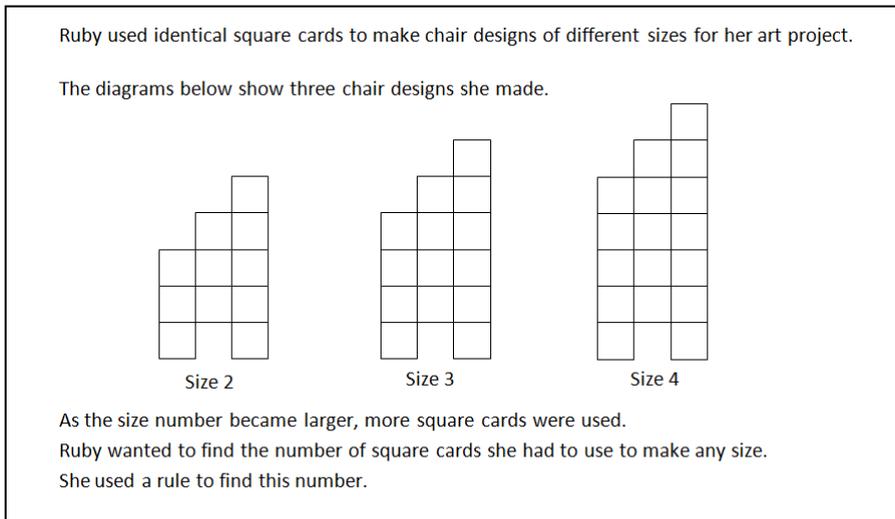

Figure 1. High Chair

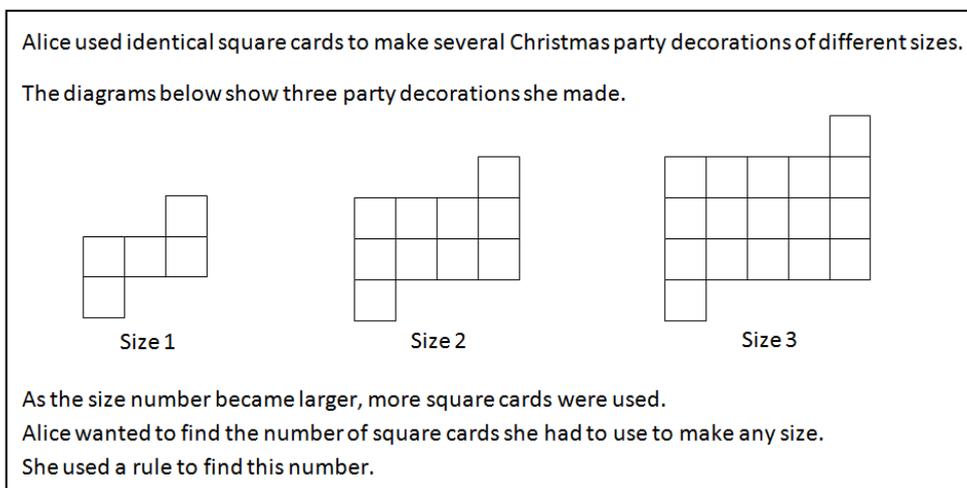

Figure 2. Christmas Party Decoration

Subsequently, the questionnaire containing those two generalising tasks, each accompanied by four possible student solutions, was distributed to each student. Figures 3 and 4 below show the four distinct student solutions for the two respective tasks. Set in a context of a discussion amongst four students, each student solution represented a different way of constructing the rule based on the classification scheme described above. Take, for instance, the solutions in *High Chair*. Method 1

Working Group 3

involves rearranging the original figures into something more familiar (S3). In Method 2, the original figures are viewed as part of a larger rectangle with four missing cards (S4). Method 3 uses a *numerical* strategy (S1) known as the repeated substitution strategy (Bezuszka & Kenney, 2008) while Method 4 employs a *constructive* strategy (S2). For *Christmas Party Decoration*, Methods 1, 2, 3 and 4 correspond to S4, S2, S3 and S1 respectively. The students were asked to choose the method that they believed would best help them to construct the functional rule. In addition, they had to provide justifications for their choices of the best-help method.

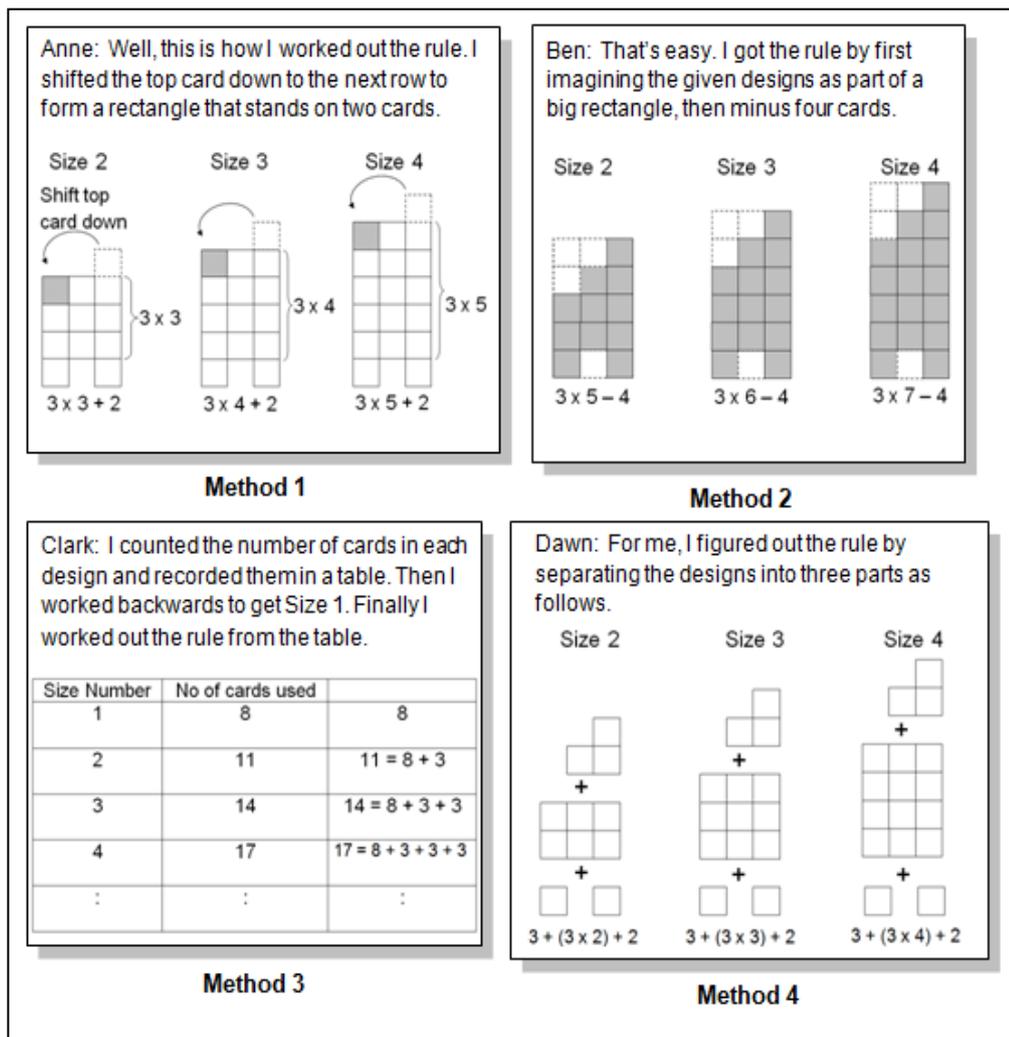

Figure 3. Student solutions to High Chair

All 45 questionnaires were collected and analysed to determine the student choices of method that they thought would best help them to work out the rule. The frequencies of the four student methods for each generalising task were then counted. The student justifications were looked into to gain a better understanding of the reasons behind their choices of best-help strategies.

Working Group 3

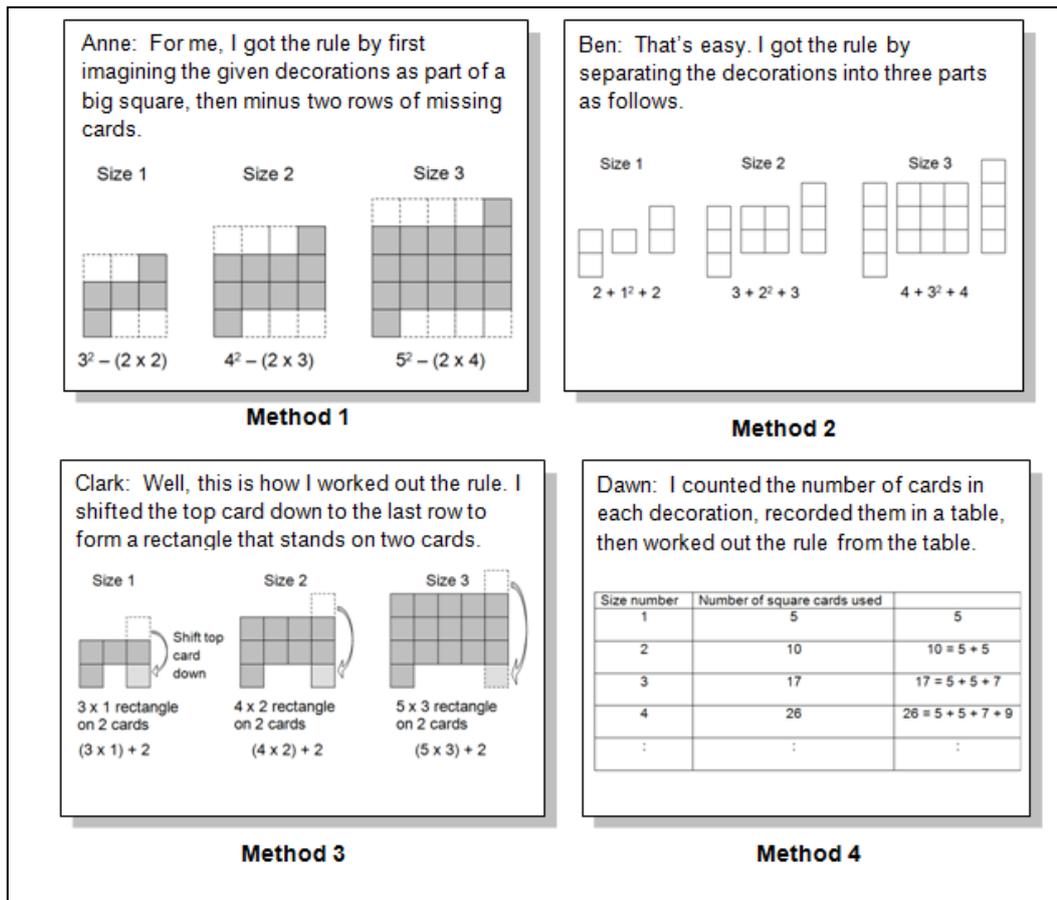

Figure 4. Student solutions to Christmas Party Decoration

RESULTS

This section presents the findings to the following two questions that guided this study.

1. Which strategies would students believe would best help them to work out the rule for High Chair?

Table 1 shows that the numerical solution S1 was the top choice of best-help strategies amongst the Express students in this study, with 13 of them selecting it. Following it, in descending order, are S2, S4 and S3. There were nearly an equal number of students choosing S2 and S4, with another three preferring S3. Taking these numbers of students collectively, 16 of the 29 Express students believed that a figural method would best help them to derive the rule. Similarly, a significant number of the Normal (Academic) students (69%) also found the numerical method S1 most helpful. As for the rest, three chose S2, two selected S3 and none opted for S4.

Working Group 3

<i>High Chair</i>	Best-help Method to students				
	S1	S2	S3	S4	Total
Express Students (n = 29)	13	7	3	6	29
Normal (Academic) students (n=16)	11	3	2	0	16

S1: Numerical; S2: Constructive; S3: rearranging the original figures; S4: viewing the original figures as part of a larger rectangle

Table 1: Student Choices of Best-help Method for High Chair

2. Which strategies would students believe would best help them to work out the rule for Christmas Party Decoration?

As Table 2 clearly shows, the Express students' choice that topped the list of best-help strategies for this quadratic generalising task was S2, with as many as 13 students choosing it. This was then followed in descending order by S1, S4 and S3. Of the remaining number of students, seven picked the numerical solution S1 and nearly the same number of them selected S3 and S4. Collectively, over 75% of the Express students believed that a figural method would best help them to derive the rule. On the other hand, 75% of the Normal (Academic) students found the numerical method S1 most helpful. For the rest of them, two each chose S2 and S3, and none opted for S4.

<i>Christmas Party Decoration</i>	Best-help Method to students				
	S1	S2	S3	S4	Total
Express Students (n = 29)	7	13	4	5	29
Normal (Academic) students (n=16)	12	2	2	0	16

S1: Numerical; S2: Constructive; S3: rearranging the original figures; S4: viewing the original figures as part of a larger rectangle

Table 2: Student Choices of Best-help Method for Christmas Party Decoration

DISCUSSION

For the less able Normal (Academic) students, their choices of best-help strategy did not seem to vary very much between the linear generalising task and the quadratic task. Their top choice was the numerical strategy S1, followed in descending order by S2 and S3. S4 was not picked by them at all. The high frequencies of these students choosing the numerical method in both generalising tasks clearly suggest that a substantial majority of them prefer to work out the functional rule using this method compared to any of the other three given figural methods. An examination of their justifications revealed that its popularity lies in its simplicity for them to represent the changes across the different cases without having to draw any diagrams, thus making the workings easier to understand. In addition, some students

Working Group 3

found that using the table of values is a well-organised and systematic way for them to detect the pattern and derive the rule.

Unlike the Normal (Academic) students, the numerical method emerged the top choice for the Express students only for the linear generalising task but slipped to the second position for the quadratic task. What is interesting to note about this finding is that some of these students seemed to be more aware of the applicability of this strategy to the quadratic task than their Normal (Academic) peers. They might have realised that while the numerical method shows how the pattern grows clearly in a table, the derivation of the quadratic rule is not as straightforward and easy as it appears. In fact, it is anticipated that such a method would pose a real challenge to all the Secondary One participating students if they were asked to use it to establish the rule. Therefore, it is not at all surprising to find some of these Express students abandoning the numerical strategy for a figural one in *Christmas Party Decoration*, thus causing a dip in its frequency by nearly one-half as compared to that for *High Chair*. As for the Normal (Academic) students who are regarded academically weaker, it is rather expected of them to not recognise the real difficulty of employing the numerical strategy to obtain the quadratic rule.

The popularity of the numerical strategy could also be traced to another plausible reason as suggested in a few students' justifications. The students explained that the numerical method was picked as the best-help strategy because it was the only method demonstrated by their mathematics teachers. This student revelation is consistent with evidence from another recent study of ours, which showed that the majority of the participating secondary school mathematics teachers would use the numerical strategy in class to show students how to work out the rule underpinning a pattern (Chua & Hoyles, 2010b). The student revelation also highlights a precarious situation students could be facing when they are only taught, in particular, what Beuzszka and Kenney (2008) called the *repeated substitution* strategy and lack exposure to other types of generalising strategies. They could be misled to think that such a strategy is an effective method that can work easily for all types of generalising tasks.

Some valuable insights have also emerged from the students' justifications of their choice of strategy. There were students who preferred the numerical method due to its clarity and simplicity, which made pattern detection and understanding easy. Subsequently, this led to the ease of obtaining a rule, a view which Beuzszka and Kenney (2008) had also pointed out. Those who eschewed this method generally found it time consuming, confusing and tedious to set up a table of values. To those who opted for figural methods, the pattern structure was easier to visualise because the explicit link between the size number and the number of cards used was more noticeable. That was why figural methods were found to be more helpful in deriving the rule quickly. Despite the evidence that figural methods can offer insight to pattern structure, some students still shunned such methods in favour of the

Working Group 3

numerical method because they found them tiresome to draw and difficult to visualise the diagrams.

CONCLUSION

The present study provides a window for teachers, teacher educators as well as curriculum developers to understand which generalising strategies would facilitate student visualisation of the structure underpinning the pattern. The findings showed that the Normal (Academic) students seemed to prefer the numerical method to the figural method for working out the functional rule whereas the Express students tended to favour the figural method. Such research-based knowledge is useful to the teaching and learning of number patterns, teacher training as well as curriculum design. For instance, teachers seeking an idea of what might be an appropriate generalising strategy to employ in class when demonstrating examples can use the findings to help them make informed decisions. Aligning their choices of generalising strategies with that preferred by students can support the efficacy of teaching and learning outcomes.

Looking from another perspective, the findings of this study also draw attention to a few implications for teachers. First, teachers will need to look into the assumptions that they are making when deciding on the kind of strategies to use in class. For pattern generalisation in particular, teachers will need to be keen observers of how their students express generality to find out how they process the strategies. Second, teachers will also need to be familiar with the different generalising strategies so that they can lead students to work out the functional rule. Finally, while the findings may be preliminary since the present study is still on-going, they appear to hold promise of creating a greater awareness amongst teachers, teacher educators and curriculum developers of what students are actually capable of doing and learning. By making an attempt to understand how students visualise patterns can help teachers and teacher educators in planning more effective teaching and learning experiences, and curriculum developers in curriculum design to improve students' ability to make generalisations.

USING EPISTEMIC ACTIONS TO TRACE THE DEVELOPMENT OF ALGEBRAIC REASONING IN A PRIMARY CLASSROOM

Thérèse Dooley

Centre for the Advancement of Science Teaching and Learning,
St. Patrick's College, Dublin City University

In this paper, the epistemic actions of recognising, building-with and constructing (RBC) are used to analyse and describe the development of algebraic reasoning by primary pupils in a whole-class setting. The lesson concerned finding the sum of positive integers, 1-100. On the basis of mathematical principles developed for the lesson, transcripts of whole-class discussion were coded using the RBC framework. Some of these epistemic actions were inferred by the language used by pupils – for example, they tended to use linguistic hedges when conjecturing ('building-with') but used language of greater certitude when 'constructing'. It also emerged that the use of 'vague language' facilitated collaborative construction of mathematical ideas.

INTRODUCTION

Blanton and Kaput (2008) argue that algebraic thinking, which they describe as “purposeful generalization of mathematical ideas and the expression of generalities with increasingly sophisticated symbol systems” (pp. 362 – 3) should lie at the heart of classroom mathematical practice. They go on to say that

[a]lgebraic thinking thrives in an instructional context that both elicits students' thinking and uses it to build a climate of conjecture and argumentation so that conjectures can be established or rejected as valid mathematical claims, especially conjectures regarding the generality of claims. (p.363)

In this paper, I describe a framework that can be used to analyse and describe the growth of algebraic reasoning in the context of whole-class discussion. In particular, it shows that a 'conjecturing atmosphere' (Mason, 2008) is central to such growth.

THEORETICAL FRAMEWORK

RBC Epistemic Actions

A theoretical framework that has been used to describe the construction of new mathematical ideas is 'Abstraction in Context' (AiC) (Schwartz, Dreyfus, and Hershkowitz, 2009). Related epistemic or observable actions are 'recognising' (R) (using a familiar structure), 'building-with' (B) (using available structural knowledge to deal with the problem at hand) and 'constructing' (C) (building more complex structures from simpler structures). These three epistemic actions are not linear but nested. In other words, 'recognising' (R) and 'building with' (B) do not precede the process of 'constructing' (C) but, rather, are nested within it. While the RBC model has been used for the analysis of a variety of mathematical topics, C-actions often

concern the generality of claims (e.g., Schwartz *et al.*, 2009). As such it is pertinent to algebraic thinking as described above. The RBC model of abstraction described by Hershkowitz, Schwartz, and Dreyfus (2001) was based on data derived from a teaching interview with one student who had a computerised tool at her disposal. However, they suggested that epistemic actions might be distributed among participants. In a paper that I presented at CERME 5, I suggested that, in the context of whole-class discussion, “[o]ne pupil’s ‘recognising’ led to ‘building with’ by another and to ‘construction’ of new ideas and strategies by others” (Dooley, 2007: 1658). Hershkowitz (2009) has since described the process where different individuals contribute different building blocks to the construction of new mathematical knowledge as one of ‘collective abstraction’.

A partial construct (PaCC) obtains if a C-action only partially matches elements of underlying mathematical principles, that is, intended constructs such as concepts, methods, or strategies (Ron, Hershkowitz, and Dreyfus, 2008). PaCCs are apparent in cases where a student’s incorrect answer overshadows meaningful knowledge s/he has constructed or, conversely, where a correct answer masks a gap in knowledge. The RBC model has been found to be an effective tool for tracing these partial constructs (Schwartz, *et al.*, 2009).

In order to investigate the construction of new mathematical ideas by pupils I conducted a ‘classroom design experiment’ (Cobb, Gresalfi, and Hodge, 2009) in three different primary schools in Ireland. I taught 32 lessons, some of which extended over a few class periods, in all. Data collected included field notes, audiotapes of whole-class and group interactions, pupils’ written artefacts, digital photographs, interviews with teachers and, in two of the schools, pupil diaries and post-lesson interviews with small groups of pupils. Data collection and data analysis were interwoven. Retrospective analysis was conducted on micro- (between lessons) and macro- (between and after cycles of research) levels. For each lesson I identified ‘mathematical principles’, that is, the constructs that pupils might be expected to develop over the course of a lesson, and these informed a hypothetical learning trajectory. Other principles arose *a posteriori* and were included in the analytic framework. Using the computer aided qualitative data analysis software package, Nvivo, I first coded all pupils’ turns as ‘R’, ‘B’ or ‘C’ with reference to these principles. Thus I was able to trace the mathematical constructions of (some) individual pupils. A difficulty I encountered was that I had to infer the epistemic action from pupils’ verbal protocol¹. Their use of ‘hedges’ and ‘pronouns’ facilitated this process.

Hedges and Pronouns

Rowland (2000) developed a taxonomy of hedges with reference to the discourse of mathematical conjecture. The first major type of hedge, a ‘shield’ indicates some uncertainty in the mind of the speaker in relation to a proposition. In the statement, “I think that the last digit of an even number is 0, 2, 4, 6, or 8”, the speaker injects a

level of vagueness into his/her mathematical assertions and thus implicitly invites feedback on his/her conjecture about a method of identifying an even (or non-even) number. There are two types of shield: (a) a ‘plausibility shield’ (e.g. ‘I think’, ‘probably’, ‘maybe’) which can suggest some doubt on the part of the contributor that the statement will withstand scrutiny and (b) an ‘attribution shield’ (e.g. ‘According to’) in which some degree or quality of knowledge is implicated to a third party. The second major category of hedges are termed ‘approximators’. The effect of the approximator is to modify the proposition rather than to invite comment on it. One subcategory of the approximator is the ‘rounder’ which comprises adverbs of estimation such as ‘about’, ‘around’ and ‘approximately’. The second type of approximator is the ‘adaptor’ – it indicates vagueness concerning class membership such as ‘somewhat’, ‘sort of’, e.g., “Zero is sort of an even number”.

In the analysis of lesson transcripts, it emerged pupils tended to use vague language (e.g., ‘probably’ ‘might’ ‘I think’) when conjecturing, an action coded as ‘building-with’. In turn, the language of a constructing action was marked by certitude – in particular, pupils often used pronouns such as ‘it’ or ‘you’ to signify generalisation (Rowland, 1999, 2000). There follows an account of a lesson on the Story of Gauss that took place with a group of pupils aged 9 – 10 years. An overview of this lesson was given at CERME 6 where my role in the constructing processes of a number of pupils was described using an improvisational metaphor (see Dooley, 2009). In this paper there is a more fine-grained analysis of the development of new ideas by one pupil, Anne. However, her construction had embedded within it the contributions of others in the class and thus their input is also described and analyzed.

THE STORY OF GAUSS

The young Gauss astounded his teacher when, as a school pupil, he rapidly calculated the sum of numbers from 1 to 100. He did so by adding 1 to 100, 2 to 99 and so on and thus found fifty 101s. The power of this story, according to Rowland (2001), is that it provides a means of finding the sum of the first $2k$ integers for any integer $2k$ (that is, $k(2k + 1)$). A ‘generic example’ is an example that is representative of a class of objects (Balacheff, 1987). What makes Gauss’ story special in the view of Rowland (2001) is that it is “generic among generic examples” (p.43), that is, it elucidates the nature of a generic example.

Mathematical Principles

The Gauss lesson that is the focus of this paper followed a lesson on the ‘Handshakes’ problem. The pupils had developed an explicit formula for this problem, that is, that the number of handshakes could be determined by application of the formula, $\frac{1}{2}n(n-1)$, where n is the number of people. Some pupils were able to verify this formula structurally. Since they had calculated the number of handshakes in the case of 100 people, I anticipated that they might be able solve Gauss’ problem with relative ease (that is, $4950 + 100$). I also thought that they might make use of

Working Group 3

the formula although I expected that this would pose a challenge since the number of handshakes for n people is $\frac{1}{2} n(n-1)$, the formula for $1 + 2 + 3 + \dots + (n - 1)$. Pupils of this age could also be expected to use ‘flexible computation methods’ (Greeno, 1991). One of the ways they might do this is to add numbers that pair to 100 (a method that is referred to in future as ‘compatible pairs’)², i.e., $100 + 0, 99 + 1, 98 + 2 \dots$

In order to use this method to solve the sum of the first n positive integers, pupils have to observe that if n is even, (a) the number of pairs is $\frac{1}{2} n$ and (b) that $\frac{1}{2} n$ (‘50’ in the example above) does not have a ‘compatible partner’. An interesting pattern emerges when sums of decades are examined. Using the notation $s(m, n) = m + (m + 1) + \dots + n$, $s(1, 10) = 55$; $s(11, 20) = 155$ (that is, $s(1, 10) + 100$); $s(21, 30) = 255$ (that is, $s(1, 10) + 200$) etc. Similarly, $s(1, 100) = 5050$; $s(101, 200) = 15050$ (that is, $s(1, 100) + 10000$) etc. One of the conflicts that pupils have to overcome in order to use either of these patterns effectively is the ‘illusion of linearity’ (De Bock, Van Dooren, Janssens, and Verschaffel, 2002), that is, $s(1, kn) = ks(1, n)$. For example, pupils might assume that $s(1,100) = 10s(1,10)$, that is, $s(1,100) = 10(55)$. On a more global level, another principle that pupils might be expected to attain is the extension of this example to other classes, such as the sum of the first n -hundred integers.

A summary of a possible learning trajectory is as follows:

- (i) Formation of an association with ‘Handshakes’.
- (ii) Finding a solution by adding compatible pairs/decades or by transforming the formula for ‘Handshakes’; noticing that linearity does not apply.
- (iii) Expanding the solution method into a more general structure.

ANALYSIS OF ANNE’S CONSTRUCTION OF INSIGHT

Early in the lesson, Anne suggested that the sum of the first 100 integers might be found by doubling the sum of one to five (that is, fifteen) and then multiplying 30 by ten, that is,

- 56 Anne: If you add one to five, that’s fifteen...
- 57 TD: Hm, hm.
- 58 Anne: ... and then fifteen and fifteen is thirty, so then if you multiply that by ten.

Her insight about the inefficacy of this strategy occurred a short while later and was prompted by an observation made by Alan. The turns chosen for analysis are therefore turns 66 – 86 and 91 – 95 since they provide the trace of her constructions³.

Working Group 3

		Pupil Action	Epistemic Action (RBC)
66	Alan: Em, well, I don't think Anne's one is right.	Alan evaluates idea proposed by Anne in Phase 2.	Building-with
67	TD: Why not?		
68	Alan: Cos ninety-nine plus ninety-eight plus ninety-seven plus ninety-six to ninety would be around over five hundred and when ...	Estimation of sum of '90s'	Recognising
69	//Ch: Oh!	Exclamation	
70	TD: Ok, so you are thinking that, you think, you disagree with Anne because you are thinking, what Alan is doing now ... Alan is thinking ninety - I haven't forgotten you now, Enda, alright, I will be with you in a moment - you are thinking ninety plus ninety-one plus ninety-two plus ninety-three would give you approximately how much?		
71	Alan: Em, I don't know.		
72	TD: But it's...		
73	Alan: But it would probably be over five hundred.	Estimation of sum of 90s	Recognising
74	TD: It would be over five hundred, so in that section, if you are thinking about all those numbers there that would give you about, even just adding ninety to a hundred so you are thinking that would give you about five hundred - I will be with you in about one minute alright. Barry?		
75	Barry: Eh, well, I disagree with Anne as well because eh I counted, I counted up all the numbers up to ten and I got fifty-five.	Further evaluation of Anne's idea	Building-with
76	TD: You counted, ok so actually in your head, so you went, so ok so you added, Barry, you went one plus two plus three and so on up to ten (<i>writes on blackboard</i>) and you just counted that section there and you said that's about fifty-five. And then Alan was saying that ninety plus ninety-one (<i>writes on blackboard</i>) up as far as a hundred would give you. About how much what would that give you if you just added those numbers there, ninety, about how much, you don't have to give the exact answer, about how much would that be if you went ninety, ninety-one, ninety-two, ninety-three added all those numbers there, what would that be about? Barry?		
77	Barry: A hundred and eighty one.		
78	TD: It would be about a hundred and eighty one, that's if you went ninety plus ninety-one plus ninety-two plus ninety-three ...		
79	Barry: No eh...		
80	TD: ... plus ninety-four plus ninety-five plus ninety-six plus ninety-seven plus ninety-eight plus ninety-nine plus a hundred? About how much would that be?		
81	Barry: Eh ... a thousand.	Estimation of sum of 90s	Recognising
82	TD: It could be yeah, it could probably be a thousand.		
83	Ch: Ah!		

Working Group 3

84	TD: Ok, so that would give you about ... Do you agree with that, that that would give you about a thousand?		
85	Barry: No around nine hundred because there's not really a hundred in the nineties.	Estimation of sum of 90s	Building-with
86	TD: In the nineties, so you're thinking that that would be around nine hundred. Ok. So this is now what we are thinking now, alright that eh this number here is about nine hundred and Enda what you might do for me if you just take out ... is just write down your idea in your diary for me please. Alright?		
[] ⁴			
90	TD: Yes, so it's not just, and as Barry said that if you were going ninety, or Alan made this point, that ninety, ninety-one all the way up to a hundred gives you about nine hundred, who else said about, oh yes and Barry was saying that one up as far as ten gives you fifty-five. And we are thinking all the numbers one plus two plus three plus four plus five plus six plus seven plus eight plus nine plus ten plus eleven plus twelve (speaking quickly) ... counting up, adding up all the numbers from one up to a hundred. Anne?		
91	Anne: I don't ... my answer wouldn't work.	Anne re-evaluates her early input.	Building-with
92	TD: What were you thinking your answer was?		
93	Anne: I thought it would be thirty multiplied by a hundred but it wouldn't work.	Anne repeats earlier idea.	
94	TD: Why would it not work?		
95	Anne: Em, because you would have to em ... cos I did eh one plus two plus three plus four plus five and then em I got fifteen and then I added fifteen and fifteen equals thirty but then it would be more em ... because you would have to add six, seven and that ...	Anne rationalises why her earlier idea would not work.	Constructing

Epistemic Actions (RBC)

I classified Alan's input in turn 66 as 'building-with' since he was reflecting on a process. The use of the words 'Well, I think...' in this instance can be explained by 'politeness theory' described by Rowland (2000: 86) as follows:

[P]oliteness theory is constructed to account for some indirect features of conversation: it claims that speakers avoid threats to the 'face' of those they address by various of vagueness, and thereby implicate their meanings rather than assert them directly.

It seems that Alan was reasonably certain that Anne was incorrect but he may not have wanted to threaten her 'positive' face (that is, her desire for approval). Use of the discourse marker, 'Well' and of the plausibility shield, 'I think' represent a form of redress (Bills, 2000; Rowland, 2000). In other words, he may have wanted to inject some vagueness into his criticism of her conjecture. His justification for this criticism was quite fuzzy as he was unsure about the sum of the numbers in the 90s. In turn 68 he used the rounder, 'around' followed immediately by a second rounder, 'over', to suggest that 'five hundred' was an estimate. When I endeavoured to get a

Working Group 3

more precise solution from him he used a plausibility shield to signify his uncertainty: “It would probably be over five hundred”.

Barry has also built-with in turn 75. It seems that he too has reflected on Anne’s input and has rejected it on the basis that the sum of one to ten is 55. He spoke with some conviction about this sum and, like Alan, his use of the word, ‘Well’ at the beginning of this turn suggests that he was being polite, in a technical sense, to Anne. In turn 76, I reviewed both of their ideas and wrote them on the blackboard. In turn 91, Anne changed her mind about her earlier idea and stated emphatically that “it wouldn’t work”. Interestingly, her rationale for this was neither of the justifications provided by Alan and Barry. It has now occurred to her that the sum of six to ten is greater than the sum of one to five. It is possible that she has reflected on the fact that the sum of one to ten (55) is less than the sum of 90 to 100 (which has been estimated by Barry in turn 85 to be “around nine hundred”). She used the pronoun ‘it’ twice in turn 93, that is,

93 Anne: I thought it would be thirty multiplied by a hundred but it wouldn’t work.

The first ‘it’ is a referent to the solution (although in error she described it as ‘thirty multiplied by a hundred’ rather than ‘thirty multiplied by ten’) but the second ‘it’ seems to be a referent to the solution method. This is reinforced by her input in turn 95 in which she described her initial strategy:

95 Anne: Em, because you would have to em ... cos I did eh one plus two plus three plus four plus five and then em I got fifteen and then I added fifteen and fifteen equals thirty but then it would be more em ... because you would have to add six, seven and that ...

The ‘it’ in the latter part of this sentence is most likely a referent to the sum of six to ten. She built-with her reflection (turn 93) and constructed the idea of the ‘non-linearity’ of partial sums of consecutive integers within ten. Although turn 95 is coded as ‘constructing’, the construction action occurred over turns 66 – 86 and 91 – 95 and had nested within it recognising and building-with actions.

During group-work Anne worked with Fiona. Although the task assigned was to find the sum of 1 - 100, they extended this investigation to the sums of the first 200 and 300 positive integers. In the final plenary session both she and Fiona discussed their (shared) strategy:

237 Anne: I got five hundred and fifty, for two hundred I got ten...for one hundred I got five thousand and fifty. For two hundred I got ten thousand one hundred, em and for three hundred I got fifteen thousand one hundred and fifty. (...)

240 Fiona: Every time you are just adding five thousand and fifty to get another hundred.

In subsequent turns, attention was given to different storylines but I returned to that expressed by Anne and Fiona towards the conclusion of the lesson:

Working Group 3

290 TD: ... I just wonder if you know, Fiona says that to add up to 200, if the answer is 5050 to add up to 200 would you just add another 5050 on to that? Would that give you the right answer ... Anne?

291 Anne: I think it ... em actually no ... eh no because ... em it would probably ... should there be hundreds em in the five thousand and ... and fifty so you would have to ... so probably there would be five ... there would probably be five thousand nine hundred and fifty.

292 TD: It could be. Yeah

‘Self-repairs’ (false-starts and self-corrections) proliferate her reasoning – this is common, according to Rowland (2000), when people are asked to make a justification or to give some kind of explanation. In this instance it seems that Anne has constructed a new idea. Her construction relates to the fact that the sum of 101 to 200 contains more ‘hundreds’ than the sum of 1 to 100. Her explanation abounds with plausibility shields, in particular ‘probably’, which is a means of presenting this idea without fully committing to it (Rowland, 2000). Although her estimate of the sum (101 to 200) was incorrect, this line of reasoning indicates that she has built-with her earlier ‘local’ construction (the non-linearity of partial sums of consecutive integers within ten) and has extended her thinking to other consecutive sets. Evidence for this building-with can be found in the language she used. Concerning the sum of six to ten, she said, in turn 95, that “it would be more” (than the sum of one to five). Concerning the sum of 101 to 200, she suggested, in turn 291, that there might be “hundreds ... in the five thousand”. The connection she seems to have made is that, just as there is ‘more’ in the sum of six to ten than in the sum of one to five, there is also ‘more’ in the sum of 101 to 200 than in the sum of one to 100.

Her construction is coded as ‘partial’ because her solution was incorrect (Schwartz, et al., 2009). However, this incorrect solution masks some meaningful knowledge she appears to have constructed: in her endeavour to find, unsolicited, the sum to 200 and to 300, there is an indication that she has seen the power of Gauss’ story as a generic example.

DISCUSSION

This paper provides further evidence for the notion of collective abstraction, that is R-, B- and C-actions were distributed among a few pupils. Furthermore, Anne’s C-action had nested within it R- and B-actions both of her own and of others. This paper builds on that which I presented at CERME 5 by focusing on the role played by vague language. It appears that the use of such language is at the core of construction because it is intrinsic to conjecturing and the ‘trying out’ of ideas by pupils. Mason (2008: 65) describes this as follows:

Mathematicians work best in a conjecturing atmosphere in which conjectures are articulated in order to try them out, see how they sound and feel, to test them and so to see how to modify them as and when necessary. This is the sort of atmosphere in which mathematics thrives, and it can be established in any classroom at any age.

Working Group 3

Linguistic hedges allow learners to test ideas without fully committing to them. The verbalization of these ideas enables both the contributor and other ‘listeners’ to scrutinize them. It is in this way that the use of vague language facilitates construction of new mathematical knowledge.

Another aspect of language that proliferated the conversation described in this paper was that of politeness. Many pupils prefaced their input with ‘Well’ as a means of ‘face-saving’. Holton and Thomas (2001) suggest that one of the reasons that a child’s peers act as an effective source of cognitive conflict is that feedback from other children is often less emotionally threatening than that from an adult. The fact that Anne remained engaged in the lesson after critical evaluation of her input by her classmates suggests that this may indeed have been the case for her. The climate of ‘conjecture and argumentation’ that was evident in this lesson facilitated the generalization of a mathematical idea, that is, the non-linearity of sums of consecutive integers. What this indicates is that pupils are capable of developing algebraic thinking if conjecturing, argumentation and the production of counter-examples are accepted classroom norms.

NOTES

1. My stance as researcher derives from an interpretive perspective and therefore the conclusions that I draw are partial and tentative (Usher, 1996).
2. The usual summation given is $100 + 1, 99 + 2, \dots 50 + 51$. Such a pairing does not involve a ‘lone’ $\frac{1}{2}n$ (50 in this case). However, the pairing method given in this paper ($100 + 0, 99 + 1, \dots 50 + 0$) was that proposed by the pupils in the lesson described.
3. There were 298 turns in total the whole-class discussion.
4. Turns 87 - 90 concerned interaction that is not relevant to the analysis of this paper.

GRAPHICAL REPRESENTATION AND GENERALIZATION IN SEQUENCES PROBLEMS

María C. Cañadas, Encarnación Castro, and Enrique Castro

University of Granada, Spain

In this paper we present different ways used by Secondary students to generalize when they try to solve problems involving sequences. 359 Spanish students solved generalization problems in a written test. These problems were posed through particular terms expressed in different representations. We present examples that illustrate different ways of achieving various types of generalization and how students express generalization. We identify graphical representation of generalization as a useful tool of getting other ways of expressing generalization, and we analyze its connection with other ways of expressing it.

INTRODUCTION

The number of works focused on the relation between the algebra and the expression of generalization has increased since the work of Mason, Graham, Pimm, and Gowar (1985). Some of this work deals with the idea that this connection does not seem to be direct for secondary students (e.g. Lee, 1996; Lee & Wheeler, 1987). Algebraic language is not the only way of expressing a generalization. For example, Mason and Pimm (1984) consider that natural language has a fundamental role in the generalization process, and Radford (2002) shows how some students used verbal and gestural means to express generalization. Currently we are engaged in a project in which some of the aims are related to the relation among generalization, and ways of achieving and expressing it.

In this paper, we focus attention on the generalization developed by students in a problem solving context and on the different representations used by students in generalization problems with different characteristics. In particular, this paper extends previous work by reporting on ways of achieving generalization through an inductive process, its relation with representations used, and how students in our investigation express generalization when they work on a written questionnaire constituted of problems involving sequences.

We first present the main ideas concerning our approach to generalization and different representations, focusing on different types of generalization. Secondly, we present our research questions. Then we present a general description of the methodology used. After this, we outline our findings and interpretations. We finally present the conclusions.

ALGEBRAIC THINKING AND GENERALIZATION

Taking a semiotic approach, we consider that students are thinking algebraically when they “act in order to carry out the actions required by the generalizing task”

(Radford, 2002, p. 258). From this perspective, generalization is achieved when students are able to identify a common pattern that arises from some particular cases and to apply this commonality to other particular cases.

We refer to *empirical generalization* following Dörfler (1991). This type of generalization starts from work on particular cases and is very close to pattern identification. Cañadas and Castro (2007) developed a model to describe Secondary students' inductive reasoning. This model is comprised of seven states, of which generalization is one. From our viewpoint, inductive reasoning is equivalent to what Pólya (1967) called *induction*. Different authors, including Pólya, assert that generalization is a key state in the process of acquiring mathematical knowledge (Neubert & Binko, 1992; Mill, 1858).

Thus generalization can be seen as “pattern generalization”, which is considered one of the prominent routes for introducing students to algebra (Mason, Graham, Pimm & Gowar, 1985; Radford, 2010, p. 37). However, it is assumed that algebra is not the only way of expressing a pattern nor is algebraic thinking the only way of forming a generalization.

REPRESENTATIONS

There is a general agreement amongst researchers of the need to distinguish between external and internal representations of students' knowledge. In our research, we focus on external representations. These representations allow the students to express concepts and ideas, since ideas must be represented externally in order to communicate them (Duval, 1999; Hiebert & Carpenter, 1992). In this paper, we pay attention to the external representations produced by students that have a trace or tangible support even when this support has a high level of abstraction.

We also consider *multiple representations* (e.g. van Someren, 1998). Multiple representations have benefits on schema construction processes; but it is not always beneficial for learning (Kolloffel, Eysink, Jong, & Wilhelm, 2009). Figueiras and Cañadas (2010) distinguish two different kinds of multiple representations: (a) combined representation, which concerns the use of different representations (as mentioned by previous authors); and (b) synthetic representations, which are multiple representations but under the additional condition we must consider them as a whole to give sense to the student's response (p. 3).

WAYS OF EXPRESSING THE GENERALIZATION

Algebra is one way of expressing a pattern, but it is not the only one. We concur with Radford's idea of algebraic generalization. “It rests on the noticing of a local commonality that is then generalized to all the terms of the sequence and that serves as a warrant to build expressions of elements of the sequence that remain beyond the perceptual field” (Radford, 2010, p. 42). This author distinguishes this kind of generalization from *arithmetic generalization*, which is characterized by staying in

the realm of arithmetic (p. 47). Students who generalize arithmetically have identified the pattern and are usually conscious that this pattern is unpractical for other terms of the sequence.

In the context of analyzing the generalization process in problems involving sequences in a written problem solving test, Cañadas and Castro (2007) distinguish between algebraic and verbal representations as two ways of expressing the general term of a sequence. The first way concerns the use of symbols and numbers, in which each term of the sequence can be obtained by substituting the symbols with concrete numbers; and the second one refers to the use of natural language to express the generalization. These authors left an open question related to the role of graphical representation in the generalization procedure and the expression of such generalization. We tackle this question in this paper.

RESEARCH QUESTIONS

We break down our research interests into three research questions for this paper, which concerns two central aspects of the generalization: (a) generalization process, and (b) generalization expression. These questions are:

- What is the role of graphical representation in the generalization process?
- How do the students express the generalizations achieved?
- What are the features of graphical expression of the generalization?

METHODOLOGY

Students

We took 359 students in years 9 and 10 of four State Spanish Schools whose teachers were close to us.

We obtained information about students' educational experiences related to generalization, problem solving, sequences, and algebra from four sources: (a) Spanish curriculum, (b) informal interviews with students' teachers, (c) mathematics textbooks used by students, and (d) students' notebooks.

Spanish Secondary curriculum does not include the generalization process explicitly. It includes reasoning as one of its main objectives. However, it contains just some actions related to inductive reasoning, such as: (a) to recognize numerical regularities, (b) to find strategies to support students' own argumentations, and (c) to formulate and to prove conjectures (Boletín Oficial del Estado, 2003).

Students had previously studied sequences. They had worked on problems using inductive reasoning, usually involving sequences, on occasion. These kinds of problems are usually presented with particular cases expressed numerically and are most of them de-contextualized. Students had begun the study of algebra between one or two years before the research commenced (depending on the year they studied

Working Group 3

by the time of this research). These lessons included work related to interpretation of formula and algebraic expressions, and first grade equations. We consider that these students had the experience required to focus on the research questions posed. Specifically, the students had sufficient content knowledge of sequences. On the other hand, our analysis of their previous educational experiences demonstrates that they were not used to solving the kind of problems posed.

Problems Posed

We prepared a written questionnaire with six problems involving linear and quadratic sequences. We asked students to work individually on this questionnaire for an hour. The problems of the questionnaire were selected according to our research objective and using the characteristics that arose through *subject matter analysis* (Gómez, 2007) of natural number sequences: (a) the order of the sequence, (b) the representation used in the statements, and (c) the task proposed.

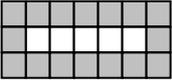

In this paper we will focus on three problems which involve linear and quadratic sequences [1], and with different representations used in the statements. Each problem was focused on a “far generalization” task (Stacey, 1989). So, particular cases were presented in the problems statements to lead the students to generalize at some point. Each problem had a complementary task consisting of justifying their responses [2]. Since sequences are a particular kind of function, we took into account the four representation systems traditionally considered for functions: (a) graphical, (b) numerical, (c) verbal and (d) algebraic (Janvier, 1987). In accordance with our research objectives, problems lead the students to work on information given through particular cases expressed in a graphical, numerical or verbal context.

In what follows, we focus on three of the six problems: problems 3, 4, and 5. The first problem, presented in a graphical context through a generic example, is a familiar generalization problem that has been presented in many different versions since Küchemann’s study (1981). Problem 4 is presented in a verbal context, and problem 5 in a numerical one.

Imagine some white square tiles and some grey square tiles. They are all the same size. We make a row of white tiles:

We surround the white tiles by a single layer of grey tiles.

- How many grey tiles do you need to surround a row of 1320 white tiles?
- Justify your answer.

Figure 1: Problem 3

We are organizing the first round of a competition. Each team has to play two matches against the rest of the participating teams (first and second leg). Depending on whether the competition is local or national; we will have 22 or 230 teams.

- Calculate the number of matches depending if there are 22 teams and if there are 230 teams.
- Justify your answer.

Figure 2: Problem 4

We have the following numerical sequence:

1, 4, 7, 10, ...

- Write down the number that should be in position 234 of this sequence.
- Justify your answer.

Figure 3: Problem 5

FINDINGS AND INTERPRETATION

We first used a quantitative data analysis to identify the stages of inductive reasoning model performed by each student in his/her response to each problem. Table 1 shows the number of students who expressed generalization using different representations.

Generalization			
Arithmetic	Algebraic	Verbal	Graphic
Problem 3			
125	3	57	11
Problem 4			
174	1	69	0
Problem 5			
222	57	26	0

Table 1. Representations used by students when generalizing

The generalization most frequently used by the students was the arithmetical one. They generalized the pattern, got the commonality of the particular cases, and used the generalization to calculate the number of grey tiles for the required case. However, they were not able to provide an expression of *any* term of the sequence. In what follows, we mainly focus on graphical representation of generalization.

Working Group 3

The students did not use graphical representation in the solving process except in problem 3, where the particular case was graphically presented in the problem itself. The use of graphical representation in its strategy is illustrated in one of the student's productions in Figure 4.

$$(1320 \cdot 2) + 3 + 3 = 2640 + 6 = 2646 \text{ baldosas blancas.}$$

Figure 4. Generalization arithmetically and graphically expressed [Note: *Baldosas blancas* means white tiles in English]

We can differentiate two parts in the student's drawing. First, the student considered the two vertical sides made by grey tiles and identified that these sides remain with the same number of grey tiles independent of the number of white tiles. The second part of the drawing is the part of the figure that has white and grey tiles, and the student interpreted that he needed to double the number of grey tiles to surround the white tiles. The student expressed graphically the pattern of the sequence, showing it in a different particular case from the one shown in the statement (for six white tiles instead of five). The suspension points show this student's awareness that the commonality applies to other terms of the sequence. In this context, the suspension points could be interpreted as "I should repeat *this* as many times as necessary". The student applied the commonality to the 1320 tiles in the arithmetic expression. Therefore, on one hand, the graphical representation helped the student to get the generalization; and on the other hand, the student identified the commonality in the graphical expression beyond the generic example shown in the statement. This is why we consider that the generalization is expressed graphically.

$$1322 + 1322 + 1 + 1 = 2646$$

"I have to add two to the number of white tiles to the top, and two more to the bottom; plus two more to each side" (Authors' student's response translation)

Figure 5. Generalization graphical and verbally expressed

Other students went beyond graphical generalization to verbal or algebraic generalization. We illustrate this with the example shown in Figure 5.

As we observe in Figure 5, this student drew a graphical representation which represents the common features from the generic example shown in the statement, without tracing the lines that separate different tiles. S/he used this generalization to calculate the number of tiles that the problem required. Therefore, this is another

Working Group 3

example of graphical generalization as well as arithmetical. S/he also provided a general verbal expression for any given number of white tiles, using natural language.

Moreover, some of the students used graphical and algebraic representation together to give sense to the generalization. We present an example typical of these students in Figure 6.

Figure 6. Generalization graphical and algebraically expressed

This student's diagram shows how s/he identified the data that remain constant and the data that change depending on the number of white tiles considered.

The three students' representations shown in Figures 4, 5, and 6 are typical examples of three groups that allow us to classify the eleven students that generalize graphically in problem 3. In the first group are the students who used suspension points to notice that the drawing would continue in the way indicated. These students used combined representation (graphical and arithmetical). In the second group are the students who used specific numbers in tiles of different sizes (the size of the tile is bigger when the number is bigger). In the third group each tile is represented by the number 1 and the number of tiles that depends on the number of white tiles is represented by x . Students in groups 2 and 3 used synthetic representations because at least two representations are considered as a whole to give sense to the generalization.

Most of the students, who expressed the generalization in problem 3, as well as in problem 4, did it verbally. For example, one student's response to problem 4 was, "The result is the number of matches that play each team against the rest of them, multiplied by two".

Most of the students generalized algebraically in problem 5. Some students even tried to use a formula which was familiar to them. The students tended to present a correct formula and used it to calculate the number in the positions requested ($a_n = a_1 + (n-1)d$). This indicated that these students expressed the generalization algebraically. Some of these students worked on particular cases in the generalization process.

DISCUSSION

We have identified four ways of expressing the generalization: (a) arithmetical, (b) algebraic, (c) graphical, and (d) verbal. Most of the student who got the generalization, expressed it arithmetically. This result is consistent with findings

Working Group 3

from the earlier study of Becker and Rivera (2005) and with what we could expect due to students' previous knowledge.

This paper contributes to understanding the use of graphical representation in generalization (Mason & Pimm, 1984; Radford, 2002; Cañadas, 2007). This kind of representation illustrates what is common to all terms using particular cases but does not provide a general expression of any term of the sequence. Students seem particularly disposed to using it when the problem was posed using graphical representation, but not in other cases. Graphical representation of the generalization appeared to help students to generalize algebraically or verbally and thus, using these expressions, obtain particular case of the sequences. Generally students who utilized this kind of representation used it in combination with other sorts of representation. In this sense, we can consider graphical representation as a way of developing algebraic thinking and of expressing the generalization verbally or algebraically. This idea complements previous work which is mainly focused on other ways of generalization.

Graphical representation is sometimes enough for students to answer the question posed because they see the general pattern in the drawing. However, some of them revert to verbal generalization when they try to justify the answer, as Cañadas (2007) noticed. This is the main reason why verbal generalization is frequent in these problems (see Table 1).

Students generalized algebraically more frequently in the problem where particular cases were expressed numerically. This seems to be a consequence of what students were accustomed to in class. Only a low number of students generalized algebraically in problems where the statements were presented in unfamiliar representation. In particular, the lowest frequency of generalization was found in problem 4, which was presented in the least familiar way. This suggests that it is more difficult for the students to establish a relationship between algebra and generalization problems in non-numerical contexts and that, at some point, the idea of generalization has not moved from one context to others.

Unless we and other researchers have made an effort to identify and describe different kind of generalizations, one conclusion of this paper is that sometimes it is quite difficult to distinguish among them. In most cases where students used graphical generalization, they used a combined-multiple representation or synthetic representation. Multiple representations in generalization seem to be useful for students to express the generalization. The distinction between the two kinds of multiple representations of Figueiras and Cañadas (2010) is a powerful way to describe how students reach generalization. This paper shows that synthetic representation appeared in tasks with graphical representation in the statement. Graphical representation can be considered the primary in the sense that it is the one that promotes the appearance of the other(s).

Working Group 3

As a practical consequence, it would be desirable to use tasks in different contexts to guide students to algebra as a way of generalization. Work on generalization tasks starting from particular cases expressed in different representations would be enriching to students and would promote algebraic thinking capabilities because they would relate algebra with representations different from the numerical one.

THE ENTRANCE TO ALGEBRAIC DISCOURSE: INFORMAL META-ARITHMETIC AS THE FIRST STEP TOWARD FORMAL SCHOOL ALGEBRA

Shai Caspi & Anna Sfard

The University of Haifa

Taking as a point of departure the vision of school algebra as a formalized meta-discourse of arithmetic, we have been following six pairs of 7th grade students as they gradually modify their informal meta-arithmetic toward the "official" algebraic form of talk. In this paper we take a look at the very beginning of this process. Preliminary analyses of data have shown, unsurprisingly, that while reflecting on arithmetic processes and relations, the uninitiated 7th graders were employing colloquial means, which could not protect them against occasional ambiguities. More unexpectedly, this informal meta-arithmetic, although not supported by any previous algebraic schooling, displayed some algebra-like features, not to be normally found in everyday discourses.

INTRODUCTION: STUDYING DEVELOPMENT OF ALGEBRA

The idea that algebra is a *language*, the language in which science and other branches of mathematics are practiced, has been with us for centuries, and so was the controversy over this description (Lee, 1996). In our attempts to follow the development of school children's algebraic thinking we take as a point of departure a definition that responds to some of the concerns voiced by the objectors of the algebra-as-language approach: We define algebra as a *discourse*, that is, a form of communication. While preserving the centrality of the motif of language, this approach transfers algebra from the category of passive tools to that of human activities. This ontological change has important ramifications for how we view the development of algebraic thinking and how we investigate it. This paper is a report on the initial phase of our ongoing study of this topic. In this project, we have been following algebraic discourse of six pairs of 7th graders from its beginnings in the form of informal talk on numerical processes and relations, and through its subsequent process of its gradual formalization in school.

SCHOOL ALGEBRA AS FORMALIZED META-ARITHMETIC

The definition of algebra as a discourse is a derivative of our foundational assumption that thinking is an individualized form of interpersonal communication (Sfard, 2008). To communicate either with others or with oneself, one has to act according to certain rules, implicitly shared by all the interlocutors. Different types of tasks and situations may evoke different sets of communicational regulations, that is, different discourses. Algebra can be defined as a sub-category of mathematical discourse that people employ while reflecting on arithmetical relations and processes.

Working Group 3

Let us take a closer look at the two basic types of meta-arithmetical tasks that give rise to algebra. First, there is a question of numerical patterns, which we describe formally with the help of equalities, such as, say, $a(b+c)=ab+ac$. Although nothing in this latter proposition says so explicitly, this is, in fact, a piece of meta-arithmetic. Indeed, the symbolic proposition $a(b+c)=ab+ac$ is a shortcut for the sentence *To multiply a number by a sum of other two numbers, you may first multiply each of the other two numbers by the first one and then add the results*. This type of meta-arithmetic narrative can be called *generalization*. The other algebra-generating tasks are questions about unknown quantities involved in completed numerical processes. This type of task is described in the modern algebraic language as *solving equations*. Indeed, equations, say $2x+1=13$, are meta-questions on numerical processes; in the present case the question is *What number, if doubled and increased by 1, would yield 13?*

According to this definition, algebraic thinking occurs whenever one scrutinizes numerical relation and processes in the search for generalization or in an attempt to find an unknown. The narratives (propositions about mathematical objects) that result from these two types of activities do not have to employ any symbolic means. Here is a rather striking historical example of pre-symbolic algebra taken from the Indian text known as *Aryabhatiya* (499 AD):

Multiply the sum of the progression by eight times the common difference, add the square of the difference between twice the first term, and the common difference, take the square root of this, subtract twice the first term, divide by the common difference, add one, divide by two. The result will be the number of terms. (Boyer & Mertzbach, 1989, p. 211)

Although this fact is hard to recognize, this lengthy piece presents the solution of an equation: it is a prescription for finding a number of elements in an arithmetic progression, whose first term, the difference, and the sum are given. While considering the communicational shortcomings of this intricate rendering it is easy to understand why symbolization of the discourse was one of the major trends in the further development of algebra. The symbolization was but a part of the more general historical process of *formalization* of algebraic discourse, the overall transformation that aimed at increasing the effectiveness of meta-arithmetic communication. This overall goal involved three types of action: *disambiguation*, that is, prevention of the possibility of differing interpretations of the same expressions by different interlocutors; *standardization*, supposed to ensure that all the interlocutors follow the same communicational rules; and *compression*, which turns lengthy statement such as the one quoted above into concise, easily manipulable expressions. The response to the need for disambiguation was *regulation*, that is, the constitution of strict, explicitly introduced rules of discursive conduct. Compression is attained through reification and symbolization. *Reification* means turning narratives about processes into ones about objects; Reifying usually involves introduction of nouns (e.g. *sum*, *product*) with which

to replace lengthy verb clauses. The above quote from *Aryabhatiya*, although formulated as a description of a process (a sequence of numerical operations; note the verbs *multiply*, *add*, etc.), includes compound noun clauses, such as "the square of the difference between twice the first term, and the common difference," which reify subsequences of computational steps. *Symbolization* means replacement of nouns, predicates, and verbs with ideograms, that is, symbols referring to objects the way words do, but without being uniquely tied to specific sounds. To make the replacement possible, a change in the grammar of the propositions may sometimes be necessary. For example, when a purely processual verbal description is translated into standard symbolic expression, the order of appearance of arithmetic operations may no longer correspond to the order of their implementation. When presented in the canonic symbolic manner, *Aryabhatiya*'s rule reincarnates into the concise expression $(\sqrt{8Sd+(2a-d)^2}-2a+d)/2d$, the special property of which is that it can be used both as a prescription for a calculation and as a *result* of this calculation.

The main difference between the two forms of algebraic discourse, *informal* and *formal*, is in the explicitness and rigorousness of regulation: of the two types of talk, only the formal is accompanied by a regulatory meta-discourse that explicitly states its meta-rules; and only in the this latter case, the meta-rules are the product of deliberate legislation, aiming at the prevention of ambiguity. The *informal/formal* dichotomy parallels the *rhetoric/symbolic* distinction, introduced by the historians of mathematics (Boyer, 1985). If we have chosen the word "parallel" rather than "identical" while describing these two distinctions, it is because the aspect of symbolization stressed in the historical dichotomy, although certainly most visible, is only one of the series of change that occurs in the transition from informal to formal algebraic discourse.

METHOD OF STUDY

Goal. The overall goal of our study is to contribute to the project of mapping the development of algebraic thinking in school. If algebra is a formalized meta-arithmetic, child's algebraic discourse may be expected to emerge from discourses that the child has already mastered and which she can now try to adjust to the meta-arithmetical tasks of finding numerical patterns and investigating computational processes. In our study, therefore, the learning of algebra has been conceptualized as a gradual closing of the gap between students' informal meta-arithmetic and the formal algebraic discourse to which they are exposed in school. The aim of our investigation is to describe this process in as detailed a way as is feasible and useful. Our attention to informal algebraic discourse is motivated by its being much less researched than its formal counterpart. Although not altogether absent as an object of study, it has not been investigated in a sufficiently systematic way, and the cases of observations conducted with the eye to the formal-informal co-constitutive processes have been particularly infrequent.

Working Group 3

Participants and procedure. In our longitudinal study we have been following middle school students as they progress in their informal meta-arithmetic while also making their first steps in the "official" algebraic form of talk. Six pairs of Hebrew-speaking 12-13 year old 7th grade Israeli students have been interviewed at intervals of circa four months, with the first author of this paper serving as the interviewer. So far, each round of interviewing consists of 5 to 6 meetings lasting for 60 to 90 minutes. The first round began just before the students were introduced to algebra in school. At the time this paper is being written, two rounds of interviewing have been completed, the interviews transcribed and partially analyzed, and the third round of interviewing is about to begin. We intend to conduct four rounds altogether, with the last one commencing about 18 months after the first.

Tools. In each round, the interviewees are asked to complete a battery of tasks that can be organized in the three-dimensional matrix, with the following binary distinctions constituting the three dimensions:

InF vs. For: the task is stated *informally* (InF), thus encouraging informal meta-arithmetical talk; or *formally* (For), e.g. by using canonic algebraic symbolism, thus inviting formal algebraic solution

Gen vs. Equ: the task invites a *generalization* (Gen) or solving an *equation* (Equ)

ReL vs. Abs: the task is set in *real-life* (ReL) or *abstract* (Abs) context

Each of the resulting 8 categories can be subdivided even further. For example, in the case of equations, we included tasks with *numerical* data (**Num**) and also tasks that ask for *parametric* (**Par**) solution (this locates this latter type of task in the mixed genre of equation-solving *and* generalization). Figure 1 presents two samples of the tasks prepared for the first, pre-algebraic round of interviews.

Task 1, Type: <InF, Gen, Abs>	Task 2, Type: <For, Equ, RealL>
Given the sequence: 4, 7, 10, 13, 16... a. Write the next three elements of the sequence b. What number appears in the 20 th place in the sequence? c. What number appears in the 50 th place in the sequence? d. Write a rule for calculating the number that appears in any place in the sequence	On the shelf, there are books in English and in Hebrew. The number of English books exceeds the number of Hebrew ones by 8. If there are n books altogether, how would you calculate the number of those in English? (Par)

Figure 1: Sample tasks from the first round of interviewing

Analysis. To map the development of the discourse, we describe and then compare samples of students' meta-arithmetic discourse collected in the successive rounds of interviewing. The descriptions focus on four defining characteristics of the discourse: (a) its *keywords* (e.g. those that denote variables or unknowns) and their use; (b) its *visual mediators* (icons, algebraic ideograms, graphs), and their use; (c) its *routines*, that is, patterned, recurrent forms of discursive actions; and (d)

narratives that the interviewees endorse and label as true. The specific questions that guide our examination of some of these discursive features will be presented in the next section, along with our sample responses.

SOME FINDINGS FROM THE FIRST ROUND OF INTERVIEWING

Our study has only begun, but even so, in this brief paper we can only present a small fraction of our findings so far. We restrict this report to the description of the students' informal activity of generalization, as observed when they tried to solve Task 1 in Fig. 1. The activity of generalization has been investigated by many researchers (Zazkis & Liljedahl, 2002; Lannin et al., 2006; Radford et al., 2007). In most of these studies the principal focus was on strategies (routines) students used to detect and describe patterns. In the present study, while employing techniques of discourse analysis, we distribute our attention evenly between all four characteristics of the discourse produced in the activity of generalizing: the use of words, visual mediators, routines and endorsed narratives. Due to the scarcity of space, we restrict our present account to the first two of them. While reporting, we list only the most salient of the observed phenomena (the salience is not formally assessed; the evaluation of relative frequencies of these phenomena is yet to be completed.)

Words and their use

The choice of verbal tools for generalizing. The first question that guides our analysis of meta-arithmetic regards the verbal means students use to generalize, that is, to perform the necessary *saming*. This last term, *saming*, regards the linguistic change that is the very essence of the process of generalizing: replacing specific numbers (e.g. 3, 5, 7, ...) with a single signifier (*odd number*) so as to turn infinitely many similarly structured arithmetic expressions (e.g. *the square of 3, the square of 5, etc.*) into a single meta-arithmetic expression (*the square of an odd number*). The *saming* signifier is called *variable*, which in formalized algebra usually comes in the form of a Latin letter, such as x or y . In the beginning of our study, the participants have not yet been introduced to algebraic symbolism, and it is thus not surprising that when asked in Task 1, part d, to write "a rule for calculating the number that appears in any place in the sequence", they used familiar words as their *saming* devices. This way of dealing with *saming* is instantiated several times in the following rule, written by one of the participants, H (highlighted are noun clauses, each of which does the job of *saming* over a specific set of numbers):

To find a certain place in the sequence I need the place that I found (it better be round) and then 3 (or any other number that is the regularity) times what must be added to the number you have now and then to add the number you have now and the product of the regularity and what you still need, and that's it. (T&H, Task 1(d), [209]; translated from Hebrew by the authors.)

This rule was written after the girls calculated the 50th element of the sequence (part c of task 1) by adding $30 \cdot 3$ to the 20th element, found previously, in response to part

Working Group 3

b of Task1. Translated into formal symbolic language, it would yield the following formula: $a_n = a_m + (n-m) \cdot 3$, or even $a_n = a_m + (n-m) \cdot d$, where a_n , n , $n-m$, a_{n-m} and d are the traditional symbols for elements of arithmetic progression. In particular, here are the formal translations of all noun clauses from the quote:

a certain place in the sequence is equivalent to a_n

the place that I found seems to appear here in the double role of

- a_m (note that H speaks about adding a multiple of 3 to this number) and of
- m (note the parenthetic remark "it better be round")

regularity is equivalent to d (the common difference of arithmetic progression)

what must be added to the number you have now – contrary to what the words seem to be saying, the use (it is said to be multiplied by 3) indicates that it is $n-m$ that is meant here

the number you have now is equivalent to a_m

This single example alerts us to a number of important phenomena, which we observed on many occasions, in the talk of this participant as well as of many other students. The phenomena are deemed important because they probably need to be considered in planning the further process of formalization of the students' informal meta-arithmetic.

As might be expected, the student opted for generalizing words that hinted at their prospective roles in the problem. In the single proposition quoted above, the hinting is done in several ways. Some of the words function as *metaphors*, as is the case when the index of an element is called a *place*. Some other names are *metonymies*, that is, represent the whole by its part. This is the case when the n^{th} element, a_n is called *the place I found*. Interestingly, there is also the "reverse" of metonymy: In the expression *what must be added to the number you have now*, which is meant to signify $n-m$, the whole (*what must be added*) appears in the role of its own part: of a multiplier with the help of which the addend is to be produced. Finally, the student made use of the *genus*, that is, of a broader category to which the given object belongs. This is the case when the common difference of the given progression, 3, is called *regularity* and when the girl refers to an element of the sequence as *number* (admittedly, this latter word was suggested by the designers of the task). To overcome overgeneralizations, H uses specifying descriptions, such as *the number you have now*. The term *regularity* has not been restricted by an additional description and this fact has two ramifications: First, the student has achieved a higher level of generalization than required by the authors of the task (the authors asked for a computational rule for the sequence in which the specific number, 3, must be added in the transition from any element to its successor). In a sense, therefore, she did even better than expected. Second, however, there is no hint in the generalizing word *regularity* that the regularities considered in the problem are those that produce arithmetic progressions. The resulting rule, therefore, is not self-

Working Group 3

explanatory and may even be dismissed by some interpreters as offering only a special case of what it promises to present.

The use of words (syntax). The main question asked with respect to the syntax of the participants' informally composed generalizing propositions regards the degree of reification: Do the propositions speak about doing (calculations) or about properties of objects? Indeed, reifying is the key move toward disambiguation and condensation of meta-arithmetic narratives and may thus be seen as a "signature" feature of formal algebraic sentences.

The formerly discussed lengthy proposition from *Aryabhatiya*, although processual in its general tone, contained noun clauses that reified several of its sub-processes. It is striking that a similar partial reification appeared in our young participants' informal meta-arithmetic sentences. Note, for example, the H's clause *the product of the regularity and what you still need* that speaks about a result (product) of an operation (multiplication) rather than about the operation as such. This property is even more salient in another version of the rule for calculating any element of the given arithmetic sequence, which the same student, H, produced toward the end of the session:

the place times the regularity of the sequence plus one (T&H, Task 1(d), [228]).

This time, the "rule" does not even sound as a prescription for action: It does not contain any verbs (*times* and *plus* are not verbs!) and does not constitute a full sentence. Unlike in the case of the previous version, no structural change would be necessary to translate it into the canonic symbolic formula $n \cdot d + 1$.

Visual mediators and their use

The salient property of our participants' meta-arithmetic was the scarcity of visual mediation other than arithmetical (numerical) expressions. Those of the students, who did try to express their rules with the help of ideograms, used either letters or markers such as boxes or lines. Thus, for example, the two students whose work was discussed above presented the simplified version of their rule as $\square \cdot 3 + 1$ (H&T, 210). It should be stressed that in most cases, the students' interpretation of boxes was different from that of letters: Whereas letters functioned mainly as *names* of objects, the box was usually understood as a marker of a *physical space* for numbers. Indeed, unlike in the case of letters, which were supposed to signify the same number in all their appearances, identically looking boxes (squares) were often used indiscriminately for all the variables in the problem. Thus, in our study, some of the students presented rules such as this one in the form $\square \cdot 3 + 1 = \square$. Interestingly, one of the participants wrote $x \cdot 3 + 1 = x$ (A&S, 49), the use clearly inspired by his former experience with squares functioning as delineators of a physical space for numbers.

DISCUSSION: WHERE THE STUDENTS ARE AND WHAT COMES NEXT

With an eye to the ultimate goal of informing instruction, we focused our efforts on identifying dissimilarities between students' informal meta-arithmetic and the formal algebra taught in schools. Let us stress that the discussion that follows and the tentative answers given in the end are grounded in a body of data much richer and more extensive than could be presented in this brief paper.

Colloquial, informally developed discourses are known for their occasional blurriness and vagueness. Therefore, it did not come to us as surprise that upon close examination, the texts produced by our participants, although quite impressive in their resourcefulness, proved also full of ambiguities. Consider H's complex prescription for calculating any element of the arithmetic progression. Here, H used a single noun for a number of purposes (see her metaphoric use of the word *place* for the index of an element and the metonymic use of the same term for the element itself) and, on another occasion, referred to a single object in a number of ways (e.g., note the difference between the expressions *the place I found* and *the number you have now*, both of which were used with reference to the previously calculated element a_m .) She also used generic names which were all too general and, as such, could be easily misinterpreted by her interlocutors. To overcome overgeneralizations, H employed specifying descriptions, such as *the number you have now*. However, this type of specification, being context-dependent (note the use of the deictic words *you* and *now*) could not possibly bar multiple interpretations.

All this said, our study, so far, has resulted also in some less predictable findings. On the basis of our own previous research (Sfard & Linchevski, 1994), we conjectured that the students' informal meta-arithmetic would be about processes rather than objects. It is because of this prediction that we were careful to formulate the first tasks in processual language. For example, in Task 1, part d we asked for the *rule for calculating* any element of the sequence rather than inquiring about what such generic element *is*. We were thus quite surprised to find out remarkable structural similarities between the students' verbal meta-arithmetic and the formal reified algebra. Two possible explanations come to mind when we try to account for this finding. First, structures of algebraic formulas are not unlike those of arithmetic expressions, and thus our students might just be building on their knowledge of the latter type of structure. Second, it is possible that these days algebra is simply "in the air": elements of algebraic discourse may be present in other school discourses well before its formal introduction in the 7th grade. With the help of media, algebraic forms of expression may even be infiltrating colloquial discourses. To check these conjectures, we decided to broaden our study and to conduct similar interviews with 6th and 5th grade students.

Whatever the results of these latter investigations, we believe that one of the present tentative conclusions from our study is unlikely to change: While much work must be invested in formalization of students' informal meta-arithmetic, the resources with

Working Group 3

which children are coming to their algebra classrooms may be a much better foundation for the development of formal algebraic discourse than could be expected on the basis of what is known about their mathematical education so far. The more knowledgeable we are about these resources, the better our chances for helping the students in closing the gap between their informal meta-arithmetic and the formal algebra taught in school. Above all, we need this knowledge to be able to teach in such a way as to preserve the all-important link between the two discourses.

STUDENTS' REASONING IN QUADRATIC EQUATIONS WITH ONE UNKNOWN

M. Gözde Didiş, Sinem Baş, A. Kürşat Erbaş

Middle East Technical University

This study examined 10th grade students' procedures for solving quadratic equations with one unknown. An open-ended test was designed and administered to 113 students in a high school in Antalya, Turkey. The data were analyzed in terms of the students' foci while they were answering the questions. The results revealed that factoring the quadratic equations was challenging to them, particularly when students experienced them in a different structure from what they were used to. Furthermore, although students knew some rules related to solving quadratics, they applied these rules without thinking about why they did so, nor whether what they were doing was mathematically correct. We concluded that the students' understanding in solving quadratic equations is instrumental (or procedural), rather than relational (or conceptual).

Keywords: Quadratic equations, instrumental understanding, relational understanding

INTRODUCTION

For many secondary school students, solving quadratic equations is one of the most conceptually challenging subjects in the curriculum (Vaiyavutjamai, Ellerton, & Clements, 2005). In Turkey, where a national mathematics curriculum for elementary and secondary levels has been implemented, the teaching and learning of quadratic equations are introduced through factorization, the quadratic formula, and completing the square by using symbolic algorithms. Of these techniques, students typically prefer factorization when the quadratic is obviously factorable. With this technique, students can solve the quadratic equations quickly without paying attention to their structure and conceptual meaning (Sönnerhed, 2009). However, as Taylor and Mittag (2001) suggest, the factorization technique is only symbolic in its nature. Since students simply memorize the procedures and formulas to solve quadratic equations, they have little understanding of the meaning of quadratic equations, and do not understand what to do and why. This can be described using Skemp's (1976) categorization of mathematical understanding as either instrumental or relational. He simply described instrumental understanding as "rules without reasons" and relational understanding as "knowing both what to do and why" (p. 20). Using the language of Skemp, it can be said that students can perform instrumentally to solve the quadratic equations by applying the factorization technique; however, few develop relational understanding.

Although quadratic equations play an important role in secondary school algebra curricula around the world, it appears that studies concerning teaching and learning

quadratic equations are quite scarce in algebra education research (Kieran, 2007; Vaiyavutjamai & Clements, 2006). Therefore, this study was designed to widen the research considering students' reasoning when engaging in different types of quadratic equations in one unknown. In particular, this study investigated students' processes for solving quadratic equations with one unknown by using the factorization technique.

The findings of this study may provide teachers with insight into the reasoning that leads to the common mistakes that students make while solving quadratic equations, and hence guide them in creating a more efficient pedagogical design for teaching how to solve quadratics.

Challenges faced by Students in Solving Quadratic Equations

According to Kotsopoulos (2007), for many secondary school students, solving quadratic equations is one of the most conceptually challenging aspects in the high school curriculum. She indicated that many students encounter difficulties recalling main multiplication facts, which directly influences their ability to engage in quadratics. And, since the factorization technique of solving quadratic equations requires students to be able to rapidly find factors, factoring simple quadratics (i.e., $x^2+bx+c=0$ where $b, c \in R$) becomes a quite challenge, while non-simple quadratics (i.e., $ax^2+bx+c=0$ $a, b, c \in R$ and $a \neq 1$) become nearly impossible. Moreover, students encounter crucial difficulties in factoring quadratic equations if they are presented in non-standard forms. For example, factoring $x^2+3x+1=x+4$ is challenging for students, since the equation is not presented in standard form (Kotsopoulos, 2007). Similarly, Bossè and Nandakumar (2005) stated that the factoring techniques for solving quadratic equations are problematic for students. They indicated that students can find factoring the quadratics considerably more complicated when the leading coefficient or constant in the quadratic has many pairs of possible factors.

