This expression was the occasion to focus on children’s informal learning, which can be used to develop out-and-out mathematical concepts, such as ten, composition and decomposition. Apart from this, the teacher decided to further develop the activity with the straws. She chose to incline the children towards additive mathematical problems, submitting them some problematic situations

starting from problems with variation. Analyzing the nine problems-scheme (Bartolini Bussi et alii, 2011) during the planning stage, she chose the first row, which provides the children with a static situation with a very short text.

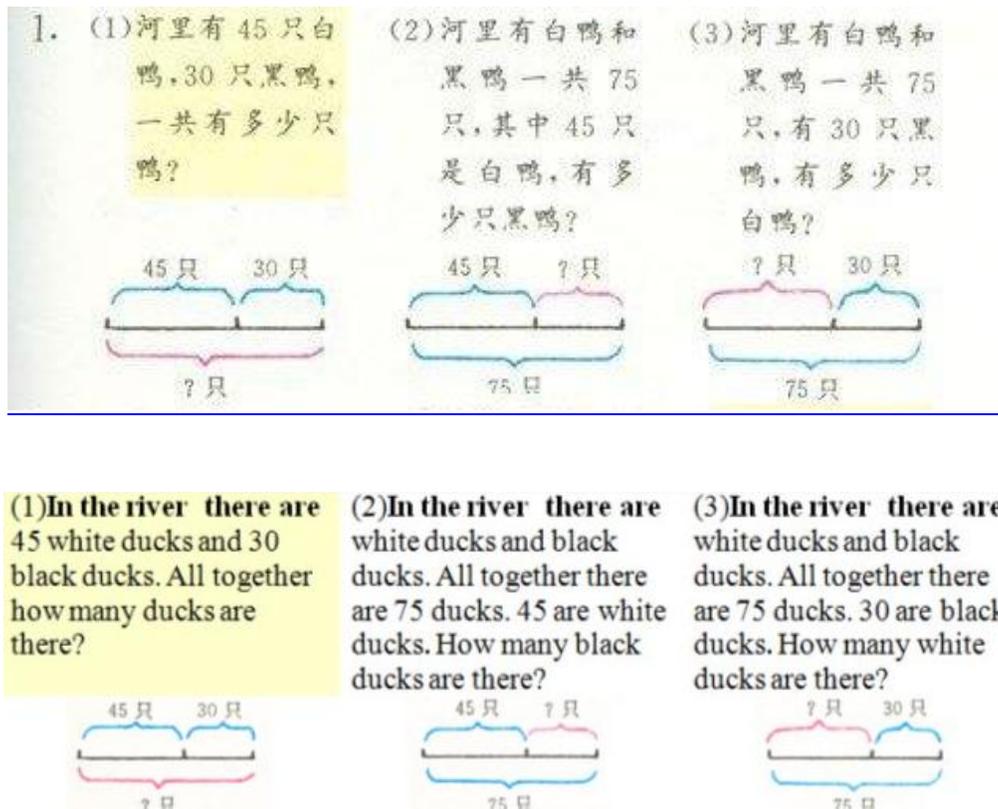

Figure 5

These aspects, of course, are essential for pupils of the first class with initial reading - writing skills. However, the major *gap* in comparison with Italian didactical practice is the simultaneous presence of addition and subtraction, which is hardly found in the Western didactics. Again, we are in front of a necessary process of transposition. Indeed, simple translation and importation of a scheme like the Chinese one in the Western didactics can be unsuitable for the activated paths. In this case, the teacher introduces a further element in Chinese problems with variation: the dramatization of the situation. She proposes different situations to the children, which have been documented on different videos.

Nevertheless, referring to what we consider to be the paradigmatic element, we will concentrate on the following proposal. The teacher sellotapes the straws on the blackboard and asks them to read the consequent situation: “On the blackboard there are 9 yellow and 6 green straws. How many yellow and green straws are there?”. The children, invited by the teacher, stand up and near the blackboard to count the straws, or, in some cases, they do the same operation from their desks.

The additive situation is clear: all answer that the straws are 15. At this point, the teacher *varies* the situation (with reference to Chinese problems with variation) and

asks: “So, on the blackboard there are 15 yellow and green straws. 9 are yellow, how many green straws are there?”.

In front of this new situation, the pupils seem disoriented and some of them propose the additive situation “they are 15” again, but the teacher points out again: “I asked how many green, not yellow and green, straws are there”. Leading the discussion with the children, she comes to introduce subtraction, which allows them to count the straws and answer correctly: “the green are 6”. The teacher, always referring to the structure of Chinese problems with variation, does not stop and asks: “Well, on the blackboard there are 15 yellow and green straws. 6 are green, how many yellow straws are there?”. The disorientation of some children shows the difficulty of this age group to deal with these variations, but in the discussion a proposal emerges: “All you have to do is to remember the question you asked us before!”. The child, here, starts to reason not about the element and the operation, but about a schematic solving process, which finds the core of this activity in the identification of the relations among the operations underlying the teacher’s three requests.

These examples seem paradigmatic to underline once again how these activities, transposed through the analysis of Chinese books, spur the child to look for solving schemes, which lead him to a methodological learning, perhaps able to create links between different contents, often too atomised in our schools.

To better understand the implications that can be caused by this kind of proposal, we believe it is important to refer to the activity conducted by F. Ferri and documented during the 2011 SEMT (Bartolini, Canalini, Ferri, 2011). It is clear that the blend of the didactic methodologies here discussed and presented to the teacher in training aims to begin the construction of mathematic meanings, which teachers can develop in their classes.

COMMENT ON THE THEORETICAL CONTEXT: FRANÇOIS JULLIEN’S REFLECTION. POSSIBLE TRANSPOSITIONS

Allen Leung, Hong Kong researcher on the concept of variation, but above all friend of ours and privileged speaker, while e-mailing on the problem of transposition, spoke about *learning across cultures*. For us, it means that learning, including that of mathematics, cannot but prescind from a dialogue, a *crossing* between cultures. Let us develop this dialogue, this *crossing* further on. François Jullien (sinologist and philosopher), in an interview in 2005 at the Modena Philosophy Festival, says: “It is not China in itself that makes the thought feel lost with its language, culture and way of thinking, but the fact that, dealing with Chinese thought, an extraneousness is reintroduced, which is not ‘China’, but the sidelong glance on thought that arises reflexively from the extraneousness in which China is”. (Jullien, 2005)

The studies of F. Spagnolo and M. G. Bartolini Bussi present this approach of contamination, continuous dialogue from *distances*, and cultures *crossing* in the didactics of mathematics. Starting from these theoretical points of reference, we will try to reread this passage like this: in order to redraw attention to the Western and

specifically the Italian didactics of mathematics, it can be useful to observe it from a perspective of absolute distance: that of Chinese didactics of mathematics, that is, in a school system with cultural and organisational characteristics which are totally *different*, totally *extraneous* and *foreign*. Therefore, F. Jullien becomes the privileged interpreter to try to describe this approach, using the *obliquity* of thought he speaks about (Jullien, 2006). To better explain this concept, we think it is appropriate to evoke an image: let us imagine to be on a becalmed sea, on a ship. Our eyes can wander in any direction and what stands out in front of them, at an always unreachable distance, is the line of the horizon. Similarly, putting ourselves *in the logos*, we place ourselves in the centre of a specific cultural horizon, whose boundaries can really seem unreachable.

However, this interpretation has to induce us also another consideration: this position, placing us in a “centre”, seems to allow us to draw a universalistic perspective, which extends the power of the *logos* to infinity. If we do not put ourselves in the logos anymore, but we *go towards the other*, that is, we adopt also the passivity dimension which allows the differentiation process to make other perspectives emerge, than the image changes: we are no more on a ship offshore, where our eyes lost to infinity towards the horizon, *in the horizon*. But, we may imagine to find ourselves in an Iceland “moonscape”, where our feet can really walk on the fault, that is Earth’s fissure, the place of the boundary, which is the differentiation process. Why looking from the fault, from the fissure, puts ourselves in front of something different? Because, suddenly, logic hypertrophy shows itself in front of me and you.

CONCLUSIONS

This brief contribution opened with some questions, which are important to resume. Why introduce a multicultural perspective in the didactics of mathematics at the beginning of primary school? Why choose China? As said before, teenagers’ positive results in China and in the wider Confucian area cannot but make us think about that specific cultural tradition. Still, this would mislead our intervention, if we would not consider these fifteen-year-olds as the result of a long educational process, whose bases are in pre- and primary school. From this perspective, to understand how Chinese didactic paths are structured, starting from school curricula translated into textbooks, gives rise to a series of reflections, which show how cultural differences can turn into an asset for interpretation and dialogue, providing us new interpretative keys for our cultural and didactic reference points (in this we see F. Jullien’s *unthought*).

In confirmation of this path effectiveness, from the didactic point of view, we believe it is sufficient to think over the activities we proposed as transposition examples starting from Chinese textbooks. In them, it is appreciable the fact that *didactic blend* gave positive results right in the very important initial stage of mathematic meanings building, corresponding to the age of 6 to 8 years old. In fact, both positionality and the approach to decimal system have been favoured by this perspective, this introduction of these elements, which are distant but never completely extraneous.

Not only that, but a path for the strengthening of the use of even very big number already in the early stages of primary school has been started. Moreover, the introduction of problems with variation into Italian didactic practice provided very interesting information, which should be examined more in depth.

Among them, we mention the shift of child's reflection from an arithmetic to a pre-algebraic way of thinking. This is proved by the attention of older children for schemes (Bartolini, Canalini, Ferri, 2011). Instead, younger children (6 - 7 years old) focus more on the quest for the unknown element through variation. From this reflection we have thought to create the summer school for teachers, aimed to develop educational paths capable of tackling *difference*.

This research in progress aroused big interest and participation, though only the training part with the teachers has been executed. Indeed, although we forecasted an attendance of 20 – 30 teachers, the registrations have been 87. Besides that, the participation in all three days of training has been the evidence of a deep interest in this kind of job prospect. This educational activity will be developed in the classes of the teachers who participated and expressed their will to continue on this research path.

This will allow us to carry out new broader-spectrum tests, in order to get, by September 2013, a series of data confirming the indications obtained from the mentioned experiments. In conclusion, our intention was to create a course allowing teachers to reconsider the educational perspective from a continuity point of view, where the age group of 3 or 6 to 8-year-olds, has a central value on which the whole children educational path is founded.

Moreover, the didactics they carry out every day in their schools can be contaminated by “more distant” approaches, in order to create transposition occasions, deconstructing pedagogic - didactic categories often too eurocentric.

FINGER COUNTING AND ADDING WITH TOUCH COUNTS

Nathalie Sinclair, Mina SedaghatJou

Simon Fraser University

This paper describes the design of a digital technology focussed on early number sense (especially counting and adding). This “TouchCounts” application (designed for the iPad) takes advantage of the direct mediation through fingers and gesture of the touch screen interface. Through an a priori analysis, we show how the perceptual and motor aspects of the application can support the development of cardinality. Using a theoretical perspective informed both by tool use and by embodiment in mathematics thinking and learning, we provide a case study analysis of how a 5 year-old child gains emergent expertise in producing and transforming numbers.

INTRODUCTION

Current mathematics education software has been developed for the desktop/laptop paradigm of technology use where the mouse and keyboard are essential interfaces. Even software for interactive whiteboards (IWBs) does not take full advantage of touch-screen capacities because the mouse/keyboard interface is the default interaction mode. In addition, IWBs, while providing a social space for interaction, do not allow individual students, or small groups of students, to each interact directly with the software. In contrast, iPad devices permit both whole-class and individual interactions. Also, iPads enable collaborative interaction between two or three students on a single device (as it recognizes multiple inputs from different individuals simultaneously), something that computers, with a single mouse, have not been able to offer. Their small size (book-sized at ~24 x 19 x 1 cm) overcomes obstacles faced by teachers using school computer labs (e.g., awkwardness of obtrusive monitors).

The touch-screen iPads also enable direct mediation, allowing children to produce and transform objects with fingers and gestures, instead of through a keyboard or a mouse. Recent neuroscience research has shown that there is a neurofunctional link between fingers and number processing, and that finger-based counting may facilitate the establishment of number practices (Andres, Seron, and Olivier 2007; Kaufmann et al. 2008; Sato et al. 2007; Thompson et al. 2004). Research has already shown that consistent use of fingers positively affects the formation of number sense and thus also the development of calculation skills (Gracia-Baffaluy and Noel 2008). This suggests that using the fingers to create numbers in a correctly ordered way, with both visual and auditory feedback can support the development of number sense and provide the foundation for successful arithmetic achievement.

The large majority of existing iPad applications are designed for game-like interactions in which learners practice arithmetic operations. Lange and Meany (in these proceedings) described several mathematics-related applications and used Bernstein’s (1971) notions of classification and framing to characterise them. They found that none of the applications they used in their study were strongly classified

(explicit in the content focus) and weakly framed (open to student agency). As an application specifically focused on number but open to student expressiveness, *TouchCounts* illustrates well this missing category. Indeed, our interest was in developing an expressive technology that supports the development of meanings related to numbers and operations. A similar project has been undertaken by Ladel and Kortenkamp (2011), who have developed a multi-touch-table environment.

DESIGN OF THE *TOUCH COUNTS* INSTRUMENT

Currently, there are two sub-applications, one for Counting (1, 2, 3, ...) and the other for Adding (1+2+3+...).

Counting World (1, 2, 3, ...).

In this world, learners tap their fingers on the screen to create small numbered circles that are also represented through both symbol (written numeral) and sound (spoken word) as fingers are placed onscreen. In the default mode, gravity makes these circles fall off the screen, unless they are placed on the horizontal bar (see Figure 1). Adding more fingers continues the counting. Fingers can be placed onscreen all at once to create a group of numbers. So, for example, placing five fingers on the screen creates five numbered circles but produces only the word ‘five’ orally. Every finger touch produces a number; it is thus not possible to move existing objects on the screen.

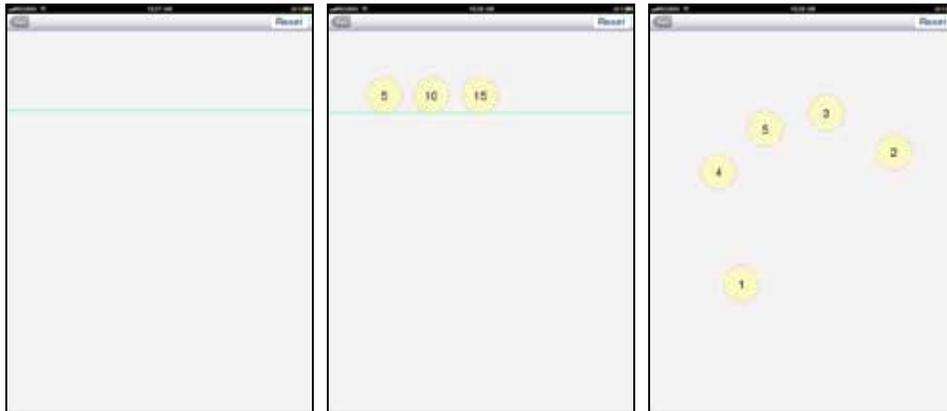

Figure 1: (a) Default Counting world; (b) Default Counting world with numbers on the horizontal bar; (c) No gravity Counting world

The goal of this simple application is to assist young children in developing an understanding of the one-to-one relationship between their fingers and numbers. Children at this age, when asked to count, do not necessarily associate the words for each number with the objects being pointed to (this is often called “rote counting”). They tend to recite the numbers as if it were a song and point at the same time, but not always coordinating the two actions (Fuson, 1988). The Counting world should directly supports two of the five aspects of counting identified by Gelman & Meck (1983): (1) when counting, every object gets counted once and only once (one-to-one correspondence principle); (2) the number words should be provides in a constant order when counting. Further, when the gravity option is turned off, it becomes

evident that the last number that is counted is the number of items on the screen, which is a third principle of counting.

Being able to select specific numbers to “pull out” is evidence of having objectified number, that is, of being able to think about a particular number as being more than just an element in the process of counting. More specifically, in order to place a given number on the bar, one must know what the previous number will be. This objectification of number enables the move from ordinality to cardinality, the latter being necessary for answering the “how many?” question.

Nunes and Bryant (2010) have argued that children need to make three types of connections between number words and quantities: “they need to understand cardinality; they need to understand ordinal numbers, and they need to understand the relation between cardinality and addition and subtraction.” While the Counting world focuses on ordinality and the objectification of number, the Adding world specifically targets the idea of cardinality.

Adding World (1+2+3, ...).

While tapping on the screen in the Counting world creates numbered objects, tapping in the Adding world creates a group of discs labelled by the cardinality of the group (see Figure 2a). Placing five fingers on the screen will create a group of five discs arranged around the circumferences of a circle as well as the numeral 5 in the middle of the circle. This focusses attention on the cardinality of five. As Vergnaud (2008) has argued, understanding cardinality involves more than knowing that the last number in the sequence of counting objects in a set is the number of objects in the set. It involves being able to use numbers in operations and, more specifically, being able to count on. Once two or more sets have been created, they can be added by using a pinch gesture (see Figure 2b), which provides a fundamental metaphor for addition (see Lakoff & Núñez, 2000).

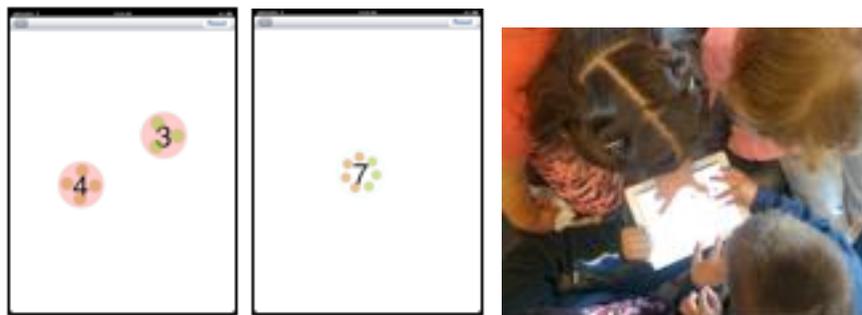

Figure 2: (a) Two groups in the Adding world; (b) resulting sum with colour-based record of the addends; (c) Children using the pinching gesture to add two groups

Thus cardinal numbers are ones that can be acted on (in this case, added). The explicit use of gesture in this application is not only based on the affordances of the iPad device, but also draws on recent research highlighting the important relation between gestures and learning (Goldin-Meadows, 2004), and the recommendation that children be exposed to and encouraged to use more gestures (Cook & Goldin-

Meadow, 2006, Singer & Goldin-Meadow, 2005). When two or more groups are added, the discs in them retain the colour of the original sets so that the sum retains a trace of its construction (see Figure 2b). When two or more sets are added, the value of the sum is given orally. Children need not know how to add before using this environment. And while a teacher might introduce the word ‘adding’ to the task, it does not appear on the screen. As such, words such as “making,” “putting together,” “joining” can all be used to describe the action of pinching sets together. Note that the pinching gesture is symmetric, which means that there is not order implied to the sum of A and B.

For Vergnaud, the student who can answer how many objects are in a set if you add some objects to the set that they have just counted has a sense of cardinality. By having the Adding world groups labelled with their cardinality, the action of counting on is facilitated since the child will focus more on the cardinal number displayed in the group than on the objects in it.

Given the presentations of Sun and Ramploud and Di Paola, we are interested in developing tasks that can help promote a more unitary approach to addition and subtraction. This might involve, for example, asking children to create a group of 7 using an existing group of 3. Current attempts to design “take away” gestures have been discarded either for physical reasons and pedagogical ones.

THEORETICAL PERSPECTIVE

Broadly speaking, we situate our work within the area of mathematics education research that examines the role of technology, tools and artefacts in mathematics thinking and learning (see Hoyles & Laborde, 2010). Within this area, given the tangible nature of the interface, we are particularly interested in the embodied practices that allow learners to interact with digital technologies. While other theoretical approaches such as instrumentalism, sociocultural theory and semiotic mediation do not discount the role of the body in mathematical practice, Nermirovsky’s (Nemirovsky, Kelton, Rhodehamel, 2013) perceptuomotor integration approach focuses specifically on the way that mathematical expertise develops through a “systematic interpenetration of perceptual and motor aspects of playing *mathematical instruments*” (in press, *emphasis in original*). This approach shares many similarities with the emerging body of work in mathematics education that moves away from a mentalist focus on structures and schemas toward a description of lived experiences in which learners’ activities are at once bodily, emotional and interpersonal (Radford, 2009; Roth, 2011).

The perceptuomotor integration approach assumes that mathematical thinking is centrally constituted by bodily activity, which may be more or less overt, and that mathematical learning occurs through a transformation in the lived bodily engagement of a learner in a particular mathematical practice. This approach takes a strong stance toward embodiment, seeing it not just as a precursor or underpinning of mathematical thinking, thereby further promoting a mind/body dualism. Instead,

mathematics learning entails transformations in the lived body experience, not just at the primary school age when children interact with physical manipulatives, but for learners of all ages. Thus, taking *TouchCounts* as a mathematical instrument, we will be interested in learners' developing fluency and the concomitant changes in the way they touch, move, talk, gesture, etc.

METHODOLOGY

The interview took place near the end of the kindergarten school year in the resource room of an elementary school located in northern British Columbia. Several children were interviewed, all between the ages of 5 and 6. The interviews protocol was intentionally open-ended since we wanted to see what children would be able to do without specific instruction and what kinds of questions/investigations they would initiate on their own. If the child did not notice particular features/techniques (that the bar keeps numbers from falling down, that the Reset button restarts the counting, that the pinching gesture assembles groups) the interviewer provided an explanation. In addition, the interviewer asked each child, after a period of play, to place a certain number on the bar (usually 5) in the Counting World and to make a group of 7 in the Adding World. Other tasks were given when the child seemed to have exhausted a certain investigation. Our hypothesis in terms of instrumentation was that the children would discover the main features of Touch Counts on their own. In terms of number sense, we hypothesised that the children would like to create big numbers and that both tasks (placing just 5 on the bar and making groups of 7) would be challenging. In this paper, we have chosen to focus on a girl named Katy, who has just recently turned 5. Her teacher described her as one of the weaker students in the class.

RESULTS AND ANALYSIS: ONE-FINGER INSTRUMENT PLAY

We divide the results into two sections, one focussed on the Counting World and the other on the Adding World. For readability, we analyse each section in turn.

Counting World: What kind of number is going to come after?

The session began with the interviewer saying, "Let's start with number." Without any instruction, Katy started by placing her right index finger on the screen and swiping it downward (Figure 3a). She did this slowly, repeating the numbers as she goes (saying some of them out loud, like 2, 3 and mouthing the others). After 9, she put her head down, created a number then repeated 10 out loud (Figure 3b). She lifted her head up at 14 and kept making numbers. At 17, she put several fingers on the screen at once and the iPad said 21. She paused and smiled. She then continued, with her index fingers, to make numbers up to 27, saying the numbers at the same time as the iPad. She looked up, no longer watching the screen and continued swiping and saying numbers (Figure 3c). She had automated her number-making, swiping the screen in a rhythmic way without having to look.

Figure 3: (a) first interaction; (b) bending over around 10; (c) counting beyond 27

After accidentally pressing the Reset button, Katy began counting again. The interviewer then invited her to put numbers above the bar. When she put her next number above the bar, she said, “It stops the number. Why?” She then tapped her index finger more quickly and said, “pop.” She continued putting numbers above the line, saying “pop” each time, and lining them up in a row moving from right to left. She stopped at 47, sat back and smiled. The interviewer asked Katy to press the Reset button. The interviewer then said, “I want to see just five up here.” Katy tapped with her index finger above the line. The interviewer says, “I don’t want to see one.” Katy resets (without being asked). She then put 1 above and 2, 3, and 4 below the bar, and then 5 above. She sat back and smiled. When the interviewer prompts her to put just 5 on the bar, Katy resets, put 1, 2, 3, 4 below the bar, saying four out loud. She paused, then put 5 above the bar, saying five out loud.

During this whole interaction, except for a brief multiple-finger tap (perhaps accidental), Katy used her right index finger. However, the way she touched the screen changed from a slow swipe when she first creating numbers, to a quick tap (“pop”) when she was putting numbers above the line. As she tried to put 5 above the bar, her tapping got slower. When she succeeded in getting only 5 above the line, her tapping became quicker and rhythmic, suggesting that she could anticipate when 5 would come.

The interviewer then asked whether Katy could put 5 and 10 above the line.

- 40 I: Imagine five and ten are your best friends and they are the only ones you want to have come over to your house.
- 41 Katy: [*Smiles, looks up*]. Okay. [*Sits up in her seat. Taps 1, 2, 3, 4 down and then 5 up. Smiles. Taps 6 down.*] What kind of number is going to come after?
- 42 I: After 6? What do you think?
- 43 Katy: Don’t know. One, two, three, four, five, six, seven! [*Taps 7 down and then looks up*]. Eight. Does he go there?
- 44 I: He’s not your friend, just ten.
- 45 Katy: [*Taps 8 down.*] Nine. [*Looks at interviewer.*]
- 46 I: Not your friend.

- 47 Katy: Is nine going to come after?
 48 I: You just did eight. What do you think?
 49 Katy: One, two, three, four, five, six, seven, eight, nine, ten, eleven, twelve, thirteen, fourteen, fifteen, sixteen, seventeen, eighteen. No. [Closes eyes, laughs and tilts her head up. Puts 9 down. Then puts 10 down.]
 50 I: Oh. Ten was our friend.
 51 Katy: [Resets. Puts 1 up. Resets. Puts 1, 2, 3, down. Pauses. Puts 4 down. Puts 5 down.]
 52 I: Oops. We lost five.
 53 Katy: [Resets. Puts 1, 2, 3, 4 down tapping quickly right below the line, up to 5 up. Taps 6, 7, 8 in the same place below the line. Looks up at the interviewer.] What's next?
 54 I: After eight?
 55 Katy: Yeah. [Taps 9 down. Puts 10 up. Smiles and claps].

Katy tapped the numbers 1 through 4 quickly in a specific area of the screen. In [41], she was pleased to have correctly put five above the bar and then immediately put 6 below. Katy then counted up from 1 to figure out what would follow 6. She used the same strategy after 8, but this time overshooting 9. After mistakenly putting 10 below the bar, Katy reset three times before [53], when she successfully got to 8. She then succeeded in [55] at putting 9 below and 10 above the bar. In [53] her tapping from 1 to 8 had become even quicker, with no pausing before 5.

Hoping to encourage Katy to use more than one finger at a time, the interviewer asked whether she could make many friends at a time. But Katy responded by tapping rhythmically (with one index finger) below then above the bar, up to 98, saying "I'm doing a pattern." The interviewer repeated the invitation to use more than one finger. Katy put her right hand down (touching the screen also with her palm) and smiled. She created numbers up to 205, then sat up and made more numbers with the left hand, this time with only the fingers (not the whole hand). She switched back to her right hand, pressed Reset with her index finger and said, "I don't want no friends."

As Katy engaged with *Touch Counts* through exploration and with the interviewer, she developed several dimensions of tool fluency. Without explicit prompting, she could make numbers on the screen. This was an activity she seemed to enjoy, as she patiently counted higher and higher, repeating the numbers with the iPad. She quickly became adept at pressing the Reset button and placing numbers above the bar. She also became proficient at being able to place a given number n (a best friend) on the bar by tapping below the bar $n-1$ times and then tapping above the bar. Katy was able to articulate a strategy for deciding where to tap her finger, as evidenced in [41] "What kind of number is come after?" Instead of saying that she has objectified number, we see her actions more in terms of developing local fluency around 5 in that she forges relationship (what's before 5, what's after 5) in the neighbourhood of 5. However, it is evident in her work on trying to get just 5 and 10, that she uses the routine for placing 5 on the bar in order to predict when 10 will come.

The episode shows her ability to pick out a given number developed through perceptuomotor integration. At first, her tapping was slow and irregular, and was often accompanied by her own oral counting, and sometimes by repeating the iPad. But as she made mistakes, hearing and seeing, for example, the number 5 fall off the screen, she would reset on her own and tap anew. The tapping became quicker and more rhythmic until eventually putting 5 on the bar involved tapping her finger four times on a spot below the line and then moving to tap the 5 above the line. We notice too that Katy, despite several prompts from the interviewer, strongly preferred one-finger playing. So, despite the fact that she can “objectify” 5 and 10, we see her as an ordinal Touch Counts player—she creates numbers one at a time.

Adding world: 7 involves making more ones

The interviewer switched to the Adding world. Katy immediately put her left hand on the screen, creating a group of 4, then a group of 5, then 4, then 2. When the interviewer asked her to bring two groups together, Katy uses her right index and middle finger to gather groups of 4 and 2. But when she tried to bring other groups together, Katy inadvertently created new groups. The interviewer showed her how to gather groups with two index fingers. Katy tried this, making a group of 5. She then unintentionally creates a group of 7. The interviewer asked, “Can you make a group of seven for me?” Katy tapped with her index finger several times, then made a group of 4. She then tried gathering the groups together, but ended up creating several more groups of 1 and 2. Seeing that she was having trouble making groups, the interviewer told Katy that she could use two hands. Katy eventually makes a group of 4 (using one hand only). The interviewer asked her again “How could you make seven?”

- 71 Katy: Four and one [*pinches groups of 4 and 1 with her right hand thumb and index fingers, making a group of 5*].
- 72 I: You have 5 now and how many more do you need to put in there [*pointing to the group of 5*] to get seven?
- 73 Katy: One? [*Katy struggles to put to groups together. Gathers the group of 6 and a group of 1*].
- 74 I: Six! Oh, you are almost there, you got six.
- 75 Katy: [*Makes groups of 1 and a group of 3.*] Not three. No. You go. [*Drags 3 to the corner of the screen.*] I need you one. One? [*Holds 1 with her right hand index finger and gathers to the group of 6 using her thumb.*] Again.

When asked whether she wants to make another group of 7, Katy used her middle and index fingers and she continued to gather more 1s together to make another group of 7. The interviewer asked her to gather a group of 2 and 4 (already on the screen), but she said, “I’m going to make more ones.” She continued to work diligently until the interviewer showed her again how to use her two index fingers to gather groups. She did it herself, made several groups, and then returned to using just one hand.

In moving to the Adding world, Katy experienced difficulty in gathering groups together since her fingers would land on a blank part of the screen instead of on an existing group. At first, her gathering was haphazard, sometimes resulting in a combination of groups but most often in the creation of a new group. She more or less refused to use two hands to make the gathering easier. Nonetheless, she became fluent in gathering two groups, especially when one of the groups was a group of one. Using the strategy of successively adding groups of one, she was able to create several groups of seven. In Vergnaud's sense, Katy was evincing a sense of cardinality as she was operating with the groups, adding 1 to 1, 2, 3, 4, 5 and 6. However, at no time did Katy intentionally add anything other than a 1 to an existing group in order to produce a group of 7. Indeed, when invited to gather a group of 2 and a group of 4, Katy was insistent on "making more ones." We hypothesise that adding-on one, in *Touch Counts* at least, offers an intermediary kind of expertise for children like Katy, who are deeply oriented toward ordinality but are using an instrument that expresses cardinality.

CONCLUDING REMARKS

As we saw in the Counting World, there seems to be a close connection between Katy's preference for one-finger (or one hand) actions and her almost exclusive use of adding-on one. We are interesting in examining the correlation between this kind of one-finger interaction and students' number sense. In addition, we would like to study whether explicit instrumentation of two or more finger touching (in both the Adding and Counting Worlds) might help develop children's number sense.

Our goal in this paper has been to describe *TouchCounts* and provide a rationale for its design. In our exploratory study, we have shown that children easily and sometimes spontaneously learn to play this instrument. Further, and this is central to the motivational context of mathematical learning, as Bartolini-Bussi noted in the working group, students enjoy playing with *TouchCounts*, spending a great deal of time creating numbers, looking at them and listening to them. We further noticed that the design decision to not let users move numbers that had already been created in the Counting World occasioned didactical opportunities in that they had to start the task over again, thus gaining further number fluency.

We have also shown that there may be a strong relationship between the way children actually use their fingers in playing this instrument and the way they think about numbers—a finding that is consonant with the dialogical nature of our theoretical framework. Finally, we have shown that the tasks offered in the two worlds enabled Katy to develop a certain kind of expertise in working with cardinal numbers, which suggests ways of thinking about ordinality and cardinality that are specific to this instrument rather than technology-independent, as suggested in the literature.

THE STRUCTURES, GOALS AND PEDAGOGIES OF “VARIATION PROBLEMS” IN THE TOPIC OF ADDITION AND SUBTRACTION OF 0-9 IN CHINESE TEXTBOOK AND ITS REFERENCE BOOKS

Xuhua Sun

University of Macau, China

Different cultures with their own advantages and disadvantages are, rather than oppositional, complementary. In this paper, we attempted to articulate a Chinese “indigenous” pedagogical practice. This “indigenous” practice, “variation problems”, in the topic of addition and subtraction of 0-9 in Chinese textbook examples and their goals and pedagogies in their textbook reference books are presented. To grasp its distinctiveness, a comparison between Chinese and American textbooks is carried out. It might enable us to see which parts of the different educational systems can learn from each other.