Skemp's (1976) description of instrumental and relational understanding can be used as a framework to discuss the difficulties students have with factoring quadratic equations. While an instrumental understanding of factorizing quadratic equations with one unknown requires memorizing rules for equations presented in particular structures, relational understanding enables students to apply these rules to different structures easily (Reason, 2003). That is, when students have relational understanding, they can transfer knowledge of both what rules (and formulas) can be used and why these rules work from one situation to another (Skemp, 2002).

Lima (2008) found that students may perceive quadratic equations just like they do calculations. Since they focus mostly on the symbols used to perform operations, they may not be aware of the concepts that are involved. Vaiyavutjamai and Clements (2006) explain that students' difficulties with quadratic equations arise from the lack of both instrumental and relational understanding of the associated

mathematics. They found several misconceptions regarding variables which were obstacles to understanding quadratic equations. For example, students thought that the two x symbols in the equation $(x-3) \cdot (x-5) = 0$ stood for different variables, even though most of them obtained the correct solutions $x=3$ and $x=5$. Hence, they concluded that students' performance in that context reflect rote learning and a lack of relational understanding.

METHODOLOGY

Participants and the Instrument

The sample of this study consisted of 113 students in four 10th grade classes, and this study was performed in a high school in Antalya, Turkey during the spring term 2009-2010.

For the purpose of the study, a questionnaire was developed by the authors since no test to specifically explore students' errors and understanding was available. The test questions were carefully selected from secondary mathematics textbooks and from research regarding quadratic equations (e.g., Crouse & Sloyer, 1977). All questions used in this questionnaire were selected to measure the study objective of "determine the roots and solution set of [a] quadratic equation in one unknown". During the selection process, two mathematics educators and a mathematics teacher were consulted about whether the content of the selected questions were consistent with the objective of the test. In light of their suggestions, seven open ended question were developed. Although the format of the all of the questions was open-ended, they varied in type so as to be consistent with the objective of the study. Questions 1 to 4 were in the standard format in which students were expected to "find the solution set of the given quadratic equation". These questions were based on procedural skills, and they were mostly used to detect students' procedural abilities in solving quadratic equations in different structures. On the other hand, questions 5 to 7 introduced a mathematical scenario that included both a quadratic equation and a solution belonging to it. In these type of questions, students were expected to determine "whether the solutions [belonging to] the equations were correct or not, and to make judgment about their decision". Therefore, in addition to procedural skills, these questions were used to detect students' understanding of and reasoning level when dealing with quadratic equations.

The mathematics teacher administered the questionnaire during the regular class period and the students were given 30 minutes to complete it.

Analysis of Data

Initially, the responses given to each question were given scores of either 1 or 0. A score of 1 was given for answers that were mathematically correct in terms of both solution process and final answer. A score of 0 was given for answers that were either omitted or incorrect in terms of either solution process or final answer. Then,

Working Group 3

in order to obtain a general view of the students' performance, the percentage of correct, incorrect and omitted questions were calculated. The aim of this process was descriptive analysis. Afterwards, qualitative data analysis was conducted. The subjects' responses were studied in order to provide substantial information about their type of understanding. The aim of this analysis was to identify the common mistakes that students made while solving the quadratic equations. Therefore, the incorrect answers for all questions have been analyzed item by item with respect to the students' focus when they solved the questions in the test situation. Students' types of mistakes were coded by two researchers of this study who worked initially separately. Next, the mistakes were both combined and renamed based on their common features, and then they were classified by two researchers together. Lastly, these mistakes were interpreted in terms of students' instrumental understanding and relational understanding.

RESULT

The first item in the instrument was related to finding the roots of a quadratic equation given in standard form (e.g., $ax^2+bx+c=0$ where $a, b, c \in R$). Almost all students correctly solved this equation by factorization. In the following questions, quadratic equations were given in different structures (e.g., $ax^2-bx=0, c=0$). In these types of questions, just 64% of them solved the equation $ax^2-bx=0$, correctly. When the solution processes of students who made mistakes (36%) were analyzed, it was recognized that their mistakes were based on two different types.

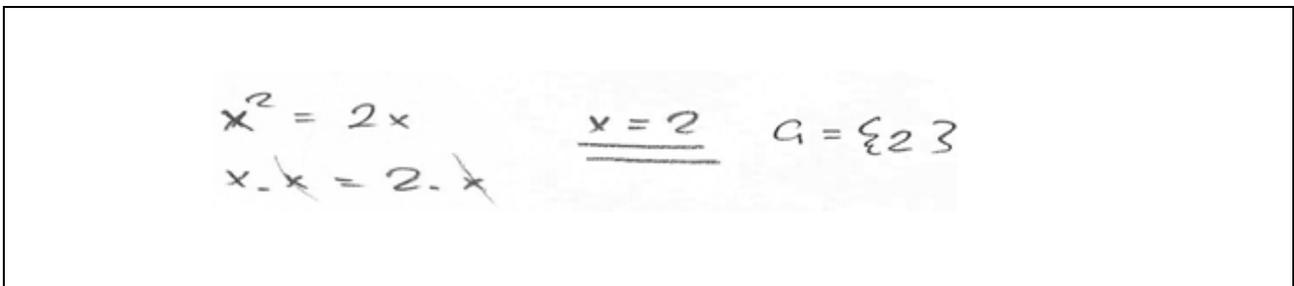

$$\begin{array}{l} x^2 = 2x \\ x \cdot x = 2 \cdot x \end{array} \quad \begin{array}{l} \underline{x = 2} \\ C = \{2, 3\} \end{array}$$

Figure 1: Find the solution set of $x^2-2x=0$: An example of students' first type of mistake

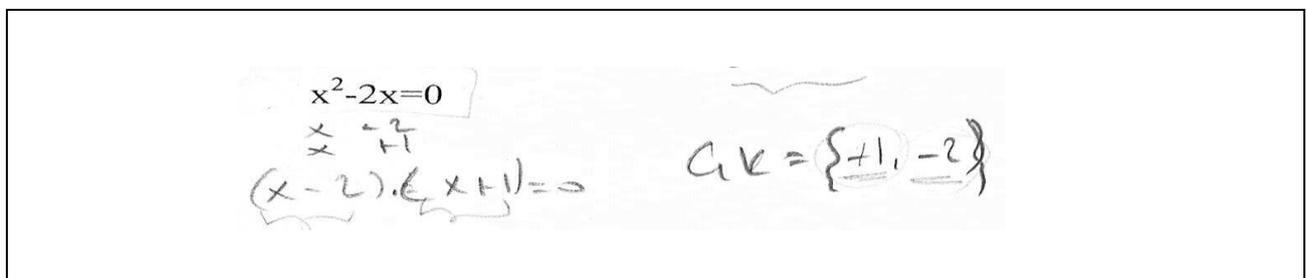

$$\begin{array}{l} x^2 - 2x = 0 \\ \frac{x^2}{x} \quad \frac{-2}{1} \\ (x-2) \cdot (x+1) = 0 \\ C = \{+1, -2\} \end{array}$$

Figure 2: Find the solution set of $x^2-2x=0$: An example of students' second type of mistake

“Find the

$$x \cdot (x-1) = 12$$

$$4 \cdot (4-1) = 12$$

$$4 \cdot 3 = 12$$

$$\underline{x = 4}$$

Figure 3: “ $x^2-2x=12$ ”: An example of students’ mistakes when just the form of equation changed.

In the first type of incorrect solution (see Figure 1), students carried the term $-2x$ from left side to the right, and then “simplified” by “dividing” both sides of the equation by x . Consequently, they ignored one of the roots of the equation, which is 0. In the second type of incorrect solution (see Figure 2), students tried to factorize the equation. Here, students perceived the form $ax^2-bx=0$ just like $ax^2+b=0$ and treated $2x$ as a constant of 2 to be factorised. When the form of the equation was changed instead of the structure (e.g., $ax^2+bx=c$ where $a, b, c \neq 0$), 12% of the students incorrectly solved the quadratic as in Figure 3. Because the constant term was in the right side, they did not perceive that the equation was in standard form. In this type of solution, they were able to find only one of the roots, 4.

Statements <u>Question 5</u>	Students’ types of responses with their reasoning			
	I. IV.	II.	III.	III.
<p>To solve the equation “$(x-3) \cdot (x-2) = 0$” for real numbers, Ali answered in a single line that: “$x=3$ or $x=2$” Is this answer correct? If it is correct, how can you show it correctness?</p>	<p>“The answer is Right” Since I wrote $(x-3) \cdot (x-2) = 0$ as $x^2-5x+6=0$ then I factorize to find roots of it. from $(x-3)=0$ and from $(x-2)=0$ “$x=3$ and $x=2$”</p>	<p>“The answer is Right” Because $(x-3)=0$ $(x-2)=0$ $x=3$ $x=2$</p>	<p>“The answer is Right”. Since we substitute “3 and 2” into x, the equation is provided. (explanation made only with words)</p>	<p>“The answer is Right”. If the $x=2$ and $x=3$ are substituted into the equation $(3-3) \cdot (2-2)=0$ $0 \cdot 0 = 0$</p>

Table 1: Common examples of students’ types of responses with their reasoning for question 5.

Working Group 3

Although all of the students stated that Ali's answer was correct by choosing either one of the statements I, II, III, and IV, their justifications were different. For instance, in statement I, students first transformed the factorized expression into the standard form, and then factorized the expression again in the same way and found the roots by rote. In statement II, students unconsciously applied the null factor law. In statement III, the way of justification for solution was based on substitution method. In all of these three statements, they could not clearly justify why the solution is correct. In statement IV, students substituted $x=3$ into $(x-3)$ and $x=2$ into $(x-2)$ simultaneously, and concluded that the solution was correct since $0 \cdot 0=0$. Namely, they thought that the two x symbols stood for different numbers and did not appear to appreciate x as a variable.

<u>Statements</u>	<u>Students' types of responses with their reasoning</u>			
	<u>I.</u>	<u>II.</u>	<u>III.</u>	<u>IV.</u>
<u>Question 6</u>				
<p>A student hands in the following work for the following problem.</p> <p>Solve ;</p> $x^2-14x+24=3$ $(x-12) \cdot (x-2)=3$ $(x-12) \cdot (x-2)=3 \cdot 1$ $x-12=3 \quad x-2=1$ $x=15 \quad x=3$ <p>Solution set= {3, 15}</p> <p><i>Is the student correct? Explain your answer with its reasons?</i></p>	<p style="text-align: center;"><i>“The answer is Wrong”</i></p> <p>Because, firstly, 3 must carry the left side of the equation and equalize the 0. Then, the other operations must be done. In this way, the equation should be</p> $x^2-14x+21=0$	<p style="text-align: center;"><i>“The answer is Wrong”.</i></p> <p>Because when we substitute 3 and 15 for x, the equation is not correct.</p>	<p style="text-align: center;"><i>“The answer is Right”</i></p> <p>Since the result is equal to 3, we equate 3 rather than 0 while factoring it. Therefore, the result is true.</p> <p>Students again solve as:</p> $“x^2-14x+24=3”$ $(x-12) \cdot (x-2)=3$ $(x-12) \cdot (x-2)=3 \cdot 1$ $x-12=3 \quad x-2=1$ $x=15 \quad x=3$ <p style="text-align: center;">{3, 15}</p>	<p style="text-align: center;"><i>“The answer is Wrong”</i></p> <p>Since the equations are separated as $(3,1)$ there is no error when $(x-12)=3$ however, there is error when $(x-2)=1$. It must be $(x-2)=3$ then, $x=5$. Therefore, the solution will be {5, 15} rather than {3, 15}.</p>

Table 2: Common examples of students' types of responses with their reasoning for question 6.

Working Group 3

In statements I and II (see Table 2), students were aware of the error in the solution of the given question. However, to explain the reasons for the mistake, they mainly referred to procedures in explanations similar to the responses in statements I, II, III for question 5 (see Table 1). In statement III, students incorrectly stated that the answer was right. Looking at the statement “since the result is equal to 3, we equate to 3 rather than 0 while factoring it”, it can be said that they wrongly tried to transfer the null factor law to this context. That is, they equated the factors of equation $x^2 - 14x + 24$ with the integer factors of 3. In statement IV, students correctly claimed “the answer of the question wrong”; however, their explanations were fully erroneous. Similar to statement III, these students tried to apply the null factor law to the equation. Nonetheless, in this case, they only equated the factors to 3 rather than to the factors of 3. In both statements III and IV, students did not check whether the roots they found were appropriate or not.

<u>Statements</u>	<u>Students' types of responses with their reasoning</u>			
	<u>I.</u>	<u>II.</u>	<u>III.</u>	<u>IV.</u>
<u>Question 7</u>				
<p>The solution of the quadratic equation “$2x^2 = 3x$” is given in the following;</p> <p>According to you, is this solution correct or not? Explain your answer with its reasons?</p> <p>Solution:</p> <p>I. step $2x^2 = 3x$</p> <p>II. step $2 \cdot x \cdot x = 3 \cdot x$</p> <p>III. step $2 \cdot x = 3$</p> <p>IV. step $x = 3/2$</p> <p>Solution set = $\{3/2\}$</p>	<p>“The answer is Wrong”</p> <p>Because $3x$ must be carried the left side of the equation and equalized the 0. Then,</p> $2x^2 = 3x$ $2x^2 - 3x = 0$ $x \cdot (2x - 3) = 0$ $x = 0, \quad x = 3/2.$	<p>“The answer is Right”</p> <p>The solution is right; however, it must be added 0 to the solution set.</p>	<p>“The answer Right”</p> <p>Because when we substitute the value for x, the equation is satisfied.</p>	<p>“The answer is Right”</p> <p>$2x^2 = 3x$ and x^2 is opened.</p> $2 \cdot x \cdot x = 3 \cdot x$ <p>Yes the x is simplified.</p> $2x = 3 \text{ so } x = 3/2.$

Table 3: Common examples of students' types of responses with their reasoning for question 7.

Working Group 3

In statement I (see Table 3), students stated that the answer was correct. They explained an appropriate procedure required for solving the equation. Since they memorized the rule without its reasons, they could only explain how the procedure should be carried out. In statement II, on the other hand, students were aware that the roots of the equation were 0 and $3/2$. However, they did not recognize that when x was simultaneously canceled from both sides, the root 0 disappeared. Furthermore, in statement III, the explanation for solution was just based on the substitution method. In statement IV, students incorrectly stated that the answer was right. Like in statement II, students were not aware of the missing root 0 when canceling x in the equation

DISCUSSION

The results indicate that most of the students used the factorization technique to solve quadratic equations. This result supports Bosse and Nandakumar (2005), who claimed that a large percentage of the students preferred to apply the factorization techniques to find the solutions of quadratic equations. Also, in parallel with the results of these authors and Kotsopoulos (2007), the result of this study revealed that factoring the quadratic equations was challenging when they were presented to students in non-standard forms and structures. After looking at the examples of students' solutions (see Figures 1, 2, and 3), it can be said that the students knew some rules (or procedures) related to solving quadratics. However, they tried to apply these rules thinking about neither why they did so, nor whether if what they were doing was mathematically correct. These results give some clues about students' instrumental understanding of solving quadratic equations with one unknown. However, to make an exact judgment about students' relational or instrumental understanding as Skemp (2002) defined, in-depth interviews with individual students are required. Furthermore, results also indicate that students incorrectly tried to transfer some rules from one form of equation to another (e.g., in Figure 2). This can be considered another clue to students' instrumental understanding (Reason, 2003).

When students were asked to examine a solution process of a quadratic equation and judge whether it was correct (i.e., in questions 5, 6, and 7), the results give additional clues about their reasoning in solving quadratics. In question 5, for example, although most of the students were aware of the correctness of the result, they did not explain the underlying null factor law used to solve the quadratics by factorization. The responses also reveal their misunderstanding of the unknown concept in a quadratic equation (see the statement IV, in question 5), which is consistent with the results of Vaiyavutjamai and Clements (2006). Students were not aware that the two's in the equation represent a specific unknown when dealing with equations in the form $(x-a) \cdot (x-b) = 0$. All of these can be regarded as clues to students' instrumental understanding. As stated by Lima (2008), and Vaiyavutjamai and Clements (2006), students knew how to get correct answers but were not aware of what their answers represented.

Working Group 3

Similar interpretations can be made for the responses of students to question 6. There are two salient points related to their reasoning in explaining the given solution. First, although students were expected to explain the reason(s) why the given solution process was wrong, they could not detect the conceptual errors in the solution. They just presented some rules or procedures to solve the quadratic. Second, as was clear from statements III and IV (see Table 2), due to their lack of conceptual understanding of the null factor law in solving quadratics given in standard form, they wrongly transferred this principle to a quadratic in a non-suitable form. This can also be a clue for students' instrumental understanding. Because when students relationally understand a rule, they can use it in a different context (Reason, 2003). Similar inferences can be made for the students' responses to questions 7 where they did not offer any explanation for why canceling s was wrong. In other words, they did not recognize that when x was simultaneously canceled from both sides, the root 0 disappeared. Also, consistent with the results reported by Bossé and Nandakumar's (2005) and Kotsopoulos' (2007), although students knew the null factor law, they could not apply it appropriately when the structure of equation was changed.

Collectively, all these results suggest that in general students attempt to solve the quadratic equations as quickly as possible without paying much attention to their structures and conceptual meaning (Sönnerhed, 2009). Although we cannot be sure if their reasoning was based on instrumental or relational understanding without in-depth interviews with students, their written answers provide clues to their reasoning, and it can be said that their reasoning underlying solving quadratic equations was based on instrumental understanding.

Having instrumental understanding does not generally cause trouble for students. It is much easier to obtain and use than relational understanding, simply because it requires less sophisticated knowledge, and with instrumental understanding, students can generally learn how to obtain the right answers more quickly. However, it necessitates memorizing, and without relational understanding the learning cannot be adapted to new tasks, and students cannot give real reasons for their answers (Skemp, 2002). For that reason, greater attention should be given to how the concept is introduced to reduce the possibility of students learning by rote. Any solution mechanism must allow students to understand the meaning of the process that they apply in order to arrive at the correct answer; otherwise, the mechanism they learn is likely to be a source of error (Blanco & Garrote, 2007).

Recommendation

As a result of this study, several suggestions can be made to contribute to improving the teaching of quadratic equations. Since factorizing the quadratic equations was challenging when they are presented in non-standard forms and structures, it would be better if teachers introduce various kinds of quadratic equations using a variety of different structures rather than only in one or two standard forms. On the other hand,

Working Group 3

it would be also helpful for students to understand the factorization techniques as relational when teachers clearly emphasize meaning of the null factor rather than presenting it just as rule. In addition, because the students can attribute different meanings to the symbols (Küchemann, 1981), their understanding of the meanings of the algebraic symbols needs to be taken into account. Therefore, if teachers emphasize the meaning of the algebraic symbols, it would also be useful for students to understand what the symbols represent in quadratic equations. Moreover, when teachers encourage students to use different techniques while solving quadratic equations, students' learning may improve, and they may also gain a conceptually understanding. Similar recommendations can also be found in the related literature (e.g., Bossé & Nandakumar, 2005; Sönnerhed, 2009).

Undoubtedly, teachers play an important role in encouraging students to learn relationally. We believe that this is the most important part of teachers' pedagogical content knowledge. However, research studies demonstrate a lack of secondary school mathematics teachers' pedagogical content knowledge in this respect (Vaiyavutjamai, Ellerton, & Clements, 2005). Indeed, there is a need to research teachers' knowledge about students' difficulties concerning quadratic equations.

INVESTIGATING THE INFLUENCE OF STUDENTS' PREVIOUS KNOWLEDGE ON THEIR CONCEPT OF VARIABLES BY USING AN ANALYSIS TOOL CONSIDERING TEACHING REALITY

Sandra Gerhard

Goethe-University Frankfurt am Main

Screening the literature on school algebra one finds various suggestions on how to implement algebra in school. But various articles also deal with problems concerning the transition between arithmetic and algebra. In order to improve school practice, teaching interventions that focus on the question of how algebraic knowledge interacts with arithmetic knowledge should be analysed while keeping in mind the influence of praxis conditions like mathematical socialisation and the didactic contract. The aim of this paper is not to give a final answer to this question, but to introduce an analysis tool meeting the above-mentioned requirements and to exemplify how such an analysis tool, according to mathematics education as design science, may help to identify integral parts of the teaching intervention.

Key words: variables, previous knowledge, approach to algebra, design research

INTRODUCTION

If one talks about school algebra the question is not only *how* to teach algebra but also *what* students are supposed to learn when they are taught about something called “algebra”. Since school algebra is a broad subject we first of all have to narrow this field.

THEORETICAL FRAMEWORK

This doctoral project is based on the perspective that learning to deal with symbolic algebra, namely with variables, is important for students (Dörfler, 2008). There are two opposing approaches towards variables. One focuses on practicing algebraic thinking without letter variables and introducing letter variables later. Linchevski (1995) calls this ‘algebra without letters’. The associated counterpart is arithmetic with letters. A more suitable opposite to algebra without letters is starting algebra with letters or to symbolize algebraic reality into being (Sfard, 2000). This perception allows different approaches to algebra and is not limited to arithmetic.

A closer examination of approaching variables via generalized arithmetic reveals advantages and disadvantages. On the one hand, variables are numbers replaced by letters and the letters can be subjected to the same operations as numbers. At a first glance it seems that students simply have to put their “number template” (Sfard, 2000) onto the letter variables and everything should be self-evident to them. On the other hand, students deal with numbers in a different way to the way they are expected to deal with letters. After a long term arithmetic education of up to six

years, students usually believe that mathematics is all about computing arithmetic problems, the equal sign merely being a sign for “calculate now” (Carraher & Schliemann, 2007, p. 670). McNeil (2004) emphasises a strong connection between children’s equation learning difficulties and their existing knowledge. An alternative may be to avoid long term arithmetic education without algebraic contents. Then there would be less time to adopt undesirable patterns and more time to deal intensely with variables.

But teaching variables early is not a panacea either. On looking closely at the various problems students have with algebraic thinking and letter variables (Carraher & Schliemann, 2007) it becomes evident that one cannot blame long term arithmetic education alone. Reasons for the problems can also be found in the nature of algebra itself. In order to develop algebraic knowledge with the help of variables, students do not simply have to transform concrete-descriptive knowledge into abstract-formal knowledge (Malle, 1993), but rather they need to develop a “flexibility in thought to move between the process to carry out mathematical task and the concept to be mentally manipulated as a part of a wider mental schema, [an] ‘amalgam of process and concepts’ [called] ‘procept’ ” (Gray & Tall, 1994,p. 1).

Regardless of the chosen approach to variables, students must and will transfer their new knowledge to different contexts at some point. This is the nature of mathematics. Thus, the new knowledge will be affected by the student’s previous arithmetic knowledge anyway. So one of the questions to bear in mind while designing a learning environment for introducing variables is how the new algebraic knowledge will interact with previous arithmetic knowledge.

METHODOLOGY

Design-based Research

Like Wittmann (1995), the author sees mathematics education as a design science. Hence this research project is based on the paradigm of Design-Based Research which “blends empirical educational research with the theory driven design of learning environments” (The Design-Based Research Collective, 2003, p. 5). It has to be emphasised that design-based research represents an integrated approach to research allowing for all facets of everyday classroom life in contrast to research methods focusing on controlling variables. The research product consists of a design-based theory where the theory explicates when and why the design works.

The author of this paper is acting in the double role of researcher and teacher. This is a critical factor in respect of the authentic setting. This being said, it also offers opportunities. First of all as teacher-researcher, the author incorporates her implicit knowledge into the teaching process which, according to Design-Based Research, is desirable as long the implicit knowledge is the object of research. Secondly, follow-up interviews have also been conducted by the teacher-researcher. Thus the interviews may also provide information about the implicit knowledge of the teacher

and the didactic contract (*see Pichat & Ricco, 2001*) between teacher and student as will be shown later in this paper.

Designing a Learning Environment: the Teaching Intervention

The aim of the doctoral project is the development of a theory-driven learning environment for introducing variables in early grades. The Measure Up–project (Dougherty, 2008) was chosen as starting point and redesigned for introducing variables in primary school.

Based on the analysis of a pre-study in lower elementary school (Gerhard, 2009) the learning environment was modified for a 5th grade of a grammar school. Focusing on the authentic setting, the teacher was included and the design was based on the federal curriculum, the curriculum of the mathematics section of the school and the textbook. The intervention “algebra” replaced the topic “calculation of length, area and volume” whereas this topic was embedded in the topic “algebra”.

The following principles underpinned the teaching intervention. The students were told to do mathematics without numbers, to find as many relations as they could, to write relations as equations and inequations to convert equations through “basic transformation rules” (Malle, 1993, p. 219) and to make auxiliary drawings.

Developing a Theory: the Interviews

For the development of theory the research focuses in particular on the question of how new algebraic knowledge might interact with previous arithmetic knowledge. The findings, by giving important information about how the learning environment affects students’ understanding of variables, are an integral part of the theory-driven design. Therefore, additional problem-centred, half-standardised interviews were conducted. During the interview students were confronted with problems that were designed to challenge their previous arithmetical knowledge and their knowledge about variables. Therefore arithmetic rather than algebraic word problems were chosen. They were modified by using letters instead of numbers.

Holiday in France I

Stefan will have a holiday in France; he wants to hike from Lyon to Lourdes.

From Buchheim to Lourdes it takes **a** km. From his home he firstly goes by bus **b** kilometres to Lyon. From Lyon to Lourdes he wants to hike for **c** days. How much kilometres does he have to hike every day at an average?

Figure 1: Sample problem

The sample problem (see Figure 1) was designed considering the following aspects:

- The students have met variables as general undetermined numbers used for modelling. The task, an arithmetic word problem with letters instead of numbers, uses variables in the same way.

Working Group 3

- The structure of the word problem ($b + (c \cdot L) = a$) was chosen firstly. The narrative was developed to go with the structure with L as solution. So the students have to conduct inverse operations of addition and multiplication.
- The students have met variables in a geometric context. The task also includes geometric quantities.
- The structure of the task asks for a multiplication. The students have seldom met the multiplication of variables as in area but they are accustomed to multiplying quantities by time or money. By choosing the kilometre as the unit of measurement for a and b and days as the unit of measurement for c , L becomes an intensive quantity with the unit 'kilometres per day'. This may cause difficulties but, due to everyday life experience, it is most likely that students treat c like a natural number without a unit.
- It is not expected that students will present $L = (a-b) : c$ as a solution. Taking into account students' previous experience with word problems, it is more likely that the students will use sub-steps.

During the interview the students had to solve this word problem and a similar word problem with numbers in place of the variables to find out if there were different approaches to the two tasks depending on the previous arithmetical knowledge but independent of the chosen context. The interviews were transcribed and the content of the transcripts together with the written products created by the students during the interview are objects of this analysis.

THE ANALYSIS INSTRUMENT

To get a holistic view on the complex epistemic process of how the previous arithmetical knowledge interacts with the knowledge about variables taught and how these two aspects are connected to become the student's new knowledge, different parameters have to be taken into account. Therefore an appropriate analysis tool had to be developed.

General Analysis: Malle's 3-Step-Model

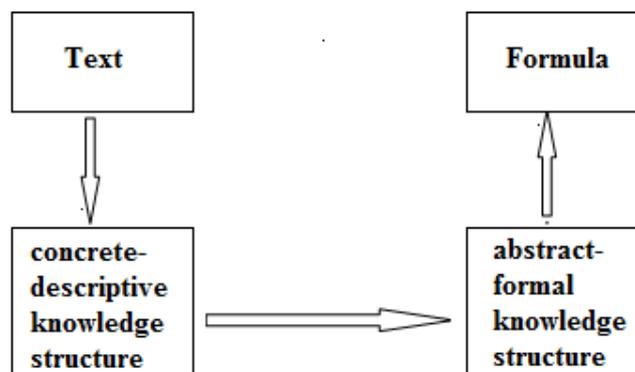

Figure 2: From text to formula, a 3-Step-Model (Malle 1993, p. 99, own translation)

Working Group 3

If we look at students working on a task, we look at a solution-oriented process. Thus we first need a tool that helps us to describe this process in a way that allows identification of important moments of transition. The 3-Step-Model of Malle (1993, see Figure 2) fulfils these needs.

The concept “knowledge structure” is defined as follows:

“A knowledge structure contains schematic, cross-linked knowledge concerning a certain scope, which has been constructed under certain conditions and has been optionally stored in the long-term memory where it can be accessed again.” (Malle, 1993, p. 98, own translation)

Certainly the transition process from text to formula is not as direct as it is shown in Figure 2. In particular steps 2 and 3 are closely intertwined and the respective steps can be passed through iteratively. (Malle, 1993, p. 99). Hence, as already remarked above, particular attention should be paid to students’ procepts, in other words the interaction of students’ procedural and conceptual view of the task.

Detailed analysis: searching for reasons using an interdependence model

After analysing the interplay of procedural and conceptual knowledge, we have to address the issue as to how this interplay is affected by such factors as the actual classroom and interview setting. Therefore, we have to tease out the extent of the effect of these different influential factors.

On one hand we have to identify the **Previous Knowledge** in terms of Everyday Life Knowledge and Mathematical Specialised Knowledge. On the other we have to look at the **New Knowledge** in terms of Knowledge the Teacher has taught. This implicit knowledge of the teacher has to be identified and related to the Knowledge the Teacher intended to teach to reconstruct the students’ understanding thereof.

In order to address the authentic setting we additionally have to take into account the perspective of social interaction (*see Pichat & Ricco, 2001*). The notion of **Previous Interaction** represents the Socialisation in the Mathematics Classroom concerning the handling of mathematical situations. Previous interaction has become independent of the teacher because the student already has internalised these habits. The term **New Interaction** or actual interaction deals with the actual Didactic Contract in an interview or classroom situation. The actions carried out here are not internalised yet and depend profoundly on those persons with whom the students are interacting. Like previous and new knowledge, previous and new interaction may interfere with each other producing conflicts from which new integrated knowledge may emerge.

The considerations above lead to a Framework of an Interdependence Analysis Model (see Figure 3).

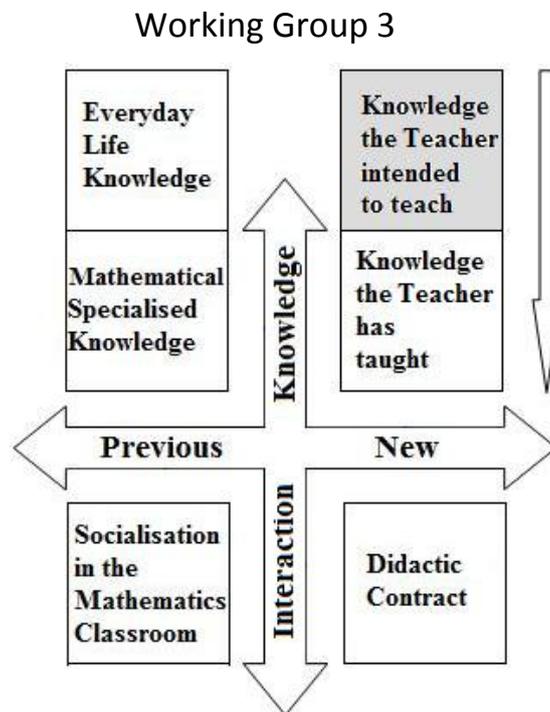

Figure 3: Framework of an Interdependence Analysis Model

ANALYSIS

After describing the background of the analysis tool its application will be exemplified in the case of Daniela. We start with a description of Daniela's background followed by a general and detailed analysis.

Daniela's Background

Daniela attended the algebra lessons at the end of grade 5. She is a good student with good marks in mathematics lessons. The evaluation of her arithmetical skills at end of grade 5 showed a performance below class average with difficulties with written procedures and inverse operations.

General Analysis

If one compares Figure 4 to Figure 2, the 3-Step-Model seems to fit perfectly. At first (A) Daniela is visualising her concrete-descriptive knowledge about the task by an external representation. The three lines match exactly the first three sentences of the word problem and contain the relevant information. Then (B) she again is visualising the task by means of an auxiliary drawing which contains information about her abstract-formal knowledge structure. She tries a (incorrect) generalisation (C, see Figure 5) and finally translates her abstract-formal knowledge into a formula (D). Fortunately we are able to observe nearly the whole transition process here because she is visualising her internal concrete-descriptive and abstract-formal knowledge by external representations.

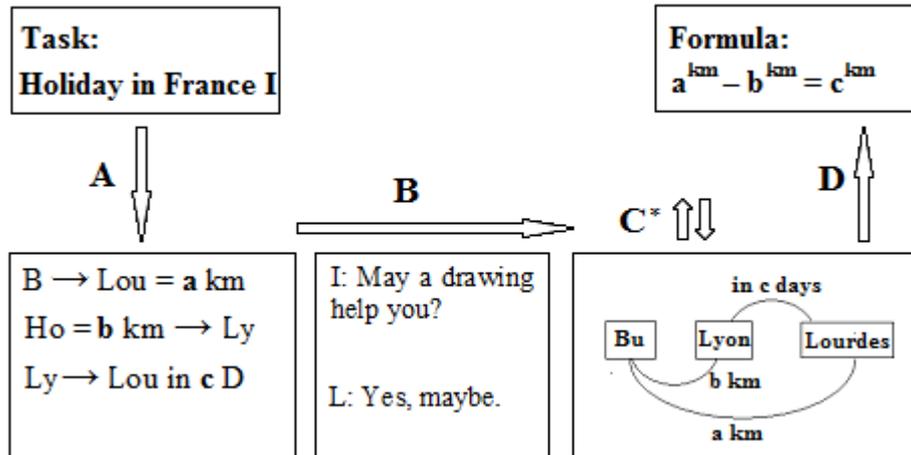

Figure 4: First classification of Daniela working with the sample problem

	<p>L: Then he has to walk b kilometres, well if, if, if in Lyon...then is exactly in the middle.</p> <p>I: Is it written there that Lyon is exactly in the middle?</p> <p>L: No (laughs)</p> <p>I: Well that would be nice, wouldn't it? But you don't know.</p> <p>L: (quietly) From Lyon that are c days and from Buchheim that are also...</p>
--	---

Figure 5: Transition C

Allowing for a process-concept-view we can describe the transitions as following:

- A) The variables themselves do not activate a conceptual view on the task. The three lines reproduce exactly the (travelling) process that is given with the text.
- B) The suggestion to use a drawing may initiate the transition from a procedural to a conceptual view but for the drawing process, conceptual knowledge does not need to be applied. She simply translates her concrete-formal knowledge step by step into a sketch. She may still be thinking procedurally from within the travelling process:

Daniela: Actually this is only an intermediate place, this village.

C) The drawing itself allows Daniela to develop a conceptual view. Lyon changes its state of an “intermediate place” to “exactly in the middle”. Daniela’s statements change from “in Lyon” to “Lyon is” back to “from Lyon”. For a moment she moves out of the travelling process into a conceptual meta-level and then back into the process without actively controlling this interplay.

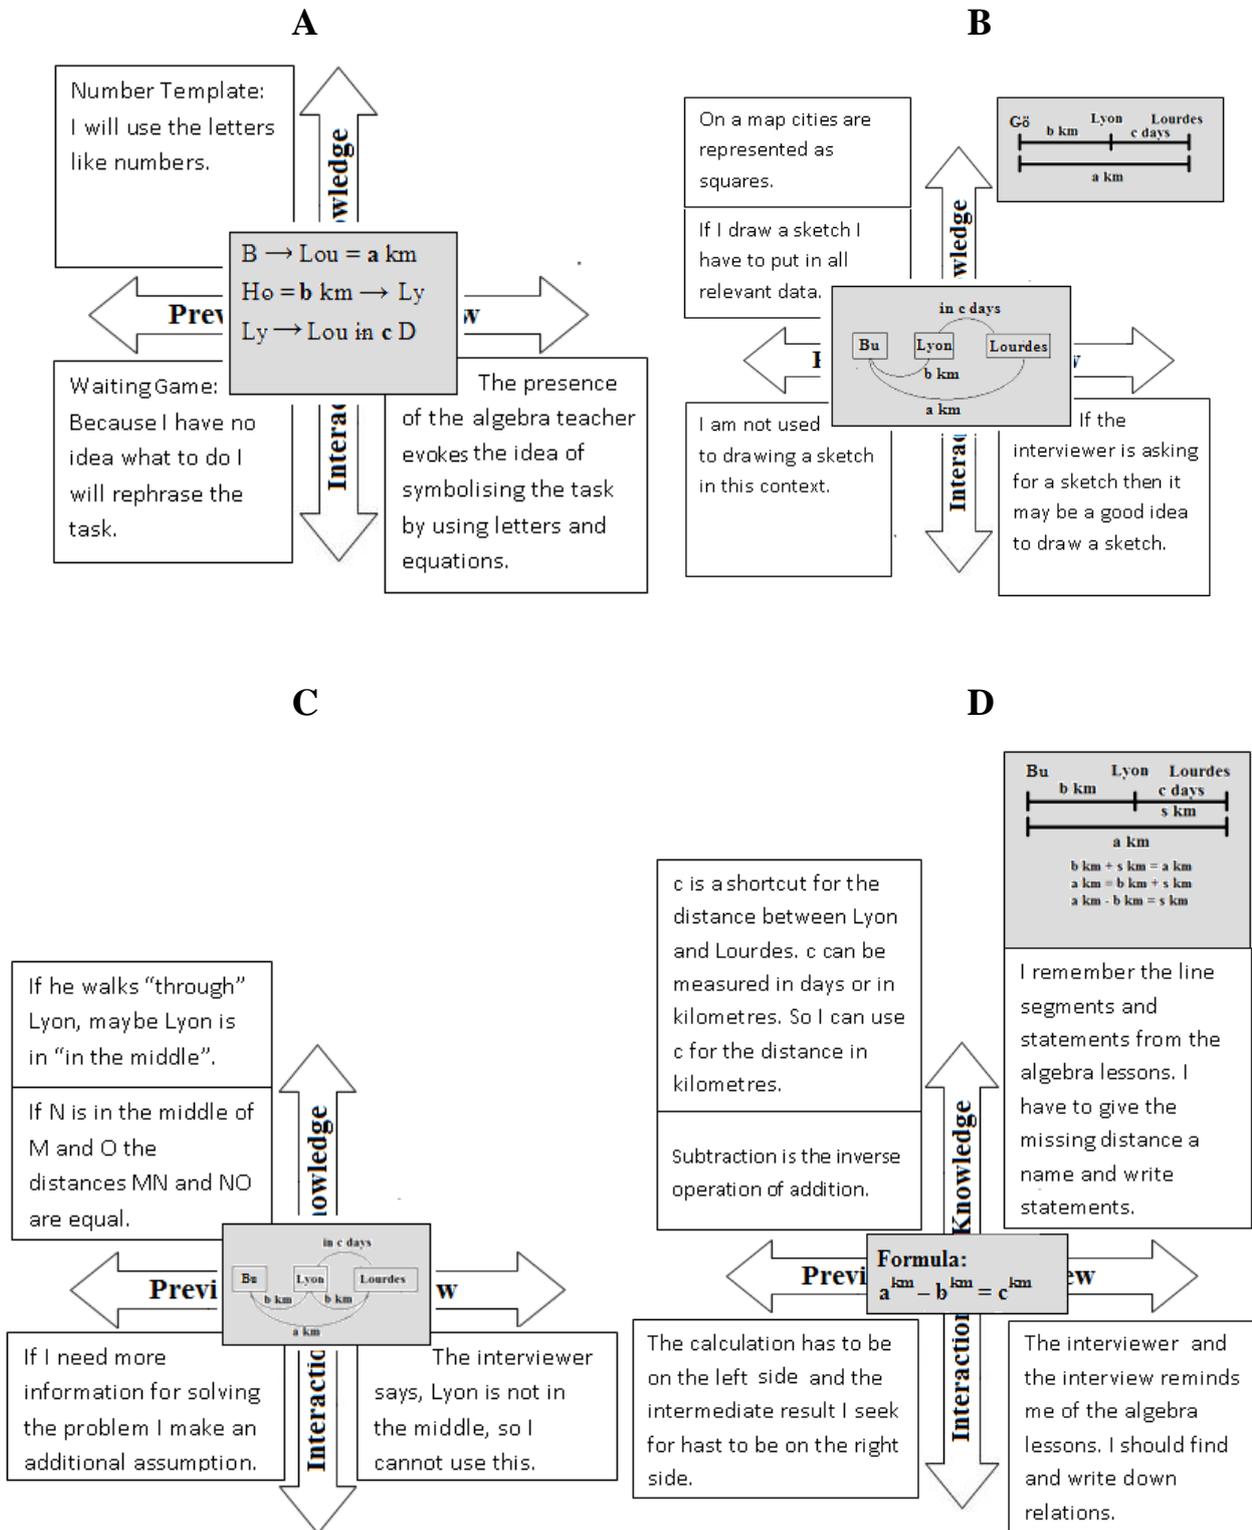

D) Now there is a time of 60 seconds where nothing observable happens, before – we are tempted to say suddenly – the following is happens:

Daniela: (quietly) Oh, minus **b** kilometre (writes “a-b” and writes “km” in small letters above the letters **a** and **b** and then writes „= c km“)

Working Group 3

If Daniela looks at the drawing, the arches that connect Buchheim, Lyon and Lourdes may all be seen as distances and she may see $b+c=a$. This interpretation is supported by the fact that Daniela added the unit “km” to all the letters. This is a conceptual view on the drawing. But she is writing $a \text{ km} - b \text{ km} = c \text{ km}$. This result- and process-oriented way seem to eclipse the conceptual view on the task.

Detailed analysis

PRELIMINARY RESULTS

To complete the demonstration of our *modus operandi* we allow ourselves to draw first exemplary conclusions about the interplay of Daniela's previous arithmetic knowledge and her new algebraic knowledge

- A) The presence of letters as part of an arithmetical task is not strong enough to activate Daniela's algebraic knowledge. Her arithmetical knowledge is dominating.
- B) Using auxiliary drawings is not a self-evident part of Daniela's mathematical socialisation. But her drawing allows her to change from a procedural to a conceptual view and to associate the task with the algebra lessons. The drawing acts as a mediator between the arithmetic task and Daniela's knowledge from her algebra lessons.
- C) The algebraic symbol system allows one generalised description of several different cases without requiring a case distinction. But Daniela wants to work with a direct relation of the two distances Buchheim-Lyon and Lyon-Lourdes. This is easy with number distances, because the order is part of the numbers. But here it is impossible, because the direct relation of the two variables is not defined.
- D) It took 60 seconds for Daniela to recall how to conduct the required subtraction. She may have known that she had to conduct a subtraction but had difficulties finding out which letter represented the minuend and which letter represented the subtrahend. Later she made the following remark:

Daniela: ...but with numbers, well, you already know from the beginning, what minus what equals what...

Again Daniela's difficulties are a result of the fact that she cannot get the order of the variables at first sight. Instead she has to take the information about the order of the variables out of the text, something she is not used to.

PERSPECTIVE

This passage of Daniela's interview was chosen as an example of findings that were also present in interviews with other students. A further analysis of the interviews will show if students can be categorised according to the interaction of their previous knowledge with exposure to variables and if there are differences between students with low- and high-achievements in arithmetic. The analysis will also show if the analysis tool can meet the claim for which it was designed.

What we already can see is that we have to differentiate between the transition from arithmetical to algebraic thinking on the one hand and the transition from numbers to variables on the other hand. The apparent difference of algebraic thinking with numbers to algebraic thinking with letters deserves further investigations.

WHAT IS ALGEBRAIC ACTIVITY? CONSIDERATION OF 9-10 YEAR OLDS LEARNING TO SOLVE LINEAR EQUATIONS

Dave Hewitt

School of Education, University of Birmingham, UK

This paper tries to raise issues about what constitutes algebraic activity through looking at number of episodes from a series of three lessons taught to 9-10 year olds using the software Grid Algebra[1]. From different viewpoints the work the students achieved could be viewed as anything from impressive algebraic activity after relatively short time of teaching, to feeling as if no algebraic activity took place at all. The aim of the paper is to raise issues rather than come to a particular position. It ends up highlighting the fact that such viewpoints are the result of us considering certain things are important and to encourage pursuit of what those are and why we give them that significance.

SOME DIFFICULTIES AND SUCCESSES WITH ALGEBRA

There has been much research reporting difficulties students have with algebra. Küchemann (1981) highlighted the fact that many students had considerable difficulty in developing meaning for letters. Difficulties students experience are not restricted to letters as Collis (1974; 1975) identified a tendency for 6 to 10 year olds to want to replace two numbers connected by an operation with a single number. He described this as students struggling with a *lack of closure*. Sfard and Linchevski (1994) talked about the need for students to be able to see an expression as an object as well as a process to be carried out. The equals sign has also been shown to have meanings for students where certain correct mathematical forms of statements are deemed to be unacceptable. Behr et al. (1980) showed that 6-7 year olds viewed the equals sign as a *do something signal*. Kieran (1981) pointed out that this was not just an issue with younger students but something which carried on throughout elementary school, into high school and even college as well. These issues with the equals sign still persist as shown in more recent studies (Knuth et al., 2005; Linsell and Allan, 2010).

Over the last 10 years there has been a number of reports on what students are able to do, rather than what they are not able to do. Younger children in primary schools have been shown to be able to work with algebraic ideas, use letters as unknowns and operate on letters without having to know their values (Schliemann et al., 2003). An example of this is students of 8-9 years of age being able to explain why $N + 3 - 5 + 4$ must be equal to $N + 2$ whatever the value of N (Carraher et al., 2001). Projects based on the ideas of Davydov have engaged 6 year old students with relational ideas using letters before formal work on numbers (Dougherty and Zilliox, 2003).

There is an interesting contrast between studies showing the difficulties that students have with algebra, and unquestionably continue to have with algebra in many secondary mathematics classrooms in particular, and the increasing evidence that

young children are able to engage with algebraic ideas and begin to work with more formal notation. Within this contrast I feel are questions about what we actually perceive algebra to be along with questions about pedagogic approaches which might be adopted as a consequence. The terms *pre-algebra* or *early algebra* have often been used, maybe as a way of being able to avoid contention as to whether something a student does might be deemed as algebraic or not. This is something I will now pursue by considering some different ways of viewing what it is to work algebraically.

WHAT IS ALGEBRA?

In jest, algebra has been described as the study of the 24th letter of the alphabet. If algebra is not as simple as the appearance of a letter then the issue of when does algebra begin is one which has been debated over some time. Mary Boole (1931, p. 1231) described the move from arithmetic to algebra in terms of acknowledging “the fact of our own ignorance” which leads to explicitly labelling an unknown. Filloy and Rojano (1989) talked about a *didactic cut* between arithmetic and algebra, this occurring when a letter appears on both sides of an equation. However, Herscovics and Linchevski (1994) argued that it was not about the form of the equation but about when a student begins to work with the unknown. For example, the equation $2x+4=19-3x$ could be solved by trying different numbers for the letter x whereas someone might change the equation into the form $5x=15$ in which case they have the worked with the unknown. For Herscovics and Linchevski, the issue was more about the human activity of how someone worked on an equation rather than the form the equation took. They talked about a *cognitive gap* with many students having difficulty with working spontaneously with or on the unknown. The shift away from symbols themselves onto human activity is one which Radford has followed, looking at algebraic activity in terms of semiotics where “mathematical cognition is not only mediated by written symbols, but that it is also mediated, in a genuine sense, by actions, gestures and other types of signs” (Radford, 2009, p. 112). He has recently argued for attention to shift from our obsession with mathematical symbolism and onto what he calls the *zone of emergence of algebraic thinking* (Radford, 2010a) where the expression of general rules can take place with the use of words, actions and gestures. Mason has for a long time considered algebraic activity in terms of expressing generality (Mason, 1996) and seeing the general in the particular and the particular in the general, where the existence of symbols is not central to the consideration of when algebraic activity takes place. He has talked about three pairs of powers which students bring with them into the classroom: imagining and expressing; specialising and generalising; and conjecturing and reasoning (Mason, 2002) and challenges us as teachers to consider whether we are stimulating these powers or trying to do the work for the students. The notion of *powers* which students bring with them has its roots with Gattegno (1971) who argued that we all possess powers of the mind, which are attributes of being human. These powers are used by very young children in their early learning before they ever enter a school

Working Group 3

and remain in daily use throughout all our lives. Gattegno (1988) argued that it is helpful to consider algebraic activity in a wider sense than only in a mathematical context. He spoke of algebra as operations upon operations which can be manifested within the learning of language (such as noticing a rule in the way verbs change tense) as much as within mathematics. As such, algebraic activity is an attribute of the mind and so everyone has already worked algebraically and continues to do so. The issue is then more concerned with Mason's challenge and whether a student's powers of working algebraically are called upon within a mathematics classroom when working on the topic of algebra!

I have offered a brief summary of different ways in which algebra might be viewed and in particular I will analyse students' work during a series of three lessons in terms of the following perspectives:

- Algebra as appearance of letters
- Algebra as working with equations with a letter on both sides of the equation
- Algebra as working with or on the unknown
- Algebra as an expression of generality using actions, words and gestures
- Algebra as seeing the general in the particular and the particular in the general
- Algebra as an attribute of the mind: operations upon operations

THE STUDY

I carried out a series of three lessons with a mixed ability group of 21 9-10 year olds in an inner city primary school. These students had never met the use of letters formally within their lessons and had never been introduced to formal algebraic notation. The students' attainment levels were based by their teachers on the UK National Curriculum levels where most 6-7 year olds are expected to achieve a level 2 and most 10-11 year olds are expected to achieve a level 4. The range of teacher assessed levels for these students was as follows: 2 (level 2); 13 (level 3); 3 (level 4); and 3 (level 5). The lessons were taught by myself and nearly all of the lesson time was spent either using the computer software *Grid Algebra* with occasional time spent on pen and paper activities related to the software. It is important for the reader to be aware that I wore three hats during this study; researcher, teacher and also the person who had developed the software. As such my comments and analysis have to be read with this in mind. One significant aspect about the way of working with the students was that at no time was anything explained to the students, including the particular appearance of formal notation. Instead, certain actions were carried out using the software on an interactive whiteboard, challenges were given to the students and questions were asked.

The teaching sessions were video recorded along with times when individual students worked in a computer room with computer generated tasks. Some pairs of students' work on computers was captured using *Camtasia* software, which records everything they are doing on the computer. Written work was also collected in.

Working Group 3

These were all analysed through a coding process which was based upon themes and links which developed through the analysis process.

GRID ALGEBRA

The software is based upon a multiplication grid with the one times table in the top row, the two times table underneath that, the three times table underneath that and so on (see Figure 1 where only the first two rows are shown).

1	1	2	3	4	5	1
2	2	4	6	8	10	2

$\frac{6-4}{2}$	2	$\rightarrow 2+1$	$5-1$	$\leftarrow 5$
\uparrow	$6-4$	$\leftarrow 4$	$\rightarrow 6$	\downarrow
		$2(5-1)$		10

Figure 1: the first two rows of the grid

Figure 2: some movements on the grid

A key feature of the software concerns the relationship between numbers in this multiplication grid. For example, moving from one number to the next number in the one times table would involve adding one and a number such as 2 can be picked up and dragged to the next cell and it would show in notation $2+1$ (see Figure 2). There would now be a peeled back corner in that cell showing that there is also another expression in the cell, in this case the original number 3. On each click of the peeled back corner the expressions in that cell would be revealed one at a time in a cycle of all expressions which have been entered into that cell. Likewise other movements are possible with any movement to the right resulting in addition, to the left would result in subtraction, a movement down would produce multiplication and up division (see Figure 2). Once a movement has taken place the resultant expression becomes an object which can be moved once again. Thus in Figure 2 the number 5 in row one has been moved one cell to the left, producing $5 - 1$, and then that has then been picked up and dragged down from the one to the two times table to produce $2(5 - 1)$. Likewise the 6 in the two times table (row 2) has been moved twice to produce $\frac{6-4}{2}$. There are a large number of other features to the software but only those relevant to particular incidents below will be mentioned.

I will now describe a number of incidents which happened over the three lessons and later I will look at these in terms of the different views about what might constitute working algebraically. These incidents are chosen so as to get a general sense of the development of activities which took place over the three lessons, although it should be noted that there were several additional activities to these which took place.

Episode 1

At the beginning of the first lesson, students were shown the grid with the times tables shown as in Figure 1. After two minutes of them describing what they saw and which numbers might come next in each row (the grid could be scrolled so that they could see which numbers do appear next), a pre-prepared grid was loaded which showed the same grid but with some of the numbers rubbed out. Below the grid was

Working Group 3

a ‘number box’ which, when scrolled through, contained the numbers from 1 to 200. The students were asked to come up and drag an appropriate number from the number box into one of the empty cells in the grid. If it was correct the number would stay in the cell. If it was wrong a sign would indicate this and the number

1			14		
2	24		28		

would drift off into a ‘bin’. Chris (pseudonyms are used for all the students) dragged the number 12 into the shaded cell in Figure 3 and I asked how he worked out that it was 12.

Figure 3: which number should go into the shaded cell and why?

He said “If it’s the one times table it’s going to be plotting one up or one down so I just counted two down from 14 which is 12.” As he did this he pointed from 14 back to 12. Abbas said that he could explain it differently and said that he halved the 24. He came up and pointed from the 24 up to the cell which now had 12 in it. Such activities continued with grids having more rows, fewer numbers given and with a greater ‘space’ between any number given and the highlighted cell.

Episode 2

Here I will describe a series of incidents where the class were all together using the Interactive Whiteboard (IWB). Towards the end of the first lesson I had placed the number 15 into a cell in an otherwise empty grid. I made a journey with 15 as indicated by the arrows in Figure 4, and rubbed out all the expressions in the cells along the route except for the final expression. Note that the arrows did not appear on the IWB. They only appear here for clarity of description.

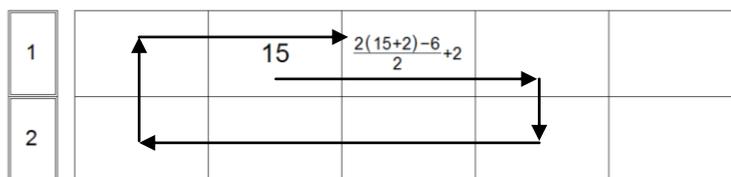

Figure 4: A journey made with the number 15.

After rubbing out the middle stages I then announced that I had forgotten what I did to make that expression and asked them to re-create the journey I had made. During this task a student came up to the board and was successfully given the directions of how to re-create it by fellow students. However, I noted these directions were in the form of *across*, *down*, etc. Mathematical operations were not mentioned. The second lesson I repeated this task with other journeys but worked on the language so that mathematical operations were being used to describe what operations were carried

Working Group 3

out with increasingly complex expressions such as $2\left(\frac{2\left(\frac{2(33-2)+2}{2}+3\right)-2}{2}-1\right)-4$.

Collectively the students were successful at re-creating these expressions with very few, if any, incorrect movements on the grid. Each time I began a new journey I talked about starting with my “favourite number” which changed every time I did this activity. Then I continued with a same activity but started with a letter and took that letter on a journey rather than a number. So, for example, they were able to tell me the order of operations with the expression $\frac{2\left(\frac{r}{2}-2\right)-2}{2}+2$.

Episode 3

Julie (a level 5 student) was working on a computer generated task from the software where she was told that $x=4$ and had to drag the correct number from the number box into the cell which had within it the expression $2(x-2+2)+8$. She said: *Four. Ex equals four. Four take away two plus... that's just the same as saying four [pointing to $x-2+2$] times two equals eight, plus eight equals sixteen.* She talked through her thinking with several of these tasks and she got many of them incorrect as her arithmetic was often faulty even though she correctly said what operations had to be carried out.

Episode 4

Abbas (level 3) was working on a paper exercise where an expression involving a letter was written on one cell on a grid and the task was to find which cell the letter must have come from. A colleague of mine asked him a question of why he chose to undo the dividing first with $\frac{2w-4}{2}$ but did not do so with the expression $\frac{n}{2}-2$ from the previous question (see Figure 5, note that both these are correct).

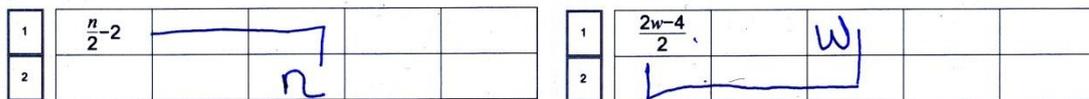

Figure 5: Inverse journey task to find where the letter was originally

In his explanation he moved his pen rapidly horizontally between $\frac{n}{2}$ and 2 in the expression $\frac{n}{2}-2$ saying “*These two are together so it just tells me that I need to do these two first. That’s why I had to do that last because these two had to so I, so I knew I had to do that, that, that, um, first.*” He struggled to express himself in words and the action seemed to hold more meaning than the words did.

Episode 5

At the end of the final lesson, Julie was working on a sheet of equations to solve. She was talking through solving $\frac{f-8}{2}+6=57$ and was able to express clearly the operations she carried out to solve this (no working was written on the paper, just the

Working Group 3

answer). Having described taking away the 6 she went on to say *Now you times by two* and at the same time she used her pen in a downwards stroking gesture from the division line to the 2 underneath it.

Other students were also able to solve equations, some with support of the grid and others without, like Julie. This included one of the level 2 students who could solve equations with the aid of the grid and write the solutions in correct notation, such as $\frac{24}{2} - 3$ for the equation $24 = 2(p + 3)$.

ANALYSIS

All students were working with confidence with formal algebraic expressions of reasonable complexity and the fact that students of this age were doing so could be viewed as impressive after only three lessons. Many of the students were able to solve linear equations, albeit some still needing the support of the grid, and express their answers in formal notation. However, it is another matter to consider whether they were doing any algebra or not, and if so, when that algebraic work started. I will now consider each of the six ways of viewing algebra mentioned earlier with reference to these episodes.

Algebra as appearance of letters

This would mean there was a shift from arithmetic to algebra when I introduced a letter in Episode 2. The interesting thing with regard to this viewpoint is that the students really did not meet a conceptual difficulty in this transition. There was an initial reaction to the idea of a letter but as I did not react to that and moved on to the activity quickly, they found they could do the activity just as well as they had done earlier when a letter was not present.

Algebra as working with equations with a letter on both sides of the equation

This never happened throughout the three lessons and so that would imply that the students never began working algebraically and stayed in the realm of arithmetic.

Algebra as working with or on the unknown

The students in this study did not manipulate an unknown from one side of an equation to the other. However, they did work with the idea of an unknown and this was manifested in the particular example in Episode 3 of Julie recognising that $x - 2 + 2$ did not change the value of x . Even though she was substituting in a particular value for x I argue that her awareness was of the generality of $-2 + 2$ and not the particularity of x being 4 in this case. So from this viewpoint she might be working algebraically even though she struggled with the arithmetic. This is similar to Carraher et al. (2001) reporting that their 8-9 year olds were able to articulate why $N + 3 - 5 + 4$ was equal to $N + 2$. They could account for this irrespective of the value of N . Other students in my study were also able to work successfully with the unknown

by working out solutions for the linear equations given at the end of the third lesson (Episode 5).

Algebra as an expression of generality using actions, words and gestures

Here I would like to discuss Episode 4 where Abbas was rapidly moving his pen from $\frac{n}{2}$ to 2 in the expression $\frac{n}{2} - 2$ when trying to explain why he did not start by undoing division in this case. The rapid speed of the pen movement was striking and it seemed to be expressing what he was struggling to express in words. I would like to argue that he had a sense of generality of which operation he would undo first and that this was expressed with a gesture more effectively than words. However, this generality concerned a notational convention and as such might be considered qualitatively different to Radford's (2010b) example of a rule for the number of squares in a geometrically arranged sequence. I argue that such a geometric sequence is also arbitrary in its nature since there are not reasons why the squares must have been arranged how they were. It was a human construct in a similar way to mathematical notation. So did Abbas reveal algebraic thinking within that gesture? In Episode 5, Julie used a downwards stroke of her pen from the division line to the 2 below whilst saying "multiply by two". The combination of this gesture on the division line whilst saying "multiplication" revealed that she could see one operation and think of its inverse at the same time.

Algebra as seeing the general in the particular and the particular in the general

In Episode 2 the nature of the activity of re-creating journeys was such that attention was placed on the mathematical operations rather than any particular starting number I used. This focus of attention allowed a letter to be introduced without causing too many issues for the students, since they often never paid attention to the start number anyway. I deliberately varied the start number to try to develop a sense of variation and also irrelevance. Fujii and Stephens (2001) talked about the idea of a *quasi-variable* where numbers were used to demonstrate a mathematical relationship which would be true irrespective of the numbers, such as $78+49-49=78$. The particularity of the number in both cases is irrelevant. In this way the general can be seen through the particular and indeed as the teacher I tried to judge when this was the case for most of the students so that I introduced a letter when that sense of generality was already present.

Algebra as an attribute of the mind

Tahta (1981) has talked about inner and outer meanings of activities. In Episode 1 an outer meaning might be to place the correct number into the highlighted cell, whereas the inner meaning in the design of such a task for myself was for students to begin to form mathematical connections between different cells on the grid (in preparation for the later activities involving movements). The students' explicit attention might have been with the numbers, whereas the work they had to do to

Working Group 3

achieve placing a correct number was to work out relationships between different cells on the grid. I argue that students were working with operations in order to carry out these tasks and the awareness of equivalence of different sets of operations was certainly operating upon operations. So with this view of algebra, the students were working algebraically already with the initial 'number' activity.

CONCLUDING THOUGHTS

How we view algebraic activity changes when we feel students have started such activity. It might be argued anything from the students in this study not doing any algebra at all over the three lessons to them working algebraically from the very first activity. Naming is an act to label that which is deemed to be significant and what is important is what someone wishes to stress. So the fruits of a discussion about what constitutes algebraic activity can come from what each person reveals to be particularly significant for them in the developing process students make within their work towards algebra and within the algebra curriculum. Not only what is significant but why it is significant. That is what I feel is particularly useful in considering the question *what is algebra?*

THE ROLE OF DISCURSIVE ARTEFACTS IN MAKING THE STRUCTURE OF AN ALGEBRAIC EXPRESSION EMERGE

Laura Maffei and M.Alessandra Mariotti

Dipartimento di Scienze Matematiche ed Informatiche, Università di Siena

The paper is based on a research study aiming at exploiting the potentialities of the natural language in the introduction to algebra calculation. By means of activities involving both the standard representation of algebraic expressions and the tree representation available in the Aplusix CAS, the natural language is used as a tool to firstly mediate the meaning of structure of algebraic expressions, and then the meaning of some specific structures, i.e. expanded and factorized expressions. After a description of the theoretical framework, the design of a teaching experiment is presented, and some results are discussed.

Keywords: natural language, structure, algebraic calculation, Aplusix

INTRODUCTION

Many studies deal with difficulties encountered by students (9-10 grade) in performing algebraic tasks and explain them as a lack of structural view of algebraic expressions (Greeno 1982; Freudenthal, 1983). But, how is it possible to make structural aspects emerge? To give a possible answer to this question we propose first of all an epistemological analysis of the resources students usually exploit to face algebraic tasks. We hypothesize that the usual representation students are used to treating algebraic expressions with, could not provide support in highlighting the ‘structure’ of algebraic expressions. In this perspective, we agree with Duval’s claim (Duval, 2006) about the need of interacting with different representation systems for developing mathematical meanings.

In the following, we are going to discuss a different type of representation, the tree-representation (TR), implemented in the Aplusix CAS (Nicaud & al., 2004). According to Morgan & al. (2009), we can classify the difference between the standard representation and the tree-representation (TR) as an ‘epistemological distance’, that is, a difference between the affordances of each system with respect to specific aspects of the mathematical concept in focus. Such a difference may be exploited for developing the meaning of ‘algebraic expression’ and specifically to make the meaning of structure emerge. As it will be discussed below, in the semiotic game between the different mathematical representation systems, a crucial role is played by natural language (NL). NL may be considered as acting at a meta-level, where we observe the emergence of specific ‘linguistic expressions’, that the teacher may use for exploiting the potentialities of TR with respect to the meaning of structure of algebraic expressions.

The research study¹ is based on an experiment conducted in the First Year of the Upper Secondary School in Italy, when students starts the Algebra course.

THE THEORY OF SEMIOTIC MEDIATION

The research is framed within the Theory of Semiotic Mediation (Bartolini Bussi & Mariotti, 2008) which allows us to analyse the potentialities of different kinds of representations of the same mathematical object (i.e. algebraic expression) with respect to a specific meaning (i.e. structural interpretation). Three different semiotic systems of representation are used, the standard representation (SR), the tree representation (TR) and the natural language (NL), which are considered as *artefacts* according to the Theory of Semiotic Mediation (TSM). TSM emphasizes how the use of artefacts to perform specific tasks helps students develop *personal meanings* (Leont'ev, 1976) related to the actual use of them. Then, through *mathematical discussions* (Bartolini Bussi, 1999) under the guidance of an expert (typically the teacher), students' personal meanings may gradually evolve into mathematical meanings. In this perspective, the evolution from the personal sphere to the mathematical domain strictly depends on the teacher's didactical actions. An artefact, intentionally used by the teacher, who is aware of her/his crucial role in managing this process, is called a *tool of semiotic mediation* (Bartolini Bussi & Mariotti, 2008, p. 754). In this perspective, the functioning of an artefact as a tool of semiotic mediation is concerned with the double relationship that such an artefact has both with the meanings emerging from its use to accomplish a specific task, and with the mathematical meanings evoked in such a use, as they are recognized by an expert. This twofold relation is called *semiotic potential* of an artefact (Bartolini Bussi & Mariotti, 2008, p. 754).

NATURAL LANGUAGE AS A NEW REPRESENTATION SYSTEM: THE SEMIOTIC POTENTIAL OF LINGUISTIC EXPRESSIONS

According to our theoretical frame, both SR and TR are considered artefacts. In fact, each of these has a specific semiotic potential with respect to the meaning of algebraic expression, in particular TR can be exploited as a tool of semiotic mediation with respect to the meaning of 'structure' of an algebraic expression. In the semiotic game between SR and TR, NL plays a crucial role in making mathematical meanings emerge and develop. Specifically, in the context of conversion tasks (Duval, 2006) from SR/TR to NL and vice versa, NL fosters the interaction between SR and TR.

As shown in the following, the repeated use of specific linguistic expressions, develops linguistic patterns which can be viewed, according to Sfard (2001), as 'discursive templates'. The peculiarities of the 'linguistic expressions/discursive templates' and their use in the semiotic mediation process allow us to consider them as artefacts, that we refer to as *discursive artefacts*. Moreover, because of their origin

in the conversion tasks, these discursive artefacts maintain a tight relationship with SR and TR.

The teacher's didactical action consists in making the discursive artefacts serve as 'tools of semiotic mediation' with respect to the meanings of 'structure of algebraic expression', and of 'expanded/factorized expression'.

TREE REPRESENTATION AND STRUCTURAL INTERPRETATION

We now explain our hypothesis concerning how TR can facilitate a structural interpretation of an algebraic expression, and consequently the production of linguistic expressions which make the structure of an algebraic expression emerge. Within the CAS, students can work with both SR or TR and switch between them (Fig. 1). The software automatically gives feedback on the equivalence between the algebraic expressions by means of different signs which appear between two

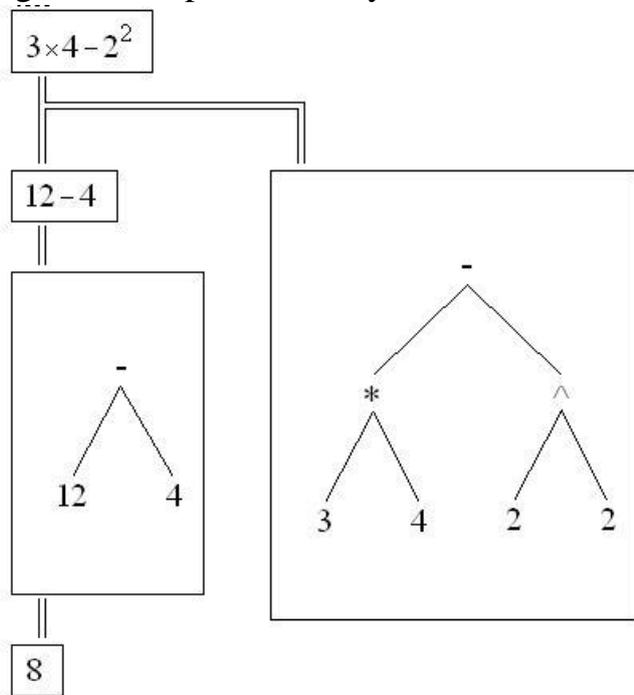

Figure 1. Switching from the standard representation and the tree representation of an algebraic expression in the Aplusix CAS.

consequent boxes enclosing the expressions. Since TR consists of a bi-dimensional structure, it can support a twofold interpretation. Actually, a tree may be interpreted ('read') both from the bottom, that is starting from the leaves, and from the top, that is starting from the root. While proceeding bottom-up implies a procedural view of the represented algebraic expression, a top-down interpretation implies a structural view.

Moreover, when calculating an expression in TR, both a procedural and a structural interpretation emerge at the same time. In fact, according to the functioning of the TR representation environment, calculation can be accomplished only by selecting (sub-) trees and substituting them with the resulting values. Algebraically inconsistent selections are not allowed, generating an error message. Selection and substitution of (sub-)trees may induce the user to conceive the expression made of chunks (i.e. sub-expressions); in other words to conceive it structurally.

THE TEACHING-LEARNING SCENARIO

According to the assumptions described above, and focusing on the development of the discursive artefacts, the design of teaching-learning process is organized, as suggested by the TSM in *didactical cycles* (Bartolini Bussi & Mariotti, 2008, p.754

). Each cycle starts with activities based on the artefact (in our case, NL-artefact, SR-artefact, TR-artefact), then it continues with written reports, and it ends with a classroom discussion guided by the teacher. Discursive templates emerge and develop through semiotic tasks assigned to the students; then, in the collective discussions, the teacher exploits the semiotic potential of specific discursive templates, triggering a semiotic mediation process. In this respect specific discursive expressions become *discursive artefacts* and are used by the teacher as tools of semiotic mediation.

The tasks given in the domain of arithmetic, mainly consisting in conversions between different representations, aim at making the discursive template emerge. Afterwards, in the introduction to algebra, the design of the tasks is based on conversions between SR and NL, and vice versa, with the aim of making the discursive templates re-emerge.

Emergence of discursive template

The phase in arithmetic starts with an activity in paper and pencil. Students are asked to *'write at least two different ways of reading each numerical expression given'*. The objective is to collect students' NL interpretations of numerical expressions. We hypothesize three different ways of reading, which can reveal three different interpretations (Maffei & Mariotti, 2010). The *linear interpretation* consists in translating the inscriptions that the numerical expressions are made of, word by word, from left to right; the *procedural interpretation* consists in translating into words the calculation procedure to be accomplished to compute the value of the numerical expression; the *structural interpretation* consists in translating into words the structure of the numerical expression and recursively of its sub-expressions.

The subsequent activities, to be carried out, both in paper and pencil and in the Aplusix environment, aim at combining the use of both SR and TR in making the structural interpretation emerge. According to our hypothesis, concerning the crucial role played by the functioning of TR in Aplusix in making the structure emerge, the tasks given at the beginning involve the use of TR, and then gradually do not necessarily require its use, although coming back to TR is always possible. In order to move towards algebra, we hypothesize the potentialities of 'empty trees', that is expressions in TR with internal nodes (i.e. operators) and branches, but without leaves (i.e. numbers). The semiotic potential of the empty tree consists in representing the relation between terms of an algebraic expression, i.e. its structure. Empty trees could emerge either in students' solution of tasks, or, in alternative, through the teacher's intervention in a classroom discussion. In any case, empty tree may become a shared sign (Bartolini Bussi & Mariotti, 2008) referring to the structure of an expression.

The main objective of this first phase is to make the different interpretations become 'shared templates' to be used in analysing and confronting different expressions, and

specifically in detecting the structure of expressions given in different representation systems. In other words, the shared templates become ‘discursive artefacts’.

Once students are introduced to algebraic calculation they are newly confronted with conversion tasks from SR to NL (the plan in the algebra context does not include the use of TR). The discursive artefacts originating in arithmetic are exploited by the teacher and the students in order to recognize different algebraic expressions having the same structure.

Mediation of discursive artefacts

The teaching-learning sequence in algebra continues in making the discursive artefacts become tools of semiotic mediation with respect to the meaning of ‘expanded expression’ and ‘factorized expression’. More precisely, an expanded algebraic expression will be defined as an expression that can be interpreted as a sum of monomials, while a factorized algebraic expression as one that can be interpreted as a power/product of polynomials. In terms of templates, the first structure can be associated with the discursive template ‘*the sum of ...*’, the second one with ‘*the product (power) of...*’. The teacher can use these kinds of templates and/or some more elaborated ones (e.g. ‘*the product of the sum between...and the difference between...*’) in order to introduce the meaning of expanding and factorizing.

SOME RESULTS

According to the two phases described above, we are going to present some results. Namely, the analysis of some students’ protocols and excerpts from classroom discussions that we consider significant to show how discursive artefacts emerge and develop, and how they are used by the teacher as tools of semiotic mediation.

The emergence and the development of the discursive artefacts

The teaching sequence in arithmetic ends with a discussion which aims at comparing the solution given to the following task: ‘*Consider the following numerical expressions given in SR, in TR and in NL and group those having the same structure*’.

Let’s now examine an excerpt from the follow-up discussion in which the teacher leads students to make the meaning of structure emerge and develop. The teacher asks students to explain how they solved the task. The first student who intervenes, says that he preferred “*using the trees*”, that is “*converting in TR any expression given either in SR or in NL*”, as the teacher states more precisely. Then Marco takes part in the discussion.

Marco: [...] I considered only expressions given in standard and in tree and I thought how I could put them in natural language. Just some words, not only the whole expression, but just some words were enough to make a comparison with the expressions given in natural language.

Teacher: Can you please explain in a clearer way what you want to say?

Working Group 3

Marco: Let's see. If you have a long expression that you can read starting with 'the product of' it cannot be structurally equal to an expression given as 'the sum of'. Well, to be honest I sometimes used trees to compare expressions, but even in these cases I put them into words.

Marco classifies expressions according to the structural interpretations that he obtains through converting the numerical expressions, which are given in SR/TR, into natural languages. It is evident how Marco uses specific discursive templates as artefacts to analyse and compare different expressions.

After a number of students' interventions addressing the use of different discursive artefacts; finally, the teacher leads the students to sum up the discussion, and at a certain point explicitly asks how they could define the structure of an expression.

Gabriele: For me it is a tree without leaves.

Rita: Yes, it can be considered as an empty tree.

Teacher: So, coming back to the task, how can we determine two or more expressions having the same structure?

Daniele: As I said before, if they have the same tree.

Teacher: What does 'the same tree' mean?

Rita: The trees of the two expressions considered without leaves are identical, that is they have the same empty tree.