INTRODUCTION

Different curriculum traditions are developed in different cultural communities (for a general discussion, see Xie & Carspecken, 2008). Priority of “contextualization problems” in the interest of facilitating connection situation is generally regarded as the common curricular trend in the West (Clarke, 2006). In contrast with “contextualization problems”, variation problems in the interest of facilitating connection concepts and methods play important roles in the eastern curriculum. It is generally perceived as one of the most valuable experiences within Chinese mathematics education community (e.g. Sun, 2011). From outside perspective, Marton (2011) argue that variation practice stems from the Chinese language expression. This study tries to indicate how this practice reflected Chinese own advantages and disadvantages of curriculum. It is interesting to note there is robust literature in textbook comparison in the field of math education. The main direction of textbook comparison focuses on contents and problems. For example, Fuson, Stigler & Bartsch (1988) concentrated on the grade placement of topics, content topic covered and page space of each topic. Li (2000) stressed the “problem” perspective (1) number of steps required; (2) context; (3) response type; and (4) cognitive expectation. However, there are little textbook studies reveal the textbook difference from variation perspective.

Problems with variation

There are two mainstreams of variation practice studies: one developed from the Chinese tradition as local Curriculum design model (e.g. Gu, Huang & Marton, 2004), another evolved from the European tradition, mainly from learning perspective (e.g. Marton and Booth, 1997). Following the European tradition, Watson and Mason (2005) pointed out two important parameters of mathematics structure: the dimensions of possible variation and the associated ranges of permissible change should be stressed in the use of examples. In this study, we aim to introduce European readers to

variation practice from the Chinese tradition. A number of studies (e.g. Gu, Huang, & Marton, 2004; Sun, 2007) consistently claimed that variation practice offers some advantages in Chinese mathematics education. For example, Gu, Huang, & Marton (2004) argued that, by adopting teaching with variation, even with large classes, students still could actively involve themselves in the process of learning. The “paradox of Chinese learners” might originally be a misperception by Western scholars due to the limitation of their theories. Sun (2007, 2011) presented a Chinese pedagogical phenomenon in organizing a curriculum with an emphasis on discerning relationships through variation approach and argued that there exists an “indigenous” variation practice uniquely rooted in cultural backgrounds. It has been used broadly in example or exercise design to extend the original examples, known widely in a certain way as “one problem multiple solution” (OPMS, 一題多解, varying solutions), “one problem multiple changes” (OPMC, 一題多變, varying conditions and conclusions), and “multiple problems one solution” (MPOS, 多題一解, varying presentations). This practice is typically regarded as a natural strategy to deepen the understanding in local curriculum as a daily routine, which perhaps makes the “indigenous” practice distinctive. Sun (2011) described these practices and their roles in the topic of fraction division. Reader could further wonder why Chinese textbook authors design them in this way and how to use them. In this study, we explore structures, goals, and pedagogies of problem with variation in the topics of addition and subtraction of 0-9, the most vital and central concept for later mathematic learning.

Addition and subtraction of 0-9

Addition and subtraction of 0-9 is vital and central concepts for later mathematic learning, which would influence numeracy, algorithm understanding of multi-digit addition and subtraction, of multiplication and division, of decimals, of fractions. It is central to developing number sense and is also the basis for the four fundamental operations on numbers and concepts that comprise elementary school mathematics. Not only does it connect to all important concepts, it is also a prerequisite for any real understanding of whole and rational number system”. For example, US national performance of subtracting with regrouping of 2-digit is only 28% correct in Grade 2 and their error remains extremely common until high school (Fuson & Li, 1990). Cross-cultural comparison indicated that Chinese teachers have a deeper conceptual understanding of subtraction with regrouping, a solid knowledge of abundant connections and much more flexible way to explain problems than their American colleagues (Ma, 1999). Is it related to their learning resources?

As mentioned before, it seemed that Chinese arithmetic development, textbooks, their textbook reference books, and particular variation practices, might be a good clue for understanding Chinese mathematics education system rarely known outside of Chinese community. To enable us to see which parts of the different educational systems can learn from each other, in this study, we would like to go further to explore

structures, goals and pedagogies of “variation problems” in the topic of addition and subtraction of 0-9. For comparison, a USA textbook and their according for teaching guide was chosen as a “mirror”, which reflected the curriculum constructed upon different philosophical traditions: Dewey’s instrumental pragmatism in the case of USA compared with dialectical materialism in the case of the Chinese mathematics curriculum (Xie & Carspecken, 2008). The research question of this study is restated as follows: *What are structures, goals, and pedagogies of variation problems in the topics of addition and subtraction of 0-9 in Chinese textbook and reference book?*

A Chinese textbook (Mathematics Textbook Developer Group for Elementary School, 2005) used for over 30 years by the majority of students composed of diverse backgrounds was chosen, a representation of the Chinese national curriculum by most scholars of textbook comparative study. This textbook with its textbook reference book (Elementary Mathematic Department, 2005) is an authoritative guide for all teachers on what to teach/learn and how to teach/learn as national examination problems are required to be “from textbooks, but above textbooks”. An American textbook Teacher edition (similar to Chinese guide book) (Gonsalves, Grace, Altieri, Balka, Day, 2009) identified as a widely used mathematics textbook was chosen to act as a “mirror”. Here we translated “indigenous” variation practices into codes by examining “problem set with /without concept connection” or “problem set with /without solution connection” (Sun, 2011). Note that this textbook is not claimed to be representative of all the textbooks used in USA, but we consider that reflect the typical practices in USA.

Why do we choose Chinese textbook? It is deserved to note textbooks play different roles in their system. Generally, teachers play much more central role than textbook in an education system. However, since Chinese teachers generally have limited space to re-design task due to the fact that Chinese curriculum evaluation (exam) is unified by government and curriculum content is required to follow strictly the unified standards and the unified textbooks, textbooks play much more central role than teachers in Chinese education system. Therefore, Chinese textbooks have been regarded as the most authoritative books in local culture. They have been both driven and governed by government system since Tang dynasty, different from those driven by markets in western culture. Chinese textbooks as textual art of pedagogy are required to rigorously present what teacher should teach and what a student should learn than those in other places. Therefore, they are generally designed by local experts collected in the entire county. They are expected to play multiple functions in Chinese mathematical education system, such as main media for teaching and learning in the classroom, self-learned instrument for out-of-school learners, tools of teachers’ professional development by intensively studying textbooks and its reference series (教學參考書) (e.g. Ma, 1999) as one of the important professional development notions in Chinese system. These textbooks have been played much more important roles in Chinese system than those in the west.

THE STRUCTURES, GOALS, AND PEDAGOGIES OF VARIATION PROBLEMS

The Chinese textbook includes 13 examples with problem sets of concept connection (OPMC), in total, accounting for about 87% of all 15 examples. Furthermore, the Chinese textbook includes 2 examples with problem sets of solution connection (OPMS), in total, accounting for about 13.4% of all 15 examples. None of these examples appear in the American textbook. The invariant mathematical meaning of addition and subtraction, that is, part-part-whole concept is the “core” idea highlighted in Chinese textbooks, which are not pointed out in American textbook.

The design of addition and subtraction content of 0-9 are typical, which could reflect the consistent features in other 4 chapters too. In the following, we present the structures, goals, and pedagogies of variation problem in the topics of addition and subtraction of 0-9 in Chinese textbook /reference books and American textbook of student/ teacher edition. We will begin with the structures, goals, and pedagogies of OPMC.

Structures, goals, and pedagogies of OPMC

OPMC in the topics plays two roles: providing foundation and making concept connections. In what follows, these are introduced with illustrative examples of providing foundation. It is interesting to note that addition or subtraction is not introduced directly, but its knowledge foundation as knowing number by OPMC is systematically provided. Fig. 1, 2 shows two examples introducing the quantity concept of 4, 6, 7, called cardinal number, by the problem variations with composition

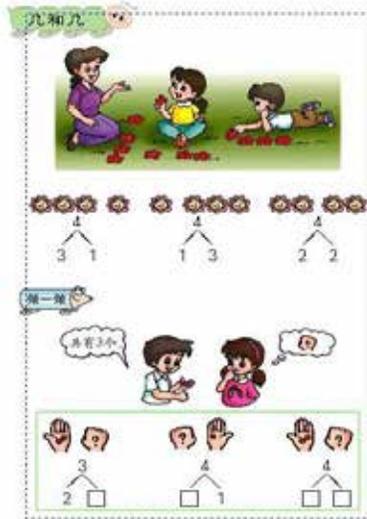

Fig. 1. The example introducing the cardinal number concept of 4 using the problem variation with composition and decomposition concept connection in the Chinese textbook (Mathematics Textbook Developer Group for Elementary School, 2005, Vol. 1, p.19)

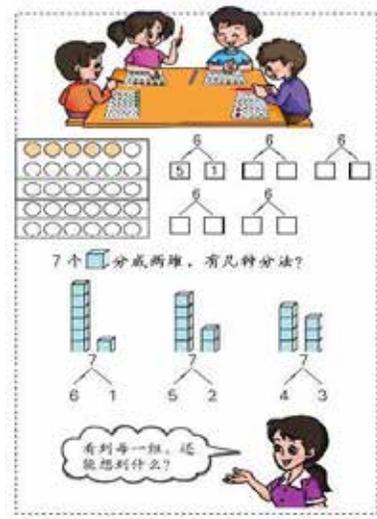

Fig. 2. The example introducing the cardinal number concept of 6,7 using the problem variation with composition and decomposition concept connection in the Chinese textbook (Mathematics Textbook Developer Group for Elementary School, 2005, Vol. 1, p.44)

and decomposition concept connection in the Chinese textbook.

It is noteworthy that the design is unique that knowing number, concept of addition, and concept of subtraction are united together in all 6 chapters and gradually expand from 0-5, 6-10, 11-20, two-digit, three-digit, above four-digit in the Chinese textbook, which is separated into 20 chapters with titles of pattern and number sense, that of addition strategy, that of subtraction strategy in the American textbook. Their design goals and pedagogies of figure 1& 2 are explained in the following in its reference book.

Knowing numbers is the premise of calculation. Conversely, calculation will help to deepen understanding of numbers. For young children, the strategy combining knowing number with basic calculations would be, not only easy for learning number concept, but also conducive to consolidate basic calculations learned inversely. (Elementary Mathematic Department, 2005, P.34)

The goal and pedagogy of figure 2 is explained in the following in Chinese reference book.

The teaching should follows the following procedure: counting → understanding of the order of number → comparison of two adjacent numbers → writing digit → order of number → composition and decomposition of number. The composition and decomposition of number is the focal point. This arrangement, on one hand, reflects the rich meaning of number concept, on the other hand, also reflects logical order of knowing number as foundation of basic calculations (Elementary Mathematic Department, 2005, 67).

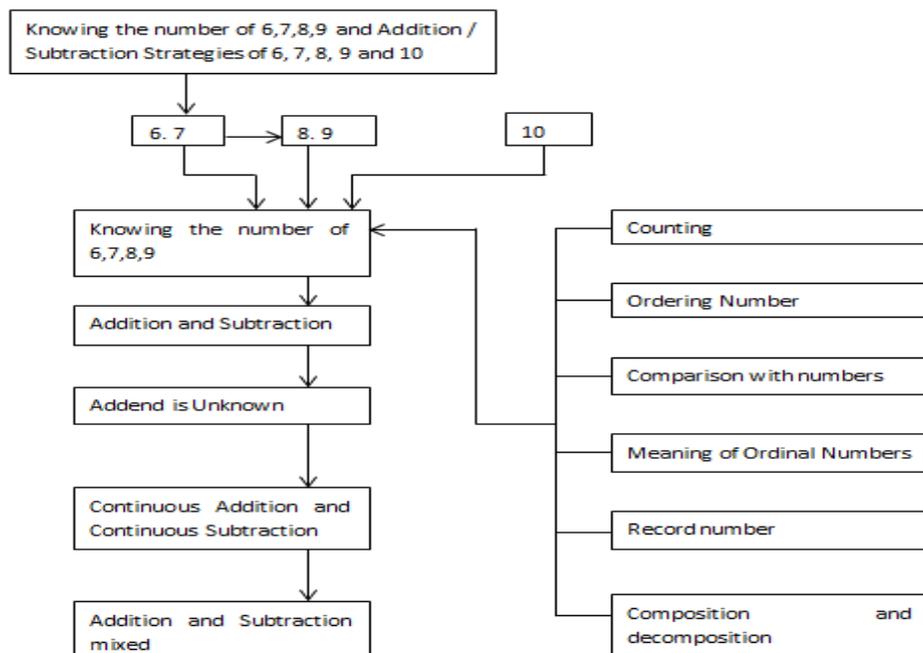

Figure 3.The concept structure of knowing number 6-10 in Chinese teaching reference book (Elementary Mathematic Department, 2005, P.35)

The design above mainly reflect Chinese curriculum tradition with focus on goals – “two bases”, namely, the curriculum foundation of addition and subtraction is “part-part-whole” (pre-algebra thinking foundation) relationship. In fact, “two bases” is regarded as the most valuable tradition in the history of Chinese curriculum reform by local experts, different from those in other counties, such as problem solving, communication, reasoning in USA. It is impressive that the concrete foundations, similar to knowledge package (Ma, 1999), in every unit clearly are presented in Chinese teacher guide book. Fig.3 is the concept structure of knowing number 6-10, the concrete curriculum foundation in a unit, in Chinese teaching reference book (Elementary Mathematic Department, 2005, P.35).

It is impressive that two concepts of addition and subtraction are always almost elicited together in term of examples of OPMC in Chinese textbook, rather than separated in the American textbook. In what follows, these are introduced with illustrative OPMC examples of making connections.

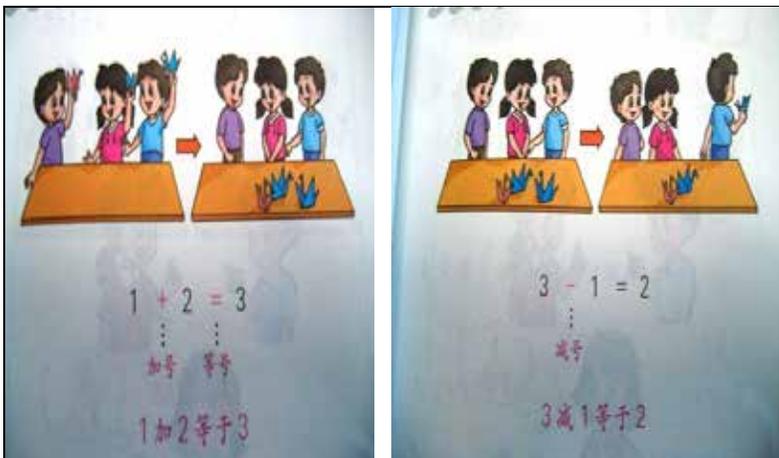

Fig. 4. The example introducing the subtraction concept using the problem variation with concept connection in the Chinese textbook (Mathematics Textbook Developer Group for Elementary School, 2005, Vol. 1, p.20-21)

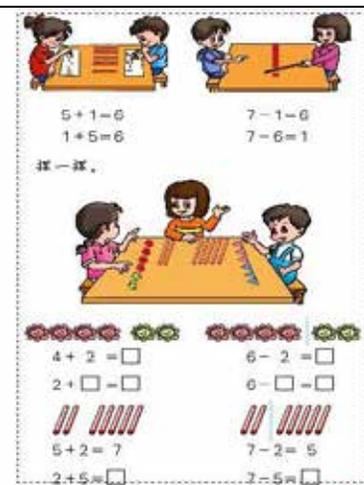

Fig. 5. The example introducing the subtraction concept using the problem variation with concept connection in the Chinese textbook (Mathematics Textbook Developer Group for Elementary School, 2005, Vol. 1, p.45)

Figure 4 shows a paradigmatic example of introducing the subtraction concept by OPMC: $1+2=3$, $3-1=2$. The problem set intends to help learners to recapitulate the relationship of addition and subtraction, and the meaning of “equal” by three figures, 1, 2, and 3, among the two problems, which may help students to focus on concept variation, rather than digital variation (general feature in the US counterpart). Figure 5 shows a typical example of introducing addition, subtraction, and exchange law of number 6 by three groups of OPMC: $5+1=6$, $1+5=6$; $4+2=6$, $2+4=6$, $6-2=4$, $6-4=2$; $5+2=7$, $2+5=7$, $7-2=5$, $7-5=2$. The three group of problem set intend to help learners to recapitulate the relationship of addition and subtraction, and the meaning of “equal”, which stress the invariant concept of part-part-whole.

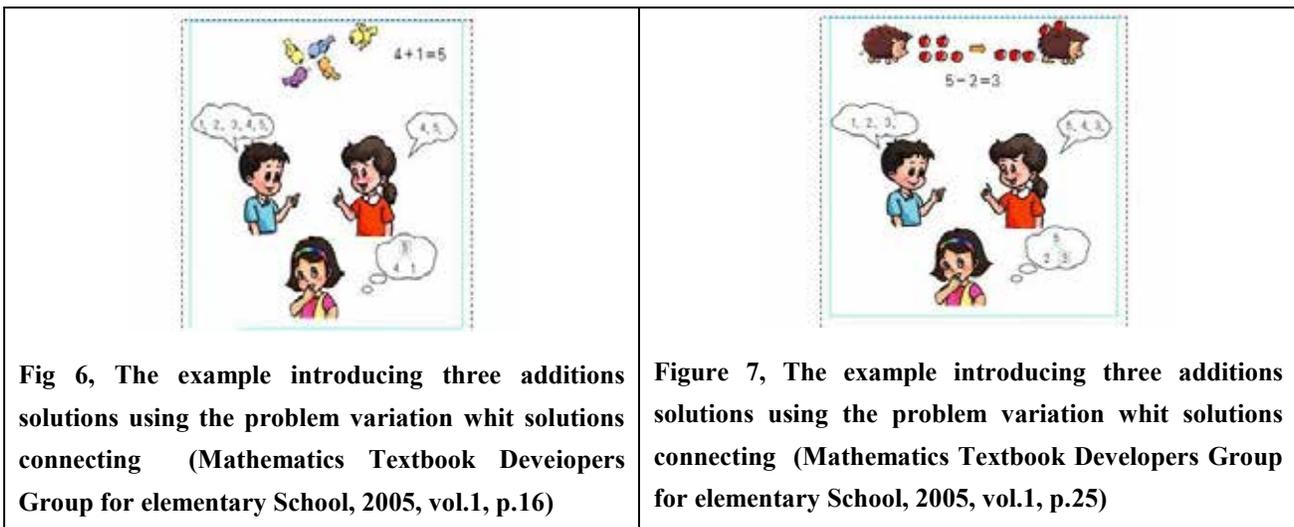

The goal and pedagogy of this design is explained below in its reference book.

The teaching idea of meaning of subtraction is same as that of addition. Textbook use the same situation to elicit subtraction which indicates the relationship that subtraction is the inverse of addition. Therefore, appropriately combining subtraction with addition in teaching will be helpful for students to grasp the relationship and difference of addition and subtraction, which will deepen the understanding of the meaning of addition and subtraction too (Elementary Mathematic Department, 2005, P.39).

Compared with Chinese design, every example in American textbook naturally introduces the concept of addition and subtraction isolated or with limited concept connection as “basic arithmetic facts” such as, “ $5+7=12$ ” or “ $12-7=5$ ”) for students simply to memorize (Ma, 1999). In the American textbook, each addition example uses multiple, different, inconsistent concepts, such as “counting”, “combining”, and “adding”. Each subtraction example uses multiple, different, inconsistent concepts, such as “taking away”, “comparing”, “cross out”, and “identifying inverse operation of addition”. The comparisons are weaker than those in Chinese textbook in each circle. The concept of part-part-whole is addressed as modelling subtraction, different from the most central status as the knowledge foundation mentioned above in Chinese textbook.

Structures, goals, and pedagogies of OPMS

It is impressive that multiple-solutions are always almost elicited together in term of examples of OPMS in Chinese textbook, rather than single solution in each example in American textbook. Figure 6 is a typical “prototype” example of OPMS in the Chinese

textbook. In the problem variation above, $4+1=5$ is designed to naturally introduce a solution system of addition. Within the problem set in the example, there are three solutions given. The first one is that of addition by counting from 1 to 5. The second solution is that of counting from the addend 4 to 5. The third is that of addition by regrouping 5 with 4 and 1. Within the problem set, three addition solutions are presented. Fig. 6 is the problem variation of OPMS above, $5-2=3$: The first solution is

that of counting what is left from 1 to 3; the second one is counting down 2 from 5 (5, 4, 3). The third is that of “separating 5 into 2 and an addend 3 as the unknown. The two group OPMS above intend to help learners to recapitulate the relationship of three solutions of addition / subtraction, and the result of “same”, which stress the invariant connection of multiple solutions .

The design goal is explained in the following in its reference book.

Algorithm diversification is one of the basic philosophies of the "new curriculum standard". It states that: "it is natural students use divertive methods because of different living backgrounds and from different perspectives; teachers should respect their thoughts, to encourage them to think independently, to advocate the diversification. (Elementary Mathematic Department, 2005, P.34)

The design pedagogy is explained as follows in Chinese reference book.

After students' presentation of multiple solutions, teachers may prompt a discussion on which solution is the simplest one, which help them realize the decomposing-solution is simpler than others. Teacher should guide student from the solution of low level to that of high level. (Elementary Mathematic Department, 2005, P.44)

Compared with Chinese multiple-solution feature, examples in American textbook always elicit the single solution with limited solution connection. It is deserved to note each example in American textbook use many “inconsistent” solutions, such as “*use number line to add*”; “*doubles*” ($3 + 3 = 6$, $5 + 5 = 10$), “*doubles plus 1*” ($8 + 9 = 8 + 8 + 1 = 17$), “*compensation*” ($6 + 8 = 7 + 7 = 14$), and “*reference number*” ($6 + 7 = 5 + 1 + 5 + 2 = 10 + 3 = 13$, *5 as reference number*) for addition strategy , such as “*counting back*”, “*use of fact families for addition and subtraction*”, and “*doubles*”, “*use number line to subtract*” for subtraction strategy emphasizing the importance of applying influenced by Dewey’s instrumental pragmatism philosophy (Xie & Carspecken, 2008). Although Chinese textbook authors use multiple solutions, double-number –solution, using-number line-to add, and count-back-solution are not introduced. Only one invariant, “consistent” solution of “decomposing/composing–number-solution” (developed making-a-ten-solution latter) is addressed by OPMS in all the addition /subtraction examples in the chapter, also other chapters with a focus emphasizing the importance of analytical and neopragmatism (Xie & Carspecken, 2008).

DISCUSSION

Many readers may argue that the variation approach may be confusing and that a sequential organization with time gaps (“one-thing-at-the-time”) should be preferred. In fact, variation approach might come from different kinds of pedagogical traditions and philosophies developed for centuries. The issue of variations in problem sets directly reflects the old Chinese proverb, “no clarification , no comparison” (沒有比較就沒有鑒別), rather than “to consolidate one topic, or skill, before moving on to another,”

a notion broadly used in most textbook development (Rowland, 2008) in Europe and throughout the world. It coincidentally emanates from the work of Marton, “variation is a necessary condition for effective discernment” as the soul of variation theory. In contrast, this “one-thing-at-the-time” design would clearly provide fewer opportunities for “making connections” compared to those of contemporaneous variation approaches. The “one-thing-at-the-time” design might possibly reflect a hidden conception, making a connection could naturally happen. In this context, the curriculum role of making connections could either be relatively neglected or taken for granted. It is deserved to note, OPMC and OPMS aim to provide opportunities for making connections and further discern, compare the invariant feature of the relationship among concepts and solutions, since comparison is considered the pre-condition to perceive the structures and relationships that may lead to mathematical abstraction. The invariant is repeatedly highlighted by the design as central idea to design Chinese textbook. Conversely, the invariant concept /solution are not stressed after multiple concepts/solutions are presented in USA textbook, which possibly link to fragmentation understanding pointed out by (Ma, 1999).

This study provides the structures, goals, and pedagogies of variation problems, compared with the American system, in the topics of addition and subtraction of 0-9 in Chinese textbook and its reference book, which is consistent with the findings on fragmentation in US textbooks and connectedness in Chinese textbooks (Ma, 1999). The comparisons above inspire us to develop much more coherence curriculum by addressing knowledge foundation, concept connections, highlight the invariant concepts and solutions in Chinese mathematics education system. Variation approaches may be critical in developing concept-connection curriculum and instruction rarely figured out before. The priority of “contextualization” in the interest of facilitating engagement, motivation, and meaningfulness is regarded as the common curricular trend in the West (Clarke, 2006). In this light, variation problems suggest a way in which way western counterparts could learn from content-orientation curricula in China. Clearly, variation problems are two-edged sword which could lead to more learning challenges compared to “contextualization” problems because they require the use of multiple concepts and solutions targeted. This study inspires us that textbook comparison with their goals (why textbooks are designed in this way) and pedagogies (how textbooks are used) in their textbook reference books would provide a much more *integrated* window for understand curriculum than textbook series alone in the field of textbook comparison (e.g. Fuson & Li, 2009).

HOW FAMILIES SUPPORT THE LEARNING OF EARLY YEARS MATHEMATICS

Kerstin Tiedemann

Universität Siegen, Germany

This paper is based on the assumption that parents are of prime importance for their children's mathematical development. It gives account of a study that focuses on the question of how families support the learning of early years mathematics. Thereby, everyday playing and reading sessions with pre-schoolers and their mothers are the context of investigation. By means of three very short transcripts from these sessions, different kinds of support systems will be reconstructed. In particular, the research question is about the aim of the support system: What is the support system focused on? The related analyses show the diversity in young children's mathematical experiences.

INTRODUCTION

Although the discussion about early years mathematics is often confined to institutional contexts a holistic perspective challenges us to keep not-institutional contexts in mind, too. When thinking about early learning processes, the family is one of the most important places to be recognized. For the young children spend much of their time with their parents, observe them and become step by step a member of their culture (Warren & Young 2002). As a consequence, the young learners become amongst other things a part of their parents' mathematical culture as well. For this reason, the family cannot be ignored as a context of particular importance for questions about early years mathematics.

This opinion is confirmed again by Street, Baker and Tomlin (2005) who conducted a large study in Great Britain about home and school numeracy practices. One of their central results is that learning difficulties might arise from differences between home and school discourses. The researchers explain that for some children there is a gulf between these contexts: "The school replicates the Primary Discourse of middle class homes whilst it presents children from other backgrounds with a Secondary Discourse." (Street et al. 2005, p. 7) According to the authors, many children are restricted in their prospects to succeed in mathematics education because they are confronted with a problem of discourse: The switch between home and school discourses can be difficult because of different values, rules and patterns (ibid., p. 44ff. and 70ff.). This result exemplifies why research about families is also important with regard to institutional contexts. Everyone who wants to teach children mathematics has to know about their earlier ways of learning mathematics to avoid difficulties:

“If children are frequently presented with tasks which are unconnected with their earlier ways of knowing about mathematics, they may come to reject it and to begin to feel that they are failing.” (Pound 2006, p. 20)

In summary, it can be said that the families’ support of learning (early years) mathematics is of prime importance for the children’s development. While we already know something about *what* children learn in the familial context (Blevins-Knabe 2008, S. 2; Blevins-Knabe et al. 2000, S. 50; Anderson 1997, S. 492), we know only a little about *how* they learn it.

“Studies of the processes by which parents encourage early numerical development in the context of parent-child interactions during routine, culturally relevant activities at home are scarce.” (Vandermaas-Peeler, Nelson, Bumpass & Sassine 2009, P. 67)

For this reason, in my research, I focus on the question of how families support the learning of early years mathematics. With this question in mind, I observed mother-child-dyads in game playing and reading sessions at their homes for a number of times in the course of a year.

THEORETICAL FRAMEWORK

In studying early years mathematics, we necessarily do it with a certain conception of what learning mathematics is all about. In my opinion, children do not encounter mathematics itself, but a cultural practice that is recognised as mathematical by capable members of the belonging culture (see Sfard 2006). In other words, I regard mathematics as a social construction and learning mathematics as a social construction too. This idea of learning is explicitly described in Sfard’s theoretical work. She defines learning mathematics as “individualizing mathematical discourse, that is, as the process of becoming able to have mathematical communication not only with others, but also with oneself.” (Sfard 2006, p. 162) Against this background, supporting the learning of early years mathematics means to help young children becoming fluent in a mathematical discourse.

Concerning the support, I draw on the notion of support as it was developed by Bruner (1983) and Rogoff (1990). Bruner worked on the question of language acquisition in the very early years of a child’s life which was for him mainly a question of culture acquisition. Assuming that a child primarily has a need for social contact, Bruner supposed that he has to learn his mother tongue in order to become a part of the given culture and, in this way, to relate to people around, first of all to his mother. In this context, Bruner postulates the existence of a so-called *Language Acquisition Support System* (LASS). This support system is established by a child and his mother and is realised in the form of ‘formats’. Here, a format is “a standardized, initially microcosmic pattern between an adult and an infant that contains demarcated roles that eventually becomes reversible” (Bruner 1983, p.120). The adult-child-dyad creates “a predictable format of interaction that can serve as a microcosm for communicating and for constituting a shared reality” (ibid., p. 14).

Bruner sees this kind of interactional and recurrent support as a condition for the child's learning. Being part of the LASS, the child becomes part of the adult's culture and, in doing it, he learns his mother tongue. According to Bruner, an increasing autonomy within the support system can be understood as an indicator for learning progress. From my point of view, the important aspect of Bruner's concept is to understand support as a support system, that means as something that is established by at least two persons. Therefore, support is not any longer an individual achievement of the mother but a certain kind of format that is established by the interlocutors. The child reacts on what the mother does and vice versa. In this way, a mother-child-dyad creates a support system that helps the child to become part of the given culture. Transferring this notion of a support system to the field of mathematics education, I assume that families establish a support system for mathematical learning processes by means of their everyday discourses. In dependence on the LASS-concept, I refer to it as a *Mathematics Acquisition Support System* (MASS).

It was Rogoff (1990, 1989) who pushed the interactional equality of adults and children even more to the spotlight than Bruner did:

“The mutual roles played by children and their caregivers rely both upon the interest of the caregivers in fostering mature roles and skills and on children's own eagerness to participate in adult activities and to push their development.” (Rogoff 1989, p. 209)

Rogoff (1990) calls the process of becoming a competent participant in a specific type of discourse ‘appropriation’. In that way, she emphasizes that learning and support of learning take place within social activities and are something different than a cognitive individual performance. In the process of appropriation, children “can carry over to future occasions their earlier participation in social activity.” (Rogoff 1989, p. 213). In regard to a MASS, this means that the child supports his learning as much as the mother does. Support systems are projects of cooperation. By the way, this is the reason why the title of this paper is “How families support...” and not “How parents support...” The children themselves should be included in the group of persons who support the learning of early years mathematics. Against this background, I understand a MASS as a condition for processes of appropriation.

One could think of many investigations concerning this MASS. In this paper, the function of the MASS is investigated as it is realised in mother-child-discourses in everyday playing and reading sessions: What is ensured by the MASS? What is the MASS focused on? In order to clarify the theoretical perspective for this specific research question, I refer to a study conducted by two German linguists: Hausendorf and Quasthoff (2005) reconstruct how children's competences in telling a story as part of a conversation develop in the course of time. At the same time, the researchers investigate how this development is influenced by an emerging support system. In terms of this object of research, the authors follow Bruner (1983) and his idea of a LASS. For this reason, they describe the support processes as a *Discourse*

Acquisition Support System (DASS). Although I neglect their specific linguistic findings, in my opinion, one special theoretical element that they developed is really helpful to my concern. Hausendorf and Quasthoff talk about so-called ‘jobs’ in order to describe empirical phenomena. Here, ‘job’ is a structural task that has to be mastered when a story should be told as part of a conversation (ibid., p. 124). ‘Picking something out as central theme’, ‘closing’ and ‘leading back to the conversation’ exemplify jobs that the linguists have found in their data. These jobs are established interactionally and are mastered by the discourse partners jointly (ibid., p.122f.). What the child is not yet able to do, is done by its adult interlocutor. So these jobs are determined by their function (ibid., p.125). They are characterized by their contribution to the story as a whole. This functional orientation makes the idea of a job suitable for my aim. But when I intend to explore the function of a MASS I cannot really talk about structural jobs as Hausendorf and Quasthoff do. For that reason, I use their further theoretical results, too. The linguists connect the jobs that are structural in nature to a higher aim. Namely, they state that the aim of all jobs is to complete the story and that is what is ensured by the DASS (ibid., p. 294). That means the support system guarantees nothing but the completion of the story. On this level, I can refer to that linguistic work. So one can say that there is a kind of higher job by which all the structural jobs are directed. And this higher job is what I intend to reconstruct as the focus of support systems in mathematical discourses. I call it a *support job*. This is the task that is mastered by means of the support system. Just like the structural jobs, these support jobs should be determined by their function: What is ensured by working on a certain support job? This approach to mathematical discourses allows for a functional investigation of the MASS in families.

Against this background, it is important to notice that Hausendorf and Quasthoff could find only one support job in their data. Namely, they reconstruct that the DASS is always focused on the completion of the story (ibid., p. 294). To be a little bit more abstract, one can say that the support job they found is to ensure the child’s participation. The child should tell a story and master the jobs as good as possible. Only when the child is not yet able to cope with a certain job the adult performs it instead.

METHODOLOGY AND RESEARCH METHODS

The data

Over one year, I met ten German families at their homes on a regular basis. In all cases, it was a mother-child-dyad that took part in the project. The year of the regular meetings was in each case the child’s last year before entering primary school. When meeting the families, I invited them to engage in games and picture books that I had brought with me. The families received no further instruction for dealing with the material or for their discourses in general. All the playing and reading sessions were filmed so that a considerable data corpus came out of that. But only those scenes that

showed a somehow mathematical topic came into consideration as a possible object of analysis.

The analysis

On the basis of my theoretical framework, I consider a MASS – and with it the support job – as a phenomenon that emerges in the interaction between a child and its mother. For this reason, my analyses are of a reconstructive manner. They are analyses of interaction (see Cobb & Bauersfeld 1995). This method refers to the interactional theory of learning, is based on the ethnomethodological conversation analysis (see Sacks 1998) and was devised by a working group directed by Bauersfeld. In contrast to the conversation analysis, it is aimed at the reconstruction of thematic developments in face-to-face interactions. For this reason, it is especially suitable for the field of mathematics education where the researcher is always interested in the content of a discourse, too. In a second step, the results of the analyses of interaction can easily be interpreted with a special focus on support systems and their inherent support jobs.

INSIGHT INTO THE RESULTS

In the following, I deliver insight into the results of my work by means of very short examples. They give an impression of the data and exemplify the three support jobs that I could reconstruct in mathematical mother-child-discourses. The scenes were chosen with the objective of showing substantially different support jobs. Later on, I will assume that the three support-jobs that are illustrated in the following are the only ones to be found. If this assumption is correct, there will be no support job that cannot be described with the given terms.

The support job “participation”

The first scene is with Paco (5 years 4 months) and his mother, Mrs. Czipin. The two are playing a game called “Max Mümmelmann” which is about rabbit families. The belonging board has the form of a regular octagon with one point on each side. Besides each of these points, one puts a deck of hidden cards. When it is your turn you roll the dice, move the counter which is a wooden rabbit and the counter for all players and draw a card from the hidden deck beside the counter. The cards show rabbits that are characterized by numbers from one up to six. On each card, the number is represented in two ways: First, you can see the digit on the card; second, the rabbit has as many dots on its coat as the number indicates. The six different rabbits are introduced as family members. So, the rabbit children have the numbers from one to four, number five is the rabbit mother and number six, finally, is the rabbit father. Below, each card is named by means of the number on it: A ‘2-card’ is a card that has the digit ‘2’ on it and shows a rabbit with two dots on its coat. To win the game, you have to be the first who completes a whole rabbit family: 1, 2, 3, 4, 5, 6. In the following scene, Paco has already three rabbit cards: 3, 6, 2. They are laying

in front of him in exactly this order. Now, it is Paco's turn. He rolls the dice and moves the counter [1].

Paco: *(draws a 2-card, moves his 3-card a little bit to the left and puts the drawn 2-card right beside it:)* 3,2,6,2

Mother: Do you have that already or not?

Paco: No. [...]

Mother: Not the colour, you have to watch the numbers.

Paco: *(looking at his mother:)* I have the five. *(pointing at the drawn 2-card:)* But this is the two, you see.

Mother: *(pointing at Paco's 2-card:)* You already have a two.

Paco: *(first looking at his cards, then at his mother:)* Which one do I have to put back?

Mother: One of the two. Each number only once.

In this short scene, Paco performs his fourth move. He rolls the dice, moves the counter and then draws a card from the right deck. As he draws another 2-card, he has to put it back. Nevertheless, Paco integrates the drawn card into his row of cards without being irritated. In a first step, his mother advises him of the rule: For deciding whether one still needs a drawn card or not, only the number is relevant, but not the colour of the rabbit. By giving him this hint, the mother supports Paco in performing his move. The only important question seems to be how Paco can participate successfully in the game. But Paco insists upon his opinion: He is convinced that he still needs the drawn 2-card. In answer to that, the mother refers directly to Paco's fault. She points at his first 2-card and, thereby, she makes clear that he has not noticed the first 2-card in his row, which is not under the rules. Thereupon, Paco obviously realizes that he has to put one of the 2-cards back. So one can say that the support job that Paco and his mother work on is focused on the game itself. The established support system ensures that Paco can participate in the game as a player who is as independent as possible. That way, the game can go on smoothly. As Paco's participation is the central purpose of the MASS, I named this specific support job as "participation".

The support job "improvement"

The second example, which should be discussed in this context, is a short scene with Alina (6 years 1 month) and her mother, Mrs. Gerlach. It is interesting because their MASS is determined by a substantially different support job. Just like Paco and his mother in the example above, the two are playing the game "Max Mümmelmann". It is the mother's second move. She rolls the dice and moves the counter.

Mother: *(drawing a 2-card:)* Now, I may draw a card. Look here. *(showing the drawn card to Alina:)* I have a...

Alina: A mother?

Mother: No. (*pointing at the digit on the card:*) Do you know this one?

Alina: It's a...

Mother: A?

Alina: **Two.**

Mother: A two. Right. (*still showing her card to Alina:*) And how many dots does my rabbit have?

In this second scene, the mother performs her second move. She rolls the dice, moves the counter and, finally, draws a card that she does not have yet. In this special move, Alina is integrated. She is asked to name the digit on the mother's card. This claim persists until Alina can meet it. Although she suggests a familial framework of reference ("A mother?"), which is actually suitable as well, the mother obviously insists on a mathematical one. Not until Alina refers to the relevant card as a two, her mother agrees. With regard to the topic one can say that knowing the number words might be helpful to talk about specific cards or moves, but it is not essential. It is even isolated from the concrete issue of the mother's move. When comparing this short scene with the one before, we can see that the established MASS is no longer focused on the child's participation. Instead, Alina is part of a move that is not hers. She has to use number words in order to name a given digit. More generally, we can say that Alina is asked to practice on her mathematical skills. So the support job that the two work on is to improve Alina's mathematical skills. Therefore, I named the support job exemplified by this second scene as "improvement". As the mother's final question indicates, the support system will continue to be focused on Alina's improvement. Next, she is asked to determine the number of dots on the rabbit's coat.

The support job "exploration"

The last example is a short scene with Tonio (5 years 7 months) and his mother, Mrs. Liermann. Just like the two mother-child-dyads before this dyad is playing the game "Max Mümmelmann". In particular, they are talking about one special card in the game. It is the card with the rabbit called Max Mümmelmann on it. When you draw this "Max Mümmelmann"-card (shortcut: MM-card), you may take a card of your choice from somebody else. In the following scene, which shows a third support job, Tonio creates an imaginary example in which the drawing of the MM-card leads to the victory. It is Mrs. Liermann's turn. She has rolled the dice, moved the counter and drawn a card. As she has rolled a six, she may now perform another move.

Tonio: Look here. (*showing one finger for each number word:*) If you have a one, a two, a three... and a six...

Mother: (*nodding:*) Yes.

- Tonio: Then, you can... And if the other one has the five, you can simply take his five.
- Mother: Right.
- Tonio: Then, you have already won.
- Mother: But, in this case, you still need another number.
- Tonio: (*shaking his head:*) Which one?
- Mother: The four. Or did you mention it?

In this scene, Tonio develops an example of a situation in which the drawing of the MM-card means winning the game. He thinks of someone who has already the cards with the numbers one, two, three and six. According to Tonio, this person is the winner of the game when he draws the MM-card and can take the five from another player. The mother considers that this devised person might still need the four, too. However, she thinks it is possible that her son already mentioned the four. After this scene, the two will work on that example so that Tonio is finally able to display it in a correct and complete version. The short transcript shows that the emerging support system is not really connected to someone's move. Instead, Tonio starts exploring the situation and his mother takes part in that exploration. They come up with a situation that helps understanding the concrete meaning of the MM-card. In that process, they talk about ideas, suggestions and better possibilities. Thereby, Tonio is a kind of director. He decides on the topic, on the development of the discourse and on its end. So the MASS that this mother-child-dyad establishes ensures primarily that Tonio has enough room for his free exploration. His mother helps him when he asks for help but she allows him to decide on the course of the situation. Mathematical aspects get only relevant when they are helpful for Tonio to make progress with his exploration. In view of this central focus, I named the third support job as "exploration".

SUMMARY AND CONCLUSIONS

First of all, the examples give an impression of the fundamental differences in familial Mathematics Acquisition Support Systems (MASS). In this context, the function of a specific MASS was the matter of interest. For that reason, I reconstructed so-called support-jobs. To distinguish the three support jobs that I could find it might be helpful to see them in connection with their situational context. In the first scene, the support system is established while the child is performing its move. Thereby, the MASS enables the child to overcome some difficulties in its participation. So, the support job the mother-child-dyad works on is the child's **participation** in a smoothly running situation. In the second scene, however, the support system is established while the mother is performing her move. In this context, the demand on the child does not really follow from the game itself.

It is rather initiated by the mother. She uses the playing situation as an opportunity to work on the child's mathematical skills. In this regard, she sets a problem and evaluates the child's solution. So the support job is focused on the child's **improvement**. It is important to note that this does not mean that the child's skills really do improve. But you can see that the support system is focused on it. In the third scene, the support system is not linked to someone's move at all. The child engages in an exploration of the game which is rarely restricted in terms of time or method. The child is free to explore its ideas, questions and interests and it is the support system that ensures that there is enough room for that purpose and help if necessary. So, the support job is focused on the child's **exploration**.

When comparing the three support jobs, one can notice the following: The support job "improvement" serves the mother's idea of the situation. She interprets the playing situation as suitable for working on her daughter's mathematical skills and insists on this view. By contrast, the support job "exploration" serves the child's idea of the situation. In the context of playing, he develops a plan of a free exploration and carries it out. And, finally, the support job "participation" points to the idea of the material. Both the mother and her child are working on realising a smoothly on-going playing situation. The mother, the child and the material – one can hardly think of another factor that the support job could refer to. For that reason, one might at least be doubtful of further support jobs to be found.

By means of further analyses, I found out that the families can be characterized by a certain support job. Comparisons over time and also over different materials showed that each family steadily establishes a certain kind of support job. In other words, the support job does neither depend on the point of time nor on the material (games and picture books). When relating these results to those from Hausendorf and Quasthoff (2005), one can see that *Mathematical Acquisition Support Systems* are not fixed to a certain support job. Instead, they vary in terms of their focus.

This variety of MASS in the familial context is a challenge for every institutional context in which children should learn mathematics. The young learners have different experiences in terms of content, discourse practices and support systems. When Paco, Alina and Tonio attend elementary or primary school they need a teacher who is able to cope with their diversity.

TWO CHILDREN, THREE TASKS, ONE SET OF FIGURES: HIGHLIGHTING DIFFERENT ELEMENTS OF CHILDREN'S GEOMETRIC KNOWLEDGE¹

Michal Tabach, Dina Tirosh, Pessia Tsamir, Esther Levenson, Ruthi Barkai

Tel Aviv University

This paper presents three different geometrical tasks which involved the same set of geometrical figures. An analysis of the affordances and constraints of each task is discussed along with the results of two children's engagement with these tasks. Results indicated that not all children take advantage of the opportunities afforded by a given task and thus a combination of tasks is necessary in order to assess both strengths and weaknesses of children's geometric knowledge.

INTRODUCTION

During the preschool years, children are developing and refining their spatial and geometric thinking (Clements, Swaminathan, Hannibal, & Sarama, 1999). Promoting geometric concepts and reasoning is also considered an important aim of several preschool programs (e.g. NCTM, 2006). Whether engaging in free play in a geometrically enriched environment or whether engaging in teacher-directed tasks, how can we know if and what children have learned from these activities? How can we know if we have achieved our goals? Ginsburg and Golbeck (2004) claimed that employing standardized procedures for measuring young children's learning is not appropriate. They note that many children are uncomfortable in or may be unfamiliar with the testing situation, and may display variable interest in the task. Instead, they suggested testing methods which might include clinical interviews and observations, methods that are "designed to be sensitive to the needs and peculiarities of young children" (p. 194). Yet, even when employing interviews and observations, children's competence may be linked to the specific nature of the tasks. What knowledge comes to the fore as children engage in different tasks?

In this article, we describe a study which aimed to investigate how different aspects of kindergarten children's geometric knowledge may become evident as they engage in different geometrical tasks. Using the context of two-dimensional figures, kindergarten children were presented with three different tasks. Two of the tasks employed the same set of geometrical figures, which was a subset of the figures employed in the third task. Keeping this in mind, we ask the following questions: (1) What elements of geometric knowledge are revealed by each task? Will the same elements come to fore in each task or will different elements be revealed in different tasks? (2) Will children display the same level of geometric reasoning (i.e. according to van Hiele) in different tasks or will different levels of reasoning be employed in

¹ This research was supported by THE ISRAEL SCIENCE FOUNDATION (grant No. 654/10).

different tasks? This paper presents in depth results of two children who took part in this study.

YOUNG CHILDREN'S GEOMETRICAL REASONING

Much of young children's knowledge, including their geometrical knowledge, is based on their perceptions of their surroundings. Later on, examples serve as a basis for both perceptible and non-perceptible attributes, ultimately leading to a concept based on its defining features. Such a process was described by Vinner and Hershkowitz (1980) who introduced the terms concept image and concept definition in reference to geometrical concepts. Visual representations, impressions, and experiences make up the initial concept image. Formal mathematical definitions are usually added at a later stage. Fischbein (1993) considered the figural concepts an especially interesting situation where intuitive and formal aspects interact. The image of the figure may promote an immediate intuitive response not necessarily based on logical and deductive reasoning. "Sometimes, the intuitive background manipulates and hinders the formal interpretation" (Fischbein, 1993, p. 14).

With regard to geometrical reasoning, van Hiele (1958) theorized that students' geometrical thinking progresses through a hierarchy of five levels, eventually leading up to formal deductive reasoning. At the most basic level, students' use visual reasoning, taking in the whole shape without considering that the shape is made up of separate components. Students at this level can name shapes and distinguish between similar looking shapes. Regarding naming, Markman (1989) proposed that when children hear a new name for an object, they assume it refers to the object in its entirety and not to its parts. In addition, children assume a given object will have one and only one name.

At the second van Hiele level students begin to notice the different attributes of different shapes but the attributes are not perceived as being related. Attributes may be critical or non-critical (Hershkowitz, 1989). In mathematics, critical attributes stem from the concept definition. Definitions are apt to contain only necessary and sufficient conditions required to identify an example of the concept. Other properties may be reasoned out from the definition. Burger and Shaughnessy (1986) claimed that an individual's reference to non-critical attributes has an element of visual reasoning. Thus, they further claimed that a child using this reasoning may either be at van Hiele level one or at van Hiele level two, as he is pointing to a specific attribute, and not judging the figure as a whole.

At the third van Hiele level, relationships between attributes are perceived and definitions are meaningful. If the student points out that a figure is a quadrilateral because it has four sides and therefore it also has four angles and vertices, then that child may be operating at the third van Hiele level. Finally, we note that research has suggested that the van Hiele levels may not be discrete and that a child may display different levels of thinking for different contexts or different tasks (Burger & Shaughnessy, 1986).

METHODOLOGY

Participants

The two children reported on in this paper were both scheduled to enter first grade during the following school year. They learned in two different classes, but both classes participated in our program *Starting Right: Mathematics in Preschools*. This program integrated professional development for teachers with onsite guidance by a program staff member (Tsamir, Tirosh, Tabach, & Levenson, 2010). Throughout the year, teachers engaged students with various geometric activities to promote their knowledge of triangles, non-rectangular quadrilaterals, pentagons, hexagons, and circles. At the time of the study, children were expected to be familiar with the names of these shapes as well as with the mathematical language used to describe these shapes (e.g., vertices, straight and curved lines, open and closed shapes).

The set of figures

The set of two-dimensional figures which served as the context for this investigation included intuitive and non-intuitive examples and nonexamples of each of the shapes mentioned above. Figure 1 illustrates with triangles how figures may be grouped along two dimensions: a mathematical dimension and a psycho-didactical dimension.

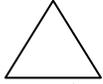

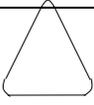

Dimensions	Psycho-didactical				
Mathematical	Intuitive	Non-intuitive			
Examples	 Prototypical triangle	 Right triangle	 Narrow scalene triangle		
Non-examples	 Circle	"Triangle" with curved side 	Elongated pentagon 	Open "triangle" 	 Rounded "triangle"

Figure 1: Intuitive and non-intuitive triangles and non-triangles

Regarding the examples, the equilateral triangle, and possibly also the isosceles triangle, are considered prototypical of all triangles (Hershkowitz, 1989). Shaughnessy and Burger (1985) showed that triangles which are rotated, triangles without one side horizontal to the page, and very narrow scalene triangles are often not identified as triangles. These may be considered non-intuitive examples.

Regarding nonexamples, because the circle is intuitively recognized as such by even young children (Clements, Swaminathan, Hannibal, & Sarama, 1999) it may be

considered an intuitive nonexample for a triangle. This reasoning holds true for other geometrical figures which the child can identify and name. Other easily identifiable nonexamples are those which are visually far removed from the prototypical triangle. On the other hand, nonexamples which are visually similar to the prototypical triangle may be considered non-intuitive nonexamples of that shape (Tsamir, Tirosh, & Levenson, 2008). Among this group of nonexamples, we specifically chose figures such that each nonexample would violate a different critical attribute. This allowed us to investigate the child's knowledge of each critical attribute separately. For example, in Figure 1, the rounded "triangle" is missing vertices, the "clown hat" has a curved side, the open "triangle" is not closed, and the stretched pentagon has five, instead of three, sides and vertices.

Examples and nonexamples for each of the other shapes were chosen in a similar manner, taking into consideration the necessity to limit the amount of figures presented at once to the children. The entire set of figures is presented in Figure 2 in the exact manner in which they were presented to the children for two of the tasks. The regular octagon, a shape that was not specifically taught to the children previously, was chosen as a non-intuitive nonexample for a hexagon, in order to investigate if the children would discern between shapes that had many sides, if they would actually count the sides, and not just group them together indiscriminately. It was also thought to possibly be a non-intuitive nonexample for a circle, especially the smaller octagon which was visually similar to a circle. In addition, we included a concave quadrilateral, pentagon, and hexagon as non-intuitive examples of each respective shape. The concave quadrilateral was drawn visually similar to a triangle and thus was considered to be a non-intuitive nonexample for a triangle.

Figure 2: The entire set of figures.

The tasks

The tasks were presented to the children in the order presented below. Task two was implemented immediately following task one on the same day. Due to the age of the children, their ability to sit and concentrate, and other time constraints, the last activity was implemented a week later.

Task one: Free-sort. All 22 cards were placed on the table in front of the child as in Figure 2. The interviewer said, "There are lots of shapes on the table. I would like you to sort them. However you like. You decide which cards go together. You can put as many cards as you want together in the same group." As the child began working on the task, moving the cards around and grouping different cards together, the interviewer asked, "Why did you put those cards together?" The interviewer also reminded the child that he or she could make changes along the way, take away a card from one group and place it with another group and that a group may contain just one card if needed. When the child seemed to be finished, the interviewer asked, "Are you satisfied? Would you like to change anything?" When the child indicated that the sorting was done, the task was considered completed. This task was completely open-ended and had not been implemented with the children in their kindergarten class.

Task two: All-at-once. All 22 cards were placed on the table in front of the child as in Figure 2. The interviewer asked, "Is there a triangle here?" If the child answered yes, then the interviewer asked the child to point to the appropriate card without moving it. The interviewer then asked, "Is there another triangle here?" And again, the child was asked to point to it. This continued until the child indicated that there were no more triangles. The interviewer then asked the same set of questions with the same procedure for the quadrilateral, pentagon, hexagon, and circle in that order. This task was a completely closed task that was somewhat familiar to the children in the sense that they had practice identifying figures but had no experience dealing with 22 figures at once that could not be manipulated.

Task three: One-shape-at-a-time. This task differed from the previous two tasks in that the child considered one shape at a time. The interview began by considering only triangles. The interviewer held in her hand the cards with the figures shown above in Figure 1. The cards were presented one at a time and each child was asked: Is this a triangle? Why? The child was allowed to take hold of the card, rotate it, and take his time to consider the one figure. After the child answered, the interviewer took back the card and placed another on the table. The same questions were repeated for each card.

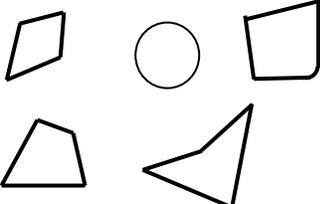

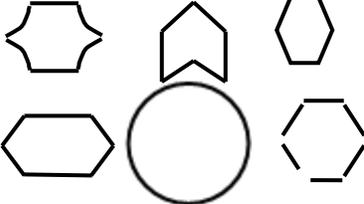

Is this a quadrilateral?	Is this a pentagon?	Is this a hexagon?
		

Figure 3: Is this a...?

When this set of cards was completed, the interviewer went on to quadrilaterals, pentagons, and hexagons using the figures in Figure 3. The same set of questions was

repeated each time. This task was familiar to the children in that they had much practice in identifying one figure at a time and explaining their reasoning.

RESULTS

Johnny

On the *Free-sort task*, Johnny built the groups shown in Figure 4. In his words, there was a group of circles, triangles, quadrilaterals, pentagons, hexagons, not triangles (there are two groups of not triangles), not quadrilaterals, not pentagons, not hexagons, and one group for which he has no name. In general, it seems that Johnny sorts the figures according to geometrical shapes naming the figures as he goes along. At no time during this activity did he mention explicitly any critical or non-critical attributes of the figures presented.

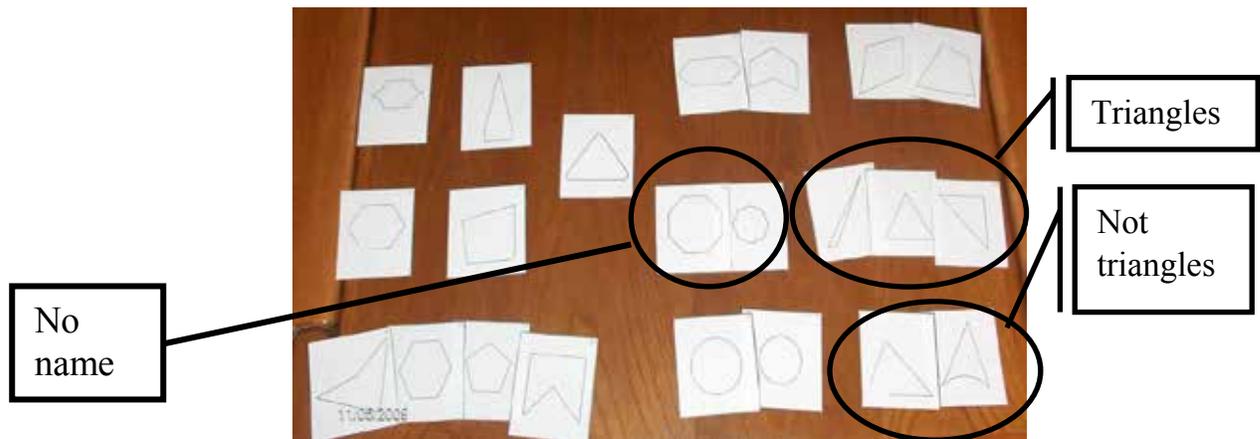

Figure 4: Johnny's sorting of the 22 figures

Within the group of "pentagons" we note that Johnny included two figures which were not pentagons, the regular hexagon and the concave quadrilateral. Yet, Johnny does not include any open figures or figures with curved lines in his groupings of the different polygons. In other words, he does not include non-polygon figures with polygons.

The first group of cards which does not consist of what Johnny terms as examples of geometric shapes includes the triangle-like shape that is not closed and the triangle-like figure with a curved side. Johnny groups together these shapes and says "not triangles". What does he mean here? There are many other figures which are also not triangles. The group of circles and the group of hexagons are also not triangles. In addition, the "not-triangle" figures are also not pentagons and not hexagons. Yet, he chooses to relate to them as "not triangles". What's more, he later relates to the quadrilateral-like figure with a rounded corner, as a "not quadrilateral". Perhaps Johnny is trying to tell us that these figures look like triangles or quadrilaterals but that he knows that they are not triangles and quadrilaterals. Perhaps Johnny is naming these figures "not triangles" and "not quadrilaterals". If this is the case, we may surmise that the name of the figure is the criterion Johnny used in his sorting and that Johnny has consistently used one criterion throughout this sorting. It is also possible

that Johnny is sorting the figures according to geometrical shapes and then subdividing them into examples and nonexamples. In other words, open and curved figures are identified in relation to the polygon they most closely resemble.

On the *All-at-once task*, For the most part, Johnny identified correctly all of the shapes. There were three exceptions. When asked to identify pentagons, he failed to point to the regular pentagon and to the concave pentagon. In addition, he pointed twice to the concave hexagon – as a pentagon and as a hexagon.

On the *One-shape-at-a-time task*, Johnny correctly identified all of the figures on each sub-task. For each figure presented to Johnny, he consistently noted both the number of vertices and the number of sides. When the figure was open or had curved lines, he correctly identified the figure as a nonexample of the requested shape, explicitly referring to the critical attribute which was violated. From this task it seems that Johnny has a wide concept image of the figures presented.

To summarize, Johnny's ability to name the figures became known only from the *Free-sort* task. This is important because some children are able to identify a shape when given the name but may not be able to name the shape on their own. From the same task, we get a sense that for Johnny, nonexamples are connected to examples. In other words, a nonexample is not generic but related to some specific figure which it is not an example of. This too, is information about Johnny that we did not learn from the other tasks. Both from the *Free-sort* task and the *All-at-once* task, it seems that Johnny's knowledge of pentagons is less stable than that of other figures. Yet, on the pentagon sub-task of the *One-shape-at-a-time* task, he made no errors. Perhaps handling 22 figures at once raised the level of difficulty for Johnny, or perhaps, he merely has a narrow concept image of pentagons. Finally, if we had only engaged Johnny in the *Free-sort* task, we might have surmised that he reasons visually with geometrical figures, actions indicative of reasoning at the first van Hiele level. Only from the *One-shape-at-a-time* task were we able to learn that Johnny is capable of using mathematical language and critical attribute reasoning, indicative of the second level of geometrical reasoning according to van Hiele.

Randy

Randy's final groupings on the *Free-sort* task is presented in Figure 5. In her words, there is a group of figures with eight vertices, six vertices, five vertices, four vertices, three vertices, two vertices, and a group without any vertices. Throughout, the only shape Randy explicitly names is the circle. She placed the rounded corner triangles with the circles because "it too does not have any vertices." She does not say that this shape is a circle nor does she say, for example, that the open "hexagon" is a pentagon because it has five vertices. Rather, she consistently counts points, or what she calls vertices, and groups together figures according to their number. Her concept image of a vertex is somewhat blurry. She claims that both the regular hexagon and the curved "hexagon" have six vertices. However, the point connecting curved lines is not called a vertex. When discussing the "triangle" with a curved side, she points to the

endpoints of the curved side and asks the interviewer, “Are these vertices?” When the interviewer does not respond, Randy goes on, “I think not. Because this is a curved line. But, let's say that there are three [vertices]. In other words, Randy notes that the figure has a curved line and questions the legitimacy of calling the points, vertices. Yet, she decides to act as if they are vertices and continues sorting along this line of reasoning. In the end, Randy sorted all the figures by one critical attribute – the number of vertices. (The only time she mentions the sides is when grouping the triangles.) In doing so, the world of geometrical figures, with its examples and nonexamples, becomes somewhat blurred.

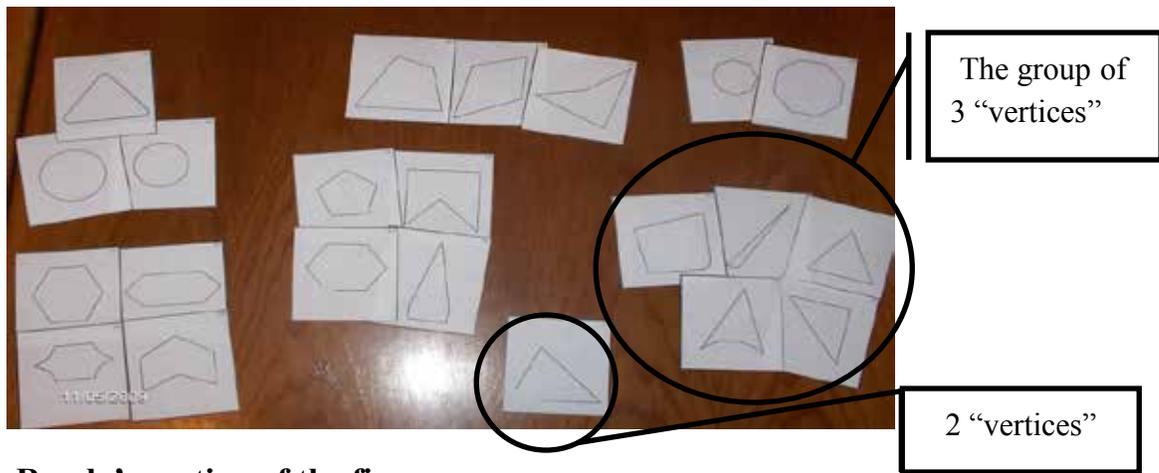

Figure 5: Randy's sorting of the figures

On the *All-at-once* task, Randy correctly identified all figures except for the concave quadrilateral, which she missed pointing to. On the *One shape at a time* task, she correctly identified all of the figures. She not only related to sides and vertices but also to the figures being closed. For example, when identifying the prototypical triangle, Randy comments, "It has 3 vertices, 3 sides, and it is closed." Reference to closure only took place on the triangle sub-task. When reasoning about quadrilaterals, Randy referred only to the sides and vertices while for the pentagons and hexagons she referred only to the vertices. When presented with a nonexample, she explicitly referred to the critical attribute which was violated using correct mathematical language to express her reasoning. Interestingly, when identifying the open "hexagon", Randy claimed "it is open and it has 5 vertices." In other words, although the figure is open, Randy still counted the points. For the curved "hexagon" Randy said that it is not a hexagon "because it has six vertices but only two sides."

To summarize, from all three tasks, we see that vertices play a dominant role in Randy's geometric reasoning. This was first evident from the *Free-sort* task and was backed up by the *One-shape-at-a-time* task, where slowly but surely, vertices were the only remaining critical attribute mentioned. If we had only implemented the sorting activity with Randy, we may not have learned that she is aware of other critical attributes. We may also not have learned that Randy is capable of identifying figures or we may have thought that handling 22 figures at once was too much. Yet,

on the *All-at-once* task, she identified all but one figure. On the other hand, if we had only implemented the *One-shape-at-time* task, we may not have learned of Randy's dilemma regarding points versus vertices. We may also have missed that for Randy the number of vertices is perhaps more critical than the other critical attributes.

DISCUSSION

As mentioned in the background section, assessment of children's geometric knowledge may vary greatly depending on the set of examples and nonexamples used in the study. However, in this study, the set of figures was constant. What varied, were the tasks themselves. Thus, as we look back on the results of this study, we focus on the tasks themselves, their similarities and differences, their affordances and constraints, and the knowledge which each task brought to light.

The *Free-sort* task was both open-ended and unfamiliar. As an open-ended task, there was no correct or incorrect way for the children to sort the figures. Yet, different aspects of children's geometric knowledge could still be assessed. Ability to name figures was one such aspect. This task also allowed us to investigate the relationships children might perceive between figures and the generalizations children might have constructed along the way. This is in accordance with Lane (1993) who claimed that tasks of this nature may shed light on the cognitive processes that underlie performance, such as discerning mathematical relations, organizing information, evaluating the reasonableness of answers, generalizing results, and justifying an answer or procedure. Johnny's groupings of "not triangles" and "not pentagons" may reflect that Johnny relates nonexamples to examples. That is, a figure is not merely a nonexample. It is a nonexample related to some specific shape.

The *All-at-once* task was a closed task. Children could either correctly or incorrectly identify each figure. The obvious constraint of this task was the set of figures. While children were familiar with the task of identifying various figures they had no experience dealing with 22 figures at once that could not be manipulated. This was a new challenge. Thus, the task afforded us a glimpse into which figures may be confused with other figures (such as the confusion between pentagons and hexagons evident by Johnny). This task was also the only task where the child's response was indirectly challenged. Recall that even after the child had pointed to all of the triangles (or quadrilaterals or pentagons, etc.) he was asked yet again if he could identify another triangle. Thus, this task also afforded us a glimpse into the child's confidence in his ability to identify figures.

The *One-at-a-time* task was both closed and open in that it began with an identification which was either correct or incorrect but continued with an explanation which was more open in nature. The closed nature of both this task and the *All-at-once* task and the focus on identifying figures on both tasks allowed us to assess which figures children may find more difficult to identify. Having children explain their reasoning on the *One-at-a-time* task afforded us the opportunity to gain insight

into the van Hiele levels at which they might be operating. Explanations also brought to light children's knowledge of appropriate mathematical language.

As noted above, different tasks afford children different opportunities to use and display geometric knowledge. But, not all children take advantage of the opportunities afforded by a given task. If a child only employs visual reasoning on one task, can we conclude that he or she is operating only at the first van Hiele level of reasoning? Previous research suggested that the van Hiele levels may not be discrete and that a child may display different levels of thinking for different contexts or different tasks (Burger & Shaughnessy, 1986). This study supports this suggestion as knowledge and reasoning which did not necessarily come to the fore on one task, sometimes appeared on another task. Thus, we conclude, a combination of tasks is advantageous when assessing both strengths and weaknesses of children's geometric knowledge. Our challenge as mathematics educators and researchers is to continue analysing the affordances and constraints of different tasks in order to optimize learning experiences.