At this point, it seems that students refer the structure of a numerical expression to its

representation as an empty tree. It means that they seem to be ready to substitute to leaves any number, that is to be ready to place unknowns in the leaves. In other words, TR has unfolded its semiotic potential in 'converting numerical expressions into potentially literal expressions'.

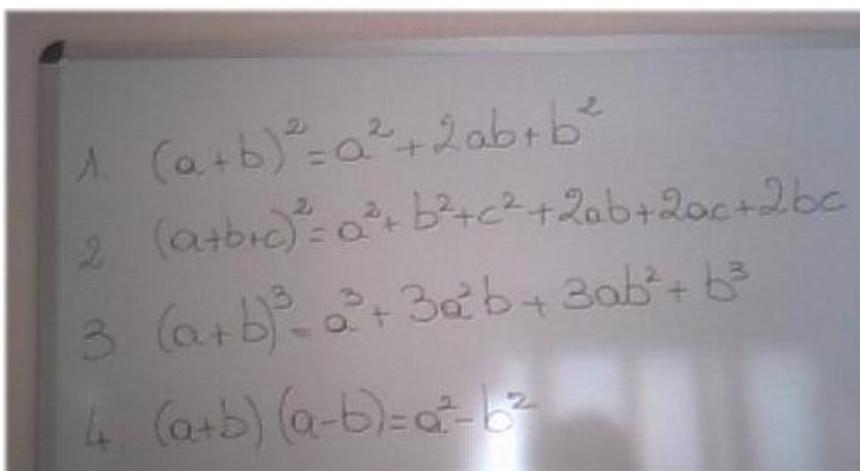

Figure 2. The formulas of the 'main products'.

Later in the teaching sequence, the discursive artefacts originating within the arithmetic domain re-emerge while students are confronted with conversion tasks between different representations in algebra. Students produce new discursive artefacts related to converting into NL expressions which represent specific formulas used to speed up algebraic calculations, i.e. the 'main products' (Fig. 2).

Working Group 3

The task given to students consists in obtaining the expanded part of the formulas in the Aplusix CAS through following instructions: ‘*write an equivalent expression not containing parentheses*’. They are also asked to ‘*write a conversion into NL of all the expressions produced in order to obtain the final expression*’.

Let’s now examine the classroom discussion after the task mentioned above. First of all the teacher writes on the blackboard all the formulas for the main products (Fig. 2) and then starts the discussion asking students to read the conversions into NL of each algebraic expression written. Most of the NL-expressions offered by students are based on structural interpretations. For instance, most of the students interpret the fourth expression (Fig. 2) as follows: “*the product between the sum of a and b and the difference of a and b is equivalent to the difference between the square of a and the square of b*”.

The discursive artefacts originated in arithmetic, now re-emerge in the algebra domain. More precisely, it seems that they mainly consist in structural discursive templates, i.e. those originated by the use of TR.

The discursive artefacts become semiotic mediators

At this point when students are able to manipulate algebraic expressions, that is to produce chains of algebraic expressions (even very long chains) using both operations’ properties and formulas of the main products, the teacher introduces the notions of ‘expanded expression’ and ‘factorized expression’. She decides to do that by exploiting the discursive artefacts that are already available in the class. She starts by commenting on the chain that one student has produced in Aplusix, showing it to the classroom.

Teacher: In this chain of equivalence Matteo produced, we have two expressions without parentheses. Notice that the last expression is shorter than the second because Matteo summed together two similar monomials. Well, from now on, we are going to call ‘expanded expression’ this type of expressions without parentheses and which are expressed as ‘the sum of’ and do not contain monomials which are similar. But, we have to define another type of expression. So, how could we read the expanded expression?

Matteo: The difference between.

Teacher: The difference between x raised to the fourth and one. Well, let’s go on. How can you read the first expressions?

Chorus: The product of.

Teacher: It’s ok, the product of. Other suggestions?

$$\begin{array}{c} \boxed{(x^2-1)(x^2+1)} \\ \parallel \square \\ \boxed{x^4-x^2+x^2-1} \square \\ \parallel \\ \boxed{x^4-1} \end{array}$$

Figure 3. Chain of equivalent expressions in the Aplusix CAS.

Working Group 3

Alessandra: The second is a sum of monomials, and the third is easy to read, it is the difference of two squares. [...]

Teacher: Now, suppose I want to produce new expressions which are equivalent to those already written, and these expressions should have parentheses. Does anyone have an idea? I'll put some labels on the expressions in the chain. (She puts A, B, C, see Fig. 4).

Marco: I think one can start from the first expression, namely from the second parenthesis.

Teacher: Please Marco, come here and write on the screen what you are saying.

(Marco goes and writes the expressions in a new box deriving it from the first box, the teacher names D the new expression, see Fig. 4). [...]

Teacher: Have we finished the process or can we go on?

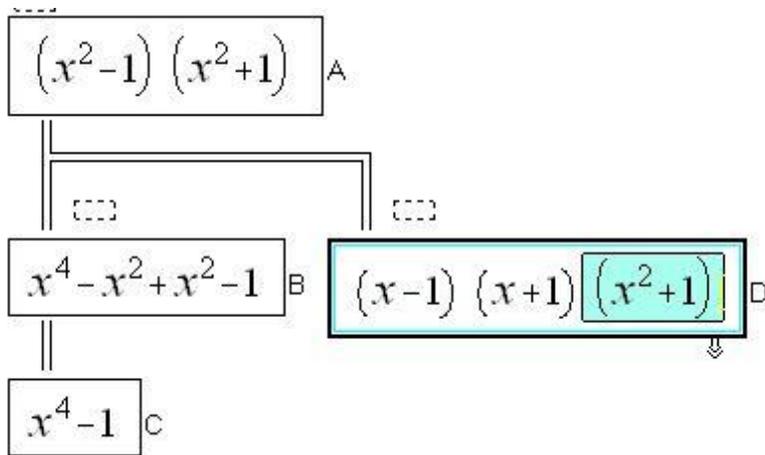

Figure 4. Chain of equivalence expressions in the Aplusix CAS where a sub-expression is

Marco: The first two parentheses have polynomials of degree one, the third has one polynomial of degree two (the teacher highlights it, see Fig. 4), but we have finished since we cannot write this as a product of two parentheses of degree one.

Teacher: Ok, then we will better clarify what 'going on' and 'stopping' mean, do you have any other cases in which you can go on?

Valentina: When for instance you have the sum of a squared, two times a and b, and b squared. In this case I can write the square of the sum of a and b and then nothing else, I would stop.

Then, all the main products are converted into NL; therefore each SR-formula has its counterpart in a NL-formula.

Teacher: To conclude, in the future I can ask you to produce an expression having the form of a sum of non-similar monomials, or to produce an expression having the product-power form. So, now I will give you time to work on these types of tasks.

The teacher, on the basis of the discursive artefacts students have used repeatedly, creates new discursive artefacts. Specifically, she coins the 'product-power' expression and uses it as a tool of semiotic mediation to make the meaning of factorizing emerge. The 'product-power' expression emerges during the discussion

Working Group 3

following the factorization task when students produced NL expressions starting with ‘the product of’, ‘the power of’. The following excerpt shows how the teacher introduces the definition of ‘factorized form’ of an expression using the product-power as a discursive artefact.

Teacher: So let’s go back to the chain we analysed last time. We said that expression B has the form of a sum of different monomials, and B and D have the form of product-power. So I can definitely call expanded form the first form. Now, remember the difference between B and D: in expression B I can go on putting it into a product-power form, while in D I have completed the process. Well, I will call expression D ‘factorized form’, while expression B does not have a name, we can continue to refer to it as a product-power form.

After that, the subsequent task given to students consists in observing a chain of equivalent expressions in Aplusix and in deciding which ones are in expanded form, which ones are in product-power form, and which ones are in factorized form, classifying the different forms of the expressions appearing on the screen. Students are also asked to explain how they solve the task’. Massimiliano gives the following comment on the solution he offers. *“As far the expanded form is concerned, I chose L because it is the form which is made of a sum of monomials which are different and for that reason I did not choose D. As far as the product-power forms are concerned I chose A, B, H because if we try to see them as trees then the formula ‘the product between...’ appears. As factorized forms I chose F and G because they could not be simplified anymore.”*

Massimiliano justifies his choices (which are correct) in terms of discursive artefacts (the ‘product between ...’ for the factorized expression). The explicit reference to TR is significant because it shows the relationship the discursive artefact maintains with its origin: the tree representation.

CONCLUSION

Our research highlights how the role of natural language goes beyond the necessity for teacher and students to communicate in both verbal and written situations. In fact, the natural language, on the one hand, is used to focus on the specific features of both the standard representation and the tree representation, and, on the other hand, it becomes itself a representation system for algebraic expressions, in which the emergence of specific templates may be exploited to express and compare different algebraic structures. We stress how the semiotic potential of the different artefacts in use does not emerge spontaneously, rather it needs a specific didactic organization. It’s only through both the design of specific tasks and the teacher’s action in managing classroom discussions that the different discourse artefacts become tools of semiotic mediation to make the structural interpretation of algebraic expressions emerge.

NOTES

ALGEBRAIC THINKING OF GRADE 8 STUDENTS IN SOLVING WORD PROBLEMS WITH A SPREADSHEET

Sandra Nobre, Escola E.B. 2, 3 Professor Paula Nogueira

Nélia Amado & Susana Carreira, FCT, University of Algarve & UIDEF

João Pedro da Ponte, Institute of Education, University of Lisbon

This paper describes and discusses the activity of grade 8 students on two word problems, using a spreadsheet. We look at particular uses of the spreadsheet, namely at the students' representations, as ways of eliciting forms of algebraic thinking involved in solving the problems, which entailed dealing with inequalities. We aim to see how the spreadsheet allows the solution of formally impracticable problems at students' level of algebra knowledge, by making them treatable through the computational logic that is intrinsic to the operating modes of the spreadsheet. The protocols of the problem solving sessions provided ways to describe and interpret the relationships that students established between the variables in the problems and their representations in the spreadsheet.

Keywords: algebraic thinking, inequalities, spreadsheet, representations.

INTRODUCTION

Representations have a dual role in learning and in mathematical communication. These resources serve the purpose of communicating with others about a problem or an idea but also constitute tools that help to achieve an understanding of a property, a concept or a problem (Dufour-Janvier, Bednarz & Belanger, 1987). This is one of the reasons why we consider students' use of representations as a lens from which we can grasp the meaning involved in the mathematical processes of solving a problem.

Spreadsheets have great potential for the construction of algebraic concepts, including the establishment of functional relationships, the representation of sequences or the use of recursive procedures in solving mathematical problems. The use of spreadsheets in problem solving has been deeply investigated by several authors (e.g., Ainley et al., 2004; Rojano, 2002) and revealed interesting processes in the development of algebraic thinking, particularly with regard to the transition from arithmetic to algebra. Within a spreadsheet environment, the symbolic representation of the relations present in a problem is initiated through the nomination of columns and writing of formulas. This is considered a stimulating environment that fosters an understanding of the relations of dependence between variables and encourages students to submit solutions gradually more algebraic and moving away from arithmetical methods (Rojano, 2002). These aspects encouraged us to carry out an analysis of how grade 8 students create their representations, how they conceive and display the problem conditions on the spreadsheet and how they achieve a solution.

PROBLEM SOLVING AND THE LEARNING OF ALGEBRA

Contextual problem solving is an important type of task leading to algebraic activity.

According to Kieran (2004) the work in algebra can be divided into three areas: generational, transformational and global/meta-level activities. Generational activities correspond to the construction and interpretation of algebraic objects. Transformational activities include simplifying algebraic expressions, solving equations and inequalities and manipulating expressions. Finally, global/meta-level activities involve problem solving and mathematical modelling, including pattern generalization and analysis of variation.

The nature of algebraic reasoning depends on the age and mathematical experience of the students. Students at a more advanced level may naturally use symbolic expressions and equations instead of numbers and operations. But for students who have not yet learned the algebraic notation, the more general ways of thinking about numbers, operations and notations, may be effectively considered algebraic (Kieran, 2007). Contexts that involve numbers, functional relationships, regularities, and other properties, are an essential foundation for the understanding of algebraic structures. For instance, writing symbolic numerical relations may favour the use of letters. However, the use of technological tools allows other representations for such relations, as well as new forms of exploration, which may be seen as analogous to generational and transformational activities in algebra. Thus, it seems appropriate that such new representations, and the mathematical thinking associated with them, are included in the field of algebra (Kieran, 1996). Moreover, Lins & Kaput (2004) claim that algebra can be treated from the arithmetic field, since there are many properties, structures and relationships that are common to these two areas. Therefore, arithmetic and algebra may be developed as an integrated field of knowledge. In this study we adopt this perspective, considering algebraic thinking as a broad way of thinking that is not limited to the formal procedures of algebra. This entails separating algebraic thinking from algebraic symbolism (Zazkis & Liljedhal, 2002).

SPREADSHEETS IN THE DEVELOPMENT OF ALGEBRAIC THINKING

A spreadsheet supports the connection between different registers (numerical, relational, and graphical). One feature that stands out in this tool is the possibility of dragging the handle of a cell containing a formula along a column. This action generates a “variable-column”. Using this tool in problem solving emphasizes the need to identify the relevant variables and encourages the search for relations of dependence between variables. The definition of intermediate relations between variables, that is, the breakdown of complex dependency relations in successive simpler relations is a process afforded by this tool, with decisive consequences in the process of problem solving (Carreira, 1992; Haspekian, 2005). As noted by Haspekian (2005) a spreadsheet also allows an algebraic organization of apparently

Working Group 3

arithmetical solutions and this kind of hybridism, where arithmetic and algebra naturally cohabit, becomes an educational option that may help students in moving from arithmetic to algebra (Kieran, 1996).

We want to see how this particular functioning of the spreadsheet is a valid route for solving problems where the formal algebraic approach is too heavy for the students' level. More specifically, we aim to understand how far the spreadsheet, while being a means to promote algebraic thinking, can relieve the burden of formal algebraic procedures and as such can advance the possibility of solving certain types of problems. So far, research has shown the value of the spreadsheet in the transition from arithmetic thinking to algebraic thinking, but less is known about the utility of the spreadsheet to set up an alternative to formal and symbolic algebra and yet allowing the development of students' algebraic thinking in problems that are formally expressed by inequalities (Carreira, 1992; Haspekian, 2005; Rojano, 2002)

METHODOLOGY

This study follows a qualitative and interpretative methodology. The participants are three grade 8 students (13-14 years). They had some previous opportunities to solve word problems with a spreadsheet in the classroom, from which they acquired some basics of the spreadsheet operation. Before the two tasks here presented, students had worked with the spreadsheet in solving other problems for six lessons. All problems involved relationships among variables (usually equations) and only one included a simple linear inequality. The detailed recording of student's processes was achieved with the use of *Camtasia Studio*. This software allows the simultaneous collecting of the dialogue of the students and the sequence of the computer screens that show all the actions that were performed on the computer. We were able to analyze the students' conversations while we observed their operations on a spreadsheet. This type of computer protocol is very powerful as it allows the description of the actions in real time on the computer (Weigand & Weller, 2001).

The two problems

King Edgar of Zirtuania decided to divide their treasure of a thousand gold bars by his four sons. The royal verdict is:

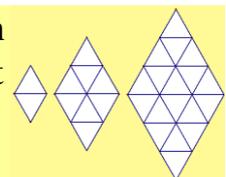

- 1- The 1st son gets twice the bars of the 2nd son.
- 2 - The 3rd son gets more bars than the first two together.
- 3 - The 4th son will receive less than the 2nd son.

What is the highest number of gold bars that the 4th son of the king may receive?

Figure 1: The treasure of King Edgar

From small equilateral triangles, rhombuses are formed as shown in the picture. We have 1000 triangles and we wish to make the biggest possible rhombus.

How many triangles will be used?

Figure 2: Rhombuses with triangles

Working Group 3

A possible algebraic approach to the problems is presented in table 1. Solving these problems by a formal algebraic approach, namely using in equalities and systems such as these was beyond the reach of these students. Therefore, it is important to see which roads are opened by using the spreadsheet.

The treasure of King Edgar	Rhombuses with triangles
$\begin{cases} s_1 + s_2 + s_3 + s_4 = 1000 \\ s_1 = 2s_2 \\ s_3 > s_1 + s_2 \\ s_4 < s_2 \end{cases}$ <p style="text-align: right; margin-right: 20px;">max s_4</p> <p>s_i – number of bars of $i = 1 \dots 4$ child</p>	$2n^2 \leq 1000$ <p>max n n – figure number</p>

Table 1: Algebraic approach to the problems

Problem 1 contains several conditions that relate to each other and the statements “gets more” and “receives less” involve an element of ambiguity and make the problem complex, for understanding it, for translating into algebraic language and for solving it. Problem 2 entails a pictorial sequence that can be translated algebraically into a single condition. However, this condition involves a quadratic function that does not arise immediately after reading the statement of the problem. These two problems represent instances of global/meta-level activities considered by Kieran (2004), insofar as they involve functional reasoning and pattern finding strategies. They both have in common the search for a maximum value, leading to some difficulties when a purely algebraic approach is envisioned. However, a spreadsheet provides alternative approaches to both problems that may make them clearer to students, facilitating their solution process and efficiently providing a solution. We examine how students approached these problems in the classroom, the strategies they used, how they connected the variables involved and expressed that on a spreadsheet. Excerpts of Excel computer protocols are offered to further clarify the description of students’ activity.

In solving problem 1, Marcelo assigned and named a column to each of the four sons and a fifth column for the total of gold bars (table 2). Then, he started writing values in the cells corresponding to the sons in the following order: 2nd, 1st, 4th and 3rd, as follows: choosing a value for the 2nd son, then mentally doubling it for the 1st son; subtracting one unit to the 2nd son’s number of bars to get the 4th son’s; add the three values of the 2nd, 1st, and 4th sons and calculate the difference to 1000 to find the 3rd son’s number. In another column, the student entered a formula that gives the total of gold bars and served as control for the total number of bars (1000).

Table 2: Print screen of Marcelo’s representation

Although Marcelo did not display the relations between the number of bars of the four brothers -using formulas or otherwise-he kept them always present in his thinking. The task required a greater effort for the student, since in each attempt he had to recall the relations, while carrying out the calculations mentally.

Marcelo: Teacher, I found the best! [The value 139 was obtained in cell G6]. If I choose 150 [for the 2nd son]it won’t do. I’ve tried it.

Teacher: But this is not the maximum number of bars for the 4th son, is it?

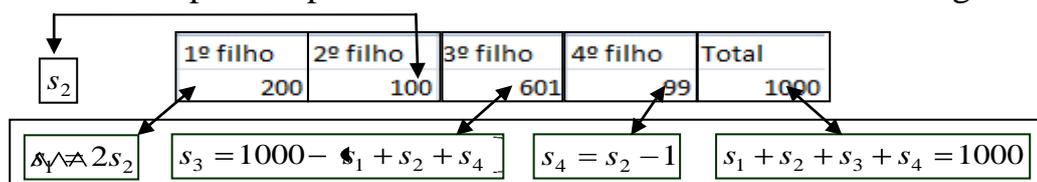

Marcelo: I went from 100 to 150, and it turns out that 150 gets worse because the other gets over 450 and the last one falls to 99.

The teacher asked Marcelo to do more experiments to which he replied that he had already made some, for example 160 and 170. So she made another suggestion:

Teacher: Here you already got an excellent value and it increased significantly from 130 to 140 [referring to column E]. So, try around these values.

The student continued to experiment, always doing the calculations mentally. He found 141, confirming that it was the best. As an answer the student wrote:“I solved this problem taking into account the conditions of the problem, making four columns, one for each child, and trying to find a higher number”.

In our view, Marcelo has developed algebraic thinking by focusing on dependence relationships between different variables to finding the optimal solution. As he stated, he took into account the five conditions of the problem and expressed them in the spreadsheet columns. From the standpoint of an algebraic approach, the student began by choosing an independent variable (the 2ndson’s number of bars) and established relationships to express the number of bars for each remaining son.

Working Group 3

The diagram above summarizes the translation of the student's algebraic thinking in solving the problem and shows how Excel allowed dealing with simultaneous manipulation of several conditions, by means of numbers, rather than with letters and symbolic algebra. It is important to note that the condition set for the 4th son demonstrates an understanding of looking for the highest possible value, given that the difference down to the 2nd was only one bar.

Maria and Jessica (Table 3) started to solve the problem like Marcelo, with the allocation of columns to the number of gold bars for each son and another column for the total of bars. Then, they created a column of integers for the number of bars of the 2nd son; the number of bars of the 1st son was obtained by doubling the 2nd son's; the number of bars of the 3rd son was found by adding a unit to the sum of the 1st and 2nd sons' bars; the number of bars of the 4th son was obtained by subtracting one unit to 2nd son's; finally, the last column computed the sum of bars of the four sons.

<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th>2filho</th> <th>1 filho</th> <th>3 filho</th> <th>4 filho</th> <th>total de baras</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>2</td> <td>4</td> <td>0</td> <td>7</td> </tr> <tr> <td>2</td> <td>4</td> <td>7</td> <td>1</td> <td>14</td> </tr> </tbody> </table> <table border="1" style="width: 100%; border-collapse: collapse;"> <tbody> <tr> <td>141</td> <td>282</td> <td>424</td> <td>140</td> <td>987</td> </tr> <tr> <td>142</td> <td>284</td> <td>427</td> <td>141</td> <td>994</td> </tr> <tr style="background-color: #c8e6c9;"> <td>143</td> <td>286</td> <td>430</td> <td>142</td> <td>1001</td> </tr> <tr> <td>144</td> <td>288</td> <td>433</td> <td>143</td> <td>1008</td> </tr> </tbody> </table>	2filho	1 filho	3 filho	4 filho	total de baras	1	2	4	0	7	2	4	7	1	14	141	282	424	140	987	142	284	427	141	994	143	286	430	142	1001	144	288	433	143	1008	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th>2filho</th> <th>1 filho</th> <th>3 filho</th> <th>4 filho</th> <th>total de baras</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>2</td> <td>4</td> <td>0</td> <td>=D2+E2+F2+G2</td> </tr> <tr> <td>2</td> <td>4</td> <td>7</td> <td>1</td> <td>=D3+E3+F3+G3</td> </tr> <tr> <td>3</td> <td>6</td> <td>10</td> <td>2</td> <td>=D4+E4+F4+G4</td> </tr> <tr> <td>4</td> <td>8</td> <td>13</td> <td>3</td> <td>=D5+E5+F5+G5</td> </tr> <tr> <td>5</td> <td>10</td> <td>16</td> <td>4</td> <td>=D6+E6+F6+G6</td> </tr> <tr> <td>6</td> <td>12</td> <td>19</td> <td>5</td> <td>=D7+E7+F7+G7</td> </tr> </tbody> </table>	2filho	1 filho	3 filho	4 filho	total de baras	1	2	4	0	=D2+E2+F2+G2	2	4	7	1	=D3+E3+F3+G3	3	6	10	2	=D4+E4+F4+G4	4	8	13	3	=D5+E5+F5+G5	5	10	16	4	=D6+E6+F6+G6	6	12	19	5	=D7+E7+F7+G7

Table 3: Print screen of Maria e Jessica's representation

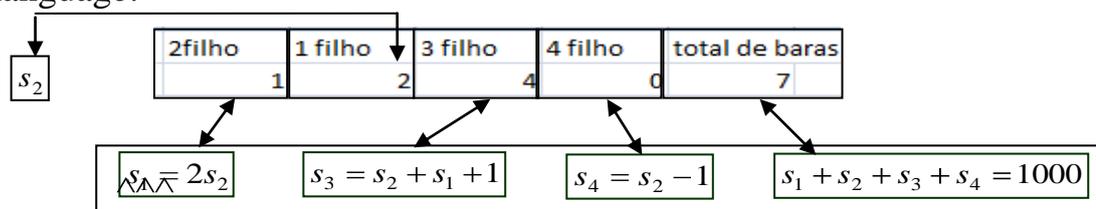

At one point the students got a value higher than 1000 in the last column and concluded that it was necessary to remove a bar from one of the sons. Yet, it was necessary to realize that one bar could only be taken from the 4th in accordance with the terms of the problem.

Maria: It shows 1001, it is wrong!

Teacher: And now?

Maria: Take one out! Take one out from the 4th!... The largest number of bars that the 4th can receive is 141.

The diagram below shows the relations as they would be expressed symbolically in algebraic language:

These students formulated two conditions intended to obtain the optimal solution: first, the difference between the number of bars of the 4th and the 2nd son must be one

Working Group 3

unit and, second, the difference between the number of bars of the 3rd and the sum of the 1st and 2nd must also be one unit.

In both solutions, the data show that students use relationships between variables but they do it with numbers through the use of the spreadsheet. The fact that they are working with numbers does not deviate them from the mathematical structure of the problem. On the contrary, it helps them to better understand the problem and to deal with a set of simultaneous conditions of different nature: equations, inequalities and a free variable. We believe that the thinking involved in either approach is consistent with the perspective of Kieran (2007) and Lins & Kaput (2004) on genuine algebraic thinking development.

For the second problem, Marcelo (Table 4) started to introduce the inputs 2, 8, 18. Then, he selected these three cells as a cluster and tried to drag them (Figure 3), noticing that the numbers generated were not all integers.

	
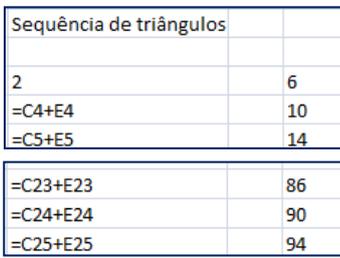

xls file	xls file (command “show formulas”)

Table 4: Print screen of Marcelo’s representation

He eventually abandoned the dragging and called the teacher:

Marcelo: I don’t know if this works... How do I do this? Is there an easier way?

Teacher: To move from the 1st to the 2nd how much did you add?

The student writes in cell E4 the number 6.

Teacher: And from the 2nd to the 3rd how much do you add?

The student wrote in cell E5 the number 10, followed by 14 and 18.

Teacher: What are you going to do now?

Marcelo: If I pull it down [referring to column E] and then by adding this column plus this one [referring to column C and column E]...

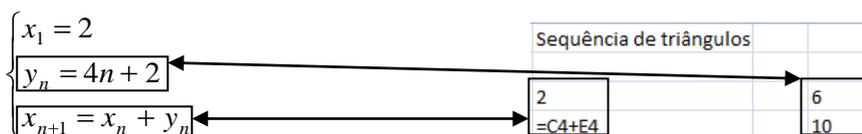

The student inserted the formula “=C4+E4” (below the first term of the sequence) and generated a variable-column:

Marcelo: 968! It’s what we will use from 1000. We have 1000, so it can’t be more than 1000 and 1058 already exceeds.

Working Group 3

The student tried to find a pattern in the number of triangles. The construction of additional figures did not help the student to find a pattern based on the figure. One useful approach was to look at the differences between the consecutive terms.

From an algebraic point of view, this student is using a recursive method to generate the sequence of triangles with the help of the arithmetic progression which gives the difference between consecutive terms. Excel easily allows handling a recursive approach. Somehow it was no longer necessary to find n^{th} element to solve the inequality, although the mathematical structure of the problem remained visible.

Maria and Jessica (table 5) addressed the problem with a similar strategy, noticing that dragging the values 2, 8 and 18 did not produce the sequence of rhombi presented in the problem. At one point they called the teacher:

<table border="1"> <thead> <tr> <th>n° de figuras</th> <th>n° de triangulos</th> <th>(+)4</th> </tr> </thead> <tbody> <tr><td>1</td><td>2</td><td>6</td></tr> <tr><td>2</td><td>8</td><td>10</td></tr> <tr><td>3</td><td>18</td><td>14</td></tr> <tr><td>4</td><td>32</td><td>18</td></tr> <tr><td>5</td><td>50</td><td>22</td></tr> <tr><td>6</td><td>72</td><td>26</td></tr> <tr><td>7</td><td>98</td><td>30</td></tr> <tr><td>8</td><td>128</td><td>34</td></tr> <tr><td>21</td><td>882</td><td>86</td></tr> <tr><td>22</td><td>968</td><td>90</td></tr> <tr><td>23</td><td>1058</td><td>94</td></tr> </tbody> </table> <p style="text-align: center;"><i>xls file</i></p>	n° de figuras	n° de triangulos	(+)4	1	2	6	2	8	10	3	18	14	4	32	18	5	50	22	6	72	26	7	98	30	8	128	34	21	882	86	22	968	90	23	1058	94	<table border="1"> <thead> <tr> <th>n° de figuras</th> <th>n° de triangulos</th> <th>(+)4</th> </tr> </thead> <tbody> <tr><td>1</td><td>2</td><td>6</td></tr> <tr><td>2</td><td>8</td><td>10</td></tr> <tr><td>3</td><td>18</td><td>14</td></tr> <tr><td>4</td><td>32</td><td>18</td></tr> <tr><td>5</td><td>50</td><td>22</td></tr> <tr><td>6</td><td>72</td><td>26</td></tr> <tr><td>7</td><td>=G7+F7</td><td>30</td></tr> <tr><td>8</td><td>=G8+F8</td><td>34</td></tr> <tr><td>21</td><td>=G21+F21</td><td>86</td></tr> <tr><td>22</td><td>=G22+F22</td><td>90</td></tr> <tr><td>23</td><td>=G23+F23</td><td>94</td></tr> </tbody> </table> <p style="text-align: center;"><i>xls file (command "show formulas")</i></p>	n° de figuras	n° de triangulos	(+)4	1	2	6	2	8	10	3	18	14	4	32	18	5	50	22	6	72	26	7	=G7+F7	30	8	=G8+F8	34	21	=G21+F21	86	22	=G22+F22	90	23	=G23+F23	94

Table 5: Print screen of Maria and Jessica's representation

Jessica: From this one to this one it goes 6 and from this one to this one it goes 10.

Maria: From 2 to 8 it goes 6...From 8 to 18it goes 10.

Jessica: Oh teacher, we don't know how to continue.

Teacher: Have you already drawn the next figure to see if there is any relation?

They drew it on paper, but only half of the picture.

Maria: 14, 15 and 16. Then 16 plus16 is...32

Teacher: And now?... How many will the next one have?

Maria: 50.

The students were still looking for a relation between the numbers.

Maria: I know what that is... Look... The link is...

Working Group 3

Jessica: The number plus 4.

This was the decisive moment to build the column with the differences between consecutive rhombuses, and then a formula for the number of triangles.

CONCLUDING REMARKS

Our main aim was to understand the role of the spreadsheet in solving two word problems, which are expressed by inequalities, and examine how the solutions reflect students' algebraic thinking, regardless of the use of algebraic symbolism. It was not our intention to consider what students have done without the use of technology, since any of the problems demanded an algebraic knowledge that was beyond the level of students. In any case pencil and paper solutions could certainly come up with methods based on trial and error. We interpreted the students' processes based on the spreadsheet in light of what would be a possible use of symbolic algebra. Thus we intended to make clear students' algebraic thinking in establishing the relationships involved in the problems. In the first problem, four columns corresponded to the four sons and the column for the 2nd son was reserved for the introduction of initial values (the *input*), serving as a column for the independent variable. The remaining columns were constructed through relations of dependence. For the second problem, the students were not able to express the general term of the sequence, but by counting the number of triangles in the sequence of rhombuses they used the differences between consecutive terms to generate the former sequence recursively. As reported in some studies students when confronted with more demanding sequences tend to use the difference method (Orton & Orton, 1999). We found that the spreadsheet helped the students to establish relations between variables, expressed through numerical sequences generated by the computer, and also with the use of formulas to produce variable-columns. We claim that algebraic thinking was fostered by the affordances of the Excel in generating the rules of the problems. This result resonates with other investigations such as Ainley et al. (2004) but it also highlights the structure of students' algebraic thinking expressed in a particular representation system. It provided a clear indicator of how students interpreted the problems in light of their mathematical knowledge and their knowledge of the tool. The analysis allows us to make inferences about what is gained in using Excel to solve algebraic problems, and helps to understand the relationship between the symbolic language of Excel and the algebraic language. The use of Excel can be seen as means to fill the gap between the algebraic thinking and the ability to use algebraic notation to express such thinking. The lack of algebraic notation and formal algebra methods does not prove the absence of algebraic thinking. The kind of algebraic thinking that emerges from the use of the spreadsheet is the kind that belongs to global algebraic activities (Kieran, 2004). We highlight the following features of the spreadsheet in algebraic problem solving: (i) *It was a way to anticipate complex algebraic problems*; our study shows how the spreadsheet was a tool that allowed 8th grade students to solve two problems that were impracticable from the point view of formal

Working Group 3

algebra. On the other hand it anticipated forms of algebraic reasoning involved in the problems that were elicited by the representation systems embedded in the spreadsheet; (ii) *It helped to understand the conditions in the problems*; students clearly understood the relations between the several variables involved and were able to express such conditions and restrictions appropriately. These were not expressed in algebraic notation but instead with the language of Excel (iii) *It led to a numerical approach of an algebraic problem*; students found ways to represent the problem through numerical variable-columns without losing the structure of the problems. Our perspective of algebraic thinking stresses the distinction between algebraic notation and algebraic structures, separated by a gap that is often underestimated. We suggest that this gap can be gainfully filled with suitable spreadsheet activities.

Rather than insisting on any particular symbolic notation, this gap should be accepted and used as a venue for students to practice their algebraic thinking. They should have the opportunity to engage in situations that promote such thinking without the constraints of formal symbolism (Zazkis&Liljedhal,2002, p. 400).

ALGEBRAIC REASONINGS AMONG PRIMARY SCHOOL 4TH GRADE PUPILS

Marta Pytlak

University of Rzeszow

The term “early algebraic thinking” concerns many phenomena connected with the introduction to the generalization process on a lower educational level. Algebraic thinking does not necessarily consist of formal algebraic symbolism. Young students who did not learn formal algebra in school are capable of formalizing a verbal rule in which spontaneous algebraic thinking is evident. In my work, I wish to present the way in which primary school 4th grade pupils deal with a series of arithmetical-geometrical tasks that lead to generalization of relations that exist there.

THEORETICAL FRAMEWORK

In the Polish mathematical curriculum, we can distinguish two branches: arithmetic and algebra. Algebra, as a branch of science, first appears in the 6th grade of primary school. So far, in school practice, there has been a conviction that actions on algebraic objects such as variables, unknowns, parameters are the central feature of algebraic thinking (Polish curriculum: www.reformaprogramowa.men.gov.pl). Initially, school algebra is focused on the introduction and use of letters. A letter is treated as some kind of a code that abbreviates the recording of a verbal or visual situation such as coding the number of carriages in a drawn two-colored train. At gymnasium level pupils are very frequently asked to use recordings of algebraic notions, regardless of previously formed intuitions.

I am of the view, that the essence of algebraic thinking is not merely the use of algebraic symbolism. Using a letter has been neither a necessary nor a sufficient condition for algebraic thinking. It is Radford’s opinion that “there is a conceptual sphere, where pupils can start their algebraic thinking even if they do not refer (or at least in a big extend) to symbolic language” (Radford, 2009, p.XXXV). Nevertheless, a letter is a generally accepted tool for expressing generality, on a certain stage of its understanding. In algebra, thinking is focused on relations because objects themselves can be indefinite (Radford 2005, 2009). Using algebraic symbolism for writing solutions is an external picture of “algebraic thinking”.

If a student is to use algebraic language (symbolic language) he or she has to understand its basic component – a letter. Letters in algebra are used in at least 4 types of meanings: as *general names*, *changeable values*, as *unknowns*, and as *constants* (Turnau, 1990). Each of these meanings appears in different forms that depend on the context. Moreover, the meaning of a letter in an algebraic record can change during the process of solving a task. This poses an additional difficulty in mastering and applying algebraic language.

Working Group 3

Another conviction is that before starting algebra, students need to be competent in the sphere of arithmetic (Hejny and Littler, 2003). Then, algebra appears as a ‘superstructure’ of arithmetic, that is, - arithmetical thinking is a basis for algebraic thinking.

My understanding is different. Arithmetic is, first of all, a science about numbers, in particular natural and integral numbers. Arithmetic in this sense is focused on the object - a number. Thus, arithmetical thinking concerns mainly numbers and using them – it is strictly connected with specific mathematics actions that lead to an unequivocal result. Algebra, in my understanding, is mainly a science about relations. However, there is an approach which combines arithmetical and algebraic thinking. Pupils get a series of tasks in which they have to discover and notice certain regularities. Then, they have to formulate noticed rules and finally write them down using symbolic language. It is done by generalizing arithmetical reflections through modifying constants (which can, according to Turnau, lead to understanding a letter as a *general name*). Then, students move to actions and reasoning typical for algebra. Initially, these are ‘early-algebraic’ thoughts connected with so called ‘early algebra’, which is gaining more and more attention in literature (Mutschler, 2005).

Developing mathematical thinking is inextricably linked with the process of generalization. It is clearly stated in the TGM (Theory of Generic Model) theory (Hejny 2002, 2004, 2005). According to this theory, cognition happens on two levels: generalization (understood locally, connected with a certain type of situation) and abstraction. These levels have a common part – a generic model. For the first part it can be treated as an ending stage and for the second as a start.

The process of building new knowledge starts from gathering experiences which are kept in mind as isolated models of certain situations. If this set of experiences is large enough, connections among similar isolated models will appear. This net will become more and more dense and certain general objects that represent a broader group (of concepts, reasoning) will appear.

The moment when one general model, representing features of all models (a general model of a certain situation) replaces a couple of isolated models, students begin to build mathematical abstract knowledge. Therefore if he/she is not able to create a general model for a certain situation, he/she will not be able to develop abstract knowledge.

THE AIM OF THE RESEARCH

The research shown here is the part of wider research concerning the development of students’ algebraic thinking. The focus is on building their personal web of cognitive connections during solving the task connected with discovering mathematical regularity. My research question were as follows:

Working Group 3

- In what way do 9-10 years old students „think” about regularities and what are their thinking processes while solving tasks in which they have to discover and use noticed rules?
- Do the proposed series of task help to shift attention from arithmetical relations to thinking about general relations?

METHODOLOGY

The research was carried out in November 2009 among students from the fourth grade of a primary school. Twenty 9-10 years old students working in pairs took part. The research contained four follow-up meetings, during which pairs of students solved tasks. The researcher talked with every group of students while they were solving the tasks. All meetings were video-recorded. After the research, the report was presented.

The students had work-sheets, matches (black sticks), ball-point and a calculator. Before they started their work, they had been informed that they could solve this task in any way they would recognize as suitable; their work would not be graded; the teacher would be videotaping their work and that they could write everything which they thought was recognize as important on the work sheet. The research material consisted of work sheets filled by students, as well as the film recording their work and a protocols record from it.

The research tool consisted of four sheets and each of them consisted of two tasks. The tasks were as following: the students make a match pattern consisting of geometrical figures – one with time there are triangles and another with time there are squares with a side length of one match. In the first two sheets the figures were arranged separately, in the second two, they were connected in one row. The following sheets concerned: (1) separated triangles, (2) separated squares, (3) connected squares and (4) connected triangles. In each of the sheets the problem was presented in a frame of two following tasks. They were constructed in such a way in order to inspire students to search for and discover occurring rules.

<p style="text-align: center;">Sheet I</p> <p>1. How many matches do you need to construct 1, 2, 3, 4, 5, 6, 7 separated triangles, which length of each sides equals one match?</p> <p style="margin-left: 20px;">Number of triangles of 1 2 3 4 5 6 7</p> <p style="margin-left: 20px;">Number of matches of</p> <p>2. And how many matches do you need to construct :</p> <p style="margin-left: 20px;">a) 10 triangles</p> <p style="margin-left: 20px;">b) 25 triangles</p> <p style="margin-left: 20px;">c) 161 triangles?</p>	<p style="text-align: center;">Sheet IV</p> <p>1. How many matches do you need to construct 1, 2, 3, 4, 5, 6, 7 connected in one row triangles, which length of each sides equals one match?</p> <p style="margin-left: 20px;">Number of triangles of 1 2 3 4 5 6 7</p> <p style="margin-left: 20px;">Number of matches of</p> <p>2. And how many matches do you need to construct :</p> <p style="margin-left: 20px;">a) 10 triangles</p> <p style="margin-left: 20px;">b) 25 triangles</p> <p style="margin-left: 20px;">c) 161 triangles?</p>
--	--

Figure 1. Research tool – sheet I and sheet IV

Working Group 3

In the first task the students had to give the number of matches needed to arrange from one to seven triangles or squares consecutively. The question was, - ‘How many matches do you need to construct 1, 2, 3, 4, 5, 6, 7 of such figures?’ The results were to be written in the table. In the task 2, there was a question about a number of matches that would be needed to construct 10, 25 and 161 of such figures (Littler, Benson 2005). In order to answer these questions correctly, the students had to discover the rule occurring in the first task.

The focus of this task was to perceive the relevant general rule. According to mathematical (algebraic) language the rules were as follows: $3n$, $4n$, $3n+1$, $2n+1$. The two last rules were equivalent to following statements: $4(n-1)+3$, $2(n-1)+3$. Perceiving these rules was connected with the ability to generalize regularities appearing in the initial series (that is an arithmetic sequence; i.e. for the third sheet it was 4, 7, 10, 13...) and with ability to draw the conclusion from previous experience.

The choice of the tasks and the order of the sheets were not random, they were clearly inspired by TGM theory of M. Hejny (Hejny 2005). The problem was to check if the students would benefit from their earlier experience while solving the new tasks. This task and the way of its presentation (four following sessions with two-three days break between meeting) were something new for students. So far, during maths lessons they had not solved the tasks concerned with the perception of the appeared rules and generalization of noticed regularities.

DEPICTED RESEARCH RESULTS

In my paper I would like to take a closer look at the work of one of my student. It is representative of wider group. Similar reasonings were found in other students. The boy, initially, worked together with his friend but his last two sheets were solved individually. In my analysis, I will focus on the third and the fourth work-sheets.

Sheet III - Kacper

After getting the sheet, Kacper noticed that it concerned squares again. Although he arranged a couple of elements correctly, at the beginning he used the strategy of the previous sheet. Fortunately, he quickly corrected his mistake and used the rule ‘add 3 to the previous number’ for the chart. Physical manipulations (arranging figures from matches) were the basis for generalizations.

- 12 Kacper: Y... ten squares it will be ... 4 [*he is writing 4*] and three times nine [*he is writing under 4: 3x9*] twenty seven ... thirty one
- 13 Teacher: How did you count it?
- 14 Kacper: Well because the first square has four [*he is showing on the first square and moving away others sticks*] and then we always attached in this way [*he is adding three sticks to the first square*] and ten times like this. [*he is talking and in this same time he is counting and writing*] (...)

Working Group 3

15 Kacper: Twenty five ... four [*he is writing 4*] three times twenty four ... [*he is writing 3×24 and he is counting*] seventy six ... and one hundred sixty one ... four plus ... one hundred sixty times three ... four hundred eighty four.

Calculations in the column for task 2 from the sheet no.3 Application of the first rule by Kacper.

16 Teacher: Ok., and if it will be one thousand squares to arranging?

17 Kacper: [*he is writing 4*] four plus nine hundred ninety nine times three [*he is writing algorithm of multiplication 999×3 , counting and to the result he adding 4*]. Three thousand one.

Kacper, on the basis of the arranged pattern, worked out a rule which he had applied to calculating the number of matches in task 2. For this, he used an interesting record: he did not write down his calculations in a line but in a column. Above each column there was a number 4 which was added to the result at the end. In some cases this addition took place in the pupil's mind, without any record of that.

27 Teacher: Good. So if I gave you a certain number of squares, what advice would I get from you? How do I count the necessary matches?

28 Kacper: First, from this number I subtract one and this is one so it is four. So I'm left with this number and we multiply it by three.

When asked how to calculate the number of matches if I know the number of squares, the boy gave a general rule that shows the process of calculating the required number. The pupil could also write down the given rule in words.

Summary of work on the worksheet III

Kacper started to work on the task from gathering physical experiences connected with arranging the current pattern. Immediately after getting the task, he noticed a similarity with the previous one, from worksheet II – the same basic figure. After analyzing the content, he noticed the difference in the layout of figures – this is why he arranged three elements before recording the data in the chart. Maybe the first association with the worksheet II was so strong that, regardless of correctly arranged figures, Kacper transferred the previous rule concerning separate squares onto the current situation. He quickly noticed his mistake and, after that, he counted correctly in the following part of the task.

Kacper did not need to arrange figures to solve previous tasks (in the first and the second worksheet) This time, the boy arranged three elements. It means that in this case, arrangement of figures was treated as a means of discovering a rule. While arranging, the boy was focused on finding relations. The knowledge he possesses is efficient to the extent that arranging even a small part of the pattern enabled him to

Working Group 3

create a general model for the chart. The manipulation he made facilitates a geometrical goal – discovering new phenomena.

From his puzzle, Kacper isolates the first element – a complete square and the others – incomplete ones. This observation helps him to generate a new way of calculating the number of matches for a specific number of squares. It is strictly connected with the way of arranging. The record of it shows the boy's thinking structure: $4+(n-1) \times 3$.

Justification that the pupil gives when asked by the teacher about the way of counting the number of matches in task 2 (14) shows that he drew conclusions after arranging only 3 elements. He is also aware of the fact that these conclusions will be valid later on. Therefore, he has developed a general model for the situation concerning the whole task, and this model works within the limits of a big quantifier.

Kacper generalizes the noticed relation, and the generalization he makes has the power of a big quantifier. When describing his rule, he interchangeably operates with sizes 'one square' 'four matches' and while giving numbers from 1 to 4 he does not add determiners such as 'a square, a match'. Also in his record, he limits his description only to the 'instruction of dealing with numbers' in which 1 is equivalent to 4. For him, such a rule is very clear and legible and he does not feel the need to specify it. He deals well with operating with two arbitrary quantities (the number of matches and the number of squares). Intuitively, he uses proportions. A written record that the pupil makes is meaningful in relation to his own actions. It is not objective, it is strictly connected with a description of the situation that the boy found himself in. The record that appeared on a piece of paper is actually not the record of a general rule but only the description of that situation (Radford 2009). It shows that Kacper has a considerable level of algebraic thinking. Since, in this case, his thinking concerns a specific. Local situation, it is not at a general level.

Sheet IV – Kacper

After reading the task content, Kacper arranged one triangle and, initially, applied the worksheet I strategy again (rule "multiply number of triangles by 3"). When the teacher focused his attention on the way the triangles are arranged (this time they are joined together), the boy arranged the following triangles and then, filled in the chart correctly (using the rule "add 2 to the previous number of matches").

- 13 Kacper: [He quietly reads task 2 content, starts his calculations] eighteen...
twenty-one
- 14 Teacher: How did you count it?
- 15 Kacper: So I left three of them, because I need three for the first one, and then
two times nine

In the task 2, he applied a rule which was analogous to the previous task (as in worksheet III), but which took into account the current situation.

He proceeded with this type of work throughout the whole of task two while giving answers to additional teacher's questions. When the teacher started asking questions

Working Group 3

about the number of matches for 1000, 10000 and one million squares, Kacper surprisingly changed his strategy, which is clearly visible in the following part of their conversation. The change of strategy resulted in discovering a new rule in the task.

- 27 Teacher: Mhm, twenty thousand and one. And what if I wanted to arrange one million?
- 28 Kacper: [*immediately, without any consideration*] two million and one
- 29 Teacher: How did you count it so fast?
- 30 Kacper: Well, cause when I did that [*points at his record*] the ending was one...so it's the same here...because it seems...
- 31 Teacher: How did it happen?
- 32 Kacper: Because these...I subtracted one from this and multiplied by two, but if I add such one but times two, because there is one more match added, because it is like a million of squares but one more match
- 33 Teacher: A million of triangles, now we have triangles.
- 34 Kacper: Yes,... [*he sighs, takes sticks and starts arranging a triangle*] So, like you see here, I arrange further [*'further' hand movement*] and then like this first one, it has three and it looks as if two and one more.
- 35 Teacher: I see, so when I told you: one million; you multiplied this million by two, right? Is there any other way of counting it?
- 36 Kacper: Right.

When justifying the correctness of the newly discovered rule, first, the pupil refers to the results of the previous calculations. He shows that all previous results ended in 1. Then, he tries to describe the procedure, in which he highlights the meaning of 'a single match' (32). Seeing that this explanation is not sufficient for the experiment, he refers to the arranged pattern. He unfolds the first element (a complete triangle) into two parts: 1(a "closing" stick) 2 ("incomplete" triangle) The multitude of explanations indicates that the reconstruction of the previous knowledge took place in the child's mind. He associated numeral results with previous triangle arrangement strategies, which led him to a new puzzle interpretation. He is aware that this way is the correct one, so, in order to check the effectiveness of the new rule, he chooses the number of triangles from the task 2b).

- 41 Teacher: So, let us check if it works for the previous ones [*points at the chart and task 2*] Would it fit here?
- 42 Kacper: Yes [*he chooses 25 triangles and counts aloud*] twenty five times two, this is fifty plus one...fifty-one

Kacper, without any difficulty, could say it for any number of triangles. When asked about the rule, he gave the newly discovered rule: multiply the number of triangles by 2 and add 1.

Commentary – description of Kacper’s work on worksheet IV

As the boy was beginning the task, he had knowledge and experience from the work of three previous worksheets. He did not analyze the content of the first task in detail. Seeing the word ‘triangle’, he arranged one figure, and then he started to fill in the chart using the rule which was present in the first worksheet. The information about the kind of figure that he has now was more important for him than the one about the correct position of it. Only the teacher’s remark and the arrangement of three initial elements of the current puzzle helped him to focus on the pattern structure. For the chart, Kacper uses the rule ‘plus 2’ which presents his way of arranging the following elements. The boy, while already while filling in the chart, created a general model for the situation described in the task. Even while writing down the number of matches for 4 triangles he was aware of the generality.

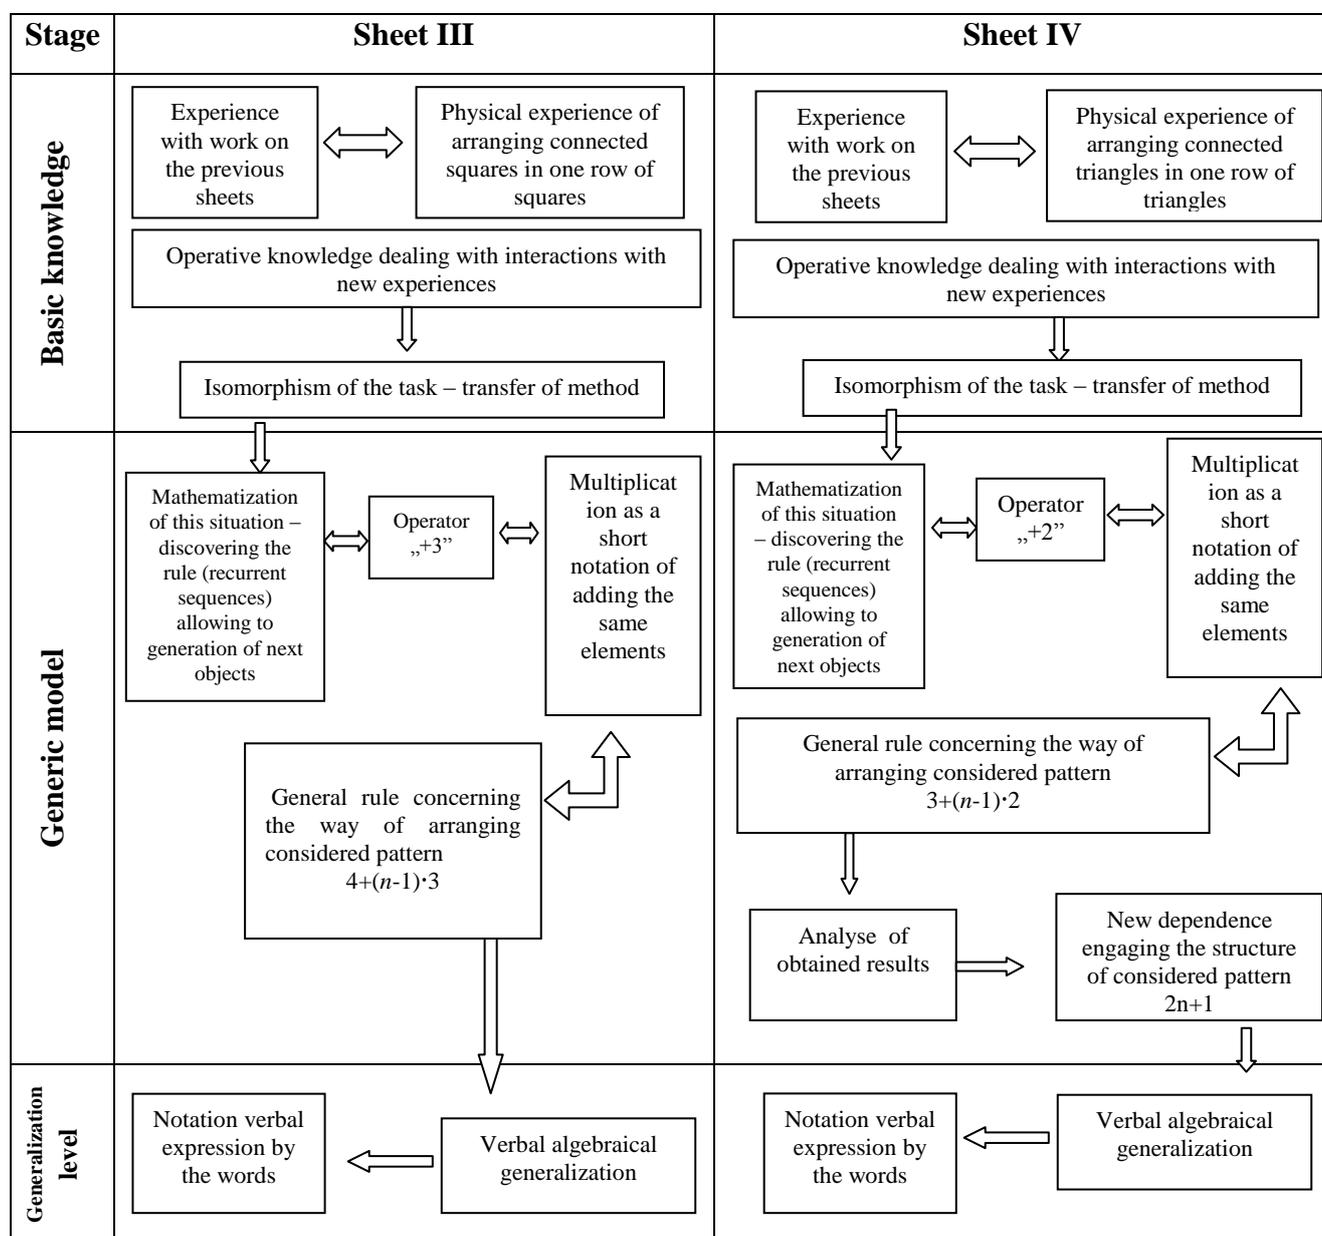

Figure 2.

Working Group 3

While justifying the way of calculating the number of matches, he stresses the fact that the operation of adding 2 will be continued until the end (5). Therefore, we assume that he possesses a certain level of generality of the situation. The fact that he stresses it himself, proves that this knowledge is important for him. Experiences from the work on the task from worksheet III are the basis of it. Isomorphism of the task and the way of work resulted in creating a general model for the task (specifically for the chart), even though the boy arranged only 4 triangles.

As the boy moves to task 2, he uses an analogous method to the one used in the previous worksheet. He unfolds the puzzles into two elements: one complete triangle and the rest of incomplete ones, consisting of two matches (16) This is a clear reference to the worked out method. Because of the task's isomorphism, there is a shift from the worksheet III to the worksheet IV.

For Kacper, the whole task is one, coherent entirety. He does not treat particular stages (chart, task 2, additional teacher's questions) as separate elements. He immediately analyses the results. Because of this stance, he could see a new relation that appeared between the number of triangles and matches. This relation was discovered on a purely arithmetical basis (analysis of results for 1000, 10000 and one million triangles), and after he justified it geometrically. The boy could link this arithmetical relation to the puzzle. He noticed, that instead of building one, complete triangle (isolating the whole element) and then adding two matches at a time, he could start from building incomplete triangles and, in the end, 'close' the entirety with one single match.

When asked about one million triangles, the boy, first, looked at the previous results. The previous examples were quite suggestive: 10 triangles -21 matches, 1000 triangles – 2001 matches, 10000 triangles – 20001 matches. The pupil, noticing the analogy between the following examples, was able to see regularity, a certain arithmetical relation. This relation helped him to get the result much more quickly than the previously used rule. It was because of this that he decided to apply this new relation. This discovery was very important for him and, therefore, he used this newly discovered principle as a general rule for the whole task.

This discovery would not be possible without the boy's willingness to look for new solutions. During research, it was clearly seen that the boy uses his previous experiences, while solving new tasks and considering the follow-up examples. He was not only motivated to getting the result but he constantly analyzed his data. His reflective stance was a crucial element for enhancing the process of discovering regularities.

Creating new relations, joining an arithmetical structure with a geometrical representation was possible because of the fact that Kacper possesses general, geometrical knowledge (in the sense of a big quantifier, objects as classes of abstraction). This knowledge is operational and it is not rigid.

Working Group 3

The pupil is absolutely aware of the fact that this new rule is correct. The examination of the rule for the previously obtained quantities is made only for external recipients (41). The chosen numbers 25 which are to be checked are also not accidental. It proves that only task 2 can be treated as the essence of the matter. The chart is only an introduction for him.

SUMMARY

The pupil solved the task from all worksheets correctly. He could notice different rules that appeared in particular worksheets. Moreover, he could generalize them. Generalized rules were written down by him in words. There was no symbolic record of it because it is quite difficult for a primary school pupil. It is possible that while solving follow-up tasks from the presented series the pupil would try to present long descriptions in an abbreviated form. This would consequently lead to application of symbolism – initially, his own symbolism, and then, generally established algebraic one. We may successfully introduce the world of algebra to pupils, even at the initial stage of their education. However, it is very important how we do it.

INTRODUCTION TO THE PAPERS OF WG 4: GEOMETRY TEACHING AND LEARNING

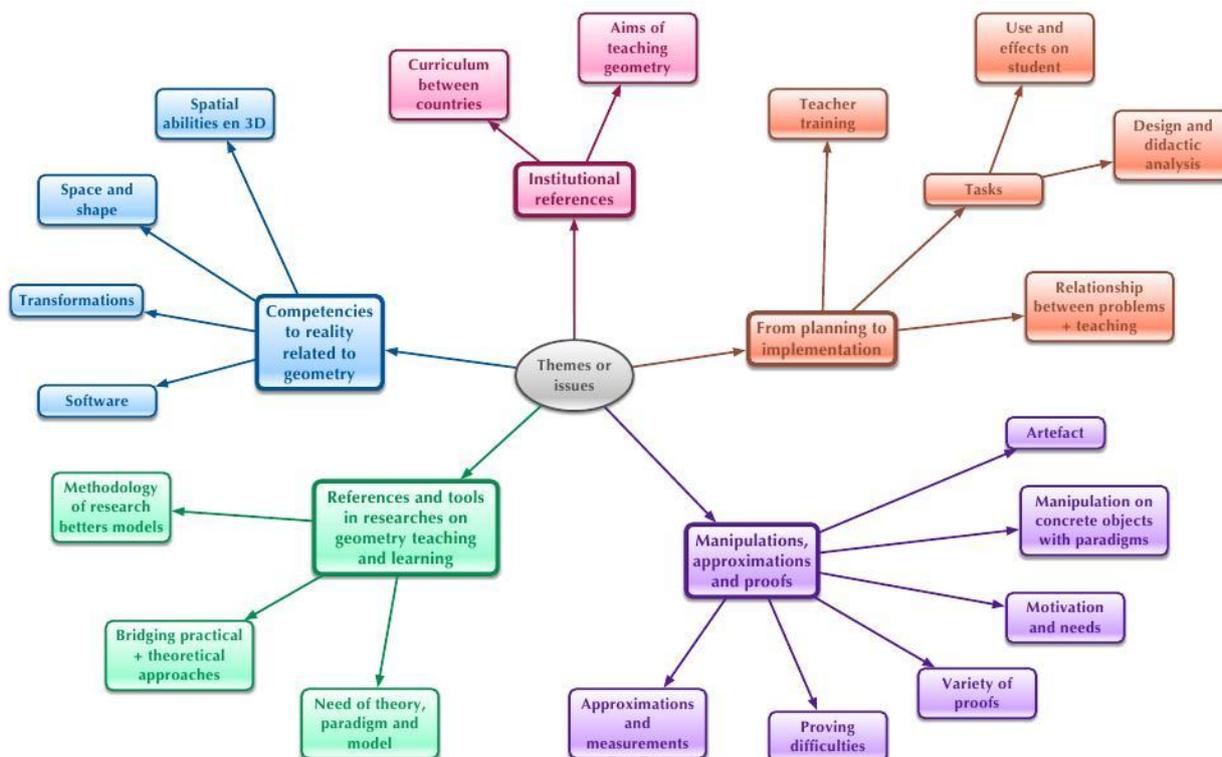

Kuzniak Alain (France),

Philippe Richard (Quebec), Athanasios Gagatsis (Cyprus), Sava Grozdev (Bulgaria)

Precious help: Kate Mackrell & Carlo Marchini

The Working Group 4 on Geometry had more than 25 participants from 12 countries all over Europe and from Quebec. During the sessions, the participants discussed 17 papers prepared for the Working Group and selected among 22 initial proposals and 15 have been retained for publication. In the continuity of the former Cerme sessions, some points can be considered as a common background and readers and future participants are invited to have a look on the former reports to know more about these points.

Some points have been developed during former sessions favoring a common approach and discussions on the following specific topics : Educational goals and curriculum in geometry, use of geometrical figures and diagrams, understanding and use of concepts and proof in geometry. More than presenting in details the work of our group, we will only give some aspects of our final discussion about the main trends involved in didactics of geometry. This can be summarized with the following colored diagram.

REFERENCES AND TOOLS IN RESEARCHES ON GEOMETRY TEACHING AND LEARNING

A characteristic of the group is certainly the attention the participants give to link theoretical and empirical aspects of research in geometry education. As mentioned in Cerme6 report, two approaches of using theory in research can be distinguished: First, theory can serve as a starting point for initiating a research study. For instance, the need to empirically validate or extend specific theories may motivate an investigation. Second, theory can act as a lens to look into the data. For example, different phenomena and behaviors observed in mathematics classes may evoke ideas to the teacher or the researcher for starting research. To start from phenomena or data is a valid first approach to research. In this case, theory may enable the teacher or the researcher to better understand and interpret the collected data.

The theoretical framework is considered important when designing a research experiment. It informs the a priori analysis undertaken before the research is carried out. Undertaking an a priori analysis helps the researchers to set up a didactic situation and to predict the common mistakes and misconception students could make. After the research has been carried out the same theoretical framework is used when carrying out the a posteriori analysis. The a priori and a posteriori analyses are then compared. Did what we thought would happen actually happen?

There were a number of theories which were used by the geometry working group when analysing the teaching and learning of geometry. Different researchers often used the same theoretical frameworks in different ways. For a cognitive and semiotic approach, the Van Hiele levels, Fischbein's notion of the figural concept and Duval's registers were used. For an epistemological and didactical approach, researchers used the geometrical paradigms and geometrical work spaces described by Kuzniak and Houdement.

It was noted that researchers from different countries tend to use different approaches to research and also that teaching practices differ between countries. This can be advantageous when sharing experiences but sometimes leads to misunderstandings between researchers.

MANIPULATION, APPROXIMATION AND PROOF

The reasoning is expressed by manipulating objects (material or informatics objects) or by means of the language tools (natural language, mathematical signs, figural register), and it can be performed as well during approaches of discovery (inductive reasoning, experimental proof) as of validation (deductive reasoning, mathematical proof). The mutual relations between proof and approximation were highlighted in the solving of real-life problems, from the process of modelling towards the interpretation of a geometrical solution in terms of the original problem, including identifying the limitations of the solution. Approximation raises the question of the perceptual information's limits, the reliability of the figural register and the use of

Working group 4

discrete models to represent continuous phenomena during some instrumented approaches with dynamic geometry software. In addition to the discretization processes, the idea of approximation appears as a fundamental tool in the conceptual construction of the geometrical objects that use measurements and the variation over time, the notion of order of magnitude, the approximate, involutorial or recursive shape in the modelling to interpretation cycle, and the dynamic equilibrium between “local” and “global” representation of the objects – for example, to perceive the infinity of the straight line with a segment, to visualise a movement with static figures, to see a 3D figure on a plane representation, etc.

Mathematical proof may be a way of facing approximations by sharing new rules for validation that are not based essentially of the material contingency or the discretization processes, so that one can leave the sensitive experience and control the results in the geometrical model.

The link between proof and manipulation appeared especially in the teaching situation and the use of the didactic materials. It is the nature and the quality of these materials that were generally approached, in particular:

- The comprehension of the space of the possibilities with the a priori or the experimented use of the material, and its feedbacks when it is interactive;
- The physical consistency of the manipulative objects, the logical coherence of the properties of these objects and the geometrical models that articulate them, of which objects defined using a dynamic geometry environment;
- The semiotic and instrumented domains of validity in the use of the manipulated objects and its relations to the geometrical models.

If the influence of the material in the proving tasks depends strongly of the teaching situation and the didactic contract, it is because the interaction of the pupil with the material is in the heart of the formation of the geometrical concepts and processes.

Finally, it seems obvious that the concepts of approximation and manipulation are intrinsically dependent of each other insofar as the approximation is used to model discrete properties on manipulation, as with measurements, and the manipulation gives meaning in the interpretation of approximation on concrete objects.

To examine manipulation, approximation and proof in the teaching of geometry led us to focus on the three interrelated aspects: using representation, the role of these representations, and the functions of proof. These three components have a strong impact on conceptualization in geometry, and on proving activity. We shall conclude that studying these three aspects closely would contribute our better understanding of complex nature of mechanisms of the learning and teaching of geometry.

COMPETENCIES TO REALITY RELATED TO GEOMETRY

Under this title, we underline some aspects of the ‘geometrical eye’ which allows to identify geometry in reality and had always justified the learning of geometry. The word ‘reality’ can be discussed, and we must extend it by including the virtual reality offered by computers.

Some papers focus on geometric transformations and its relationships to movement. For more than two thousand years movement disappeared from geometry and was hidden in the concept of geometric transformation which assumed the role of movement in the exploration of a timeless space. In 1872 Felix Klein’s research was focused on the invariance by transformation and properties of geometric transformations as organizing principle of all kind of geometries. As a consequence, the concept of space depends on possible transformations. If these concepts of invariance and transformation are relevant from cultural point of view, they are also a structuring elements of geometrical knowledge at school. Various studies show that isometries are suitable also for young pupils as an appropriate way for introducing geometrical thinking. Non-isometric transformations are important too and can help students and teachers to ground their own intuition on change and movement.

The use of software in geometry (DGS) makes possible continuous and visible transformations of a drawing. However this kind of change is often not a geometrical transformation in the meaning of Klein. Nevertheless some studies show its importance for the exploration of the geometrical domain and for the learning of proof and the impact on the geometrical work space especially with impact on visualisation and use of appropriate language and representations.

INNOVATIVE EARLY TEACHING OF ISOMETRIES¹

Carlo Marchini & Paola Vighi

Mathematics Department – University of Parma - ITALY

By a teaching experiment, we introduced isometries and their practice in an experimental sample of 3rd graders (8 years old), assuming that learning and training of isometries might affect the standard geometrical understanding in primary school. Comparison with a control sample of the same grade supports our hypothesis.

Keywords: Teaching experiment, Plane isometries, Primary School.

THE ITALIAN PRIMARY SCHOOL SCENARIO ABOUT ISOMETRIES

In only one learning target of the Italian primary school new ‘curriculum’, isometries are quoted: «To recognize rotated, translated, reflected figures.» (MPI, 2007). This topic must be treated in Grade 4 and/or 5, only by observation and recognition. The official document does not pay attention to the different difficulties of diverse kinds of plane isometries (Xistouri & Pitta-Pantazi, 2011). Practice with these concepts has not been suitably developed. The official curriculum fosters a nominalistic approach to geometry, by introducing it in grade 3 (more often in grade 4 and 5) as «To recognize, to denominate and to describe geometrical shapes» and also «To measure segments by the means of both metre or arbitrary units; to connect the measure practice to the knowledge regarding numbers and operations».

THEORETICAL FRAMEWORK

Felix Klein in 1872 reorganized geometry suggesting that the ‘content’ of its foundation is the concept of a group of transformations, therefore the learning of geometrical transformation is, at least, a cultural target. Nevertheless these subjects run into difficulties in Italian schools. Indeed, the topic is assumed to be unrelated to ‘true’ geometry (Iadrosa & Malara, 1998); it is perceived as a ‘different kind’ of geometry for which the teacher has neither traditions nor standards for its teaching and assessment, hence it is relegated to an occasional and phenomenological practice.

Research literature suggests classroom activities using isometries for middle school (e.g. Gorini (2007) and Bulf (2010)) or exploring using available software. Research about the aims, introduction, and use of isometries in primary school received little attention. Contributions of Swoboda (2005, 2006, 2007), Jagoda (2009) and Marchini & Vighi (2007, 2009) show the early presence of intuitions about isometries, from kindergarten. Marchini *et al.* (2008, 2009) analysed the presence of intuitions about isometries and continuity. We assume that standard teaching does not pay attention to the children’s attitudes, preferring geometry made by computation and formulas.

Working group 4

Our teaching experiment in grade 3 proposes an innovation for improving geometry learning, starting from Swoboda's outcomes. We hypothesize that by enhancing the learning of isometries the standard geometry learning will improve.

From a cognitive point of view, isometries offer a worthwhile training since they require mastery simultaneously of static and dynamic aspects (Jagoda & Swoboda, 2011). Our experiment uses artefacts which are concrete pieces of paper. They encourage a continuous development between different cognitive levels: they 'call on' geometric figures by the means of the drawings on them, taking into account its idiosyncratic features. The same tile can be 'read' differently, depending on a pupil's attention (Marchini *et al.*, 2009). We think, thence, that our approach should develop a kind of 'flexibility', i.e. the use of a variety of strategies and/or the skill of adaptive strategy choice to task specific characteristics, as a resource for mastering everyday life problems.

In the 3rd stage of the experiment we verified, by Escher's drawings, whether the practice with isometries can be extended from simple drawings to complex non-standard ones.

THE EXPERIMENT: Aims and planning

Experiment aims: 1st - Are isometries a suitable topic for grade 3 pupils? 2nd - Do plane isometries learning affect the (above) 'standard' Italian school geometry?

Positive answers to these questions can support our proposal of the innovative introduction (1st aim); isometries could play a relevant role for integrating deeply the traditional teacher's practice in geometry with transformations (2nd aim) as useful tools for improving the learning of 'standard geometry' and geometrical culture.

We planned: an experimental sample (ES) (40 learners), a control sample (CS) (39 pupils), a pre-test (PT) in both samples, a treatment in ES, and the final test (FT) in both samples, one school year later [2]. The time delay between ES treatment and FT was necessary since the 'standard' geometry was introduced in grade 4 in the same way in both samples, and we need it in order to detect a possible influence of isometries on standard problems. Treatment and assessment tests were the researcher's duty; ES teachers recorded the treatment sessions, assured the discipline, and administered tests. We asked ES and CS teachers to continue her/his projected teaching, without reference to the PT. In particular, in the second school year, ES teachers avoided reference to isometries. This 'contract' aimed at the similarity of both samples.

THE EXPERIMENT: Pre-Test

Table 1 is the 'portrait' of ES and CS (Table 1) offered us by the PT administered in (2008/2009) before treatment. It resumes the rate of success, and the related probability of χ^2 -Test for the statistical relevance of the score differences between

Working group 4

samples [4]. Test consists in three sheets, here named *Shepherds*, *Pizza* and *Patterns* [3].

Sample rates	Shepherds					Pizza				Patterns					PT
	Sh ₁	Sh ₂	Sh ₃	Sh ₄	Tot	Pz ₁	Pz ₂	Pz ₃	Tot	Pa ₁	Pa ₂	Pa ₃	Pa ₄	Tot	Tot
ES	45	82	32	24	45	55	29	45	32	76	53	74	24	57	49
CS	12	88	9	24	33	6	0	44	13	79	73	88	48	72	43
χ^2 -Test	0.21	43	1.76	99		0.00	0.07	96		80	8	13	2.91		

Table 1. Results of the PT: rate of exact answers and χ^2 -test probability

Issues employ everyday language, avoid mathematical terms, require only visual estimate regarding perimeters and area and isometries.

Sample	No.	Shepherds			Pizza			Patterns			PT		
		Aver. score	σ	z	Aver. score	σ	z	Aver. score	σ	z	Aver. score	σ	z
ES	38	1.82	1.05	2.49	1.29	1.05	4.01	2.26	1.14	-	5.37	2.61	1.37
CS	33	1.33	0.53		0.48	0.61		2.88	0.88	2.56	4.70	1.40	

Table 2. Results of the PT: statistical test about average scores

Table 2 aggregates results of Shepherds', Pizza and Patterns questions, with the statistic 'z'. Global 'portraits' of the two samples do not show relevant differences ($z = 1.37$). In PT difference in patterns issues is statistically probable favourable to CS children. It can be surprising since the right solutions require a 'sensitivity' to isometries such as intuition of translation for Pa₁ and of rotations for tasks Pa₂ and Pa₄. This 'feeling' could be useful for solving tasks Pz₁ (translation/symmetry), Sh₁ and Sh₃ (rotation), but the results of these issues show a statistically relevant superiority of ES children.

THE EXPERIMENT: Treatment for the experimental sample

The treatment was planned for six sessions of two hours each, one session per week, in three stages, with non-quantitative approach. Its realization lasted 16 hours.

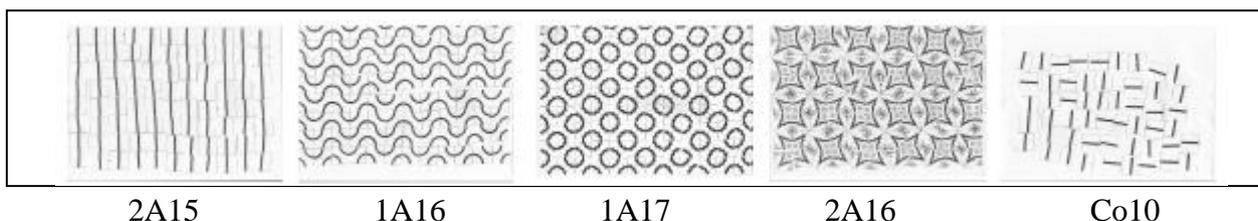

Figure 1. Treatment protocols in the order of their presentation to ES classrooms

The 1st stage (6 hours). In sessions 1 and 2, ES pupils discussed in groups the first four documents of Figure 1, realized by other pupils in another experiment (Marchini & Vighi, 2007) in which it is possible to individuate the use of isometries; for each one they recorded the worth aspects, they assessed protocol, and they presented orally their 'conclusions'. Afterwards, Carlo made an 'institutionalisation' activity, drawing on the black board four squares as in Figure 2, reproducing by a schematic way the four consecutive tiles as they appear in the upper left corner of the document. Carlo asked eventual 'tie-in' between two consecutive tiles, for recognizing rotated, translated, reflected figures (MPI, 2007). For 2A15, in a class the word *trasloco* (move)

Working group 4

came out immediately. For 1A16, in both ES classes, the word *specchio* (mirror) came out without difficulty, looking at horizontal tiles disposition. Hence, during the 1st session the presence of translation (T) and (axial) symmetry (S) in the construction of protocols were detected. Pupils realized that T works in 2A15 both from left to right and from up to down, in 1A16, S acts from left to right and T going down.