GAME PROMOTING EARLY GENERALIZATION AND ABSTRACTION¹

Paola Vighi

Department of Mathematics and Informatics, University of Parma, Italy

The paper presents and studies some cases of mathematical reasoning observed during a game, proposed to pupils 5-6 years old. The analysis of pupil's behaviours in front of the task furnishes some examples that prove the possibility of early and significant mathematical activities of generalization and abstraction.

THEORETICAL FRAMEWORK

Relations between play and learning in early mathematics are object of investigation and study. In particular, Bartolini Bussi (2008, p. 262-263) emphasises that:

“The collective play is important both as socializing element, and as “instrument of production” of problematic situations. Fundamental is the encounter with the play with rules; it requires the overtaking and the solution of problems that we can relate to three areas.”

These three areas are: language (understanding, presentation and invention of new rules), socialization (respect of rules) and abilities of mathematical kind (order and behaviour organization).

Schuler (2011), about the relations between play and learning, observes that theoretical models and empirical researches confirm the evidence of learning while playing, since plays offer situational conditions for learning. In particular, she highlights three main blocks: affordance, liability and conversational management:

“[...] rules can offer mathematical activities beyond a material's intuitive affordance and thus create liability. Intuitive affordance of materials is replaced in games by (*the affordance of*) keeping the rules and winning *the game*” (Schuler, 2011, p. 1919).

Moreover she emphasises “the central role of the educator”. In fact, sometimes it is difficult to adopt a good equilibrium between a free and spontaneous play and a guided play. In other words, “Play is not enough. [...] children need adult guidance to reach their full potential” (Balfanz, Ginsburg, & Greenes, 2003), but when the teacher proposes a play finalised to promote particular abilities, he risks to force in some way the child and to impose directions of work connected with the finality of the play.

We chose to report here some definitions of ‘generalization’ and ‘abstraction’ since they are concepts very difficult and their meaning depends from the theories. In the

1. Work done in the sphere of Italian National Research Project Prin 2008PBBWNT at the Local Research Unit into Mathematics Education, Parma University, Italy.

following part of the paper we will refer to these quotations, with the aim to explain our ideas and results.

Generalization is cited as typical form of mathematical thinking. Very often it is related to algebraic reasoning, but it is possible to observe the use of generalizations also in other mathematical activities. Generalization is often associated with abstraction, but, Mac Lane (1986) writes:

“Generalization and abstraction, though closely related, are best distinguished. A ‘generalization’ is intended to subsume all the prior instances under some common view which includes the major properties of all those instances. An ‘abstraction’ is intended to pick out certain central aspects of the prior instances, and to free them from aspects extraneous to the purpose at hand. Thus abstraction is likely to lead to the description and analysis of new and more “abstract” mathematical concepts.” (p. 435-436).

Malara (2012, p. 57-58) describes the ‘generalization process’ as:

“... a sequence of acts of thinking which lead a subject to *recognize*, by analyzing individual cases, the occurrence of common peculiar elements; to *shift attention* from individual cases to the totality of possible cases and *extend* to that totality the common features previously identified”.

Also Mac Lane (1986) uses the locution “shift of attention”, but referring it to abstraction:

“*Abstraction by shift of attention*. Some abstractions arise when the study of a Mathematical situation gradually makes it clear that certain features of the situation – perhaps features which were originally obscure – are really the main carriers of the structure. These features, with their properties, are then suitably abstracted” (p. 437).

In his theory of ‘universal model’ Hejny (2004) distinguishes six different stages: motivation, isolated (mental) models, generalisation, universal (mental) model(s), abstraction, abstract knowledge. In particular, concerning the ‘Stage of generalisation’ he writes:

“The obtained isolated models are mutually compared, organised, and put into hierarchies to create a structure. A possibility of a transfer between the models appears and a scheme generalising all these models is discovered. The stage of generalisation does not change the level of the abstraction of thinking” (Hejny, 2004, p.2).

He describes the ‘Stage of abstraction’, as a stage in which a new concept, process or scheme is constructed, bringing a new piece of knowledge.

Dörfler (1991) differentiates two forms of generalization: empirical and theoretical.

“The basic process in **empirical generalization** is to find a common quality or property among several or many objects or situations and to notice and record

these qualities as being common and general to these objects or situations. The common quality is found by comparing the objects or situations, with regards to their outward appearance, isolated mentally, and detached from the objects and situations.

In contradistinction to this form Dörfler introduces another one - called **theoretical generalization** – and describes it with the help of a theoretical model for processes of abstraction and generalization which can often lead to the genuinely mathematical concepts (propositions, proofs, etc.)” (Ciosek, 2012, p. 38).

Dörfler criticizes the first, since it realizes only a recognition process, while the second can contribute to the concepts construction. In its “model of the processes of abstraction and generalization” he emphasises the role of “invariants of actions” that emerge as a consequence of the repetition of actions and define a “schema”.

Finally, we want to speak about row-column arrangements and related difficulties:

“Children have a different awareness of the rows and columns arrangement. Some of them prefer rows, some of them columns. It appears that it was difficult to see both rows and columns, especially for young children” (Rožek & Urbanska, 1998, p. 304).

RESEARCH QUESTION

The present research is placed in the theoretical framework of early mathematical education by play. In particular, it deals with development of reasoning promoted in children from a game (play with rules). The initial hypothesis is that a suitable play can produce an early and spontaneous use of generalization. Our aim is to give answers to the following question:

“Is it possible to promote in children the recourse to generalization in a game context?”.

METHODOLOGY

The participants

The experiment took place in the last year of kindergarten (pupils 5-6 years old), in school years 2010/2011 (15 children) and 2011/12 (13 children), working weekly. They worked sometimes in groups (7-8 pupils), under the guide of the teacher², sometimes individually. The researcher was present for the whole activity.

The game of coloured houses

We describe only a part of a wider research based on a game (without winner), named “The game of coloured houses”, invented from the author of the present paper³ (Vighi, 2010). The game is based on a disposition of houses with three different

2. I wish to thank the teacher Palma Rosa Micheli (Scuola dell'Infanzia Statale "Lodesana", Fidenza (PR), Italy), for her collaboration and helpfulness.

3. The idea of this game bore during a conversation with prof. E. Swoboda (University of Rzeszów, Poland).

colours (green, red, yellow) in a grid 3×3 , respecting this fundamental rule (as an ‘axiom’): in each row and in each column must be present three different colours. The possible different villages constructed following this rule are twelve. We report here some examples:

G	R	Y	Y	R	G
Y	G	R	G	Y	R
R	Y	G	R	G	Y
<i>a</i>			<i>b</i>		
<i>a</i>			<i>c</i>		

Figure 1: Examples of villages

We observe that *a* and *b* present an exchange of colours (Green with Yellow), *c* is obtained from *b* exchanging the second row with the third row, *a* and *c* present an exchange of columns (they are ‘symmetric’).

The game can be seen as a simplified version of Sudoku, with a grid 3×3 (instead of 9×9) and only three ‘symbols’ (it is possible to use also digits 1, 2, 3 or letters in place of colours). From the mathematical point of view, it is a ‘Latin Square’, an $n \times n$ array filled with n different symbols, each occurring exactly once in each row and exactly once in each column.

The game can be executed with orderliness or by means of ‘method of trials and errors’. It requires the contemporaneous management of rows, columns and colours. It is difficult, but important since it prepares to the concept of array that has a fundamental role in different significant mathematical concepts as multiplication, area of rectangle, Cartesian plane etc. Observing and working with two-dimensional dispositions of objects, pupils can make argumentations, discover theorems and use hypothetic-deductive reasoning. The game involves also local and global observation: during the construction of the village child applies rules working ‘step by step’, afterwards it needs to control if the whole village respects the task. So, she/he passes from an activity of construction to the ‘lecture’ of an array.

The procedure

The activities took place in the every day context. Teacher presented the game and she conducted it, promoting and fostering the viewpoints of children, without forcing their thinking, but waiting to listen their suggestions. Researcher observed, recorded on video, later she analyzed and transcribed dialogues, making comments.

Firstly teacher worked on the linguistic level: to understand the rules of the game it needs to clarify the meaning of the words “row” and “column” and their use. Afterwards she proposed the game in a context of motor activity (Fig. 2a), with the aims to involve pupils, to promote understanding, application of rules and socialisation also. Subsequently pupils played with coloured tiles and appropriate

supports: small cardboards to fit in appropriate grooves (Fig. 2b) or to glue in a sheet of paper opportunely arranged (Fig.2c). At last teacher proposed a general conversation and a discussion about the constructed villages and their features.

ANALYSIS OF CHILDREN BEHAVIOURS

We present here only a brief qualitative analysis of the activity concerning village's construction with tiles.

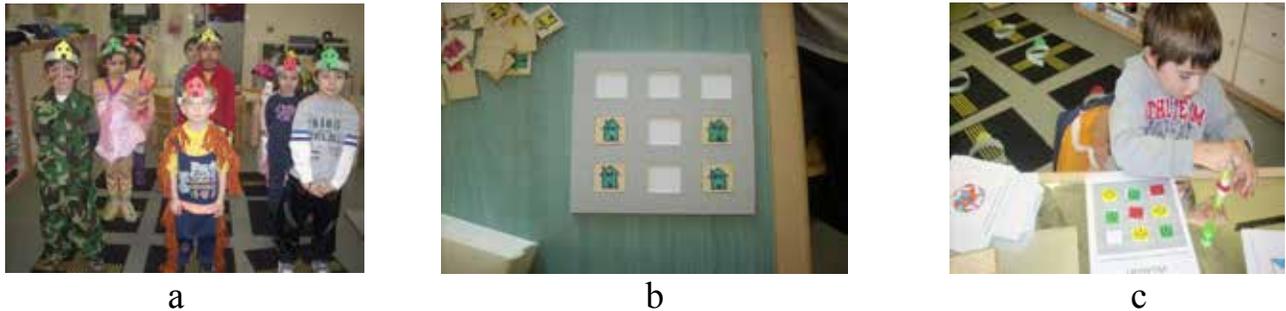

Figure 2: different ways to play with coloured houses

A first important observation is about different behaviours, emerged from the analysis of videotapes: in some cases the child brings a tile and after he puts it in a box, in others cases the ‘anticipatory thinking’ leads to observe before the map of the village and after to choose an useful tile.

The village constructions were very different. Some pupils worked realizing systematically rows, starting from the top and proceeding without hesitation from the left to the right, constructing before the first row and afterwards the second and the third; in this way, the game became a simple exercise. But, as we forecast, most children had difficulties to coordinate rows and columns: some respected rules only in rows, others only in columns, others in part in row and in part in columns, jumping from the one to the other. Some pupils putted tiles on the grid without any organization. Sometimes rules were respected only locally, so, when the village was finished, its global construction was wrong. Sometimes child arrived in front of an impossible situation, for instance he cannot finish her/his village since no colour can be used without make a mistake. So, the concept of ‘impossible’ appears, which is important in mathematics, since it forces to cogitate and to formulate hypothesis of change and promoting hypothetical-deductive reasoning. For example, we report here the sequence followed by Mattia:

Y	R	G	Y	R	G	Y	R	G	Y	R	G	Y	R	G	Y	R	G
					Y	R		Y	R		Y	R		Y	R		Y
									G			G	R	Y	G	R	

Figure 3: Mattia's construction

Mattia stops and, observing the first column, he says: “There are two yellow”. So, he

uses the number two to explain why the column is incorrect. Finally he decides to change some tiles and his village is correctly finished.

During the game pupils make argumentations as “It is impossible to have a red house here”, or “Here it must be a yellow house”. They use also hypothetic-deductive reasoning: “If I put here a green house, then ...” and so on. In this way, they use theorems that are consequences of rules.

The final activity of control was often suggested from the teacher. In many cases we observe that if the first construction of the village is wrong, for children it is difficult to come back and to modify their own previous execution. Child, invited to control her/his village and eventually to modify it, showed different reactions: refusal or inability to continue, procedures based on trials and errors, fast and opportune individuation of modification. In fact, as Vygotskij and Luria (1987) observed, to show the contradictions present in their conclusions creates a big difficulty in pupils, but obviously it depends on didactical contract.

THE ‘LITTLE LADDER THEOREM’

After the village’s realization, teacher putted the sheets of paper with villages on classroom walls and she suggested pupils to compare their productions. It is well known that comparison is fundamental in mathematics, to construct concepts: to think about analogies and differences could promote it. A lot of suggestions emerged during this comparison: a local way of seeing leads to remark only some couples of tiles with the same colours, placed in the same places (e.g. “In the first village there is a green house here, in the second also”), while a global way to see promotes the individuation of “equal villages” or “symmetric villages” etc.

In particular, as Brousseau (1983) highlighted, the passage from the work on the desk (micro-space) to the observation of the classroom walls (meso-space), along with the visual perception stimulated by colours, promoted an important ‘shift of attention’ (Malara, 2012) from rows and columns, explicitly mentioned from the game rules, to the monochromatic diagonal present in each village. Some pupils said that “Villages have three houses disposed as a ladder, with the same colour”, others observed villages and confirmed this conjecture. To indicate the monochromatic diagonal discovered in each village some pupils used the locution “little ladder” since the disposition of tiles suggested the steps of a small ladder, others “bandy row”, some others ‘arrow’.

It is an “empirical generalization” (Dörfler, 1991), but also a generalisation in sense of Hejny (2004): the structure appears as generalizing isolated models, the connection between isolated models, created from a particular disposition of tiles, produces generalization.

In this way, pupils found and formulated a theorem: “In each village, there is a diagonal with houses of the same colour”. We named it the ‘Theorem of little ladder’. It is an example of “theorem in action” (Vergnaud, 1983), a theorem which children

use when they deal with problems, obviously without a mathematical formulation, but as relational invariant.

Afterwards some of them observed the presence of two different kinds of diagonals: “from down to up or vice-versa”. It promotes the observations of both the diagonals and the formulation of another theorem: “In the other diagonal there are three different colours”, but this was perceived as no relevant aspect, since it seems to respect the game rule.

FROM GENERALIZATION TO ABSTRACTION

In the following activities we decide to investigate if children use ‘diagonal rule’. We observed different behaviours, as example we report here Chiara’s strategy (Fig. 4).

Y			Y	R		Y	R	G	Y	R	G	Y	R	G	Y	R	G
	Y			Y			Y			Y		R	Y		R	Y	R
		Y			Y			Y	G		Y	G		Y	G		Y

Figure 4: Chiara’s strategy

Chiara, using the ‘little ladder theorem’, starts with a yellow diagonal, she continues with two correct passages, after she makes a mistake that leads to have at the end a ‘wrong village’. When the teacher asks to control the village, Chiara realizes that in the third row there are two green tiles near, but she don’t perceive the error present in the second row, since the red tiles not are next to each other. Chiara remember and use ‘small ladder theorem’, but her execution shows mistakes and a difficult management of game rules. In fact, for Chiara the presence of a monochromatic ladder is only a new rule of the game, a starting point for her activity.

In the school year 2011/2012, we decided to submit to pupils of preschool (5-6 years old) a new game in 3D, consisting in the construction of a ‘palace’ (a cube), of three floors using 27 cubes, with similar rules: “In each wall face it needs to have three different colours in each row and in each column”⁴. In particular, the previous activity on village construction was realized putting coloured cubes (instead of tiles) one near to the other in a grid three times three (Fig. 5). Really cubes are more similar to houses and, as research documents, to work in 3D dimension is suitable for young

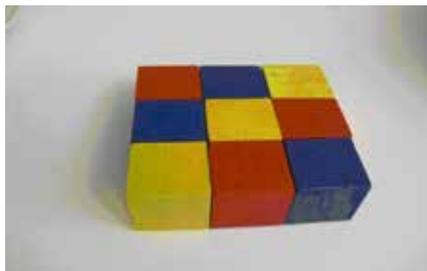

Figure 5: Village of coloured

⁴ The complete experience is described in (Vighi, 2012). See Poster Presentation in CERME 8.

pupils.

This change of didactical variables (from tiles to cubes) promoted an important breakthrough, since, as Rožek (1997) writes, in a row-column arrangement of figures the distance between objects influences in depth the observation. After the village construction with cubes, it happened that a child observed the presence of a yellow line (Fig.5), suggested from the colour and also from the idea of “straight line” and he incorrectly said that “there was a mistake”. Teacher suggested that in fact all rows and columns respected rules and the child replies that “Yellow cubes are as an arrow” (‘little ladder’ in the previous experience).

Another breakthrough happened when a child observed that in the other diagonal there were three different colours: he indicates it with his hand, accompanying with gesture and sound: “here, blue, yellow, red, pum, pum, pum” and he added: “A ‘point’ entirely yellow, another of three colours, it is an ‘X!’”. In other words, the disposition of diagonals suggested the mental image of letter X. Its presence in all villages produced a passage from isolated models to a general model in the meaning of Hejny (2004), but ... not only this.

Of consequence of “X discovery” some children changed their way of village construction, also in the following activities. They started putting cubes in ‘X disposition’ and completing the remaining parts. Obviously, in this way the game becomes easier: the construction of a coloured village changes a lot, since starting from diagonals, the placement of the other houses is obliged. We describe here, for instance, Nicholas strategy (Fig. 6):

Y			Y		B	Y	R	B
	Y			Y		B	Y	R
		Y	R		Y	R	B	Y

Figure 6: Nicholas strategy

There is a fundamental difference between the use of one diagonal or two diagonals as starting point: in the first case (Chiara example) it is only an use of a theorem obtaining by generalization, in the second (Nicholas example) it appears another important and very strong ‘shift of attention’, but related to abstraction, in the sense of Mac Lane (1986): ‘letter X’ is understood as one of the “main carriers of the structure”. It is an example of “theoretical generalization” in the meaning of Dörfler (1991): the ‘letter X rule’ becomes an “invariant of action” and it creates a “schema”.

This finding of X was unexpected for us. As we said before, when we planned the activity our interest was on row-column arrangements, early reasoning etc. It is very surprising that, after its discovery, some pupils chose to adopt and to use the method of ‘letter X’ in the following activities. In particular, some children (38%) always used the ‘rule of two diagonals’, 32% the ‘rule of a diagonal’, and the remaining 30% other various methodologies.

The main result of the second experiment, maybe promoted from the use of wooden cubes, is the recourse to generalization and abstraction, promoted from the “X discovery”.

CONCLUSIONS

The “Game of coloured houses” is surely motivating for pupils: speaking with the teacher, I knew that children often proposed the game at home to their parents or brothers. It is a first goal; in Hejny’s theory the “motivation” is the first stage of development and structuring of knowledge.

The experimentation furnished positive answers to our research question. In particular, the mathematical learning is related to understand and to use mathematical methods. We expected only generalization, but also abstraction appeared. So, learning is realized on meta-mathematical level, since it is related to generalization (Malara, 2012) and abstraction processes (Mac Lane, 1986).

When we planned this game and its implementation in preschool, our aims were different, but generalization appeared along with the discovery of a monochromatic diagonal in each village. The use of X-strategy, we think, promoted the passage from generalization to abstraction. The recognition of an “invariant” or “schema” (letter X) to describe it, is a “symbolic description” in the Dörfler’s theory meaning.

So, for the young pupils involved in our experimentation, generalization and abstraction become an instrument of work. Also ‘theory of semiotic mediation’ (Bartolini Bussi & Mariotti, 2008) can furnish an interesting interpretation of the present research: an artifact (cubes) and a task (game rules) promoted the use of a sign (letter X) that express relation between artifact and knowledge. As we said before, in our case it is a metacognitive knowledge and it appears unexpectedly. We are determined to analyse our experience having the mentioned theory as theoretical framework.

About methodology, we agree with Schuler (2011): “Potentially suitable materials and games need a competent educator with regard to didactical and conversational aspects”. In our experience the role of the teacher and the conversational management appeared determinant. We want to add another important conclusion about “conversational management”: as we wrote before, the game was entirely conducted from the teacher with the presence of researcher as observer. The latter had the possibility to “peek and catch” some observations made from children, while the teacher was involved in the action. After an exchange of opinions with the observer, teacher took advantage from these suggestions and she used them in the following activities and conversational managements, improving in this way the activity in classroom.

VIDEOCODING – A METHODOLOGICAL RESEARCH APPROACH TO MATHEMATICAL ACTIVITIES OF KINDERGARTEN CHILDREN

Rose Vogel and Judith Jung

Goethe University, Frankfurt/Main, Germany

In this paper a methodological research perspective is taken on the mathematical activities of Kindergarten children in mathematical situations of play and exploration. Videotaped verbal and gestural expressions of children as well as activities with the material are encoded with the help of a coding guideline, which is developed for mathematical activities. So courses of mathematical activities can be traced during a mathematical situation of play and exploration and even over several data collection points. At the same time connections of using different mathematical activities between the participants become clear. The introduced methodology of video coding connects qualitative with quantitative analysis methods.

INTRODUCTION

Starting point for the development of an instrument for video coding are videotaped mathematical situations of play and exploration, which occur within the framework of the project ‘erStMaL’ [1]. One overarching aim of ‘erStMaL’ is to trace the development of mathematical thinking of children aged between four and nine years from a mathematics-educational perspective (cf. Acar Bayraktar, Hümmer, Huth, Münz & Reimann, 2011; Krummheuer, 2011). The mathematical domains numbers & operations, geometry & spatial thinking, measurement, patterns & algebraic thinking and data & probability serve as reference points for the conception and the development of the mathematical situations of play and exploration (cf. Clements & Sarama, 2007). Within the ‘erStMaL’-project the mathematical situations of play and exploration [2] serve as an empirical research instrument (Vogel, in preparation). The developed situations provide a situational framework within the children work in tandems, together with a guiding adult, on mathematical tasks. The guiding adult has an expert status concerning these mathematical tasks. These situations are designed dialogically. The children’s mathematical activities, which are usually tied to the selected materials (artefacts) of the particular situation, are the centre of consideration (cf. Wells, 1999; van Oers, 2004). The materials (artefacts) are selected in a way that they, on the one hand show a narrative character and on the other hand they provide connection points for mathematical activities. The materials can therefore be seen as ‘culture tools’ (Bodrova & Leong, 2001, p. 9). Overall, an ‘overlap situation’ between the world of mathematics and the world of experience is generated by the designed mathematical situations of play and exploration (cf. Prediger 2001; Vogel, in preparation).

THEORETICAL BACKGROUND

In terms of a social-constructivist perspective on learning mathematics, the situations of play and exploration activate the involved person's ability to negotiate the objects' mathematical meanings. Dealing with the objects and how the objects can be used for the solution process of the mathematical task has to be clarified in a negotiation process by the children (cf. Brandt & Höck, 2011). This theoretical learning approach can be combined with the theoretical development approach of the co-construction, which is discussed primarily for early education processes (cf. Brandt & Höck, 2011). In the context of these interactionist approaches, the area of tension "between interaction processes between partners with equal rights" and "interaction processes with a rather disparate role allocation and clear differences" (Brandt & Höck, 2011, p. 249, translated by R. Vogel) must be taken into account amongst the participants. At the same time, the mathematical situations of play and exploration create an area in which knowledge can be expressed situationally (cf. Vosniadou, 2007). According to conceptual changes, which do not exclusively exchange concepts but also change perspectives, a further development of mathematical concepts is integrated (cf. Vogel & Huth, 2010; Vosniadou, 2007).

RESEARCH PERSPECTIVE

Against this theoretical background, it is necessary to develop an analytical tool that enables the reconstruction of the childrens' mathematical activities in the situational processes of negotiation. Through this reconstruction, on the one hand it is possible to track the development of mathematical concepts of children over the course of time. On the other hand, video sequences can be identified, which can be analyzed with other qualitative analysis tools on a micro level, in terms of the mathematical concept development. Particularly, the significance of the interaction of different semiotic resources for the development of mathematical thinking can be worked out (cf. Vogel & Huth, 2010; Givry & Roth, 2006).

VIDEO CODING – THEORETICAL FRAMEWORK AND APPLICATION

The presented method of video analysis combines qualitative and quantitative analysis steps. By using a coding guideline and by determining frequencies of the emerging categories, quantitative analysis of the videotaped mathematical situations of play and exploration are carried out. Ginsburg and Seo (2004) investigated children's everyday mathematical activities and developed inductively mathematical content codes. For the development of our coding guideline a qualitative content analysis has been fulfilled. In this process an offset of deductive and inductive developed categories has been created (cf. Mayring, 2000). Figure 1 shows an overview of the process of category determination. Several relevant mathematical concepts from the five mathematical main domains, which are the basis of the different situations of play and exploration, formed the starting point (cf. Clements & Sarama, 2007). Considering the video data, this first category-system was

supplemented and extended inductively through the mathematical activities that were expressed by the participating children. Therefore we looked at various videotaped situations of each domain considering the first four data collection points. After determining a constant category system the coding accordance of different persons was checked and the categories were proved and verified again.

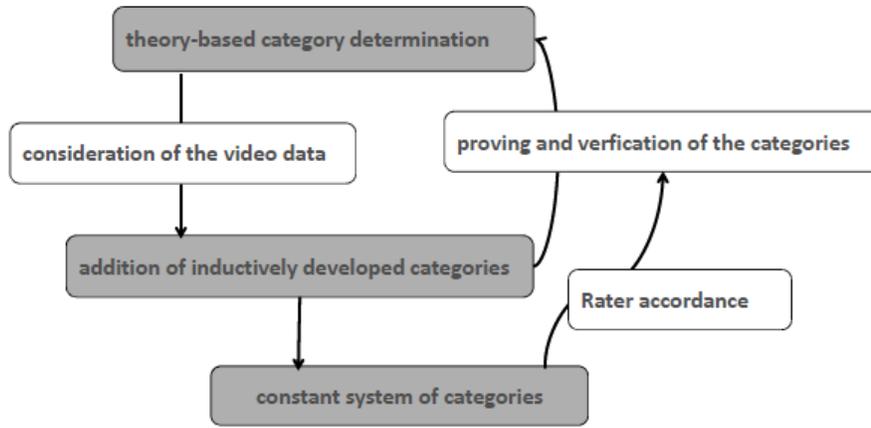

Figure 1 Process of developing the coding guideline

The coding guideline consists of eleven main categories, which are divided into several subcategories. The main categories refer to mathematical activities, which are attributed to the five mathematical domains already mentioned above. In the following paragraphs the main categories will be presented briefly.

The main category ‘determination of quantities – operation (QO)’, which is attributed to the domain of ‘numbers & operations’, will be presented in detail because of its importance for the selected example. A reference to empirical research context is given. It is a domain that has been elaborately researched for mathematical early education. A distinction is made between counting as a series of numbers (right or wrong) and one to one assignment of numbers and objectives (cf. Fuson, 1988). Additionally, the field of subitizing is mentioned. This kind of entry of quantities is often described as a preliminary stage of counting. ”Results suggested that spontaneous focus builds subitizing ability, which in turn supported the development of counting and arithmetic skills.” (Clements & Sarama, 2007, p. 473). Another subcategory serves to register children’s activities and statements in the fields of seriation (cf. Clements & Sarama, 2007). Further subcategories serve to register simple operative activities in the field of addition and subtraction. Subcategories are indicated with numbers after the short cut of the main category (e.g. QO1 for ‘counting’, QO2 for ‘determination of quantity without recognizable counting processes’).

The main categories ‘mathematical structures (MS)’ and ‘patterns (pattern units, band ornaments, parquets) (PA)’ are attributed to the domain of ‘patterns & structures’: The central focus of the main category MS is on the construction of structures in a set of objects as well as between several sets (cf. example of the video coding process). It

becomes apparent that the children integrate structures of their every day life into the situations and partially interpret these structures mathematically (MS1). The category PA includes geometrical activities with regard to the work with patterns, e.g. band ornaments should be added, continued or should be reinvented by the children. Here, it is taken into consideration that children might create patterns, which cannot be interpreted as patterns from a mathematical perspective, but are described as patterns by the children. As a result, sequences from the video data can be identified where several patterns of interpretation from within the children's world and the world of mathematic become apparent. Comparable subcategories have been developed for dealing with parquets.

Within the coding guideline, activities in the domain of geometry and spatial thinking are determined through three main categories: 'topological fundamentals and activities (TP)', 'components of spatial thinking (ST)' and 'geometric shapes and 3-D figures - transformation between plane and space (GE)'. There is a distinction between dealing with closed and open lines and finding ways in narrative contexts e.g. within 'railway-situations' and activities of Euclidian geometry. Components of spatial thinking should also be taken in account in a separated category. The domain of 'measurement & size' is represented by the main category 'measurement (ME)'. It is proposed that within the subcategories, activities of direct or indirect comparisons are coded.

The mathematical domain of 'data and probability' is included in three main categories: 'data (DA)', 'chance (probability) (CH)' and 'combinatorics (CB)'. In view of the example, the domain data must be emphasized. Focus is on elementary and complex processes of sorting as well as on adequate representations for comparison of quantities. The category 'sundries (SU)' subsumes all activities (expressions) that can not be interpreted mathematically.

The process of coding involves mathematical interpretations of verbal and gestural based statements of the children as well as actions with the material according to the coding guideline. The multimodal statements of several persons are coded separately. Therefore, a coding unit of 30 seconds is allocated to a maximum of two subcategories. The following example of transcription [3] reproduces most of the coding units 16 and 17 (cf. Figure 2) and it also shows which subcategories are allocated to the involved persons' statements.

Coding unit 16 (extract from the 30 seconds, start):

- < René look. one two three four *pointing at the dots of a 'ladybug-card' which is in front of him* one two three four *pointing at the dots of the 'ladybug-card' in his hand*
- < Marie **two** *taking a 'ladybug-card' with two dots out of the middle and dropping it in front of him on the floor together with the other 'two-dots ladybug-cards'*
- B yes-

Marie and three\ do I have a three/ *observing a 'ladybug-card' with three dots, which is lying in the middle and then looking at a 'ladybug-card' which is in a row in front of her on the floor*

René *taking the 'three-dot ladybug-card' out of the middle*
he/ . I have a three\ *dropping the card to the other 'three-dot ladybug-card' in front of him on the floor*

Coding (Subcategories):

René: counting (QO1) & elementary sorting operations according to one category (DA1)

Marie: recognizing structures within sets (MS1) & elementary sorting operations according to one category (DA1)

B (guiding adult): mathematical structures (stimulus) (MS (x))

Coding unit 17 (extract from the 30 seconds, start):

< René Mum and Dad\ *pointing at two red 'four-dots ladybug-cards'*
 Brother and Sister\ *taking two red 'three-dots ladybug-cards' in his hand*
 Mum and Dad\ Brother and Sister\

< Marie *pushing all 'ladybug-cards' lying in front of her on one pillar*
 mine is a whole kindergarten\...should be a whole kin-

Marie that is a whole Kindergarten\

B *laughing a whole Kindergarten/*

Coding (Subcategories):

René: recognizing structures within sets (MS1)

Marie: recognizing structures within sets (MS1) & determination of quantity without recognizable counting processes (QO2)

B: mathematical structures (MS)

EXAMPLE OF AN ANALYSIS

For this paper the mathematical situation of play and exploration 'Ladybugs' is selected for an exemplary analysis. In the settings the participating children are observed in constant tandem (pairs). In these pair settings the children always attend the same mathematical situation however for each data collection point the mathematical tasks and materials are adapted to the children's age if necessary. For the current analysis the selected tandem consists of René and Marie. They deal with this situation at three different data collection points. The data collection point T2 is missing due to the research design (situation with the kindergarten teacher). At the data collection point T1 René and Marie were 4;9 years old.

In the 'Ladybugs'-situation the children can differentiate between similar objects, which differ in several attributes. The children work with 'ladybug-cards' which differ in colour (red, green, yellow), in number of spots on them (one, two, three, four) and in the shape of the spots (circles, triangles, squares). No 'ladybug-card'

appears twice. In the first working phase the children are encouraged to sort the ‘ladybug-cards’ according to different criteria and to establish different ‘ladybug-groups’. In the second working phase the member of the research team presents a triplet of big ‘ladybug-cards’. The big ‘ladybug-cards’ also differ in colour, shapes, size and number of spots. The children should decide which of the three cards does not fit.

The results of the analysis are visualised in two different forms. Below, a time course that shows the emerging mathematical activities, its transitions and connections at one data collection point in one situation is presented. Here, it is possible to follow the interaction between the participating persons regarding its influences on the mathematical activities carried out by one person. The second form of representation shows the quantities of the mathematical activities over time. The percentage frequency of main categories or subcategories at different data collection points can be compared and a possible transformation may become apparent. Children’s preferred mathematical domains can be described through comparing and contrasting their percentages.

Time course

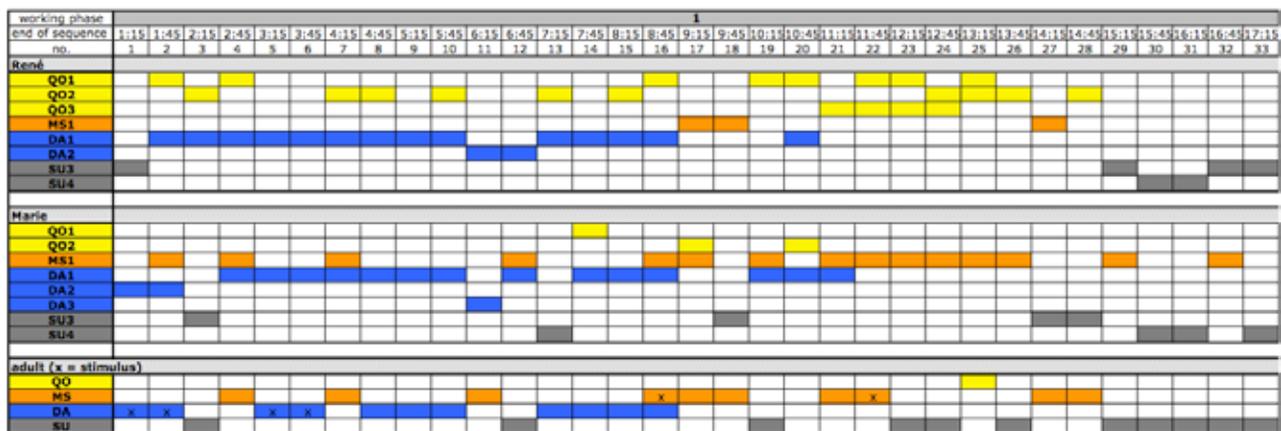

Figure 2 Time course of the first working phase of the ‘Ladybugs’-situation carried out at the data collection point T3

Figure 2 shows the time course with the coding of the mathematical activity of the two children and the guiding adult in the first working phase of the ‘Ladybugs’-situation at the data collection point T3 (Marie and René: 5;10 years). The guiding adult starts with impulses from the domain data (DA), which are picked up by the children. In the sequences from 1-16 the ‘ladybug-cards’ primarily are sorted by one specific criteria (colour, shape, number) (DA1). Marie and René combine the sorting process with various mathematical activities. René has a particular interest in determining the numbers of spots on the ‘ladybugs-cards’. Therefore he uses different strategies: ‘counting (QO1)’ and ‘determination of quantity without recognizable counting processes (QO2)’. Marie is specifically focused on the structural relationships of the objects of different sets (MS1). She uses the context of family and kindergarten. There is an intensive exchange between the main categories QO, MS

and DA to be seen during the coding units 16 and 17. This indicates a so-called ‘dense’ sequence, in which different mathematical concepts within the activities become apparent and are placed in relation to one another (cf. example of the video coding process). After those coding units Marie remains in the domain of algebraic structures until the end of the working phase, deepening her idea of structuring the sets. René’s mathematical activities can mainly be attributed to the domain ‘determination of quantities – operations’. Once he has sorted the ‘ladybugs-cards’ according to colours he starts to bring the cards in an order according to the number of spots upon the back and determines which ‘ladybug-group’ is the biggest one. Over time it becomes evident that during the span of a mathematical situation of play and exploration sequences can be observed in which the activities of the involved persons cannot be interpreted as mathematical activities. Nevertheless, these activities can also be important for the children and the course of the situation. From coding unit 29 until 33 Marie begins with a detailed description of her ‘ladybug-kindergarten-groups’ and starts talking about a fictional excursion for the groups. René is sitting next to her, not entirely detached and listening partially. Overall, it becomes obvious that the children combine activities from within different mathematical domains and they switch from one domain to another.

Quantities of the mathematical activities

If you compare the percentage frequencies of the emerging major activities of René to the ones of Marie you will get to the point that they remain true to their favourite mathematical activity (Figure 3). The fact that through all the data collection points the domain data remains constant is a result of the situation’s and the material’s design. Compared to Marie René’s obviously preferred activity is out of the domain of determination of quantity - operations. The courses over time allow the following interpretation: At point T1 from the data collection the children bring up a diversity of mathematical domains. This diversity of different mathematical activities decreases over time. It is possible that this is a result of the fact that the children already know the task and the material and it does not require much testing anymore.

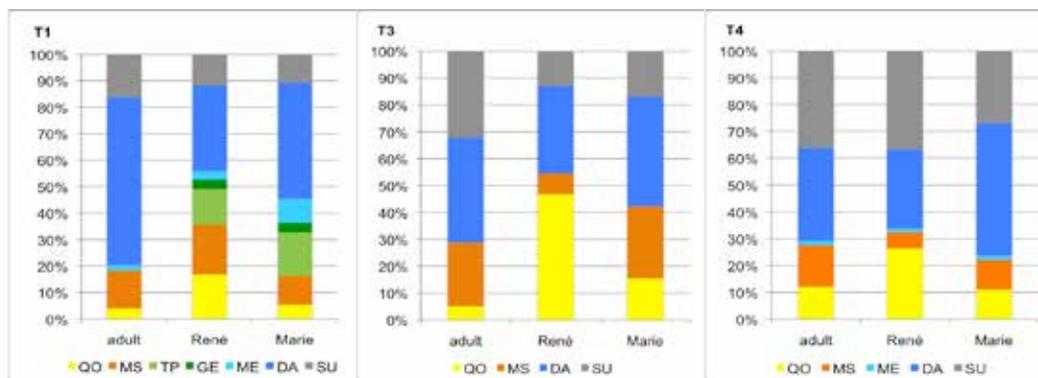

Figure 3 Percentage frequencies of main categories at different data collection points

If you focus solely on the main category there does not appear to be a major change between the data collection points. But when taking the subcategories into account

one notices that there are changes in the mathematical activity over time. Figure 4 shows the subcategories of the main category ‘determination of quantities – operations (QO)’. The subcategories are counting (QO1), determination of quantity without recognizable counting processes (QO2), ordering (QO3), operations – addition and subtraction (QO4) and operations – multiplication and division (QO5).

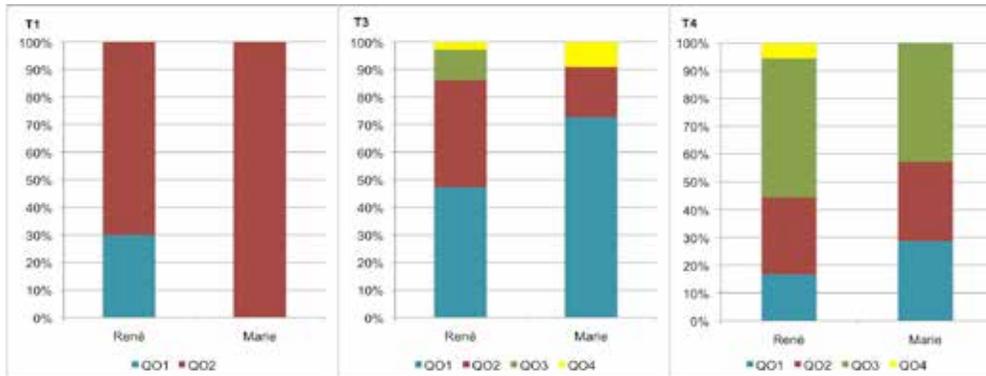

Figure 4 Percentage frequency of the subcategory ‘Determination of quantities – operations’ at different data collection points

At the first data collection point Marie’s activities out of the domain ‘determination of quantities – operations’ can be exclusively assigned to the subcategory determination of quantity without recognizable counting processes (QO2). She distinguishes between less and many ‘ladybug-cards’ however without counting them, whereas René tries to confirm these assumptions with noticeable counting processes. Nearly one year later at the third data collection point the children focus on counting processes. At the data collection point T4 (Marie and René: 6;5 years) the focus of the children is on sorting the ‘ladybug-cards’ in series according to the number of spots and bare counting processes are less frequently realized.

CONCLUSIONS AND FUTURE PROSPECTS

The example already shows the potential of this type of video analysis. The results show that the mathematical main categories remain constant over time, while the subcategories change. Therefore the results of the video coding process offer reference points for the reconstruction of the development of mathematical thinking in different mathematical domains. The results of analysis of various mathematical situations of play and exploration and different tandems of children suggest the existence of preferred mathematical domains for particular children during the process of problem solving. This result could be used to examine specific groups of children in their mathematical preferences. In addition, the results show that the procedure of video coding enables an identification of sequences with reference points for further analysis regarding mathematical concepts. The coding can also be used as an evaluation of the situations of play and exploration which is necessary for a possible advancement to a diagnostic tool.

NOTES

1. The project ‘erStMaL’ (early Steps in Mathematics Learning) is a longitudinal study, which accompanied the children during their time in kindergarten and primary school. 178 children in 12 day-care centers participate in the study. Data collection takes place twice a year and is carried out in the familiar environment of the day-care-centers. The project is established at the IDeA centre (Individual Development and Adaptive Education of Children at Risk) in the context of the LOEWE-Initiative.
2. All the situations of play and exploration were developed by the research team of the project ‘erStMaL’.
3. Explanation for understanding the transcript: / ... lifting the voice, \ ... lower the voice, - voice in abeyance, pause in speech: one point according one second, action are in italics, < ... happened at the same time.

ACKNOWLEDGEMENT

This research was funded by the Hessian initiative for the development of scientific and economic excellence (LOEWE).

HOW FOUR TO SIX YEAR OLD CHILDREN COMPARE LENGTHS INDIRECTLY

Johanna Zöllner, Christiane Benz

University of Education, Karlsruhe

This article will introduce one part of a research studying how four to six year old children develop an idea about indirect comparison of length, with the aid of diverse tools. In a qualitative survey the solution processes of altogether 40 children have been observed. Hence, this paper will show the system of categories and will also present initial results.

INTRODUCTION

“We are convinced that dealing with measures is the most suitable way to introduce five-year-old children to the world of figures and mathematical terms” (Castagnetti & Vecchi, 2002, p. 14). In spite of this statement, Copley notices that “measurement is an often neglected mathematics topic for young children“ (2006, p. 17). Furthermore, Benz states that, during mathematical activities, German kindergarten educators mainly focus on arithmetic (2012, p. 22). Only 17% of the kindergarten educators who took part in that survey (n=589) answer that measurement is part of their mathematical activities in kindergarten. A fact which is “astonishing, because the reference to everyday activities is very obvious concerning measurement“ (ibid. 2012, p. 22). This is also true for the area of length “although of the [...] physical quantities, length is undoubtedly the most primary“ (Buys & Moor, 2005, p. 18). It can be stated that in descriptions of the development of a concept of length, comparing objects indirectly constitutes an important aspect (e.g. Battista, 2006; Clements & Sarama, 2009; Piaget, Inhelder & Szeminska, 1975). Therefore, this article focuses on comparing items indirectly.

Looking on empirical studies it can be stated that there is a lack of studies investigating especially younger children’s ideas about length and also about children’s competences of comparing indirectly (Gasteiger, 2010). Still, these findings are indispensable in order to have the possibility in kindergarten or in school to tie in with the abilities and perceptions of the children.

Nevertheless, there are some studies which investigated children’s concept of length focusing especially on competences of comparing indirectly. But these studies took place with children starting school or attending school (e.g. Hiebert, 1981; Nunes, Light & Mason, 2003; Schmidt & Weiser, 1986). The focus of this paper will be on competences concerning comparing items indirectly of four to six year old children.

THEORETICAL BACKGROUND

The following section deals with a normative aspect of what kind of competences are identified for comparing items indirectly. Empirical results are included as well

while describing these competences. One must have in mind that all research results are referring to children in primary school. Only the study by Schmidt and Weiser (1986) children were asked who were just starting school.

Concepts of length and its linear character

In order to be able to compare lengths indirectly it is necessary to develop an idea about lengths and its understanding of the attribute (Nührenbörger 2002, p.100). This means that children have to learn to focus their attention only on the length of an object while ignoring its other attributes, for example like colour or taste.

Comparing objects directly

In order to compare objects directly understanding additivity (Clements & Sarama, 2009), decomposing (Battista, 2006) and part-whole relationships are essential. Referring to children just starting school, Hiebert (1984) showed with his survey that the idea that the length of an object consists of the sum of its different parts is not new to these children. Griesel (1996) and Nührenbörger (2002) are convinced that children who are capable of comparing objects directly have learned that it is possible to divide the longer object in two parts. Whereas one of these two parts is as long as the shorter unit that has to be compared and the second part is as long as the overhanging piece. Consequently, children who can compare things directly would also understand the different concepts of additivity, decomposing and part-whole relationships.

Conservation and transitivity

Regarding the importance of conservation there are different positions. Piaget et al. (1975) emphasized the importance of understanding conservation and transitivity. They are convinced that children are only able to measure when they have learned to understand transitivity and conservation. In contrast to that, Hiebert (1981, p. 208) observed that first-grade children who did not yet have developed an understanding of conservation and transitivity were able to implement different measurement strategies successfully (cf. also Schmidt & Weiser 1986, p.150f.).

Unit iteration

If a shorter medium is used to compare an object indirectly the comparison will only be successful if the children can control the unit iteration and if they are able to count these units. Together with the transitivity many authors highlight the key role of this expertise (Battista, 2006; Clements & Sarama, 2009; Piaget et al., 1975; Schmidt & Weiser, 1986). While repeatedly conducting the unit iteration, it is important to focus on the fact that there are no gaps in between the units. Schmidt and Weiser (1986) observed in their survey that even those children starting school who implemented the idea of the unit iteration did not attach value to an entire measurement without gaps.

Application of suitable adjectives

In order to be able to successfully compare objects indirectly children have to be able to describe the results with the aid of suitable adjectives. Relational terms such as *longer, wider, lower...* are prerequisites for being able to communicate about lengths (Gasteiger, 2006, p.11). Nührenböcker (2002) showed that faulty comparisons were not wrong because the comparison itself was wrong but because the comparison and its result were not described correctly with the second graders. Whereas Schmidt and Weiser (1986) could prove that children starting school use relational terms properly in connection with measures even if they do not have an idea about measurement. For example, when being asked if three meters or five meters are longer the children answered correctly. It seems as if children who have an understanding of figures a “transfer within” (Schmidt & Weiser, 1986) takes place. The relational term ‘is longer than’ can – at least verbally – be referred to relations between figures in a correct way (“is a bigger number than”, “is bigger than”, “is more than”) (Schmidt & Weiser 1986, p. 145).

Regarding these aspects it becomes obvious that comparing length indirectly requires many different competences. Is dealing with measurement, especially length, (Castagnetti & Vecchi, 2002) to demanding for young children particularly an indirect comparison? In order to answer this question the following research question has been addressed.

RESEARCH QUESTIONS

Which individual solution processes can be observed for the different aspects of comparing two different lines indirectly?

STUDY DESIGN

In order to get first insights into children’s solution processes at the age of four to six for comparing indirectly a qualitative method was chosen: Qualitative interviews were conducted. All children had to solve the same task, however, the following strategy was oriented on the children’s expressions and strategies. Consequently, the following study is a cross-sectional study with „investigating“ interviews (Lamnek, 2005) with the aim to investigate the strategies of children when doing an indirect comparison.

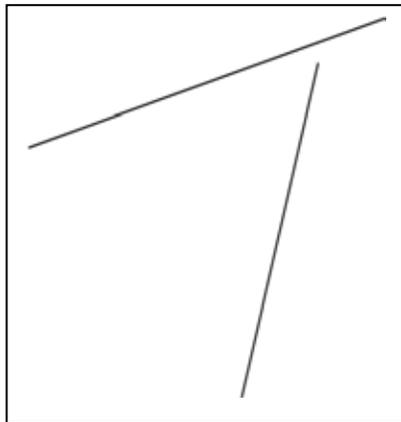

The interview is an artificial situation for the children where they are confronted with tasks that they would not have asked in such a way or would have answered in another way in a different situation. A participant observation would picture a „natural“ situation but with the help of the interview it is ensured that the child passes through the steps of the solution of the task. Moreover, the child uses the material of which the interviewer is convinced to get the most information of the strategies children are using to do an indirect comparison (cf. Marotzki, 2011, p. 114). The artificial situation can lead to the fact that a child tries to meet the expectations of the interviewer and answers respectively (cf. Beck & Maier 1993, p.

162). The children might possibly not show their original concept concerning the indirect comparison but show the concept, which is in their opinion the “correct” concept or the concept, which they think the adults expect them to use. Through the possibility to ask questions in the interview and to demand explanations concerning the strategy that is used this differentiation between the original strategy of the child and the strategy that is shown isn’t a problem. In contrary, it establishes more possibilities to unscramble the actual often complex view of the children in how to manage an indirect comparison.

The qualitative interviews were videotaped. In the analysis of the interviews categories were generated to describe the children’s processes.

The research was conducted with 40 children as a cross-sectional study with four to six year old children. The children were selected randomly.

On the basis of one task, which was used in the interviews, the generating of the categories will be described and first results will be illustrated. Following with Oswald there will be also some quantitative data given, due to the fact that quantitative data can be one aspect of qualitative reality (Oswald 2010, 186). Moreover, through quantitative data expressions like typically, generally, frequently, rare, can be avoided. These expressions are not clearly defined and might complicate the comprehension. Besides the interpretation of the qualitative data there will be quantified details (e.g. number of children using the same arguments).

In the beginning, two stripes of sellotape (1,20m and 1,30m long) were taped on the floor (see figure). Initially, the children were asked to state which line is the longer one. After that, they not only had to give a reason for their idea but also had to give an idea about how to proof their answer. The second step included giving the children several tools which helped them to proof their first statement: different wooden sticks and cords, a 30cm long ruler, a set square, a measuring tape, a surveyors tape and a folding yardstick. Use of the terms “longer” and “shorter” the clarification what

property it is on, if one talking about “length”, was previously audited by other tasks.

RESULTS AND INTERPRETATION

While the children were trying to solve that task the following steps could be identified: at first length comparison without any tools, selection of a tool, the application of the tool and the reasoning.

In the following, some parts of the classificatory scheme that was generated to analyse the children`s actions will be explained and interpreted.

First length comparison without any tools

All children followed the request to compare the two lines with each other. It was especially interesting how the children reasoned the results of their comparison. Thereupon, the following four categories could be generated:

- The endpoints were related to each other as if compared directly (n=10).
- “I have seen it” was explained as a substantiation (n=8).
- Imaginary units were counted (n=4).
- 18 children did not give any explanation.

Luka (female; 5;4 years old) can be included into the category *Imaginary units were counted*. She tried to implement the task in the following way:

Interviewer: What do you think, which of these stripes is longer?

Luka: (points her finger in the air) This one!

Interviewer: Why do you think so?

Luka: Because I have counted it.

Interviewer: Can you show me again how you did that exactly?

Luka: (taps her finger along the line and counts imaginary units) 1,2,3,4 40
(doing this, she not only skips some numbers but also not every tap with her finger corresponds to one number).

Luka knows that if two lengths are measured and the figures are contrasted it is possible to compare them with each other. Thus, she equalizes the idea of measuring with the idea of counting. In the course of this, she does not consider equal units.

Selection of the tool

Referring to this solution step it becomes apparent that in this survey¹ fourteen children took a measuring tape, sixteen a folding yardstick, five a surveyors tape and five took a ruler. Solely four children used a stick or a lace as a non-standardized tool. Finally, one child did not use any tool² at all.

Nunes et al. (1993) could observe that most six to eight years old children – provided that there is one at hand – prefer a standardized tool to compare things indirectly. Consequently, the study underlying this article approves Nunes et al. observation for younger children. It can be assumed that children equate the process of comparing things indirectly with a measurement process and thus, while measuring, try to imitate adults. Likewise, it could be possible that the children taking part in the survey did not take sticks or laces because these are ordinary toys, whereas standardized measuring tools could be much more attractive in the children's eyes.

¹ In Zöllner (2012) there are slightly different numbers of children, because there vague situations were not included. In terms of intersubjectivity. These ambiguous cases were discussed later with a team of researchers and, consequently, they can be included here.

² Some children used different tools which have been counted.

Usage of the tool

While analysing the usage of the tool the focus will be on how children apply it, whether they have taken into consideration to use the tool straight and on how the children deal with the endpoint. Here, not only the approaches of those children who used a standardized measuring tape have been regarded but also of those children who used a stick or a lace.

*Applying the tool*³: It is salient that all children applied the tool in a way that the stripe's and the tool's starting point meet each other (n=31). Except for the ruler, the starting point of each tool equals the scale's zero point. Four children tried to apply the tool so that one of its endpoint coincides with the endpoint of the stripe and five children applied it without any visible relation to either the one or the other endpoint.

Process: To compare the lines successfully the children have to put the tool straight on the line. Due to the fact that, when using an inflexible tool, such as a ruler, one automatically uses it in an even way. It is not possible to come up with a statement explaining whether the children have consciously tried to apply the tool in an even way and, thus, those cases will not be regarded. Six of those children who have used a measuring tape tried to use it in an even way, meaning that they tried to use it straight.

Reading of measured values: Thirteen children either tried to read a number from the scale of the tool on their own or asked the interviewer to read it to them. In other words, those children paid attention to the scale's figures and use them as an aid. Whereas others used a certain point as a marker (without paying attention to the figures) or they used their finger. On the other hand, eight children opened the tool so far that it equalled the length of the line. Eleven children completely ignored the endpoint of the line in relation to the endpoint of the tool.

Usage of the tool by the second line: Measuring the second line, ten children did not use any tool (neither the one used for measuring the first line nor another one). Therefore, one could conclude that they observed adults using the meter and, thus, try to imitate these movements without having developed an idea of comparing indirectly.

In observing of how the children applied the tool on the second line it was examined whether they did it in a similar way as they had tried to measure the first line or whether they chose another approach.

It could be observed that twenty-four children used the same tool in the same way to compare with the first as well as with the second line, whereas six children used a different approach for using the tool with the second line. . To determine the result

³ Regarding those children who used several tools, in the analysis the focus was on that solution process which the children favored most. Two children have processed several approaches with the same tool and, thus, both of these processes have been acquired.

twenty children used the same approach as before. Four children did not do that. Six children completely ignored the endpoint of the second line in relation to the endpoint of the tool.

Generally, it can be stated that those children who used a standardized tool were more successful in comparing the lines indirectly than those who used an arbitrary tool. Only one of these children that had used an arbitrary tool gave an explanation. Indeed, this explanation does not refer to the process of measuring itself but the child tried to correlate the endpoints as if it is a direct comparison.

Again, this result equals the ones that Nunes et al. (1993) observed in their survey with older children. This investigation showed that children are more successful with a standardized tool even though – accordingly to its construction – they did not use it correctly. This approach becomes visible when regarding Elsa's (female; 6;3 years old) approach:

Elsa: (opens the folding yardstick and tries to apply it in a way that its starting point coincides with the line's starting point (130cm). Then she uses the edge of her hand to mark the line's endpoint)
So far, that much.

Elsa: (still holding her hand on the folding yardstick, she walks towards the other line (120 cm) and applies it so that the "handmarked" point equals the starting point of the line. The yardstick's endpoint is above the line's endpoint) Well no, they are not of equal length!

Interviewer: And which one is the longer one?

Elsa: This one! (points to the line which is 130 cm long)

Elsa chose a folding yardstick to compare the stripes indirectly. She used it very proficient but, nevertheless, as if it was a non-standardized tool. This means that, considering the fact that she used her hand as a marker, the scale on the yardstick is not relevant to her at all.

Conclusion

Finally, after measuring the children have not only been asked again to compare the length relation of the two line, but they also have been asked to reason their thoughts. Some children (n=9) came up with their first explanation again – which shows that using a tool did not make them choose another reason to describe their result. Ten children did not reason their result at all. Twelve children reasoned their result with the aid of markers and a direct comparison. With the help of a marker, a figure or by adjusting the tool the children tried to depict the first line on the tool. After that, they compared their result with the second line and deduced their outcome. Two children gave up this task before they came to an end. Seven children reasoned because of the larger/ smaller relations between numbers, meaning that those children used a standardized tool and, if necessary, they asked someone to read

the figure to them or they read it themselves. After that, they compared those figures to be able to conclude the stripes' lengths.

Luka can also be included into this category. Due to the fact that both numbers (130 and 120) exceed her active range of numbers, she always asked, after having measured both lines with the measuring tape, which of the two numbers is the bigger one. Nevertheless, she correctly correlates the bigger number with the longer line. As this example shows, it is noticeable that Luka accomplishes a “transfer within” (Schmidt & Weiser 1986) from the numbers to lengths.

Summary

Summarizing the results and referring them to the aspects that have been emphasized before the following results become apparent: The participating four to six years old children had no difficulties to clearly identify the different lengths and their linear character at this task. This is not surprising because concerning lines, the linear character and the usage of the concept “length” is clear. All children of that survey could easily compare objects directly. Some children had the idea: Measuring equals counting.

As it was described above, some researchers claim that developing an idea about transitivity is the most important aspect in order to be able to compare things indirectly (Piaget et al, 1975). Indeed, observing the children's actions it becomes obvious that none of them employs transitivity in its mathematical sense (if $A > B$ and $B > C$ then $A > C$). Moreover, the tool has the function of representing the length of the first line. In the following, the children compare the second line directly with the aid of their chosen tool. In the case that the children consider the figures on their standardized tool, they use them as a marker. Then, they either follow the same approach as described above or, as Luka did, they compare the two figures and thus, identify the longer line. Consequently, in these situations those children do not think deductively and transitively. Concerning the conservation the following two aspects could be seen:

Shifting a rigid tool (a stick, a ruler or a yardstick), none of the children wondered about the fact that its length always stayed the same.

Nine children did not pay attention to the course (lace and measuring tape). Regarding those children it can be assumed that they either have no idea about conservation at all or that they cannot recognize the conservation in connection with this situation.

In order to compare an object indirectly, these young children prefer standardized measuring instruments and are more successful when using standardized measuring instruments. They use seldom shorter tools in order to compare indirectly, regardless of whether it is standardized or not. The unit iteration of a shorter tool was not observed.

In order to describe their result the children were able to choose correct adjectives. Due to the fact that the interviewer could ask the children in case of vagueness it can be assumed that the children understood the relational terms correctly.

DISCUSSION AND CONCLUSION

In conclusion it can be stated that many of the competences considering normative aspects for an indirect comparison can be observed by four to six year old children.

All children had an idea on how to solve the task and it became obvious that concerning comparing items indirectly children already have acquired some competences and thus do not enter school as tabula rasa. Many children already have experiences with comparing lengths. Dealing with length (Castagnetti & Vecchi, 2002), especially indirect comparison, can therefore constitute a challenging task for young children.

Looking on instruction about length this study reveals that emphasizing the unit iteration before using a standardized tool does not correspond the children's natural approach. These insights can provide a basis for an instruction approach which is orientated on children's own constructions.

CUBES OF CUBES

Paola Vighi & Iginio Aschieri

Mathematics Department, University of Parma, Italy

We present the three dimensional version of a play that is the topic of a paper sent for submission to Working Group 13. Its aim is to complete the presentation made in WG13, showing the potentiality of the play when we pass from 2D to 3D dimensions. In Cerme 8 session poster, the poster will be presented accompanying it with the same equipment utilised during the experimentation. The study of pupils' behaviours in front of the task furnishes some examples that prove the possibility of an early mathematical activity of generalization.

Keywords: kindergarten, play, generalization.

THEORETICAL FRAMEWORK

Generalization is often cited as typical form of mathematical thinking, but without using a definition or specify its meaning.

In her analysis of the act of understanding, Sierpinska (1994) considers four basic mental operations: identification, discrimination, generalization and synthesis. Her definition of generalization is the following:

“Generalization is understood here as that operation of the mind in which a given situation (which is the object of understanding) is thought as a particular case of another situation. The term ‘situation’ is used here in a broad sense, from a class of objects (material or mental) to a class of events (phenomena) to problems, theorems or statements and theories” (p. 58).

Hejny (2004) write also:

“The generalisation of isolated models (experiences and pieces of knowledge) is determined by finding connections between some of isolated models. This web is the most important product of the stage of the isolated models” (p.5).

The authors present and study an example of generalization that appears during a play. It is well known that the play can promote logical and mathematical competences. Schuler (2011) highlights that:

“[...] *play and relationship of playing and learning* have to be explored more closely when talking about mathematics for the early years” (p.1912).

In particular, in the play utilised in this research, an important role is done to row-column arrangements. Rožek & Urbanska (1998) studied in depth this topic:

“The children have a different awareness of the rows and columns arrangement. Some of them prefer rows, some of them columns. It appears that it was difficult to see both rows and columns, especially for young children” (p. 304).

THE ‘CUBE OF CUBES’ CONSTRUCTION AND ITS PROPERTIES

The play named “Cube of cubes”, proposed to pupils of kindergarten (5-6 years old), is based on the construction of a ‘palace’ of three floors (a cube $3 \times 3 \times 3$), following these rules: “In each wall face it needs to have three different colours in each row and in each column”. Pupils in groups following the indications suggested from the teacher. The materials used are: 27 wooden coloured cubes (9 red, 9 yellow, 9 blue) (Fig. 1a), their wooden support, named from children “palace” or “house with a lot of floors”, and a wooden rotating disk (Fig. 1b) to facilitate gestures and the observation. In a second time, teacher removed the support and she putted the cubes one near to the other (Fig. 1c).

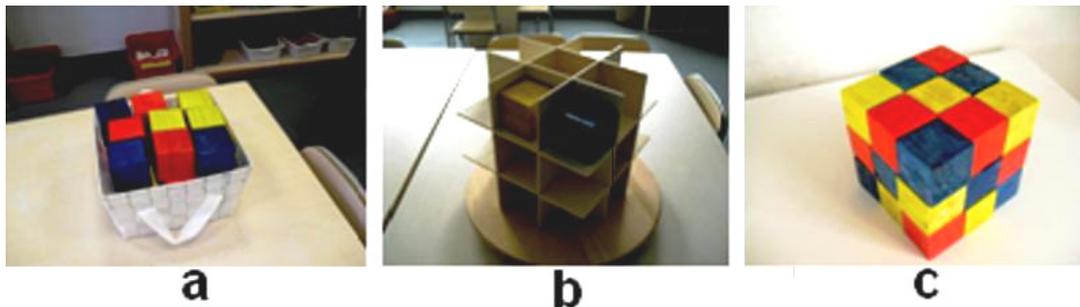

Figure 1: Materials and an example of ‘Cube of cubes’.

Observing the final cube, children noticed a lot of properties, in particular they found a theorem: “In the cube there is an “internal monochromatic diagonal” and the other diagonals of cube are of three different colours”. It is an example of generalization from 2D to 3D (the 2D version of the theorem is in Vighi paper, WG13, Cerme 8).

Figure 2: The monochromatic diagonal

WG14: UNIVERSITY MATHEMATICS EDUCATION

Elena Nardi¹

Irene Biza², Alejandro S. González-Martín³, Ghislaine Gueudet⁴, Carl Winsløw⁵

¹University of East Anglia, ²Loughborough University, ³University of Montreal,
⁴University of Brest, ⁵University of Copenhagen

WG14 (*University Mathematics Education*, hereafter UME) was introduced in CERME7 (Nardi, González-Martín, Gueudet, Iannone & Winsløw, 2011) in recognition of its distinctiveness as an area of mathematics education research: within UME, researchers in mathematics education are often teachers of mathematics and in recent years the number of mathematicians specializing in UME has been growing. Furthermore, as the papers presented in CERME7 and CERME8 demonstrate, theories and methods from research on mathematics teaching at other levels must and do find specific adaptations within UME.

The WG14 Call for Papers invited contributions from a wide range of research topics. These included: mathematical reasoning and proof in university mathematics; challenges for teaching mathematics at university level (including the perspectives of university teachers); the role of ICT tools (e.g. CAS) in the teaching and learning of university mathematics; transition issues “at the entrance” to university studies of mathematics, or beyond; novel approaches to teaching Calculus and Linear Algebra; the teaching and learning of advanced university mathematics topics (beyond Calculus and Linear Algebra); challenges of teaching mathematics to students in non-mathematics degrees; assessing the learning and teaching of mathematics at university level; and, theoretical approaches to the study of teaching and learning mathematics at university.

This report draws on the presentations, reactions to, and discussions of the 21 *Research Papers* that were accepted for presentation at the conference and publication in the proceedings. In the proceedings there are also six *Short Contributions* to WG14, most based on posters presented and discussed at the conference. This report also draws briefly on these. Its structure is based on that used for the WG14 presentation on the final day of the conference. This presentation was structured around four broad themes: *Transitions*; *Affect*; *Teacher practices*; *Mathematical topics*. In what follows we present the papers clustered under each of these four themes. We do so with a focus on *theoretical perspectives* and *research paradigms* underlying the research and on key *results* presented in the papers. We conclude with a few thoughts on issues of rigour and quality that emerged from the discussions of papers across the four themes.

Transitions

A substantial number of WG14 papers raised transition as an important issue in students' learning of mathematics at university level as well as in teaching practices and approaches. In this sense transition, as a key issue, runs across many of the

papers. Three of these studies however focused exclusively on transition. Two focused on the transition from secondary to tertiary education and proposed approaches that can enhance students' first year experiences – teaching for students' enculturation in the mathematical thinking and teaching for students' conceptual understanding. The third study discussed the transition at the other end of the students' experience at university, namely the transition from university mathematical studies to secondary education teaching, and analysed the nature of the mathematical knowledge in these two institutions. All three papers deployed qualitative approaches (interviews and observations). Specifically:

Hoffkamp, Schnieder & Paravicini highlight the importance of students' enculturation in the foundations of mathematics and propose a teaching approach that is based on the philosophical aspects of mathematical epistemology and introduces first year university students to mathematical reasoning, argumentation and proof. In the paper the design and the rationale of a math-bridging course based on the above assumptions are presented with clear recommendations for further research.