During the 2nd session, pupils analysed the 3rd and the 4th protocols. In the ‘institutionalisation’ phase, they found in 1A17 the application of S in the horizontal and in the vertical. Pupils’ analyses of 2A16 agreed that its author made a ‘mistake’. The protocol was chosen on purpose, for making evident the presence of a rule in the construction of the protocol, by the means of its violation. The different appearance of protocols 1A17 and 2A16 could hide the fact that the construction rule is the same. In the ‘institutionalisation’ phase this identity came out. In Vigatto school pupils suggested that the mistake was the fact that a tile was turned. Carlo seized the opportunity to introduce rotation (R - *rotazione*), avoiding the discussion of Co10. During 3rd session, in Vicofertile school, the discussion of Co10 allowed the introduction of rotation.

The 2nd stage (4 hours). It aims at the consideration of isometries as mathematical objects. We prepared a card game: three ‘playing’ cards with the letters T , S and R in a jar, and the game board of Figure 2 as an array of two times two squares (on the blackboard). The four squares determine a cross (it is grey in Figure 2).

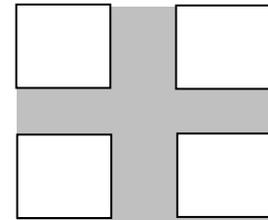

Figure 2. The game board

Now the rule is to draw, with restitution, four times one card at a time and to write the letter of that card in the empty cross arms, in this conventional order: top - left - right - bottom. Finally a tile is placed (or drawn) in the top left board square. Pupils copied the stuff in their exercise-book. We gave a homework task with the sequence of letters R , S , R and T , and a tile of the type used in 2A16. Children proved the task was impossible. To single out simple instances of impossible tasks is an effective way to introduce pupils to control procedures. In the homework discussion, pupils suggested possible different rotations of multiples of ‘one quarter clockwise rotation’. Therefore the cards R_1 , R_2 and R_3 were added in the urn instead of R . The playing with the new card game concluded the 2nd stage. In this way pupils produced protocols on the basis of simple [5] rules (Marchini & Vighi, 2011) showing a good mastery of isometries. The card game with isometries could be used in every school environment to introduce isometries, both as procedure and mathematical objects. In our experiment we avoided ‘structural’ properties of functional composition, but these topics can be useful in other grades.

The 3rd stage (6 hours). Paola recalled plane isometries through Escher’s paintings: Escher’s 28 (shortly E_{28}) for translations; E_{79} for rotations and E_{12} for symmetry. E_{55} presents shapes suitable as a summary of previous plane isometries. The aim was to attach attractive and affective aspects to transformations. For each drawing Paola asked children, in sequence, “What can you see in this drawing?”, then to individuate

with letters or colours many figures obtained from a starting figure by a suitable isometry. In particular, for rotation, she required to individuate ‘rotation centres’. The shape complexity hampered only a few pupils.

THE FINAL TEST: Analysis of FT

We chose, on purpose, a test which is far enough (in time and topics) from the teaching of isometries. The tasks can be considered suitable for children having a standard teaching of geometry; nevertheless the issues require geometrical thinking since straightforward applications of rules for perimeter and area are not enough.

The FT (in Enclosure) was administered in 50 minutes at the end of grade 4 in school year 2009/2010. It was inspired to some PT items. The issues of the test were problematic for children, since they learnt perimeters of rectangles and a few about area. The leading idea was to assign problems about three roughly ‘rectangular’ figures in which we gave the measure of the length for some segments (represented in proportion); for solving them the application of isometries can be useful or necessary. Some data are missing; they can be found by geometrical thinking and arithmetic computation (with an implicit didactic contract suggesting that what looks like a rectangular shape is a rectangle, or congruent-like parts of the same shape, are congruent). In our opinion, the identifying the missing data requires a sort of deduction in a ‘natural axiomatic’.

For perimeter of Shape₁, six data are given and two are missing; for perimeter of Shape₂, eight data are given and four are missing [6]. Therefore the computation of the perimeter involves long addition with decimals. In the first case it is necessary to solve the equation $x+y = 5.0+1.5$; in the second case, the solution is found by the means of the equations $6.5 = 3.0+x+1.5$ and $1.0+2.0+y = 4.5$. The drawings help to avoid algebraic computations since evidence suggests solutions with the help of a deduction in a ‘natural axiomatic’.

For Area₁, it could be useful to add $5.0+1.5$, and then to make 4.5×6.5 . Otherwise the shape can be divided into two rectangles. For Area₂ and Area₃, all the necessary data are given, and searching the missing data can only corroborate the hypotheses of congruence of some pairs of pieces from the same shape. The difficulty of computing Area₃ can be solved correctly in two different ways.

16 The solution can be found only by insight (Divišová & Stehliková, 2010) i.e. by an intuition of congruence, similar to the one required in items of PT, since in Shape₃ there is a semi-circular part for which area 4th graders do not know a formula. This way requires only the computation of 4.5×6.5 . Thence pupil can return back to Area₁ and Area₂, recognizing a local isometry [7] which can be applied to small rectangles.

17 The simplest way of computing areas Area₁ and Area₂ is to think that all the shapes

Working group 4

become equal to a rectangle $4.5 \text{ cm} \times 6.5 \text{ cm}$, by shape suitable decomposition. Congruence of parts of each shape can be proved by appealing to local plane isometries. The direct computation of Area_1 and Area_2 could be considered a sort of ‘distractor’, even if it, with the sameness of results, can give the good hint for Area_3 , by recognizing the role of local isometries for semicircles.

A different analysis of the results is in (Vighi & Marchini, 2011).

THE FINAL TEST: Results of FT

We assessed FT protocols in various ways. The simplest is to assign the score 1 for the correct numerical value and 0 for the wrong or missing numerical value, as a measure of the understanding (Kilpatrick, 2009). Another kind of data is the average number of children which try to solve the problems. We consider an attempt as a positive behaviour towards the topics, so we label it as ‘confidence’. Lastly we look at solving procedures, disregarding possible mistakes, the ‘competence’ (Godino, 2003). We considered a right procedure the product 4.5×6.5 , or for Area_1 and Area_2 , a suitable shape decomposition in rectangles with the corresponding products. As to perimeters we considered a right procedure when all the missing data are found and summed to the given one, or even if one of them was forgotten, for scarce attention, but the finding of the other missing data is a sufficient proof of competence.

Average	Perim ₁	Area ₁	Perim ₂	Area ₂	Area ₃	Perimeters	Areas	Total
ES score	0.18	0.13	0.11	0.24	0.18	0.29	0.55	0.84
CS score	0.27	0.06	0.03	0.09	0.03	0.30	0.18	0.48
Statistical test	$\chi^2=37$	$\chi^2=32$	$\chi^2=22$	$\chi^2=10$	$\chi^2=4.08$	$z = -0.10$	$z = 1.91$	$z = 1.34$
ES confidence	0.82	0.79	0.82	0.76	0.76	1.63	2.32	3.95
CS confidence	0.94	0.67	0.85	0.39	0.36	1.79	1.42	3.21
Statistical test	$\chi^2=12$	$\chi^2=24$	$\chi^2=71$	$\chi^2=0.16$	$\chi^2=0.07$	$z = -1.03$	$z = 3.39$	$z = 2.06$
ES competence	0.32	0.29	0.26	0.39	0.42	0.58	1.11	1.68
CS competence	0.39	0.12	0.24	0.12	0.06	0.65	0.30	0.91
Statistical tests	$\chi^2=49$	$\chi^2=8$	$\chi^2=84$	$\chi^2=0.94$	$\chi^2=0.05$	$z = -0.14$	$z = 3.35$	$z = 2.32$

Table 3: Results of the FT: Average values and statistical tests

The low average score in Table 3 results from many mistakes in computations and/or in procedures. We aggregate the scores for perimeters, areas and global. Without another table of quantitative data, we can conclude by ‘z’ statistic that differences between the scores of the two samples are not statistically significant.

Table 3 shows a big difference between confidence, competence and understanding of the topics, using these names in our meaning. CS children are more confident about perimeter, but the difference is not statistically significant. Moreover ES children show a greater confidence with area than the CS children, and this difference is statistically significant. The χ^2 -test states that this fact is due to the confidence with Area_2 and Area_3 . With data aggregation (perimeter+area), samples difference in confidence is statistically probable only for Shape_2 ; difference in competence for

Area₂ and for Area₃ are statistically significant.

THE FINAL TEST: Analysis and interpretation of the FT results

In school year 2009/2010, in both samples, measure of length, perimeters for triangles and rectangles were taught and area was introduced briefly. The CS teacher also dealt with isometries. This substantial knowledge ‘sameness’ of both samples is confirmed by the global FT results of Table 3 for Shape₁, which is closer to standards.

ES confidence presents similar results for perimeter and area. For CS, instead, the differences about perimeters are statistically significant, both for confidence and competence. Moreover there are statistically probable differences for confidence with Area₁ and Area₂, and for Area₁ and Area₃.

The greater number of missing data could be an obstacle for determining Perim₂: from Table 3 it seems that the reductions in average scores should be provoked by mistakes in the sum because of the number of addends. Only one protocol seems to determine smartly Perim₂ by adding 1 cm (or 0.5 cm twice) to Perim₁.

Few protocols used an explicit procedure. We got 7 protocols (6 of them in ES) in which pupils obtained the same results all for the three problems with area (even if wrong). As regards scores, the number of right computations is lessened: we detect 4 cases, 1 of them in CS. Equality of Area₂ and Area₃ only is affirmed by 3 ES pupils and 1 CS child.

An ‘isometric thinking’ can be present in 10 ES pupils since at least one perimeter is computed wrongly by the sum $4.5 + 6.5 + 4.5 + 6.5$. In fact, 5 of them applied the correct procedure at least once for area (4 of them for both areas). They seem to be aware of isometries, but unaware that local isometry preserves area, but does not preserve perimeters.

In Area₂ and Area₃ are involved local roto-translations; for Area₁, instead, we can consider local translation or local axial symmetry (as stated explicitly by one CS pupil). It could be relevant to the fact that the application of procedure identifying Area₂ and Area₃ is the most frequent (10 ES, 1 CS) and when a pupil individuates the equality of Area₁ (the simplest) and Area₃ (the most difficult), then s/he possibly comes back for obtaining the same result for all the shapes. On the basis of the previous remarks, of Table 3, and by the fact that children can determine Area₃ only by intuition of a local roto-translation, we can state that in CS a method based on local translation / symmetry is applied more than the one requiring roto-translation. The ‘equality’ of average confidence for Areas in ES could be justified with the previous learning of isometries.

We cannot exclude the point that even if the same school topics were presented in both samples, other factors could affect the results.

COMPARISON BETWEEN PT AND FT

Working group 4

We can compare the results of FT and PT taking in account the ‘sameness’ of intuition/knowledge necessary for solving the tasks. The relevant differences, mainly for area questions, between the two samples in FT can follow from an evident initial difference in PT results as regards to problems from which FT issues were inspired. Notice that in the PT we did not ask quantitative results, therefore we think as unsuitable to compare PT with the FT scores. The difficulties of the passage from qualitative to quantitative can justify some results of Table 4.

A qualitative treatment can be assessed with children’s confidence and competence. Thence we compare the PT and FT looking at the average number of children who improved (equalled, made worse) their performance from PT to FT [8]. The last two columns of Table 4 are obtained by aggregation of all FT task results the PT task results.

Average no. children	Perim ₁ & Perim ₂ /Sh ₄		Area ₁ /Pz ₁ & Pa ₁		Area ₂ & Area ₃ /Sh ₁ , Sh ₃ , Pa ₂ & Pa ₄		FT/PT	
	Confid.	Comp.	Confid.	Comp.	Confid.	Comp.	Confid.	Comp.
ES improve	0.66	0.29	0.42	0.11	0.76	0.39	0.82	0.29
ES equal	0.29	0.53	0.45	0.32	0.08	0.21	0	0

Table 4. Comparison of FT and PT: Average number of change in performance

Negative sign in Table 4 is a warning: the ‘intuitive’ test gave a better result than the quantitative task. This fact could be a consequence of little attention to a practice promoting the evolution of child’s idea towards a more complete knowledge.

CONCLUSION AND DISCUSSION

The research has clear aims, but during its implementation we faced other issues:

- *Does practice with non-conventional shapes help pupils in FT tasks? b) Does the treatment improve flexibility in our meaning? c) Does the treatment improve pupils’ performance in FT tasks?*

Research 1st aim had a big number of corroborations, during the treatment (Marchini & Vighi, 2011) and also with the permanence of the taught concepts one year later e.g. by words or drawings mention of isometries in the 50% of ES pupils. Only 5 CS pupils prove their acquaintance with isometries; they testify that the same arguments were introduced in their CS class and, by results comparison, the relevance of treatment in ES. Therefore the 2nd aim of our research has been achieved.

Area problems distinguish the most (Table 3) the confidence difference between samples. The ‘distance’ of our shapes from school practice can be measured by the

Working group 4

average confidence, which values diminish from Shape₁ to Shape₃ for CS. The same values are nearly constant for ES pupils which show familiarity with complex shapes. Perimeter and area of FT shapes cannot be found by application of ‘one’ rule. They could block diligent pupils able to solve standard exercises. The FT tasks require insight (Divišová & Stehliková, 2010) or more flexibility and an inventory of geometrical tools going far beyond of the simple formulas for rectangles. Flexibility also has been helped by practice with isometries and complex and non-regular shapes. It is worth the improvement of competence of ES in comparison with CS for area questions (Table 3). Therefore issues a) and b) have positive answers.

Issue c) has a more complex answer. The samples present many differences which are favourable to ES versus CS, even if, often, without a statistical relevance. Table 3 affirms that ES pupils show a greater confidence with FT questions since there was an improvement of performance from PT to FT (Table 4). In this sense the treatment had a good effect. We can assume ES children were in better position for connecting new and treatment knowledge (Mayer, 2002). But the competence performances (Table 4) do not support this statement, even if diminution is favourable to ES. Therefore we could conclude that there is a wide field of research to be investigated assessing our issue c).

NOTES

1. Work done in the sphere of Italian National Research Project Prin 2008PBBWNT at the Local Research Unit into Mathematics Education, Mathematics Department, Parma University, Italy.

2. We thank teachers Ferrarini (Vigatto - PR), Tomasini (Vicofertile - PR) for their participation to ES. and Mancastroppa (‘Corazza’ of Parma) for CS. From PT to post-test (here named *final test*, for a distinct acronym, FT) the samples changed for the absence of some pupils. Our samples for the statistics are reduced to the ES 38 pupils and the CS 33 children which took part to all PT and FT activities

3. The PT presented three sheets (30 minutes each) which were administered in different days. The issues are freely inspired from literature: Shepherds from Marchetti *et al.* (2006), Pizza from Vighi (2010) and Pattern from I.Q. folklore. Notice that Vigatto schoolboys treated the original Vighi (2009) issues in the school year 2007/2008 (when they are 2nd graders). We assume that difference of questions and elapsed time made this previous experience irrelevant.

4. In the tables we single out with boldface font the relevance of a statistical test.

Datum is	In χ^2 -test probability	In statistic z
Statistically significant	$p \leq 1\%$	$z < -2.58$ or $2.58 < z$
Statistically probable	$1\% < p \leq 5\%$	$z < -1.96$ or $1.96 < z$

5. I.e. the rule which is explicated for the first four tiles is extended to the whole protocol (cf. Marchini & Vighi, 2011).

6. With $Perim_n$ ($Area_n$) we refer to the task of computing perimeter (area) of Shape_n.

7. With ‘local isometry’ we want to consider a bijection such as some part of the figure remains fixed and some other parts of the same figure are isometric. Thence a ‘local isometry’ could be globally an example of a non-isometric transformation. The Enclosure examples can explain this concept.

8. The comparison of FT with PT is realized as follow. For each pupil the change of performance in confidence (in competence) is given by the sign of difference between the sum of results of FT task, and the corresponding PT issues, both normalized at 1, dividing by the number of tasks.

STATIC AND DYNAMIC APPROACH TO FORMING THE CONCEPT OF ROTATION

Edyta Jagoda¹, Ewa Swoboda²

¹Charter School No.1 Rzeszów, ²University of Rzeszów, Poland

Our research was based on arranging many different didactical situations that could be the source of intuitions for different geometrical transformations. In this case study, we deal with the concept of rotation. On the basis of different experiences, we were looking for the answer to a research question: how should we create a coherent picture of a geometrical transformation that enables us to understand the concept both statically and dynamically. The analysis of students' behavior displayed a number of common properties related both to static and dynamic understanding of the concept. Our work also reveals that intuitions can contain elements which are inconsistent with the definition of rotation

Key-words: isometries, geometrical intuitions, rotation.

INTRODUCTION

According to Piaget, in the case of logical – mathematical concepts, we encounter the interplay of operations, separated not from the perceived objects, but from the actions taken on them (Piaget & Inhelder, 1999). In Piaget's view, the transformation of reality is of fundamental significance and action is the tool for that transformation. In accordance with this idea, perception (vision) influences the formation of logical – mathematical thinking to a small degree; including geometrical thinking. To support such a standpoint, Aebli quotes Piaget's views:

Investigating what activity is itself, we repeatedly verified its great importance contrary to the importance of an image. Geometrical view is, indeed, an active one as it mostly consists of potential actions, shortened schemata of effective actions or anticipatory schemata of future actions: in case of the lack of effective action, the view is inadequate (Aebli, 1982).

Uncritical implementation of Piaget's views in the field of geometry methodics raises many objections worldwide (Clements, Battista, 1992; Clements et al., 1999, van Hiele, 1986). It is generally believed that the development of geometrical concepts is different from that of arithmetical ones (Gray, Pinto, Pitta & Tall, 1999; Hejný, 1995, Vopěnka, 1989). The process of forming geometrical concepts has been the focus of a number of theories, of which van Hiele's (1986) is the most popular. He describes the first level of understanding as "visual", connected with non-verbal thinking. At this level the emphasis is placed on the ability to recognize shapes, which are perceived as a 'whole' and connected with visual prototypes. Not much is mentioned about the role of action, although a didactical conception of the theory suggests activities with objects (de Lange, 1987).

Static Arrangement Figure To Figure

If we accept the fact that the visual is of significant importance in the first level of geometrical cognition, we also have to consider psychological provisions concerning cognition. Results of psychological research (Kaufman, 1979) confirm that in the process of grasping shapes pictorial designates are of great importance. In addition to that, dominance of the whole over the part is the regularity in perceiving shapes. The rules of structuring an image investigated in view of the information analysis system suggest that regular, symmetrical forms and shapes are the most easily recognized, as one element can be predicted from another (Grabowska & Budohoska, 1992). Regularities, groups creating some logical wholeness can be elements of a composition regulated through visual perception.

W. Demidow (1989) gives a broad account of the research conducted by physiologists concerning the mechanisms governing the recognition of shapes. We can also find there information about invariant transformations conducted by our eyesight. For example, pictures of different sizes are invariant (unchangeable) to the organ of sight (the eyesight identifies them), and the same happens while changing the position of an object - but only up to 15 degrees. The mirror image is not invariant even though children are born with such a property of perception; as humans develop, the eye loses the invariance of mirror images.

These remarks have an essential meaning in a geometrical environment, referred to as 'patterns'. Creating bands or mosaics was unequivocally assessed by van Hiele as operating on the visual level that did not require internalization of actions. He refers to the structures of the first level as optical, structures of appearance; they are manifested in recognizing regularities or certain wholeness. According to this theory all perceived regularities are classified as visual structures. The things that inspire children, propel them to action and which undergo control and are reflected upon are: rhythm, order and regularity. Such action seems to be in accordance with the original meaning of Greek 'symmetros' which stood for 'harmonious', 'well-proportioned'.

The aforementioned sense of order tends to be verified visually by children. During the creation of geometrical compositions, the creative process is regulated by perception. Hence, propaedeutics of geometrical figure to figure relationships may reside in the sense of certain order, harmony - specific arrangement of a surface or available fragment of space.

This leads us to the conclusion that in situations where balance is present, stemming from an appropriate arrangement of elements that constitute an image, there is no need to introduce movement. Children working in an environment of visual regularities do not resort to the idea of movement, placing one object onto the other. This interpretation resembles the assessment of the mosaics that have been created by humans from the earliest days of history. According to some historians of this

discipline, mathematical relations can already be identified in the geometrical decorations of items created by the late ice-age man. In the book by Kordos (2005, p. 23) we read that:

It is worth paying attention to the richness of geometrical forms used in decorations. In particular, it is worth seeing that the ribbon ornaments from the Neolithic period all had 7 one-dimensional crystallographic groups on the surface. (...) However, we cannot be certain that some kind of geometrical reflection was followed.

Therefore, it seems that recognition of a specific figure to figure position is only a static image of this relationship, not connected with the movement of one object onto the other. On a certain level and in a certain context, it will be a rather general depiction, adjusted by the perception of certain regularity.

Dynamic Understanding

The understanding of relationships between figures as a dynamic arrangement of space is placed, so to say, at the opposite pole. Acts of perception are important but they are not a sufficient source of geometrical cognition. Szemińska (1991, p.131) states that perception gives us only static images; through these we can only catch some states, whereas by actions we can understand what causes them. It also guides us to the possibilities of creating dynamic images.

The history of mathematics as a scientific discipline shows the importance of the transition from a static to a dynamic interpretation of geometrical objects (Kvasz, 2000). This can be seen in Greek mathematics, in which the traces of general reasoning were based on dynamic object transformations. A significant part of this geometry was based on constructions, which – in an indirect way – required the use of translations, rotations and mirror reflections. The overt description of symmetry as a transformation appeared rather late in mathematics – as it can be linked to the Erlangen Programme of F. Klein – but the dynamic approach itself is crucial for geometry. Geometrical reasoning requires mental transformation of objects.

In order to understand translation, rotation or axial symmetry as a transformation it is necessary to conceive the specific movement that is transforming the initial figure into the final one. From a didactic point of view, it is important that such conception stems from mental reflection on the phenomenon of movement. This is the idea of transformations as a function. If we want to trace the origins of this concept in the realm of physics, physical movement of an object will be suitable. Nevertheless, such transformation happens in a given time and while making a movement and we can possibly trace the trajectory of an object. Everyday experience does not offer the possibility of recording consecutive stages of the object's movement. On the other hand, Piaget's widely known results (Piaget & Inhelder, 1973) show that children (on the pre-operational level) have great difficulties in movement reproduction – they are not able to foresee a movement of an object in space. The process of acquiring such skills is lengthy and gradual (Szemińska, 1991). During

manipulations, the child's attention should be focused on *action*, not on the *result of action*. It requires a different type of reflection than the one that accompanies his or her perception.

Such a problem is unnoticeable in school practice. Generally it is stated that creating their own patterns is a good starting point for children's understanding of transformations. In some handbooks for teachers, there are suggestions to do *exercises with changing the figure position such as drawing patterns, mosaics where translation, rotation and mirror symmetry are used...* Jones, Mooney, (2003), while analyzing school curricula in United Kingdom states, that *the link between symmetry and the various transformations is not always made explicit. In the "Framework", for instance, rotation appears to be considered solely as a transformation and the opportunity is missed to extend this to include rotational symmetry, even though the latter is specified in the statutory National Curriculum.*

RESEARCH ORGANIZATION

Our research was based on arranging many different didactical situations that could be the source of intuitions for different geometrical transformations. Tiles were the basic tool for all situations. Patterns imprinted on tiles were different but they all had one general rule: on a piece of paper, one has to create an arrangement of tiles. Pupils from different age groups – from 5 year old children to gymnasium students took part in the research. This was a multistage research that started in 2002 and lasted until now. The organization of various stages was different. In some situations the work of a large group of students was analysed (more than thousand pupils), in the others – we observed lessons with only 20 students. Children worked at groups, during their regular activities. Some working sessions were videotaped. We observed and analyzed children's behavior during their work and we analyzed their worksheets. On this basis, we estimated to what level classes that we propose can be treated as the basis for creating the picture of specific isometries by children.

In this case study, we will deal with the concept of rotation. We will present examples of results and commentaries connected with the following didactical situations:

- 18 Creating a tiled floor by 4-6 year old children
- 19 Creating a free tile composition by 10 – 13 year old children
- 20 'Guided puzzle' with a suggested subject area and musical background.
- 21 'Domino' task (12 year old children)

The first two situations concerned static situations, and the following two were associated with movement.

Research questions were as follows:

Working group 4

1. What intuitions connected with rotation will appear either in static situations or dynamic ones?
2. Which of those intuitions should we enhance and which should we discourage during the further stages of mathematical education?
3. On the basis of different experiences, how should we create a coherent picture of a geometrical transformation that functions as the one that enables us to understand the concept both statically and dynamically?

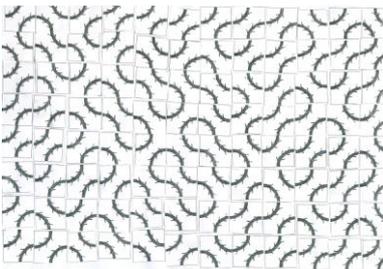

RESEARCH AND OBSERVATION RESULTS

In children's work, intuitions of rotation appeared in different forms. Each of them stressed a different rotation property that together exist in a mathematical understanding of rotation on a plane.

STATIC SITUATIONS

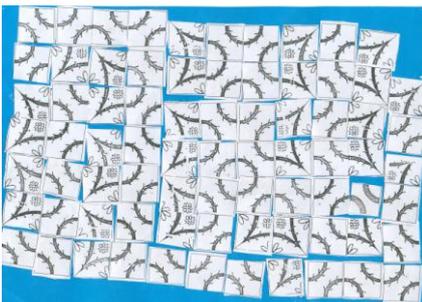

A. Puzzles – filling the floor

- a) Arrangement of one *figure* to another using a particular angle.

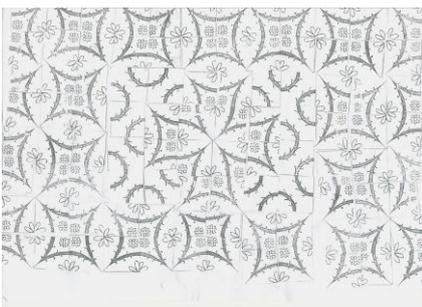

Ania, 6 years old. In this work, the child tried to fill the plane with congruent figures arranged one to another using a particular angle. The size of the angle was dependent on the shape of the tool but it is clearly seen that the child was interested in a frequent change in the basic figure's position.

- b) Arrangement of figures around a particular centre. Figures in this arrangement do not have to change their positions in relation to privileged directions. They only 'surround' one chosen element.

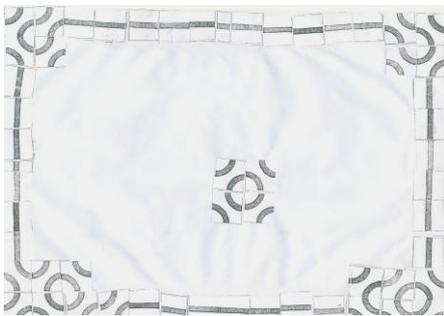

Julia, 6 years old. The process of gluing started from the central part of the paper sheet. Then, the girl tried to surround the circle with bells but she managed to do it only partially. In the following part, she focused on different regularities.

Milosz, 6 years old. A four-leaf clover was a central figure in his composition. The rest stressed the central figure, surrounding it with contrasting elements and closing it within symmetrical frames.

Working group 4

c) ‘Along the edge’ arrangement, directed inwards. In certain places, especially at the corners of a sheet of paper, motifs are created. They are directed to a common point of the inside – diagonal intersection

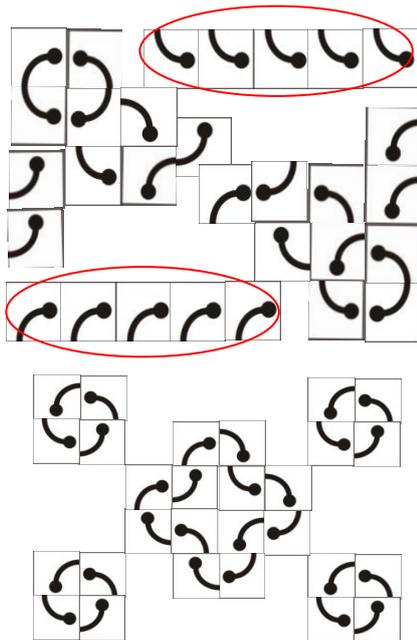

Boy, 7 years old. He started gluing from the frame. He managed to construct two elements in the upper parts such that they were symmetrical to each other. However, despite visible attempts to create corresponding elements, he could not repeat the same thing for the lower parts. In the central part, he only placed a symmetrical figure consisting of 4 tiles.

B.

Puzzles – free activities

Older pupils, whose task in the initial stage was to arrange a free tile composition, worked in similar ways to those described above. Much of their work spontaneously realized the idea of symmetry – axial symmetry was the most frequent one. Going ‘beyond’ such arrangement did not happen often. In the observed group there were only two works where we can find traces of the idea of rotation.

Krzysiu, 13 years old. The pupil started his work from circles placed in the opposite corners of the paper (but the placement of dots is not correct). Then, he diagonally moved inwards. At the end, he glued elements at the corners. The placement of glued elements shows that point symmetry was present in his arrangement strategy.

Ala, 13 years old. Her work is an example of a perfect rotation, while the parts of the puzzle have an opposite orientation (the central part – clockwise orientation, circles in the corners – anticlockwise orientation). Rotation was present in the girl’s arrangement strategy from the beginning because it is impossible to see axial symmetry in her puzzle.

Both of these works can be classified by categories distinguished in 6 year old children’s work. The first of these reflects the ‘along the edges’ arrangement idea, where the corresponding elements are in the opposite corners of a rectangular sheet of paper. Some deviations from the arrangement reflecting real rotations (elements marked with an oval) indicate that the child, during her work, did not make any manipulations of a sheet of paper to check the arrangement of elements.

The second work is dynamic but compositionally close to the ‘around the centre’ arrangement. A closed central composition arranged according to a rotational movement by a closed wavy line sticks out in the foreground. Rotation also organizes four smaller sets surrounding the centre, but the direction is different. It is clearly seen that movements are local. The whole composition is enclosed within a symmetrical area determined by a sheet of paper.

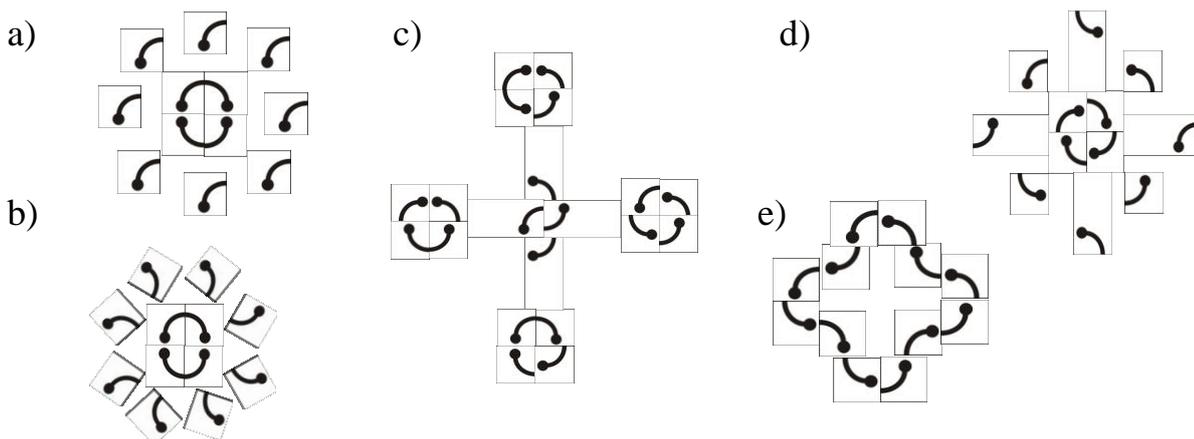

DYNAMIC SITUATIONS

C. „Directional puzzles”

In another stage of the project with specially prepared music, the children created puzzles with a specific theme. Music functions in a natural way, speaking of a sort of transition and changing from moment A to moment B. In the assumptions, we referred to building dynamic associations with the visual representations created by the child. The suggested theme was *merry-go-round*—the use of rotation.

The music and the topic actually inspired pupils to create compositions in which one could see relations connected with the idea of rotation. Placing several tiles required many full turns of single elements. Observation of the process proved very interesting. Some of the works started by distinguishing the central element and then other elements were arranged around it — rotational arrangement. A two-dimensional pattern with rotational symmetry was formed. Maintaining only rotational symmetry was difficult, as can be seen in the children’s work (fig. b,c).

Regardless of the external similarity of these creations to work created in the previously described stages, these puzzles tried to represent the idea of a specific movement. This results mainly from the way of organizing pupil’s work. Some children added tiles with regard to the rhythm of the music. There was also

work where axial symmetry gradually transformed into rotations. Observation of the children’s work did not pose any doubts that they try to match the constructed arrangement with rotation—the pupil would draw an oval line with their finger, trying to see if the tiles go round one after another (fig.e). While doing this, the pupil

Working group 4

would adjust the tiles and rearrange them in such a way that the dot pattern would represent rotational and not mirror symmetry.

D. “Dominoes”

The pupils (10-12 years old) had the following task:

How many different “domino” blocks can be created by using two squared tiles with the motif presented in the picture below?

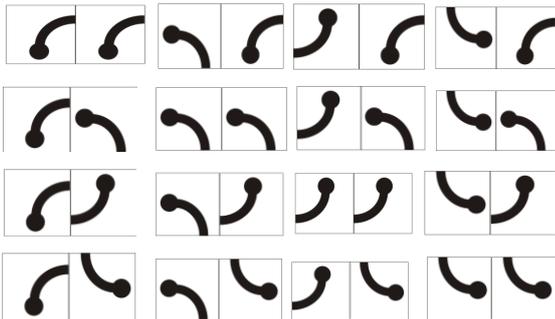

The first solutions were random. Pupils, sitting close to one another, could not recognize whether they had the same or different solutions. They also could not say whether they had all the possible solutions. Moreover, they did not know if the arrangements in front of them were actually different from one another or the same.

Such a situation was a good starting point for discussion and for a more ordered way of looking for

a solution.

An ‘unfailing’ strategy was proposed by a different pupil from the class. Below, we present his arrangement.

Analysis of this arrangement was a starting point for examining the position of one object in relation to another. This arrangement had the layout of a column: the boy started his arrangement from the first tile. A transition from one ‘domino block’ to another happened through a conscious rotation of the second tile.

Here, notions like ‘rotation by 90 degrees, 180 degrees, 270 degrees’ were appearing spontaneously. Although each domino block presented a relation of a rotation of two congruent figures, this relation was not the subject of research at this stage. For pupils, the way of constructing the whole series of dominos was very important, and this construction happened through rotating one of the tiles.

OBSERVATION CONCLUSIONS

We conclude, that in the *static* recognition of rotation certain specific properties can be found:

- Rotation is understood locally.
 - ✓ The center of rotation is an element which sticks out in the foreground. One of the figures can serve this function.

There are elements which are inconsistent with the definition of rotation:

Working group 4

- During arrangement on a plane, there may be a lot of figures which are not congruent to one another.
- Figures that determine rotation themselves (around a given centre) are not rotated towards one another by a given angle. Their shift is rather parallel.

At the intuitional level of comprehending rotation, a *dynamic approach* can be characterized by the following:

- Movement representations are varied, strictly connected with a physical movement representative.
- They express only single definitions of rotation properties.
- A physical rotation of one figure results in the removal of the rotation center from the interest domain.

SUMMARY

We believe that regular ways of filling a sheet of paper with tiles can be treated as an intuition of geometrical transformations, even though initially they are not connected with the interiorization of movement. As far as quality is concerned, this knowledge is different from the mathematician's knowledge, mainly because of the fact that it functions by totally different rules. If we want certain relations to be clear to children, we need to introduce a 'rich structure' in which not only two figures (e.g. polygons) remain in a particular relationship with each other but a certain fragment of space is organized according to this relationship. Introduction to the understanding of geometrical relationships that function in mathematics as a science is created through the feeling of regularity on a statically organized plane. Here, a child can arrange and organize tiles on a sheet of paper and ideas arise at the moment of reflection on what he or she sees.

The exterior effects of the work of pupils who create representations for a rotation both in a static and dynamic environment do not vary that much. It does not mean though, that these approaches can be identified with each other. In both approaches, the organization of pupil's work which pointed at different pictures associated with the performed activity was different. However, since these works (as a final effect) look alike, they give the possibility of building an integrated static-dynamic picture.

Presented didactical examples are not just 'clear' models of the mathematical notion of rotating by any angle. It is consistent with our understanding of the constructivist approach towards the creation of mathematical concepts. A pupil should function in such a rich learning environment that, through gaining various experiences and reflecting upon them, he would be able to create his own understanding of isometric transformations.

In spite of this, the relationship between visual recognition of geometrical objects and actions that can lead to the creation of dynamic images of such objects needs further investigation.

ELEMENTARY STUDENTS' TRANSFORMATIONAL GEOMETRY ABILITIES AND COGNITIVE STYLE

Xenia Xistouri and Demetra Pitta-Pantazi

Department of Education, University of Cyprus

This study investigated 93 elementary students' abilities in solving transformational geometry tasks and how they relate to cognitive style. A test was developed to assess students' transformational geometry abilities, which included translation, reflection and rotation tasks. Students' cognitive styles were assessed using the Object-Spatial Imagery and Verbal Questionnaire (OSIVQ) (Blazhenkova & Kozhevnikov, 2009). Results suggest: 1) that the elementary students had average performance in solving the transformational geometry tasks, with rotation tasks being the most difficult and 2) that although both spatial imagery and object imagery cognitive styles relate to performance in transformational geometry, highly spatial imagery students perform better, because their cognitive style gives them an advantage in the case of solving the most difficult tasks, those of rotations.

Key-words: transformational geometry, cognitive style

INTRODUCTION

The growing emphasis on geometry teaching during the last few decades has modified its' traditionally Euclidian-based content, by introducing new types of geometry such as transformational geometry (Jones, 2002). There are several suggestions that there is limited research on transformational geometry (Boulter & Kirby, 1994; Hollebrands, 2003), which is imputed to its' underemphasis in mathematics curricula. However, it is considered important in supporting children's development of geometric and spatial thinking (Hollebrands, 2003) and it is related to a variety of activities in academic and every-day life, such as geometrical constructions, art, architecture, carpentry, electronics, mechanics, clothing design, geography, navigation and route following (Boulter & Kirby, 1994). Performance in geometric transformations has been previously connected to the holistic-analytic types of processing (Boulter & Kirby, 1994). However, despite its' rather obvious relation to visual imagery and the fact that it has often been connected to spatial abilities in literature, there doesn't seem to be a study that examines abilities in geometric transformations in relation to the visual-verbal cognitive style. This paper will study the relation between abilities in solving transformational geometry tasks and a new three-dimensional cognitive style model proposed by Blazhenkova and Kozhevnikov (2009) that distinguishes between Object imagery, Spatial Imagery and Verbal dimensions. Specifically, the aim of the paper was to investigate nine to eleven year old students' abilities in transformational geometry tasks of translations, reflections and rotations, and to investigate the relationship between these abilities and the students' cognitive style.

THEORETICAL FRAMEWORK

Transformational Geometry in Mathematics Education.

The inclusion of transformational geometry in mathematics curricula in the early 70's raised an emphasis around the importance of teaching and understanding geometric transformations (Jones, 2002). Early studies focus on providing evidence for suggesting that teaching geometric transformations in elementary and high school education is feasible and may have positive effects on students' learning of mathematics (Edwards, 1989; Williford, 1972). Later studies focus on more psychological aspects, such as students' ability and misconceptions (Kidder, 1976; Moyer, 1978), strategies for solving transformational geometry problems (Boulter & Kirby, 1994) and configurations influencing students' ability in transformational geometry (Schultz, 1983). During the early 90's, research started to focus on investigating a hierarchy that describes students' acquisition of transformational geometry (Molina, 1990).

It seems that research in transformational geometry decreased substantially around the late 80's, leaving unanswered questions on the cognitive development of transformations (Boulter & Kirby, 1994). For instance, Moyer (1978) raised questions on whether some geometric transformations are more difficult than others and emphasized the need to search for a successful sequence of learning activities in transformational geometry for children. There were also some issues raised concerning individual differences and different types of processing information in transformational geometry problem solving (Boulter & Kirby, 1994). It is thus important to understand the role that individual differences such as students' cognitive style may have in their abilities to solve transformational geometry tasks. Such information would guide educators in providing further assistance to the less able students in transformational geometry to overcome their difficulties.

The Object-Spatial-Verbal Cognitive Style Model.

Cognitive styles refer to psychological dimensions representing consistencies in an individual's manner of cognitive functioning, particularly with respect to acquiring and processing information (Witkin, Moore, Goodenough, & Cox, 1977). One of the most commonly acknowledged cognitive styles dimension is the Visual-Verbal (e.g. Paivio, 1971), which describes consistencies and preferences in processing visual versus verbal information, and classifies individuals as either visualizers, who rely primarily on imagery when attempting to perform cognitive tasks, or verbalizers, who rely primarily on verbal-analytical strategies.

However, neuropsychological data suggest the existence of two distinct imagery subsystems that encode and process visual information in different ways: an object imagery system that processes the visual appearance of objects and scenes in terms of their shape, colour information and texture and a spatial imagery system that processes object location, movement, spatial relationships and transformations and

other spatial attributes of processing (Blazhenkova & Kozhevnikov, 2009). The distinction between object and spatial imagery has been also found in individual differences in imagery (Kozhevnikov, Hegarty, & Mayer, 2002). Recent behavioural and neuroimaging studies have identified two distinct types of individuals, object visualizers, who use imagery to construct vivid high-resolution images of individual objects, and spatial visualizers, who use imagery to represent and transform spatial relations (Kozhevnikov, Kosslyn, & Shephard, 2005). Based on these distinctions, Blazhenkova and Kozhevnikov (2009) have developed a self-report instrument assessing the individual differences in object imagery, spatial imagery and verbal cognitive styles, the Object-Spatial Imagery and Verbal Questionnaire (OSIVQ).

Mathematics education researchers have often linked the verbalizers/visualizers distinction to mathematical performance (Presmeg, 1986). Nevertheless, the results of the relationship between visualisation and mathematical performance are unclear. Some studies found that visual–spatial memory is an important factor which explains the mathematical performance of students (Battista & Clements, 1998), while other studies showed that students classified as visualizers do not tend to be among the most successful performers in mathematics (Presmeg, 1986). In the case of transformational geometry, although it has not yet been linked to the verbalizers/visualizers distinction, it has been connected to spatial ability (Dixon, 1995; Kirby & Boulter, 1999), thus it is hypothesized in this study that the spatial imagery cognitive style will be related to abilities in transformational geometry tasks.

METHODOLOGY

The purpose of the study is to investigate elementary school students' abilities in transformational geometry tasks and the relation of these abilities to the students' cognitive style. Ninety three students were selected to participate in the study (34 fourth-graders and 59 fifth-graders), based on their teachers' willingness to provide access to their classes during school-time. A transformational geometry ability test and a self-report cognitive style questionnaire were administered to all students at the same week, in groups of approximately 15 students.

The transformational geometry ability test was used to measure students' mathematical abilities in the concepts of translation, (axial) reflection and rotation. The test consisted of 33 tasks, of which seven were translations, fourteen were reflections and twelve were rotations. The test included multiple choice and drawing tasks which focused mainly in 1) performing a specific transformation, 2) finding the parameters of a given transformation, and 3) identifying the result of a given transformation (see Appendix for examples). It is noted that the students were taught 2-3 lessons on symmetry at every grade, and were informally introduced to the concept of transformations but not to the mathematical terms. They were given 40 minutes to solve the test during normal lesson time. Each correct response to an item in each of the tasks was assigned a positive point. Half point was assigned when a response was partially correct, for example when a requested transformation was

Working group 4

performed correctly, but there was no accuracy in the shapes' dimensions or orientation. The points were summed up separately for translations, reflections and rotations, in order to give the students' scores for each type of geometric transformation, and also in total to give an overall of each student's performance.

The students were then administered a modified version of the Object-Spatial Imagery and Verbal Questionnaire (OSIVQ) to assess the individual differences in spatial imagery, object imagery and verbal cognitive style. This is a self-report questionnaire, which includes 45 statements with a 5-point Likert scale for students to rate themselves on how much they agree with the content of the statement. Fifteen of the items measured object imagery preference and experiences, fifteen items measured spatial imagery preference and experiences and fifteen items measured verbal preference and experiences. Examples of the statements are: "If I were asked to choose among engineering professions or visual arts I would choose visual arts" (measuring Object Imagery dimension), "My images are more schematic than colourful and pictorial" (measuring Spatial Imagery dimension), and "I usually do not try to visualize or sketch diagrams when reading a textbook" (measuring Verbal dimension). The test was translated in Greek and was modified to be comprehensive to elementary students. The students were given 30 minutes to complete the questionnaire. For each student, the fifteen item ratings for each factor were averaged to create object imagery, spatial imagery and verbal scale scores.

RESULTS

The main purpose of the study was to investigate elementary school students' abilities in transformational geometry tasks of translations, reflections and rotations, and how these are related to the students' cognitive style. Students' means of performance were calculated to describe their abilities in transformational geometry. The object-spatial-verbal cognitive style dimension was used as predictor variable for students' performance in transformational geometry tasks. Specifically, through multiple regression analyses with criterion (dependent) variable the students' performance in translation tasks, performance in reflection tasks, performance in rotation tasks and overall performance, and predictors (independent) the spatial imagery, object imagery and verbal cognitive style scores.

	\bar{X}	SD
Translations	0.59	0.26
Reflections	0.54	0.20
Rotations	0.38	0.21
Overall	0.49	0.18

Table 1: Means and Standard Deviations for each type of tasks in the transformational geometry abilities test

Table 1 presents the means and standard deviations for each type of transformational geometry task, as well as for overall performance. It appears that students performed

Working group 4

slightly better in the translation tasks ($\bar{X}=0.59$, $SD=0.26$), rather than the other categories, indicating that these might be the easiest type of tasks for elementary school students. Mean performance in reflections ($\bar{X}=0.54$, $SD=0.20$) is next, but very close to performance in translation tasks. In order to test these observations, students' means in translation tasks and in reflection tasks were compared in a paired sample t-test analysis, which showed that this mean difference is not significant ($t=1.842$, $p=0.069$). This finding is in accord with Moyer (1978), who found that translations are as easy as reflections. The most difficult tasks for the students seem to be the rotation tasks, where this group of students had a much lower mean performance ($\bar{X}=0.38$, $SD=0.21$). A paired sample t-test for comparing students' mean performance in reflection tasks and in rotation tasks revealed this mean difference is statistically significant ($t=7.266$, $p=0.000$). Students' overall performance mean in transformational geometry tasks is 0.49 ($SD=0.18$), which is near average, considering zero as minimum value and one as maximum.

	Translations	Reflections	Rotations	Overall
Spatial Imagery Cognitive Style	.162	.231*	.236*	.266*
Object Imagery Cognitive Style	.174	.231*	.199	.254*
Verbal Cognitive Style	.031	.169	-.097	.050

* Correlation is significant at the 0.05 level (2-tailed).

Table 2: Correlations among performance scores and spatial imagery, object imagery and verbal cognitive styles.

The correlations among students' cognitive styles and their performance in translations, reflections, rotations and overall are presented in Table 2. As can be seen from Table 2, the spatial imagery cognitive style is significantly correlated with students' transformational geometry abilities in reflections, rotations and overall performance, while object imagery cognitive style is significantly correlated only with reflections and overall performance. The verbal cognitive style dimension did not correlate with any of the students' abilities in transformational geometry. We further examined the nature of these correlations and non correlations between cognitive styles and students' abilities in translation, reflection and rotation tasks, as well as their overall performance in the test.

Table 3 presents the results of the multiple regressions, using the stepwise method. It should be noted that the regression analysis for students' abilities in the translation tasks did not enter any variables in the equation, which means that none of the cognitive style variables - object, spatial or verbal - can significantly predict performance in translation tasks. This was expected, as none of these variables were significantly correlated to the translation tasks, as seen in Table 2. Therefore, Table 3 presents the coefficients and levels of significance for predicting performance in reflections, rotations and overall.

Working group 4

	Reflections		Rotations		Overall	
	<i>b</i>	<i>p</i>	<i>b</i>	<i>p</i>	<i>B</i>	<i>p</i>
Spatial Imagery Cognitive Style	.154	.209	.327	.005**	.266	.013*
Object Imagery Cognitive Style	.231	.031*	.222	.083	.161	.183
Verbal Cognitive Style	.075	.536	-.228	.047*	-.068	.554

* Indicate statistical significant $p < 0.05$

** Indicate statistical significant $p < 0.01$

Table 3: Multiple regression analyses with dependent variables reflection tasks, rotation tasks and overall performance, and independent variables spatial imagery, object imagery and verbal cognitive styles.

One characteristic that rises from the analysis of the data is that object cognitive style can significantly predict performance in reflection tasks ($b=0.231$, $p=0.031$). It seems that this was the only significant factor for performance in reflection tasks, and it can predict more than 4% of the variance of performance in reflection tasks. This means that as the object cognitive style of the students increases, their performance in reflection tasks of transformational geometry increases also.

Another important characteristic presented in Table 3 is that spatial imagery cognitive style can significantly predict performance in rotation tasks ($b=0.327$, $p=0.005$) and the verbal cognitive style is negatively related to performance in rotation tasks ($b=-0.228$, $p=0.047$). The negative sign of the beta in the case of the verbal cognitive style means that as the verbal cognitive style increases, students' performance in rotations decreases. This suggests that students who tend to prefer verbal processing are not so successful in solving rotations tasks, while students who tend to prefer the spatial imagery processing perform better. Spatial cognitive style and verbal cognitive style can explain a proportion of variance of 7.8% in performance in rotations tasks.

In the same way we can interpret the negative relation between the verbal cognitive style dimension and overall performance, although it is not statistically significant. The last and most important observation from Table 3 is that spatial imagery cognitive style is the only significant predictor of students' overall performance in transformational geometry tasks ($b=0.266$, $p=0.13$). The proportion of variance explained by this factor is 6%. This means that as far as students tend to prefer the spatial visualization processing, their overall performance in transformational geometry is higher than those who seem to prefer the verbal and object visualization processing of information. This finding is in line with the results in a study by Kirby and Boulter (1999), who suggest that performance in transformational geometry can mainly be predicted by students' score in spatial ability tests.

DISCUSSION

Although transformational geometry is considered important in supporting children's development of geometric and spatial thinking (Hollebrands, 2003), research in the field seems to have left unanswered questions concerning children's abilities in performing transformations. And despite the rather obvious relationship of transformational geometry to visual imagery, it has not yet been related to the visual-verbal types of processing. This study goes a step further, by investigating students' abilities in transformational geometry tasks of translations, reflections and rotations, and relating them to two distinct types of visual processing – object imagery and spatial imagery cognitive style - and verbal cognitive style.

The results of this study have shown that the students' overall performance was average in these transformational geometry tasks. An important finding of this study is an indication of hierarchy in students' understanding of transformations: translations and reflections are equally difficult to students, while rotations seem to be more difficult. This is in accord to Moyer's (1978) findings. However, another study by Schultz and Austin (1983) suggests that translations are easier compared to reflections and rotations, whose level of difficulty is influenced by the direction (vertical, horizontal, diagonal) of the transformation. Apparently more studies are required in order to clarify the hierarchy of difficulty in different types of geometric transformations, by considering configurations such as direction.

In regard to the relation between transformational geometry abilities and students' cognitive style, the results of this study show that the spatial imagery cognitive style is a significant predictor of performance in rotation tasks, but more important to overall performance in transformational geometry tasks. This was expected, considering the connection between transformational geometry performance and spatial abilities found in the literature (Dixon, 1995; Kirby & Boulter, 1999). On the other hand, the object imagery cognitive style seems to be related to transformational geometry abilities as well, but only by contributing significantly in predicting performance in solving reflection tasks. This was unexpected, since object imagery cognitive style is usually more related to visual arts rather than scientific fields (Kozhevnikov, Kosslyn, & Shephard, 2005). Perhaps further research with a bigger sample of students would help clarify and validate this finding.

However, a possible explanation for this finding could be that highly spatial visualizers were rather more flexible in their strategies and could manipulate both reflections and rotations tasks, whereas highly object visualizers were successful in reflections tasks, but couldn't handle the most difficult tasks of rotations. Object visualizers may have been able to see the image be reflected as a whole and then find its' position analytically over a single axis, but were inhibited in keeping track of the orientation of an image in space when rotated. This point of view may lead to the conjecture that, although students with high visualization abilities - either spatial or object imagery – can perform well in transformational geometry tasks, it is the ones

Working group 4

with high spatial visualization abilities that are flexible enough to deal with the most difficult tasks, those of rotations, and who eventually outperform others. However, since this is a quantitative study, further investigation with qualitative data of object imagery and spatial imagery cognitive style students' strategies for solving reflection and rotation tasks is needed to provide more evidence and deeper insight.

The fact that verbal cognitive style did not have a significant positive correlation to any type of tasks probably means that students with preference to verbal type of processing do not perform so well in transformational geometry tasks, and especially in the case of rotations, this type of processing preference may somehow raise more difficulties to students' task solving. It should also be noted that performance in translations tasks was not related to any of the three different types of cognitive styles. Although this finding was unexpected, it may mean that the concept of translation is more comprehensive to students, regardless to their cognitive style. Translation tasks can be solved either visually or verbally: one can either visualize the image move as a whole, or one can visualize the image move part by part, or one can verbally count the steps to the new position and copy the image. Some qualitative research could provide information on how students with different cognitive styles solve translation tasks and answer how and why it doesn't differentiate their performance.

In closing, we note that this study is a first investigation of students' abilities in transformational geometry and their relation to cognitive styles. The results presented in this paper are initial results and there appear to be some discrepancies which are not easily explained. There is still no clear picture for the relation between abilities in transformational geometry and cognitive styles, since different types of transformations seem to be related to different cognitive styles. The important finding is that there is some relation, but further investigation with a larger sample and more qualitative data is necessary to clarify its' nature. Overall, the results of this study suggest that it is helpful to know students' cognitive styles, especially to educators, to facilitate developing flexible methods of teaching transformational geometry to accommodate all types of learning, and also in providing appropriate assistance to each student to overcome their difficulties. Perhaps students could be guided into applying strategies of processing of their less preferred type of imagery effectively in tasks when necessary. This could be a challenging question for further research.

GEOMETRICAL TRANSFORMATIONS AS VIEWED BY PROSPECTIVE TEACHERS

Xhevdet Thaqi*, Joaquin Giménez**; Nuria Rosich**

*University of Prishtina; **University of Barcelona.

An empirical study is developed to find the meanings attributed to geometrical transformations by prospective primary teachers in Kosova and Spain. The study reveals that students' previous background had more influence than cultural differences.

Key words: Geometrical transformations, prospective teachers, comparative study

INTRODUCTION

A new challenge for teacher training in European Higher Education is to reduce international differences, considering immigration processes, exchanges, and globalization. A continuing interest of the CERME community is to understand how mathematical practices are developed by using cultural writings in different countries (Stigler et al, 2000) as culturally situated mathematical practices (Llinares & Krainer 2006). The way in which mathematics is construed by participants is a hidden variable in researching mathematic knowledge for teaching (Andrews, 2009). In particular, some authors explore differences in the use of geometry: from natural and intuitive to axiomatic perspectives (Girnát, 2008), analyzing and reconceptualising their geometric ideas, progressing to higher levels of geometrical understanding. There is a considerable amount of research about the knowledge and use of geometrical transformations in secondary school (Hoyos, 2006) but less research has been conducted for primary schools. It has also been shown that difficulties in primary students' conceptualizations depend on the weak knowledge of teachers (Law, 1991, quoted by Yanik & Flores, 2009), in particular about geometrical transformations (Pawlik, 2004).

Such studies reveal that teachers' lack of mathematical subject knowledge and confidence in mathematics are contributory factors to the low standard of pupil mathematics attainment in many countries. It has also been shown by several authors that pre-service elementary teachers have difficulties in determining: (1) the correct *attributes of transformation and motion* to move an object from one point to another; (2) the results of *transformations involving multiple combinations of figures*; (3) the use of *transformations as mathematically-general operations* which require the specification of inputs, but as particular actions, each with given 'default' or prototypic parameters. It has also been observed that the use of technological devices has strong advantages in the use of isometries, because of the possibilities of variability analysis (Harper 2003).

A recent study concerning prospective teachers' knowledge of translations and other rigid transformations (Yanik & Flores 2009) revealed that scholars (1) started by

Working group 4

referring to *transformations as undefined motions of a single object*, (2) followed by using *transformations as defined motions of a single object*, and (3) the understanding of *transformations as defined motions of all points* on the plane.

In Spain, studies using Van Hiele's levels found prospective primary teachers' difficulties in using symmetrical notions in an isometry task (Jaime & Gutierrez 1995), but few proposals were made to analyze teachers' ideas qualitatively before developing professional tasks. Even the term "transformation" is mentioned only at the end of secondary school and does not solve the problem of transition from the use of natural environmental geometry in primary school into secondary school axiomatic perspectives (Kuzniak & Vivier 2008). Therefore, in our research study, we focus on analyzing the influences of prospective teachers' prior cultural background before developing training activities about learning to teach geometrical transformations. We studied and compared the results in Kosova and Spain in a bridging collaborative international framework (Jaworski, 2006), where we expected to find different conceptualizations in their responses.

METHODOLOGY

An ethnographical research case study was planned, with two groups of future teachers: 13 students from a 2nd year course at the Faculty of Teacher Training at Barcelona University (UB) in Spain, with only one prior mathematical/didactical course and 15 students from the Faculty of Education at University of Prishtina (UP) in Kosova, with two prior geometry courses based on classic Euclidean geometry, but no previous didactical training. Students were 18-22 years old. A prior curricular-cultural comparative analysis based on textbooks, official curricular proposals and teacher training materials showed deep differences between both previous preparation and cultural frameworks (Thaqi, 2009), but is not detailed in this presentation.

The results of an initial semi-structured questionnaire are considered in this paper, in order to analyze beliefs, meanings, and prototypes from transcriptions of student text. Such a questionnaire is the first step in a wider developmental study in which both groups of students have the same training about transformations in geometry (Thaqi, 2009).

An initial semi-structured questionnaire was designed by using 14 open (mainly contextualized) written questions, together with subsequent interviews considered necessary to capture students' ideas about the topic (see the main ideas in Table 1). Some other questions were added to identify reasoning and specific ethnic-cultural elements of geometrical transformations, ideas about teaching and learning, and student ideas concerning the future teaching of geometrical transformations.

Aspect of meaning of geometrical transformation	Identified Activities
Terminology. Types of transformation.	1, 2, 3, 4, 5, 6, 7, 9, 11, 12, 14
Properties. Relations and hierarchies	1, 3, 4, 5, 6, 7, 11, 12, 14
Transformation as a process or simple change	1, 2, 3, 4, 5, 6, 7, 9, 12
Others aspects (reasoning, teaching, etc)	8, 10,13, etc.

Table 1: Sets of questions related to mathematical ideas about transformations.

Further analysis about learning to teach transformations and professional activities was given from videotaped transcriptions not included in this article. Furthermore, the first sessions serve as confirmation of attributed meanings found in the questionnaire, about training practices (Stigler, Gallimore and Hiebert, 2000: 87) showing us cultural objects with specific languages or symbolic systems.

Data collected through the developmental process were analyzed using ongoing analyses. During the ongoing analysis phase, the researcher tried to understand the participant's way of thinking, not presented in this article. After each teaching episode, the research team coded and analyzed the video records of students' interactions during the given tasks. The main purpose was to find patterns and create descriptions of the development of students' mathematical knowledge over time as a hypothetical learning trajectory of participants. During ongoing analyses the researcher tested his initial hypotheses and generated new conjectures to be tested in the following teaching episodes.

ABOUT ATTRIBUTED MEANINGS

Based upon student answers in both countries, we divided the results into three parts: (a) the meanings and use of geometric transformations as a mathematical object and associated examples; (b) definitions and conceptual structure, and (c) representations and non-isometric transformations.

Transformation as mathematical object

To identify degrees of knowledge (table 2), we assume students develop more or less pseudo-conceptual perspectives (Vinner, 1997) by analyzing their justifications, argumentation, properties, and use of examples and counterexamples. It was not surprising that none of the students showed consolidated knowledge about the idea of transformation or the idea of transformation as a function, even in the case of projection (usually defined as a function). The majority (64%) belonged to an intermediate level in the case of the University of Prishtina (UP). The main class of mathematical objects they identified was symmetry, as we expected.

Table 2: Results compare between Barcelona (UB) and Prishtina (UP)

We analyzed student text by observing their answers to find their ideas about the set characteristics and to find semiotic conflicts.

We deduced that Kosovar students (UP) assume a “*transformation perspective*” by using deep mathematical expressions. When we asked how transparent paper could be used to show the rotation, Vj indicated: “...*they draw the part of the figure through the paper to be turned in order to obtain the whole figure. Thus, it will show the rotation*” (Vj, p5:3, UP). In some other cases students identified the expression “*through displacements...*” as a way for describing the transformation that generates figures from a module.

In the case of the Spanish students, transformation was mainly considered to be a simple relationship between objects and their transformed images, in which some characteristics of the object are changed (called *undefined motion* in Yanik & Flores, 2009). Change in position was not always taken into consideration: “... *the movement does not mean a change of form, but only the position, while the transformation involves change of the form*” (A1, p.9: 8, UB).

A few students told us about the invariant terms of a transformation, and gave interesting properties of transformations such as the knowledge of repetition by period $T=2\pi$ (student Pe in UP group) when they explained the rotation of a door. When we asked “*tell us some statement to give a meaning for rotation*”, several students from UP spoke about the invariance of shape and size when talking about isometries. They used the expression “*change of a same thing*”, and others used the expression “*without changing...*” even when they talked about projectivity.

A lot of mathematical inconsistencies appeared with the Spanish students, associating rotation with the class of isometries, but then stating that a rigid movement was not a transformation. In some cases, the question seemed to promote intuitive or pseudo-conceptual knowledge, more than structured knowledge, as in the case of tiling, in which students explained rotation as the only isometric transformation: “...*I understand a movement to take some object or image and displacing it, without any change...*” (Mc, p5: 2 – 3, UB).

About definitions, properties and structure

Only in two cases did we find that the (isometric) transformation was seen as defining the motion of all points on the plane. After naming the vertices of the triangle, Ad (UP) expressed the functional dependence between their positions: "... first has been the displacement of point A, and during the movement of point A, points B and C takes position presented on figure (see Fig. 1a), so the points have changed columns ... the point B has moved to the place of point A ..." (Ad, p12: 7-8, UP). Few UP students adequately affirmed that the movement was only one type of geometric transformation and established the correct relationship between the properties of conservation of size and form in isometric transformations.

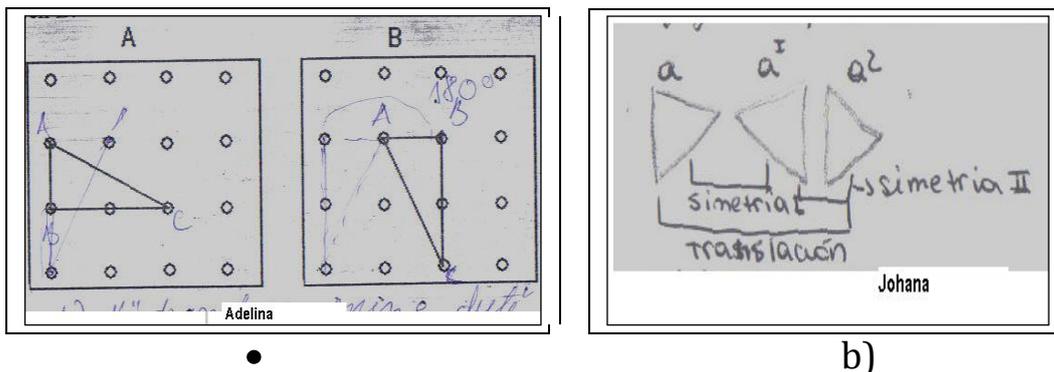

Fig.1 Transformations of triangle A onto triangle B by Ad (UP) and Jo (UB)

In the case of UB, most of the students identified isometric transformations as repetitions, but generally reflection was not identified in that set. Another group of UB participants were limited in identification of the visual characteristics of symmetry to rotations and translations. The main image for a transformation is based upon visual understanding (transforming=deformation), and isometrics movement is interpreted as displacement. Few students visually identified the translation vector, and confirmed that the translation of a figure is equal to the product of two reflections with parallel axes (Figure 2b): "*The translation is the product of two reflections because this is the reflection of the reflection....figure a2 is the translation of initial figure a.*" (Jo, p8: 4, UB).

Many UB students identified similarities as a commonsense word, without mathematical explanations. Sometimes they accepted that "*I don't know the properties of similarity*". In general in both countries, all the necessary elements for definitions were not stated, such as change of direction in relation to some movements. When they talk about rotation, only angles were observed but not the center of rotation and the invariance of distance. Some Kosovar students (UP) established the correct relationship between conservation properties and the corresponding transformations, but only one UB student: others talked about repetitions or similar figures as commonsense. For example, student Al stated "*It can be when you open an orange, because it can appear equal parts, but they are not*" (Al, p5:2, UB), and Jo stated "*The similarity would say that is when something is very similar to another but not the same*" (Jo, p7:1,2 UB).

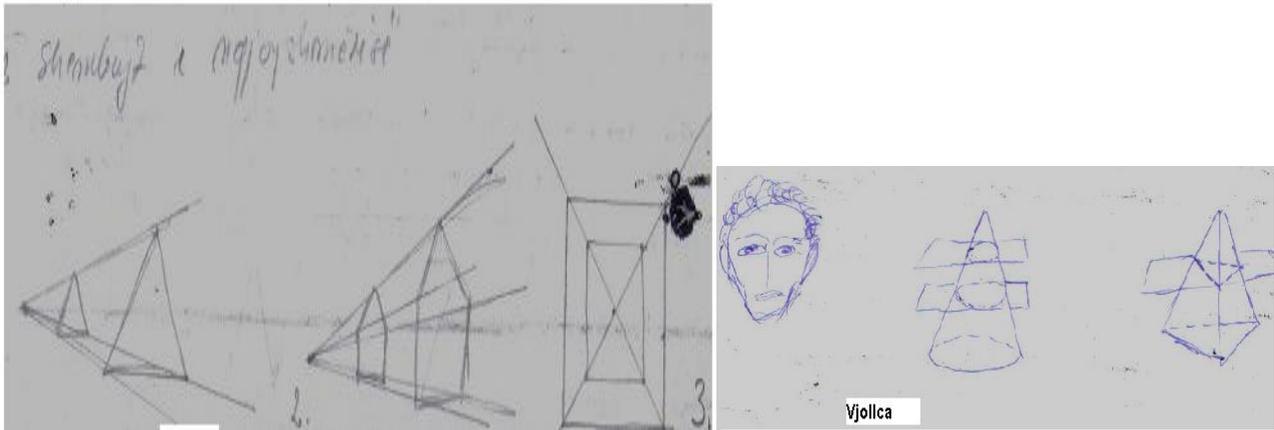

Figure 2. Drawings showing the transformational idea for similarity

When they tried to establish a functional approach, only a figural perspective was used, arguing by means of artefacts such as paper folding, or rays of the sun. Only two students from Kosova (UP) identified a functional idea for similarity by using conic sections (Figure 2) presenting their previous mathematical knowledge.

Conservation of shape was observed in almost all UP students, but not UB, as this was viewed as a figural phenomenon. A nice description was given by student Ar: *“the shadow will be different in a human body example,... the focus of light is considered the centre of the projection, and light arrows are the right lines for the projection.”* (Ar, p10: 7, UP).

In UB, some students explained the transformation as a relationship between two different stages of an object. Other students saw the transformation as a radical change in a physical object. We were really surprised that many of the students thought that projections were not transformations as Na comment: *“There are not transformations. The shadows are the projections of an image due to the light”* (Na, p10: 4, UB).

About representations and non-isometric transformations.

This is not analyzed in many studies. In fact, students are usually trained to visualize isometric transformations by using problem solving activities. We have more consolidated answers in UB than in Kosova because it is more common for students to be confronted with isoperimetric manipulation tasks. It was also expected to find that deformations were not considered globally as transformations. Some students identified projection as deformation, without considering the conservation of the shape. Ol responded to the question *“Is the shadow a transformation?”* with *“...when we work with shadows, we say it’s a work about projections because the figures have been deformed. An image is obtained from another, as we see in the overhead projector. The projected image is deformed, it stretched or enlarged”* (Ol, 10:9, UB)

Working group 4

Figural explanations were typical in UB, and light/shadows phenomena were only explained in terms of dependence, without any explanation about the transformed elements. Some UP students told us about dependence, indicating the main variables in projective transformation: *“the shadow depends upon the place where is observed, because the shadows grow when a light source is incident on a body and this is projected on an opaque background. If we would have a light bulb on an opaque background, we would have no shadow. It also depends on where we shine the spotlight”*(Ad, p10:3-5, UP).

One possible explanation is that Klein’s perspectives are not introduced in the curriculum and are hence unfamiliar to many teachers. Figural judgements are based upon a few prototypical examples, using incorrect comparative arguments. For example Da explained an isoperimetric transformation as follows: *“the transformation converting a rectangle 3cm x 7cm made with a 20 cm string into another rectangle using the same string, is a conservation of perimeter and area”* (Da, p14:5, UP).

CONCLUSION

The generally low results about transformations in both countries reveal a lack of previous background, not only because of a lack of mathematical knowledge, but a lack of tasks in which transformations plays usually a restricted mathematical role. To enhance performance in geometry, students need to increase their level of geometric thinking through increased exposure to informal geometric activities throughout their training. To accomplish this goal we need to start with deepening geometric content knowledge and increasing the level of geometric thinking of prospective primary teachers. Increasing the teacher’s knowledge and level of thinking can only improve the mathematical instruction that students receive.

The acquisition of the concept of transformation is important for the development of spatial reasoning and the geometrical understanding of the immediate environment, in which phenomena are encountered that require familiarity with isometric and non-isometric transformations. Another benefit of studying the intuitive and informal aspects of transformations is the dynamic nature of transformation – transformational geometry encourages students to investigate geometric ideas through an informal and intuitive approach.

In Spain, it was found that natural images influenced the development of a functional idea of projection, but that there was a lack of deep understanding about the role of properties in definition processes. This aspect was better in the case of the Kosovar students, as expected due to the German-Russian tradition. In general, the fact that similar results appear shows that the background of mathematical content knowledge is not enough to develop these concepts. None of the students in either country had a complete concept of transformation and structure as a function and they showed different figural images in each task.

Working group 4

The construct of variability is needed to understand Klein's meaning of invariance for associating geometries and transformations. It also means that simple visualization is not enough to understand such concepts. More emphasis on a wider sense of contextualization is also needed to discuss the functional features of transformations. Nevertheless, the Euclidean orientation of the Kosovar curriculum for lower secondary school gives the possibility that some students can relate their prior theoretical framework with their didactical purposes as future teachers. In fact, their comments were based not only upon intuitions about transformations, but also upon relating these to mathematical knowledge.

We also found that in both countries students had not enough time to develop powerful images about types of transformations, and we suggest the need for experiences of transformations other than isometries. During developmental activities, we could reinforce such a didactical research conjecture (Thaqi, 2009) by doing professional tasks in which we insist on invariance as a phenomenon. Representing transformations with function notation requires more abstract thinking and is crucial for understanding transformations as one-to-one mappings of the points of the plane. Our results are coherent with the emergent global/punctual dialectics (Jahn, 1998) as a semiotic conflict.

Teaching isometric and non-isometric transformations permits a richer study of oft-neglected topics, as well as investigation of topics heretofore not studied in the elementary school. For example, the shadow is an important but frequently neglected topic in elementary school geometry. These visual experiences can help students develop the ability to manipulate images mentally - the essence of spatial visualization.

A problem such as "What composition of transformations will move triangle A onto triangle B?" necessitates that students formulate and test hypotheses about sequences of transformations. This transformation approach makes geometry an appealing, dynamic subject that will develop both spatial visualization and also reasoning abilities. Properly designed activities could help students bridge the gap between informal experiences and later formal study of transformations. We found the importance of using interactive environments to analyze invariance (Harper 2003) and the need to visualize when doing global transformations.

APPENDIX

Some items of the questionnaire.

- Observe the typical Kosovar embroidery shown in the figure. There is a repeated part. Find it and draw it on the figure. Explain how to use transparent paper to show rotation as a transformation conserving size. What do you call transformations which conserve the size and shape of an object but change the position of the object?
- Observe the tiling in the following figure. There is one repeated part. Find it and draw it. Explain how to use transparent paper to show the translation as a transformation conserving size. What do you call transformations which conserve the size and shape of an object but change the position of the object?.
- Present three tasks you can use to explain symmetry and three examples to explain similarity (homothetic).
- Explain the meaning of the statement “Translation is a product of 2 symmetries”
- Transformation and movement are the same? Explain.

PRESERVICE TEACHERS AND THE LEARNING OF GEOMETRY

Lina Fonseca & Elisabete Cunha

School of Education of the Polytechnic Institute of Viana do Castelo, Portugal

The purpose of this paper is to share some ideas about an experience in teacher training. An issue that mathematics educators need to face is how to adequately work methodologies in different mathematical subjects to answer the needs of preservice teachers. Often they have little mathematical knowledge and reveal negative attitudes towards mathematics learning. In the discipline of Geometry we use a dynamic geometry application (DGA) and pattern tasks to work on geometrical concepts, to motivate preservice teachers to learn geometry and to encourage them to try to change their attitudes towards geometry.

Keywords: Teacher training, Geometric invariant, Pattern tasks.

INTRODUCTION

Nowadays in Portugal, according to Bologna, teacher training for Basic School (kindergarten to 6th grade) needs a master degree. All students who have completed secondary education and who have carried out successful tests of access to higher education can apply to these courses., although, we can have, as preservice teachers, students who have studied mathematics for twelve years and others who have only studied nine years. Besides their results, most frequently negative, they also expressed negative attitudes to learning Maths. In September 2010, a new maths programme for Basic Education (grade 1 to 9) (ME, 2007), will be generalized in all schools across our country. The goal of this document is to develop mathematical knowledge of all students in subjects like Numbers and Operations, Geometry and Measure, Algebra, Statistics and Probability, and, at the same time, to develop their capacity to solve problems, to communicate mathematically and to reason. These two issues set challenges for teacher training, such as deciding which type of methodologies to use with future teachers in ways in which they develop knowledge, capacities and attitudes which will allow them to work with children, in accordance with the new mathematics programme.