Breen, O'Shea & Pfeiffer report a project in which they designed unfamiliar to the students tasks with the aim of promoting conceptual understanding and developing mathematical thinking skills. These tasks were employed with a group of first-year undergraduate Calculus students. In the paper, the authors draw on the evidence from the interviews with five students in order to highlight that the tasks were beneficial in the development of students' conceptual understanding and suggest that unfamiliar tasks are useful in the transition from school to university mathematics.

Finally, *Winsløw* focuses on students' transition from university (as students of mathematics) to secondary school (as mathematics teachers). The paper proposes a theoretical model for the analysis of this transition based on the Anthropological Theory of Didactics and analyses the changes of mathematical knowledge in relation to the individual who occupies a position (student or teacher) within an institution. The model is exemplified in the institutional context of a capstone course and in the case of exponents and exponential functions.

Affect

The number and quality of WG14 papers that focused on issues of affect is indicative of the upsurge of interest in research in this area. The five studies reported under this cluster focused on a range of socio-affective issues that included: student perceptions of and expectations from mathematics-related studies; the concept of interest in university studies of mathematics; university students' preferred ways of working and learning in mathematics; differences between beginners and experienced students' approaches to learning mathematics; and, students' perceptions of themselves as capable mathematics learners. The theoretical perspectives underlying these studies ranged across sociological and psychological perspectives and the research paradigms espoused included an equally broad assortment of qualitative, quantitative and mixed methods approaches. Specifically:

Bergster & Jablonka deploy Bourdieu's three forms of cultural capital (embodied, objectivised, institutionalised) to explore the rationale and expectations underlying engineering students' choice of study. They report that mathematical studies are seen as a means to access economic power and master the use of a versatile and potent thinking tool.

Liebendörfer & Hochmuth illustrate the potency of using Self Determination Theory (autonomy, competence, social relatedness) to analyse interview data that explore perceptions of interest in university studies of mathematics. They do so through the illustrative case of data from one student.

Sikko & Pepin present a survey of university students in their second year which explored the teaching and study methods from their first year that the students found most effective. They report the proliferation of active and collaborative ways of working in the student responses; and, the limited appreciation for lectures.

Stadler, Bengmark, Thunberg & Winberg deploy Stadler's triad (mathematical learning objects; mathematical resources; students' actions as learners) to explore differences in approaches to learning mathematics between beginners and experienced students. The statistical analyses reported here (descriptive and inferential) show that beginners rely heavily on the teacher, while experienced students re-orient themselves from the teacher to other kinds of mathematical resources, such as peers and Internet-based resources.

Finally, *Toor & Mgombelo* explore how undergraduate mathematics students perceive themselves as capable mathematics learners and whether differences exist between male and female students' perceptions. The quantitative analyses establish the existence of gender differences. The qualitative data analyses reveal that participant construct perceptions of themselves as capable mathematics learners from two positions: direct experience and ideal images of mathematical ability.

Teacher practices

Research on mathematics teaching has increasingly focused on teachers' roles, methods and knowledge, as evidenced in CERME congresses by the growing number of papers dealing with teachers' practices and teacher education (WG17). It is only natural that UME research develops a similar direction, with a focus on everything that could make teachers at this level specific – engagement in research, relative autonomy in terms of methods and contents to teach, etc. WG14 received five papers dealing explicitly with small-scale studies of university teachers.

In two of these papers, the teacher involved was the paper author, who adopts a reflective practitioner (insider research) approach:

Biza reflects on her role as a novice teacher of statistics in a British engineering programme. Based on three episodes from practice, she explains how involvement in different communities of practice – including her activity as a mathematics education researcher – has contributed to shape her approach to this teaching task.

Nardi analyses the challenges of teaching a graduate course on mathematics education to students with a variety of backgrounds, including bachelor degrees in pure mathematics and native languages other than the language of instruction. She also outlines key didactic techniques and principles to cope with these challenges.

The three remaining papers offer small-scale studies of how teachers prepare and deliver their teaching, involving more ethnographic and sociocultural approaches which include observation, interviews and other forms of data collection:

Jaworski explains the use of Niss' competency framework to describe the aims and effects of an inquiry-oriented development project, and in particular the design of a specific set of tasks aiming to deepen engineering students' grasp of the notion of function. Observations and analyses of classroom practice illustrate this further.

Gueudet studies a university mathematics teacher's use of digital resources as he prepares and delivers a course on mathematics for computer science students, and points out the importance of internet-based platforms to enable *shared* documentational work related to university teaching of mathematics.

Pinto examines two lessons on calculus given by two different instructors, based on the same lesson plan. Based on observations and interviews, he demonstrates the relevance and importance of teachers' resources, beliefs, attitudes and goals, for explaining the substantially different development of the two teachers' lessons.

Mathematical topics

In a group like WG14, some of the research works presented naturally a focus on the teaching and learning of specific mathematical topics. We observed it here once again, with topics that were already present in CERME7: functions, proof, and linear algebra. Furthermore, new topics appeared in CERME8: infinite series and abstract algebra. Some of these papers are written by mathematicians, using a mathematical, epistemological, or historical analysis, and drawing on their teaching experience. Others present research that makes use of different theoretical frameworks, and methodological tools, to analyse students' difficulties with these specific topics, to better understand the teaching of a specific topic and the consequences of this teaching, or to formulate propositions for the design of teaching to overcome these difficulties. The range of approaches varied from developmental ones (such as concept image – concept definition), to models for abstraction (such as the RBC model), to analysis of discourse (commognitive approach) and the consideration of institutional matters (anthropological approaches).

González-Martín retains a theoretical perspective articulating Anthropological Theory (an institutional perspective, Chevallard) and the concept of didactic contract from the theory of didactic situations (Brousseau). Textbooks, and teachers' practices, shape the institutional didactic contract and in particular its rules about the teaching of infinite series. When confronted with tasks which do not obey these rules, the students produce inappropriate answers.

Schlarmann's work concerns the concept of basis. Referring to the work of Skemp, she considers that the conceptualisation process, taking place during the learning of the concept of basis, lead to the development by the students of mental structures. She draws on the triadic sign model of Peirce to build a methodological tool to study these mental structures. She illustrates the use of this tool for the analysis of data concerning two students with different mental structures.

Hausberger focuses on the concept of homomorphism. This concept, he argues, is abstract and difficult to learn for students; a test, for third year students, confirms this statement. He proposes an epistemological analysis, evidencing that the learning of homomorphisms requires a clear view of what a “structure” is, in the context of abstract algebra, in order to understand that homomorphisms are structure-preserving functions. He formulates propositions for teaching supporting this point of view.

Berman, Koichu and Shvartsman also develop a precise epistemological analysis, concerning the concept of equivalence of matrices. They articulate this analysis with a conceptualisation of understanding, drawing (similarly to Schlarmann) on the work of Skemp, and distinguishing between formal, instrumental, representational, relational and applicational understanding. They propose different tasks, which should contribute to the development of each form of understanding. They consider in fact that equivalence relation is a “threshold concept” for linear algebra.

The notion of *threshold concept* is at the heart of the work by *Pettersson, Stadler and Tambour*, who analyse the development of students' understanding of the concept of function. A commognitive approach is deployed towards the analysis of the variations in the discourse of the students, and the identification of the discursive elements employed by the students – mainly an expansion in the use of mathematical words and visual mediators.

A commognitive approach was also used by *Viirman* to study the concept of function, this time from the perspective of teaching. The discourse of three different teachers is analysed, and inferences about the learning that can be achieved are made. The main differences in the discourses appear in the emphasis put on the use of different representations of functions, as well as on the use of more process-oriented or more object-oriented discourses.

The concept of function was also the main focus of *Hyvärinen, Hästö and Vedenjuoksu*. Using a developmental approach, and through a longitudinal study making use of questionnaires, their work focuses on students' development of the concept of function and on their awareness of this development. Their theoretical approach combines the concept image – concept definition construct with tools that emphasise self-awareness. Their main results indicate that, during the first year at university, students' construction of the concept of function evolves. However, many students are not aware of this development, and, in some cases, students' estimation of their proficiency did not match their proficiency as evidenced in their performance.

Finally, the notion of proof, essential in Calculus, was addressed by *Alvarado Monroy and González Astudillo*. In particular, they studied the construction of definitions as a prerequisite for proof. Their paper presents the analysis of an activity developed in the classroom, making use of interactions and group work. The authors consider the RBC-model to describe the process of reconstruction of a definition. Their main results indicate that students had difficulties to manage mathematical language correctly, and in many cases the definitions they produce are erroneous. In this case, the teacher's help was needed to propose constructive definitions.

A concluding note on rigour and quality

Across presentations, reactions-to and discussions of the WG14 papers a range of issues emerged that concerned issues of *rigour and quality* in UME research. We noted that often in UME practitioner research, subject and object of research can be precariously *and* potentially close and that the collection of data may often rely exclusively on practitioner reflection. This generates the need for triangulation, for transparency of data interpretation, and for acknowledging, and aiming to eliminate, bias. We also noted that results are often heavily dependent on the context and vary significantly across local institutions.

We also identified the challenge of theoretical coherence: 'is the choice of framework adequate for addressing the research issues in question?' we asked. And, in the cases where a combination of frameworks was selected, we asked 'is this choice underlain by coherence and compatibility?'. In the case of quantitative approaches we often recommended caution in the interpretation of statistical data. We also acknowledged that UME data frequently provide the ground for apparently self-evident claims, or simply a more nuanced account of empirically known facts. We noticed that authors, particularly of brief papers such as the ones presented in CERME, understandably choose to present an isolated slice of data from larger studies and that, in these cases, a broader contextualisation of the paper in the larger study is necessary.

We felt that results from small-scale studies usually need further verification and that in CERME papers results sometimes are emerging, therefore are not yet ready for more formal dissemination. Apart from smallness of sample, UME studies often rely on opportunistic sampling and researchers need to acknowledge the potential limitations of this reliance. In this sense there was broad recognition of the need to verify conjectures in other contexts. Overall however we were content with the way in which UME researchers choose WG14 as a platform for presenting analyses from ongoing and often daring and innovative work.

INTERACTIVE RECONSTRUCTION OF A DEFINITION

Angelina Alvarado Monroy

Juárez University of the State of Durango

María Teresa González Astudillo

University of Salamanca

For future mathematicians to be able to construct proofs, they must understand what a correct mathematical definition is and how to use it properly. In this sense, a task was proposed to college students for reconstructing the definition of even numbers through discussion in small groups and then a socialization guided by the teacher was carried out. Both interactions were recorded and analysed entirely with the RBC-C model (Schwarz, Dreyfus & Hershkowitz, 2009). The results show that the students had difficulties to manage mathematical language correctly and that the definitions they produce are erroneous; they needed the teacher's help to propose constructive definitions.

INTRODUCTION

One of the most important aspects in the process of doing proofs is language accuracy, which means realizing how arguments are presented and how concepts are defined (Vinner, 1991; Mariotti & Fischbein, 1997). This requires students to have a clear idea of what a mathematical definition is. Pinto & Tall (1999) indicate that students handle formal definitions in two different ways: by giving them meaning through consideration of examples or by extracting their meaning through manipulation and reflection.

Regarding ways of defining, De Villiers (1998) classified definitions considering ones that define *descriptively* (a posteriori), if “the concept and its properties have already been known for some time and is defined only afterwards... A posteriori defining is usually accomplished by selecting a subset of the total set of properties of the concept from which all the other properties can be deduced” (De Villiers, 1998, p.250). The other way is to *define constructively* (a priori). This takes place when a “given definition of a concept is changed through the exclusion, generalization, specialization, replacement or addition of properties to the definition, so that a new concept is constructed in the process” (De Villiers, 1998, p.250).

These forms of defining are distinguished by their function. Whereas the function of a posteriori defining is to systematize existing knowledge, the main function of a priori defining is the production of new knowledge.

When students define, they appeal to two types of generalisation: result pattern generalisation (RPG) or process pattern generalisation (PPG) (Harel, 2001). The first one is based on the regularity in the results, obtained, for example, by substitution of numbers in a formula whereas the other is a way of thinking in which one's conviction is based on the regularity found in processes.

CONCEPTUAL FRAME

Schwarz, Dreyfus and Hershkowitz (2009) defined Abstraction in Context (AiC) as “a vertical activity for the reorganization of previous mathematical constructs within mathematics and by mathematical means so as to lead to a construct that is new to the learner”(p. 24).

A process of abstraction has three stages: the need for a new construct, the emergence of a new construct and its consolidation. The need may arise from an intrinsic motivation to overcome obstacles and contradictions, surprises, or uncertainty. In the second stage the new construct emerges by means of three observable epistemic actions: Recognizing (R-actions) that a specific prior construct is relevant to the problem or situation at hand; Building-with (B-actions) acting on or with the constructs recognized for achieving the goal of understanding a situation or solving a problem; Constructing (C-actions) to fit and integrate previous constructs by vertical mathematization to produce a new construct. Constructing refers to the first time the new construct is used or mentioned by the learner. In this process, Recognizing is nested within Building-with actions, and these in turn in the Constructing actions that can be nested in other Constructing actions of higher level. Finally, the third stage, corresponding to Consolidation, is a long-term process that occurs when the construct is mentioned, constructed or used after a constructing action is observed. This last stage is characterized by personal evidence: self-confidence, immediacy, flexibility and care when working with the construct (Dreyfus & Tsamir, 2004) and also when the language is increasingly more accurate (Hershkowitz, Schwarz & Dreyfus, 2001), although Kidron (2008) and Gilboa, Dreyfus and Kidron (2011) consider that the increase in language precision is characteristic of the construction stage itself and not just the consolidation stage.

In AiC these epistemic actions are known as the RBC model (Recognizing, Building with, Constructing) and the RBC-C model with the second C corresponding to the consolidation phase.

Below we present an activity about the process of reconstructing the definition of simple mathematical concepts as a prelude to using these concepts in a proof. Our objective was to describe how this process is developed in order to reach a minimal mathematical definition (Zaslavsky & Shir, 2005). Although the mathematical concepts proposed to the students were elementary, this was necessary because the teacher considered that some preliminary work with definitions was needed, in view of the difficulties faced by the students with the use of mathematical language when they were proving.

We analysed the production of various small-groups regarding different definitions. Specifically, in this paper we present the productions of one of these groups concerning the concept of even number, analysed according to the AiC model (Hershkowitz, Schwarz & Dreyfus, 2001). To get an overall picture of the entire process followed, we also present a whole class interaction led by the teacher.

Thus, the question this study aims to answer is: What are the epistemic actions that arise in the course of small group and whole class interactions or during the process of reconstructing a minimal definition of even numbers?

METHODOLOGY

The activity described below is part of a broader research about the introduction of mathematical proofs to university undergraduate students of mathematics. In this context sets of activities have been designed and experimented in a university classroom during eleven sessions. The activities were designed by the researchers, who explained their purpose and aims in advance to the teacher. The teacher was neither of the researchers and he put the activities into practice in his regular classroom. The activity in this paper was developed in the first session, in order to know how definitions are handled and generated.

The construction of proofs requires an understanding of the concepts involved and the appropriate use of their definitions. Different researchers have found that students do not understand the content of relevant definitions and how to use them for writing proofs (Moore, 1994). In an exploratory study (Alvarado & González, 2010) it was found that students do not use the definitions of mathematical objects to prove a statement in which they are involved; rather, they use an example of the object, a formula that represents it or some characteristic of the object. Edwards and Ward (2004) suggest that the special nature of definitions should be treated in introductory courses about proofs as a content in its own right and suggest that its effectiveness must be investigated in future research.

Specifically, in this activity, students had to reconstruct definitions for already known mathematical concepts or objects through negotiation in small groups and then they had to share their definition in a whole class discussion mediated by the teacher. The construction process carried out in each of the teams allowed the students to verbalize their ideas, thus making it possible for us to analyse the evolution of this process in the light of the RBC-C framework. This experiment involved 23 students that were studying the first semester of Applied Mathematics in the University of Juarez in Mexico. The group was divided into 9 small-groups of 2 or 3 students.

DATA ANALYSIS

Below we describe, characterize and analyze the interactions that took place in one of those small-groups (team X) as they tried to reconstruct the definition of even numbers followed by whole group socialization influencing their small group work. During this task we could see that although some mathematical concepts are familiar to the students, they have difficulties to pose a correct definition; instead, they generate examples as a help to reconstruct the definition.

Small-group interactions

In the dialogues included in this section, only students participate. The contributions of each of them are consecutively numbered to refer to them easily in the text. At the

beginning of the interaction, the students suggest a rather poor definition [1]. They evoke the concept of division (R-action) and relate the concept of even numbers to composite numbers using some examples to reconstruct the definition of even numbers to show their truth.

- [1] Then an even number is one that can be divided by itself.
- [2] And others.
- [3] And others?
- [4] Yes, because for example 10 can be divided by itself, by 5, by 2.
- [5] ... the bigger the number the more numbers it can be divided by.
- [6] Look, another even number.
- [7] 18.
- [8] 18, by 18, by 9, by 2.
- [9] What else?

The generalization process being used is based on patterns of results (RPG) and not on processes (PPG) (Harel, 2001). The above examples led them to guess a more appropriate definition [10] which is verified again (B-action) with other numbers.

- [10] All even numbers can be divided by 2, right?
- [11] Yes, I think so.
- [12] By 2 yes, 4 yes, 6 also, 8, 14 also.

By linking (B-action) the above [1 and 10] with the fact that 2 is a prime number [17, 18 and 20] they produce a “definition” [14, 19] in which similarities with the definition of prime number are seen: both of them have two divisors [19 and 20]. This is caused by their difficulties with the use of quantifiers.

- [13] So even number. [he writes]
- [14] Is that which is divided, which can be divided by ... oh no!
- [15] By itself.
- [16] And another number.
- [17] The number 2 we did not say.
- [18] By 2, right?
- [19] By itself and by 2.
- [20] By 2, isn't it? It's a prime number.

The definition produced [21] is obtained by a B-action to verify similarities between the examples found earlier.

- [21] Yes that's right [pointing to the examples above], all numbers can be divided by themselves and by 2.

Another student suggests another definition [22] which is considered a C-action (C_{X0} as this is the first C-action shown by group X), but their peers did not take it into account.

- [22] Even numbers are those who go two by two. Because 4, 6, 8 go two by two.

Similarly, we include the wrong definition they proposed of odd numbers, which is accepted [23] without discussion by the other peers. It can be seen the similarity with the definition of even numbers and the confusion with prime numbers.

- [23] You can only divide it by itself and by 1.

Whole-group interactions

Small-group work allowed for an interaction that simultaneously provided some progress, but also some limitations. Some of these limitations would be overcome during the whole-group discussion because it addressed aspects or views not suggested during the small-group interactions, such as an input from a student of small-group X which was not taken into account, and would now be taken up by the teacher. During the socialization the teacher played an important role supporting the development of a mathematically productive discourse and also progress in the learning processes. Sometimes the teacher constructed the definitions by himself without allowing the students to modify their proposals.

To organize the discussion, the socialization starts by presenting the definition contributed by small-group Y. Then the definition of X is discussed, and while extending it, the production of T comes into play. Finally, we discuss the productions of small-groups V, W and Z which allow the construction of another definition.

This began with a spontaneous and intuitive notion: a list of numbers from zero that is increased by 2. This C-action C_0 [24] built by small-group Y is equivalent to a C-action that occurred during the interaction in small-group X (C_{X0} [22]). Demanding an explanation of the meaning with the purpose of clarifying the language used [25] constitutes an R-action. Students will refine the language using different words and examples that serve as B-actions giving rise to a C-action [31] C_1 : a definition of even numbers that is neither accepted nor rejected pending further "definitions".

- [24] Student: They are the numbers that ascend from zero 2 by 2. [small-group Y]

- [25] Teacher: "Ascend", what does this mean?

- [26] Student: That they go up.

- [27] Teacher: Okay, explain.

- [28] Student: That we are adding and adding.

- [29] Teacher: For example.

[30] Student: 2, 4, 6...

[31] Teacher: Okay. So they are the numbers to which you keep adding 2 beginning with zero. Any other input?

The teacher shows that this definition can be completed and formalized. It should be noted that while the original idea of the students is respected, the teacher used the role of authority to extend the mathematical knowledge in a *constructive way* of defining (De Villiers, 1998).

[32] Teacher: It turns out that we only get positive even numbers, so to complete the definition with the negative even numbers, I have to subtract to the left.

[33] Teacher: But that thing, of using “ascend” – it’s a very ambiguous word. Let’s get used to the fact that in mathematics we must be very precise.

[34] Teacher: In this case we can define it as the sequence of integers where starting from zero we add and subtract two units successively. This would look like this [he writes on the blackboard] $\{\dots -8, -6, -4, -3, -2, 0, 2, 4, 6, 8\dots\}$.

[35] Teacher: It can also be formalized as $\{0 \pm 2n / n \in \mathbb{Z}\}$. This means that n is an integer or that n varies within the integers.

An R-action takes place when it is recognized that negative numbers must be included and that appropriate language must be used. This is concluded with two C-actions, C_2 [34] and C_3 [35]; the second as an extension of the first but the teacher does not encourage the interaction with students to build the definition.

Returning to the definition produced by X, the teacher tries to adjust it to produce a more economical definition because it is not necessary to include the number 1 in the definition.

[36] Student: They are the numbers that are divisible by themselves and by 2. [small-group X]

[37] Student: And by 1.

[38] Student: And 1.

[39] Teacher: Let’s go over that again. Do we need to say that they “are divisible” by themselves and by 1? In fact, any number can be divided by itself and by 1. So this is not an exclusive feature for even numbers. Let’s see, what distinguishes the even numbers?

This last statement and the students’ answers to the teacher’s suggestions are an attempt to clarify the language to formulate a more operational definition.

[40] Student: That even numbers can be divided by 2.

[41] Teacher: Right, but then we have a problem, for example, I can divide 3 by 2, can’t I?

- [42] Student: Yes.
- [43] Teacher: Then the word “divided by” must be refined.
- [44] Student: The matter is that we must get an integer.
- [45] Student: Yes, a number that has no decimal.
- [46] Student: That gets me zero as remainder. [small-group V]
- [47] Teacher: ...A number that when divided by 2 the remainder is...
- [48] Student: Zero.

A B-action [40] is activated when an exclusive feature of the even numbers is mentioned. During this time [41-43], with R-actions, a negotiation of the meaning of the term “can be divided” is elicited because for some students it means that the quotient must be an integer [44 and 45], which does not guarantee that the remainder is zero [46]. This expression appears repeatedly in the interactions of most of the small-group work with the idea of expressing that the remainder of a division must be zero. This can be attributed to the fact that when 3 is divided by 2, for example, it is common to hear young children say “can’t be done” or “it won’t fit”, and thus the spontaneous use of language is maintained until university level.

Moreover, although the contributions of small-groups X and Y are discussed, the teacher takes advantage of this discussion to include another definition produced in small-group T; when this happens a new C-action C_4 [47 and 48] takes place.

Finally we discuss what small-groups V, W and Z did to build another definition refining the language.

- [49] Teacher: Let's see, what happens if I divide 10 by 2, what will it be? How much is left over?
- [50] Student: 5 and zero as remainder.
- [51] Teacher: So I say that it is an even number. Remember when you were in elementary school you were told: “check your calculations to see if they are correct”. What operation did you have to do?
- [52] Student: The inverse operation of division is multiplication, adding what is left over.
- [53] Teacher: For example here, in this case $2 \times 5 + 0$, and since the remainder is zero, we just write 2×5 and say that 10 looks like 2×5 . So, what form do the even numbers take?
- [54] Student: 2 times “something”.
- [55] Teacher: Does 12 take the form 2 times “something”?
- [56] Student: Yes 2 by 6, so it is even.
- [57] Teacher: Does 13 take the form 2 times “something”?

[58] Student: No.

[59] Teacher: So, even numbers, what do they look like?

[60] Student: 2 times an integer.

[61] Teacher: Well, then we have another definition, even numbers are those that take the form $2 \times n$ where n is an integer [writing on the blackboard] Even numbers look like $\{2n / n \in \mathbb{Z}\}$. The $n \in \mathbb{Z}$, this is interpreted as n ranging over the integers or n belonging to the integers. This is a clear way to say it and if this doesn't happen, what occurs?

[62] Student: Well, is not an even number.

Although previously were obtained definitions of even numbers accepted by the group, now the idea is to achieve a correct definition obtained constructively. This is how the C-action C_5 [61] takes place, built on B-actions oriented and provoked by the teacher presented as a string of examples in which transitions are made from a particular example [49], to a process [51], to generic constructions [59, 60] via a check that ensures that non-examples are identified and ruled out [57, 58].

The following diagram summarizes the progression between the different definitions produced by the teams to reach more operational definitions.

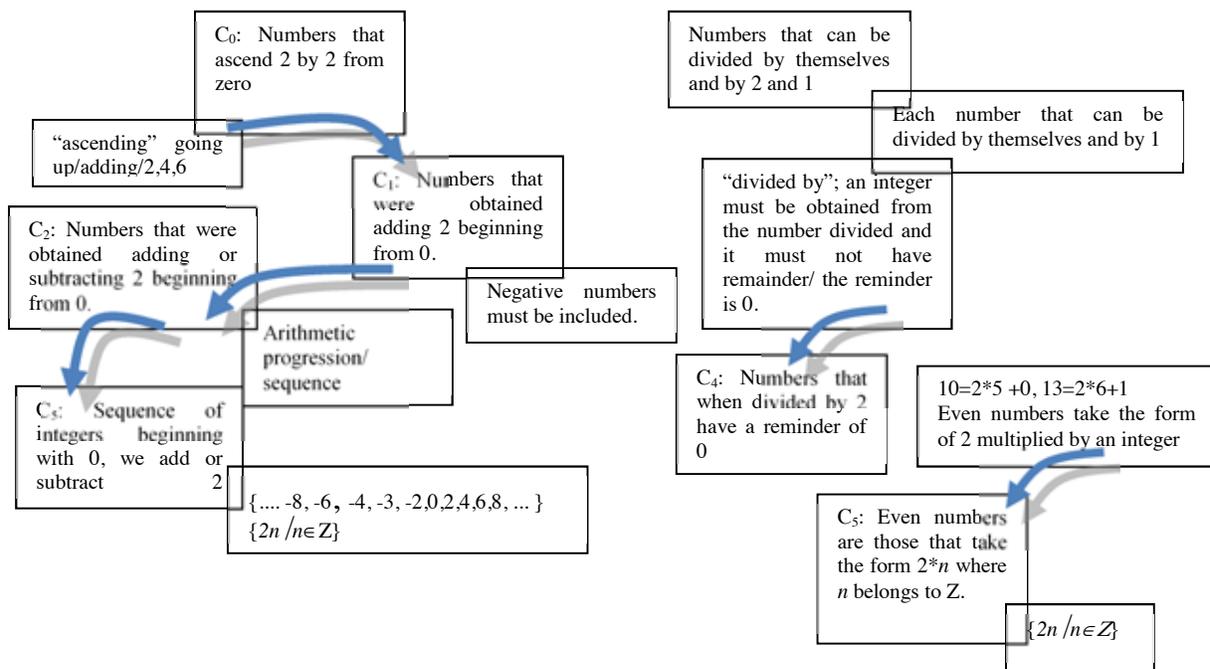

Diagram 1. The process of generalizing the definition of even numbers in whole-class.

The confusion between different types of numbers and the difficulties managing their definitions is present when solving other activities. For instance, when these students had to prove that "For any whole number n , $n^2 + n + 41$ is a prime number" they related prime numbers with odd numbers saying things like "3 times 3 equals 9, and 3 are 12, plus 41 are 53, 53 is an odd number so is prime".

CONCLUDING REMARKS

The RBC model is a tool for analysing the process of reconstructing a definition from a more informal view of mathematics to make definitions that require more formal reasoning (Gravemeijer, 1999). Even in the simplest situations, students use examples as verifiers and conjectures derived from the results rather than processes (Harel, 2001). This is shown essentially in the B-actions. Vinner (1991) states that the development process of a concept involves two cognitive mechanisms: identifying similarities and distinguishing differences. However, students look only at the former and disregard the latter completely. Some difficulties with quantifiers are perceived, resulting in the formulation of inconsistent definitions in the small-group interaction.

When the teacher led a whole-class discussion it was possible to produce a definition focused on the generalization of patterns based on the regularity (PPG) and not obtained from each example (RPG) (Harel, 2001). In this sense Harel (2008) points out that only the students that generalize across PPG suggest the required arguments for the construction of proofs by mathematical induction. In this sense, the definitions proposed by students in small-groups were mainly obtained descriptively whereas during the whole-class socialization sometimes the definitions were obtained descriptively and other times in a constructive manner (De Villiers, 1998). The analysis of the role of the teacher during the whole-group interaction will form the basis of another study.

Finally, we argue that negotiated defining in small-groups seems to help the students to extend their understanding of the meaning of the terms they use. On the other hand, our results suggest that defining should be taught and learned in school classrooms in order to improve the mathematical communication, instead of assuming that students already have those skills. During all the teaching process the students realised the importance of having correct definitions to develop new concepts and to manage proofs and they learned to act more and more autonomously.

MATHEMATICS AS “META-TECHNOLOGY” AND “MIND-POWER”: VIEWS OF ENGINEERING STUDENTS

Christer Bergsten¹ and Eva Jablonka²

¹Linköping University, ²King’s College London

The paper reports an exploration of first year undergraduate engineering students’ rationales for choosing engineering programmes at master’s level and the potential gains for their future professions they see from studying mathematics. As a means for organising the data, we used some notions of Bourdieu’s theory of the economy of forms of social practice. The study aims to contribute to understanding differences in the students’ experiences of and interest in university mathematics.

INTRODUCTION

In informal conversations at the mathematics departments where the authors have worked, engineering students from different programmes often are attributed different study habits, different approaches to mathematics and different chances to reach higher achievement levels, in particular on the more theoretical parts of the examination. This observation invites an investigation into the “reality” of such differences, but also asks for explanations of their origin. While descriptions of differences by referring to students’ attitudes and beliefs might help to investigate similarities and differences within “categories” of students (e.g. Berkaliiev & Kloosterman, 2009; Hassi & Laursen, 2009), an approach including student background and professional aspiration may contribute to further understanding students’ experiences of and interest in university mathematics. Based on the observations outlined above, this paper investigates the following research question(s):

What are the rationales of students from different engineering programmes for choosing university studies at master’s level in general, and for the choice of particular programmes? Are there differences in the potential gains they see from studying mathematics for their future professions?

CONTEXT

University education in Sweden encompasses professional training of, for example, pre-school teachers and nurses, besides traditional academic programmes. Despite educational reforms to open admission to university studies for students from less theoretical upper secondary programmes, statistics show no increase of students from families without university education. The pattern over the period from 1999 till 2009 instead shows decreasing numbers of these students, in particular for civil engineering, where in 2009 only 23% of the beginning students come from a family where none of the parents has higher education (Högskoleverket och SCB, 2009, p. 39). Policy discussions about the structure of the work force in Sweden continue to emphasise the need of more qualified engineers to secure that the country does not drop in economic development, which is seen to rely heavily on a strong development of technologically based industries. In this scenario mathematics and science education,

at all school levels and in higher education, have been given key roles. Statistics of the number of university entrants and completed exams of engineering master's in Sweden show, however, very small changes during the last years, with around 6000 new students and 3500 exams per year (Högskoleverket och SCB, 2012, p. 89).

THEORETICAL CONSIDERATIONS

Paton's (2007) analysis of literature on educational decision-making identifies three main models of students' 'choices' for higher education: economic or instrumental rationality assuming strong individual agency, social and economic structures with weak individual agency, or a hybrid of both. Linked to a structural or hybrid model for their study and career choices, some notions provided by Bourdieu's theory of the economy of forms of social practice seemed relevant and useful for organising our data. Bourdieu (1983) assumes that even practices seemingly unrelated to the economic system can be analysed in terms of maximising material or symbolic profit. Capital and profit appear in a range of forms. In different fields, these forms of capital possess different values and thus contribute differently to the chances of gaining profit. According to Bourdieu (1983), capital is accumulated labour in the widest sense that exists in material form or in an embodied form, 'incorporated' within the individual. It is a *force* inhabiting both objective and subjective structures, as well as a *principle* shaping the structural regularities of the social world (p. 183). Bourdieu (1983) discusses three forms of capital (economic, cultural and social capital) and their interrelations. As Bourdieu notes a dominance of the economic field, economic capital seems to be more relevant than the other forms, which can be transformed into economic capital, or acquired through economic capital, including more or less transformational work for producing the kind of power relevant in different fields. Economic capital comprises all things that are institutionalised through "possession" and are more or less directly transferable into money. Cultural capital refers to different kinds of cultural productions. Even if under certain conditions it can be exchanged into economic capital, the reproduction of cultural capital follows its own logic. Social capital includes actual and potential resources that rely on an affiliation with a group and it is realised through exploitation of social networks.

In mathematics education research, notions from Bourdieu's work have been productively employed in diverse contexts, such as by Gates (2001) to explore how teachers' beliefs are grounded in the social fields they operate, and are maintained and reproduced, by Teese (2000) to account for secondary students' achievement, or by Zevenbergen (2005) to account for middle-class students' advantage in classroom interaction. In the context of studying the school-university transition, Bourdieu's notion of cultural capital has been used in reports from the UK based 'TransMath' projects, e.g. by Hernandez-Martinez and Williams (2013), who link it to the notion of resilience, and by Williams (2012) in discussing the relation between the use and exchange value of mathematical knowledge.

Most relevant for this paper is the notion of cultural capital, which according to Bourdieu (1983) exists in three forms, an *embodied*, an *objectivised*, and an *institu-*

tionalised. The notion of objectivised cultural capital shows some overlap with the one of economic capital, as it comprises all reified forms of cultural capital, available for example in the form of books, machines or pieces of art. Embodied cultural capital (also referred to as *cultivation* or *Bildung*, *ibid.*, p. 187) comprises all forms of skills and cultural orientations that can be acquired through education and socialisation and it is realised as a habitus of the one who possesses it, for example in the form of knowledge, competence or taste. Accumulation of this form of capital needs time and personal investment, and also a form of a socially constructed *libido sciendi* (*ibid.*, p. 186). Institutionalised cultural capital includes all forms of certificates or titles that formally accredit a person's possession of some specified form of embodied cultural capital. Further, Bourdieu states that symbolic capital is the potential of the other forms of capital for gaining social status within a system of struggle over symbolic power. Along with the more obvious transmission of economic capital, cultural capital and social capital play a major role in social reproduction. Bourdieu (1983) notes a dynamic relation between all forms of capital acquired by a group, as the possession of one form reinforces the acquisition of the others. We have taken up the latter idea in our research question, as we assume that the students' previously acquired cultural capital might account for differences in the potential gains they see from studying mathematics for their future professions.

We were thus interested in how engineering students, depending on their background and career aspirations, think they would make use of their mathematical knowledge. It is not evident that the cultural capital acquired in more theoretically oriented mathematics studies is seen by the students as directly applicable in the field they want to enter, but there are often gains in symbolic capital. The symbolic value of mathematics is in the context of symbolic production kept high by means of policing, most prominent with strategies that draw on knower characteristics, such as being a good problem solver or being able to think logically (cf. Bergsten, Jablonka, & Klisinska, 2010). We were also interested in whether the students from different programmes see their academic achievement differently, as exchangeable into economic capital, or primarily useful as institutionalised cultural capital or as symbolic capital.

METHOD

The empirical basis for this study is interview data from students enrolled in five different engineering master's programmes at two Swedish universities. Within a larger study (funded by The Swedish Research Council) about the transition from upper secondary to university mathematics education, three series of audio taped individual semi-structured interviews, each lasting around half an hour, were conducted during the students' first year at university. Among the questions asked in the last of these interviews, conducted at the end of the year, some focused on the students' backgrounds and reasons for their choice of studies, as well as on their views about the use of the mathematics studied at university at a possible future workplace. In particular, the students' answers to the following four questions will be analysed:

Q1. Why did you choose to study at university?

- Q2. Why did you choose to study to become an engineer (master's programme), and to start the particular engineering programme that you follow?
- Q3. What do you think influenced you to make these choices?
- Q4. Do you think that you will use the mathematics you are studying at your future work place, and if so how?

As data for the reported investigation, interviews with 20 and 13 first year engineering master's students from the two universities, respectively, were selected to represent the five main different study programmes (see "Outcomes" below) as well as different achievement levels within each programme (low, medium, high). For the analysis of the transcribed interviews, similarities and differences among the responses from students across the different engineering programmes were investigated. The study followed the ethical guidelines of the Swedish Research Council, granting participant information, openness, freedom of participation, and anonymity.

OUTCOMES

In the interview quotes below, the code 1XY3 (for example) means student number 3 from university 1 in programme XY. H stands for 'Parents with higher education'.

Computer Technology, CT (4 students: 4 male, 1 H)

Q1: Most of the students referred to the possibility of getting a good job, while some saw it as the only reasonable option after having completed a theoretical programme in upper secondary. Many also referred to their parents:

Nice to get a little higher salary (1CT7, H)

It felt well like the only real alternative... didn't know what else to do after leaving upper secondary... and then yes the parents always encouraged you to go on studying (2CT1)

In addition, one student mentioned his living environment, a middle class area, as a contributing factor. *Q2*: All emphasised their interest in computers (or programming), while two students also said that owing a master's in engineering is a very strong educational merit, and one that he is good in mathematics. *Q3*: While two students did not say much, the other two saw their family as a main influence. *Q4*: Two students were hesitating about the use value of mathematics for their future profession, two said mathematics is useful, one of them emphasising the understanding of mathematical relations as a route to a more general ability.

You learn to take in to understand mathematical relations then you learn to understand relations kind of generally (1CT6)

However, one student did not think mathematics is of any use:

No, to be completely honest I don't think so (1CT7, H)

Energy and Environment, EE (5 students: 4 female, 1 male, 3 H - 1 unclear)

Q1: Four students said that it was the natural option after the theoretical programme at upper secondary; the fifth mentioned the influence of her parents and that she

would not be satisfied with herself if she did not get a university education. *Q2*: All uttered aspirations to do something good for the world, the environment or the future.

You do want to influence and make the world to something better in some way (1EE3, H)

You kind of feel that you do something ... good you contribute with something that is good ... meaningful (1EE8)

If we are going to take care of the next generation I guess we will have to do it (1EE4, H)

Two of these students also mentioned a good job as a reason to become an engineer along with an interest in energy management. *Q3*: Three mentioned family influence.

Both parents have studied at university ... that surely has an influence (1EE3, H)

Two reported experiences from upper secondary, and one also mentioned an interest in nature and a wish to help. *Q4*: Three pointed to a general learning experience from (mathematical) problem solving as most useful for their future professional work:

That is I guess what it means to be an engineer master's to be a problem solver (2EE1, H)

One student mentioned "learning to learn" through mathematics, and one said that mathematics is "there in everything".

Industrial Economy, IE (6 students: 2 female, 4 male, 5 H)

Q1: To get a good job was mentioned by four students:

You can get a somewhat better job ... that was the main thing (1IE1, H)

Two students said that it was natural to them to go on with their studies. An additional reason given by two students was the influence from their parents:

It was quite natural /.../ I did the science programme at upper secondary so I liked math and I wanted to go on studying and also both my parents have higher education /.../ but then all my relatives kind of my aunts and uncles also (1IE6, H)

Q2: Three students referred to their parents and three to the wide scope and the strong combination of, or an interest in, economy and technology of the programme, while two again pointed to the possibility to get a good job:

I think I was very much influenced by my father to become a master's engineer ... yes that he thought it was good (1IE9, H)

... quite a lot about leadership in this programme ... you kind of want to become a boss and then it felt like a good alternative (1IE6, H)

Q3: All four students from university 1 pointed only to the influence from their parents, one emphasising the values.

Yes I don't know at least the values ... so that technical subjects are pretty good ... yes of course I am inspired by my parents it would be hard to say something else (1IE12, H)

Q4: Only one student saw mathematics as clearly useful but then mainly very basic mathematics. However, almost all students very strongly emphasised the role of mathematics for developing a general problem solving ability:

If not doing the calculations it is more this way of thinking ... the problem solving ability (1IE9, H)

You more easily see through the problem somehow ... you can put it down into small pieces somehow so that it doesn't get so big ... I will probably I will definitely use this I think ... I already feel that one has kind of changed as a person by the math (1IE12, H)

One always has a structured way, in math, to solve a problem and then one can bring that way of thinking into many other things in life (2IE2)

Mechanical Engineering, ME (10 students: 10 male, 3 H)

Q1: Six students mentioned the opportunities for a good job as a reason to study at university. That it is natural and rewarding to go on studying after secondary school was mentioned by four, while only one referred to an interest in technology. *Q2:* In contrast, as much as eight students pointed to such interest, most often with the specification of "construction". Some also mentioned the wide scope of the programme.

The interest in technology has always been there ... more interesting [when comparing with energy] with CAD and construction (2ME3)

To construct ... cool to understand what is happening (2ME4)

Q3: Eight students attributed the main influence of their study choice to their family. In some cases practical work was emphasised, while one student explained that in his family it was not a tradition to enter higher education.

It became like that my daddy has an engineering master's and my mother a physician ... so I was directly accepted for the engineering master's (1ME5, H)

Actually I am the first one in the whole family (1ME7)

Q4: Doubts were raised about the usefulness of mathematics at a future workplace. It was most common (six students) to underline the value of understanding the foundations, for example what is behind automated calculations:

I don't think one will use it so much but yet I think it is good for the understanding (1ME5, H)

You have to understand the basis, otherwise there is no purpose. If you don't understand what you are doing you can't understand if something gets wrong (2ME5, H)

The calculations are done by the computer but the very understanding of what you are actually doing, the process, is perhaps important but not calculation ability itself (2ME1)

Also the general ability to solve problems, or to think analytically, was seen as an important outcome of their mathematics studies:

Yes ... that is maybe not the mathematics itself but ... the analy- analytical thinking and ... yes but maybe not just sitting calculating but ... you learn to analyse the problem in a somewhat different way than you did in high school (1ME1, H)

Yes I think so definitely ... eh ... partly that one learns to solve a problem, not ... not just to calculate but also ... one does learn a certain way of thinking and to break up a

problem into smaller parts and then solve each part kind of separately ... and so finally solve the whole thing (1ME9)

Technical Physics and Electric Engineering, TE (8 students: 2 F, 6 M, 4 H)

Q1: The answers were quite varied for this group. Some said they did not want to work in an “ordinary” job, wanted to “become something”, and that it was natural to continue the studies after secondary school. *Q2*: Seven students referred to an interest in mathematic and/or physics, and some argued that the engineering master’s will provide a strong background, especially with technical physics. Only one student explicitly mentioned to get a good job as the reason, and one seemed to aim at doing research. *Q3*: Family influence on the choice of study was mentioned by four.

My father had an engineering master’s and my mother was a teacher ... and then I always heard shall you be like your mother or your father ... and it was no I shall not be a teacher I shall get an engineering master’s (1TE2, H)

One student emphasised that the parental influence was not experienced as forcing, while another one said “probably” and one “not much”. Two students said they did not know. *Q4*: The potential use of mathematics at a workplace was seen mainly as indirect, through the ability to understand what is behind the calculations (five students), while a problem solving ability or an ability to “learn to learn” was mentioned by two students. As one student formulated this aspect:

It is easier to formulate the problems if you can do it mathematically (1TE3)

One student was wondering and two hoping that they will have an opportunity to use their mathematics knowledge later on, for example to develop mathematical models.

Patterns in interview data

There are some patterns visible in the data, which are relevant for the overall research question set up for this paper. These concern similarities across the five engineering programmes as well as some noteworthy differences between the programmes.

Students from different programmes provided some similar rationales for starting to study at university, such as to get a ‘good’ job (where ‘good’ referred to a job that pays well and/or is not so boring) and that it was a ‘natural’ continuation of their choice of study at upper secondary school (or that it was the only real option). The first rationale, however, was less common amongst EE students. Linking to this the reasons for choosing an engineering master’s, and a particular programme (study direction), an interest in this kind of study programme was mentioned by most of the students in all programmes except the EE and IE. The answers to the question about the use of mathematics in a future profession varied and developed in some cases into much detail and discussion. However, a very strong common view on this issue was that a general problem solving ability, or way of thinking in problem solving, was the outcome of their mathematics studies which they thought would be the most useful one (but not any specific mathematical skill, such as to calculate integrals ‘by hand’). It was also common, across programmes, to point to the importance of an ‘under-

standing’ one has developed through the work in the mathematics courses included in the engineering studies, as for example to be able to evaluate mathematical inputs and outputs in computer software. However, this view on understanding was much more dominating in the ME and TE groups.

Some very clear differences can also be seen between the programmes. The aspect of getting a good job was much more emphasized by students from the IE and ME programmes than by students from other programmes. However, the reasons given by IE and ME students for their choices seem to be of a different character, the former acknowledging a stronger influence of their parents and expressing a stronger focus towards a career (this is also the group with the largest proportion of parents with higher education), while the latter provided reasons of a more pragmatic character, including an interest in the kind of work normally done by a mechanical engineer (this is the group with the smallest proportion of parents with higher education). A strong individual “will” behind their choice of study was expressed in particular by the TE students, also the group that most explicitly pointed to an interest in mathematics as one reason for their choice. However, the most programme-dependent rationale for their choice was given by the EE students, who all expressed a very explicit wish, or even need, to change the world into something better (related to sustainability). The CP students were the least ‘optimistic’ group in relation to how much they would be able to use the mathematical knowledge acquired during their studies.

DISCUSSION

Not surprisingly, the outcomes clearly show how the cultural capital possessed by the families influence the choice to enrol at a university [1]. However, in the group of students interviewed there were about a half from families without higher education, which are more than suggested by the Swedish statistics. Many talked about ‘a natural continuation’, suggesting that during their studies in the science or technology programme at upper secondary school, these students have acquired a cultural capital that has developed into a disposition towards academic studies.

When differentiating between positions the students aim at in social space (from an intellectual towards an economic pole), then it is visible that the EE students see the embodied cultural capital resulting from their studies as most important, and to some extent also the TE students, while the IE students hope for accumulation of economic capital. As to their position towards engineering, they see different roles for themselves. The EE group sees their future field of engineering more independent from the economic field and more related to the political field, as they think of themselves as an autonomous group who aim at transforming technology. The ME students talk about constructing technology, and for the students in the CT and TE programmes there is no clear tendency, except that the TE students also see their field as not very much linked to economy, possibly due to its clear theoretical nature.

Even if we started by expecting differences in their views of mathematics as more or less helpful for further gains in economic or cultural capital, respectively, or

differences in the type of cultural capital they think mathematical studies provide, we did not find very clear patterns, with the only exception that most of the CT students did only see a use in its institutionalised form as symbolic capital provided by the certificate. The others referred to very general notions of problem solving competences or to an ability of structured thinking, including one who states that mathematics has changed him as a person, and two who say it helps learning to learn. These general abilities reflect an essentialising discourse about mathematics as enhancing individuals' problem solving abilities. The focus is less on particular mathematical skills as a form of cultural capital, but rather on a habitus to which engagement with mathematics amounts, seen as a general habituation to solve problems in a rational way. Only one TE student mentions that mathematical knowledge would help to build mathematical models, which constitutes it as a technology-related cultural capital. However, students from this programme generally expressed a disposition towards studying mathematics. A couple of students referred to mathematics as a means for understanding the principles behind other technology. The IE students did not mention any relation between mathematics and economic models, despite the tradition in their field to use theoretical models and statistics.

All of these views reflect a view of mathematics as unlinked to the social context of its use, despite the differences in social positions the students aim at. Mathematics is either conceptualised as *mind-power*, a kind of universal thinking tool in the form of a general embodied cultural capital contributing to the formation of a person (a habitus), or as a universal method, a *meta-technology*, that helps to access otherwise hidden principles [2]. We did not employ notions of ideology or discourse, to which the engineering students' views could be linked. However, the outcomes show some unexpected uniformity in their views, which did not depend so much on their different career aspirations or backgrounds, that is, on different forms of cultural capital, as we had anticipated. It is rather a discourse about the value of mathematics that might have shaped their conceptualisations, which foregrounds the values of rationality and objectivity that are associated with technological and economic progress. The students' views match very well the general discourse about the role of mathematics education in secondary schools that aim at channelling more students towards engineering careers to sustain economic development, which is seen to rely heavily on a strong development of technologically based industries.

NOTES

1. For another context, see for example Kleanthous and Williams (2013).
2. The term *meta-technology* is being used in several different contexts, e.g. in the philosophy of technology or in bio- and information technology, with a meaning differing from that given here.

THE UNDERSTANDING UNDERSTANDING EQUIVALENCE OF MATRICES

Abraham Berman^{*}, Boris Koichu^{*}, Ludmila Shvartsman^{**}

^{*}Technion – Israel Institute of Technology

^{**}Academic ORT Braude College, Karmiel, Israel

The title of the paper paraphrases the title of the famous paper by Edwina Michener "Understanding understanding mathematics". In our paper, we discuss what it means to "understand" the concept of equivalence relations between matrices. We focus on the concept of equivalence relations as it is a fundamental mathematical concept that can serve as a useful framework for teaching a linear algebra course. We suggest a definition of understanding the concept of equivalence relations, illustrate its operational nature and discuss how the definition can serve as a framework for teaching a linear algebra course.

INTRODUCTION

One of the major dilemmas that teachers of linear algebra face is whether to start with abstract concepts like vector space and then give concrete examples, or start with concrete applications like solving systems of linear equations and then generalize and teach more abstract concepts. Our personal preference is to start with systems of linear equations since they are relatively easy-to-understand and are connected to the students' high school experience. Unfortunately, for some students this only delays the difficulty of abstraction (Hazzan, 1999). The students also often tend to consider less and more abstract topics of the course as disjoint ones. Since the concept of equivalence relations appears both in concrete and abstract linear algebra topics, we think of equivalence relations as an overarching notion that can be helpful in overcoming these difficulties.

In this paper we first suggest a review of topics, in which the notion of equivalence relations appear in high school and in a university linear algebra course and then theoretically analyse what it means to understand this notion, in connection with the other linear algebra notions. For this purpose we suggest a definition of understanding the concept of equivalence relations in linear algebra and argue, by means of presenting mathematical tasks aimed at testing particular aspects of the definition, that it can be operationalized. The paper is concluded with suggestions for future empirical research.

EQUIVALENCE RELATIONS

Examples of equivalence relations known, latently, to high school students include equality of numbers and algebraic expressions, and congruence and similarity of geometric shapes. Enriched mathematics high school curriculum may also include congruence modulo and equivalence of (systems of) equations.

Equivalence relations between matrices are ubiquitous. Equivalence of systems of linear equations is usually the first time when a university linear algebra student explicitly encounters the concept (e.g., Berman & Kon, 2000; Carlson, Johnson, Lay & Porter, 1993; Hoffman & Kunze, 1972). The concept of row equivalence of matrices is introduced in this connection. The concept of column equivalence of matrices is introduced for the sake of symmetry, and an experienced lecturer would emphasize that elementary row operations transform a system of equations to an equivalent one, whereas elementary column operations do not. Matrix equivalence naturally appears in connection with rank, matrix similarity – in connection with eigenvalues, and matrix congruence – in connection with quadratic forms. Figure 1 describes the logical-hierarchical connections between these types of equivalence relations. An arrow in the figure between a relation α and a relation β means that if relation α exists between two matrices, then so does relation β ; the matrices P and Q are invertible.

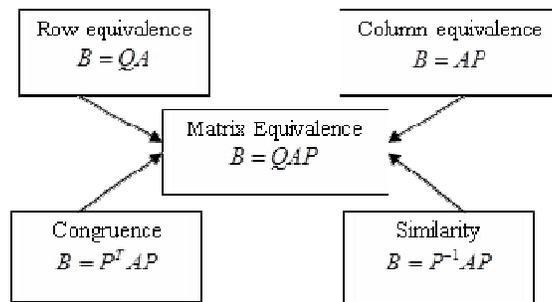

Figure 1: Examples of matrix equivalence

Other types of equivalence relations between matrices are restricted to complex matrices. These types are presented in Figure 2.

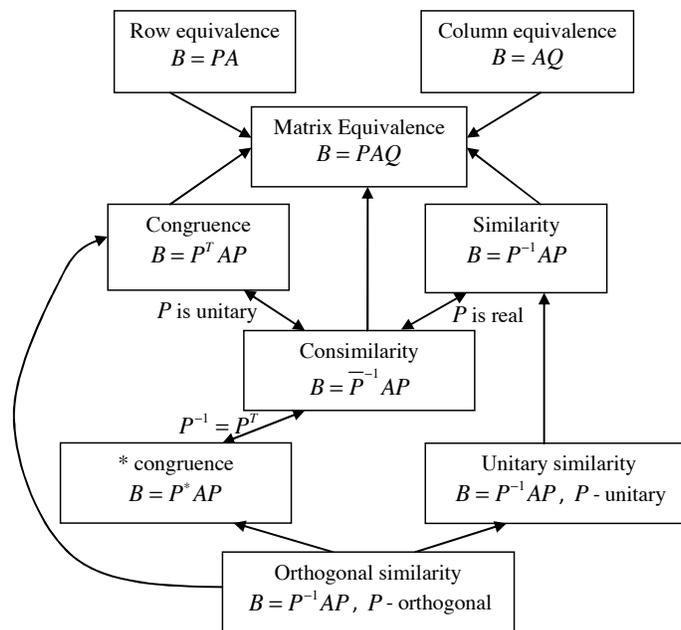

Figure 2: Equivalence relations of complex matrices

As in Figure 1, the matrices P and Q are invertible, and a one-side arrow between a relation α and a relation β means that if relation α exists between two matrices, then so does relation β . A two-side arrow in Figure 2 between a relation α and a relation β , accompanied by condition γ , means that under condition γ the relations are the same. By an orthogonal matrix we mean a real matrix P satisfying $P^{-1} = P^T$. Note that in the condition $P^{-1} = P^T$ that accompanies the arrow between consimilarity and *congruence, the matrix P is not necessarily real.

UNDERSTANDING EQUIVALENCE RELATIONS

In CERME 8, Gila Hanna (Hanna, 2013) talked about the concept of "memorability" discussed by Gowers (2007). She mentioned that for Gowers "easy to memorize" is intimately connected with understanding. Michener (1978) accounts a mathematician's perspective of what it means to "understand" as follows:

When a mathematician says he understands a mathematical theory, he possesses much more knowledge than that which concerns the deductive aspects of theorems and proofs. He knows about examples and heuristics and how they are related. He has a sense of what to use and when to use it, and what is worth remembering. He has an intuitive feeling for the subject, how it hangs together, and how it relates to other theories. He knows how not to be swamped by details, but also to reference them when he needs them. (p. 361)

We apply this perspective to conceptualizing students' understanding in linear algebra. As will be evident shortly, our conceptualization of understanding is also stimulated by the work of Skemp (1976) on *instrumental understanding/relational understanding*. According to Mousley (2005), Skemp (1976) treated understanding as forms of knowing (cf. also Harel, 2008, for the compatible approach to conceptualizing *ways of understanding*).

Generally speaking, we refer to *understanding* a concept in a given mathematical subject as knowing to provide different representations of the concept, link it to other concepts by logical-hierarchical relations, and apply it in central issues of the subject. Specifically, in the context of equivalence relations in linear algebra, we suggest the following definition.

Understanding of an equivalence relation of matrices consists of:

- *Formal understanding* – knowing to recall (on demand or when needed in problem solving) its formal definition(s).
- *Instrumental understanding* – knowing to transform a matrix to an equivalent one.
- *Representational understanding* – knowing to recall (on demand or when needed in problem solving) properties of an equivalence class and knowing to find simple representatives of the equivalence classes.

- *Relational understanding* – knowing to relate the relation to other concepts, including other equivalence relations (e.g., Figure 1 and Figure 2 above).
- *Applicational understanding* – knowing to identify (not necessarily to solve) problems in which the relation may be useful.

Understanding is manifested by all, or some, of the above mentioned forms of knowing. Note that there is no hierarchical relation between the different types of understanding. For example, it is possible that a student may possess representational understanding without instrumental one, or vice versa. Also it is clear that each type of understanding has its own spectrum of deepness, from a basic to an advanced one. Deepness of understanding can be characterized in terms of available arsenal of relevant proofs, generic examples and problem-solving strategies. For operational reasons, we consider the following levels of understanding. A basic level of *formal understanding* is when the student can recall the relevant definitions. In case that there are several definitions, the ability to prove that they are equivalent demonstrates an advanced understanding. The levels of *instrumental understanding* can be characterized by the fluency of performing the transformations. A student at a basic level of *representational understanding* can only recall simple representatives. A more advanced student can prove existence and uniqueness of the representatives. A basic level of *relational understanding* presumes that a student knows how the equivalence relation relates to other concepts. A more advanced level is expressed by the ability to prove these relations. An advanced level of *applicational understanding* is when a student not only knows in which problems the concept may be useful, but also knows how to solve some of the problems.

These definitions can be operationalized since each of the above types and levels of understanding can be evaluated by means of appropriate tasks. In the next section we give some examples.

UNPACKING THE DEFINITION BY MEANS OF TASKS

As examples we explain the five types of understanding for row equivalence, matrix equivalence and matrix similarity. In addition, for matrix equivalence, we show how formal, representational and applicational understanding can be evaluated by tasks. For matrix similarity we discuss the pedagogical consequences of the lecturer's decision to stress some types of understanding more than the others. We also discuss the potential of teaching orthogonal similarity for creating an overall picture of the course through promoting its relational understanding.

Row equivalence

Formal understanding: the students are capable of recalling that a matrix B is row equivalent to a matrix A if B can be obtained from A by a finite number of elementary row operations. They should also know that this is the same as $B = QA$, where Q is invertible.

Instrumental understanding: the students can perform elementary row operations and know how to transform a given matrix to a row equivalent one.

Representational understanding: the students know that every matrix can be reduced to a row echelon form and is row equivalent to a unique matrix in a row reduced echelon form, and thus A and B are in the same equivalence class if and only if they have the same row reduced echelon form.

Relational understanding: the students are capable of associating row equivalence with systems of linear equations, can recall that row equivalent matrices have the same rank, but that the converse is not true, and that row equivalence implies matrix equivalence. The students also know that matrices of the same order are row equivalent if and only if they have the same row space.

Applicational understanding: the students can recall that a system of linear equations can be solved by reducing the augmented matrix to a row equivalent row reduced matrix (Gauss elimination) or to its row reduced echelon matrix (the Gauss-Jordan method). More advanced applications include vector independence, finding a basis and matrix inversion.

The concept of row equivalence is a basic concept and thus it is important that all students will develop all the five types of its understanding, at least at the basic level.

Matrix equivalence

The concept of matrix equivalence is less basic and it is not necessary to emphasize it in a very basic linear algebra course. However, in a more advanced course it makes sense to develop some of the following:

Formal understanding: the students recall that matrices A and B are equivalent if one can be obtained from the other by a finite number of elementary, row or column, operations, or, equivalently, if $B = QAP$, where P and Q are invertible.

Instrumental understanding: the students can perform row and column elementary operations.

Representational understanding: the students know that every $m \times n$ matrix of rank r is equivalent to an $m \times n$ matrix of the form $\begin{pmatrix} I_r & O \\ O & O \end{pmatrix}$, where I_r is the $r \times r$ identity matrix.

Relational understanding: the students know that $A, B \in F^{m \times n}$ (The $m \times n$ matrices over the field F) are equivalent if and only if they have the same rank, that equivalent matrices represent the same linear transformation, and that the row equivalence, column equivalence, similarity and congruence are special cases of matrix equivalence (see Figure 1).

Applicational understanding: the students know that reducing a matrix to its simple representation $\begin{pmatrix} I_r & O \\ O & O \end{pmatrix}$ can be useful in problems involving rank.

As an example, consider the following classical proof of the fact that for $A, B \in F^{m \times n}$, AB and BA have the same characteristic polynomial:

Proof: Suppose $\text{rank } A = r < n$ (If $r = n$, AB and BA are similar and thus have the same characteristic polynomial). Then A is equivalent to $\begin{pmatrix} I_r & O \\ O & O \end{pmatrix}$, i.e., there exist invertible matrices P and Q such that $PAQ = \begin{pmatrix} I_r & O \\ O & O \end{pmatrix}$. Let $Q^{-1}BP^{-1} = \begin{pmatrix} C & D \\ E & F \end{pmatrix}$, where C is $r \times r$. Then $PABP^{-1} = PAQQ^{-1}BP^{-1} = \begin{pmatrix} C & D \\ O & O \end{pmatrix}$, and $Q^{-1}BAQ = Q^{-1}BP^{-1}PAQ = \begin{pmatrix} C & O \\ E & O \end{pmatrix}$. Hence AB is similar to $\begin{pmatrix} C & D \\ O & O \end{pmatrix}$ and BA is similar to $\begin{pmatrix} C & O \\ E & O \end{pmatrix}$. The matrices $\begin{pmatrix} C & D \\ O & O \end{pmatrix}$ and $\begin{pmatrix} C & O \\ E & O \end{pmatrix}$ have the same characteristic polynomial, and thus so do AB and BA .

In terms of understanding matrix equivalence, knowledge of the above proof requires basic level of formal and representational understandings, and an advanced level of applicational understanding. A lecturer interested in developing the applicational understanding of matrix equivalence may include this proof in the course. A lecturer who needs time for other purposes may use other proofs. We remark that the proof can be used for evaluating different types of understanding when divided into sub questions or stages.

Similarity

Formal understanding: the students can recall the definition of similarity.

Instrumental understanding: the students can implement the definition of similarity; they are aware that elementary operations do not preserve similarity.

Representational understanding: at the basic level, the students know that two diagonalizable matrices are similar if and only if they have the same characteristic polynomial and, in particular, the same determinant and trace. At a more advanced level they also know that triangulable matrices are similar if and only if they have the same Jordan form, and, in general, two matrices are similar if and only if they have the same rational form.

Relational understanding: at the basic level, the students know that similar matrices are equivalent. At a more advanced level, they also know that similar matrices represent the same linear operator: if T is a linear operator on a finite-dimensional vector space V and if A represents T with respect to a basis α of V , and B

represents T with respect to a basis β , then $B = P^{-1}AP$, where P is the transformation matrix from α to β .

Applicational understanding: the students know that similarity to a diagonal matrix (similarity to a matrix in a Jordan form) is very useful in differential equations, difference equations and computing polynomials of matrices.

The concept of similarity is a fundamental concept and thus it should be taught in all linear algebra courses. Ideally, the lecturer should aim at developing all types of understanding similarity in all students. The least demanding linear algebra course should aim at developing basic formal, instrumental, representational and relational understandings of similarity. In between the ideal and the least demanding scenarios, there is a room for the lecturers' trade-offs. The trade-offs may be decided upon accordingly to characteristics of the class, and it is important that the lecturer will be aware of the pedagogical consequences of the choices. For instance, for engineering and applied mathematics students the applicational understanding should be emphasized, and for pure math majors, for whom the course is an introduction to more advanced algebra courses and to functional analysis, achieving advanced level of representational and relational understanding of similarity is crucial. Another example of a trade-off is teaching the Jordan form but giving up teaching the rational form and, in this way, gaining some time for applications. This decision would be appropriate for courses of mixed audience. We are aware, of course, that in many cases the trade-off decisions depend on the teacher's preferences, and hope that this discussion may result in better grounded decisions.

Orthogonal Similarity

Orthogonal similarity has an important role in highlighting the connectedness of the course. For this reason, we focus here on the relational understanding of the concept. Relational understanding of orthogonal similarity presumes the knowledge that orthogonal similarity is both similarity and congruence, that it is a special case of unitary similarity and that two matrices are unitary similar if and only if they represent the same linear operator with respect to different orthonormal bases. In addition, orthogonal similarity is related, by means of Sylvester Inertia Theorem, to comparison of different methods of diagonalization, and, in turn, to Givens Method for computing the eigenvalues of real symmetric matrices.

DISCUSSION

Equivalence relations play an important role in mathematics, in general, and in linear algebra, in particular. Halmos (1982, p. 246) points out that the concept of an equivalence relation "is one of the basic building blocks out of which all mathematical thought is constructed". In CERME 8, Kerstin Pettersson (Pettersson, Stadler & Tambour, 2013) studies the concept of a function as a "threshold concept" (Meyer & Land, 2005). Motivated by her talk we observe that equivalence relations

is a threshold concept in linear algebra since by understanding it the students get a general comprehension of the whole topic. Skemp (1986) notes that the idea of equivalence relations helps to form a bridge between the everyday functioning of intelligence and mathematics. Many researchers and lecturers pointed out that constructing such a bridge is not an easy endeavour (e.g., Asghari & Tall, 2005; Mills, 2004), in particular, because the notion of equivalence relation is mathematically and epistemologically complex.

Stimulated by the famous paper "Understanding understanding mathematics" by Michener (1978), we try to understand and explain what it means to "understand" the concept of equivalence relations, and in particular equivalence relations between matrices. This is in line with and in continuation of the extended effort that has been made so far to promote students' conceptual understanding in linear algebra (e.g., Day & Kalman, 2001; Dorier, 2000, 2002; Dreyfus, Eisenberg & Uhlig, 2003; Harel, 2000; Jaworski, Treffert-Thomas & Bartsch, 2011).

In this paper we suggested a multi-facet definition of understanding equivalence relations between matrices and exemplified how the definition can be operationalized by means of mathematical tasks sensitive to its particular facets. We have also argued that an understanding of different types of equivalence relations between matrices, when taken as a central objective of a linear algebra course, can embrace most (if not all) topics usually taught in linear algebra courses. This also may educate the students to appreciate the applications of linear algebra and, at the same time, the mathematical structure and beauty of the subject. Consequently, the presented definition can be used as an organizational framework for planning, teaching and evaluating a linear algebra course.

More specifically, the choice of the equivalence relations, for teaching, depends on the level and the purpose of the course. Most one-year courses include row equivalence, column equivalence, matrix equivalence, similarity, congruence, unitary similarity and orthogonal similarity. A least demanding course can deal only with the first four relations, and a more advanced course can include also *congruence and consimilarity. The suggested definition of understanding equivalence relations may guide the lecturer in establishing feasible goals, in planning the course to achieve these goals and in evaluating the results. In some cases, a lecturer may be content with teaching aimed at particular types of understanding of the concepts at different levels of deepness. Reasons for this may be, for example, time constraints or the students' needs. Experienced teachers will decide what the minimum level of understanding of each type they want to achieve should be. We hope that our paper will help not only experienced teachers in doing the same. In addition, our operational definition may be useful as a part of a theoretical framework in a study dealing with students' learning of linear algebra or with development of lecturers' pedagogical and epistemological knowledge.