THEORETICAL PERSPECTIVES

International and national documents (e.g. NCTM, 2000; DEB, 2001) argue that during the compulsory education of mathematics students should acquire knowledge and understanding of facts and basic procedures of mathematics, develop their ability to solve problems, to investigate, to formulate, to test and to evaluate conjectures, to argue mathematically, to analyze mathematical arguments presented by teachers and peers, to communicate their mathematical ideas and options, thus contributing to the organization and systematization of their mathematical thought, should develop a positive attitude towards mathematics, and also to develop their autonomy at work.

Working group 4

On the same line the new Maths Programme for Basic Education (ME, 2007) maintains that all students should be able to identify and understand facts and basic procedures of Mathematics, develop a positive attitude towards mathematics and must be able to work with mathematical ideas in diverse representations. They should be able to communicate their ideas and interpret other's ideas, organizing and clarifying their mathematical thinking, to elaborate maths reasoning, to solve problems, to make connections, and be autonomous. Teacher educators need to address challenges created by the principles sustained in these documents.

Mathematics is usually considered as a science of patterns and the study of patterns could be a way of motivating the students to learn mathematics (Fonseca, 2009; Rivera, 2009). When we observe aspects that repeat themselves in a given situation, if you comprehend the means that produce the repetition, if you observe relations that remain invariant when everything around them changes, if they try to understand and explain the reasons behind those relations, students develop a more profound comprehension of the matters worked on. They create a more dynamic conception regarding mathematics and can say that the patterns are in fact subjacent to mathematics, particularly to geometry.

In the scope of geometry the resource on a DGA could help students gain many experiences focusing on invariants, which allows them to see the general through the individual and to establish, analyse and evaluate conjectures and mathematical relations (Chazan & Yerushalmy, 1998; Laborde, 1993; Villiers, 2000). We consider this important for students' motivation for the comprehension and explanation of the reasons that justify the relations detected, contributing to the treatment of proof in mathematics, helping them to understand the importance of justifications that explain (Hanna & Jahnke, 1996; Villiers, 1999). We use many images in geometry connected to geometric concepts and, sometimes preservice teachers try to build reasoning having as a base mistaken drawings and only visual appreciation, as for example the fact that 'building' a triangle in which the side lengths measurement is represented by consecutive whole numbers, 1, 2 and 3 cm, by analogy with rectangular triangle sides 3, 4 and 5 cm, without having addressed the question of impossibility. This is an example that sets them into the geometric paradigm I (GI) (Houdement & Kuzniak, 2006), when you aim them to use figures representing a class of mathematical objects, they establish general relations and build justifications, even though with a resource to local axiomatic, and therefore they would have to be on the geometric paradigm II (GII). The passage from one paradigm to the other and the paradigm recognition in which they work on turns out to be a difficulty, just as referred by Parzysz (2003).

Some authors (e.g. Malone, 1996; Hefendehl-hebeker, 1998) refer to the difficulty that preservice teachers show when embracing the ideas of the proposed reforms to mathematics teaching and that those difficulties are rooted in the way their prior mathematical education took place and highlighted the beliefs and the attitudes,

many times negative, that they relatively manifest to mathematics learning and in particular to geometry (Carrillo & Contreras, 2000; Pajares, 1992; Thompson, 1992). For that reason, we share Swars, Smith, Smith & Hart's (2009) opinion that defends the focus on beliefs of preservice teachers during the initial education when new programmes are proposed, as is happening at this moment in Portugal. Therefore in their teacher training courses, preservice teachers need to be successful through the same experiences, which we hope they will develop with their future students.

Thus, the next question is unavoidable: how do we train future teachers so they can develop the principles sustained by international documents and by the mathematical national curriculum?

THE EXPLORATORY STUDY

As in Portugal, according to the new maths program (ME-DGIDC, 2007), all students must develop some mathematical abilities, our problem is knowing "*How to work with preservice teachers in geometry in such a way that it is possible: (a) to develop their mathematical knowledge; (b) to develop their reasoning; (c) to develop a positive attitude toward mathematics; and (d) to gain more confidence in their capacities to do maths?*".

The exploratory study was oriented by the following general questions: (a) which geometric knowledge do preservice teachers display?; (b) which difficulties do preservice teachers display in solving the proposed tasks?; (c) which attitudes do preservice teachers display regarding geometry? We focus on an exploratory qualitative approach. To obtain more detailed information we selected two future teachers per class, from the ones that had only studied up to 9th grade in maths, that were available to participate in the study and were willing to share their difficulties. Five were between the ages of 20 and 23 and one was 33 years old. Data was collected through tasks, sorted out by all students, and even observations and semi-structured interviews with the six case students. The interviews were managed with the objective to know which geometrical knowledge was acquired, which difficulties they had in the task resolution and which attitudes they expressed regarding the study of geometry. Data analysis was in a holistic, descriptive and interpretative way.

Context and participants

The exploratory study was developed in the 2009/2010 school year in a semester course (16 weeks) of geometry, with a weekly workload of four hours. Topics worked in Geometry are: plane geometry, triangles, congruent triangles and similarity, area of polygons and of the circle, space geometry, polyhedron, regular polyhedron, surfaces and volumes. Of the 79 students involved, organized into three classes, only 8% had studied mathematics from kindergarten to grade 12, with the remaining having studied mathematics until the 9th grade. The majority of the students revealed negative attitudes toward mathematics and they were "afraid" to study geometry: "to say the word [GEOMETRY] is horrifying" (S1); "I never liked

Working group 4

geometry” (S4); “I never understood geometry” (S2); “I can’t see anything” (S3); “I can’t see the plans” (S3).

According to the profile of the preservice teachers we decided to organize the teaching of geometry in two dimensions: work with problem solving and a DGA to look for analogies and patterns. Thus, we tried to develop the geometrical knowledge of the preservice teachers, but also giving them the possibility of experiencing a different method of learning mathematics, focusing more on their work and, we expected it, to be more challenging.

Some tasks and discussion

To give students opportunities to develop their capacity, to notice patterns and aspects that remain invariant while everything around them is changing, we used a dynamic geometry application (Geometer'Sketchpad). We chose this application because it already existed at school, teachers were used to working with it and because in certain situations it becomes more “demanding” than other similar applications: for example, for the construction of an equilateral triangle or a square it is necessary to resort to geometrical properties and not only the use of the application.

Polygons were built with this tool and the students explored triangles and quadrilaterals properties, as the sum of the amplitudes of the internal angles, location of the notable points of the triangle and solved problems.

Task 1 - Construct a dynamic triangle. Measure the angles. What is the sum of the angles? Drag a vertex of the triangle. Does the sum remain the same? Formulate a conjecture on the sum of triangle's angles. Explain why the conjecture is true.

We began with this simple task using the DGA for exploration and students easily began to solve the task. The triangle's construction did not raise problems and the actual task indicated the following step “sum of the angles”. The conjectures arose immediately: “It's 180°”, “The sum is 180°”. Just as the actual task indicated, they dragged a vertex from the triangle and verified that the sum was unchangeable. We discussed if the invariant was characteristic of some type of triangle, having concluded that it was general. It was a property. When we asked why the conjecture presented was true they responded that the examples were there. They considered the examples sufficient, just as Kunimune, Fujita & Jones (2009) related. One of them said:

S1- We can see. Why do we need a proof?

Tutor – You know that but how do you explain the conjecture?

S1 – I see.

Tutor – Ok, you see. Tell me why this happens in triangles?

Other student goes on:

Working group 4

- S2 - We may make some copies of each of the angles and join them together.
Tutor - What do you think you will get?
S2 - ...
Tutor - Try.
S2 - ... [I get] an angle with 180° .

Students revealed difficulties in explaining why the conjecture was true. They were convinced that it was, by the experimentation carried out, but they did not know how to explain why. Even student S2 had to be helped in concluding his idea. After that, another explanation of this relation was discussed resorting to paper folding, justification that can be used with 5th and 6th grade students and a parallel was made with a proof that normally appear in maths text books in which we turn to the sketch of a straight line parallel to one of the triangle's sides passing through the opposite vertex. This proof (in GII) turned out to be more demanding to the students because they needed to resort to the various relations of congruency between angles. The preference for paper folding was unanimous because "this way I understand" (S1).

During this task the six case students revealed their knowledge regarding the types of triangles, internal angles and the straight angle. They had the capability to present the conjecture, although with some difficulties with mathematical language used, in understanding that the particular cases experienced did not explain and difficulties in the construction of an explanation for the conjecture, difficulties that confirm previous studies also carried out with preservice teachers, in spite of them being students with more mathematics education (Fonseca, 2009). They revealed expectation in the DGA exploration and showed confidence during the task and in the conjecture formulation, confidence that was conferred on them by DGA. The justification option by paper folding had an objective to captivate the student's attention and improve their attitude regarding justification constructions, that by their point of view is beyond their capacities "I can't justify... as intended ... many times I don't understand (the justifications) ... but I understood this one, I didn't know that we could do it like this" (S4).

Task 2 - Construct a dynamic triangle. Construct an external angle of the triangle. Measure the external angle. Try to relate this angle with the triangle's internal angles. Formulate a conjecture. Drag a vertex of the triangle. Does the conjecture remain the same? Explain why your conjecture is true.

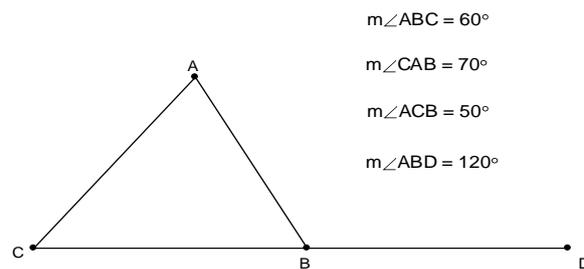

Students initiate the task by the construction of the triangle and the external angle's marking. Unlike the previous task, it was not suggested how to find the conjecture.

Various conjectures took place that not always revealed themselves to be valid, as for example, "the external (angle) is bigger (smaller) than the internal (adjacent angle)", "the external (angle) is bigger than the other (angles)" and that were abandoned with DGA's help, by the triangle's vertex dragging. We discussed the possibility of the external angle being congruent with the internal adjacent angle and the students

Working group 4

concluded, without difficulty, that it always happened with one of the angles, external or its internal adjacent angle was right. Other conjectures came up “both (internal and external adjacent angles) make a 180° angle”, “the four angles present more than 180° ”, but students reveal difficulties in relating the external angle with the internal ones to make the conjecture intended. After some exploration, students ran out of ideas to continue the work and teachers decided to make a suggestion – to observe the angle’s measurement values attentively, that they were obtaining, and to think of everything that they knew about triangles - which proved to be useful for the continuation of student’s work.

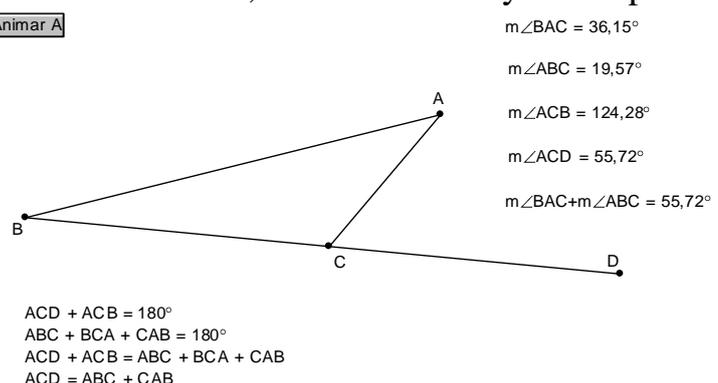

Observing the values produced by the application, some students, very few, noticed special cases (Fig. 1) they observed “120 is 70 plus 50.” Is that it?, they questioned. This aspect reveals the necessity to obtain the teacher’s agreement for the relations that they were detecting, which displays a low confidence attitude in their capacities to construct mathematical knowledge.

Using the **DGA** they tested if the relation maintained itself. When they verbalized the conjecture it already had been tested. The conjectures presented needed to be analyzed and rewritten. The following version was accepted “An external angle of a triangle is equal to the sum of the internal angles that has a different vertex”.

We want our students to understand that mathematical results always need an explanation. Why does this happen? This question was put forward. To focus the student’s attention, the teacher asks “What do you already know about angles and triangles?” The following aspects were related to, even with very little precise language: “The internal angles’ sum is 180° ”, “the external can be bigger, smaller or the same to the interior”, the bigger angle objects to the larger size“, “both (external and internal adjacent angles) create a 180° angle“. We discussed what could be useful and focused on relations implicating 180° .

Animar A

In each class some students, excluding case students, get an explanation accepted by their peers. It was an algebraic explanation (in GII) as shown below.

One student asked if he could do paper folding. We asked how he would like to do it and he explained “we can cut out two angles in the triangle and cover the external angle. It’s going to work” (S3). His idea was carried out with all the students. It is

Working group 4

understood as an explanation in GI.

During this task the six case students turned out to have knowledge regarding triangle properties, which they related to while they looked for an explanation for the relation they claimed. They had difficulties in formulating the conjecture, since it was not suggested by the task. It was necessary to guide the observation carefully by the values provided by the DGA to be able to conjecture although they showed to have difficulties with the mathematical language being used. They continued to be “trapped” into the particular cases tested and revealed difficulties in proof, to explain the conjecture, difficulties that confirm previous studies also carried out with preservice teachers (Fonseca, 2009). They continued to reveal expectations in the DGA exploration, but as it was referred to by various students “I thought that it would be easier, but it helps” (S2).

After these tasks were explored tasks relating to the sum of the internal angles of a quadrilateral, pentagon, hexagon, ... guided by teachers, students formulated a conjecture on the sum of the angles of a n-polygon. Some tasks follow each other, and students said that they had never worked like this in geometry.

In order to enhance their creativity, students were asked to prepare and submit to the class a theme associated with the areas and volumes of solids. Each class was divided into five groups and the subjects were randomly selected. To carry on with their work students needed to present exercises and problems, among other things. One of the items was tied to the posing of problems, in this case from the scope of geometry, as one of the aspects is referred to as an enhancer of creativity (e.g. Meissner, s/d).

Task 3 - For your geometric theme (cubes and quadrilateral prisms, other prisms, cylinder, pyramids, cone) present:
(a) Examples of the solids in the world; (b) Solid Planning; (c) Formulas (areas and volume); (d) Exercises /problems.

The students had teacher support in their study and topic organization. Issues related to proposals intended to be present and would be shared among all students via a digital platform, which were discussed. During preparation or during work in the classroom, one of the most common questions was related with the need to use different formulas for calculating the surface areas of the solids. This fact frightened the students. The real need for all those formulas was discussed. Most of the students relied on their necessity, with some voices questioning this option, saying that they already knew the formula to calculate the areas of squares, rectangles, triangles, ... and knew that they had just to think about it and apply them.

They [math teachers] always asked me to do as I was taught and not otherwise. I could do it but it was wrong. Now in geometry I realized that I could do it in a different way. We just need to explain and do things right (S3).

I didn't know that I knew maths (S4).

FINAL REMARKS

Based on data collected, we can say that the case students revealed:

(a) basic geometry content knowledge, as types of angles, triangles, quadrilaterals, polygons, solids, regular convex polyhedrons, geometrical relations in triangles and some formulas for the area and volume calculation. They revealed the ability to formulate conjectures in simple situations, in starting to communicate their reasoning and in certain situations they showed an ability to reason correctly and in an autonomous way. One of the paradigmatically cases was the student S4. In questions involving the area and volume calculations he said:

S4 - I don't know the formulas. I don't know how to do it.

Tutor - Which formulas don't you know?

S4 - The lateral and total areas.

Tutor- Find another way. Do you know any formulas?

S4 - I do, but not these ones.

Tutor – Can you use the ones you know?

S4 – Can I? I don't have to use these ones?

Tutor- What do you think?

S4- I don't know.

Tutor- Try.

This challenge allowed him to solve the particular questions that occurred and allowed him to understand that the formulas that “they didn't know” could be derived from the ones they knew. This was an episode that caused a change of attitude in this student regarding geometry, after that he was not so preoccupied with what he did not know, but in reason to use the knowledge he possessed. This change happened because the student shared his frustration, the teacher had the opportunity to challenge and the student accepted the challenge. Even in teacher training environments where the teacher intends that the students are comfortable to share their doubts, many times they do not and opportunities for change are lost. This is an aspect that, in our opinion, should continue to deserve the reflection of teacher educators.

(b) difficulties, as in visualizing, using mathematical language, conjecture in more complex situations, reason and making proofs, justification /explanation.

(c) commitment, striving themselves to solve proposed tasks, although showing very little confidence in their reasoning capacities and almost always hoping for the teacher's guarantee, regarding the quality of their work. In case students signs of changing of their negative attitudes to geometry were detected; changes were influenced by their responsiveness to the adopted methodologies. To develop

students' confidence in their capacities seems to be a path to the improvement of their knowledge.

After this exploratory study we conclude that most preservice teachers revealed that they understood some facts and basic geometry procedures; they worked with diverse representations (iconic, symbolic, ...); they began to communicate their reasoning; they found analogies and solved some problems. However, they revealed many difficulties in visualizing, reasoning and explaining their reasoning, in making connections between different mathematical topics, in being confident in their capacities, because most of them were always afraid of making mistakes, and being autonomous. Most of the time students need teacher support to validate the quality of their work. They said that this was a different way to learn geometry.

As mathematics teacher educators we consider that the options taken revealed themselves to be positive for the students, but we are conscious that we have a long way to go, to learn, to experiment and to reflect on our options when we decided on methodologies and tasks to present and challenge our preservice teachers, but our goal is to make them become more knowledgeable and confident in mathematics.

This research study examined the fit of various models regarding geometrical figure understanding and its relation with proof. Data were collected from 457 middle and high school students. Structural equation modelling affirmed the existence of nine first-order factors revealing the differential effect of perceptual and recognition abilities, the ways of figure modification, construction of a figure and proof. The three second-order factors which represented the perceptual, operative and sequential apprehension were regressed to a third-order factor that corresponded to the geometrical figure understanding. Results indicated that geometrical figure understanding has a strong effect on logic apprehension. Data analysis provided support for the invariance of this structure across the two educational levels.

INTRODUCTION AND THEORETICAL FRAMEWORK

Fischbein (1993) called geometrical figures “figural concepts” since these entities are simultaneously concepts and spatial representations. Generality, abstractness, lack of material substance and ideality reflect conceptual characteristics. A geometrical figure also possesses spatial properties like shape, location and magnitude. In this symbiosis, it is the figural facet that is the source of invention, while the conceptual side guarantees the logical consistency of the operations (Fischbein & Nachlieli, 1998). The double status of external representation in geometry often causes difficulties to students when dealing with geometrical problems due to the interactions between concepts and images in geometrical reasoning (e.g. Mesquita, 1998). Duval (1995, 1999) distinguishes four apprehensions for a “geometrical figure”: perceptual, sequential, discursive and operative. To function as a geometrical figure, a drawing must evoke perceptual apprehension and at least one of the other three. Each has its specific laws of organization and processing of the visual stimulus array. Particularly, perceptual apprehension refers to the recognition of a shape in a plane or in depth. In fact, one’s perception about what the figure shows is determined by figural organization laws and pictorial cues. Perceptual apprehension indicates the ability to name figures and the ability to recognize in the perceived figure several sub-figures. Sequential apprehension is required whenever one must construct a figure or describe its construction. The organization of the elementary figural units does not depend on perceptual laws and cues, but on technical constraints and on mathematical properties. Discursive apprehension is related with the fact that mathematical

properties represented in a drawing cannot be determined through perceptual apprehension. In any geometrical representation the perceptual recognition of geometrical properties must remain under the control of statements (e.g. denomination, definition, primitive commands in a menu). However, it is through operative apprehension that we can get an insight to a problem solution when looking at a figure. Operative apprehension depends on the various ways of modifying a given figure: the mereologic, the optic and the place way. The mereologic way refer to the division of the whole given figure into parts of various shapes and the combination of them in another figure or sub-figures (reconfiguration), the optic way is when one made the figure larger or narrower, or slant, while the place way refer to its position or orientation variation. Each of these different modifications can be performed mentally or physically, through various operations.

Recently, some researchers (Deliyianni, Elia, Gagatsis, Monoyiou, & Panaoura, 2009; Elia, Gagatsis, Deliyianni, Monoyiou, & Michael, 2009) made an effort to verify empirically some of the cognitive processes underline the geometrical figure understanding proposed by Duval (1995, 1999). Elia et al. (2009) gave emphasis on the cognitive processes involved in operative apprehension. Furthermore, Deliyianni et al. (2009) affirmed the existence of a third-order model that involved six first-order factors indicating the differential effect of perceptual and recognition abilities, the ways of figure modification and measurement concept, three second-order factors representing perceptual, operative and discursive apprehension and a third-order factor that corresponded to the geometrical figure understanding. Both studies also suggested the invariance of this structure across elementary and secondary school students. Keeping in mind the underlying cognitive complexity of geometrical activity (Duval, 1995) and the transition problem from one educational level to another universally (Mullins & Irvin, 2000) the main aim of this research study was to confirm a comprehensive theoretical model concerning middle and high school students' geometrical figure understanding which involves the whole spectrum of geometrical figure apprehension types, i.e. perceptual, discursive, sequential and operative apprehension and the relation between their corresponding cognitive processes. It should be mentioned that concerning discursive apprehension Harada, Gallou-Dumiel and Nohda's (2000) conceptualization is used. Harada et al. (2000) indicated that the hypothetical-deductive proof is produced by this kind of apprehension. In fact, the discursive apprehension or logic apprehension, the term which is used in the present paper, is produced by inferences based on definitions and valid procedures of proof.

HYPOTHESES AND METHOD

In the present paper the following hypotheses were examined: (a) There is a relation between students' geometrical figure understanding and their performance in proof tasks, (b) Perceptual, sequential and operative apprehension influence middle (grade

Working group 4

9) and high (grade 10) school students' geometrical figure understanding, (c) Perceptual and recognition abilities have a differential effect on perceptual apprehension, (d) The three ways of figure modification (i.e. mereologic, optic and place way) have a differential effect on operative apprehension, (e) The abilities to construct and describe a figure's construction differentially affect sequential apprehension, (f) Inferences based on definition and procedures for proof differentially affect discursive (logic) apprehension, (g) There are similarities between middle and high school students in regard with the structure of their geometrical figure understanding and (h) Differences exist in the geometrical figure understanding performance of middle and high school students.

The study was conducted among 457 students, aged 15 to 16, of middle (Grade 9) and high (Grade 10) schools in Cyprus (252 in Grade 9, 205 Grade 10). Taking into account, Duval's (1995, 1999) apprehensions for a "geometrical figure" the a priori analysis of the test (Appendix) that was constructed in order to examine the hypotheses of this study is the following:

1. The first group of tasks includes task 1 (PE1a, PE1b, PE1c, PE1d, PE1e, PE1f, PE1g), 2 (PE2a, PE2b, PE2c, PE2d, PE2e, PE2f) and 3 (PE3a, PE3b, PE3c). These tasks examine students' perceptual apprehension of a geometrical figure. The task 1 examines students' ability to name figures. The tasks 2 and 3 examine their ability to discriminate and recognize in the perceived figures several subfigures.
2. The second group of tasks includes task 4 (OP4), 5 (OP5), 6 (OP6), 7 (OP7), 8 (OP8) and 9 (OP9). These tasks examine students' operative apprehension of a geometrical figure. The tasks 4 and 5 require a reconfiguration of a given figure, the tasks 6 and 7 an optic way of modification, while the tasks 8 and 9 demand the place way of modifying two given figures in a new one in order to be solved.
3. The third group of tasks consists of the tasks 10 (SE10), 11 (SE11), 12 (SE12) and 13 (SE13) that correspond to sequential figure apprehension. The tasks 10 and 11 require students to construct a figure, while the tasks 12 and 13 investigate students' ability to describe the construction of a figure.
4. The fourth group of tasks includes the verbal problems 14 (LO14), 15 (LO15), 16 (LO16), 17 (LO17), 18 (LO18) and 19 (LO19) that correspond to logic apprehension. On the one hand, the verbal problems 14, 15, 16 and 17 demand inferences based on definitions in order to be solved. On the other hand, tasks 18 and 19 require inferences based on procedures for proof for their solution.

Right and wrong or no answers to the tasks were scored as 1 and 0, respectively. The results concerning students' answers to the tasks were codified with PE, OP, SE and LO corresponding to perceptual, operative, sequential and logic apprehension (proof tasks), respectively, followed by the number indicating the exercise number.

Confirmatory factor analysis (CFA), by using the EQS program, was used to explore the hypotheses about the structural organization of the various dimensions investigated here (Bentler, 1995). The tenability of a model can be determined by using the following measures of goodness-of-fit: χ^2 , CFI and RMSEA. The following values of the three indices are needed to hold true for supporting an adequate fit of the model: $\chi^2/df < 2$, $CFI > 0.9$, $RMSEA < 0.06$. A multivariate analysis of variance (MANOVA) was also performed to examine if there were statistically significant differences between middle and high school students concerning their performance in the various dimensions of the figure understanding.

RESULTS

Confirmatory factor analysis model. A series of CFA models were tested and compared. Specifically, the first model involved only one first-order factor associated with all the tasks. This model was the most parsimonious, it disregarded though the related theory and past empirical work which pointed out that different cognitive processes are needed in order to solve: perceptual, operative, sequential and logic apprehension tasks. The fit of this model was poor [$CFI= 0.52$, $\chi^2(702)=3933.98$, $RMSEA= 0.10$]. The second model that was constructed and tested involved four first-order factors corresponding to the perceptual, operative, sequential and discursive apprehension and one second-order factor on which all the first-order factors were regressed. A chi-square difference test indicated a significant improvement in fit between the first and the second model [$\Delta\chi^2(43) = 1505.09$, $p < 0.001$] due to the second-order factor inclusion. However, the fit of the second model was also poor [$CFI= 0.81$, $\chi^2(459) = 1682.99$, $RMSEA= 0.08$].

The third model took into account Deliyianni's et al. (2009) findings and moved a step forward involving sequential apprehension dimension, the three ways of figure modification in operative apprehension dimension and the deductive reasoning dimension. A chi-square difference test indicated a significant improvement in fit between the second and the third model [$\Delta\chi^2(52) = 611.83$, $p < 0.001$]. Besides, the fit of the third model was acceptable [$CFI= 0.91$, $\chi^2(511) = 1071.162$, $RMSEA= 0.05$]. Even though the third model fitted the data reasonably well, the need to confirm that this was the best fitting model arose. Taking into account that visualisation is thought to be useful to some aspects of mathematical proof (Hanna & Sidoli, 2007), a fourth model was tested. Its fit was acceptable [$CFI= 0.94$, $\chi^2(444) = 815.08$, $RMSEA= 0.04$], as well. A chi-square difference test indicated a significant improvement in fit between the third and the fourth model [$\Delta\chi^2(67) = 256.08$, $p < 0.001$] due to the causal relation between geometrical figure understanding and logic apprehension inclusion. The first, second and third tested models are presented in Figure 1. Factor loadings are omitted.

Working group 4

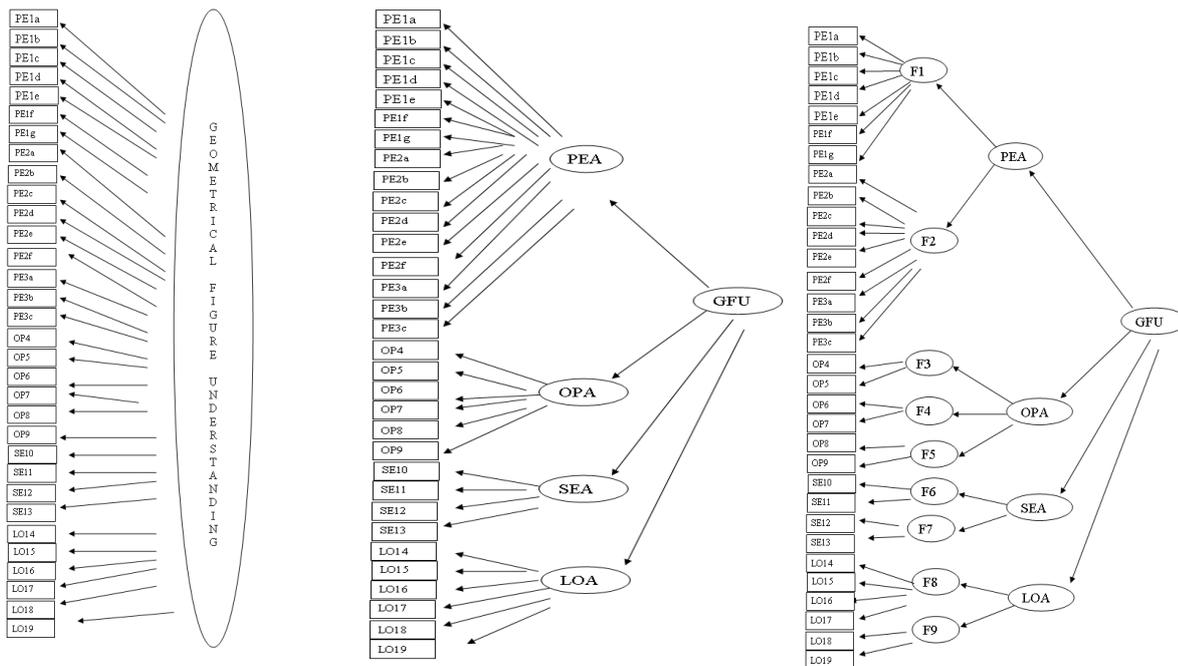

Figure 1. The first, second and third CFA tested models

Figure 2 shows the results of the elaborated model, which fitted the data reasonably well. The first, second and third coefficients of each factor stand for the application of the model in the whole sample (Grade 9 and 10), middle (Grade 9) and high (Grade 10) school students, respectively. Particularly, the third-order model which is considered appropriate for interpreting geometrical figure understanding, involves nine first-order factors, four second-order factors and one third-order factor. The four second-order factors correspond to the geometrical figure perceptual (PEA), operative (OPA), sequential (SEQ) and logic (LOA) apprehension, respectively. Perceptual, operative and sequential apprehensions are regressed on a third-order factor that stands for the geometrical figure understanding (GFU). Therefore, it is suggested that the type of geometric figure apprehension does have an effect on geometrical figure understanding, verifying our second hypothesis. On the second-order factor that stands for perceptual apprehension the first-order factors F1 and F2 are regressed. The first-order factor F1 refers to the perceptual tasks, while the first-order factor F2 to the recognition tasks. Thus, the findings reveal that perceptual and recognition abilities have a differential effect on geometrical figure perceptual apprehension (hypothesis c). On the second-order factor that corresponds to operative apprehension the first-order factors F3, F4 and F5 are regressed. The first-order factor F3 consists of the tasks which require a modification of a given figure in a mereologic way. The tasks which demand an optic way of modifying a given figure compose the first-order factor F4 and the tasks demanding the place way of modifying two given figures in a new one in order to be solved constitute the first-order factor F5. Therefore the results indicate that the ways of figure modification have an effect on operative figure understanding (hypothesis d). The first-order factors F6 and F7 are regressed on the second-order factor that stands for sequential

Working group 4

apprehension. The first-order factor F6 refers to the tasks which demand the construction of a figure, while the first-order factor F7 consists of the tasks in which the description of a figure's construction is needed. Thus, the results indicate that the two abilities differentially affect sequential apprehension (hypothesis e). According to the factor loadings, operative apprehension is more strongly related with geometrical figure understanding than perceptual and sequential apprehension.

On the second-order factor that stands for logic apprehension the first-order factors F8 and F9 are regressed. The first-order factor F8 refers to the tasks which require inferences based on definition, while the first-order factor F9 to the tasks which inferences based on processes of proof are needed. Thus, the findings reveal that the kind of inferences has a differential effect on this kind of apprehension (hypothesis f). Loadings indicate that geometrical figure understanding have a strong effect on logic apprehension (hypothesis a).

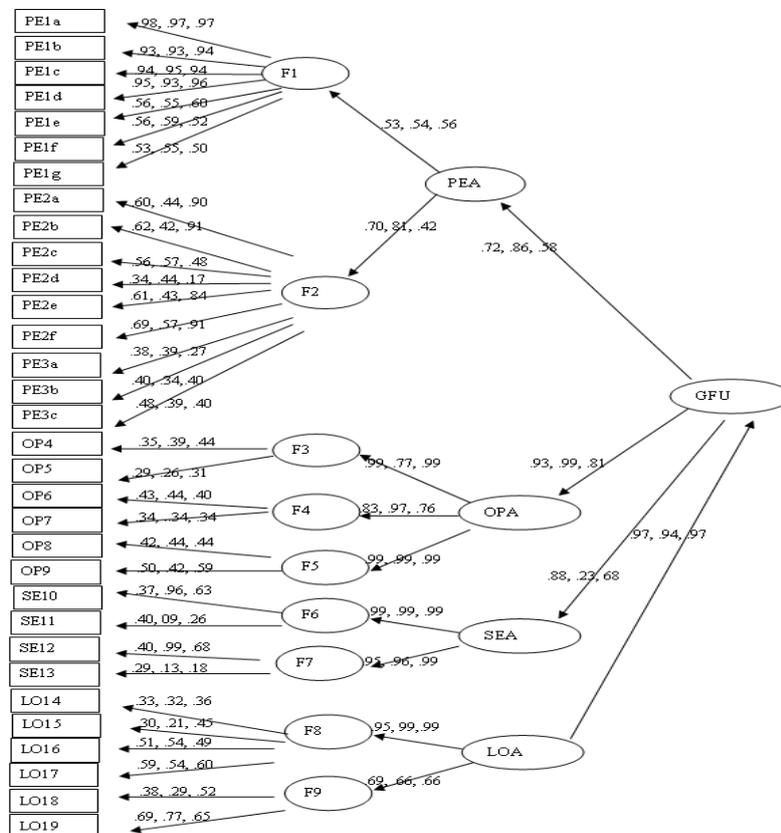

Figure 2. The CFA model of the geometrical figure understanding in relation with proof processes.

To test for possible similarities between the two educational levels concerning their geometrical figure understanding the proposed three-order factor model is validated for middle and high school students separately. The fit indices of the model tested for both middle [$\chi^2(445) = 658.59$, CFI= 0.94, RMSEA= 0.04] and high school students are acceptable [$\chi^2(438) = 659.61$, CFI= 0.94, RMSEA= 0.05]. Thus, the results are in line with our hypothesis that the same geometrical figure understanding structure

Working group 4

holds for both the middle and the high school students. It is noteworthy that some factor loadings are higher in the group of the high school students suggesting that the specific structural organization potency increases across the ages. Besides, the factor loading in grade 10 regarding perceptual apprehension is lower than in grade 9, while the factor loading for sequential apprehension is higher than the corresponding in grade 9. This finding indicates that as students grow up are based more on mathematical properties and less on perceptual laws and cues.

The effect of students' educational level. Table 1 presents the means and the standard deviations for perceptual, operative, sequential and logic apprehension in the two educational levels. Overall, the effect of students' educational level is significant (Pillai's $F_{(4, 452)}=7.03$, $p<0.001$). In particular, the mean value of high school students in geometrical figure perceptual apprehension (PEA) is statistically significant higher ($F_{(1,452)}=16.94$, $p<0.001$) than the mean value of middle school students. Similarly, the mean value of high school students in operative apprehension tasks (OPA) is statistically significant higher ($F_{(1,452)}=14.26$, $p<0.001$) than the mean value of middle school students. In the same way, the mean value of high school students' performance in sequential apprehension tasks (SEA) is statistically significant higher in comparison with middle school students' performance ($F_{(1,452)}=11.88$, $p<0.001$). Even though, the performance of high school students in logic apprehension tasks (LOA) is also higher than the performance of middle school students this difference is not statistically significant ($F_{(1,452)}=3.83$, $p=0.05$). Therefore, the findings verify the last hypothesis stating that differences exist in the performance of middle and high school students. In particular, high school students' performance is higher in all the types of geometrical figure apprehension.

Educational Level	PEA		OPA		SEA		LOA	
	\bar{X}	SD	\bar{X}	SD	\bar{X}	SD	\bar{X}	SD
Middle	0.78	0.21	0.59	0.23	0.08	0.18	0.27	0.21
High	0.86	0.20	0.67	0.24	0.14	0.21	0.31	0.25

Table 1: Means and standard deviations in the different dimensions of the geometrical figure apprehension for middle and high school students

CONCLUSIONS

This study examined the fit of various models regarding geometrical figure understanding and its relation with proof processes. Using structural equation modelling we constructed and verified a comprehensive model for geometrical figure understanding. Moving a step forward in relation with previous studies (e.g. Elia et al., 2009; Deliyianni et al., 2009) which verified Duval's (1995, 1999) taxonomy, the proposed model involves the whole spectrum of geometrical figure apprehension

types and the relation between their corresponding cognitive processes with cognitive processes concerning proof.

According to the results, the three second-order factors which stand for perceptual, operative and sequential apprehension are regressed to a third-order factor that corresponds to the geometrical figure understanding. Results suggest that geometrical figure understanding has a strong effect on students' performance in proof tasks. This is in line with the findings of previous research studies (e.g. Hanna & Sidoli, 2007; Giaquinto, 2007) that suggested that there is a potential contribution of visual representations to mathematical proof. Findings reveal also that operative apprehension is the one which contributes the most to geometrical figure understanding. Taking into account that visualization consists only operative apprehension (Duval, 1999) the important role of this kind of apprehension confirms empirically Duval's (1999) opinion that there is not understanding in geometry without visualization. The specific result indicates also that teaching and learning should give emphasis in this kind of apprehension since visualization is not primitive. In fact, the use of visualization requires specific training, specific to visualize each register (Duval, 1999). However, the model points out the important role of the other types of geometrical figure apprehension, as well, taking into account that even though coordination between them is needed each one is distinct from the other (Duval, 1999). Besides, findings affirmed the existence of nine first-order factors revealing the differential effect of perceptual and recognition abilities and the ways of figure modification, construction and proof. Thus, the results verified Duval's (1995, 1999) and Harada's et al. (2000) categorization, respectively.

In addition to extent our knowledge about students' geometrical figure understanding, this study may give valuable information to curriculum designers and teachers of both middle and high school education. The elaborated model offers teachers a framework of students' thinking while solving a wide range of geometrical tasks in a systematic manner within and between the two educational levels. Therefore, the proposed framework may be used as a tool in mathematics instruction and designing tasks on geometry in both middle and high school. The framework of this study appears to be useful from an assessment perspective, as well. It may provide teachers with valuable and specific information on students' thinking in geometry based on prior knowledge and enable them to enhance this thinking by giving appropriate support through the tasks focused on the competences and cognitive processes for the geometrical figure understanding and the proof.

Concerning age, it is important to stress that the structure of the processes underlying the geometrical figure understanding in relation with proof processes was invariant across the two age groups tested here. These findings enhance the validity of the proposed framework and support its potential to coherently describe and predict students' understanding in geometry irrespectively of their grade, even during the transitional phase from middle to high school. However, findings reveal differences

Working group 4

between middle and high school students' performance. In fact, the results provide evidence for the existence of three forms of elementary geometry, proposed by Houdement and Kuzniak (2003). We may assume that in this research study, middle school teaching is mainly focused on Geometry I (Natural Geometry) that is closely linked to the perception, is enriched by the experiment and privileges self-evidence and construction. On the other hand, high school teaching gives emphasis to Geometry II (Natural Axiomatic Geometry) that it is closely linked to the figures and privileges the knowledge of properties and demonstration. As a result, in the case of middle school students geometrical figure is an object of study and of validation, while in the case of high school students geometrical figure supports reasoning and "figural concept" (Fischbein, 1993). However, the knowledge produced by quantitative research studies might be too abstract and general for direct application to specific local situations, contexts, and individuals. For this reason, further research is needed to evaluate the feasibility of using this framework for developing effective instructional programs for the teaching of geometry in regular classroom situations in middle and high education.

ACKNOWLEDGE

This paper is a part of the research project "Ability to Use Multiple Representations in Functions and Geometry: The Transition from Middle to High school" (0308(BE)/03) founded by the Research Promotion Foundation of Cyprus

Alain Kuzniak**

*University of Cyprus, ** Université Paris Diderot, France

This research study examined and compared 109 9th graders' and 103 10th graders' behaviour in proof tasks, giving emphasis on their understanding of proof and the influence of the nature of the geometrical figure, either as an object or as an illustration. The results indicated differences, but also similarities between students of the two grades. Students were categorized into three levels according to their proof understanding, whereas the importance of the geometrical figure as a heuristic tool for proof was revealed.

THEORETICAL FRAMEWORK

Nowadays, the development of a sense of proof constitutes an important objective of Mathematical Education. There seems to be a general trend towards including the theme of proof in the curriculum (Mariotti, 2006). Marrades and Gutiérrez (2000) defined proof as any justification which satisfies the requirements of abstraction, rigor, language, etc. demanded by professional mathematicians to accept a mathematical statement as valid within an axiomatic system. Mathematical proof in a wide sense includes formal proofs but also any attempt made by students to convince themselves, the teacher or other students of the truth of a mathematical statement or conjecture by means of explanations, verifications or justifications (Fiallo & Gutiérrez, 2007).

Even among mathematicians there is a diversity of opinion regarding the role and functions of proof (Healy & Hoyles, 2000). According to Marrades and Gutierrez (2000) the main objectives of mathematical proof are to verify or justify the correctness of a statement, to illuminate or explain why a statement is true, to systematize results obtained in a deductive system (a system of axioms, definitions, accepted theorems, etc.), to discover new theorems, to communicate or transmit mathematical knowledge and to provide intellectual challenge to the author of a proof. For Mariotti (2006) the purpose of proof is validation. Based on de Villiers (2002) some of the functions of proofs are: explanation, discovery, communication, intellectual challenge and systematisation.

¹⁰ This paper is in the context of the research project "Ability to use multiple representations in Functions and Geometry: The Transition from Middle to High school" of the Research Promotion Foundation of Cyprus (ΙΠΕ) [ΑΝΘΡΩΠΙΣΤΙΚΕΣ/ΠΑΙΔΙ/0308(BE)/03].

Working group 4

Duval (2000) considers that the cognitive processes underlying the understanding of a mathematical proof require students to realise that a valid reasoning can produce intrinsically an evidence of necessity and become aware of the discrepancy between a valid reasoning and a non-valid reasoning. Kunimune, Fujita and Jones (2008) examined students' understanding of proof in terms of the 'Generality of proof' and the 'Construction of proof'. Considering these two aspects, they proposed three levels of understanding. In Level I students consider experimental verifications are enough to demonstrate that geometrical statements are true. In Level II students understand that proof is required to demonstrate geometrical statements are true and finally in Level III students can understand simple logical chains between theorems.

As for the understanding of the valid reasoning functions, the learner have to work in another register than language and to come back to linguistic expression, since geometry involves the mixing of two registers: the figure register in order to 'see' and the natural language register in order to 'explain' (Duval, 2000). According to Hanna (2000) diagrams and other visual aids have been used as facilitators of understanding and as heuristic accompaniments to proof, inspiring both the theorem to be proved and approaches to the proof itself.

The nature of external representations in geometry, either as an object or as an illustration, was examined by Xistouri, Nicolaou, Koukkoufis and Gagatsis (2005). According to Mesquita (1998), an external representation has the nature of an *object* when it is possible to infer geometrical relationships from the construction of the figure that may be used in geometrical reasoning and proof and when the visual perception of the figure is consistent with the verbal statements of the problem. On the contrary, when the external representation has the nature of an *illustration*, it is then impossible to directly extract a geometrical relationship from the construction of the figure, the figure seems to 'mislead' and the visual perception of the figure is in contradiction within the verbal statements.

Based on the above the purpose of this study was to examine and compare Grade 9 and Grade 10 students' geometrical proof – problem solving ability. In particular, we focussed on the following: 1) *The differences between Grade 9 and Grade 10 students' behavior in geometrical – proof tasks*, 2) *Students' understanding about the geometrical proof*, 3) *The impact of the geometrical figure on students' proving ability according to its nature: as an 'object' and as an 'illustration'*.

METHOD

The study was conducted among 109 9th graders and 103 10th graders of mixed mathematical ability, randomly selected from secondary schools in Cyprus. The test that examined students' geometrical proof – problem solving ability consisted of 8 proof tasks: 2 proof tasks whose solution is '*based on definition*' (VEde1, VEde2) and 6 proof tasks '*based on procedures*' (VEp), according to Harada's, Gallou –

Dumiel's and Nohda's (2000) categorization of proof. The '*based on procedures*' proof tasks were distinguished into two special categories of tasks:

1. Tasks that examined the impact of the nature of the geometrical figure (Mesuita, 1998) in students' geometrical proof – problem solving ability. There were two sets of corresponding tasks in which the first task included a figure functioning as an '*object*' (VEpo1 and VEpo2) and the second a figure functioning as an '*illustration*' (VEpi1 and VEpi2)
2. The second category was comprised of a set of corresponding tasks, based on Kunimune et al. (2008), examining the '*Generality of proof*'. In particular, the tasks included three different types of proof: an empirical proof (VEp1m2, VEp2m2), a semi – empirical proof (VEp1m1, VEp2m1) and a formal proof (VEp1m3, VEp2m3). Students had to declare whether they accepted each type as a proof.

Representative samples of the tasks used in the test appear in the Appendix.

For the analysis of the collected data, the hierarchical clustering of variables and Gras' implicative statistical method has been conducted using the software C.H.I.C. (Bodin, Coutourier, & Gras, 2000). The similarity diagrams produced allow for the arrangement of students' responses to the tasks into groups according to their homogeneity. This aggregation may be indebted to the conceptual character of every group of variables. The implicative diagrams contain implicative relations, which indicate whether success to a specific task implies success to another task related to the former one.

RESULTS

Grade 9 students' behaviour according to the similarity diagram

The similarity diagram of the 9th graders' responses to the tasks of the test (Figure 1) is divided into two similarity clusters. In the first similarity cluster two subgroups are distinguished. In specific, the first subgroup is comprised of procedure proof tasks (VEpo1, VEpi2, VEpo2, VEp1m3 and VEpi1) and one definition proof task (VEde1). This definition task has a significant and strong relation with the second procedure task that includes a figure as an illustration (VEpi2). In the second similarity group of the similarity diagram the variables concerning the acceptance of the semi – empirical proof in the two corresponding tasks (VEp1m1 and VEp2m1) are significantly connected with the solution of the second definition proof task of the test (VEde2). These three variables are significantly related with the acceptance of the formal proof in the second procedure task of this type (VEp2m3).

From the 9th graders' similarity diagram concerning the nature of the geometrical figure we notice that the tasks in which the figure functions as an illustration are involved in significant relations. This is indicative of the fact that 9th graders behavior during the solution of proof tasks is influenced by the nature of the

Working group 4

geometrical figure and specifically when the geometrical figure functions as an illustration. The second subgroup consists of two variables that are related to the acceptance of an empirical proof in a set of corresponding tasks (VEp1m2 and VEp2m2).

We also notice that as regards the acceptance of the three types of proof, there is a distinct group of students. In this group belong students who accept the empirical proof (VEp1m2 and VEp2m2) ($\bar{X}=0.11$, $SD=0.22$). Furthermore, the significant relation between the variables VEp1m1 and VEp2m1 allows us for the consideration of a second group of students, those who accept the semi – empirical proof ($\bar{X}=0.10$, $SD=0.21$). The definition tasks are located into different clusters, showing that students' behavior is not differentiated in definition and procedures tasks.

However there seems to be a relation between students of this group and some students of the formal proof group. This might be indicative of some common characteristic between these two groups. The two variables representing the formal proof are separated into two different similarity clusters. This is indicative of a not stable behavior of students yet for this type of proof tasks. The acceptance of the formal proof in the first task is connected with the variables concerning the nature of the geometrical figure. Thus we can infer that the nature of the geometrical figure affects, at a degree, the 9th graders proving ability. Particularly it seems that students who accept the formal proof ($\bar{X}=0.07$, $SD=0.20$), are more able to overcome the negative influence of the figure functioning as an illustration.

Grade 10 students' behaviour according to the similarity diagram

Two similarity clusters are identified in Figure 2. Cluster 1 consists of two subgroups. The first subgroup includes a procedure proof task accompanied with a figure operating as an object (VEpo1) linked to the second definition proof task (VEde2). In the second subgroup important relations are observed between some variables. In particular, there is a connection between the variables VEp1m3 and VEp2m3, indicating students' stable behavior in accepting the formal proof in the two corresponding tasks. These two variables are also connected with a definition proof task (VEde1). Another significant relation is formed between the variables VEp2 and VEpi2, which concern two corresponding procedure proof tasks, having a figure as an object and as an illustration respectively. This important relation indicates that the presence of the geometrical figure as an illustration does not negatively influence students' behavior in this proof task, since their behavior remains stable in the two corresponding tasks. The two variables concerning the first task that examines the nature of the geometrical figure (VEpo1 and VEpi1) are separated. The variable that concerns the figure as an illustration (VEpi) is linked with variables VEp2 and VEpi2. In the second cluster two subgroups are also found. The first subgroup is formed by the two variables concerning the acceptance of a semi – empirical proof (VEp1m1 and VEp2m1). The second subgroup is

Working group 4

comprised of the two variables related to the acceptance of an empirical proof (VEp1m2 and VEp2m2).

In the similarity diagram of the 10th graders three distinct groups of students are identified. There are students who accept the empirical proof ($\bar{X}=0.14$, $SD=0.27$), students who accept the semi – empirical proof ($\bar{X}=0.22$, $SD=0.33$) and students that accept the formal proof ($\bar{X}=0.07$, $SD=0.20$). The first two groups are situated in the same similarity cluster, indicating that students of these two groups have many common characteristics in their proving behavior. The significant relations of this group with the variables representing the role of the geometrical figure leads us to the conclusion that the students that are mostly able to overcome the negative influence of the geometrical figure as an illustration are those who are also able to recognize and accept the formal proof. Moreover, the location of the definition tasks in the same similarity cluster shows a more stable behavior of students in these tasks, but again no differentiation related to procedure proof tasks.

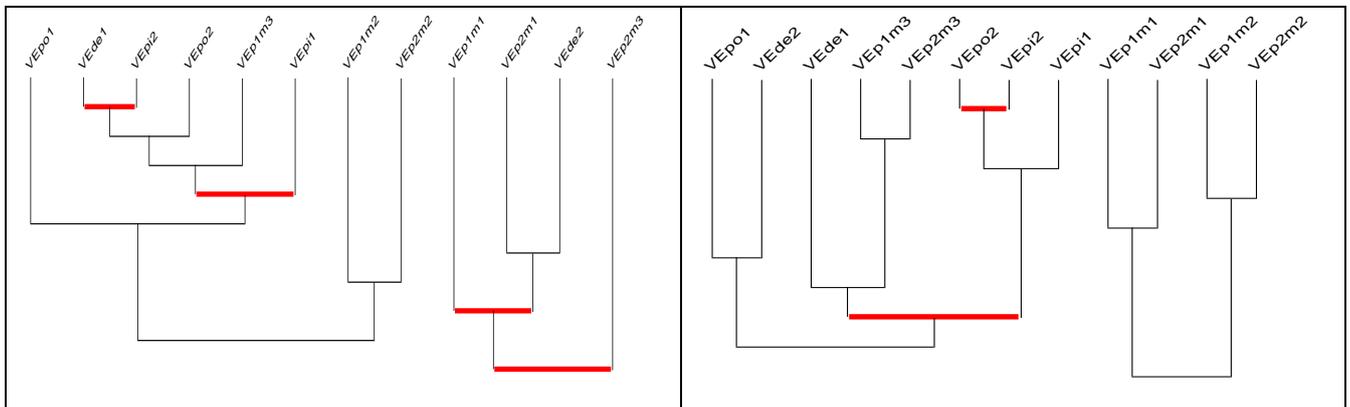

Figure 1: Similarity diagram for Grade 9 students

Figure 2: Similarity diagram for Grade 10 students

Grade 9 and 10 students' behaviour according to the implicative diagrams

In the 9th graders' implicative diagram (Figure 3) two implicative chains are formed. The first implicative chain provides important information concerning students' behavior related to the nature of the geometrical figure. In particular, it is obvious that students who solved the second task including the figure as an object (VEpo2) were also able to solve the first task of the same type (VEpo1). Thus, there is a relation based on the common function of the figure, as an object in this case. From the second implicative chain we can infer that the solution of the second task including an illustration figure (VEpi2) leads to the solution of the definition task 1 (VEde1). This implicative chain ends with the solution of the first task including a figure as an object (VEpo1).

In the implicative diagram of the 10th graders (Figure 4) two distinct implicative chains are formed. The first implicative chain consists of two tasks. The solution of

Working group 4

the definition task 2 (VEde2) leads to the solution of the first procedure task which is accompanied by a geometrical figure as an object (VEpo1). The second implicative chain is comprised of two corresponding procedure tasks. Particularly, if students succeeded to the solution of the task with a figure as an illustration (VEpi2), which is proved to be more difficult for them, then they were also able to solve correctly the corresponding task including a figure as an object (VEpo2). This shows that students are not misled by the figure as an illustration in this task.

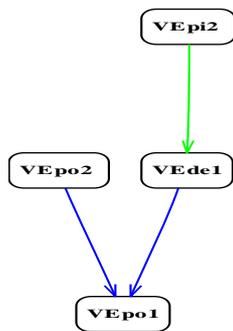

Figure 3: Implicative diagram for Grade 9 students

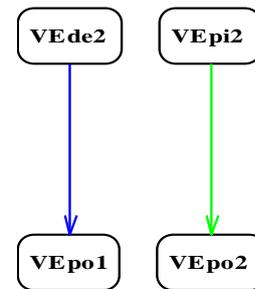

Figure 4: Implicative diagram for Grade 10 students

Grade 9 and 10 students' performance according to the nature of the geometrical figure

Students' performance relatively to the nature of the geometrical figure is presented in table 1. We can see that students of both grades perform better in the tasks in which the figure has the nature of an object. Specifically, the paired sample t test revealed that the means in task 1 are statistically significant higher for the figure as an object for both grades [grade 9: $t(108)=-8,1$, grade 10: $t(102)=8,2$]. This is also the case for task 2, although the difference is statistically significant only in grade 10 [$t(102)=3,8$]. These results are in line with the outcomes of the similarity concerning the influences in students' behaviour and those of the implicative diagrams regarding the difficulty of the tasks.

	Task 1				Task 2			
	object		illustration		object		Illustration	
	\bar{x}	SD	\bar{x}	SD	\bar{x}	SD	\bar{x}	SD
Grade 9 (N=109)	0,48	0,50	0,06	0,25	0,11	0,31	0,06	0,23
Grade 10 (N=103)	0,60	0,49	0,14	0,34	0,26	0,44	0,10	0,30

CONCLUSIONS

The aim of this research study was to examine 9th and 10th graders proving behavior, especially in respect to the understanding of proof and the role of the nature of the geometrical figure, either as an object or as an illustration. The results revealed that there are mainly differences, but also some common characteristics in the way students solve geometrical proof tasks.

Considering students' understanding of proof, we can classify them into three levels. Level I refers to the acceptance of the empirical proof, Level II refers to the acceptance of the semi – empirical proof, while Level III concerns the acceptance of formal proof. Referring to the 9th graders, they can be clearly situated into Level I and Level II. Although there are students that seem to have reached Level III, they cannot be clearly distinguished as a group. The relations revealed from the similarity diagram between the students of Level II and Level III indicate that there are some common characteristics between students of these two groups. Thus, we can say that 9th graders are more situated in the first two levels of proof understanding and some of them are at a transitional stage to the third level. The situation differs for Grade 10 students, since there is a quite clear classification of the students into the three levels of proof understanding. 10th graders who reach Level III constitute an independent group, since they do not have any common characteristics with the students of the other two levels. On the contrary, students of Levels I and II appear to have some common features. The three levels used in order to categorize students' proof understanding can be connected to the three levels proposed by Kunimune, Fujita and Jones (2008), despite the fact that we have only examined students' understanding regarding the 'Generality of proof' and not the 'Construction of proof'. Besides, the formation of the three levels of proof understanding can be indicative of the existence of the forms of geometry, as suggested by Houdement and Kuzniak (2003). We could claim that students of Level I are still situated in Geometry I (Natural Geometry), in which intuition is often linked to immediate perception and enriched by experiment. Students of Level III have characteristics of Geometry II (Natural Axiomatic Geometry), where a system of axioms is necessary. The axiom system can be uncompleted, but the demonstrations inside the system are necessary requested for progress and for reaching certainty. At last, Level II students seem to have characteristics of both Geometry I and Geometry II. Kuzniak (2011, in press) suggests that the constant emphasis on a transition towards Geometry II based on Geometry can let us suppose that a mixed Geometry (GI/G2) is possible.

Another difference between 9th graders and 10th graders concerns the definition proof tasks. Based on the similarity diagram, 10th graders' behaviour is more coherent compared to the 9th graders. Nevertheless, the implicative diagrams show that the definition tasks are more difficult for 9th and 10th graders, than the procedure tasks in which the geometrical figure functioning as an object. Furthermore, the solution of these tasks is achieved by students that belong to Level III of proof understanding for

Working group 4

10th graders, while for 9th graders a relation with the students of Level II is observed. A common feature for the students of both Grades is that the phenomenon of compartmentalization is not observed in their behaviour during the solution of definition and procedure tasks.

Concerning the impact of the nature of the geometrical figure on students' proving ability, it emerged that the geometrical figure plays an important role for the solution of proof tasks, since proof does not depend solely on sentential representation and visual and sentential reasoning are not mutually exclusive (Hanna, 2000). In some cases it does not influence students proving ability when it is functioning as an illustration. However it still has an impact on their behaviour, since it sometimes leads to different behaviour during the solution of corresponding tasks. Specifically, according to the implicative diagram, although 9th graders show consistency when the figure has the nature of an object, their proving behavior is influenced and they are misled when the geometrical figure functions as an illustration. This is not the case for 10th graders, since they show more consistency in the solution of tasks including a figure as an illustration. Although students of both grades seem to start overcoming the negative influence of the geometrical figure as an illustration, grade 10 students show a more stable proving performance in tasks of this type. Despite the fact that they use the figure, they do not exclusively base their proving procedures on it. The findings give support to Duval (2000) who distinguishes between a heuristic and a supportive function of the geometrical figure. Thus, Grade 9 students' proving behaviour is more affected by the nature of the figure, than the common characteristics of the exercise, while Grade 10 students seem to be in a transitional stage in which they start overcoming the negative influence of the geometrical figure on their proving ability. For Grade 9 students the geometrical figure is more an object of study and of validation, while for Grade 10 students the geometrical figure is supportive for reasoning (Houdement & Kuzniak, 2003) and concerned as a "figural concept" (Fischbein, 1993).

Despite the differences mentioned above, findings indicate an important common characteristic for Grade 9 and Grade 10 students as far as the relation between the nature of the geometrical figure and the levels of proof understanding is concerned. Students belonging to Level III are those who are able and make efforts to overcome the impact of the figure as an illustration. For these students, who are also at the level of Geometry III, the figure functions as a heuristic tool (Houdement & Kuzniak, 2003). Therefore, the overcoming of the negative influence of the geometrical figure leads students to the recognition and acceptance of the formal proof or vice versa. In this sense it is well accepted that a diagram is a legitimate component of a mathematical argument (Hanna, 2000).

It is vital to know students' conception of mathematical proof in order to understand their attempts to solve proof problems. The knowledge of what it is for them to prove a statement or what kind of arguments convince students that a statement is true is

Working group 4

very important for teaching (Marrades & Gutiérrez, 2000). Thus the necessity for qualitative research is evident in order to gain a deeper insight in students' proving behaviour and constitutes the next step of our study. Besides, longitudinal performance investigation in geometrical figure understanding related to proof understanding for students (e.g. low achievers) as they move from Grade 9 to Grade 10 should be carried out.

RELATIONS BETWEEN GEOMETRICAL PARADIGMS AND VAN HIELE LEVELS

Annette Braconne-Michoux

IUFM de Lyon, LEPS-LIRDHIST Université Claude Bernard Lyon1

Following previous CERME sessions on Geometrical Thinking, this paper addresses the link between the geometrical paradigms and the van Hiele levels of thinking in geometry. It records the experimentation I conducted with pupils from grade 5 (10-11 years old, last year of Primary School) and grade 6 (11 – 12 years old, first year of Secondary School). Two main points arose: first, that a pupil tends to use a lower paradigm or van Hiele level when facing a difficult task, second, that the second van Hiele level (analysis) seems to be “the overlapping zone” between GI and GII.

INTRODUCTION

During CERME3 (2003), for the first time, Houdement-Kuzniak presented a paper in which they referred to the van Hiele levels theory and the geometrical paradigms. They introduced in a two dimensional table the idea that Geometry GI integrates the first two van Hiele levels of thinking in geometry (identification-visualization and analysis) while Geometry GII integrates the fourth level (formal deduction), the third level being the transitional one between GI and GII. Parzysz (2003) suggested that, from an educational point of view, the same third van Hiele level (informal deduction) could be the “overlapping zone” between GI and GII. Houdement-Kuzniak’s research had been based on pre-service teachers’ understanding of geometry, that is to say on adults working in geometry. According to the French curricula, as Parzysz (2003) put it: “roughly, GI is Primary School geometry and GII is Secondary School geometry”. If the van Hiele levels theory is to be considered as a pedagogical reference to geometry teaching, how can it relate to the geometrical paradigms when considering pupils entering Secondary School?

These suggestions had to be tested among pupils able to work in GI and approaching GII, that is to say, at grade 5 (end of Primary School, pupils aged 10 - 11) and grade 6 (first year of Secondary School, pupils aged 11 - 12). This paper reports the experimentation conducted in June 2004 among 250 primary school and 250 Secondary school pupils.

THEORETICAL FRAMEWORK

Geometry is an important topic in the mathematics curricula in France both at Primary and Secondary School levels. Though the geometrical objects have the same name in Primary School and Secondary School, it has obviously different meanings. For instance, a square as drawn by a 8 years old pupil with ruler and set square is different from a square as sketched at free hand by a 15 years old student. The first one depends on the quality of the drawing (precision in measures and accuracy in the

Working group 4

use of instruments) while the second is only the graphic support for reasoning and may be used as a heuristic tool.

Since we are to use the two theories of geometrical paradigms and the van Hiele levels of thinking in geometry, we have to summarize the main aspects of both theories, particularly those relevant for the purpose of our study that is, GI and GII as far as the geometrical paradigms are concerned and the three first van Hiele levels: identification-visualization; analysis and informal deduction.

Geometrical paradigms

As Houdement-Kuzniak (2003) put it: “our fundamental principle is that the various proposed paradigms are homogeneous: it is possible to reason inside one paradigm without knowing the nature of the other. Students and professors, and it is a source of misunderstanding, are not necessarily situated in the same one.” The following table is a summary of the description of the three different paradigms as defined by Houdement-Kuzniak. Parzysz (2003) added the lines about validations and the nature of the object as considered or studied by the person working in a specific geometrical paradigm.

	GI	GII	GIII
Intuition	Sensible, linked to the perception, enriched by the experiment	Linked to figures	Internal to mathematics
Experience	Linked to the measurable space	Linked to schemas of the reality	Logical
Deduction	Near of the Real and linked to experiment	Demonstration based upon axioms	Demonstration based on a complete system of axioms
Kind of space	Intuitive and physical space	Physical and geometrical space	Abstract Euclidean space
Status of drawing	Object of study and of validation	Support of reasoning and “figural concept”	Schema of a theoretical object, heuristic tool
Privileged aspect	Self-evidence	Properties and demonstration	Demonstration and links between the objects, Structure
Objects	Physical	Theoretical	
Validations	Perceptive or by use of instruments	Deductive	

Table 1: The geometrical paradigms

The Van Hiele levels¹¹

The van Hiele theory of levels of thinking in geometry has been less popular among French researchers than among the English speaking didactical community. We will give here the major aspects of the theory relevant to our study, that is the first three levels: identification-visualization, analysis, informal deduction.

At the first level (N1 identification-visualization)

The geometrical figures are judged according to their appearance. The pupils do not see the parts of the figure, nor do they perceive the relationship among the components of the figure. They cannot even compare figures with common properties with one another. [...] They recognize, for example, a rectangle, a square and other figures. [But] they conceive of the rectangle as completely different from the square. [To such pupils] these figures are still completely distinct. (Wirszup, 1976; p.76)

At the second level (N2 analysis)

The pupil begins to discern the components of the figures; he also establishes relationships among these components and relationships between individual figures. [...] The properties of the figures are established experimentally; they are described but not yet formally defined. At this stage, the figures are the bearers of their properties [they are recognised by these properties...] however these properties are still not connected with one another. (ibid; p.78)

At the third level (N3 informal deduction)

Students can establish relations among the properties of a figure and among the figures themselves. At this level there occurs a logical ordering of the properties of a figure and of classes of figures. The pupil is now able to discern the possibility of one property following from another, and the role of definition is clarified. The logical connections among figures and properties of figures are established by definitions. However, at this level [...] the pupil does not yet understand the role of axioms, and cannot yet see the connection of statements. [...] At the third level a square is already viewed as a rectangle and a parallelogram. (ibid; p.78)

At the fourth level (N4 formal deduction) “the students grasp the significance of deduction as a means of constructing and developing all geometric theory.” (ibid; p.78)

¹¹ In this text, the van Hiele levels will be numbered from 1 to 5 following Uziskin (1982), Guttiérrez & als (1991) Clements and Battista (1992) etc. ; the main reason being that some students do not reach the first level of identification-visualization.

A new framework

If we are to consider both theories, we can assume that a pupil mastering only the first van Hiele level (N1 Identification-visualization) is not yet working in a any geometrical paradigm, that is to say even not in GI: he/she can only name a figure by global recognition and is not using any instrument or geometrical property to assess his/her answer. Though at the end of Primary School most pupils should master not only the first van Hiele level (N1) but be able to work in GI as well. At the opposite, a pupil mastering the third van Hiele level (N3 informal deduction) is definitely able to work in a more theoretical geometry that is to say GII named either “natural axiomatic” (Houdement-Kuzniak; 1998-1999) or “proto-axiomatic” (Parzysz; 2003). Such an ability is expected from the students finishing Secondary School in France.

So the question is: if a student masters the second van Hiele level (N2 analysis), is he/she working in a specific paradigm? If the answer is yes, is it GI or GII? Since for a student at level N2, the geometrical object is not necessarily a physical one but can be a meaningful free hand drawing, we cannot consider that such a pupil is working in GI. Is he/she working in GII? We cannot be sure of that either: the deductions and validations he/she makes are based on a list of properties and are not organised deductively. So we can suggest that the second van Hiele level could be an “overlapping zone” between GI and GII in terms of teaching references.

The following table summarizes these new relations between the geometrical paradigms and the van Hiele levels.

Geometrical paradigm	GI		GII	
Status of drawing	Representing itself	Object of study and of validation	Representing a class of objects	Schema of a theoretical object
Characteristic of drawing	“straight lines”	“straight lines coded”	Free hand coded drawings	
Validations	Perceptive or using instruments	Using instruments or deductive (through description and lists of properties)		Hypothetical-deductive
Van Hiele level	N1 Identification-visualization	N2 Analysis		N3 Informal deduction

Table 2: Relations between the geometrical paradigms and the van Hiele levels

Is such an organisation accurate? Can we detect in which geometrical paradigm a pupil at this age is working? Can we assess the van Hiele level he is mastering in a particular situation?

METHODOLOGY

In order to assess these questions, 250 pupils at grade 5 (last year of Primary School in France; 10-11 years old) and 250 pupils at grade 6 (first year of Secondary School) were asked to answer the same tests. Each test consisted of two questions, the first one supposedly easier than the second among 17 different tasks about triangles, quadrilaterals and circles, such as illustrated in figure 1. The first tasks were numbered from 1.1 to 1.8; the second ones from 2.1 to 2.9. The tasks consisted in recognizing or identifying a specific figure among a lot of different figures, drawing a specific figure according to different conditions, identify and explain or justify some property of a figure; etc.

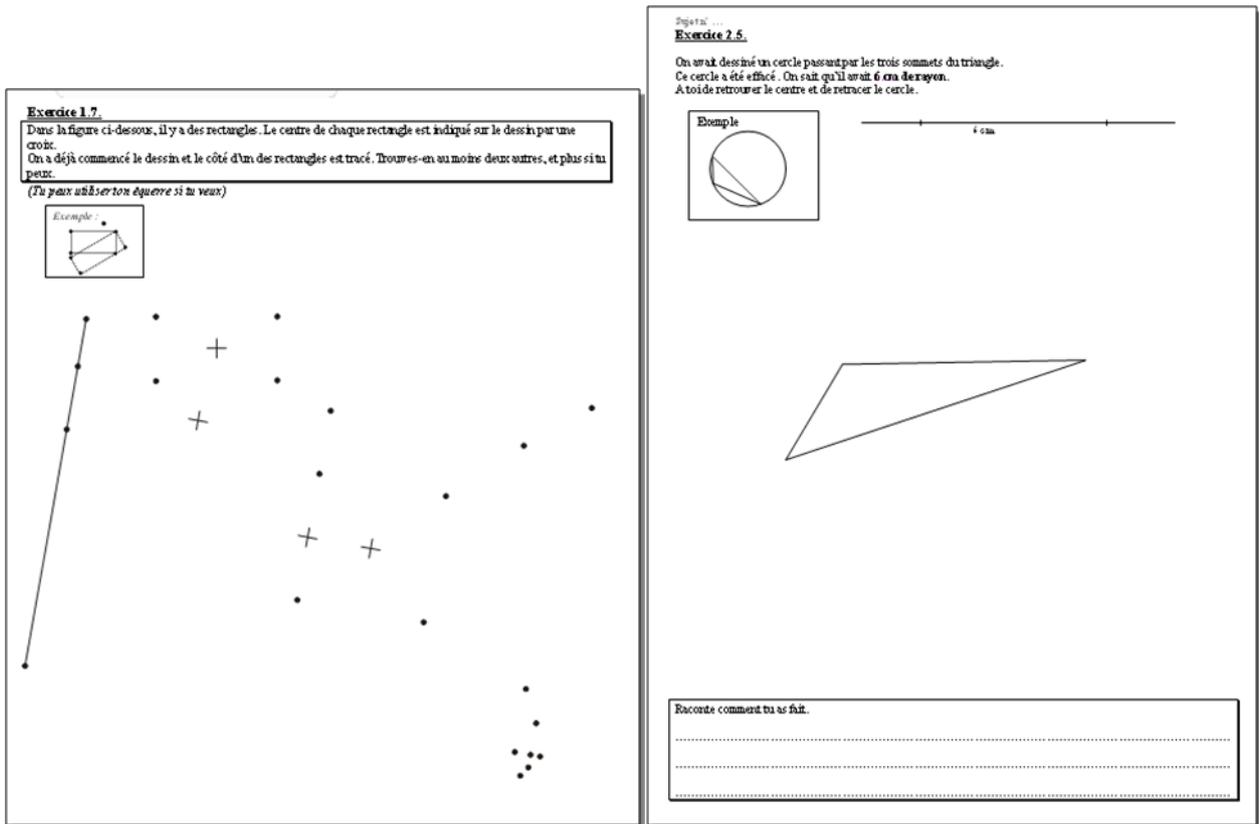

Fig 1: “The rectangles” and “the circle” questions¹²

¹² Translation:

Exercice n°1.7. : In the figure below, there are some rectangles. The center of each rectangle is indicated by a cross. The drawing has already been started and the side of a rectangle is drawn. Please, find at least two other rectangles and more if you can. (you may use your set square if you want to) [the biggest rectangle is 16 cm long and 11 cm wide]

Exercice n°2.5.: A circle passing through the three vertices of the triangle had been drawn. It was erased. We know that the radius is 6 cm. Please, find the center and draw the circle again. Tell us how you did it.

Working group 4

Each task could be worked out either in GI or GII. The way the pupils answered the questions was to give us some indication about the paradigms they were working in and the van Hiele level they were mastering.

As examples, the tasks illustrated in figure 1 are analysed here.

In “exercice 1.7.” a pupil mastering the first van Hiele level 1 would identify only the small rectangle on the top left part of the page and try to finish the small rectangle with one of its sides already drawn. At level 2 (analysis), the pupil could identify three out of the four rectangles. Mainly at this level, the pupil could not cope with the recognition of the square and the biggest of the four rectangles. Most of the answers at level 2 indicate that the square previously identified as a rectangle has been erased thus rejected as a particular rectangle. The pupils at level 3 (informal deduction) could identify the four rectangles.

Considering the geometrical paradigms, pupils having rejected the square or wrongly connected the vertices of the biggest rectangles were considered as working in GI at most. These pupils could not cope with the different properties of the rectangle (length of sides and right angles) at the same time, even when using the ruler and/or set square. From the traces left on the sheets, we could tell that most of these pupils had made a perceptive validation of their drawings. We considered that the pupils working in GII were able to accept the square as one of the rectangles to be identified in the figure and were very précised when searching the fourth vertex of the biggest rectangle: opposite sides equal and right angles. Some of them indicated that the lengths of the opposite sides or the half of diagonals should be equal.

In “exercice 2.5.”, the van Hiele levels were identified according to these criteria.

At level 0, the pupil did not answer or drew a circle with a radius different from 6 cm passing at most by one of the vertices.

At level 1 (identification-visualization), the circle is a 6 cm radius one but it passes by one or two of the vertices of the triangle. Others drew a circle passing by two of the vertices but the radius is not 6 cm. Not all the conditions are taken into account.

At level 2 (analysis), by trials and errors, the pupil draws a 6 cm radius circle passing by the three vertices but he cannot explain why he is successful. There are many holes in the sheet of paper. The explanation is generally: “I tried as many times as necessary.” At this van Hiele level, the pupil is able to grasp the different constraints (circle with a 6 cm radius passing by the 3 vertices) but he cannot give any theoretical explanation.

At level 3 (informal deduction) the pupil is able to use the compasses the other way round and use the vertices of the triangle as centres of 6 cm radius circles, drawing two or three arcs and using their intersection as the centre of the circumcircle of the triangle. The explanations are descriptions of the different actions and very rarely refer to the definition of a circle.

Working group 4

As far as the paradigms are concerned, we considered that a pupil using the compasses with a 6 cm opening and working with trials and errors was working in GI. Though he could be successful in drawing a convincing circle, he could not give any explanation of his success. The validation was a perceptive one.

As soon as a pupil was able to use the vertices of the triangle as centres of circles, he was using the definition of a circle the other way round: every point lying on a 6 cm radius circle is the centre of a 6 cm radius circle passing by the centre of the first circle. Such a pupil is working in GII, even though he cannot word it through a hypothetical-deductive reasoning.

Each answer was coded according the van Hiele theory on one side and the geometrical paradigms on the other one. Every pupil being given two tasks, we had for everyone two sets of codes: the van Hiele levels and the geometrical paradigms he could work in.

RESULTS

First of all, as the two theories are concerned, we discovered that most of the answers given by the pupils could be identified as belonging to a specific geometrical paradigm and a van Hiele level. 12 answers out of 457 (<3%) were impossible to code in one paradigm or a van Hiele level. So we have 445 answers: 209 from grade 5 pupils and 246 from grade 6 pupils.

Grade 5				Grade 6			
Recto	GX + GI	GII	Total	Recto	GX +GI	GII	Total
Verso	(recto)	(recto)		Verso	(recto)	(recto)	
GX + GI (verso)	120	57	177	GX + GI (verso)	69	76	145
GII (verso)	18	14	32	GII (verso)	43	58	101
Total	138	71	209	Total	112	134	246

Table 1: the geometrical paradigms (grade 5 and grade 6)¹³

Considering the geometrical paradigms (see Table 1), as expected, three quarters of grade 6 pupils could work in GII when answering at least one of the two questions while only one out of 15 (<7%) from grade 5 pupils could do it. This happened mainly when the answer could be worked out without wording, like in “exercice 1.7.” where they were asked to retrieve the four rectangles, a square being among

¹³ The code GX was used for the answers we could not clearly identify as referring to GI or GII. But, we considered too that at that level of schooling, most pupils were no longer working in G0. So we figured out that they were working in GI, even with some awkwardness.

Working group 4

them. As the pre-service teachers do (Jore-Lemonnier 2006), one pupil can work in both paradigms depending on the task itself or the interpretation he/she has of the task. In most cases, even if the pupil can answer the first question working in GII, when the second task seems more difficult to him/her, he/she may work in GI to give an answer. The validations are then more frequently perceptive or obtained by use of instruments rather than by reasoning.

Grade 5					Grade 6				
Recto	N0 + N1 (recto)	N2 (recto)	N3 (recto)	Total	Recto	N0 + N1 (recto)	N2 (recto)	N3 (recto)	Total
N0 + N1 (verso)	67	28	20	115	N0 + N1 (verso)	32	29	31	92
N2(verso)	32	13	25	70	N2(verso)	13	32	19	64
N3(verso)	8	10	6	24	N3(verso)	17	34	39	90
Total	107	51	51	209	Total	62	95	89	246

Table 2: the van Hiele levels (grade 5 and grade 6)¹⁴

As far as the van Hiele levels theory is concerned (see Table 2), the same report can be done. In most cases, we could identify the level mastered by a pupil when answering a specific question. As Burger and Shaughnessy (1986) and Gutiérrez (1992) report, one pupil can master different van Hiele levels at the same time depending on the subject. We observed too that, when the second question seemed more difficult than the first one, the answer given by the same pupil proved to pertain to a lower level. When considering the specific level of analysis (N2), we have this result: a quarter of grade 5 pupils and a third of grade 6 pupils were able to give at least one answer at this level. At the same time, a third of grade 5 pupils and half of grade 6 pupils proved to master level 3 (informal deduction) on one occasion at least. These answers were identified as such through worded validations relying on theoretical properties of figures.

CONCLUSION

As expected, 57% of Primary School pupils worked only in GI and 32% of them mastered only the first van Hiele level (N1 identification-visualization) on both tasks. 28% of Secondary School pupils worked consistently in GI but 13% mastering only the first van Hiele level. Such results suggest that some pupils are working in

¹⁴ The code N0 was used for the answers we could not clearly identify as referring to any other van Hiele level. But, we considered that at that level of schooling, most pupils knew some elements of geometry, even with some awkwardness and could be added to those who were clearly identified as mastering N1.

Working group 4

GI but master van Hiele level 2 (N2 analysis). At the same time, some answers were coded as GII – N2, meaning that the pupil working in GII was mastering only the van Hiele level 2.

When analysing the characteristics of the different answers identified as belonging to level 2 (analysis), it seems that this level is the “overlapping zone” between GI and GII.

We could describe as GI – N2 any situation where:

- The drawing is called “figure” and is made at scale 1 with instruments (ruler, set square, compasses, etc.).
- The pupil can read the information given in such a “coded” drawing.
- He/she can give a list of the properties of the figure but cannot work out any new piece of information or conclusion.
- He/she can identify sub-figures within a figure but cannot make any connections in terms of incidence.

We could describe as GII – N2 any situation where:

- The “figure” is a coded sketch or a free hand drawing and the pupil is able to give the list of the properties of the figure.
- The pupil can identify sub-figures in a figure but he/she cannot explain or justify the existence of such sub-figures.
- The pupil can tell what he/she did when drawing the “figure” at scale 1 but the story is not organised. It does not refer to any theoretical property or hypothetical-deductive reasoning.

These results tend to indicate that teachers should be advised that not all the pupils entering grade 6 are ready to work in GII. When proposing tasks to their pupils, the van Hiele level theory could come in hand, the focus being on level 2 (analysis).

This research was the first one on such a hypothesis: level 2 being “the overlapping zone” between GI and GII. More research has to be done particularly clinical investigation in order to understand how and when a pupil switches from one paradigm or a specific van Hiele level to another. It would be particularly interesting to investigate if a pupil entering GII is still working back and forth from GII to GI just as any professional mathematician do. Research on the tasks themselves could be fruitful and offer the teachers, activities helping the students moving forward in their learning of geometry. Investigation should be undertaken in order to connect these results with the different working geometrical spaces as identified by Kuzniak (2010) too.

GEOMETRY AS PROPAEDEUTIC TO MODEL BUILDING – A REFLECTION ON SECONDARY SCHOOL TEACHERS’ BELIEFS

Boris Girnat

University of Education Freiburg, Germany

This article presents a qualitative study of teachers’ beliefs about applying geometry, setting application-oriented beliefs in the context of the teachers’ whole geometry curricula. Surprisingly, geometry is not perceived as a field of good applications, especially not for model building. Three classes of objections are discussed and connected to a prevalent Euclidean view of geometry and a preference for proofs and problem-solving tasks. Despite these objections, applications are taught, but the analysis of the teachers’ tasks implies that the teachers’ implicit theory of applying geometry differs from didactical requirements and is not compatible with common approaches to model building. The teachers’ predominant alternative, which is called a propaedeutic use of geometry, is described in detail.

CURRICULAR ASPECTS OF TEACHERS’ BELIEFS ABOUT GEOMETRY

The research on teacher beliefs has become a prospering branch of mathematics education, revealing subtle influences on student learning. The focus of this study is secondary school teachers’ beliefs about teaching geometry in the context of applied mathematics. Beliefs are customarily understood as “psychologically held understandings, premises, or propositions about the world that are thought to be true” (Philipp 2007, p. 259). In contrast to the general notion of beliefs, this study is only interested in a subset of teacher beliefs which has a similar content, structure, and purpose to a written curriculum. This part of a teacher’s belief system is called his individual curriculum (cf. Eichler, 2007). Its aspects – content, structure, and purpose – can be explained as follows (cf. Stein, Remillard, & Smith, 2007): the purpose of an individual curriculum is equal to the function of a written curriculum, i. e. it is used to structure lessons and to guide instructional practice to the goals of education through various steps of content and method. Hence, its structure can be seen in means-end relations between mathematical content, methods, and educational goals.

Teacher beliefs about mathematical content are split into beliefs about concepts, theorems, objects, tasks, and textbooks. Beliefs about educational goals are separated into three levels of generality: content-specific abilities, general competencies, and top-level goals of education. The choice of the competencies enquired about during data collection is guided by the written curriculum the teachers have to act on: arguing, problem-solving, modelling, communicating, formalising, algorithmising, and using mathematical description and symbols (KMK 2004, p. 7).

Against this background, a qualitative study was designed to examine the individual curricula of nine teachers teaching geometry at German higher-level secondary

Working group 4

schools (so-called Gymnasien, in which about 35-40% of German students are taught and whose school leaving certificates are normally necessary to get access to university). To invite teachers to participate in this study, four districts of the governmental school hierarchy in different regions of Germany were contacted, each responding with a list of two or three teachers willing to participate in this study. The teachers were visited and interviewed by the author.

The focus on curricular aspects was chosen because investigations of the implementation of curricula are scarce in Germany. In addition, no study has been carried out about the ways in which the changes to the new national curriculum (KMK 2004) are reflected by teachers – especially its emphasis on the competencies mentioned above and its increased emphasis on applications and model building. This lack of information was the reason to focus this study on modelling and to examine how beliefs about this topic are integrated into the teachers' whole geometry curricula.

Individual curricula as subjective theories can provide a bidirectional contribution to mathematics education (cf. Girnat 2010): it is possible to detect disparities between prescribed goals and teacher objectives in order to discover possible errors in practice. On the other hand, individual curricula can also be analysed in comparison with didactical opinions on a cooperative level to integrate teachers as semi-professional researchers and to expedite theoretical thinking on the ground of differing views from classroom practice. Both aspects are pursued within this study.

THEORETICAL BACKGROUND, METHODS, SETTINGS, AND DATA

The data were collected by semi-structured in-depth interviews, each taking about 90 minutes. They were interpreted according to the research programme of subjective theories (Groeben et al. 1988). This framework was invented by psychologists to collect and interpret complex systems of beliefs used by professionals to make their decisions when acting occupationally on the basis on a more or less commonly shared, but individually interpreted, theory, containing empirical knowledge and normative prescriptions similar to curricula or didactical theories. Due to the usual complexity of a professional's subjective theory, a qualitative approach is normally preferred and is used in this study.

To interpret the data, a so-called dialogue-hermeneutic method was invented (Scheele & Groeben, 1984) consisting of three steps: an interview to collect the main data, interpretation of the data by hermeneutic methods to define the subjective theory, and spot check observations of participant behaviour to validate whether the assumed subjective theories are in fact relevant to the teachers' practice. In this case, observations consisted of five lessons per teacher and a collection of the application-oriented tasks used in approximately the last quarter before the observation.

The teachers' geometry curricula were analysed in all the aspects mentioned above, and not limited to topics of applications, mathematisation or modelling. The reason for such a "holistic" approach is the idea that the common instructional practice is

guided by several goals of education not necessarily related to applications. Hence, application-oriented goals have to find their places within the totality of curricular aims and convictions. The central questions of this study can be only answered concerning a whole individual curriculum: what significance do the teachers attribute to application-oriented goals? Of what kind are the connections between application-oriented goals and other goals of education? Are teachers' application-oriented goals similar to or different from didactical ideas and the new written curriculum?

THE FOCUS ON MODEL BUILDING

Before presenting some results, it is necessary to briefly sketch some didactical perspectives on applied mathematics. The most essential issue seems to be the relationship between general mathematical theories and empirical knowledge in singular situations. Kaiser-Meßmer (1986, pp. 83-92) has proposed a classification whose extremities are called the pragmatic and the scientific-humanistic approach. The latter emphasises mathematical concepts and theories as the main goals of education and incorporates real-world situations mainly as subordinate tools to develop mathematical concepts and insights into manifold realistic associations. Empirical knowledge is of minor interest; the teaching process follows a mathematical taxonomy of problems, concepts, and techniques, and is not derived from empirical questions connected to real-world situations. The real-world situations are just "illustrations". The pragmatic view, in contrast, stresses empirical insights into real-world situations and includes a meta-theory about the relationship between mathematics and reality to be picked out as a central subject when teaching applied mathematics. This approach rests on three classes of educational goals (Kaiser-Meßmer 1986, p. 86): 1) utilitarian aims: the situations are not selected according to mathematical taxonomies, but on the basis of the current or expected benefit to the students' lives. 2) methodological aims: the students shall obtain general competencies in and meta-knowledge of applying mathematics. 3) meta-scientific aims: applying mathematics is perceived as model building. The concept of model building can be explained by the model building cycle and has to be reflected in classroom practice as "one of the main components of the theory for teaching and learning mathematical modelling" (Kaiser, Blomhoj, & Sriraman, 2006, p. 82).

Both approaches to applying mathematics imply different standpoints on the goals of education in general; the pragmatic view sees its contribution in universal model building competencies and a preparation for life situations. The scientific-humanistic approach instead rests on the generality of mathematical theories. The new written curricula in Germany based on the national prescriptions (KMK 2004) underline the pragmatic view and introduce model building as obligatory; it was incidental or ignored in former German curricula. For this study, a simple version of the manifold modelling cycles (fig. 1) is used, which seems to be sufficient to determine if a teacher possesses a concept of model building in the sense of the contemporary academic debate and written curriculum.

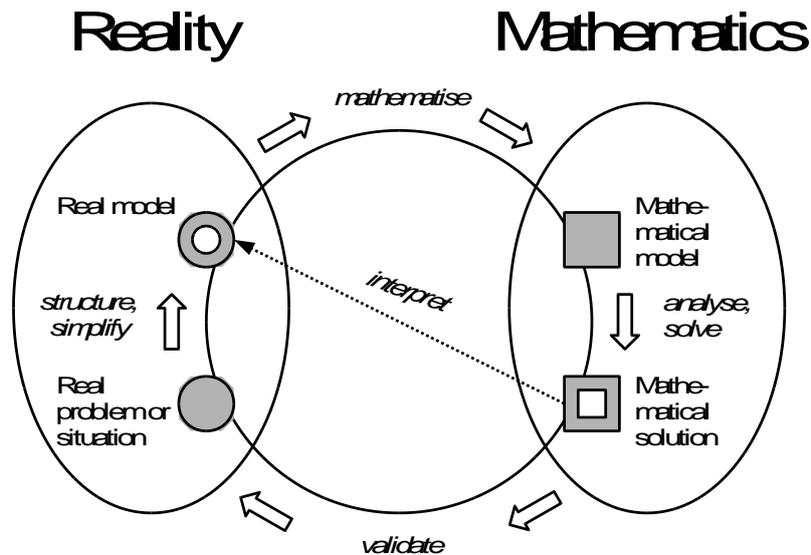

Figure 1: The modelling cycle used in this study

FINDINGS: THREE OBJECTIONS TO GEOMETRICAL MODELLING

To summarise the results: seven of the nine teachers had objections to integrating applications into their geometry lessons, though being open-minded about modelling in other parts of school mathematics. The spectrum of objections ranges from strict exclusion to a moderate use. But even if geometrical applications are taught, the way of applying geometry differs from didactical suggestions. The interpretation of the data leads to three classes of objections which are based on different reasons.

Ontological Aspects

The strictest opposition to an application-oriented way of teaching geometry is based on ontological beliefs about the nature of geometry and its objects. In Girnat (2009), the following classification of geometrical ontologies is proposed (fig. 2).

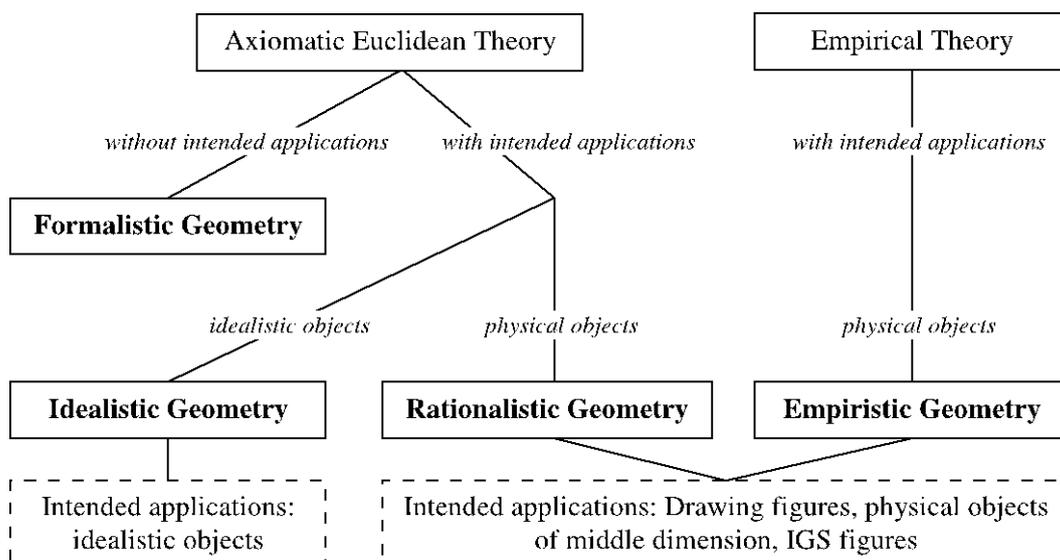

Figure 2: An ontological classification of geometry

Working group 4

This classification rests on two aspects: 1) the theoretical aspect: is geometry taught on the basis of a given axiomatic Euclidean theory (whose rigour may be restricted to an adequate school level) or is it derived from experience, observations, and measurement as an empirical theory? 2) intended application: does geometry refer to ideal objects in the sense of Plato or to physical objects or is it regarded as purely formalistic in the sense of Hilbert?

The two aspects of this classification follow the main ideas of the theory of geometrical working spaces (cf. Houdement & Kuzniak, 2001). According to this approach, geometry is split into three paradigms: a formalistic theory (called GIII), an idealistic theory strictly based on deductive arguments (GII), and an empirical theory based on measurement and experiments (GI). Compared to the classification used here, the theory of geometrical working spaces combines the aspects of justification (deductive or empirical) and reference (the connection of objects) to each other, leading to the consequence that an empirical reference is tacitly bounded to empirical, non-deductive methods in GI. For our purposes, it is necessary to separate these aspects and to allow a geometry which refers to empirical objects, but is mainly based on deductive arguments (just including some empirical initial conditions). This type of geometry is called the rationalistic one.

Idealistic Platonists: No applications intended

Two of the teachers can be classified as exponents of an idealistic view of geometry. They do not perceive geometry as a theory of real objects, but of ideal entities which correspond to ruler-and-compass constructions and which fulfil the theorems of Euclidean geometry without any exceptions.

Mrs. D: The beauty of mathematics is the fact that everything is logical and dignified. [...] Everywhere else, there are approximations, but not in mathematics. There is everything in this status it has ideally to be in. [It is important for the students] to recognise that there are ideal things and objects in mathematics and that, in reality, they are similar, but not equal.

From this point of view, applying geometry is barred by definition. Instead, constructive descriptions are promoted to get access to ideal objects. Physical objects, typically limited to drawings, are only used as symbolic representations of the “true” ideal objects of geometry. Every empirical investigation is seen as a heuristic tool, but does not have any relevance for justifying geometrical insights.

Mrs. D: Besides proof abilities, problem solving is in fact the most important thing I want to convey in my lessons on geometry.

Mr. C: If geometry just consisted of measuring, calculations, drawing, constructing, and land surveying, then I would regard it as poor. [...] [Geometry as a] tool to get access to the real world? No, problem solving would be my favourite. Why? Problem solving is a keyword that includes everything. It is the final

Working group 4

goal to make students work systematically, identifying premises and drawing conclusions to solve a problem.

Classroom observations support the impression derived from the interviews: the lessons on geometry held by these two teachers are focussed on proof, construction, and problem solving tasks, using drawings only as heuristic tools.

Model building versus proof and problem solving tasks

Not only by the two “idealistic” teachers are proof and problem solving tasks seen as the main aspects of teaching geometry, but also by six teachers who are not strict opponents of geometrical applications. Applying mathematics is not a top level goal, but rather is subordinated to proof and problem solving competencies. The tasks the teachers presented as good examples to convey these competencies match the typical characteristics of problem solving tasks (Holland 2007, pp. 170-195) and lead to the hypothesis that the aspects and methods demanded are contrary to the settings of a model building process. The main differences are summarised as follows (tab. 1):

Aspect	Model building	Proving or problem solving task
<i>Objects of interest</i>	singular situation	general theorem or configuration
<i>Access to objects</i>	by measurement and experience	by constructive descriptions
<i>Building a real model</i>	by simplifying	simplifying not allowed
<i>Mathematical treatment</i>	inventing a mathematical model	using known operators, theorems, or methods
<i>Validation</i>	empirically	by deductive arguments

Table 1: Differences between model building and proving or problem solving tasks

Most of the teachers want to prevent their students from getting confused by mixing the standards of modelling, proving, and problem solving. They hence typically split their courses on geometry into pure and application-oriented sections:

Mr. B: Geometry as a tool to get access to the real world is legitimately not in the first place. An application is useful to introduce a new subject, to legitimise it, and to test the competencies of this field by realistic tasks in the end. But in between, a lot has to be done without any reference to the real world, detached from these accessory parts which are not important to the mathematical theory. In between, applications are counterproductive. They seduce the students into not arguing strictly deductively.

Insofar as the deductive view of geometry is predominant and geometrical applications are mostly seen as appendices to the “serious” treatment of geometry, the

consequence is that aspects of model building are not integrated into the geometry curriculum and that geometry is “applied” to real-world problems in the majority of cases in the way that a problem-solving task is “decorated” by an empirical-sounding vocabulary, which is seen as characteristic of a rationalistic use of geometry.

The contrast: Geometrical applications as the main focus

To contrast the first two types of objections, the only teacher who approves and practises application-oriented tasks extensively shall be quoted comprehensively. After arguing for teaching “geometrical modelling”, Mr. H was confronted with the question of what significance proofs and problem solving tasks had in his opinion:

Mr. H: Proofs, not in the sense of what is called a proof at university, shall demonstrate that something could be plausible, more plausible than something different. [...] My students shall be able to judge if a solution can be plausible, if the units match, if something could really have happened [...] if you throw a stone into a basin of water, then if the gauge could really rise by 3 meters. [...] They have to solve specific problems, and they have to use their geometrical tools. That needn't to be exact, that depends on the situation, and they have only to know if the methods and solutions may be plausible and realistic and how they can be used in the specific context.

Mr. H stresses the pragmatic aspects of applied mathematics, holding an empirical view of geometry at G1 level; and in doing so, he dispenses with the educational goals which the teachers mentioned above pursue by proofs and problem solving.

Geometrical applications as being uninteresting

The third and last class of objections against geometrical applications is based on the assertion that they do not lead to interesting insights.

Mr. A: The better applications can be found in algebra or stochastics, per cent calculations, linear optimisation. It is important to get a deeper insight into reality by modelling. In geometry, there are such things as dividing a pizza by a compass. I saw a trainee teacher do so. That's ridiculous.

It is remarkable that this objection is focussed on purely geometrical applications. The classroom observations and the teachers' statements about “good” examples for modelling reveal that the teachers in fact use geometrical applications, but that they are small and, for themselves, uninteresting parts of more complex modelling tasks guided by non-geometrical questions. These tasks typically possess a two-step structure. In the first step, geometry is used to calculate some initial or boundary conditions, e. g. some lengths, areas, or volumes. Afterwards, these values are committed to a second, non-geometrical step which includes stochastics, algebra, optimisations or a problem derived from the natural or social sciences, e. g. some price, weight or velocity calculations. Five teachers used these two-step applications and stated that the interesting insights first and foremost arise in the second step. A typical example is mentioned and explained by Mr. B:

Working group 4

Mr. B: To grasp the sense of what I like to say, let us regard the following task: “A businessman wants to sell salt in small rectangular packages of 250 gram. What would be your advice to reduce the waste of material?” That’s an interesting problem providing some surprise, if you take the situation serious, and it is quite challenging, but the geometry in it is not, it’s standard, it’s only a vehicle to manage the interesting aspects, and it has to be well understood before deliberating about this problem.

If the modelling cycle is the core concept to analyse the learning and teaching of applied mathematics, then it will be difficult to reconstruct this two-step application by a cyclic structure (fig. 1). It rather seems appropriate to perceive geometry as “propaedeutic” to modelling, outside and “a priori” to the modelling cycle (fig. 3).

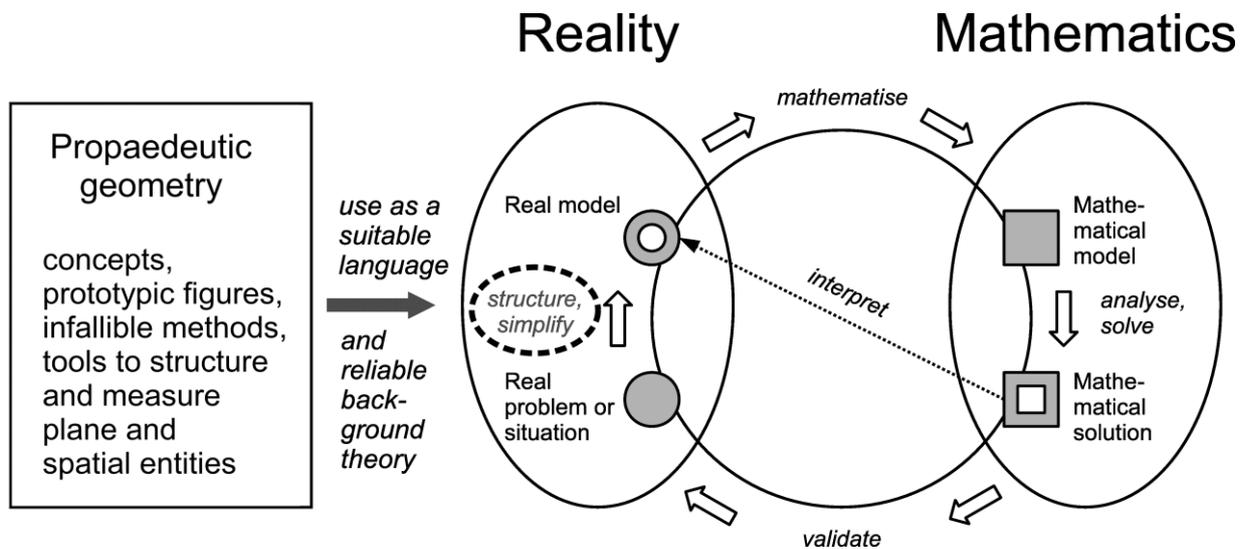

Figure 3: Geometry as propaedeutic to model building

The meaning of “propaedeutic” can be explained in three aspects: 1) A propaedeutic use of geometry is characterised by a static view on geometry: It is seen as a pre-established theory, based on rigid concepts, proved theorems, and infallible methods.

2) A propaedeutic geometry is used as a suitable language and reliable background theory to structure and simplify a situation by geometrical concepts. This way of applying geometry is different from a modelling process, since geometrical concepts are already used to structure the real situation, and not to build a mathematical model after structuring the real situation independently. Hence, the use of geometrical concepts and methods is prior to any kind of mathematisation in the sense of the modelling cycle. This aspect is best to observe in the two-step structure of the teachers’ “good” examples for modelling tasks. Geometrical concepts and theorems are already necessary to “see” geometrical objects in reality and to calculate the values of areas or volumes before the second step, the “true” modelling process, can get started. Additionally, and as a further contrast to the modelling cycle, the propaedeutic use of geometry does not include any kind of validation, since geometrical theorems and methods are treated as already proven. In the salt example,

the relevant second step is the optimisation process, based on proposals on how to shape the packages. The calculation of its shells, volumes, and cut-offs is just an algorithmic task, based on pre-established geometrical knowledge and methods.

3) The teaching method is propaedeutic, since most of the teachers follow Mr. B's suggestion to avoid connections to reality at first and to integrate realistic situations at the end of a teaching unit. The observations indicate that five of our teachers approve of modelling tasks and pose them in their lessons, but either geometrical problems are not involved and are taught separately or geometry is integrated propaedeutically into a two-step structure.

CONCLUSIONS

The study reveals objections to an application-oriented approach to geometry based on three reasons: a traditional idealistic view of geometry, a preference for proof and problem solving competencies, and a propaedeutic treatment of geometry. In particular the pragmatic view of modelling with the model building cycle as its core concept could not be found as a part of the teachers' geometry curricula and teaching practice, though being observable in non-geometrical contexts.

It is interesting to see how several of the teachers integrate application-oriented aspects into their geometry curriculum on basis of their "non-application-oriented" view, combining a Euclidean perception of geometry with a propaedeutic use. This finding suggests some further reflections: although the classroom observations of most teachers reveal no application-oriented tasks which could be described as "good" modelling tasks in the sense of the academic debate and the new German curriculum, the teachers are not just unwilling to teach application-oriented geometry, but are focussed on educational goals connected to proving and problem solving tasks, which are also parts of the written curriculum, and which presuppose a geometrical ontology and methodology that provokes a conflict with the background theory of modelling objectively, and not only in the subjective perceptions of these teachers. The academic debate needs to propose a way to manage these conflicting demands in practice.

The observed two-step structure poses a particularly interesting question to the academic debate on modelling: is this way of teaching applied geometry just a consequence of the teachers' traditional Euclidean view of geometry or is it based on a typical way in which geometry "naturally" refers to reality? In the latter case, it would be questionable whether the model building cycle is an adequate representation of applying geometry. In contrary to common didactical debates (Kaiser et al., 2006), the findings suggests the conjecture that it may be advisable to shape the modelling debate less as a "top-down theory", establishing a single framework to be applied in every part of school mathematics identically, but more as a "bottom-up research programme", exploring the existing uses of applications in different contexts and parts of school mathematics following from the question of

whether there are ways other than the modelling cycle in which mathematics and the different parts or disciplines of school mathematics refer to reality.

GEOMETRIC WORK AT THE END OF COMPULSORY EDUCATION

Kuzniak Alain

Laboratoire de didactique André Revuz, University Paris-Diderot France

Abstract. The purpose of this contribution is to define the nature of the geometric work implemented in France at the end of compulsory education. To do the study, the notions of geometric paradigms and Geometric Work Space (GWS) have been used. The reference GWS is clarified through an analysis of the curriculum written in 1996 and 2005; then the “appropriate” GWS is studied by confronting textbooks and observations in class. From this analysis, it results that the GWS are becoming more and more split and oscillate in a confusing way between the geometric paradigms. This dispersion of the GWS is largely due to the fact that the geometric work is not any more controlled by epistemological concerns but tends to adapt the mathematical level of the students.

INTRODUCTION

This article focuses on the nature of the geometric work implemented at the end of compulsory education in France (Grade 8 to Grade 10). These grades correspond to the end of the compulsory education and also to the end of a common education program for the quasi-totality of students. Grade 9 is the final year of the “collège unique”, called unique because it is dedicated to welcoming all the students by giving them the same learning within a common framework. Grade 10 is the first class of the Senior High School and it provides the time when students choose the school sections that are more specialized in some particular domains. Due to this, most of the students receive their last education in geometry in this grade. To examine the nature of geometric work, the notions of Geometric Working Space (GWS) and geometrical paradigms (Houdement and Kuzniak, 2003, 2006) are used. The three geometrical paradigms, named Geometry I, II and III, are not presented in detail, but some elaboration of the notion of geometric work and GWS are given to frame the questions studied in the paper.

THE NOTION OF GEOMETRIC WORKING SPACE

Towards a definition

The geometric working space (GWS) is a workspace organized to ensure the work of people solving geometry problems (geometricians). It has two levels: the "components plan" and the "cognitive plan".

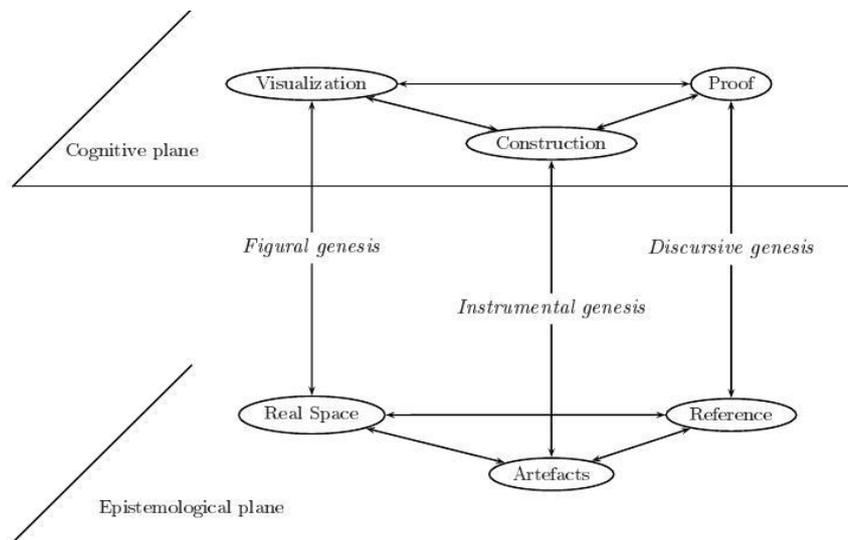

The "components plan" comprises three parts: the real and local space as material support with a set of concrete objects; artefacts such as drawings instruments and software available to the geometrician; a theoretical system of references made of properties organized in a way that is dependent on the geometrical paradigm.

Working group 4

The sole components are not sufficient to define the global meaning of a GWS which depends on the function that its designer and its users give to it. A first reorganization of these various constituents is of an epistemological nature and directed by the geometrical paradigms.

The GWS function can evolve in connection with the social and economic context which influences the educational institutions where geometry is taught. Moreover, this function depends strongly on the cognitive ability of a particular user. The

cognitive plan was introduced to clarify the cognitive processes involved in geometry. Adapting Duval (1995), the three following cognitive processes have been introduced: a visualization process with regard to space representations and the material support; a construction process depending on the instruments and on the configuration; a discursive process in relation with proving and reasoning.

As the GWS is created within the framework of school institutions, we need to introduce different levels in order to describe the diversity existing in school education.

As the GWS is created within the framework of school institutions, we need to introduce different levels in order to describe the diversity existing in school education.

The reference GWS or the expected reorganization The choice of a paradigm by the members of a community implies that problems have to be formulated and solved in a particular GWS that we name the reference or expected GWS. To describe this GWS, it is necessary to exhibit these specifics ways of working and clarify the expected style with its treatment and presentation rules. The reference GWS depends on the chosen paradigm: Geometry I, II or III.

The “appropriate” GWS or the question of the implementation Once the bases of the geometry taught have been determined, it remains to be worrying about its actual learning which requires the existence of GWS convenient to carry out the expected geometry with a chance of success. The experts in charge of the GWS design play a role similar to that of an architect who conceives a working space for future potential users. They develop a GWS which can be appropriate with regard to the intentions of the institution, but which can turn out to be not adequate to its expected function and not successful during its implementation in classes.

The personal GWS The appropriate GWS must be invested by students who use it with their knowledge and their cognitive abilities and these new GWSs are named personal GWSs. They are formed in a progressive way depending on the individual and can sometimes not be operational. Not only are students concerned by this notion but also teachers in charge of shaping it. Indeed, they have to have a clear consciousness of the nature of the GWS to avoid some misunderstandings resulting from a vague and implicit management of the interplay between paradigms.

We can finally express both questions which we aim to clarify in this paper.

Question 1: What is the current reference GWS proposed at the end of compulsory education in France?

Question 2: What are the characteristics of the corresponding appropriate GWS?

We wish to study more particularly the consequences of the division announced of the reference GWS on the appropriate GWS and also on the students' personal GWS. Our research into the characteristics of this geometric work agrees well with the systematic approach privileged by the study TIMSS (Kaiser, 1994) where the focus on various types of curricula are called intended, implemented and attained.

ON THE REFERENCE GWS AT THE END OF COMPULSORY EDUCATION IN FRANCE

During periods of educational stability, access to the reference GWS is facilitated by what might be called “treaties” which organize and determine the reference corpus. For a long time, Euclid's Elements played this role and fixed the nature of the geometric work. It is no longer the case in our education system. Today only the texts of the official programs and the documents accompanying them seem fulfill this reference role. On the one hand, mathematicians are practically absent from the process of elaboration of the curriculum which is left chargeable to the school institution and the teachers. On the other hand, the absence of organization of the theoretical set of reference in a treaty explains the impression of parceled work space that we attribute to the current GWS of reference. The programmes that we study are those published in 1996 and 2005.

In school, both versions of the programme, the older and the newer one, insist on the notion of mathematical activity defined as the fact « to identify a problem, speculate a result by experimenting on examples, build an argumentation and control the obtained result. ». As for the geometry, it has assigned to it the role « to pass from a perceptive identification of figures and configurations to their characterization by properties ». In the documents accompanying the programme, it is clarified that the properties to be demonstrated can be “seen” on the drawing but that students have to understand the necessity of demonstrating this result. By using the framework of paradigms, we can assert that the curriculum is mainly concerned with the question of the transition between GI and GII. However, the passage from one geometry to the

Working group 4

other one is not once definitively established at a specific moment in the curriculum, and the transition seems ceaselessly put back on every new notion. The new notions are introduced and structured around geometric objects which can be seen also – and the programs insist on it – as objects of the sensitive space: triangles, circles, polygons. The geometric transformations are also used as a structuring element. In the curriculum of 1996, a new transformation (orthogonal symmetry, symmetry through a point, translation and rotation) was introduced at each level of the college. In those of 2005, translations and rotations disappeared with the effect of decreasing the global structure of the theoretical set of reference which appears more and more like a collection of objects juxtaposed.

This indecision on the final choice of the paradigm is particularly clear with the emphasis on experimental studies made to speculate on properties in every Grade. Constructions (in freehand or using drawing instruments or software) play a key role in this process. But at the same time, the notion of a minimum base (le socle) is imposed by the school institution and all the students are supposed to reach this minimal level on all the topics. In the case of geometric constructions, no formal proofs are expected and the basic knowledge is limited to the mastery of techniques useful to make constructions. At the end of the schooling, a student must know how to build and master some elementary techniques without necessarily knowing the theoretical justifications stemming from Geometry II. Through this sole expectation of techniques, we already guess the possible gliding towards an appropriate and personal GWS directed by a technological horizon in Geometry I with the accent put on the perception and the artefacts. To characterize this gliding not assumed towards Geometry I, we will speak of a surreptitious Geometry I.

By contrast and always in the syllabi of 2005, the learning of the demonstration is the object of a more steady attention. In a paragraph entitled « a progressive initiation to the demonstration » it is explained that « the question of the proof has a central place in mathematics ». The practice of the proof allows gradually the implementation of the demonstration. This distinction between proof and demonstration is new in the French education. The proof depends on social context and it can take various forms while the demonstration is fundamentally a rhetoric shape characteristic of the mathematical style. This distinction between proof and demonstration leads the authors of the curriculum to differentiate two phases in the learning process of demonstration: the reasoning and its shaping. At the same time the authors insist on the phase of discovery and it has some consequence on the work set up in the classes because it suggests introducing two different contexts in the appropriate GWS: a context of discovery and context of justification.

Dynamic geometry software is also introduced and used for changing the students' viewpoint on figures that are no longer considered only in their iconic form. By giving the possibility of moving points and of multiplying experiments, software is supposed to favour the access to the general notion of figure contrasting to the

Working group 4

drawing. In this optimistic view, dynamic geometry software is used to favour conjecturing and reasoning to validate the conjectures. But, the ambiguity of the appropriate GWS is again stressed by the role they have: in certain cases they can be used instead of a demonstration when students are not able to produce the expected reasoning in Geometry II. So, software is not only at the origin of conjectures but they can also guarantee the validity of a result. There is then an implicit and potential gliding towards a GWS where the geometric work is directed by experiment and artefacts. In Grade 10, in another institution, the Lycée, the goal announced by the authors of the programme is to stabilize the geometric work developed before during the Junior High School education. New notions such as isometric and similar triangles are not introduced for their own interest but for using the tools developed for proving in Junior High School. The recommended working methods have to be very close to the implemented ones at Junior High School. The starting-point in geometry must be intuitive and experimental and based on perception. Software remains a source of conjectures of properties. These must be proved and then demonstrated in a more formal way.

To conclude this part, we shall speak from a mixed Geometry (GI / GII) because if the authors of the programme insist on the difference between demonstration and experimental proofs, both forms live ceaselessly and seem also justifiable. Furthermore, the theoretical set of reference is split and does not allow to assume completely the passage to Geometry II due to the lack of an axiomatic horizon. Only, isolated and proof dedicated islands are developed and proofs have to be supported by experiments every time. This evanescence of an organized theoretical set of reference is not new and was starting at the end of “modern maths” in reaction to the “all axiomatic” of this period. What is new is, on the one hand, the ambiguous status given to instruments and to constructions and, on the other hand, the multiplicity of the demonstrative islands dependent of configurations in poor connection with each other. This multiplicity contributes to the breaking up of the theoretical set of reference.

TODAY APPROPRIATE GWS

We are now going to try to appreciate the effects of this Geometry mixed and split on the appropriate GWS which we met. In other words, how is this evolution of the reference space echoed in textbooks and in practice of the teachers? To address this question, we now attempt to assess the effects of this mixed and fragmented geometry on the appropriate GWS which we met. In other words, how does this evolution of the reference GWS affect textbooks and teachers' practice?

Describing the appropriate GWS is more complex than specifying the reference GWS because it is rare to be able to have a unique source to define these GWSs. To understand their functioning, it is necessary to resort to various, sometimes contradictory, sources such as the courses of the teachers and the textbooks, very

Working group 4

numerous in France (where there are no textbooks accredited by the Ministry). Furthermore, it is often only possible to approach the GWS in a local way from a study of a subject or even of a type of prescribed task. For our approach of the appropriate GWS, besides our personal observations in class, we shall lean on different works realized within the Laboratory André Revuz and which give information stemming from textbooks but also from the practice in class. To describe the process of didactisation existing in class and determine the appropriate GWS, we present successively:

- A study of the notion of inscribed angle in Grade 9 which provides a first characterization of the standard appropriate GWS;
- The gliding introduced into this GWS by the large use of geometry software from the years 2000;
- The break between the standard appropriate GWS and a great part of the students engaged in another type of geometric work than the expected one by the teacher.

Standard appropriate GWS

We are going to observe the treatment of the notion of the inscribed angle at Grade 9. This notion seems relevant for our study because it takes place at the end of the Junior High-school and it forces the teachers and the textbooks to integrate it into a GWS already in place and that allows us to see some stable characteristics of the GWS. Two properties appear in the Grade 9 syllabus and correspond to the properties expressed by Euclid in his book III: property 20 gives the relation between the central angle and the inscribed angle intercepting the same arc, and property 21 asserts the equality of the inscribed angles as a consequence. The implementation of the notion of the inscribed angle in class has been studied by Roditi (2004) who was able to show the close relation of the approach developed by a teacher with the proposition made in the textbook retained for our study. Roditi points out that this textbook is well known for being well-adapted to the level of the students. So in that case, the implementation of the appropriate GWS is already very influenced by the students' mathematics level. The notions of inscribed angle and central angle are introduced by an activity. Students are asked to draw these two notions from two questions on a corpus of six figures. Definitions are given a little farther by the authors of the book. They are then associated to prototypic images of the notions of acute angle and central angle. So the mode of production of the definitions is of empirical type. Based on some particular drawings, the defining process suits to an abductive way, something which is confirmed in the activity dedicated to the two fundamental properties of inscribed angles and central angles.

« Draw a circle with centre O. Draw several inscribed angles in a circle which intercept the same arc BC. Measure these angles. What conjecture can we do?

Draw a circle with centre O. Draw a central angle and an inscribed angle in this circle which intercept the same arc BC. Measure these two angles. Repeat several times these drawings. What conjecture can we do? »

Working group 4

This activity allows the showing of both properties, written in red in the book and presented in an order different from the Euclidean order. « If two inscribed angles in a circle intercept the same arc then they have the same measure. If, in a circle, a central angle and an inscribed angle intercept the same arc then the measure of the central angle is the double of the measure of the inscribed angle. »

Both properties are identified from very few examples. We can actually speak here of an abduction: the idea of property being present, it is sufficient to extract it from a small number of examples verifying it. The use of measuring is recommended to speculate the property even if the abductive process incites to neglect the approximation and tends to make useless the actual measurement. So, the appropriate GWS which is set up leans determinedly on Geometry I but do we really enter in Geometry II? Settling the question is not evident in this book since both properties are not demonstrated. They are admitted without knowing exactly their validation. In other words, are these properties included in a GWS directed by Geometry II or Geometry I?

Furthermore, the two properties are not presented in the order usually used in the Euclidean tradition and which allows the deducing of the property of the inscribed angles from that of the central angle. This absence of a concern with the global organization of the deductive schema takes away the appropriate GWS from Geometry II. This impression is confirmed by the study of the only use of the property in the textbook. It is asked to prove that some points lie on a straight line on a very particular configuration without any degree of generality – with specific measures – that a more general formulation would have been able to introduce. So, the work remains joined to a particular figure without reaching the level of the generic figures which marks the entrance in Geometry II. The appropriate GWS is so characterized by the absence of generic figure and by the support on particular figures. It is also allowed to measure. The reasoning is mainly based on abduction to clear properties which are then used as techniques to give numerical values. To us, all these elements characterize a GWS, actually, rather directed by surreptitious Geometry I.

In his study, Roditi observed a class session given by a young teacher who used the earlier textbook to prepare his course. He did a certain number of changes with the goal of limiting the degrees of freedom of the students during the activity. The fact of limiting the work and the initiatives of the students allows the teacher to manage more easily the behaviour of the class. In his study, Roditi asserts that students have worked even less than the teacher was waiting, notably at the level of calculations and speculating. So, we note a phenomenon of progressive crumbling of the appropriate GWS which is more and more oriented by the teacher trying to adapt the work to the level of the students. These last ones, in a well-oiled role game, still try to simplify the task to make easier their work of student.

The impact of the software on the appropriate GWS

In her Masters dissertation, Boclé (2008) described the typical situation given in the French textbooks to introduce a new notion in geometry at the end of Junior High-school. In textbooks, conceived just after 1996, the typical structure SP1 was the following:

1. Construction of some particular figures with drawing instruments.
2. Measurement on these figures by using instruments (marked ruler or protractor).
3. Conjecture of the property.
4. Institutionalization of the property accepted without proof or formally proved later.

In the textbooks printed after 2005, a new tendency appears. A new notion is introduced with digital geometric software. The typical situation SP2 is then the following one:

1. Construction of a figure with digital geometric software.
2. Measures given by the software.
3. Dragging of points to notice that the property remains true.
4. Institutionalization of the property accepted or accepted without proof or formally proved later

In both cases, to introduce the property, students have to build several figures satisfying some criteria. Thanks to the measures made on the figures, it is possible to notice an invariant then to draw a conjecture. In the textbooks written according to the programs of 2005, the activities of construction and measuring suppose the use of geometry software. Every activity starts clearly in the GWS directed by Geometry I and favouring perception and instrumentation. In both approaches, with and without software, the point 4 is the crucial point to determine the type of geometry really used and the appropriate GWS. If the property is only proved in a deductive way without any use of measuring, it is possible to enter into Geometry II. On the other hand, what happens if the property is not demonstrated? It seems that students stay in Geometry I. These typical situations well fulfil the programme instructions recommending the implementation of activities leading to conjecture of properties. The recent emphasis on the use of geometry software is taken into account in textbooks but the real contribution of this software in the transition from Geometry I to Geometry II deserves to be questioned. Indeed, the use of digital geometric software is justified in the textbooks by improving the measuring accuracy and the possibility of multiplying the examples. But a measure remains an approximation and it is thus not exact. This imprecision can create a contradiction within the class and lead some students to convince themselves on another way and then to prove without any measurement. By contrast, insisting on the precision of the software and their advantage with regard to ruler and compass constructions could risk to take away students from the necessity of proving which was one of the stakes expected within the reference GWS. In her work, Boclé tried to see if the use of software in

these typical situations favoured the transition to Geometry II or if, on the contrary, it created a blocking element. She noticed that the strength of the proof by experiment overcame the classic work on demonstration with a purely deductive proof. In that case, it seems that the use of the software in a standard situation stabilizes rather a GWS of type Geometry I and not a transition to GII.

The break achieved in Grade 10 or when the ostension becomes demonstration.

We are going to find again this contradiction between the work expected by the institution and the work effectively set up in the case of the teaching of similar triangles in an ordinary class at Grade 10. Similar triangles are not seen by the programs as a new notion but as an opportunity to stabilize the geometric work at the end of the compulsory education. We shall consider here only the result of a session managed by a teacher who first follows the typical way SP1 but who changes on phase 4 of institutionalization and then follows the process SP2 by using uniquely himself the software.

The activity is the first activity on similar triangles.

A sheet of paper is given to the students with a drawing: Part 1 Create a triangle DEF such that $\widehat{BAC}=\widehat{EDF}$, $AB=DE$

Under the figure, the following questions appear on the sheet given to the students: What can we say about angles ACB and DFE? Compare the sides of the triangles with your ruler. What can be noticed? Finish the sentence: We can speculate that if two triangles have then their sides are

For the teacher the construction does not cause a problem. He anticipated two possible configurations, what seems an interesting difficulty to him. He wants to motivate the origin of a property in Geometry I which will be completely in Geometry II when it will have been proved in the following lesson. For him, the figure is a generic example and he has not really thought about the measures given on the paper sheet. The great majority of students, but not all, undertake completely in the activity of construction which turns out long and complex. Students have difficulties with the use of their drawing instruments: the task « to make an equal angle » does not fit to a well-known technique. Furthermore, the two existing possibilities of the figures cause problems in the class since students are working on particular and not on general figures. Other students understood that the construction is not important for the teacher and they quietly wait that the course goes on. They give, by abduction, purely linguistic conjectures by trying to adapt their mathematical knowledge to the situation. At the same time, students engaged in the construction task produce very different and contradictory results but actually these results and the work of these students will be left aside by the teacher who will privilege the solution with the software Geogebra and presented on video-projector to the class. The teacher follows the structure SP2 but without making any devolution to the students. He is the unique user of the software and he proceeds to

Working group 4

an institutionalization which denies all the previous work of the students. On the computer, the figure is the start-point and measures are given with five digits and this even for angles. The ratio of proportionality calculated by the computer was 1.875 and was exactly the same for the three ratios. The accuracy of the measures indicated by the computer shows the students the imperfection of their work with instruments on a very violent way. Strictly speaking, the students' work is of little utility because it is left aside by the teacher. Moreover, the accuracy of the software turns it into a proof tool and a source of truth and, this, without the teacher knowing, as it can be seen in the dialogue which closes the class after the statement of the conjecture.

Teacher : « *Did we demonstrated the property?* »

Almost of the students: « *Yes! We have done a demonstration.* »

Teacher (taken aback) « *Hum.. No, it is too imprecise!* »

So after more than three years of progressive entrance in Geometry II and in spite of the curriculum which insist on the necessary awareness on the status of the statements, accepted or demonstrated, the gap between the expected work and the effective work is deep. It largely results since the appropriate GWS proposed to the students is very ambiguous itself and probably fundamentally a surreptitious Geometry I.

CONCLUSION

From our study, some characteristic points can be drawn of the GWS implemented at the end of the compulsory education in France. The GWS of reference can be characterized as relevant to parceled Geometry II. Numerous demonstrative islets are introduced to show well the link between geometry and space intuition. Then, the emphasis is put on the necessity of developing the demonstrative work by separating it from experimental proofs and from perceptive assertions. However, this reference GWS leaves the door opened, in certain cases, to the implementation of techniques and properties only validated by students experimenting with software. Furthermore, the constant emphasis on a transition towards Geometry II based on Geometry I can let suppose that a mixed Geometry is possible. This opened door becomes a boulevard when we look on the appropriate GWS which appears particularly unstable and dependent on the students' level and the choices of the teacher. The traditional play between the Geometries I and II turns out to be particularly ambiguous because of the probing power of the software for the students. In the observed examples, the gliding towards Geometry I was favoured by the use of software which establishes a computer proof faced the axiomatic proof. This last one is weakened all the more as the theoretical set of reference given to the students does not appear, even between the lines.

Finally, the reorganization of the GWS seems more and more managed by a teacher adapting at the level of the students more than by assuming epistemological choices. The geometric work evolves by successive impoverishment what can explain the

Working group 4

recent attempt to abolish the discursive and figural geometry in Grade 10 for the benefit of the sole analytical geometry. Another way would be possible, in equivalence with the current social demand: to assume a Geometry I in the compulsory education. It would allow again a rich geometric work to be in place and for the GWS to be structured in a coherent way.

LANGUAGE IN THE GEOMETRY CLASSROOM

Bulf C., équipe DAESL, LACES, Université de Bordeaux

Mithalal J., LDAR, IUFM de Paris

The purpose of this paper is to examine how it is possible to relate the way students perceive, act and talk about objects in geometry class. Based on the analysis of an "emitter-receiver" situation in a French geometry classroom at primary school, our contribution provides a theoretical tool in construction, called "frequentation mode".

Key word: geometry, language, "frequentation mode"

INTRODUCTION

In French primary school, manipulating objects is a usual and attractive way of teaching geometry in order for the pupils to get familiar with geometry objects and concepts. Yet, this is only a first step as there is no obvious link between material and conceptual objects (Lismont, 1999). Now, this relationship between the physical world and the geometry world necessarily induces problems of meaning due to the gap between the students' understanding and the sense that we, as teachers or researchers, give to these confrontations with objects.

Until today, French researchers (Berthelot and Salin, 1991; Gobert, 2001) in geometry education have approached this question by linking actions on selected material objects to geometrical knowledge, as Theory of didactical situations mainly focuses on material feedback from the *milieu* (Brousseau, 1998). However, these researchers' results, as well as our various experiments in teaching geometry (Bulf, 2009; Mathé, 2006), suggest that the relationship between the physical world and the geometry one is a very tough problem. Bartolini-Bussi (1994) or Sfard (2008) stress that analyzing the students and teacher's discourse in mathematics classroom is relevant to better understand learning and teaching phenomena in geometry. Our aim is to analyze how the way students act on the objects, the way they talk about them and how they act on them, are interrelated. In this paper, we give an overview of our work and introduce theoretical and methodological tools to be used for a joint analysis of physical and language facts in the geometry classroom.

A SHORT EXAMPLE

The following example is an extract from Fregona's thesis (1990), recorded in a CM1 classroom (4th grade, 9 year-old students) at the Corem [1]. We focus on the analysis of a part of the second session of a sequence in which a "transmitter-receiver" situation is implemented. The announced aims of this lesson were to create

conditions to confront basic knowledge of figures from elementary geometry, to develop geometrical vocabulary and to use methods of figures construction.

The teacher gave the "transmitters" a cardboard-made geometrical figure and asked them to write a message, without any drawing, which should allow the "receivers" to construct a figure that can be superposed on theirs. In the session we analyzed, the teacher and students reviewed the messages referring to rectangles and organized a collective validation of the productions, by superposing the figure constructed and cut on the cardboard model figure.

For now, we focus on the following message, describing a rectangle shape: "*Take a set square and plot 19cm4mm for the larger side and 11cm7mm for the smaller side.*" There are at least two possible interpretations of this message: the "receivers" draw a triangle whereas the "emitters" thought about a rectangle. It seems there was a misunderstanding about the meaning of "set square" in this message. So, what happened, and how to deal with this? A didactical analysis might conclude that the students' understandings of "set square" were different: set square as the shape of a triangle, used to draw a triangle and on the other side, set square as the shape of a right angle, used to draw perpendicular sides (in this case, of a rectangle).

Naive analysis

The two interpretations we identified tally with Duval's ways of seeing in geometry (Duval, 2005): the "receiver" focuses on shapes with an interpretation of *iconic visualization*, whereas the "transmitter" may have described a way of representing relations between sides in a *non-iconic visualization* way.

Furthermore, we have to say that this misunderstanding was not clear to the pupils at the beginning, and three main stages are to be distinguished:

- First of all, a message with an "invisible" misunderstanding about the description of the shape;
- Next, a material feedback (the drawn shape doesn't fit the original): this revealed the misunderstanding as a fact, but it gave no explanation or solution to the problem;
- Then, a discursive interaction (arguing about what "set square" means): each student tried to *justify* how he defined "set square", used this tool, and to convince his opponent that his conception about set square was right : the meaning of set square is negotiated through language beyond a shared use and meaning. Thus, the use of set square changed and students moved from triangle to rectangle.

The first stage only doesn't make the pupils change their interpretation of "set square", whereas the negotiation about set square is about explaining and justifying and plays a significant role in the learning process. Actually, these two discursive interactions' functions are very different, and have to be clearly distinguished. Nevertheless, the role of material feedback is essential; that is why systems of representation and pupils' actions have to be taken into account simultaneously.

First of all, this preliminary analysis allows us to bring out the initial findings our development is based on. Two systems of representation are to be linked in order to understand student's actions: graphical representations and language representations. The study of each system of representation led us to use the notion of action in the sense of the following definition. *We shall define* an action in a system of representation as *the deliberate transformation of an object within this system* (Mithalal, 2010). The observables that we seek to identify are material actions - such a plot - or speech act - and the transformation of meaning assigned to a term.

Moreover, from the former short example, it seems that the students' geometry understanding evolved because of the combination of discursive and material activities. The various roles of these activities – description, construction, justification – as well as their interactions, have to be analyzed.

In the next section we present the theoretical model that we designed in order to get ahead with the comprehension of these two points. Our first aim is to analyze and to have an influence on the students evolving to a shared conception.

JOINT ANALYSIS OF MATERIAL AND DISCURSIVE ACTIONS: FREQUENTATION MODES [2]

The first purpose of defining frequentation modes is to elaborate a tool which simultaneously takes into account students' discourse and actions. Indeed, material feedback mainly leads to local and unstable changes in the students' conception (Mithalal, 2010). At the same time, we assume that only taking into account language is not sufficient either. As a consequence, this may be the result of a dialectic relationship between manipulation and language interactions, without any subordination link.

Three points of view on geometrical activity

Frequentation modes have to take into account three dimensions at the same time:

- The different *ways of seeing* in geometry (Duval, 2005) ;
Indeed, the underlying hypothesis in Duval's work is that *ways of seeing* drawings are strongly linked to the kind of geometrical reasoning.
- The types of action undertaken by the subject and the instrument usage rules.
We refer here to geometrical work from research directed by Marie-Jeanne Perrin-Glorian (Offre, Perrin-Glorian, Verbaere, 2006).
- The subject's discourse on objects and actions.

Therefore, defining a frequentation mode consists in describing a geometry activity by a way of seeing and considering modalities of action – drawing a plot, complying with a given instruction – consistent with a certain discourse characterized by its structure – descriptive, explanatory, etc. – and the meaning assigned to the terms by

the subject. In particular, it should be stressed that this notion is essentially local, being attached to a determined context and subject of study.

Deeper analysis of the former example

In the example presented earlier in this paper, students explained that the group who constructed a triangle was wrong because the message received was “*Take a set square*”. Yet, they considered that a set square “*is used first of all to draw a triangle*”. These students explained to the teacher that they drew the rectangle using the graduated ruler, by measuring three consecutive sides, and then “[*they checked*] it was right”. The transmitters of this group said it was necessary to use a set square so that “*the angle be right*”. As we can see, the interpretation of the retroactions led students to be explicit about the meaning they gave to the set square. Here and now these two dimensions clearly appeared to be closely interrelated: the action was determined by the way students considered the set square and by its understanding of the word “set square”. It is also because they used the set square as a shape template that they interpreted the message this way. Through the longitudinal analysis of the meanings of the words “set square” and “rectangle” and of their action modes, we can start to outline two conflicting frequentation modes of the set square and the rectangle, each one being shared by many students, and which coexist in the language interactions observed:

- For those who read and interpreted the message the students considered as wrong, the word “set square” referred to a triangle template and the rectangle to a 2D surface the general looking of which was known. Consistently, they used the set square as a surface template (“indivisible” triangle) and their rectangle construction method consisted in drawing a rectangle-looking shape using the graduated ruler, and taking into account the measurements of the sides so that the rectangle drawn could be superposed on the model figure. This frequentation mode refers to an iconic visualization (called “botanist” by Duval).

- For those who transmitted the message, “rectangle” referred to a quadrilateral with two pairs of equal opposite sides and four right angles. The word “set square” applied to an instrument used to plot right angles. Their instrument usage mode was consistent with this meaning and their rectangle construction method consisted in plotting right angles and equal opposite sides using the graduated ruler and the set square. This frequentation mode rather referred to a “surveyor-geometer” or “constructor” vision of the *rectangle* figure (because the angle rightness is an invariant property of the rectangle) according to Duval’s meaning.

This analysis allows us to interpret the difficulties encountered by students as the confrontation between two contradictory frequentation modes, with outwards signs concerning at the same time the material actions made by students and their discursive activity.

Three focuses that make frequentation modes operational

The analysis of the former example made us distinguish three consecutive parts of the pupils' co-constructing a shared frequentation mode of the set square. First, there were different interpretations of the words "set square", and various corresponding ways of using the tool; then material feedback highlighted the differences between these contradictory frequentation modes; and eventually there was a negotiation about what could be a shared suitable interpretation of "set square".

Our aim is now to better understand how the pupils' frequentation modes evolved and turned into this shared interpretation, suitable to geometry. Studying this dynamic process made us see that different stakes crystallized the opposition of these frequentation modes: physical transformations and usage of words in the students' discourses, or judgment on the validity of a drawing construction or of "set square" and "rectangle" the semantic values.

Our second concern, making a judgment of validity and semantic value, constitutes a "meta" level for the first one – drawing and description. Therefore, our analysis is based on identifying stakes, each one of them being a meta-stake for another one. By "meta", we mean that it is about judgments made on the sense or validity.

Defining meta-stakes, from the two we mentioned before, would be an infinite process. We decided to add a third one in order to take references to theory into account, and the example of the next part shows its role, but it seemed that a fourth one – epistemological – would have been irrelevant. These stakes are the following ones.

- **Stake 1**

The first stake is based on the actions students perform on drawings: plotting, constructing... We assume that these actions are a sign of their frequentation modes. We also assume that they are strongly linked to the meaning they assign to the words, which has to be analyzed from description of objects – *here, it is a rectangle* – or of actions – *take, measure, check, etc.*

Then, this stake is about discourse representatives and material actions.

- **Stake 2**

This stake is a "meta-stake 1", which means that we here focus on judgments about validity of constructions according to a description, and then judgments on semantic values of terms.

Then, we focus at the same time on making a judgment on the sense or validity of the plot drawn – meta material actions – and on changing the meaning of words – semantic action.

- **Stake 3**

The last stake refers to a theoretical framework and highlights properties on which depends the meaning and the finality of the performed actions. Therefore, concerning material actions, we focus here on a “judgment on the judgment” (invoking a theoretical reference framework), and at the same time this stake is about judgments on the validity of semantic values (which is also linked to the pupil’s theoretical point of view)

UNDERSTANDING THE DYNAMICS OF FREQUENTATION MODES

Back to the example

We have already described the confrontation between the two frequentation modes identified in the previous section. The physical productions were drawings, in a paper-and-pencil environment, using ruler and set square. Now, the rest of the session was about reproduction of rectangles, and mainly with the construction of four right angles; therefore our analysis focuses on the frequentation modes of the geometrical objects – rectangle, triangle, etc. – of the available artefacts – ruler, set square – and of the properties called for, in particular the notion of right angle. In the following analysis, we try to show how the three stakes we defined allow us to characterize the pupils' frequentation modes, analyze how these three parts of geometrical activity dynamically interact and which is more important. Our analysis highlights the role of this dynamic process in the evolution of the frequentation modes.

First move by teacher’s intervention

The teacher intervened and went back to the expression “right angle” mentioned by the student then she established that a rectangle had four right angles. The teacher confirmed the relevancy of stressing the property of the right angles of the rectangle. By doing so, she gave students strong indications on the adequacy of the rectangle frequentation mode that paid particular attention to the right angle, and on her expectations.

Next: changes of some students towards a shared frequentation mode

The teacher focused the discussion on the confrontation between the two rectangle constructions methods already mentioned, one using the set square while the other only took the graduated ruler. A student pointed out that the problem was that the message mentioned: “*take a set square and plot*”; now, she considered that “*a set square is not used to plot, but to have “right angles”*”. The teacher formulated the student’s speech: “*You mean that a set square is not used to measure ... it is used to make a right angle*”. As we can see, she did take into consideration that splitting the angle into a network of 1D elements and considering the possibility of plotting an angle is highly difficult for pupils: “to plot” meant “to draw a line” and the only instrument for this was the ruler.

Working group 4

Both teacher and students' interaction were about the second stake, since they tried to justify a specific way of using a set square coherent with their respective frequentation mode, and we could see the teacher changing the language form used by the student. Nevertheless, her attempts in language actions were not sufficient to make the different frequentation modes of the set square converge.

Prompted by the teacher (*"Now [...] they tell me they do not need a set square but still, you needed it"*), some students who used the set square as a surface template for drawing a triangle now considered another usage of it: the set square became an instrument used to "check right angles".

Because of language interactions, these students changed their frequentation modes of set square and rectangle to an intermediate frequentation mode : they could split rectangles and set squares into 2D sub-elements, admit the property of right angles as one of the specific properties of the rectangle and consider the set square as a right angle template. Moreover, this change occurred because of language interactions, through the simultaneous questioning of the actions performed, of their result and validity. The different terms semantic values were affected by the language interactions which, in turn, affected the usage modalities of designated objects. Thus, language activity made the notion of angle connected to "rectangle" and "set square", and the attention drawn on constituent parts rather than on shape.

Overcoming the contradictions and changing the frequentation mode basing on the pragmatic validation of a rectangle constructed on the blackboard

At first, a student recalled that he only needed the graduated ruler. Spontaneously, he underlined the necessity to make sure that "the line" was "not askew". Two conflicting ways of checking the drawn figure appeared; the first one, upheld by the student, lied on the property establishing that the opposite sides of a rectangle are equal; the second one, repeatedly recalled by the teacher, called for the property laying down that the rectangle has four right angles.

If some students succeeded in making their frequentation mode change from the previous language interactions, others resisted in considering a non-iconic visualization of the rectangle in which the right angle is an invariant property of the rectangle. For these students, the set square still could not be used to check the construction of the rectangle. Here, the confrontation between the different frequentation modes appeared in the conflict between different checking means, each one calling for rectangle properties we consider as specific to each frequentation mode: for these students, the equal opposite sides that had to be measured using the ruler; for the teacher, the property of right angles. Communication couldn't work. Students were in a necessity of operating plotting whereas the teacher complied with theoretical requirements (taking into account the property of the right angle as the main criterion).

Working group 4

The teacher asked a student to construct a rectangle on the blackboard, using the ruler, as he said he did. He organized the validation of the rectangle by asking the student to measure the last side drawn. Then the student realized that the fourth side was too small. Immediately, students in the classroom raised “the problem of angles”. The teacher incited to explain how he could establish the figure built was not a rectangle. The student mentioned the property of equal opposite sides. Prompted by the teacher, he finally explained the property of right angles and the set square now appeared to be the instrument that had to be used to check the angle rightness. The teacher asked the student to check the rightness of angles using the set square. Once again, the set square was considered as an instrument used to check the rightness of angles but not as a plotting instrument.

During the plotting operation or when he made his first judgments on the validity of the produced figure, the student was still in a frequentation mode based on the relation to measurement and guided by an iconic visualization. At the same time, the teacher guided him towards a pragmatic validation (sides don't have the right length) because she tried to make him change his vision mode of the figure. The mistake was found out in a mode called “surveyor-geometer” (as it lies on the reading of the measuring instrument which is the graduated ruler). Again, the teacher and the student used the same language level since they intended to judge the validity of plots (stake 2) “*yes, but he wanted to draw the line directly here. I told him he should check because ...*”. The student's frequentation mode changed via the interpretation of the pragmatic invalidation of his action results. He eventually related the terms “askew sides” and “right angles” when he investigated the origin of the found mistake. Thus, he adapted his frequentation mode to the teacher's one and made the set square *compulsory* to check an angle rightness. Here, the negotiation took place in a level of action and entailed a change not only in the rectangle construction method but also in the usage mode of the set square and in the meaning assigned to the terms set square and rectangle (stake 1).

Reinvestment

The teacher organized a reinvestment phase during which she asked students to collectively write down a message allowing for a receiving student to construct a rectangle with modified side lengths. The teacher asked whether it was relevant to specify the necessity to use a set square in the message. Unanimously, students agreed that “*a rectangle can't be plotted with a ruler*” and that “*we should know that a ruler must be used!*”. Finally, the message only retained the words rectangle, which now implicitly contained the property of right angles, and its side lengths.

The gap between the students' point of view was reduced via a negotiation in stake 2, according to two modalities: through a questioning either of the semantic value of terms, or of the validity of the result or modalities of a physical action. We can state that here the agreement concluded by students in this stake 2 induces an agreement on actions at stake 1 (construction method, set square usage mode) and on discourse:

now the reference of the term “rectangle” is shared and includes the “4 right angles” property.

CONCLUSION

In our work, we assume that the different students’ ways of doing geometry are related to the modalities of interaction between them and sensitive objects of the situation. We do consider that these modalities of interactions apply in two dimensions: a physical dimension which refers to the modalities of students’ physical actions and a language dimension. The students’ geometrical activities are to be seen via their frequentation modes of the various sensitive objects of the situation, in which their modalities of action and their discourse on objects form consistent wholes. Therefore we consider that the gap between various points of view results in the coexistence of conflicting frequentation modes in the students’ geometry activity. This gap is reducing as their respective frequentation modes of the various objects of the situation (rectangle, set square, right angle, etc.) progressively change until converging towards a shared one (shared discourse and action modes). Then, how can we better understand what makes it possible to negotiate a change to a shared frequentation mode, operating in the situation and that fits the framework of Euclidian geometry?

Then, we consider that the different levels of (physical as well as language) actions we identified may provide some lines of research on the possible modelling of relationships between different frequentation modes. Our first analysis suggests that these contradictions are overcome when these different types of confrontation are linked at different levels. Indeed, the analysis elements examined in this paper put forward that the conflict only appears as far as the language forms used in order to describe a sensitive object or a physical action differ for two individuals, or when on the contrary, two identical terms are used to designate different objects or actions. Therefore the contradiction comes from retroactions that emerge from a first level to be subjected to the interpretation of a second level. In return, the negotiation allowing for solving a conflict between two frequentation modes depends on the judgment made on objects or actions or on the terms that designate them: as such, the negotiation will take place in the second level, possibly calling for the third level. This negotiation makes it possible to agree not only on the modalities of action on the sensitive objects of the situation but also on the reference of the terms used (“set square” and “rectangle in our example”).

These theoretical and methodological tools are in a construction phase and should undoubtedly be improved. However, we believe that they can contribute to questions about the place of language in the Geometrical Working Space (GWS) by putting in parallel the physical and language actions of students in a geometry activity and by examining to what extent the negotiation for a shared GWS can be reached through a dialectic change in students’ ways of seeing, speaking and acting.

NOTES

[1] Centre pour l'Observation et la Recherche sur l'Enseignement des Mathématiques (Centre for Observation and Research on Mathematics Education) based in Jules Michelet school in Talence, France, until 1998.

[2] We mean by “mode” the way a student carries out or handles a geometric concept through the consideration of three dimensions (we shall develop these three dimensions later: a way of geometrical seeing, a way of acting and a way of speaking). By “frequentation”, we refer to the degree of familiarity, the student’s understanding about the geometric concept at stake, according to his own in-school and out-of-school acquired knowledge.

In this paper, we report on a teaching experiment in which we focused on students tackling 3D geometry problems in which, in general, they initially tended to produce 'primitive' conjectures by relying on visual images rather than geometrical reasoning. Following the work of Larsen and Zandieh (2008), we utilise the ideas of Lakatos (1976) on managing the refutation process and how the use of counter-examples can be important in promoting the growth of students' capability with geometrical reasoning and proof. We found that students' primitive conjectures can cause an unexpected result and that this can trigger further reviewing ('Monster-barring') and modifications of the conjecture ('Exception-barring') amongst students. Whole classroom discussion followed by small group discussion allowed students to exchange various ideas and opinions and this process was important for their construction of a proof of their new conjecture ('Proof-analysis').

Key-words: geometry, conjecturing, proof, refutation; 3D tasks

INTRODUCTION

The teaching of geometry provides not only a key vehicle for developing learners' spatial thinking and visualisation skills in mathematics, but also a major opportunity to develop their capability with deductive reasoning and proving (Battista, 2007; Royal Society, 2001). Through classroom-based research (for example, Kunimune, Fujita & Jones, 2010; Fujita, Jones & Kunimune, 2010), we are working on several themes in the teaching of geometrical reasoning and proof at the lower secondary school level, encompassing the design of problem-solving situations in geometry for students, the integration of geometrical constructions, ways of providing students with explicit opportunities to examine the differences between experimental verifications and deductive proof, and approaches to the teaching of deductive geometry based around a set of 'already-learnt' properties which are shared and discussed within the classroom.

In this paper we extend our previous research by focusing both on the design of problem-solving situations in geometry for students *and* on the teaching of deductive geometry based around a set of 'already-learnt' properties. While designing suitable classroom tasks is very important in mathematics education (e.g. Wittmann, 1995), using such tasks with students does not necessarily lead to 'good' results: something

which Schoenfeld (1988) has illustrated in detail. Hence, additional factors need to be considered if the teaching of geometry is going to be more effective. In this paper, and following the work of Larsen and Zandieh (2008), we utilise the ideas of Lakatos (1976) to show how managing the refutation process and the use of counter-examples can be important in promoting the growth of students' capability with geometrical reasoning and proof. The tasks we use involve geometrical reasoning on simple 3D shapes - one of the topics considered by several papers from the CERME geometry working group (e.g. Mithalal, 2010; Pitallis et al, 2010).

REFUTATIONS IN THE PROCESS OF PROVING IN MATHEMATICS

Given that conjecturing processes are known to be important in the teaching and learning of mathematics in general, and geometry in particular, (Cañadas et al, 2007), our focus in this paper is on the relationship between conjecture, refutation, and proof. It is known that, on the one hand, treatment and understanding of refutation and counter-examples are not straightforward for learners (e.g. Balacheff, 1991; Stylianides and Al-Murani, 2010): indeed, Potari, Zachariades and Zaslavsky (2009) show that even trainee teachers find it difficult to identify correct counter-examples to refute false statements. Yet, on the other hand, counter-examples play an important role within the process of conjecture production and proof construction. Mathematical activity, it has to be said, is not straight-forward, but rather more like a zigzag path. Mathematicians typically make a conjecture, find counter-examples, refine the conjecture, find more counter-examples and so on, during their proving process. Lakatos (1976, p. 127), in his historical and epistemological study, considered that the proof and refutation process consists of the following:

- Primitive conjecture
- Proof (a rough thought-experiment or argument, decomposing the primitive conjecture into sub-conjectures)
- 'Global' counter-examples emerge (counter to the primitive conjecture)
- Proof is re-examined as a new theorem or improved conjecture emerges

While mathematicians, historians and philosophers remain engaged in on-going discussions into the validity of this process (see, for example, Hanna 2007, p. 10), there is some evidence in the mathematics education literature that Lakatos' framework can be a useful guide to promoting students' conjecture production and proof construction process. For example, Larsen and Zandieh (2008) utilised Lakatos' framework to analyse undergraduate students' proof construction processes in abstract algebra. They categorises the types of proof and refutation activities in terms of students' responses, described in their words as follows (p. 208):

- *Monster-barring*; any response in which the counter-example is rejected on the grounds that it is not a true instance of the relevant concept

Working group 4

- *Exception-barring*; any response that results in a modification of the conjecture to exclude a counter-example without reference to the proof
- *Proof-analysis*; the resulting modification to the conjecture is intended to make the proof work rather than simply exclude the counter-example from the domain of the conjecture

Larsen and Zandieh showed that Lakatos' framework "can serve as heuristics for designing instruction" (p. 215). In a similar vein, Komatsu (2010) revealed how a focus on counter-examples can encourage primary school pupils to refine their conjectures and extend their reasoning to reach a correct answer in a number task. We designed the teaching experiment below with a view to giving lower secondary school students valuable opportunities based on the 'proof and refutation' framework.

RESEARCH SETTING

The teaching experiment was undertaken in a Japanese lower secondary school where geometry has a major role in developing pupils' ideas about proof and proving. In Japan, the curriculum states that, in geometry, students must be taught to "understand the significance and methodology of proof" (JSME, 2000, p. 24. In terms of the 'paradigm of geometry' proposed by Houdement and Kuzniak (2003), Japanese geometry teaching may be characterized as within the *Geometry II* paradigm (in that axioms are not necessarily explicit and are as close as possible to natural intuition of space as experienced by students in their normal lives).

In our teaching experiment, by following the principles of the geometry curriculum, the following lessons were designed for Grades 7 and 8 students (aged 12-14);

- 21 lesson for Grade 7 (students aged 13 yrs old at the time): Introduction of 3D shapes and nets (2 lessons), Points, lines and planes (1 lesson), Positions and angles in 3D shapes (3 lessons, **our focus in this paper**), Distances of two points (2 lessons), Rotated shapes, circles and sectors (1 lessons), Surface areas volumes of 3D prisms and pyramids (2 lessons), line and rotational symmetry (1 lesson), Construction of parallel lines and tangents of circles (2 lessons), vertically opposite angles, alternate and corresponding angles in parallel lines (3 lessons), and Angles in polygons (4 lessons).
- 28 lessons for Grade 8 (students aged 13 yrs old at the time): Congruent triangles (3 lessons), Theorems and definitions in geometry (3 lessons), Constructions and properties of isosceles triangles (5 lessons), Constructions and properties of parallelogram (4 lessons), Construction of a cube (2 lessons, **our focus in this paper**), Congruent right-angled triangles (2 lessons), Relationship between triangles and quadrilaterals (2 lessons), Properties of circles (3 lessons), Parallel lines and areas (2 lessons) and Summary (2 lessons).

Working group 4

These lessons were implemented in one class of 40 students in a university-attached school where the teachers and researchers work together to undertake classroom-based research. The students' standard in mathematics is generally high. The regular teacher of the class, in line with Sekiguchi's (2002) account, generally considers a good lesson to be one in which the students are encouraged to share their ideas and solutions with each other.

In this paper, we focus on the lessons from *Positions and angles in 3D shapes* (taught in Grade 7) and *Construction of a cube* (taught in Grade 8). Our reason for focusing on these lessons is that, in trialling the lessons, students in general tended to produce their 'primitive' conjectures by relying on visual images rather than through geometrical reasoning. Thus, our concern is how to break this situation.

Recent studies (e.g. Christou et al, 2006; Mithalal, 2010) have shown how the use of technology and dynamic 3D geometry environments might help counter the difficulties that students have in studying the properties of 3D shapes. In this paper, we consider the method of 'proof and refutation' with practical activities and group discussions might also be effective and accessible way of teaching. In the analysis that follows, we consider this issue by using 'proof and refutation' framework of *Monster-barring*, *Exception-barring*, and *Proof-analysis*.

ANALYSIS OF EPISODES FROM OUR CLASSROOM EXPERIMENT

Episode 1 – what size is angle PQR in a cube?

In Grade 7 in Japanese schools, the main purpose of geometry teaching is to introduce students to geometrical reasoning through the study of 3D shapes and the angle properties of 2D shapes. In this episode (during the third of three lessons on *Positions and angles in 3D shapes*), and after learning some basic concepts of cubes and cuboids during the previous five lessons, the students were asked to investigate the size of the angle PQR in a cube ABCDEFG (see figure 1).

Of the forty students in the class, 25 of them considered that 'the angle is 90 degrees', 11 thought that 'angles will be changed' and 4 said 'I don't know'. As such, the dominant 'primitive' conjecture can be taken to be 'the angle is 90 degrees'. One student (referred to as student 1) stated his reasoning as follows:

Student 1: I think wherever P, Q, and R are, the size is 90 degree. Because angle PQR looks like 90 degrees if you look at it from the face BFGC.

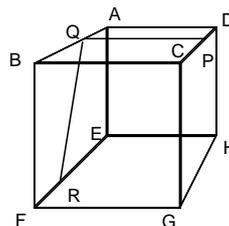

Figure 1: angle PQR in a cube

Working group 4

Students exchanged their ideas and opinions in groups and subsequently in whole classroom discussions which led them to modify their conjecture. The following presentations were made by students during the whole classroom discussion:

Student 2: I investigated by cutting a model of a cube. If we cut AC and AF, then we have an angle, and I think it won't be 90 degrees as the angles are formed by AC and AF.

Student 3: I also used a model, and I used protractor as well. I have got about 60 degrees, and not 90 degrees.

We consider these as *Exception-barring* responses, as their focus is not rejection of the 'primitive' conjecture, but the production of a new conjecture that 'angles will be changed'. After these presentations, the following idea was proposed by a student:

Student 4: I consider why Students 2's and 3's angles are 60 degrees. If we connect C and F, then there will be a triangle. It is a bit difficult to see the figure on the blackboard [as this is a 2D representation of a cube], but these lines should be the same and since all the angles are the same, this triangle should be an equilateral triangle. Therefore, angle CAF is 60 degrees.

We consider this as a *Proof-analysis* response wherein the new conjecture 'angles will be changed' is now justified by a simple proof.

Episode 2 – What shape is face DPFQ in a cube?

In Grade 8 in Japan, students continue to study geometry and are gradually introduced to more formal ways of geometrical reasoning. In the two lessons on *Construction of a cube* (16th and 17th lessons of their geometry work), the students undertook the following problem: 'Consider the net of a cube [see Figure 2]. Construct a net including the face DPFQ [where P and Q are the mid-points of AE and CG respectively].'

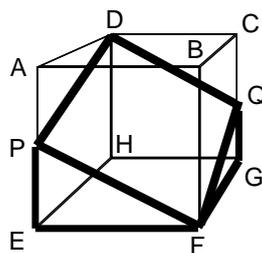

Figure 2: a half-cube for Grade 8 students to construct

In this task, the students were not only expected to identify the face DPFQ, but also to construct an actual net and make the model. This additional practical requirement is particularly important in the teaching experiment as we consider this is more likely to create 'unexpected situations' (such as the square DPFQ does not fit) for many students more easily than a question that solely asks students to determine the shape of the face DPFQ. In the latter case, students might say that the face DPFQ is a square, but it might be more difficult for them to recognise that it is not.

Working group 4

First, the teacher introduced the problem by referring to the students' experiences in Grade 7:

Teacher: Do you remember we made the solid ABCDEGH [illustrated as Figure 3]

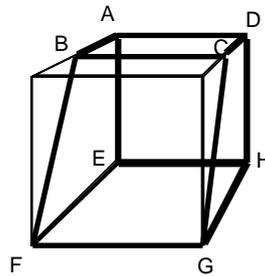

Figure 3: a solid ABCDEGH

Students: Yes, I remember. I think we managed to make it.

Teacher: Yes, and today, we try the task 'Let us consider a net of this 3D shape (where P and Q are the mid-points of AE and CG respectively). Construct a net including the face DPFQ'.

In this problem, a challenging point, on the one hand, is that the quadrilateral DPFQ is not a square, but a rhombus. On the other hand, this can lead the students to making a conjecture, refuting their conjecture, modifying the conjecture and so on, until their final decisions. After investigating this task individually, the students found that their 'primitive' conjecture 'the DPFQ is a square' might not be true as a square did not fit their models. The students then started exchanging their ideas within each group. For example, students in Group A (with students referred to as A1, A2, etc) had the following discussion (relating to models represented by Figures 4 and 5):

Student A1: I think DPFQ is a square. First the original shape was a cube, and all faces are squares, and therefore $\triangle APD \cong \triangle EPF \cong \triangle GQF \cong \triangle CQD$ and all the sides are the same [note that this student's model was incomplete as the quadrilateral DPFQ did not fit perfectly].

Student A2: I thought, like you, that DPFQ is a square, but it did not fit... I drew a square first, and cut and pasted in my model.

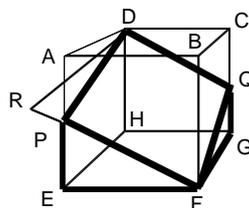

Figure 4: the model by student A2

Student A3: But [see Figure 5] if we follow A2's method, then I wonder if we would have a rhombus? I think, if the first shape we make is a square, then all

Working group 4

sides should be the same, $DQ=DR$, and we cut $\triangle DRP$, and this is a right-angled triangle. Therefore, DP is longer than DR , and $DP \neq DQ$, and this is not a rhombus?

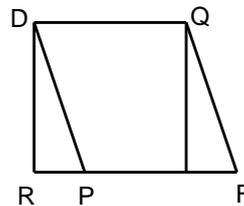

Figure 5: student A3's reasoning about shape DPFQ

We consider the above responses as *Monster-barring* and (incorrect) *Proof-Analysis*. The students tried to reject the counter-example and keep their original conjecture by using (incorrect) reasoning. It is interesting that their *Monster-barring* led to a proof which they tried to use to justify their original conjecture.

In another group (group B), however, two students (B1 and B2) first made their models without drawing DPFQ, and then student B3 showed his answers as follows (see Figure 6):

Student B1: My method is probably cheating, but I drew a net without DPFQ, and then made a model without a lid. Then, I put my half-completed model on a piece of paper, traced DPFQ and then made the lid (DPFQ).

Student B2: My method is similar to B1, but I did it a bit differently. I also made a model without a lid, and then I measured the angle PDQ, and it was 79 degrees. I made a quadrilateral with the angle PDQ 79 degrees, and then put the lid.

Student B3: I tried the method which is similar to B1 and B2, started from a net without DPFQ, and made a model. But I noticed that the length of PQ, the diagonal of DPFQ is the same as EG, the diagonal of HEFG. If we use this fact, we can construct $\triangle DQP$ by using ruler and compass. If we can construct $\triangle DQP$, then we can also construct $\triangle PQF$, then we can complete the net [see Figure 6]

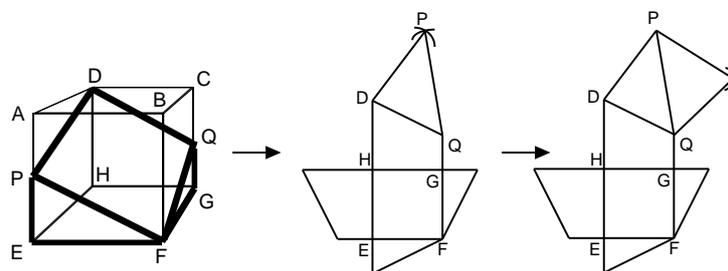

Figure 6: the net made by student B3

The above process can be considered as *Exception-barring*. This is because the students' original conjecture was abandoned and new ideas were searched for to make the situation consistent. Neither arguments by student B1 nor B2 were proofs.

Working group 4

In addition, it is difficult to consider B3's argument as a proof as his method still does not explain what DPFQ is.

After the group discussion, all the group arguments were shared with the whole class. After listening to the presentation of student B3, a student G1 (from group G) added his reasoning as follows:

Student G1: I did like B3's way, but if you looked at the shape without the lid from above, we can see PQ is equal to EG, and as the four sides of DPFQ are the same, so I think it is a rhombus. I then measured PQ and then used compass to complete the face DPFQ.

Student G1's response is again *Exception-barring*, and now a new conjecture 'the face DPFQ is a rhombus' is shared in the classroom. Finally, student H1 (from group H) presented his idea and the new conjecture was proved as follows (see Figure 7):

Student H1: My idea is that I dissected the solid first. If we cut it vertically from PQ to EG, then it will be a rectangle. Therefore, $PQ=EG$. Also, if we cut it by connecting DH and F, then it will be a right-angled triangle, and DF is its hypotenuse and the other line is HF [and therefore, DF is longer than PQ].

Figure 7: illustration of student H1's proof of why the face DPFQ is a rhombus

This reasoning, triggered by group discussions and whole classroom discussion, is considered as *Proof-analysis*. It is also interesting to see that the properties of quadrilaterals and triangles are used effectively by the student to justify the reasoning. Before this lesson, in addition to the 21 lessons in Grade 7, students have already completed 15 geometry lessons in which they practiced their geometrical reasoning in using a set of already-learnt properties which are shared and discussed within the classroom. The properties of quadrilaterals and right-angled triangles were already studied, and this student (H1) used them effectively to advance his reasoning.

DISCUSSION AND CONCLUDING COMMENTS

These episodes show that the first conjecture 'DPFQ is a square' caused an unexpected situation, and then this triggered further reviews (*Monster-barring*) and modifications of the conjecture (*Exception-barring*) amongst students. Whole classroom discussion followed by small group discussion allowed students to exchange various ideas and opinions and this process was important for their construction of a proof of their new conjecture (*Proof-analysis*).

Working group 4

In focusing, in this paper, on students' conjecture production and proof construction within the proof and refutation framework, we can conclude that the framework is useful not only for describing students' proving processes but also in indicating some helpful instructional approaches in geometry lessons. Through our analysis of data from our classroom-based research, we illustrate how managing students' discussions of counter-examples, both in group and whole classroom work, can act as a vehicle for promoting the development of their geometrical reasoning. We found that *Monster-barring* can sometimes lead to an incorrect proof from students (for example, students A1, A2 and A3 in the second episode). As such, *Exception-barring* and classroom discussions are important to construct legitimate proofs (*Proof-analysis*) (see student 4 in the first episode, and student H1 in the second). In future research, in addition to continuing to design suitable tasks for students, we aim to investigate other factors which could facilitate students' conjecture production and proof construction in geometry.

NOTE

The lessons in this teaching experiment were based on the Japanese 'Course of Study' first published in 2000 (JSME, 2000).

IDENTIFYING THE STRUCTURE OF REGULAR AND SEMIREGULAR SOLIDS – A COMPARATIVE STUDY BETWEEN DIFFERENT FORMS OF REPRESENTATION

Jürgen Steinwandel, Matthias Ludwig,

University of Education Weingarten

This paper presents the current status of a scientific study that investigates the impact of three different working environments (illustration, real model or interactive computer-animation) on the recognition and processing of spatial structures. Current literature does not give a consistent picture of this matter. This inconsistency could have several causes, e.g. the spatial-geometrical and arithmetic skills of the test persons, or the complexity of the spatial-geometrical task. We tested the working environment with $n=242$ students from grade 5 to 9 (10 years to 15 years old students). We selected the students from three types of secondary schools in Germany, "Hauptschule (low track), Realschule (middle track) and Gymnasium (high track)". It emerges that the working environment "model" is superior to the other two forms of representation-like illustration or interactive animation. Furthermore, we are exploring whether it is possible to quantify the complexity of a regular or semi-regular solid.

INTRODUCTION

To detect spatial structures of polyhedra (e.g. number of faces, edges or vertices, shapes of their faces, symmetries etc.) students use models (e.g. from the school's collection), illustrations or pictures (e.g. textbooks), as well as partly-interactive computer animation in school. Studies in this field have mainly focused on the torsion angle between two illustrations of a solid that are to be compared and analyzed here for example the processing speed or the frequency of errors (Peters et. al, 1995). Other variables, for example the age or gender, were taken into consideration. Further studies analyzed the impact of computer environments and their training effects (Souvignier, 2000, Hartmann & Reiss, 2000; Hellmich et. al, 2002; Ahmad, 2009). The findings of these studies are inconsistent or contradictory, and in this paper we aim to contribute to clarifying the situation.

THEORETICAL FRAMEWORK

Numerous authors strongly emphasize the great importance of spatial abilities both as a factor of human intelligence and a human skill with practical importance in life generally. However, it seems to be very difficult to define this complex construct. Different authors use terms such as spatial ability, spatial imagination, spatial orientation, spatial awareness and spatial thinking to name just a few. Glück (2006) suggests the high complexity of the underlying issue as a possible cause of the

Working group 4

inconsistent definition and application of this term. Glück herself uses the term spatial imagination performance and means "the use of visual, nonverbal information [...], which is stored in the memory, usually transformed in some way or manipulated and / or which has to be retrieved." In contrast to this, Franke uses the term "spatial ability" as a generic term and distinguishes between visual perception and spatial imagination (see Franke, 2007).

Linn and Petersen (1985, 1986) identified three basic factors as part of a meta-analysis:

- *Spatial perception* is defined as the ability to determine spatial relations despite distracting information.
- *Spatial visualisation* is the ability to manipulate complex spatial information when several stages are needed to produce the correct solution.
- *Mental rotation* is defined as the ability to rotate, in imagination, quickly and accurately two- or three-dimensional figures.

It should be noted that these three factors cannot be considered in isolation to each other because of their various dependencies and influences. It is, for example, highly unlikely that a child has the ability for mental rotation while not possessing abilities in the other two areas. In recent years the analysis of the factor "mental rotation" has become a key area. Numerous studies focused on this aspect with diverse emphasis in their observation, e.g. the ability to learn "mental rotation" (see Glück, 2006, Hellmich & Hartmann, 2002; Souvignier, 2000 etc.). Furthermore, factors or dispositions such as gender, performance groups, age, mother language etc. have been evaluated (see Hirnstein & Bayer et.al, 2009; Kruger & Krist, 2009; Peters & Battista, 2008). The related results show trends but mainly do not give definite answers that remain consistent even under detailed observations. For example, male subjects frequently called into question gender-specific advantages with regards to spatial abilities by carrying out analysis with various filterings of the independent variables (see Jordan et al., 2002).

Another field of research evaluates the interrelation between several factors, e.g. the dependence of the processing speed and the processing correctness with regards to the rotation angle of a distorted body (see Shepard & Metzler, 1971; ter Horst & van Lier et.al, 2010 etc.). To some extent the findings demonstrated an almost linear interrelationship. However, these studies remain limited to composite cubes, which play a minor role in the classroom. Investigations with regards to solids that are introduced in grade 5 to 9 (students from 10 years to 15 years) such as cubes, cuboids, pyramids etc. play a very minor role. In our investigation we try to describe and to investigate the complexity of a body. Therefore we used a very simple and easy understanding model. We defined the complexity (C) of a solid as follows:

$C(\text{solid}) = \text{number of faces}(\text{solid}) + \text{number of edges}(\text{solid}) + \text{number of vertices}(\text{solid})$

Working group 4

If we use the polyhedra formula of Euler $V - F + E = 2$ we can simplify the sum for the complexity of a solid. So we get

$$C(\text{solid}) = 2 + 2 \times \text{number of vertices (solid)} \quad C(S) = 2(1+V)$$

Looking at various studies from the field of educational psychology and psychology about the general topic of “learning with animations in computer-based learning environments” and from research of the didactics of mathematics into the specific topic of “learning of spatial-geometrical contents” and “training of spatial imagination” with or without a computer, an ambiguous picture about the impact of these learning environments transpires. Lowe (2003) for example shows in a study of students of meteorology that a multimedia learning environment does not necessarily impact positively on the learning outcome. He describes that in many cases arrows as movement indicators and illustration series would build sufficient understanding. Furthermore, it appears that the potentially supportive factor of animation is lost with that result that individuals have less control over their own learning route.

In a study similar to spatial geometrical matter, Schwan and Riempp (2004) in turn note that subjects learn the tying of nautical nodes significantly faster with interactive videos (that the subjects can themselves rewind and pause the animations) than with non-interactive videos. In connection with other investigations, they outline an ambiguous picture about the effectiveness of multimedia environments (see also Hellmich & Hartmann, 2002; Cohen, 2005).

The discussion of current research areas highlights several aspects that seem to make a detailed reflection meaningful:

- Most studies stand within the tradition of psychology and therefore hardly ask their primary questions about teaching directly.
- Generally the descriptions of the solids in rotation that are to be compared limit themselves to the angle of rotation. Other attributes such as the number of faces, angles etc. have not been extensively studied.
- Statements regarding different types of presentations and their impact - including those that relate to training impact assessments - are in parts still inconsistent especially in connection with other set variables (sex, performance level, origin, social status, age, arithmetic knowledge etc.).

Accordingly, the research questions were established.

RESEARCH QUESTIONS

The paper presented here has its emphasis on training at schools providing secondary education in Germany. In particular we explore whether it is possible to describe solids in terms of their spatial complexity. Furthermore, it is of interest what form of presentation (illustration, model or simulation software) is the most optimal for the

individual student. For the study we choose half-regular and regular solids. With regards to that we have key research questions:

- How much will different performance groups benefit from the different representations "illustration (pictures), computer animation and model" with regards to the processing of related specific questions?
- Is it possible to describe the complexity of a solid by virtue of specific properties (number of faces, vertices and edges) and how far will such a model retain its validity for differing performance groups?

STUDY DESIGN

N=242 students in 11 different classes from grade 5 to 9 (students between 10 and 15 years old) were tested in five secondary schools covering the three different types: high track (Gymnasium), middle track (Realschule) and low track (Hauptschule). First, two preliminary tests were carried out: an arithmetic test with content regarding the understanding of numbers and basic arithmetic - as well as the brick-test of Birkel & Schumann (2002). Using the data of the brick-test, the student groups were scaled and allocated to the three different working environments of the structure-identification-test (SIT) resulting in comparable groups of similar performance (mean) nearly same standard deviation (SD), while attention had also been given to gender.

In the SIT, eight regular and semi-regular solid had to be worked on. Six students were tested in a laboratory in parallel. Each student worked alone at one of the three working environments (picture, model and computer).

We want to emphasize that the SIT is not a treatment in a traditional way. With this test we do not check any learning or training effects. We only want to test which working environment (illustration, real model or interactive computer-animation) supports the students better by doing spatial geometry tasks. It is just a snapshot.

The brick-test (BST)

The brick-test of Birkel & Schumann (2002) primarily evaluates the "mental rotation" ability. The basic structure of all solids that were used is composite cubes. These composites are placed in the space more or less rotated. The students have to pick two solids from a selection of four to build the needed composite solid (see Fig. 1).

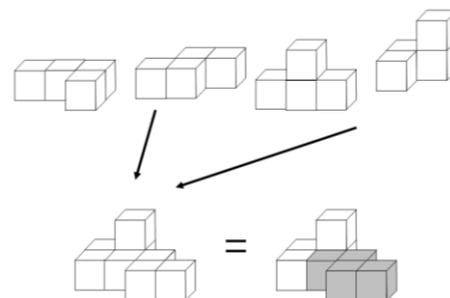

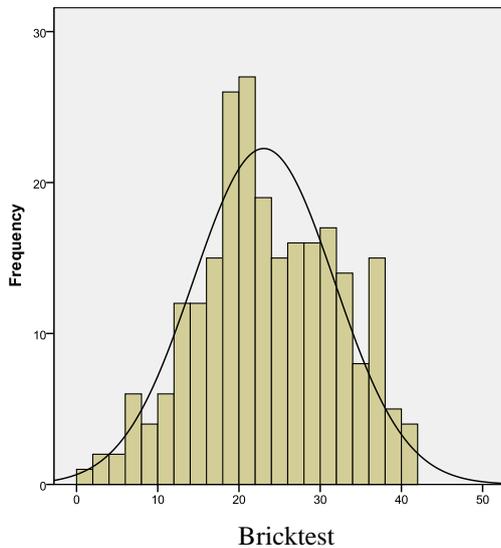

Fig. 1: Composite Cubes of the brick-test

The students had to assess a total of 40 composite solids in a time of 20 minutes. At the beginning two examples were

Working group 4

assessed together with the students. The maximum the students can achieve are 40 points.

The samples

Mean =	23,05
Std.Dev. =	8,676
N =	242

Table 2: Tests for similar power distribution

Working group 4

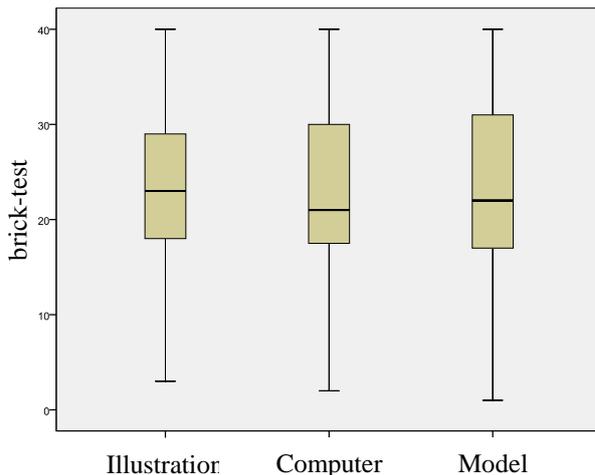

Fig. 3: Boxplots of the groups illustration, computer and model

To compare the three working environments (illustration, computer and model) we need three samples of students who have similar spatial ability. Therefore we created three samples from the results which the students had got from the Brick-Test. For this we divided all students into three performance groups (low, middle and high) and distributed students from these three performance groups in similar way to the three samples. Now we run this method until all students were distributed over all the working environments. The result is that all the three working environments have nearly the same mean and SD (see Table 2 and Fig. 3).

The structure-identification-test (SIT)

The structure-identification-test of Ludwig/Steinwandel deals with a total of 8 semi-regular and regular solids (Platonic and Archimedean solids) as follows (see Fig. 4).

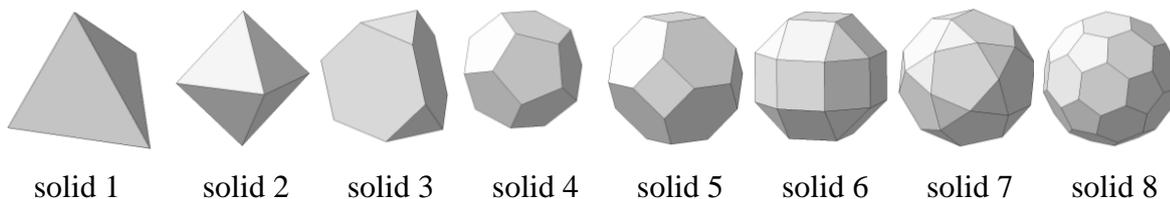

Fig. 4: The Platonic and Archimedean solids used by the SIT

For each solid 6 questions of two levels had to be answered by the students. Questions of level A (questions about the shape of the faces, the number of edges, faces which touch at one vertex) could be answered without abilities in "mental rotation" and "spatial visualization", while these abilities were necessary to answer questions of level B (questions about the number of faces, edges and vertices). The handling time was set and controlled. These periods have been empirically identified following a preliminary investigation. (e.g. solid 1 \rightarrow 1 minute, solid 4 \rightarrow 2:30 minutes). Thus the total duration was 22 minutes.

FIRST RESULTS

Comparison of working environments

In the subsequent short analysis we want to explore the question how helpful the different presentations (or working environments) are for a student in dealing with the questions. In order to be able to make specific statements we set different subsets of the data records.

*. The mean difference is significant at the 0.05 level.

Table 3: Post Hoc Tests

The illustration in Table 3 shows the correlations between performances with the various representations. For the subsequent analysis the data sets were adjusted as follows: we only evaluated solid 2 to 6 as solid 1 is considered to be a "warming-up shape" while the very complex bodies 7 and 8 differentiated poorly and we only considered absolute correct solutions (an approximation to the correct value has not been taken into account).

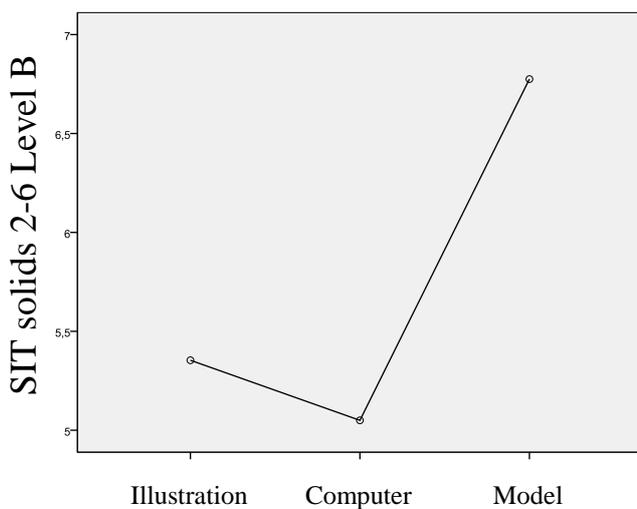

Fig. 5: Mean Plots

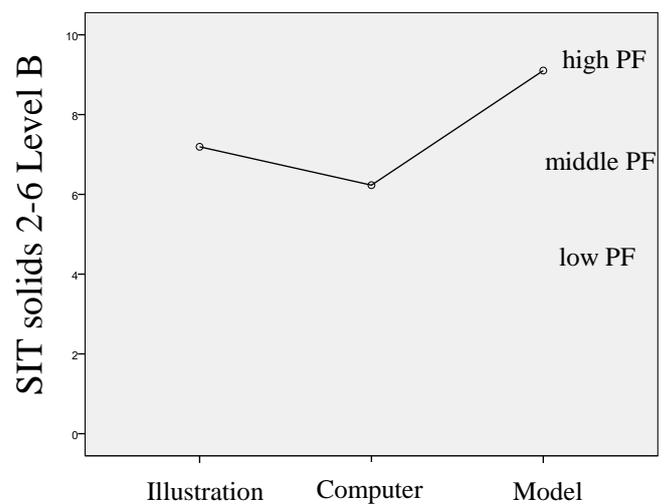

Fig. 6: The performance (PF) in the different working environments of low, middle and high achievers in the BST

Working group 4

The ANOVA-analysis (Table 3 and Fig. 5) shows a similar performance of students working with illustrations and pupils operating with the computer. Students who worked with the model-based environment show significant better results as students who dealt with the other working environments.

In summary we can establish that the illustration-based and computer-based environments in comparison hardly bring about any advantages and lead to results on a similar level (see Fig. 5 and Table 4).

representation	representation	Significance low performance	Significance middle performance	Significance high performance
illustration	computer	,244	,119	,614
computer	model	,000	1,000	,001
model	illustration	,253	,085	,061

Table 4: detailed significances for students with low, middle and high performances

In Fig. 6, three ability groups (low, medium and beneficial students, related to the brick-test) are represented individually. The previous restrictions and filtering have been retained. For weak and beneficial students the interactive computer-animation was the least helpful. For medium students, there is little relevance to what environment they work. Remarkably the similar results for students with low and high performances are observed. Students with low performances show a different finding – the working environments computer and model are equally “successful”. So we can assume, that the model-based environment offers some advantages in dealing with the issues, but not always. For a more detailed view, the significances are illustrated in Table 4.

A model to define the complexity of a solid – a first evaluation

The findings for level A (questions about the shape of the faces, the number of edges, faces which touch at one vertex) show clearly that these questions were usually answered correctly by the large majority of participants.

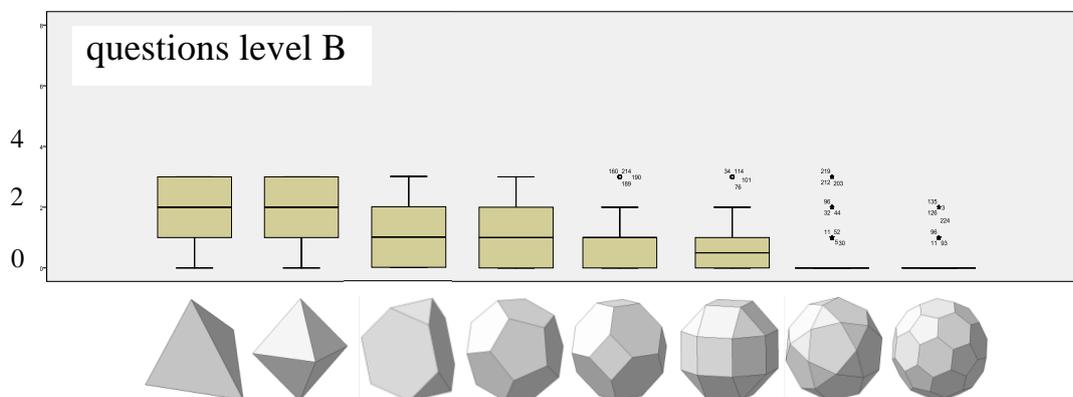

Fig. 7: Performance of level B questions in boxplots for each solid

Working group 4

The following chart (see Fig. 7) was put together in response to questions of level B (questions about the number of faces, edges and vertices). It demonstrates clearly that the model to calculate the level of complexity does partly not differentiate pairs.

Reflections on performance-bands

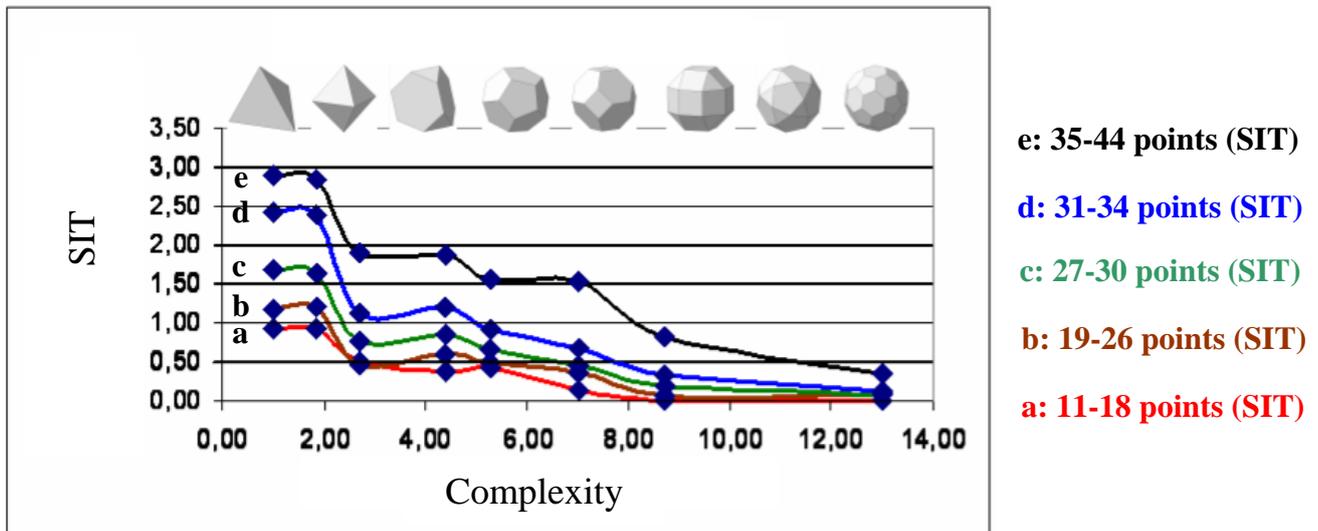

Fig. 8: Results of the SIT as a function of the complexity of the solid for different performance samples

In Fig. 8, we test the hypothesis whether a solid can be described by the applied model to determine the level of complexity. Since we do not have normal distributions – as already demonstrated – we will argue with help of five performance samples (from a = very poor to e = excellent) with regards to the structure-identification-test (SIT).

The graphical illustration shows that sometimes the necessary differentiation between solids is not confirmed by the students' performance. For example, the learners experience the level of difficulty of two different solids as of equivalent value, e.g. solid 1 and 2 or 3 and 4 or 5 and 6. As mentioned above solid 1 has to be interpreted cautiously as it is considered to be a "warming-up shape". Tests in this respect will follow. In addition, we only evaluated solid 2 to 6 while the very complex bodies 7 and 8 differentiated poorly and we only considered correct solutions (an approximation to the correct value has not been taken into account).

The depicted parallel curves suggest the following interpretation: students with better results show this performance bonus with all solids to a similar extent and regardless of the degree of complexity.

CONCLUSION

Based on the analysis of these initial assessments the following two "conservative" theses are posed.

Working group 4

- The findings confirm the rather inconsistent findings of various recent works. For example we cannot confirm that students with strong abilities in the field of spatial thinking benefit from a computer-based environment. On the contrary, this group benefits particularly strong from a model-based environment. For individual performance groups (see Fig. 4) we notice several shifts, which however due to the number of subjects studied should only be used cautiously as direction.
- The model to define the level of complexity of a solid does not differentiate appropriately. It proofs a trend. However, this is not particularly surprising. This model is definitely not sufficient for a description of learning or testing environment in the field of spatial geometry. From a current point of view it appears that the description of a solid is not easy because other parameters such as the angle between two surfaces, the flat of rotation etc. may be relevant. For example a linear connection such as between the angle of rotation and the speed or correctness of processing cannot be detected (see Shepard, Metzler 1971, ter Horst & van Lier et.al, 2010).

Critical remarks and limits are as follows:

- Unfortunately, the experience in dealing with the computer could not be tested. Both an interview and a reaction test with the mouse have been unusable. It should be noted that dealing with the visualization program does not assume any computer skills.
- To estimate the complexity of a solid there are more properties necessary than these few we had considered.
- Because the SIT is not a learning environment but a working environment there are no statements possible about training effects. We only consider which working environment (illustration, model or computer) will support the students more in solving easy spacegeometry tasks.

GENERATING SHAPES IN A DYNAMIC ENVIRONMENT

Sue Forsythe

School of Education, University of Leicester, UK

The study described in this paper aims to investigate the ways in which 12 – 13 year old students conceptualise 2 dimensional shapes. Two students were observed while working together at a task in a Dynamic Geometry Environment where they were required to generate shapes by dragging 2 rigid bars which formed the diagonals within a figure. The students appeared to be attending to the symmetry of the shapes generated which helped them to position the bars, with a high degree of accuracy, to create specific shapes with the expected properties concerning equal sides and angles.

Keywords. Dynamic Geometry Software, Dragging, Symmetry.

HOW DO CHILDREN CONCEPTUALISE SHAPES IN 2 DIMENSIONS?

The study described in this paper was designed to investigate how 12-13 year old students reason about the geometrical properties of 2D shapes while working in a Dynamic Geometry Environment. Whilst geometry appears to be a practical area of mathematics, understanding geometrical concepts requires abstract thought. Researchers have suggested that this dichotomy leads to problems in geometry because students find it hard to appreciate the difference between the actual figure on paper and the theoretical object that it represents (Battista 2007). Students often focus on the material representation of a figure such as a drawing on paper or a figure on a computer screen. However, when solving problems in geometry it is necessary to work with the ideal perfect geometrical figure. The notion of the ‘figural concept’ describes this perfect geometric figure which, when fused with its conceptual properties, is what we manipulate when working on geometrical problems (Fischbein, 1993).

Using Dynamic Geometry Software (DGS) may act as the mediator for the figural concept and as such it can provide students with a means to understand the properties of geometrical figures. In ordinary school geometry, a theoretical object (figural concept in Fischbein’s terms) is mediated by its material representation on paper (Laborde, 1993). Laborde explains that the introduction of DGS enables us to redefine the distinction between the theoretical object and its material representation. There is now a figure on the screen (which can represent a whole class of figures) and this figure is a new kind of mediator for the theoretical object. It is different from a paper drawing in that it is dynamic. Its behaviour when dragged (when objects such as points and lines making up the figure are picked up by the dragging tool and moved on the screen) is determined by the method used to construct it, that is the geometrical properties designed into its construction.

Mariotti (1995) extends this point by claiming that drawings act as mediators between concrete and theoretical objects. Screen images of geometrical figures represent the external version of the figural concept. To construct a figure in DGS the conceptual and figural aspects must be made explicit in the construction process. In this way working in a dynamic geometry environment is useful to develop the correct interaction between the figural and conceptual aspects of geometrical reasoning. The internal logic of the geometrical figure becomes apparent when it is dragged since the geometrical relationships that defined it remain constant under dragging.

Important affordances of Dynamic Geometry Software

There are a number of different ways students can use dragging to explore and conjecture in geometry (Arzarello, Olivero, Paola and Robutti, 2002). Dragging a figure can also be used as a way to test the validity of a construction. Jones (2000) noted that DGS has given us a way to validate a construction through the dragging feature and the drag test can provide the motivation for students to learn about geometrical principles. The dynamic nature of the software influences how students reason about geometrical objects. Measuring is another important affordance of DGS: measures of lengths, angles and areas continually update as the figure is manipulated by the dragging tool. Hollebrands (2007) describes two strategies that students use when dragging and measuring as reactive and proactive. When students drag in a fairly random fashion in order to see what happens and when their decision of what to do next is based on the results of the previous action then the students are using **reactive** strategies. An example (not one that Hollebrands gave) would be if students are given a quadrilateral whose diagonals are fixed length bars and they drag the diagonals in order to see which special quadrilaterals they can make. They can use the measures of sides and angles to check whether they have made the special quadrilateral and adjust the diagonals until the measurements are satisfactory.

As the students develop their understanding of the technology and the mathematics then they are able to predict the outcome of their actions and become **proactive** in their strategies. An example here would be if the students predicted that placing the diagonals so that they bisected at right angles would result in the quadrilateral being a rhombus. Hollebrands (2007) noted that encouraging students to use strategies that are more proactive may be achieved by asking students to explain and justify what happens on the computer screen in terms of geometrical properties.

Olivero and Robutti (2007) say that dragging and measuring can help students to move between the experimental or practical side of geometry (where students can measure lines and angles on geometrical figures) and the theoretical area of geometrical concepts. In my work I hope to see that students working in the practical, experimental side can progress into reasoning in the theoretical side of geometry.

The Van Hiele Levels

The Van Hiele levels are an important model to describe the development of geometrical reasoning (Jones, 1998, Battista, 2007). Briefly, level 1 is the visual level at which children recognise a shape as a totality without considering any of its properties. Level 2 is where children start to understand shapes as being collections of properties and recognise shapes by their properties. At level 3 children are able to infer one set of properties from another and understand the hierarchical classification of quadrilaterals e.g. that a square is also a rhombus. A further two levels deal with deductive proof and advanced level geometry (Van Hiele, 1986). In England the National Framework for Teaching Mathematics gives the specific learning objectives for geometry in year 8 (12-13years), the age of the students in this study, as:

Solve geometrical problems using side and angle properties of equilateral, isosceles and right angled triangles and special quadrilaterals, explaining reasoning with diagrams and text and classify quadrilaterals by their geometrical properties (Department for Children, Schools and Families, 2007).

Thus the students in this study are expected to be working between Van Hiele levels 2 and 3.

METHODOLOGY

The research described here is part of an ongoing study being undertaken for the author's doctoral degree. It follows a design based methodology which uses the design experiment to study and develop theories about how people think and learn, in the setting of a learning environment, and allows the researcher to study the learning process in context (Cobb, Confrey, diSessa, Lehrer, and Schauble. 2003, Barab and Squire, 2004). The design process goes through a number of iterations where the experiment is designed, trialled, the results are analysed and reflected on and the experiment is then refined to test the robustness of any observations made.

Figure 1 A toy kite

The experiment was devised with the intention of creating a meaningful task for students to work on where they would perceive the utility of the mathematics involved, in this case geometrical concepts of 2D shapes (Ainley, Pratt and Hanson, 2006). It is based on the idea of a toy kite whose structure is formed from two sticks (or bars). In a basic kite as shown in the Figure 1 these bars are fixed at right angles and are of different lengths. The resulting structure is covered with fabric and, if we attached a long line of string, we might be able to fly it. If you imagine the shape, it will probably be as a geometric kite, i.e. the vertical bar will intersect the horizontal bar at its mid point.

Working group 4

Working with the idea of 2 rigid bars providing the structure for a 2D shape let's say that the bars can be moved inside the shape (the fabric is elastic and stretches to stay with the bars). This would be difficult to demonstrate using pencil and paper except for showing different positions of the bars at discrete moments in time. However it can be done in the human imagination and also in DGS.

Using the Geometers Sketchpad version 4 (Jackiw, 2001) a file was created containing a vertical bar and horizontal bar of 8cm and 6 cm respectively. The students working with the file were asked to drag one bar over the other and to use the line tool in the software to join up the ends of the bars. They then constructed the interior of the shape which fills it with colour (equivalent to putting fabric onto the kite) and helps with visualisation especially when the shape is concave.

Some researchers (eg Arzarello et al, 2002) have noted that students, working with DGS, often need to be encouraged to use the drag mode. The task in this study requires students to use dragging. Rather than asking students to construct a figure with drag proof properties, this task uses the dynamic nature of the software in a different way where the constraints are the two rigid bars inside the shape. These restrict the shape to a quadrilateral or triangle, the types of which are dependent on the lengths of the bars and the angle between them.

The task was given to pairs of students aged 12-13 years and, at the time of writing, 8 pairs had worked on the task. The students worked for two sessions each lasting fifty minutes and their on screen activity and dialogue were recorded. Dialogue and screen activity were analysed and emerging themes were identified.

Assessment of the prior knowledge of the students was carried out informally at the beginning of the task through questioning about the shapes they had made and about their properties. The students were assessed by their regular class teacher as being of average attainment with respect to their peers. Each pair were chosen as being students who would enjoy working at computer tasks and who were sufficiently confident to be able to talk about what they were doing with the researcher, whom they had not met previously. The students generally studied mathematics in the same class as each other but did not necessarily work together in class.

OBSERVATIONS FROM THE RECORDINGS

At the beginning of the research I had hoped to observe that the students could classify 2D shapes in a hierarchical manner e.g. accepting that a square is a special case of a rhombus. However my observations indicated that the students were reluctant to accept this kind of reasoning. In fact De Villiers (1994) described many students' unwillingness to work with a hierarchical classification of quadrilaterals, preferring instead to use a partitional classification (e.g. where squares have equal length sides and equal angles, rhombuses have equal length sides but unequal angles) unless they can see a reason for using a hierarchical classification. Nevertheless I was able to make observations about how the students may conceptualise shapes and

the ways in which they used symmetry emerged as an important feature. Battista (2007) has conjectured that students might unconsciously perform visual transformations on shapes which help them to conceptualise properties and I argue that I have observed something akin to this.

Three different strategies using the affordances of Dragging and Measuring

The students appeared to use dragging and measuring in three different ways; using the reactive and proactive strategies mentioned by Hollebrands (2007) and a third way that I noticed when they used dragging and measuring together. The reactive dragging style was observed when the students dragged bars around fairly randomly to see what different shapes they could make. This happened at the beginning of the sessions when the students did not yet know what to expect. They dragged the bars around to make shapes that they recognised from their previous experience in geometry.

Proactive dragging occurred when the students had a little more experience of working with the tasks. If the students decided to make a kite, say, then they dragged the bars straightaway to generate the shape they wanted. Several pairs of students were observed to drag the horizontal bar up and down the vertical bar treating it as a perpendicular bisector, maintaining the symmetry of the shape. In this way, using the 6 cm and 8 cm perpendicular bars, they quickly generated a kite, rhombus, isosceles triangle and arrowhead (which they did not recognise as being a concave kite).

The students attended only to the holistic shape when dragging proactively. After the shape was considered finished the students would typically check the length and angle measures to prove that they had indeed made a kite or whatever shape it was supposed to be. However the measures of sides and angles which were meant to be equal very often were not exactly equal. The students would then try to make subtle adjustments to the positions of the bars. I have named this third strategy 'refinement.' They would typically make very small dragging movements so as to get the required measurements as equal as possible. They usually got them to be close to within one degree for angles and one decimal place for lengths in centimetres and this was considered to be acceptable. Using a refinement strategy also helped the students to check and review the properties of the shapes which they already knew. For example one pair of boys decided the angles in a rhombus are equal. They tried to drag the bars to make the angles equal and still retain the shape of a rhombus but were unsuccessful. However this activity helped them to see that there are two different sizes of angles in a rhombus.

Using symmetry

The most useful strategies the students used were the proactive dragging and the refinement strategy. The work of two girls will be described as an example of what the student pairs have typically done while working with the files. The girls, working in the file with the 6 cm and 8 cm bars, made an arrowhead as their first chosen

Working group 4

shape to explore. They proactively dragged the horizontal bar AC so that it was bisected by the (extension of) vertical bar BD. After having decided that a symmetrical arrowhead would have pairs of equal length sides, the girls used the refinement strategy to make the two pairs of adjacent edges congruent. When analysing the recording it was noted that the refinement activity took up 3: 55 minutes of the recording while the girls were trying to make an accurate arrowhead. Subsequent intervals of refinement took less than one minute, usually just a few seconds. This seems to indicate that the girls improved in their ability to position the bars using their judgement and they appeared to use the symmetry of the shape to help them to do this.

The screen shot in Figure 2 shows an instance, when Alice was making the arrowhead kite and focused on getting two of the measurements to be equal at the expense of the symmetry of the shape. Tilly pointed out that she needed to position the vertical bar in the middle of the shape and, although symmetry is not specifically mentioned, it is symmetry to which she is referring.

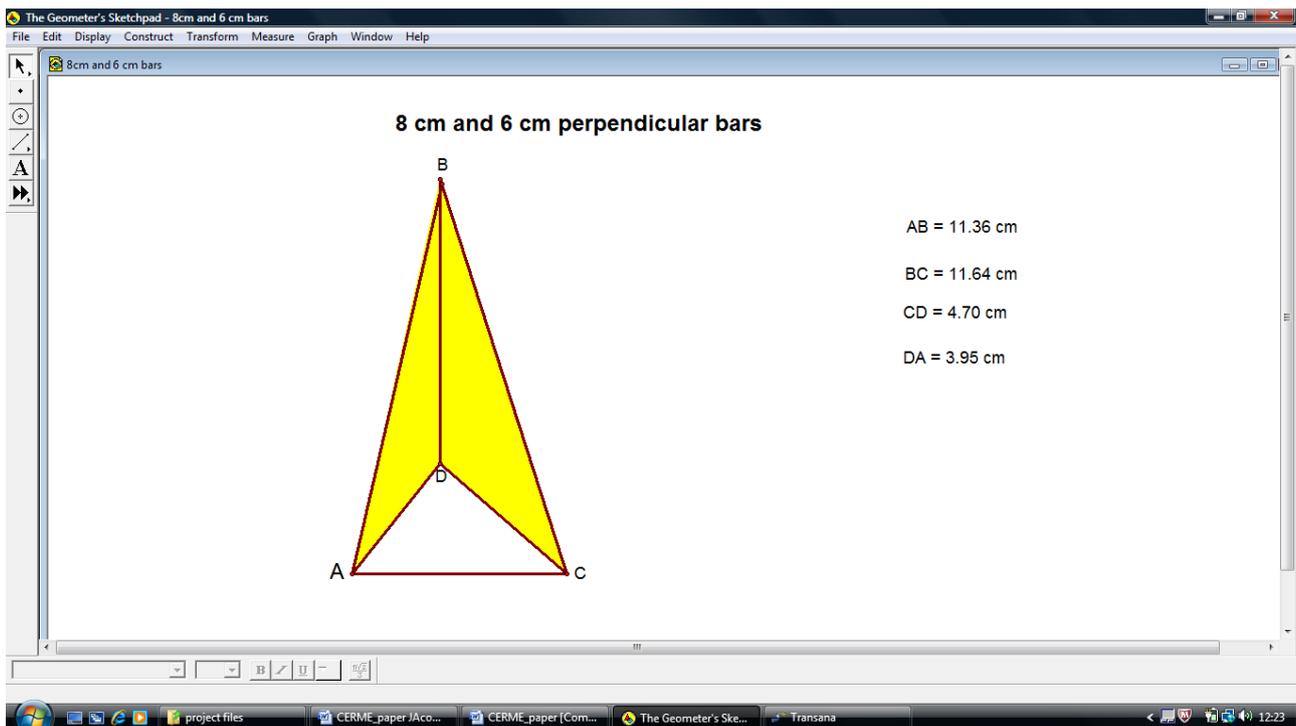

Figure 2

Tilly: Oh that was right a minute ago, it was eleven nine seven, point nine seven, you need to go higher

Res: DA and DC have changed now haven't they

Tilly: cos you've gone to that side more. You need to be in the middle and then move up. That's still a bit that side I think.

Working group 4

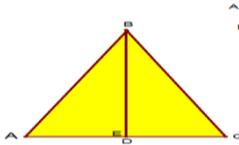

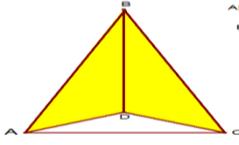

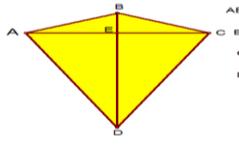

Alice: It still looks wonky to me

Tilly: So move that way a bit, no the other way. Nearly got them two. We're try and aim for D and A first then B and A and BC. If you move that a tiny bit, the other way

Res: So what are you trying to do, how are you trying to position BD?

Tilly: Yeah we're trying to get BD in the middle of the shape.

Eventually the girls decided that the best way to make a symmetrical arrowhead was to place the bars in the position of an isosceles triangle and then move the horizontal bar AC up or down from there. They moved AC so that it would be perpendicularly bisected by BD although they did not use this kind of terminology. First of all Tilly suggested they move the point D to sit on the horizontal bar AC and then move the bar BD up from that central position. Tilly had the computer mouse at this point and spent some time ensuring that the measures on the isosceles triangle were as close as she could get them (Figure 3) before moving the vertical bar BD down making an arrowhead (Figure 4) and then up (through the rhombus), to make a kite (Figure 5).

8 cm and 6 cm perpendicular bars	8 cm and 6 cm perpendicular bars	8 cm and 6 cm perpendicular bars
 <p>AB = 8.54 cm BC = 8.53 cm CD = 2.98 cm DA = 3.02 cm</p>	 <p>AB = 10.03 cm BC = 10.06 cm CD = 3.42 cm DA = 3.36 cm</p>	 <p>AB = 3.30 cm BC = 3.32 cm CD = 7.25 cm DA = 7.24 cm</p>
Figure 3 Isosceles triangle	Figure 4 Arrowhead	Figure 5 Kite

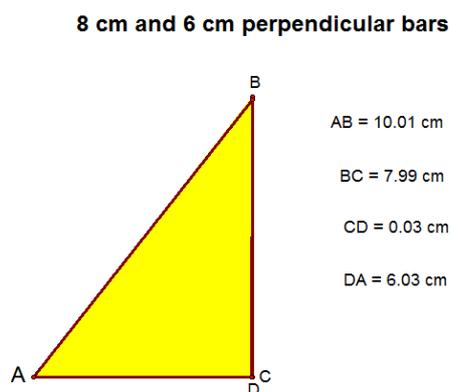

These students had realised that simply sliding the horizontal bar AC up and down the vertical bar BD such that its mid-point touched BD resulted in shapes they recognised. Later in the same session the girls observed that they simply needed to slide the horizontal bar AC down in order to make the kite (in one position) and the rhombus. “That’s a diamond and that’s a kite” was accompanied by the horizontal bar being moved down then up again keeping vertical bar AC as the perpendicular bisector.

When it was suggested they slide AC below the position for a rhombus they decided that they had generated an ‘upside down’ kite (thus focusing on the orientation of the typical representations of a kite). In each case the girls only needed to spend the smallest amount of time using refinement to make the measurements equal as they seemed to have gained experience in how to place the bars by eye in order to create a shape with symmetry. The girls visualised the shapes holistically when attending to symmetry which suggests reasoning at Van Hiele level 1. They were also focusing on moving the bars, which were the diagonals, inside the shape and noting the relative position of the bars, which indicates reasoning at Van Hiele level 2.

Working group 4

The girls only investigated the use of the vertical bar as a line of symmetry which may reflect vertical dominance in the natural world. When they generated the rhombus they did state that it had two lines of symmetry, i.e. both the bars. When questioned, their concept of symmetry seemed to be process based rather than coming from an esoteric understanding of the meaning of symmetry. They had clearly been taught that, if a line of symmetry exists then the shape can be folded along that line, edges and angles will coincide and therefore must be equal in size. They used this explanation as their working definition of symmetry and it helped them to decide which sides and angles in the shape need to be congruent.

HALF A SQUARE OR HALF A RECTANGLE?

At one point the girls dragged the bars to make a right angled triangle (Figure 6). A discussion followed as to whether this shape is half a rectangle or half a square. This was interesting because the girls clearly visualised that if the right angled triangle was copied and then the copy was transformed the result would be a rectangle (or square, until they had argued it through). When Tilly said that it will make a square, Alice disagreed and had to persevere for a while until her colleague came round to her point of view.

Figure 6

Tilly: Cos if you get another one of them, and turn it round and make a

Alice: It would make a rectangle

Res: So you think it would make a rectangle?

Tilly: No a square

Res: If you have two of them?

Tilly: yeah

Alice: that'll make a rectangle

Tilly: Wouldn't cos they're the same

Res: Which are the same?

Tilly: er B and A, well er AC and BC

Res: Have we got those two measurements?

(A discussion took place where they decided the 2 perpendicular sides of the right angled triangle were not the same length).

Working group 4

Tilly: I think it'll still be a square because if you put that one there. And if you put A er D at the top, join it with the B point then put BC on the other side then it would be a same I think.

Res: What do you think Alice?

Alice: er, er, wait, I need to

Tilly: no actually it would be a rectangle

Alice: It would because, if you think about it, if you did, if you flipped that over the other side so it was like symmetry, you would get the same, and if you had both of them, then it would be a rectangle

Tilly: yeah it would be

Res: OK so why should it be a rectangle and not a square?

Tilly: because BC is longer than AD.

Although it is unclear whether Alice was thinking incorrectly that the copy of the right angled triangle would be reflected to make the rectangle (although Tilly considered that the extra triangle had to be turned round, indicating rotation) it does seem that the girls were looking at the rectangle through the lens of symmetry.

CONCLUSION

In analysing the recordings it has become evident that the students are implicitly aware of the symmetry of 2D shapes and that this awareness is powerful for their understanding of the properties of the shapes. A preliminary conclusion from this study is that it may be more intuitive for students to focus on symmetry first and to derive other properties from it. In future iterations of the study, bars which are at different orientations to the vertical and also bars at adjustable angles will be used to investigate further.

INTEGRATING NUMBER, ALGEBRA, AND GEOMETRY WITH INTERACTIVE GEOMETRY SOFTWARE

Kate Mackrell

Institute of Education, University of London

In order to compare the potential for the integration of number, algebra and geometry using interactive geometry software, a series of tasks related to finding the area of a circle was performed using Cabri II Plus, Cinderella, GeoGebra and Geometer's Sketchpad. It was found that, while each program had the facility to perform the tasks, there were differences in the design of the programs that could lead to either facilitating or impeding the development of student understanding.

Keywords. Technology, interactive geometry software, geometry, number, algebra.

INTRODUCTION

There is an increasing awareness that the details of the design of pedagogical tools are significant and should be researched (Jackiw, 2010). This paper arises out of research on the design of four different interactive geometry (IGS) programs: Cabri II Plus (Cabri), Cinderella, GeoGebra and Geometer's Sketchpad (GSP). The focus has been on the identification of affordances and design decisions as a basis for further research on the impact of such differences on student learning.

Current IGS software provides a means by which algebra, geometry, and number can be meaningfully linked. Falcade (2007) showed that geometric construction could be used to enhance student understanding of the concept of function. Laborde (2010) explored the creation of dynamic graphs. Jackiw (2010) suggested that dynamic number provides an appropriate link between algebra and geometry.

A particular series of tasks involving the integration of number, algebra, and geometry were hence used to compare the four programs. The topic, finding the area of a circle, is universal, and each task (e.g. constructing a geometric object or an algebraic expression) involved processes common to other topics. The pedagogical approach (involving exploring and gathering information about a mathematical situation, making and testing conjectures, then generalizing and proving results) has been promoted extensively in the UK since the 1980's: the specific tasks were based upon the principle stated by Laborde (2010, p. 218) that "the teaching of mathematics must help students learn how to adequately use various representations and to move between them if needed."

As the aim of the research has been to identify rather than study the impact of design decisions, the tasks were performed only by the researcher in order to:

Working group 4

- a) ensure that the same tasks were performed with each program as a basis for comparison. The pedagogical approach emphasizes student choice and, in a classroom, would result in different tasks being performed by different students.
- b) address the issue of familiarity. The researcher was in communication with the developers of all the programs to ensure that any initial lack of understanding was not reflected in her conclusions.
- c) ignore the effects of any differences in task presentation necessitated by differences in the programs and in student familiarity with the programs.

METHOD:

Each task was performed several times with each program as questions concerning the affordances of the programs arose and were answered by the software developers, or when more detail was required.

RESULTS:

Task 1: Create a circle and a segment to represent its radius

In this task, the basic mathematical situation to be explored was set up.

In Euclidean geometry, a circle is a set of points equidistant from a given point, and does not depend on location. Cabri and Cinderella each had a tool by which a circle could be created and explored simply by clicking to create a centre point and define an initial radius. Dragging the centre point of this circle moved the circle without changing its size; dragging on the circle itself changed its radius. In the other programs objects such as a point on the circumference or a segment or number giving the length of the radius needed to be chosen.

The simplest option offered by all the programs (and hence the option used in further tasks) was to create a circle given a centre point and a point on the circumference (referred to as the radius point). Dragging the centre of this circle changed both its location and its size: only by dragging the circle as a whole was its radius maintained.

In Cinderella and GSP the same motion, dragging, is used to create the circle and to move it. Making the circle by clicking at the centre, holding down and pulling felt analogous to pulling one arm of a pair of compasses away from the other. Cabri and GeoGebra required a click – release - move – click motion, a different motion from dragging, but with the same visual effect and hence potentially confusing. In GeoGebra, the algebra window needed to be hidden: otherwise coordinates of the centre point and radius point appeared after clicking and before releasing which was distracting, unnecessary, and potentially off-putting to learners who had not yet encountered coordinates.

Working group 4

In the geometry of Euclid, distances, areas and volumes could be compared but were never assigned a number. Introducing a number moves away from the origins of geometry, but, if the number is variable, enables a move toward algebra. In each program, a circle may be created from its centre and a number to represent its radius.

Possibilities for the radius of the circle can be ordered by variation and naming, both of which are important in developing the concept of a variable. A conjecture is that the process of manipulating numbers which are linked to objects that change may be important in developing the idea of a variable. Changing a number such as the radius of the circle and noticing the effect may be a useful introduction to the idea of variation without algebraic terminology and notation. Using names for variable numbers may be a later step in developing the idea of the variable.

In Cinderella, the number, input through a dialogue box, cannot be edited or used for any purpose other than defining the circle. GeoGebra gives the same option, although the number may be edited. In Cabri and GSP, the number is selected by clicking on any number displayed on the page, either entered directly or the result of previous measurement or calculation. Cabri allows numbers to be placed on the page without being assigned names. GSP requires a new parameter to be defined, which will be assigned a name. GeoGebra also allows previously defined numbers to be used, but only by typing in the name of the variable, such as the name of a slider, representing the number. A slider, whereby a number changes as a point is dragged, gives a visual representation of the variability of a number, and enables numbers to be changed by the same operation, dragging, that changes geometric figures. It has the potential to be an important link between geometric and algebraic representations. GeoGebra sliders have the appearance of points on segments, but the points and segments are not actual geometric objects. In the other programs, geometric sliders, which give measurements such as the relative position of a point on a segment, may be created. The numbers defined by such sliders will not necessarily have names.

Task 2: Measure the area and radius of the circle.

In this task, information is found about the mathematical object being studied.

With measurement, the introduction of numbers becomes necessary. In each program, it is straightforward to find the area of the circle and the distance between the centre and radius points.

The table below gives a screenshot for each program with a list of construction steps so far. The algebra window is also displayed for GeoGebra. Cabri objects (but not measurements) have been labeled. Other labels were supplied by the programs.

GeoGebra																																									

Table 1: Constructed figures and figure descriptions

Working group 4

An issue with measurement is that GeoGebra and Cinderella do not display units (although this can be changed in Cinderella). Although not apparent above, trailing zeros are also not displayed. For example 3.004 to two decimal places would be written as 3 rather than 3.00, which can lead to statements such as “ $3 \times 4 = 12.02$ ”.

Unlike Cabri and GSP, Cinderella and GeoGebra distinguish names, which appear in the figure descriptions, from labels, which appear on the page. For example, the area of the circle in Cinderella has the name “A0” but the label “|C0|”, and in GeoGebra has the name “areac” and the label “Area”.

A confusion concerning objects and algebraic variables is evident in GeoGebra. Geometric objects and measurements of these objects may each be given a name, and the names may look equally “algebraic”, but only the name of the measurement refers to a variable (assuming that the measurement is not fixed), as only numerical quantities may be variables. Every program identifies the segment from A to B as a geometric object, a segment. However, GeoGebra treats it as a variable, and assigns it the value of the length of the segment: apparently “the algebraic representation of a segment is its length” (Hohenwarter, 2010, personal communication). This is also a puzzling misuse of the phrase “algebraic representation”: the length is a measurement rather than an algebraic expression, it is not the only measurement which can be made of a segment, and it does not determine the segment in the way the equation of the circle can determine the circle.

A further issue here is the naming of coordinates and equations as “values” in Geogebra. Particularly in interactive geometry, the coordinates of a free point are an indication of its (temporary) location relative to certain coordinate axes: equating a point to its coordinates is simply wrong.

There is also the issue that the information concerning coordinates and equations is displayed at all. For Cinderella, such information must be shown. In GeoGebra, such information must be hidden.

Task 3: Change the radius of the circle and observe the effect on its area.

In this task, further information concerning the mathematical object was obtained, and a conjecture was made about the relationship between two variables.

Dragging is one of the chief links between geometry, number and algebra in an IGS. By dragging the radius point, a static circle, with a fixed radius and area, becomes a circle whose radius and area are now variables, capable of being related.

Unless the algebra window is hidden, GeoGebra shows the coordinates of the radius point as it is dragged: the other programs enable a focus on the way in which the area changes as the radius is changed without distraction. The measurements move with the figure in Cabri and Cinderella and can be attached to the figure in GeoGebra and GSP (although this is not straightforward). It is clear that as the radius increases, so does the area.

A conjecture is hence that the area is some multiple of the radius.

Task 4: Test the conjecture by calculating area/radius and seeing how this changes as the radius is changed.

In this task, the conjecture about the relationship between the two variables was tested, and refuted.

An advantage of Cabri and GSP is that the general division of area by radius could be achieved simply by using a calculator tool to divide the existing area value by the existing radius value, with numbers entered into the calculator by clicking on them. As the radius and area changed, the calculation was continually updated. It is unnecessary for the student to deal with the abstract idea of dividing one variable by another. However, the calculator can also act as an introduction to this idea. In GSP, when a number is selected on the page, its name appears in the calculator, making it clear precisely what is being calculated, and the label “area/radius” will appear next to the completed calculation. In Cabri, calculation involves more algebra; when a number is selected on the page, the number is assigned a variable name, starting with “a”. This name appears both on the page next to the number and in the body of the calculator. An expression is built up in the calculator, and the variable names on the page indicate which number will be substituted for each variable in the expression when the expression is evaluated.

The use of the function tool for calculation in Cinderella immediately made calculation seem more daunting. Numbers could be selected either by clicking on them on the screen to place their names in the calculation box, or by typing in the names. The possibility of dual input means that the user could either see the calculation as just involving numbers or as involving a relationship between variables.

In contrast, GeoGebra required the names of variables be typed in the input bar in order to perform any arithmetic operations, hence demanding the awareness that one variable might be divided by another with no means to build this awareness. The algebra window, with a large amount of distracting information, needed to be open to find the names of the variables and the text input requirement created issues with syntax, made more difficult by the confusion regarding the segment name, which behaved as a variable in the calculation.

Having performed the calculation, it is clear that the result changes as the radius changes: the conjecture concerning a linear relationship was incorrect.

Task 5: Using the measurements to create a graph of area against radius

In this task, a new representation of the mathematical situation was created to give further insight on the relationship between the two relevant variables.

Working group 4

One of the most powerful features of IGS is the ability to visually represent the way in which measurements vary: a graph of area against radius may be constructed directly from the existing measurements.

It is possible in all programs to show inbuilt coordinate axes and directly plot the point representing (radius, area), but with Cabri or GSP the basic idea of coordinate representation may be explored. A number can be transferred to a linear object which acts as an axis. For example, the radius measurement of 2.5 cm may be used to create a point which is 2.5 units from a fixed point along a line functioning as the x axis. As the radius changes, this point will move along the axis accordingly. The corresponding area of 19.4 cm^2 may be represented by a point along another axis. Parallel axes form a dynagraph (Goldenberg, 1992); axes at an angle enable the construction of the point that is reached by travelling 2.5 units along the x line followed by 19.4 units along a line parallel to the y line.

Once the point was plotted, each program enabled it to be traced, to create a visual record of the way in which area varied as radius was changed. The set of all possible points representing (radius, area) could then be obtained by creating a locus, which represented the graph of area against radius. This graph was constructed through an understanding of coordinate representation with no recourse to algebraic equations.

In order to make more of the graph visible, it would be useful to reduce the scale on the y axis. This is unproblematic in Cabri and GSP. However, although zooming in or out is permitted, Cinderella does not allow axes to otherwise be rescaled. Geogebra allows rescaling, but with the consequence that the circle changes shape, as shown below.

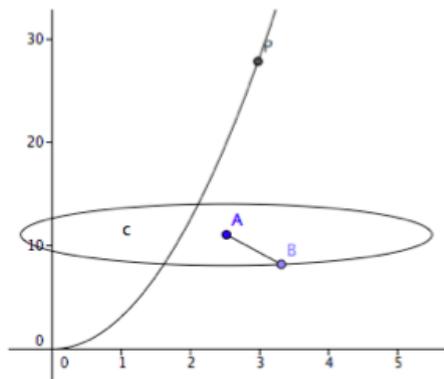

Figure 2: GeoGebra circle with unequal axis scaling

In Cabri and GSP, a fundamental design decision was to treat the screen as a simulation of a Euclidean plane, where distance is measured by a rigid ruler. Coordinate axes provide a reference frame relative to which objects such as the circle have a location and possibly an algebraic equation. When axes change, the relative location and equation of objects will change, but the objects will not.

Working group 4

In contrast, Cinderella and GeoGebra define all objects by using a coordinate system related to the intrinsic screen coordinate system; selecting the centre point and radius point for the circle define it by an equation referring to this coordinate system. This is why these programs give coordinates and equations in the figure descriptions.

This provides an equally acceptable model of the Euclidean plane – provided that the coordinate axes cannot be scaled independently. Hence Cinderella does not allow such scaling. In GeoGebra, when the axes change, the fixed defining equation means the circle visible on the screen needs to change shape and consequently visible area, which in an investigation likely geared to 12 or 13 year old students might be highly confusing.

Task 6: Graph an algebraically defined curve to fit the locus and hence find a formula for the relationship between radius and area.

In this task, a further construction is made to test the conjecture that the graph is quadratic and to find its coefficient.

Cabri is the only program that will find the equation of a locus directly (GeoGebra does not even list the locus as an object in the algebra window). All programs will fit to the locus a graph defined by means of an algebraic equation. Cabri II Plus requires an expression to be defined and applied to an axis, whereas GSP, GeoGebra and Cinderella require the definition and plotting of a function. A parameter p can be introduced to create the graph of $y = p x^2$. Manipulating this parameter will give the curve of best fit as $y = 3.14 x^2$.

Task 7: Test the formula found

In this task, the specific conjecture represented by the formula found in the previous task is tested.

This was achieved by editing the calculation from task 4 to $\text{area}/\text{radius}^2$, which now gave a constant value of about 3.14. It was also possible to create a function or expression $3.14*r^2$, substitute the radius for r and compare the result with the measured area. Cabri used the simpler language of evaluating an expression, and the other programs used the language of functions, with text input needed for GeoGebra.

The final stage pedagogically would be to prove this result, or at least give some reasons why the area of a circle has this particular relationship to its radius, but this has been beyond the scope of this paper, although not beyond the scope of IGS, which could, for example, be used to compare the area of the circle to that of the square containing it, or to “unfold” the circle into an approximate parallelogram.

CONCLUSION

The series of tasks shown here illustrate the ways in which IGS could be used to develop links between number, algebra and geometry through representation of a mathematical situation in different ways. In particular, dynamic number has emerged

Working group 4

as especially important, as predicted by Jackiw (2010). Dynamic number can serve as an introduction to variation, and naming such numbers as an introduction to algebraic variables. Relationships between dynamic numbers may be explored and expressed as graphs or algebraic formulae.

A circle could be created according to its fundamental definition, without numbers, showing the primacy of geometry in this context. However, a circle could also be created by using a number to define its radius. Changing this number and noting its effect on the circle might be important in developing the idea of variation, whereas naming the number might be a move toward the idea of variable.

Measuring the area and radius of the circle involved introducing number as a description of geometry. In an environment where geometric objects may be changed by dragging, measurements are variables between which relationships may be conjectured. Such relationships may be tested by calculation, ostensibly involving just numbers, but in fact involving variables. Calculation itself may be a means of developing awareness of general expressions.

Creating a graph meant creating a visual representation of the relationship between the variables of radius and area. This was done first without algebra by using the basic definition of a graph as a locus (a unique feature of IGS environments), and then by means of an algebraic definition, showing that the relationship between radius and area could be expressed algebraically. The relationship found could be tested algebraically by substituting measurements into a formula. The relationship was not proven, however, although some justification would have been possible with IGS. Although quite different in some respects, Cabri, GSP, and Cinderella were each well suited to the tasks, giving scope for students to explore the idea of variability before requiring the use of specific variables. What was critical in these programs is that text entry involving the names of variables was not necessary. Each had specific perceived strengths and weaknesses, which will be reported in more depth in further research.

What was surprising, however, is the number of problems that arose using GeoGebra, specifically “developed as a tool to support dynamically linked multiple representations of mathematical objects” (Hohenwarter, 2010, personal communication). Jackiw (2010) pointed out a number of the problems in GeoGebra’s algebraic representation, and similar problems were found in this study. GeoGebra had mathematical errors in number (rounding of decimals), algebra (treating a segment name as a variable and assigning it a value) and geometry (not consistently representing the Euclidean plane). In addition, information was continually given which was irrelevant and distracting (the display of coordinates whenever an object was created or dragged). Its reliance on text entry made it slow to use, liable to syntax errors, and meant that students needed to understand the meaning of a variable in order to use it, an understanding that could be developed in the process of using the other programs. Text entry also meant that the algebra

window, with unnecessary and distracting coordinate information, needed to remain open in order to access the names of variables. It lacked the functionality that would enable students to understand coordinate representation from first principles. The “algebraic” representation of objects given by GeoGebra was at best irrelevant in exploring connections in the task described here. At worst it was distracting and misleading.

Future research will compare student responses to similar tasks using Cabri, GSP and Cinderella, testing conjectures made here concerning the role of dynamic numbers linked to geometric objects in facilitating the development of algebraic concepts and looking more closely at the effect of differences between these programs. The programming language available within Cinderella has been beyond the scope of this exploration. This is likely to open new possibilities for the linking of number, algebra and geometry in the context of an IGS.

INTRODUCTION TO THE PAPERS OF WG 5: STOCHASTIC THINKING

Dave Pratt, Institute of Education, University of London, UK

and

Carmen Batanero, Universidad de Granada , Spain

Rolf Biehler, Universität Paderborn, Germany

Andreas Eichler, University of Education Freiburg, Germany

Maria Meletiou-Mavrotheris, European University, Cyprus

Efi Paparistodemou, Ministry of Education, Cyprus

OVERVIEW

Our focus on stochastic thinking intentionally avoids any marginalisation of probability, which we see as a key component alongside the consideration of data in statistical analysis. Probabilistic thinking, distinct from thinking about the deterministic, involves modelling randomness and expressing subjective beliefs about uncertainty. Statistical thinking involves handling data, seeking patterns and making predictions. We see stochastic thinking as embracing both probabilistic and statistical thinking.

WG5 was attended by 35 delegates and 24 papers were accepted for the proceedings covering various aspects of stochastic thinking. This large programme stimulated much discussion. Each paper was presented for 7 minutes as a reminder of its focus with time for clarifying questions afterwards. Papers were clustered and after each cluster there was a 10-minute reaction. Following this there was an hour's discussion around that set of papers. Notes were taken during each session and these were used to create the final presentation and this report. We organized the summary of the discussion below into four themes, which roughly represent the clusters of papers:

(i) Curriculum and teaching

The discussion was based around the papers by: Janet Ainley, Tina Jarvis and Frankie McKeon; Arthur Bakker, Monica Wijers and Sanne Akkerman; Maria Meletiou-Mavrotheris and Efi Paparistodemou; Anneke Verschut and Arthur Bakker.

There was also a contribution through the poster by Raquel Santos.

(ii) Sampling and graphs

In this section, we discussed the papers by: Pedro Arteaga and Carmen Batanero; Dani Ben-Zvi, Katie Makar, Arthur Bakker and Keren Aridor; Helen M. Doerr and Bridgette Jacob; M^a Teresa González Astudillo and Jesús Enrique Pinto Sosa; Oduor Olande.

There were further contributions resulting from the posters by: Adri Dierdorp, Arthur Bakker, Harrie Eijkelhof, Jan van Maanen; Einat Gil and Dani Ben-Zvi.

(iii) Attitudinal and conceptual

The discussion in this section was stimulated by papers from: Andreas Eichler and Markus Vogel; Verônica Y. Kataoka, Claudia Borim da Silva, Claudette Vendramini and Irene Cazorla; José Alexandre Martins, Maria Manuel Nascimento and Assumpta Estrada.

A further contribution was made through the poster by Assumpta Estrada and Ana Serradó.

(iv) Probability and risk (the most popular theme).

There were a substantial number of papers contributing to this discussion: Chiara Andrà; Egan J. Chernoff; J. Miguel Contreras, Carmen Batanero, Carmen Díaz and José A. Fernandes; M. Pedro Huerta, Fernando Cerdán, M^a Ángeles Lonjedo and Patricia Edo; Antonio Orta and Ernesto Sánchez; Bernard Parzysz and Michel Henry; Dave Pratt, Ralph Levinson, Phillip Kent and Cristina Yogui; Susanne Prediger and Susanne Schnell; Caterina Primi and Francesca Chiesi; Theodosia Prodromou

There was also a poster by Hasan Akyuzlu.

Of course, papers in one theme often raised issues equally relevant to another theme.

CURRICULUM AND TEACHING

There was considerable discussion about the role of context in teaching stochastics. In particular, the debate was around what is a ‘real’ problem or question. Was reality located in the positioning of the activity inside or outside of school, or was it related to how engaging was the task for students? Did it matter that the data were collected by students themselves? Could reality be found in the power of the statistical ideas to solve problems? Such expressions of where reality might be found seemed to indicate different communities: school vs. out of school; cultural differences across countries; statistics vs. mathematics; different curriculum layers.

There was therefore discussion about the notion of boundaries between communities that can lead to discontinuities and research that attempted to cross those boundaries. This research looked to build boundary objects (artefacts that live in both sides of the community) and to engage people such as researchers, teachers, teacher educators who tried to live in both communities, on either side of the boundary, and acted as brokers.

SAMPLING AND GRAPHS

Sampling was a topic that received particular attention in the discussion of the working group. Innovative technological tools such as *Fathom* and *TinkerPlots* were helping students to visualize complex statistical concepts, such as distribution, variability and sampling distribution.

Working Group 5

Such tools were not necessarily familiar to practicing teachers and so it was recognised how important it was to provide teachers with opportunities to experience similar learning experiences as their students in order to be able to anticipate the difficulties their students might encounter.

These tools have changed the way in which students could engage with graphical information, placing more emphasis on interpretation and expression, but, at the same time, present a challenge to how skills might be assessed.

There is considerable research in recent times on informal inferential reasoning (IIR) and this approach, often based around exploratory data analysis (EDA) has put an accent on representing and interpreting data in the context of the sampling process. IIR promises new directions for bridging between statistics and probability, which had become increasingly separated with emphasis on data in EDA.

For example, one of the research studies provided an inquiry based learning environment, in which young students developed useful ideas about whether inferences could be made from samples of different sizes. Initially, they oscillated between absolutist and relativist conclusions, but they came to reason in more sophisticated ways with increasing awareness of what was at stake when making inferences from samples.

ATTITUDINAL AND CONCEPTUAL

Stochastics education suffers from the negative attitudes in society in the same way as mathematics but even mathematically-minded scholars often reject the stochastic way of thinking. We need to know more about these attitudes to see how they might be changed. In contrast to the very limited research on adults' attitudes regarding the stochastic, there has been considerable research about students' concepts. For example, we heard research which aimed to identify the knowledge and thinking of students in different ages and levels of schooling to gain an empirical basis for future teaching of stochastics. This research adopted the SOLO taxonomy to structure the empirical data for different tasks, but not to classify students referring to knowledge and thinking levels.

PROBABILITY AND RISK

In considering the research specifically on the conceptualisation of probability, there was discussion around the role of intuitions, representations and embodiments (research in psychological and semiotic perspectives). Enriching and refining stochastic ideas are good ways of thinking about how learning often involves coming to appreciate the power of what you already know (enriching) or its limitations when the knowledge has been over-generalised (refining). For example, knowledge that chance is unpredictable was typically over-generalised and needed to be refined to appreciate that aggregation in the long term is in a sense predictable. In contrast,

Working Group 5

knowledge such as '*the more times, I throw the spinner, the more even is its pie chart*' needed some enrichment to realise that it applies also to dice, coins and so on.

The role of context in the process of enrichment was compared to that reported in the mathematics education literature, where contexts in word problems can present children with additional difficulties, but can provide meaning if the learners are encouraged to engage deeply with the situation. If we provide students with an artificial context, we should not be surprised if they try to make it real by bringing in personal knowledge that is not necessarily statistical. Rather than thinking of abstracting as a process of de-contextualisation, enriching and refining seemed to place emphasis on abstracting as generalising. The knowledge of teachers is key in the conceptualisation of probability by their students. Research was reported which was based on a structural model of teacher knowledge. The insufficiencies of pre-service training leave teachers with difficulties around stochastic thinking. Research has been finding evidence about what teachers do not know. To design effective teacher education, we need to know what we might expect teachers to know already, including their attitudes.

SOME CONCLUDING THOUGHTS

We noted a discrepancy between research results, often taking place in particular situations, and the opportunities for large-scale implementation and dissemination.

We worried that EDA has led to isolation of probability in the curriculum and discussed the need to reconnect data and chance, perhaps through modelling tasks such as in the beta version of Tinkerplots and perhaps by placing more emphasis on subjective probability to escape the specialised uses of probability (in coins, spinners, dice etc.).

The use of subjective probability was apparent in research on risk, presented in the working group. We wondered at what age would this be appropriate? Perhaps it is possible at a younger age than we have been able to teach classical probability? Indeed, could it be the case that the teaching and learning of risk offers new opportunities for modelling with subjective probabilities?

FINAL COMMENTS

The group work was seen as very useful and efficient. The group was larger than in previous years and this created new challenges. The use of a reactor had been introduced in previous years but because of the large number of papers it was felt better to react to a group of papers. Inevitably this sometimes meant the reactions were at a higher level of abstraction and perhaps less specifically useful to individual authors. Nevertheless, there were a number of strong papers and much interesting content. It is hoped that some of these authors will be able to contribute developed papers to a special issue of ZDM.

DESIGNING PEDAGOGIC OPPORTUNITIES FOR STATISTICAL THINKING WITHIN INQUIRYBASED SCIENCE

Janet Ainley, Tina Jarvis and Frankie McKeon

School of Education, University of Leicester, UK

We describe aspects of our work on a European project concerned with inquiry-based mathematics and science education. A framework has been developed which offers a novel perspective on integrated planning, based on deep connections between 'big ideas', and on the process of inquiry. We aim to exploit the potential of such integration to provide opportunities for mathematical and statistical ideas to be used in purposeful ways, stressing their utility. A sequence of activities embodying a possible learning trajectory concerning variability is described as an example of the application of the framework.

BACKGROUND: THE FIBONACCI PROJECT

This paper presents a theoretical framework developed during planning for our participation in the Fibonacci Project¹⁵; a project involving around 36 European partners that focuses on the dissemination of Inquiry-based Mathematics and Science Education. Each of the partner Centres will work with a group of teachers over a period of two years, developing materials to support inquiry-based teaching. An important feature of Fibonacci is a model for dissemination through 'twinning' Centres with different levels of experience and expertise, and other collaborative events. The project thus focuses at three levels, on Centre, teacher and pupil learning.

Centres choose whether to focus on mathematics or science, or on both subjects, and also decide the age group of the pupils involved. In Leicester we have chosen to focus on the primary age range (ages 4 – 11), and to take an integrated approach to inquiry across mathematics and science. We shall be working with a group of about 25 teachers who teach children from across the whole age range. Half of these have been selected because they have previously engaged in mathematics education or science education programmes at the School of Education, and they will each involve another colleague from their school. As primary teachers, they are unlikely to regard themselves as 'specialists' in mathematics or science, and few will have formal qualifications in either subject beyond the minimum qualification levels required to enter teaching. Their level of experience as teachers varies from some with substantial experience, to some within the first 5 years of their careers.

Starting in Autumn 2010, the teachers will come to five workshop sessions at the School of Education each year (two whole days and three shorter twilight sessions). In these sessions, the teachers will work through carefully designed sequences of

¹⁵ The FIBONACCI Project - Large scale dissemination of inquiry based science and mathematics education, FP7-SCIENCE-IN-SOCIETY-2009-1, Grant Agreement Number 244684

activities that model the inquiry process. They will be encouraged to select appropriate activities to use in their own classrooms between the University sessions.

DEVELOPING A PLANNING FRAMEWORK

As a team of teacher educators and researchers in mathematics (Ainley) and science (Jarvis and McKeon) education, our focus during the development stage of the project has been on developing a cohesive framework around which to plan the sequences of activities which we will present to the teachers. In particular, we have explored the similarities and differences in our two disciplines, what ‘inquiry’ might mean in each of them, and how the strands of content from each area might be brought together in meaningful ways. In these explorations, *handling data* quickly emerged as an area of relevance to both disciplines. We focus here on the place of statistical thinking in our planning, as an example of our overall approach.

Challenges and opportunities in linking mathematics and science

As well as choosing to focus on both mathematics and science, we have also set ourselves the challenge of linking the disciplines in an integrated way which has the potential to improve and enrich learning opportunities. We recognise that this is potentially problematic, and will certainly be a way of working which is relatively unfamiliar to the project teachers. Further, we wish to avoid a superficial approach to making such links, for example by identifying where mathematical ideas might be taught ‘in preparation’ for where they are needed in science, or drawing attention to the Fibonacci patterns in sunflowers. Whilst these sorts of links might be relatively easy to make, we believe that there are potential advantages in integrating mathematics and science in a deeper way. We see at least three such advantages.

First, there is a widely recognised concern within mathematics education about the separation between ‘school mathematics’ and the ways in which mathematics is used in everyday life, which is not adequately addressed by traditional attempts to contextualise the school mathematics curriculum (e.g. Boaler, 1993, Cooper & Dunne, 2000). Ainley and Pratt have argued that this separation inhibits the development of an understanding of the *utility* of mathematical ideas, that is, why and how the ideas are useful (Ainley et al., 2006). In order to create opportunities to develop an understanding of *utility*, they emphasise the importance of pedagogic tasks that have *purpose* for learners. Scientific inquiry is a rich source of purposeful tasks in which the *utility* of mathematical ideas can be made transparent.

Secondly, mathematical ideas play an important role in the explanatory power of models in science, which is not generally exploited in the primary school curriculum. For example, in order to understand why a small child might get cold more quickly than an adult, and thus need more layers of clothing, or why large sugar crystals dissolve more slowly than regular sugar, it is important to have an understanding of how the ratio of volume to surface area might vary in different shapes.

Working Group 5

Finally, scientific inquiry provides a purposeful context in which learners collect sets of data of various kinds. This contrasts with traditional approaches to data handling within primary school mathematics (in the UK), which tend to fall into two categories. Either ready-made sets of (clean) data are provided for children, with little consideration given to how or why the data might have been collected, or children collect data about a familiar context (such as the colours of cars in the car park), and use this to produce graphs, but without any real purpose to stimulate more than a superficial reading of the graphs produced (Pratt, 1995). In the course of a scientific experiment, decisions have to be made about which data to collect, how best to collect it, the most appropriate way to display it, and how to interpret the resulting graphs and tables. In addition, the data collected will be messy: issues about appropriate accuracy, variability, and sample sizes are both visible and of real importance. We thus see statistical reasoning, which is generally poorly developed in UK primary schools, as a key area of mathematics that can be developed through our integrated approach to mathematical and scientific inquiry in the Fibonacci Project.

Approaches to linking mathematics and science

The notion of a cross-curricular approach to teaching mathematics and science may conjure up a range of different images. Czerniak et al. (1999), in a review of studies that attempted to demonstrate benefits of curriculum integration, argue that a serious impediment to such research is that

... a common definition of integration does not exist that can be used as a basis for designing, carrying out and interpreting results (Czerniak et al. 1999 p. 422)

In another review of research, Hurley (2001) identifies five categories of 'integration' reflected in a wide range of studies. These categories move from a 'sequenced' approach, in which the two subjects are planned and taught separately, but in an appropriate sequence to provide cross-subject support, to 'total' integration in which the two subjects are taught 'together in intended equality'. However, the definitions of the intervening categories are somewhat unclear.

Offer and Vasquez-Mireles (2009) offer two more specific descriptions of how cross-subject planning may be approached. They take a somewhat dismissive view of what they refer to as a 'traditional approach to integration' in which mathematics is used as a tool in science lessons, and science is used to provide a context in mathematics lessons. In their own study, Offer and Vasquez-Mireles take an approach which builds on this pattern of integration, which they describe as *correlation*.

To be a correlated mathematics and science lesson, both mathematics and science learning objectives must be clearly identified and direct the instruction (Offer and Vasquez-Mireles, 2009 p. 146)

In addition to this focus on learning objectives, correlation involves attention to the use of language, and to parallel concepts in the two disciplines.

MAKING DEEP LINKS THROUGH INQUIRY

The perspectives described above offer pragmatic approaches to planning lessons, or sequences of lessons, which go some way to exploiting the opportunities offered by linking mathematics and science. Our explorations have led us to look at ways in which links of a more fundamental kind may be made by looking beyond the detail of curriculum content, and unpacking how the processes of inquiry play out in the different subject areas. The way in which we conducted our exploration was for the scientists to prepare an activity sequence which they would use to develop a particular concept in science (such as insulation and heat loss) and for the mathematician to work through this, drawing out the opportunities for developing mathematical understanding. In doing this, our aim was not only to find opportunities to use particular mathematical ideas (such as the use of place value in the scales on measuring instruments), but also to identify opportunities for mathematical thinking to offer explanatory power (such as considering the ratios of volume to surface area.)

After going through this process for a number of scientific themes, the pattern emerged of a relatively small number of ‘big’ mathematical ideas underpinning very different areas of science. One such ‘big idea’, which we take as our focus here, is that of the variability of data, including ideas about ‘signal’ and ‘noise’.

In contrast to approaches which take the content of the school curriculum as the starting point for linking the learning and teaching of mathematics and science, we have developed a model for considering links at the deeper level of ‘big ideas’, based on a consideration of the function and processes of inquiry. Because of the significant overlap between mathematics and science in the area of handling data, we have considered statistics as a distinct discipline in this model. In Table 1 we summarise our planning framework, indicating the different levels at which we need to consider the links between mathematical, statistical and scientific ideas. Whilst our planning begins with consideration of the ‘Deeper level’ of big ideas, which informs progression, we are conscious of the need to make explicit links at the ‘Surface level’ of the school curriculum which is familiar to teachers. The design of individual tasks is built upon the bottom two rows in the table, utilising the processes of inquiry, and drawing on differing purposes to determine the specific emphasis within each task.

EXPLORING THE USE OF DATA IN SCIENCE EDUCATION

In scientific inquiry, children are encouraged to design and carry out experiments and to test hypotheses with the aim of finding an explanation for the observed phenomena. The need to compare the outcomes of different experiments drives the move beyond descriptive observation to measurement and quantification. The choice and use of units and measuring instruments is often ‘taken for granted’ in science teaching, and the ease with which particular instruments can be used may disguise

Working Group 5

the complexity involved in interpreting the results. For example, digital stopwatches are accessible timing devices, but will give readings in tenths, hundredths or even thousandths of a second. The emphasis placed in science on fair testing and accuracy may engender an inappropriate respect for results given in 2 or 3 places of decimals (particularly when the meaning of such results is not well understood).

	Science	Statistics	Mathematics	
Surface level: the School curriculum	Electricity Forces Properties of materials Plants ...	Drawing graphs Collecting data Mean, median and mode ...	Counting Calculation Naming shapes Measurement ...	<i>Links at this level are easy to make, but may be superficial, using mathematical or statistical ideas intermittently as tools during science activities without continuity. However, teachers need the reassurance of seeing links at this level.</i>
Deeper level: 'big ideas'	Energy Particle theory Inheritance ...	Variability Distribution Chance Inference ...	Pattern Proportion Equivalence Ratio...	<i>Links at this level are more challenging, but offer opportunities to develop sequential learning in all subjects as the big ideas recur.</i>
Nature and processes of inquiry	Observation, posing questions, collecting data, analysing data to draw conclusions, predicting, hypothesising, evaluating modelling, raising further questions, ...			<i>We see strong similarities in the process of inquiry across all three disciplines, which can be reinforced with different emphases.</i>
Purposes of Inquiry	Generalisation that explains the world, or observed phenomena	Generalisation that informs decision making	Generalisation that holds in all cases and is internally consistent	<i>Whilst the processes of inquiry are common, we see the purposes as distinct: this provides a way of creating different emphases in task design.</i>

Table 1: summary of the model of integration used for planning

Such experiments provide potential opportunities to experience *variability*: a key statistical idea. Following Reading and Shaughnessy's (2004) terminology, we shall focus here on *variability* as 'the [varying] characteristic of the entity that is varying', rather than the process of describing or measuring *variation*.

In the context of a practical experiment, variability can be observed at two levels. At the macro level, the whole focus of the experiment may be on the behaviour of one (dependent) variable as another variable is deliberately changed by the experimenter. For example, children might change the gradient of a sloping surface, and measure how far a toy car travels when rolled down the slope. Here children may expect that the distance travelled will vary as the gradient is increased or decreased, and look for a pattern in their results. However, variability can also be experienced at a micro level, and this may initially be unexpected. If a particular experiment is repeated, that

is, the car is rolled again down a slope with the same gradient, the distance travelled will not be exactly the same as the first attempt. Repeating the experiment a number of times will produce a spread of results. Rather than seeing this as an opportunity to explore variability as an important statistical idea, the pressures of the curriculum tend to lead science teachers to take a pragmatic approach to the ‘problem’ of variability, using the algorithm ‘collect three measurements and then take the average (i.e. mean) value’. Observations of student teachers carrying out scientific inquiries have provided us with many examples of the uncritical use of this approach, presumably remembered from their own school experiences. In the following sections we describe a sequence of activities designed to ‘unpack’ this issue.

PEDAGOGIC DESIGN FOR EXPLORING VARIABILITY

We now describe a learning trajectory through a sequence of inquiry activities we have designed to provide opportunities to learn about variability in the context of scientific ideas. The activities all focus on aspects of exploring flight. Our general approach has been to start with inquiry sequences which focus on the development of science concepts, and then weave across these sequences which develop the related mathematical concepts, whilst reinforcing the processes of inquiry. Any particular task or activity could then be viewed through a number of different lenses, with different aspects being emphasised as appropriate for the learners (e.g. scientific or mathematical content, aspects of inquiry, statistical thinking). The sequence of activities described here will be used with the group of project teachers, who will then try activities in their classrooms. We aim to make our planning decisions explicit, in order to support teachers’ in developing classroom activities.

Cylinder gliders: explicit variability

The first task is based on exploring the behaviour of small gliders, made from loops of paper attached to a drinking straw (see Figure 1). The construction of the glider allows the smaller (tail) loop to be moved along the straw. In the way we structure the activity in response to this task we will focus on *making the process of inquiry visible* as a way to explore a phenomenon, on *macro-level variability* as part of that exploration, and on explicitly confronting *micro-level variability*.

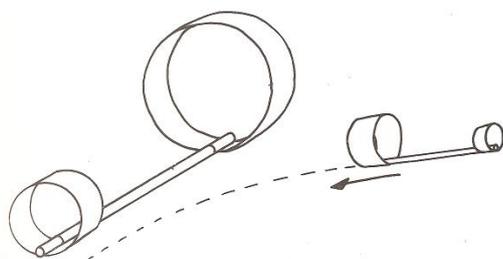

Figure 1: a loop glider

<p>Things I could change</p> <ul style="list-style-type: none"> Size of loops Width of loops Distance between loops Length of straw Where I fly it How I launch it <p>Things I could observe or measure</p> <ul style="list-style-type: none"> Length of flight Time of flight Straightness of flight 	<p>I will change</p> <ul style="list-style-type: none"> Distance between loops <p>I will measure</p> <ul style="list-style-type: none"> Length of flight <p>I will keep these the same</p> <ul style="list-style-type: none"> Size of loops Width of loops Length of straw Where I fly it How I launch it
--	---

Figure 2: the discussion framework

Working Group 5

After an opportunity to observe the behaviour of the gliders in an unstructured way, a question is posed about what affects the way in which the gliders fly. A discussion framework (Figure 2) is used to identify variables, and then design experiments to explore the affects of changes to the design (*inquiry process, macro-level*). In the example given, the focus is on the distance between the larger and smaller loops.

The variable *how I launch it* is problematic, and is likely to generate considerable discussion. It will quickly become clear that it is not possible to launch the glider in exactly the same way each time, however careful you are. This generates the need both to repeat the experiment a number of times, and to address how the resulting measurements may be interpreted. Different coloured pins are used for each distance between the two loops and placed on the floor to mark where the glider lands. This gives an immediate visual image of the variability of results (at both micro and macro level), which can be discussed. Guided questioning will focus attention on both the ‘noise’ in the array of pins, and the ‘signal’ that might be detected. However, the floor display is messy, and cannot be left in place for long, and so results are also recorded in Tinkerplots. The resulting display provides a different image of variability (see Figure 3) and may make the pattern in the results easier to see, making the utility of graphing explicit.

Scientific content will not be a focus in this task as it is not easily accessible: the emphasis needed on the *mathematical content* will vary for different age groups.

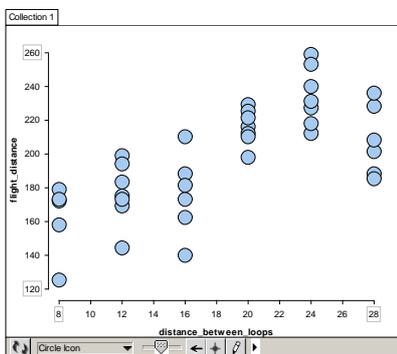

Figure 3: results for different gliders

Figure 4: parachutes being made

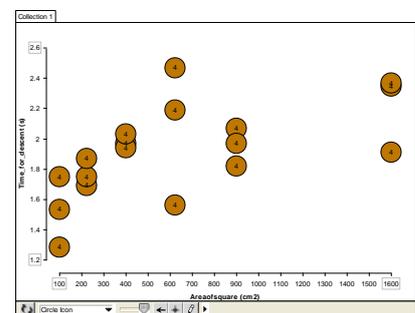

Figure 5: results from square parachutes

Parachutes: a context for looking more closely at variability

The next task in the sequence uses the same inquiry approach to exploring the performance of small parachutes made to carry toy people (see Fig. 4). Activity in response to this task could emphasise *scientific content*, exploring the properties of different materials, and forces (gravity, air resistance). *Mathematical content* could focus on the area of different sizes and shapes of parachutes, and how measures of area relate to other dimensions. Our emphasis will be more on reinforcing aspects of the *inquiry process*, using inquiry to develop *explanations of observed phenomena*, and on *statistical thinking* about *micro-level variability*. In this activity, it is easier to control the launch than it was with the gliders, but the need for repeated tests is still

Working Group 5

emphasised. As the parachutes are best dropped from a height of at least 3-4 metres, such as down a stairwell, repeats tests are time consuming, and so there is a need to consider an appropriate sample size. In the experiment recorded in the graph shown in Fig. 5, square cloth parachutes of different sizes have been used. Each has been tested 3 times, from a height of 4 metres. Note that the size of each parachute has been recorded by area, rather than by the side length: there is rich potential for mathematical discussion in this decision.

Discussion of the results, such as those shown in Fig. 5, will focus on understanding and explaining what the graph is telling us. Discussion of the signal in the results will link to *scientific* explanations concerning the effects of air resistance, fabric flexibility etc., supported by *mathematical* ideas about proportion. In discussion of the noise, emphasis might be given to a number of *statistical* ideas. One focus could be possible reasons for the *micro-level* variability, and how the experimental procedure might be improved. Another discussion might address whether three repetitions gave a big enough sample to provide reliable evidence. Through such discussions we would want to emphasise the range and spread of values, and how the signal emerges around values towards the centre of the data set for each parachute, introducing the utility of larger samples, and of a focus on the data set, rather than individual data points.

An Active Graphing approach: the utility of a measure of centre

In the third task in the sequence, we make a change to the way in which the inquiry is carried out, shifting the focus to developing generalisation to inform decision making. The setting is again in the context of flight, this time using small paper spinners (see Fig. 6). Attention could be focussed on scientific or mathematical ideas, but our choice is to structure activity to emphasise the purposeful use of average values from experimental results in a way which makes the utility visible, rather than as a black-box which can be used to ‘solve the problem’ of micro-level variability.

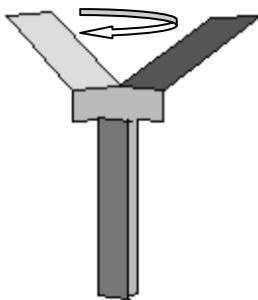

Figure 6: a spinner

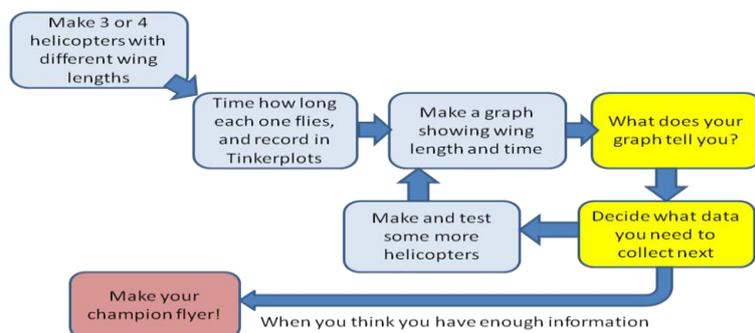

Figure 7: the active graphing approach

The task is to make a champion flyer: that is, a spinner that will fly for the longest time. Following a similar introduction to the identification of variables as that used in the previous two activities, a decision is made about which feature of the spinner

Working Group 5

to vary (e.g. wing length). In contrast to the two previous tasks, where the whole experiment was carried out before the data was displayed on a graph, we will now use an Active Graphing approach (as shown in Fig. 7) in which a graph is produced as soon as two or three pieces of data have been collected, and then used to support decisions about further experiments and data collection (Ainley, Nardi, Pratt, 2000). Active Graphing focuses attention on the utility of graphs as analytic tools: the challenge to make a champion flyer provides a purposeful context for this.

By now the idea of repeating each test in order to obtain a set of data is well established. The need to make decisions about the optimal wing length emphasises the need for accuracy, especially as the overall pattern of results may be somewhat unexpected. In the sequence of snapshots shown in Fig. 8 there is an attempt to ‘home in’ on the best wing length. From the spread of results (top row) it is not clear whether 10cm wings perform better than 9cm ones. This provides an opportunity to introduce the *utility of using the mean* of a number of results, which produces a clearer graph (bottom row). The third pair of graphs shows that 14cm wings are not an improvement, and so the next step will be to try a wing length between 10 and 14.

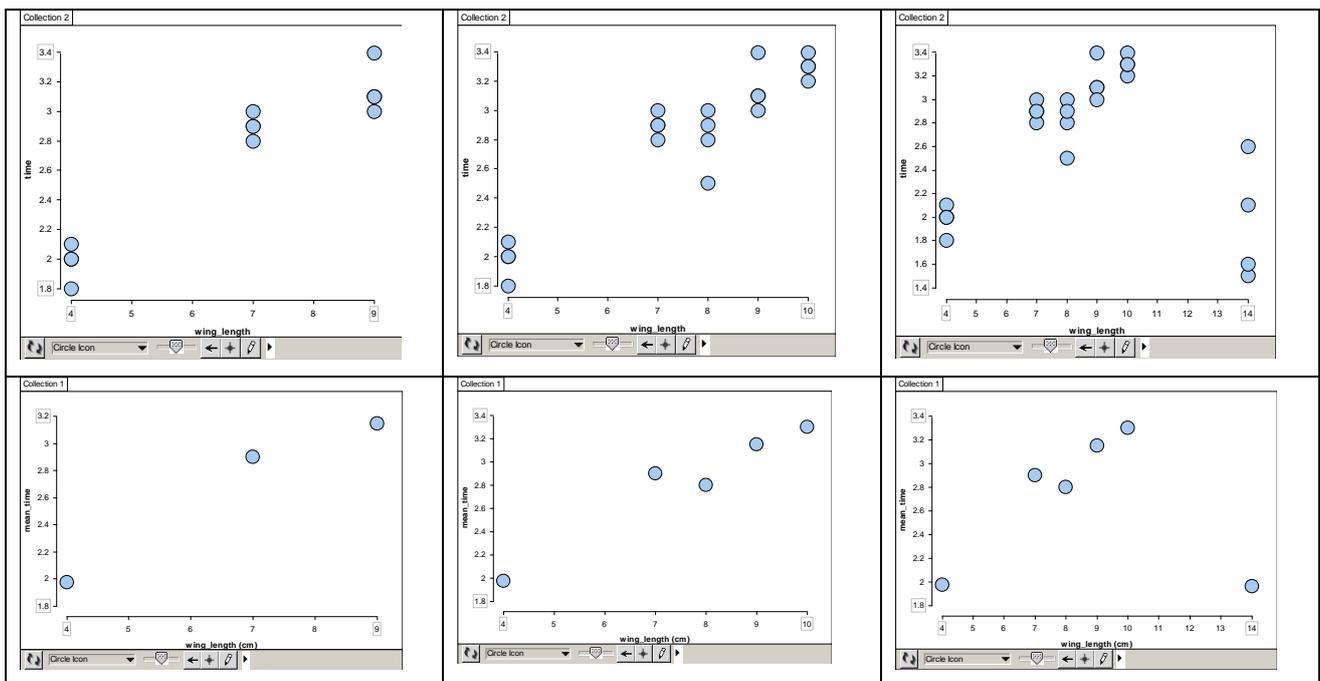

Figure 8: three stages of activity, using full data (top row), and mean values (bottom row)

DISCUSSION

In this sequence of tasks, and the associated activities, we have aimed to offer a learning trajectory that exploits the rich opportunities of an inquiry-based integration of mathematics and science education. There is an overt focus on variability at the macro level, as the effect that changing one (independent) variable has on another (dependent) variable relating to the flight of the glider, parachute or spinner, is measured and recorded. This relates to ‘Surface level’ curriculum content concerning measurement and fair testing. Within the experimental situations, we focus at the

Working Group 5

level of ‘big ideas’, creating opportunities to confront and accommodate variability at the micro level, by recording and displaying the distribution of results and trying to identify patterns within the noise of a spread of results. The three tasks progressively move towards the need to see the distribution of results as an aggregate, which could be represented by its mean, rather than as a collection of individual points, which Makar and Confrey (2005) see as a key goal in learning about distributions. This provides a clear rationale for the need to repeat experimental measurements, and the expediency of working with the mean value of an appropriate sample of results. Unlike approaches to teaching about variation and distribution which may be offered in mathematics lessons, the data involved is meaningful and used in purposeful ways.

PRESERVICE PRIMARY SCHOOL TEACHERS' INTUITIVE USE OF REPRESENTATIONS IN UNCERTAIN SITUATIONS

Chiara Andrà

University of Torino, Italy

This paper focuses on primary school teachers' intuitive approaches to uncertain circumstances. In an exploratory study, data from a basic undergraduate course in probability for preservice primary school teachers were gathered and examined through semiotic lenses. A cognitive model is presented and discussed and an example is provided.

Key-words: elementary probability, preservice teachers, intuition, semiotics.

It is well acknowledged that human beings have to often deal with uncertainty and they may judge, decide and behave under the sole guidance of their intuitions. Along with their intuitive reasoning, human beings may somehow represent the situation in their mind. The relationship between the representations people use and their intuitive reaction in uncertain situations is the focus of this study. Within this perspective, teachers are in charge of planning, carrying out and evaluating classroom activities. Hence, the analysis of their intuitive approaches to probability when using representations – during their training – is a relevant issue.

THE COGNITIVE MODEL AND ITS THEORETICAL BACKGROUND

Intuitions and semiotic representations

Intuitions in the process of learning probability have been a fruitful branch of research in Psychology and in Mathematics Education since 1970s (see for example Kahneman and Tversky, 1972; Fischbein, 1975). In the 1980s, a rich literature in Mathematics Education concentrated on (children's) probabilistic intuitions (see for example Fischbein & Gazit, 1984; Hawkins & Kapadia, 1984). Later a number of researches focused on this topic: for example, Konold *et al.* (1993) studied students' inconsistent reasoning about different aspects of the same situation. This kind of research addresses students' approaches to uncertain situations, and consequently helps to frame and analyse students' misconceptions and intuitions that can arise and be driven by such different approaches. In the subsequent decades, the discussion in the field shifted to the notion of *statistical thinking* (for a review, see Borovcnik, 2005). Taking into account both probabilistic and statistical reasoning led researchers to coin the idea of *stochastic thinking* that combines both probability and statistics. Recently, researchers have not only focused on the theoretical issues of stochastic thinking, but also on teachers' professional development, on their attitudes towards probability and statistics, on students' understanding of basic concepts (Eichler, Ottaviani, Wozniak, Pratt, 2010). In this varied scenario, the research presented in my paper addresses both intuitions and the semiotic resources

prospective teachers activate when dealing with uncertain situations. The term ‘intuition’ is used in opposition to logical knowledge, according to Fischbein:

“the process of thinking is composed of two basic interwoven aspects: the logical, analytical, discursive one (the evolution of which, in children and adolescents, has been studied by Piaget and his co-workers), and intuitive cognitions characterized by self-evidence, immediacy, globality, coerciveness.” (Fischbein, 1998, p.1)

Now, a few words need to be said about semiotic approaches. Semiotics is a powerful tool for interpreting didactical phenomena. For lack of space, I will refer solely to an example: the work of Batanero, Arteaga and Ruiz (2010) that generalizes the notion of representation by taking into account an ontology of objects that intervene in mathematical practices and analyze the graphs produced by prospective teachers through a semiotic lens. In their work, semiotic complexity is addressed. In this paper, the way teachers use representations is analyzed from Duval’s perspective (Duval, 2008): it identifies mathematical thinking and learning with the *coordination* of a semiotic system according to the following operations: *treatment* (transforming a representation into another within the same semiotic system), and *conversion* (transforming a representation into another in another semiotic system). My contention is that the coordination of different semiotic systems support/constrain intuitions in probabilistic reasoning. Depending also on the task, the semiotic resources employed, and the background of the individual, I have singled out three levels to which people can refer when estimating the probability of an event.

Three levels to estimate probability: experience, discrete quantities, theory

The first level is the *level of experience*. At this level dice are rolled, playing cards are randomly selected, coins are flipped, etcetera. And at this level people win or lose. There is a huge literature in Mathematics Education focusing on and discussing the role of the context in mathematics tasks, the relationships between experience and beliefs, the goal of mathematics to prepare for citizenship, and so on (van der Kooij, 2010). Using this background, which is still the focus of several studies, I take into account experience and its role in probability learning processes for two main reasons. The first reason is that probability – as a modeling activity and more than other mathematics domains such as algebra – has a special relationship with experience. Outcomes in probability, in fact, often refer to real objects. Moreover, the frequency of such outcomes has a relationship with the estimate of the probability of an event (Piattelli-Palmarini, 1995). The other reason is that – just for its special relationship with the world of experience – probability and its learning result strictly intertwined with intuitions and misconceptions (Fischbein & Gazit, 1984).

At the experience level, people have to estimate the probability of the outcomes. Hence, people start to somehow represent in their mind the situation: the representations are likely to be perceptive and approximate, and they can serve the

Working Group 5

purpose of counting the number of possible and favorable events. Sometimes people (and, above all, teachers when teaching) represent the events using less perceptive representations such as arrows, Venn diagrams, tables, etcetera. When using representations that help counting, people are no longer at the level of experience, but stay at the second level: the *level of arithmetic thinking*. This is the level at which people shift from perception and approximation to quantities. Such quantities, at this level, may be integer numbers, and become ratios or percentages.

There is a third level, the *level of theory*. At this level lie the formulas, the axioms and the theorems of probability. The representations are formal and abstract. However, in some tasks there is no need to (know and) stay at this level, but in order to correctly solve the task a proper use of representations at the arithmetic level is enough. Outside the level of theory, in fact, it is possible to introduce probabilistic tools in a more immediate way. At each one of the three levels, in fact, it is possible to accomplish an estimate of uncertain situations, following different approaches. As a consequence, the three levels should not be regarded as in a certain hierarchy, but as different modalities for approaching and representing uncertain situations. This approach differs from the model by Pratt (2003), who “sees the phenomenalisation of randomness as providing an intuitive route towards the operationalising of chance to be taken before following a more conventional route”. The main difference is that my model does not predict an evolution, for the individual, from a *naïve* world to a theoretical one, but it concentrates on the relationship between intuitions and representations (as meaning-making activity) at each one of the three levels.

Different approaches to uncertain situations

At the level of experience, estimating the probability of an event means avoiding the use of quantities. Semiotically speaking, it entails the use of mainly graphic and pictorial registers, related to perceptive and sensorial experience. I claim that people in general – and young children in particular – are able to say that an event is nearly impossible or almost certain, without involving any sort of computation. A confirmation of my claim has been given by Jeong, Levine & Huttenlocher (2007), who examined whether children are able to reason about proportions in the context of continuous amounts before they are able to do so in the context of discrete sets.

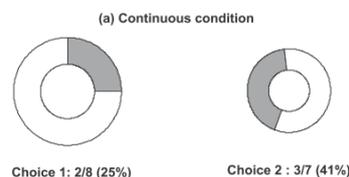

Figure 1: one of Jeong, Levine and Huttenlocher (2007) tasks: donuts. Which donut has the greater percentage of its area in grey?

The tasks they proposed used a graphic register. Figure 1 shows an example: children had not to use any sort of number, but were able to say which figure had the

Working Group 5

largest area. Jeong's and his colleagues' interpretation of children's better performance in the continuous than in the discrete conditions was that

“It seems likely that they used a perceptual strategy similar to that used by infants and young children to code the extent of one length or region in relation to another.” (Jeong, Levine & Huttenlocher, 2007, p. 252)

In order to characterize it, two keywords related to the approach at the level of experience may be: ‘perception’ and ‘approximation’. Moreover, it is characterized by self-evidence, immediacy, globality, and coerciveness, entailed by graphical/pictorial representations. The experience level can be considered intuitive, since such characteristics – accomplished by graphical/pictorial representations – are the features that define intuitions mentioned above, according to Fischbein (1998).

The concept of proportion is, according to Fischbein (1998), another form of intuitive thinking. I claim that this kind of approach belongs to the level of arithmetic, since it is necessary to overcome the level of experience and quantify the situation to deal with it. In this case, immediacy and globality are characterized by internalized operational schemas, conveyed by arithmetical representations. At the level of arithmetic, moreover, I distinguish two approaches: one is more related to the experience level and it consists in using only percentages and proportions; the other one is linked to the level of theory and it involves the use of ratios. For a better framing of the ‘percentage approach’, I refer also to Huerta & Lonjedo (2007), who describe the *mostly arithmetical type of thinking* as

“students think in quantities but they recognize events and their associated frequencies or percentages.” (Huerta & Lonjedo, 2007, p. 735)

Hence, this level is characterized by arithmetic representations and proportional schemas: on the one hand frequencies/percentages, on the other one ratios/fractions.

The approach at the level of theory regards probability as a function that assigns a number between 0 and 1 to an event. It overcomes operational thinking and, through symbolic registers, it is characterized by functional and relational reasoning. At this level, intuition is the result of specific mathematical training. It allows students to deal with more complex situations: for example, Lecoutre and Durand (1988) showed that solely using ratios may induce misconceptions in estimating the probability of composite events. Other examples in the literature concern misconceptions in Bayesian thinking (for example Falk, Falk & Levin, 1980).

Research focusing on students' learning processes in terms of intuitions belongs to *didactics B* (didB), defined by D'Amore (2006) as an epistemology of learning. According to D'Amore, *Didactics A* (didA) concentrates on effective teaching environments (assuming implicitly cognitive transfer). But the couple *teaching environments-students* does not completely describe the learning process: the teacher, together with his role, his training and his beliefs, constitutes the third component. Research in *didactics C* (didC) (*ibidem*), grounded in Shulman's work

(1986), focuses on the teacher. It is known, in fact, that for example teachers' beliefs determine and influence knowledge (didA) and the learning process (didB). Moreover, the relationship between the resources/tools teachers choose and their epistemology belongs to the teacher's sphere: why did the teacher use that tool? According to which model did he operate such choice? Following this perspective, a more complex analysis may focus on how teachers' education and training influence the way they teach and how students learn (probability) in primary schools. This question that informs the research presented in this paper lies at the boundary of didB and didC.

The issue of teachers' training in probability and statistics is central in several studies. The work by Batanero, Arteaga, and Ruiz (2010) is interesting, since it focuses not only on teachers' education, but also on teachers' graphical competence in statistics from a semiotic perspective. Batanero, Arteaga, and Ruiz defined three levels of semiotic complexity, but (unlike my model) these levels inform a hierarchy.

Relations with the existing literature

I have shown the three levels at which judging under uncertainty may occur. With respect to the aforementioned approaches, Hawkins and Kapadia (1984) distinguished four definitions for probability, and labeled them as: (1) 'a priori', (2) frequentist, (3) subjective and intuitive, and (4) formal probabilities.

The level of experience is similar to the definition provided by Hawkins and Kapadia for subjective probability: "subjective probability may rely merely on comparisons of perceived likelihood" (Hawkins & Kapadia, 1984, p.350). In fact, they also refer to the perceptive nature of this kind of thinking. It should be noticed that Hawkins' and Kapadia's (1984) definition of subjective probability does not correspond to (but has some connection with) the one provided by de Finetti (1974) as the ratio between the amount of money a person is willing to bet on the outcome of a certain event, and the amount of money he will receive in case of win, if he is willing to change his place with that of any other involved in the game. In their paper, Hawkins & Kapadia (1984) related the subjective probability not only to perception, but also to coherence. The term 'coherence' highlights that any personal judgment should be made in accordance to some 'axioms'.

Formal probability (*ibidem*) informs and characterizes the level of theory.

Some features of the 'a priori' probability (*ibidem*) lead to relate it to the arithmetic approach with ratios at the level of discreteness, and the frequentist probability has something to do with the use of percentages. On the one hand, in fact, the assumption of equal likelihood in the sample space that characterizes the 'a priori' probability may lead to the same misconceptions that arise when the classical definition of probability, as the ratio between successful and possible cases, is used (see also Lecoutre & Durand, 1988). On the other hand, the frequentist probability is obtained from observed relative frequencies of different outcomes in repeated trials

and entails the use of percentages. As the approach at the level of discreteness, the frequentist probability is still linked to the experience, but is an attempt of coming out from the real world alone.

The main differences between the model introduced in this paper and Hawkins' and Kapadia's (1984) work are two: the first difference is that the latter does not take into account any semiotic approach, the second one is that the three levels of the former depend on the kind of relations between intuitions and representations, regardless the definitions of probability.

METHODOLOGY

During the academic year 2009/10 at the University of Torino (Italy), data from two undergraduate one-semester 30-hours basic courses in probability were gathered and are being examined. Data consist in written answers to open-ended exercises, which were administered to students all along the semester. 500 undergraduate students were involved: respectively, 150 students in Mathematics (M), and 350 for a master course for Primary school teachers (P). The content of the two courses differed, but in this paper data from a series of exercises that were administered at the beginning of the course are analyzed. Students' mathematical background of the two groups differed: while the P students attended one basic mathematics undergraduate course, the M students were attending the second year in mathematics undergraduate course. However, the probability backgrounds were similar in the two groups: both of them did not receive any prior teaching in probability. In Italy, probability is neither taught at lower levels of education, nor in secondary schools. I focus my analysis on the P group, while the M group is referred to for comparisons.

The example below helps illustrate the cognitive model and its applications. It is taken from a series of exercises that were given at the beginning of the undergraduate course in probability.

A company employs 75 men (M) and 25 women (F). 12% of M and 20% of F work in the accounts department (a.d.). Compute the probability that, drawing the surname of an employee in the a.d. it would be the surname of a M .

In the exercise it is necessary to deal with conditional probability. There is a huge literature concerning conditional probability in Mathematics Education. The reader is referred to Huerta & Lonjedo (2007). In their paper, the authors consider three versions (one with percentages, one with probabilities, and one with integer numbers) of a problem, and they show that it is possible to recognize probabilistic or arithmetic thinking when data is expressed in terms of probabilities or percentages respectively. It is well known that dealing with conditional probability is not immediate for students and needs the use of complex semiotic transformations and of possibly counter-intuitive solving strategies.

DATA ANALYSIS

Table 1 shows the solutions provided by three *P* students for the a.d. exercise.

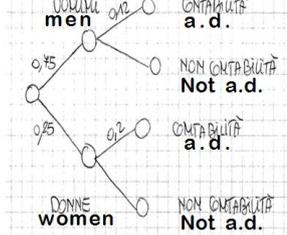

<p>45 uomini → 12% di 75 → 9 75 men → 12% of 75 → 9 25 donne → 20% di 25 → 5 25 women → 20% of 25 → 5 9 + 5 = 14 (dipendenti reparto contabilità) 9+5=14 (employees in the accounts department) $\frac{9}{14}$ → probabilità di un uomo $\frac{9}{14}$ → probability of being a man $\frac{5}{14}$ → probabilità di una donna $\frac{5}{14}$ → probability of being a woman</p> <p style="text-align: center;">Simona</p>	 <p style="text-align: center;">Daniele</p>	 <p>Uomini men 0,12 0,75 0,25 Donne women 0,2 0,8</p> <p>CONTABILITÀ a.d. He the man who Not being employed in the a.d. Nella probabilità (IP) In the conditional probability of being man given a.d. Ho raccolto i valori delle case probabilità nel diagramma ad albero e ho usato la formula di Bayes.</p> <p style="text-align: center;">Emanuela</p>
--	--	---

Table 1: three representations used by *P* students for solving the a.d. exercise.

Let us look first at the Daniele’s representation in table 1: he does not solve the exercise, but uses the Venn diagrams to represent the starting point of the exercise: there is the set of M employed in the company, there is the set of employees in the a.d., and the intersection between the two sets provides the number of M in the a.d.. Even if he does not go on with the computations, Daniele is able to represent the situation in a perceptive and intuitive way, using a pictorial register. Hence, Daniele’s solution belongs to the level of experience. In fact, he does not arrive to a quantitative solution, but nevertheless he is able to give an approximate estimate of a (complex) uncertain situation.

In her solution, Simona operates within the arithmetic register (table 1). No theoretical tool from the probability theory is used, with the exception – in the end of the solution – of the classical definition of probability as the ratio between the number of favorable cases (9 M) over the total number of cases (14 employees in the a.d.). This kind of solution has been taken by the majority of *P* students: they first compute the (integer) numbers of M and F working in the a.d., using the percentages and the integer numbers provided by the exercise. Then, working with integer numbers, they sum up the number of M and the number of F, obtaining the total number of employees in the a.d.: 5+9=14. In the end, they compute the ratio between the number of employees in the a.d. and the total number of employees in the a.d. and obtain P(M|a.d.). The solving process is carried out transforming representations within the

Working Group 5

arithmetic register, and the intuitive schema of proportion is involved. This sophisticated (and correct) solution does not (explicitly) take into account either the law of alternatives, or Bayes' theorem. *M* students do not adopt these solutions, which lie at the arithmetic level, and apply the rules of probability.

M students, in fact, applied Bayes' theorem to solve the exercise, like Emanuela. In the *P* group, only two students (Emanuela and another one) followed this strategy. She operates at the level of theory, using a symbolic register and complementing it with a graphic register. The fact that Emanuela uses a graphic register does not imply, however, that she is working at the level of experience. Indeed, she is accomplishing a very difficult cognitive task (Duval, 2008), namely coordinating two semiotic registers. It is interesting that Emanuela uses a tree-diagram for representing and computing the probabilities, and in the end she is able to come up with the frame of a tree-diagram and apply Bayes' theorem correctly.

The solution of Simona lies at the discreteness level, since she uses ratios. An example of a solution at the discreteness level using percentages is not present in the protocols relative to this exercise. It comes from another exercise:

Which is the probability of getting an ace among 52 playing cards?
--

One of the *P* students, Chifan, does not make computations, but writes only a percentage: 10%. Orally interviewed afterwards, he provides this explanation

Chifan The probability of getting an ace would be around 10%. There are, in fact, 4 aces in the pack of 52 cards. Hence, more or less the probability is 10%.

Chifan does not compute the ratio between the number of successful cases (4) and the total number of cases (52), but assigns a percentage that seemed to him to be likely (and is pretty close to $4/52 = 0.0769$). Chifan's approach does not belong to the experience level only, since he resorts to the arithmetical and percentage registers to represent the situation, but it is not completely within the arithmetic level either, since approximation and perception are still part of his reasoning process.

As a side remark, this last task does not involve conditional probability. The cognitive model presented in this paper, in fact, applies to all uncertain situations, and not only to conditional probability.

CONCLUDING REMARKS

In this paper a cognitive model to frame probabilistic reasoning within intuition and semiotic perspectives has been shown. Intuitions and semiotics may have two kinds of relationship: they can either support task solution, as in the case of Emanuela, who is able to operate a complex semiotic transformation (table 1), or impede task solution, as in the case of Daniele, who has strong intuitions, bound to pictorial representations, that do not allow him to overcome the experience level and operate a proper semiotic transformation to solve the task (table 1). Supporting or impeding

task solution depends both on the immediacy of choosing the representation that is the most proper for the task, and on the transformation(s) the subject operates starting from such representations. Hence, both the individual (together with his abilities, knowledge, etcetera) and the task contribute to determine the supporting or impeding nature of the relation between intuition and semiotic representations.

Future perspectives

Dubinsky's APOS theory assumes that mathematical knowledge consists in an individual's tendency to deal with perceived mathematical problem situations by constructing mental actions, processes, and objects and organizing them in schemas to make sense of the situations and solve problems. The underlying idea of this theory is to extend to the level of collegiate mathematics learning from the work of Piaget on reflective abstraction in children's learning. From a bird's eye view, it seems that there are many connections between this theory and the model presented in this paper. Hence, it would be interesting to go deeper into details in exploring possible integrations of the two aforementioned theoretical perspectives.

In this paper, only Duval's semiotic point of view has been taken into account. It would be interesting, in the future, to consider also other semiotic points of view, such as Radford's Objectification Theory, Arzarello's APC Space and Godino's and Batanero's Ontosemiotic Approach.

RELATING GRAPH SEMIOTIC COMPLEXITY TO GRAPH COMPREHENSION IN STATISTICAL GRAPHS PRODUCED BY PROSPECTIVE TEACHERS

Pedro Arteaga and Carmen Batanero

University of Granada, Spain

In this paper the graphs produced by 207 prospective primary school teachers in an open semi-structured statistical project where they had to compare three pairs of statistical variables are analysed. The graphs are classified according their semiotic complexity, and the teachers' levels of comprehension in Curcio's (1989) categorization. Most participants produced graphs with sufficient semiotic complexity to solve the task proposed; however, the correct conclusion was only reached by a minority of prospective teachers who were able to read the data produced at the "reading behind the data" level. When relating semiotic complexity of graphs to the reading level, teachers producing graphs at the highest semiotic level also reached the highest combined percentage of "reading beyond data" and "reading between data" levels.

Keywords: statistical graphs, semiotic complexity, graph interpretation and comprehension.

INTRODUCTION

Graphical language is an important part of statistical literacy (Watson, 2006). It is also a tool for transnumeration, a basic component in statistical reasoning consisting of "changing representations to engender understanding" (Wild & Pfannkuch, 1999, p. 227). In this work we complement our previous research on Spanish prospective primary school teachers' graphical competence (Batanero, Arteaga & Ruiz, 2010) with the aim to relate the semiotic complexity of graphs produced by prospective primary school teachers with the graph comprehension levels defined by Curcio (1989).

Understanding Statistical Graphs

Previous research suggest that competence related to statistical graphs is not reached in compulsory education, since students make errors in establishing the graph scales (Li & Shen, 1992) or in building specific graphs (Pereira Mendoza & Mellor, 1990; Lee & Meletiou, 2003; Bakker, Biehler & Konold, 2004). Several authors investigated levels in graph understanding. For this particular research we are using Curcio's categorisation (1989), that consists of the following levels: (a) Reading the data, is the level of a student who is only able to answer explicit questions for which the obvious answer is right there in the graph; (b) Reading between the data involves interpolating and finding relationships in the data presented in a graph. This includes making comparisons as well as applying operations to data; (c) Reading beyond the

data involves extrapolating, predicting, or inferring from the representation to answer questions related to tendencies in the data or extrapolation from the data. In this research we are only considering these three levels, which do not imply the need to look critically at the data. This would be a new level looking behind the data, according to Friel, Bright, and Curcio (2001).

Graphical Competence in Prospective Teachers

Few studies have focused on teachers' knowledge and conceptions about statistical graphs and most of these studies are related to prospective teachers (González, Espinel, & Ainley, in preparation). Results from this research highlight the scarce graphical competence in prospective teachers. For example, in a study conducted with 29 prospective primary teachers in Spain, Bruno and Espinel (2009) found frequent errors when building histograms or frequency polygons. In another study with 190 prospective primary school teachers, Espinel, Bruno, and Plasencia (2008) observed lack of coherence between the graphs built by participants and their evaluation of tasks carried out by fictitious future students. Monteiro and Ainley (2007) suggested that many Brazilian prospective teachers in a sample of 218 teachers did not possess enough mathematical knowledge to read graphs taken from daily press. In Burgess's (2002) study some teachers made graphs in their reports but were unable to integrate the knowledge they could get from the graphs with the problem context.

Batanero, Arteaga, and Ruiz (2010) analysed the graphs produced by 93 prospective primary school teachers in an open semi-structured statistical project where they had to compare two statistical variables. They defined a *semiotic complexity level* in these graphs and analysed the teachers' errors in selecting and building the graphs, as well as their capacity to reach a conclusion on the research question. Although about two thirds of the participants produced a graph with enough semiotic complexity to get an adequate conclusion, half the graphs were either inadequate to the problem or incorrect. Only one third of participants were able to get a conclusion in relation to the research question. In this paper we increase the sample size and the number of variables to be compared in the same semi-structured statistical project in order to relate the graphs semiotic complexity with the prospective teachers' level in reading the graphs.

Semiotic Complexity in Statistical Graphs

In mathematical work we usually take some objects (e.g. a symbol or a word) to represent other abstract objects (e.g. the concept of average). In these situations, and according to Eco "there is a *semiotic function* when an expression and a content are in correlation" (Eco 1979, p. 83). Such a correlation is conventionally established, though this does not imply arbitrariness, but it depends on a cultural link. Font, Godino, and D'Amore (2007) suggested that all the different types of objects that intervene in mathematical practices: *problems, actions, concepts, language, properties and arguments* could be used as either expression or content in a semiotic

Working Group 5

function. In our study we proposed an open semi-structured project to prospective teachers. To address the project, the participants had to solve some mathematical *problems* (e.g., comparing three different pairs of distributions) and perform some mathematical practices to solve these problems. The focus in our research is the statistical graphs produced by the teachers and the mathematical practices linked to the different types of graphs. When teachers produce a graph they need to perform a series of *actions* (such as deciding the particular type of graph or, fixing the scale), they implicitly used some *concepts* (such as variable, value, frequency, range) and *properties* (e.g. proportionality between frequencies and length of bars in the bar graph) that vary in different graphs. Consequently the semiotic functions implicit in building each graph also varies. We therefore should not consider the different graphs as equivalent representations of a same mathematical concept (the data distribution) but as different configurations of interrelated mathematical objects that interact with that distribution. Taking into account these ideas, Batanero, Arteaga, and Ruiz (2010) defined different levels in graphs semiotic complexity, as follow (see examples in Figure 1).

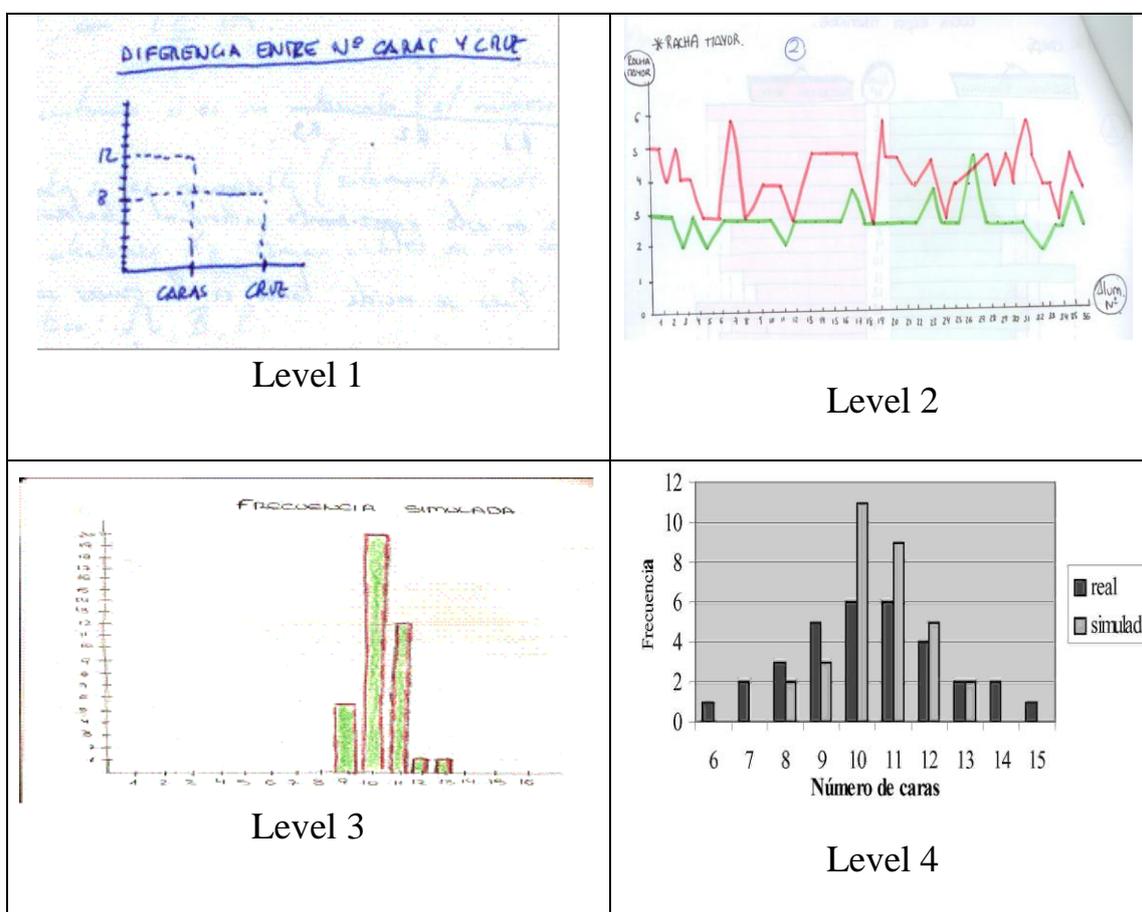

Figure 1. Examples of graphs at different semiotic complexity level

L1. Representing only individual results. When given a set of data, some students do not complete the graph for the whole data set; instead they only represent isolated data values. When the data are collected in the classroom they only represent their own data, without considering their classmates' data, for example, they represented

Working Group 5

the number of heads in his /her individual experiment. These students do not use the idea of statistical variable or distribution when producing their graphs.

L2. Representing all the individual values for one or several variables, without forming the distribution. Some students do not form the frequency distribution of the variables, when they are given a data set. Instead, they produce a graph where data are represented one by one, without an attempt to order the data or to combine identical values. Consequently these students neither compute the frequency of the different values nor explicitly use the idea of distribution.

L3. Producing separate graphs for each distribution. When comparing a pair of distributions, some students use the idea of frequency and distribution but produce a separate graph for each variable to be compared. Often, these students use either different scales in both graphs or different graphs for the two distributions, which makes the comparison hard.

L4. Producing a joint graph for both distributions. This level corresponds to students that form the distributions for the two variables to be compared and represent them in a joint graph, which facilitated the comparison. These graphs are the most complex, since they represent two different variables in the same frame.

THE STUDY

Participants in the sample were 207 pre-service teachers in Spain, in total 6 different groups (35-40 pre-service teachers by group). All of them were following the same mathematics education course and studied descriptive statistics at a secondary school level, and in the previous academic year (for 20 hours), where they had worked with another statistical project. In this paper we analyse the graphs produced by these teachers when working in a semi-structured statistical project in which participants were asked to perform a random experiment, collect data, compare three pairs of distributions and come to a conclusion about the group's intuition of randomness, basing their conclusion on the analysis of the data. The sequence of activities in the project was as follows:

- 1. Presenting the problem, and experiment.* We proposed that the prospective teachers carry out an experiment to decide whether they had good intuitions on randomness or not. The experiment had two parts. In the first part (simulated sequence) each participant wrote down apparent random results of flipping a coin 20 times (without really throwing the coin, just inventing the results) in such a way that other people would think the coin was flipped at random. In the second part (real sequence) each participant flipped a fair coin 20 times and wrote down the results.
- 2. Collecting data and instructions.* Each prospective teacher performed both experiments. After the lecturer started a discussion about how the simulated and real sequences for the whole group could be compared, some students suggested to collect data from the number of heads or number of runs. Finally the lecturer

suggested comparing the following statistical variables: number of heads, number of runs and longest run. Each prospective teacher provided his/her results in each of the variables that were recorded on a recording sheet. At the end of the session the prospective teachers were given a printed copy of the data set for the whole group of students. They were asked to produce a written report including their statistical analyses and their conclusions. There was no restriction in the report length; teachers were given freedom to use any statistical method or graph they wished and were allowed to use computers. They were given a week to complete the reports (for more details of the project, see Godino, Batanero, Roa & Wilhelmi, 2008).

RESULTS AND DISCUSSION

Once the prospective service teachers' written reports were collected, we made a qualitative analysis of these reports. From a total of 207 students 181 (87,4%), 146 (70,5%) and 128 (61,8%) produced some graphs when analysing the number of heads, number of runs and longest run, even if the instructions given to the students did not explicitly ask them to construct a graph. These high percentages suggest that prospective teachers felt the need of building a graph to reach, through a transnumeration process (Wild & Pfannkuch, 1999) some information that was not available in the raw data. In Table 1 we present the results. These data show the relative difficulty of the variables to be analysed, as the number of heads was more familiar to the teachers than the runs.

Semiotic complexity	N. of heads	N. of runs	Longest run
L1. Representing only individual data	6 (3.3)	6 (4.1)	3 (2.3)
L2. Representing the data list	40 (22.1)	23 (15.7)	21 (16.4)
L3. Producing separate graphs for each distribution	91 (50.3)	77 (52.7)	67 (52.3)
L4. Producing a joint graph to compare both distributions	44 (24.3)	40 (27.4)	37 (28.9)
Number of participants producing graphs	181	146	128

Table 1. Frequency (percentage) of participants producing graphs in each semiotic level and pair of variables

Few participant produced level L1 graphs, that is, only analysed their own data and less than 25% represented the data list in the same order given in the data sheet without making an attempt to summarise the data, producing the variables distributions. Consequently the concept of distribution seemed natural for the majority of students who produced a graph, since about 75% of them built a distribution to compare each pair of variables, although the instructions did not explicitly require this. Results agree with those reported by Batanero, Arteaga, and Ruiz (2010).

Graph comprehension

In table 2 we classify participants according to Curcio's (1989) categorization of graph comprehension, in the following way:

R0 Do not read the graph or incorrect reading: About 30% of the teachers in each pair of variables only produced and presented the graph in their report with no attempt to read the graph, and reached no conclusion about the problem posed. In addition, after producing the graph, between 11% to 14% of the teachers in each pair of variables failed when reading the information. Some of these failures were produced by errors in the graphs that reproduced those described in Bruno and Espinel (2009) or incorrect choice of the type of graph that was inadequate for the information represented in the graph. Other failures in reading the graph were due to incorrect understanding of a concept; for example confusing frequencies and values of the variable or misinterpreting the meaning of the standard deviation.

R1 Reading data: Between 22- 25% of the participants made a correct literal reading of graphs labels, scales and specific information on the graph in each pair of variables. However they only considered superficial features of the graph. For example, they compared isolated values of the two variables, provided the frequency for a given value or made a general comment about the shape of the graph with no consideration given to tendencies or variability in the data.

Graph comprehension level (Curcio)	N. of heads	N. of runs	Longest run
R0. Do not read the graph	51 (28.2)	45(30.9)	42(32.8)
R0. Incorrect reading	21(11.6)	17(11.6)	18(14.1)
R1. Reading data	41(22.6)	34(23.3)	32(25)
R2. Reading between data	44(24.3)	32(21.9)	21(16.4)
R3. Reading beyond data	24(13.3)	18(12.3)	15(11.7)
Number of students producing graphs	181	146	128

Table 2. Frequency (percent) of participants producing graphs according to comprehension level

R0. *Reading between data:* Teachers classified in this level were able to make comparisons and look for relationships in the data. They either compared averages (means, medians or modes) alone in both distributions (with no consideration of variation in the data) or else compared spread (without comparing averages).

R1. *Reading beyond data:* Making inferences and drawing conclusions from the graph: Participants at this level were able to compare both spread and average in the distribution and conclude about the differences taking into account both data

features.

Less than 25% of the prospective teachers who built graphs reached the Curcio's (1989) intermediate level (reading between the data) and only 13% reached the upper level (Table 2). Notice that the percentage of students building graphs without interpreting them is high, which agrees with Burgess (2002). The difficulty of reading the data increased for variables related to runs that were less familiar to participants.

In Figure 2 we take into account only the prospective teachers who interpreted the graphs they built themselves, classifying their representations according to the graph semiotic complexity level and reading comprehension level for each pair of variables and for all the graphs combined. The Chi-square test to check independence of reading levels and semiotic complexity levels for all the graphs combined was statistically significant ($\chi^2=40.4$, $df=9$, $p<0.0001$) and therefore we can accept that these two types of levels are related.

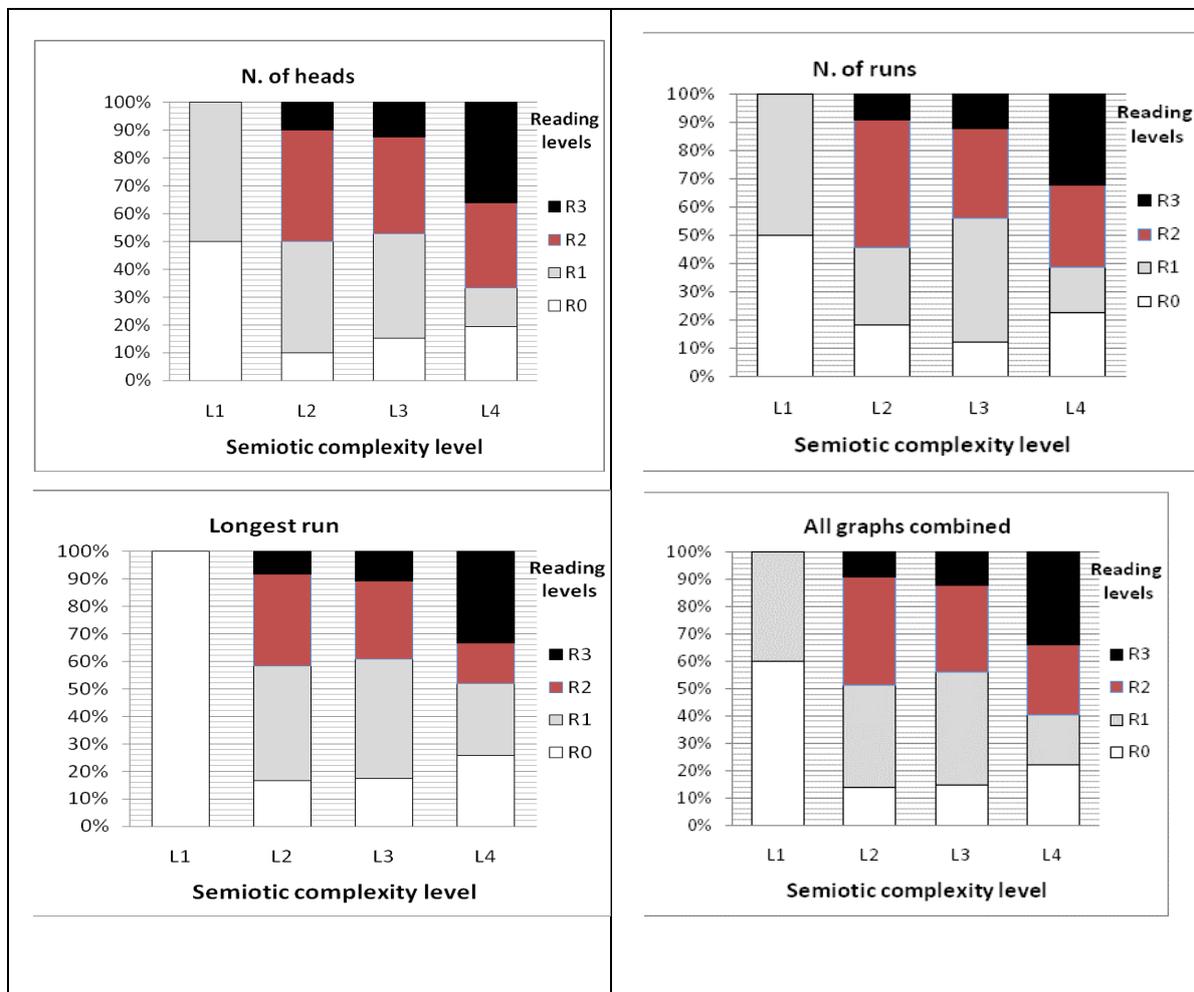

Figure 2. Reading levels by semiotic complexity in the graph

Prospective teachers producing semiotic level L1 graphs either made an incorrect reading or only reached the literal “reading data” level. The percent of incorrect reading dramatically decreased in the remaining levels; however this percent is higher in level L4 than in levels L2 or L3. This is probably because more complex

Working Group 5

graphs were harder to be interpreted correctly by participants. Although there is no clear tendency as regards literal “reading the data” level, reading the data only is not productive to reach a conclusion on the problem posed. “Reading between data” level is more frequent in level L2 graphs, because in these graphs the data variability is very easily perceived (as compared with levels L1 or L3 graphs). The highest percentage of “reading beyond data” level, when teachers are able to analyse both the tendency and spread in the data and reach a conclusion, as well the combined percentage of “reading between data” and “reading beyond data” levels were reached in semiotic level L4 graphs because in level L4 graphs students can perceive spread and tendencies more easily. Therefore level L4 graphs provide more opportunity for students to get at least a partly correct reading. Consequently, it is important that the teacher’s educator try to promote higher reading levels when possible.

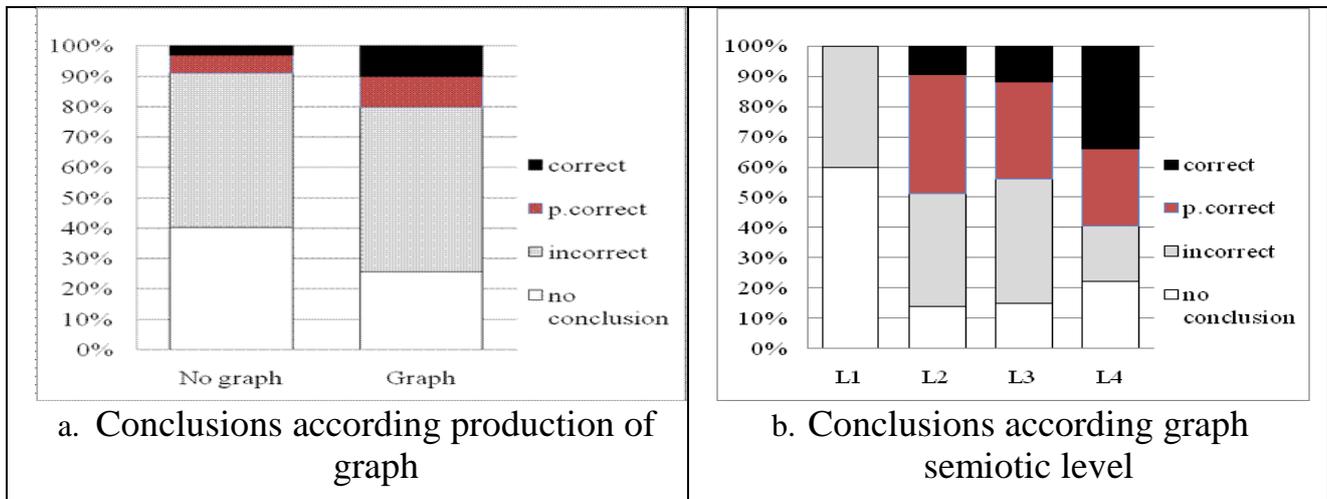

Figure 3. Conclusion according to (a) production of graph; (b) graph semiotic level

In the project proposed the students should reach a conclusion regarding the group intuition on randomness. Only 8.9% of those prospective teachers who produced no graph got a correct or partly correct conclusion. This percentage increased to 20.2% in those teachers who produced graphs as part of their analyses (10.2% and 10%); the differences are significant in the Chi-square test ($\chi^2=18,72$, $d.f.=3$; $p=0.007$). Therefore, building a graph helped the teachers in their conclusions (Figure 3.a). The percentage of correct conclusions increased to about 30% in teachers producing level L4 graphs (Figure 3.b), because, at these levels the teachers read the graph at a higher reading level and in these graphs the perception of both tendencies and spread is easier. The percentage of partly correct conclusions was higher at level L2 graphs, because of easy perception of variability in these graphs. The Chi-square test to check independence of type of conclusions and the semiotic complexity levels for all the graphs combined was statistically significant ($\chi^2=40,45$; $d.f.=9$; $p=0,0000$) and therefore we can accept that these two variables are related.

IMPLICATIONS FOR TEACHER EDUCATION

In agreement with Bruno and Espinel (2009) and Monteiro and Ainley (2007) our research suggests that building and interpreting graphs is a complex activity for

prospective school teachers. We agree with these authors in the relevance of improving the prospective teachers' levels of competences in both building and interpreting graphs, so that they can later transmit these competences to their own students. Many participants in the study limited their analysis to producing graphs with no attempt to get a conclusion about the problem posed. Consequently, prospective teachers need more training in working with statistical projects, since working with projects is today recommended in the teaching of statistics from primary school level.