Although our paper is theoretical, we would like to mention here that we used the operational definition of equivalence relations as a framework for teaching a first year linear algebra course at the Technion. In addition, the tasks presented in the paper were tried in a series of informal interviews with the students who took part in the course and volunteered to participate in the interview. The interviews helped us to get an initial impression to which extent our conceptualization of understanding a concept is compatible with what students mean by understanding a concept and in particular, which types of understanding the concept of equivalence relations can be identified in students' mathematical performance. The interviews seem to confirm that the types and levels of understanding a concept of equivalence relations, described in the paper, are plausible. The validity of the suggested definition of understanding and the helpfulness of the suggested didactical approach will hopefully be tested in future empirical studies.

TEACHING STATISTICS TO ENGINEERING STUDENTS: THE EXPERIENCE OF A NEWLY APPOINTED LECTURER

Irene Biza

Loughborough University

In this paper I will adopt the reflective practitioner approach (Schön, 1987) to analyse the experience of a newly appointed lecturer in teaching statistics to engineering students. The lecturer is seen as entering a new for her community of practice (Wenger, 1998), the community of teaching mathematics at university level, which does not necessarily have universal characteristics. Different (sub)communities of students, lecturers and researchers are involved and in some sense affect teaching decision-making. Observations indicate that these communities interact to each other with potentially contradictions and affect the experience of the new lecturer.

INTRODUCTION

The last two years I have been offering a module on Statistics to engineering students in a well-regarded university in the UK. I am a mathematics graduate, I used to be a mathematics teacher and currently I am a researcher in mathematics education. When I started, two years ago, it was the first time I offered a module to a big group of engineering students and the first time I taught Statistics. In this paper I will offer an account of my reflection on this experience. I will adopt the *reflective practitioner* approach (Schön, 1987) to analyse this experience in two directions: the experience of teaching Statistics to engineering students and the first year experience of a newly appointed lecturer. I can see a newly appointed lecturer as a person entering a new community of practice (Wenger, 1998), the community of university lecturers. This community does not necessarily have universal characteristics. It seems that there are different (sub)communities that are involved and affect teaching decision-making and practices. In the experiences I am going to discuss in this paper I will consider the context and the different groups of people involved – engineering students, lecturers of Mathematics or Statistics, statisticians, etc. These groups can be seen as communities with characteristic practices. Drawing on my teaching practices and the feedback I received from the students, I will present three incidents related to: introduction to theory; creation of adequate intuitions; and, critical use of formulae.

In what follows I present the theoretical construct on which my analysis was based, a brief literature review on the topics mentioned above, the methodological approach and some observations related to these topics. Finally, I discuss some potential implications of this reflection to teaching practices at university level.

THEORETICAL CONSTRUCT

According to Wenger (1998) communities of practice are formed by people who engage in a process of collective learning in a shared domain of human endeavour. In these communities people are involved in activities that have same objectives and

share a concern or a passion for this and learn how to do it better as they interact regularly. Learning is not necessarily the reason one community comes together as it might be the incidental outcome of member's interaction. On the other hand not any community or a group of people (e.g. a club, a neighbourhood or a company of friends) can be called a community of practice. A combination of three elements constitutes a community of practice: the *domain*, the *community* and the *practice*. The community needs to have a shared domain of interest that defines an identity of its members, who commit themselves to this domain, engage in joint activities and discussions, help each other and share information. A relationship is built between members and enables them to learn from each other. However, common interests are not enough to establish a community of practice – as, for example, in a film club. Members need to have a shared practice, namely a shared repertoire of resources such as experiences, stories, tools or ways of addressing recurring problems.

Research discusses several communities of practice related to teaching and learning of mathematics especially at university level: undergraduate students, mathematicians or mathematics education researchers. These communities are characterised by particular practices and ways of communication and potentially interact with each other. Solomon (2007) investigates potentially conflicting communities of practice within which undergraduate students find themselves, and presents a typology of their related learner identities. Additionally, Wenger's community of practice construction has offered a theoretical base for the analysis of students' beliefs about mathematics and their self-positioning within the school classroom or university lecture theatre community (for students beliefs about proof, see Solomon, 2006).

In a developmental study on engineering students' conceptual understanding of mathematics, Jaworski and Matthews (2011) regard university an institutional environment with "norms and expectations which can be seen to form an established community of practice" (ibid, p. 179). The elements of this community regard the curriculum, the assessment, teaching arrangements, student culture and expectation and teacher culture and expectation. Lecturers are "aligned with all of these to some extent and there are differing degrees to which change is possible" (ibid, p. 184).

Nardi (2008) describes mathematicians and researchers in mathematics education as two different communities with overlaps and conflicts that tantalise their relationships. She discerns the fragility – but also the importance – of the relationship between these two communities. Mathematicians admit the benefits of pedagogical practice being informed by mathematics education results, they reflect – often with scepticism – on research in mathematics education practices, and they acknowledge the influence of stereotypical perceptions on mathematics, mathematicians and educational research in their relationship (ibid, p. 257-292).

In my reflection on teaching Statistics to engineering students I can see different groups of people being involved: engineering students; lecturers of Mathematics or Statistics for specialist or non-specialist students; statisticians; users of statistics; and, researchers in mathematics education (see Figure 1). These groups can be seen as

communities with characteristic practices. There are overlaps between these groups and this distinction might be seen not so realistic. However I found this construction very helpful on my teaching reflection and I will refer to some of these groups in my account in the paper. Putting myself in this spectrum of communities, at the time I was appointed, I was a mathematician (graduate of mathematics but not researcher), I had been practitioner in mathematics teaching, I was an active researcher in mathematics education, and I was a user of statistics in educational research.

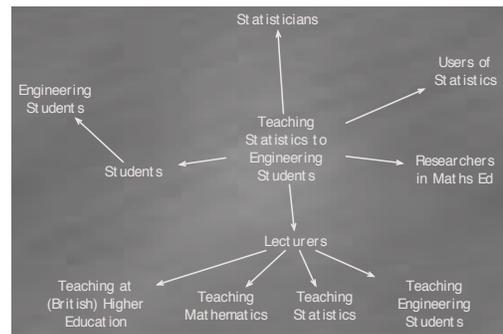

Figure 1: Sub-communities

ISSUES RELATED TO THE TEACHING AND LEARNING OF STATISTICS

Lecturing is a widespread mode of teaching at higher education in the UK, especially in mathematics and engineering departments. There is a scepticism and sometimes critique on lecturing as an effective teaching method for students' learning (Biggs, 2003). However we cannot ignore that numerous cases of lectures have been highly rated by students (Morton, 2009) and that both students and academics see value in this type of teaching (Folley, 2010). In the case discussed in this paper the big group lecture was the only teaching option and this characterise unavoidably the interaction between lecturer and students.

Statistics is “often regarded as being difficult to understand” (Kyle & Kahn, 2009, pp. 258). Several challenging aspects of the statistical concepts have been highlighted in research: the formulation of hypothesis; the distinctions and the application of different types of tests; the interpretation of the results (especially regarding the recognition of the significance level); and, the understanding the terminology used in stating a decision (Batanero et al., 1994). Garfield (1995) proposes five scenarios to support students' understanding of statistical concepts: activity and small group work; testing and feedback on misconceptions; comparing reality with predictions; computer simulations; and, software that allows interaction. Especially for non-specialist of statistics students, data-driven approach to the subject without insight to the mathematical foundation of the concepts is recommended (Kyle & Kahn, 2009).

Statistics teaching had changed dramatically in the last two decades. Older instructions used to be dominated by probability-based inference and abstract approaches with emphasis on memorising of formulae and techniques. A modern approach offers more opportunities for students' engagement with authentic activities. Also, this approach includes a more balanced use of the steps of data production, data analysis and inference. The transition between these steps has a lot of *back and forth* critical movements and it is not anymore straightforward as it used to be in the traditional statistical calculations (Moore, 1997). This modern approach is at an epistemological conflict with the formalist mathematical tradition and the

persistence of students' difficulties in statistical reasoning might be the result of the continuing impact of the formalist mathematical tradition (Meletiou-Mavrotheris, 2007).

I discuss some of these issues regarding the teaching and learning of Statistics in the examples from my experience I present in the following section.

METHODOLOGICAL APPROACH

Throughout the academic year I had been keeping reflective notes on my experiences, annotated lecture notes with my comments just after each session and notes on my occasional communications with my colleagues. The observations I present in the next section draw on these resources and my background readings. I can consider myself as a *reflective practitioner* in the terms of Schön (1987). There are studies in which practitioners develop their reflection on practice while they are working with researchers in mathematics education (Jaworski, 1998; Nardi, 2008). In the case presented in this paper the arrangement is different as the researcher in mathematics education (myself) becomes a practitioner and develops her practice in parallel with her interaction with other practitioners.

THE EXPERIENCE OF FIRST YEAR TEACHING

In this section I will discuss a Statistics module that was offered to a group of 132 second year engineering students. This module is one of the service courses the Department of Mathematical Sciences offers to other departments. The students were from five different engineering programmes. Although all of them are engineering students their studying habits, needs and background vary across the subgroups. The teaching approach of the module is a combination of 11 two-hour lectures and 4 one-hour lab sessions using statistical software. As the module has been running without problems in a similar structure for several years, I used the existing module specifications without having any involvement to their design. The module is assessed through a coursework (20%) and written examination (80%).

When I started, two years ago, I had not taught statistics before and moreover I had not offered any module to engineering students. So, using Shulman's language the first challenge for me was to build a pedagogical content knowledge Shulman (1986) appropriate for this kind of teaching. This knowledge had to do not only with the statistical content that was necessary for these students but also had to do with the pedagogy that should be adopted in this particular teaching

I was a newcomer in this *world* and I had a lot to learn from the long experience of my colleagues. I aimed to have informal contacts with lecturers who had similar modules or researchers on statistics. I also participated in informal discussion organised in my department for lecturers who offer mathematical or statistical courses to engineering students. In parallel I was attending the "New Lecturers' Course" of my institution and regular seminars on "How we teach" offered by other lecturers of Statistics and Mathematics. I based my lectures on the plan and the

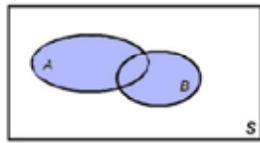

lecture notes used in previous years with the support of the lecturers who had designed these notes in the first place. Recently, colleagues (including myself) have been forming a forum for members of staff at our institution with an interest in teaching statistics or quantitative methods, to enable us to meet and share ideas, experiences and resources. As a result I felt myself communicating with different groups of people (academics and students; cf. Figure 1). In the next sections I present three examples from my practices in teaching, as I experienced them in my lecturing and my reflection, especially in relation to the groups of people who are involved or related to these teaching practices.

Example 1: Theoretical explanations: Are they necessary and to what extent?

In the first session I had to introduce students to basic concepts of probability theory. According to Kyle and Kahn (2009), students with a strong mathematical background would be able to cope with a theoretical foundation of the subject. On the other hand non-specialists of statistics would find a data-driven approach to the subject more beneficial. In agreement with this recommendation, the lecture notes from previous years included a very brief introduction to elementary probability without any reference to theoretical parts, such as set theory. When I started designing my lectures, I found talking to my students about probability without introducing them to the basic concepts of the set theory impossible. How, for example, could we discuss the *addition law of probability*: $P(A \cup B) = P(A) + P(B) - P(A \cap B)$ without talking explicitly about sets, union and intersection of sets and their representation through Venn diagrams? For this reason, I added a brief section on sets (Figure 2a). Later on, I realised that the sets after their theoretical introduction turned out to be implicit components of the probability laws without any explicit reference to them. For example, no tasks on sets were included in the students' practice and exam questions. As a result, students ignored the sets and focused directly on the section on probability that was necessary for the tasks and the assessment. So by the end of the year, I decided that, given the restricted time-schedule of the module, this choice would be a *waste of time*. The year after I deserted this section by keeping only the corresponding Venn diagrams illustrating each of the probability laws (Figure 2b), and I used more time on examples.

Thinking about this choice retrospectively I can say that it was my mathematics teaching background that favoured a lecture that had all the necessary theoretical elements. I was looking for a structure that was theoretically complete without considering the students' needs and the practical constraints. In the language of communities of practice, I was coming from a community that practises the teaching mathematics for specialists, to a community related to teaching applications of statistics to non-specialists.

- The union of two sets A and B contains all the elements of A together with all the elements of B .

$$A \cup B = \{x : x \in A \text{ or } x \in B \text{ or both}\}$$

Figure 2a

- $P(A \cup B) = P(A) + P(B) - P(A \cap B)$.
- If A and B are mutually exclusive then $P(A \cup B) = P(A) + P(B)$.

Example 2: How can we help students create correct intuition about the processes they apply?

It is usual practice for users of statistics to interpret the results from statistical tables or outputs without necessarily understanding their meaning. In anecdotal conversations with colleagues who use statistics in their research or offer research methods courses, I heard that this is enough to make an accurate decision. Other colleagues believe that students need to be offered more explanations about these techniques in order to apply them and interpret the results properly. I see myself in the second group, as I believe that students will be more flexible and safer in their decisions if they know what is behind the procedures they apply. An unconscious use of a technical procedure without alternative confirmation methods may result in erroneous responses. A characteristic example is the interpretation of the p -value in the decision making of hypothesis testing: when the p -value is less than the significance level (usually in practice 0.05 or 0.01), there is a statistically significant result and therefore there is enough evidence to reject the null hypothesis. However students have trouble to interpret this result (Batanero et al., 1994). There are cases in which students, although aware of the need to compare the p -value with the significance level (e.g. 0.05), are not sure if the p -value needs to be *more* or *less* than this level. Alternatively, they would be more confident in their decisions if they were relying not only on their memory, but on knowing the meaning of the p -value. With the above in mind, I decided to offer students different aspects of the same concept as backing to their decisions.

The expectation in the mathematical community is that warrants of arguments are based on theoretical foundations. In the community of engineers who use statistics and mathematics in their applications, warrants should be based on appropriate intuitions of the concepts. With this aim in mind for my teaching design, I tried to highlight the connection of different aspects of the same concept towards the creation of correct intuitions. In this endeavour, I acted by putting together my personal intuitions, the content knowledge as well as my pedagogical content knowledge from mathematics education. According to the latter, research suggests that different and interconnected representations facilitate mathematical understanding (e.g. Presmeg 2006). Also, the provision of different representation and the manipulation of

different aspects of a particular representation appear to help students learn basic statistics concepts (Garfield, 1995). In this spirit, and regarding the example of the p -value I mentioned earlier, I tried to put together the result of a statistical test and the corresponding critical value in the distribution graph and explain on it the meaning of the significance level and the p -value (see Figure 3). I did this not only in the first introduction of the test, but I kept using it in each of the examples we discussed in the lectures. I aimed the graph to become a validation tool for the students in their statistical interpretation of the p -value.

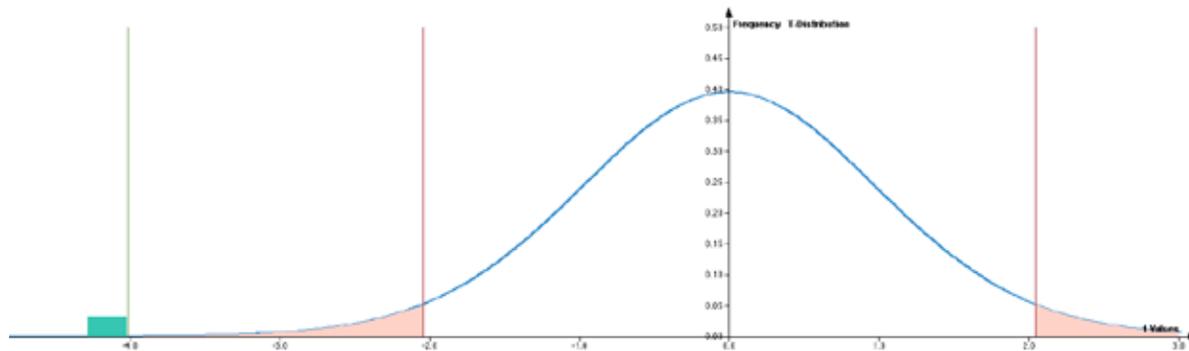

Figure 3: The statistical test and the critical value in the distribution graph

I do not have evidence that this approach was helpful to the students. In some cases I noticed little graphs made by students next to their responses in the exams. However, there were still students who misinterpreted the outcomes of the processes (e.g. by saying that there is significant difference when the p -value is more than 0.05).

In this incident, my actions were strongly influenced by the community of mathematics education. However, students who act under the norms of their community did not necessarily follow my intentions. Although lecturers may believe that representations are helpful for student understanding – especially us who are strongly influenced by mathematics education research – it's not always clear whether students notice these representations, what they see in them, and how they connect them. There are cases in which students interpret a representation differently from what the lecturer intends, and cannot see the mathematical meaning that is embedded in these representations. This is an area that calls for further investigation in two directions. One is on what students really notice and how they connect different aspects of the same concept. Another direction is whether students' practices are related to their community's practices, e.g. if their community is interested only in the application of methods, students might not put enough effort on the understanding of the meaning of this method.

Example 3: How can we help students to use formulae critically?

In Statistics many complicated formulae are used. Usually, remembering these formulae is not necessary and very often more emphasis is put on the correct use of a formula instead of its memorisation. To this aim, formulae sheets are used for students' practice and their written class assessment. In the module I describe in this paper students' practice both in applications of the formulae with calculator and in

statistical analysis with software in the lab. The former is assessed through their final written examination and the latter through a written coursework in a form of essay. Throughout the term and in the exams, students use the tables and the formulae list from the Tables for Statisticians (White, Yeats & Skipworth, 1979). Additionally, they practice on examples from the HELM textbooks (Helping Engineers to Learn Mathematics (HELM) workbooks, <http://helm.lboro.ac.uk/>). The two resources use different versions of the tables and different notation in the formulae. For example, the formula I used in the lectures for the calculation of the *slope* in the *simple linear regression model* (the same as the one used in the HELM workbook, HELM workbook 43, p. 6) and the formula students had in the exams (White et al., pp. 65) are presented in Figure 4.

$$b = \frac{\frac{\sum xy}{n} - \frac{\sum x}{n} \frac{\sum y}{n}}{\frac{\sum x^2}{n} - \left(\frac{\sum x}{n}\right)^2}$$

HELM workbook 43, p. 6

$$b = \frac{n \sum_{i=1}^n x_i y_i - \left(\sum_{i=1}^n x_i\right) \left(\sum_{i=1}^n y_i\right)}{n \sum_{i=1}^n x_i^2 - \left(\sum_{i=1}^n x_i\right)^2}$$

White, Yeats & Skipworth, 1979, pp. 65

Figure 4: Simple linear regression formulae

The mechanical application of a formula without understanding its meaning may result in trouble. This trouble may be arising from different notations or because of the implicit algebra of a formula. I have been raising these issues in my lectures and let my students know from very early on what formula sheet they would get at the exams. This is technical information that might be overlooked by the students as the following incident exemplifies:

One of the students just after the exams emailed to me that the formula of the slope in the simple linear regression model at the lecture notes was *not correct* and although it took him some time to *memorise* it he was unable to give a correct answer to the exam question. Also, he said that this was *unfair*.

There are a couple of issues I would like to highlight in this incident. Firstly, it seems that for the student there was only one version of the formula and he was not flexible enough to see that the two formulae were equivalent. This might be because of the notation or because of his inadequate algebraic knowledge. Also, he claimed that he spent so much time *memorising*, indicating a practice that was in conflict with what I have been trying to encourage my students to do. Finally, he assumed that limited learning resources (in this case lecture notes or/and HELM workbook) are enough for his preparation and he defended himself by saying that the formula in the notes was incorrect. It would appear that there is a conflict between lecturer' and student' anticipations. Lecturer expects university students to be individual and critical learners. However, the student expects specific study guidelines and transfers the responsibility for his learning (or his mistakes) to the lecturer. The two communities have different expectations regarding this responsibility as well as approaches to university study.

DISCUSSION

In this paper I presented examples from my inaugural experience of teaching Statistics to engineering students. While this account is not a systematic study, I draw on my reflections in order to discuss the complexity of the experience of a newly appointed lecturer especially when she comes from different teaching and research communities.

A first observation is that, although I tried to adopt a more modern approach in teaching statistics (Moore, 1997) with less focus on memorising techniques and formulae, students were still keen on a rather mechanical approach to learning. A second observation is the different identities through which I experienced my first year of teaching: mathematician, lecturer of statistics, university lecturer, lecturer to engineers and mathematics education researcher. The relationship of these identities was not always smooth and many contradictions occurred between them.

It seems that although we may consider ourselves as part of the broad community of practice (Wenger, 1998) of teaching undergraduate mathematics with shared practices and ways of communication, in practice other (sub)communities are involved and establish their rules (cf. Figure 1). One of these communities is the community of students, which has its own regulations and interacts with the teaching community of lecturers – with some potential conflicts. Other (sub)communities are related to the mathematical content (e.g. mathematics or statistics) and the type of study programmes (e.g. prospective mathematicians or engineers). My enculturation to this new environment was not straightforward and the interaction with my colleagues was crucially helpful. In this paper I report observations on how communities interact and how this interaction affects the experience of a new lecturer. Further, systematic study is needed, firstly on the existence and the characteristics of these communities and secondly on the ways these communities affect the lecturer and student experiences. Finally, I can envisage the potentials of this study for new lecturers' training programmes.

THE USE OF UNFAMILIAR TASKS IN FIRST YEAR CALCULUS COURSES TO AID THE TRANSITION FROM SCHOOL TO UNIVERSITY MATHEMATICS

Sinéad Breen, Ann O'Shea, Kirsten Pfeiffer

CASTeL, St Patrick's College Drumcondra, National University of Ireland
Maynooth, National University of Ireland Galway

Research has shown that mathematics courses at university often focus more on conceptual understanding than those at secondary school (Clark & Lovric, 2008). Moreover, the literature reports that the types of tasks assigned to students affect their learning. A project was undertaken by the authors in which tasks were designed and presented to first-year undergraduate Calculus students with the aim of promoting conceptual understanding and developing mathematical thinking skills. Here we present data from interviews with five students; they reported an increased emphasis on conceptual understanding at university, and found the tasks assigned beneficial in the development of conceptual understanding. We suggest that unfamiliar tasks are useful in the transition from school to university mathematics.

INTRODUCTION

The transition from school to university has been the object of much research in recent years. Gueudet (2008) conducted a review of the literature and found four broad categories of research activity in this area. Two of these are research on thinking modes and research on the organization of knowledge and reasoning modes. In this paper, we will consider the views of students on their experiences as they deal with types of thinking and organization of knowledge new to them at the beginning of their university studies. Views of the students were collected as part of a project in which the authors designed a range of tasks for use in first year differential calculus courses. The aim of the design process was to create tasks that would promote conceptual understanding by encouraging students to develop some of the practices and 'habits of mind' of research mathematicians. According to Cuoco, Goldenberg, and Mark (1996) these include finding patterns, experimenting, conjecturing, arguing, using mathematical language, visualizing and inventing. Mason and Johnston-Wilder (2004) also mention exemplifying, generalizing, justifying, convincing and refuting as processes and actions that mathematicians employ when tackling problems. A selection of tasks was trialed in a first-year calculus module, following which five students were interviewed. The data from these interviews form the basis of this paper. We will present the students' views on the difference between mathematics at school and at university and on the effects of the tasks on their ways of working and on the promotion of understanding. We will then discuss the effect of the tasks on the students' experience of the transition process.

LITERATURE REVIEW

Clark and Lovric (2008 and 2009) have described the secondary-tertiary transition as a ‘rite of passage’ and detail the changes that students experience as they commence their mathematical studies at tertiary level. These include changes in the type of mathematics taught and changes in the way mathematics is taught. They contend that compared to the mathematics taught at school, mathematics at university involves an increased emphasis on conceptual understanding, multiple representations of mathematical objects, advanced mathematical thinking, proof, abstraction, and the importance of precise mathematical language. De Guzman, Hodgson, Robert, and Villani (1998) had previously reported on the difficulties that first year university students faced and had categorized them into three types: epistemological/cognitive difficulties; sociological/cultural difficulties; and didactical difficulties. The cognitive difficulties related to the transition from elementary to advanced mathematical thinking but also to students’ ability to organize their mathematical knowledge and to develop connections between concepts.

Mathematical understanding has been characterized by many different authors (for example, Pirie & Kieren, 1994). Skemp (1976) spoke about instrumental understanding (or ‘rules without reason’) and relational understanding (knowing both what to do and why to do it). In the US, the National Research Council (2001) described ‘conceptual understanding’ as the “comprehension of mathematical concepts, operations and relations” (p116). Much of the literature in this area refers to the understanding of school mathematics; however, Sofronas et al. (2011) asked 24 experts the question ‘What does it mean for a student to understand the first-year calculus?’. They were able to construct a set of four core goals that defined student understanding in this context. These goals were: mastery of the fundamental concepts and-or skills of the first year calculus; construction of connections and relationships between concepts and skills; the ability to use the ideas of first-year calculus; and a deep sense of the context and purpose of the calculus (Sofronas et al., 2011, p132).

Gueudet (2008) observed that many studies on transition compare the practices of students with those of mathematicians. In this regard, Gueudet discusses the work of Lithner (2000) on mathematical reasoning. He noted that first year university students often rely heavily on past experience when solving mathematical problems, while mathematicians usually display more flexibility in their thinking and reasoning. Gueudet (2008) reported that in order to deal with this issue, researchers have called for changes in the teaching methods both at school and at university. In particular, a wider range of tasks which would allow students to develop autonomy and flexibility have been proposed. Boesen et al. (2010) also contend that the types of tasks assigned to students affect their learning and the use of tasks with lower levels of cognitive demand leads to rote-learning by students and a consequent

inability to solve unfamiliar problems or to transfer their mathematical knowledge to other areas competently and appropriately.

In Ireland, research at secondary level has shown that teaching in Irish mathematics classrooms tends to be focussed on the use of algorithmic procedures, with very little emphasis on conceptual understanding, and that students appear unable to apply techniques learnt in unfamiliar contexts (for example, Lyons, Lynch, Close, Sheerin, and Boland, 2003).

In discussing how students might accomplish a successful secondary-tertiary transition in mathematics, Clark and Lovric (2009) state "what we certainly can claim is that the success depends, in great measure, on the robustness of certain parameters in secondary education (attitude, motivation, approach towards work, and, in particular, learning styles and cognitive models) that might need to be significantly modified at tertiary level" (p.759). The paragraphs below consider to what extent the series of unfamiliar tasks assigned did modify some of these parameters in the view of the five interviewed students.

THE TASK DESIGN PROJECT

The first two authors are mathematics lecturers in different third level institutions in Ireland. In the academic year 2011/12, both were teaching first year differential calculus modules. Given the procedural nature of mathematics instruction at second level in Ireland, they endeavoured to design a series of unfamiliar non-procedural tasks for their students in an effort to give students opportunities to develop their thinking skills and their conceptual understanding. (In this paper, the National Research Council's (2001) description of conceptual understanding has been adopted.) An 'unfamiliar task' is one for which students have no algorithm, well-rehearsed procedure or previously demonstrated process to follow. Following Lithner's (2000) observation that students often rely heavily on past experience when solving problems, the authors hoped, by presenting the students with unfamiliar tasks, to discourage such reliance and help them to develop the flexibility in their thinking and reasoning characteristic of mathematicians.

The tasks designed in this project required students to make use of definitions, generate examples, generalise, make conjectures, analyse reasoning, evaluate statements, or use visualisation. A sample is shown below (note that students were asked to think about this problem after they had encountered the concept of continuity but before they had seen the Intermediate Value Theorem):

[1] Do you believe the following statement is true or false?

If $f(x)$ is a continuous function on the interval $[a,b]$ and k is a number between $f(a)$ and $f(b)$, then there is at least one number c in $[a,b]$ such that $k=f(c)$.

If you think the statement is false, provide a sketch as a counterexample.

A selection of other tasks designed along with a rationale for the task framework used can be found in Breen and O'Shea (2011). Each problem set (and the final examination) contained unfamiliar non-procedural tasks as well as some more procedural tasks. For example, the following procedural task appeared on the same problem set as question 1 above:

[2] Use the definition of continuity to determine whether the function $f(x) = \frac{x^2 - 1}{x + 1}$ is continuous at $x = -1$.

In this paper we will concentrate on the module taught by the first author at St Patrick's College, Drumcondra. There were 35 students registered on this module, who had chosen to study Mathematics as part of a BEd (Primary) or BA (Humanities) degree. (BEd (Primary) students at St Patrick's College to date must choose to specialise in one Humanities subject; this subject accounts for 40% of credits awarded for the degree.) The designed tasks were assigned to the students either as homework (for students to work on independently) or as tutorial problems (for students to work on in small groups). A number of tutorial sessions were observed by the third author as part of this project. Towards the end of the module, the fourteen students who had previously attended the tutorials observed were invited to volunteer to be interviewed. (These students were selected in order to maximise later collation of the data collected.) Five students volunteered and were interviewed individually by the third author, as she was not involved in the teaching of the module nor in the design of the homework and tutorial tasks. The interviews were semi-structured and lasted between 15 and 25 minutes; they were audio-recorded and fully transcribed. The identity of the interviewees was not revealed to the first author (module lecturer) unless the interviewees chose to do so themselves. The students were assigned pseudonyms A, B, C, D, E.

Students were asked about their impressions of mathematics at university, how their experience of mathematics at school differed from that at university, how their study habits or ways of working had changed and about the tasks that they had worked on. In particular, the interview schedule produced in advance of the semi-structured interviews outlined the following questions: *What do you think of your maths course (at university)? How is it different from school mathematics?; Different types of questions were used on the problem sheets in the Calculus course, were you aware of the difference? Can you give examples?; [Showing students two tasks on the same topic (one familiar/procedural, the other not):] Which of these tasks is familiar to you? Why this one? How did you feel when you first saw the task? What are the differences between the tasks? What was the purpose of each of the tasks? What did each of the tasks help you learn? Did these tasks aid your development of understanding in the same way?*

Our research questions for this paper are:

1. What are the students' views on the difference between mathematics at secondary and tertiary level?
2. What are the students' views on how the designed tasks have impacted on their practices, learning and conceptual understanding in the transition to tertiary level?

The authors coded the transcripts separately in line with these research questions. Each author grouped the codes into broad categories and then all three met to discuss the codes and agreed on common categories. This paper reports on the main themes that emerged from this analysis.

RESULTS - STUDENTS' VIEWS ON DIFFERENCES BETWEEN MATHEMATICS IN SCHOOL AND UNIVERSITY

The students were first of all asked what they thought of their university mathematics course; two of them (B and E) immediately volunteered that their experiences of mathematics courses at university were very different to that of school. The other three students were asked if they had found differences between second and third level mathematics and they were all able to point to specific differences. The differences that the interviewees spoke of were categorised and two themes are reported here: a change in emphasis from procedural fluency to conceptual understanding, and a move to independent learning.

All the students interviewed described a change in emphasis from a focus on instrumental understanding or procedural fluency in school to a focus on relational or conceptual understanding at university. They all mentioned the importance of procedures in school. For example, students A and B said:

Student A: In school it was kind a lot of procedural – you just, when you saw something you knew you did this. Like there were bits you'd understand and other bits you'd just take for granted.

Student B: It's just procedure... You learn the methodologies [sic] rather than learning why you are doing what you are doing

The students also spoke about working with formulae at second level in a procedural manner.

Two students (B and D) spoke about memorisation or 'learning off' as being important at school. Two students (A and D) also felt that there was a lack of linkages between different topics in the second level curriculum:

Student D: For the [senior cycle of secondary school] they were separate questions and they didn't really tie together at all.

Student A mentioned a specific example of the disjointed nature of her mathematics course at secondary school:

Student A: It was never explained to us that limits had – dealt with functions. They were nearly kind of separate.

This was in contrast to the five students' perception of the importance of conceptual understanding and connections between topics at university. All of the interviewed students spoke about the emphasis on conceptual understanding, for example

Student C: The emphasis in the college course is about actually understanding the principles

Student D: It kind of explains why you were doing it before

The interviewees also noticed an increased emphasis being placed on connections or relations between mathematical topics and ideas in university. Both Student A and Student D asserted that links between concepts were made explicit in their university mathematics course:

Student D: It kind of ties together really everything from the [senior cycle of secondary school] ... It kind of interlinks them more.

The five students also alluded to a change in teaching style between second and third level. This change seems to concern a move from a teacher-led classroom environment to one where more independent learning is required. For example:

Student B: It's hard to change from that mindset I find within a few months...Like from being given all the information to then having to find it yourself.

One student also indicated that, although unfamiliar tasks had been assigned at university, she would have been unlikely to encounter such tasks in school:

Student B: We hadn't done that in class, so we had to try to figure it out for ourselves. Whereas in school the teacher would have done that with you.

In addition, the students spoke about having to think for themselves and to schedule their own study timetables without the framework of daily homework assignments. However, the students interviewed acknowledged that the transition from school to university mathematics can be difficult and that it can be hard to make this transition in a short timeframe.

RESULTS - STUDENTS' VIEWS ON THE IMPACT OF UNFAMILIAR AND FAMILIAR TASKS

The five students were asked a series of questions concerning the tasks assigned to them during the module. We categorised the responses and report on the main themes that emerged: the students' views on the effects of the tasks on their conceptual understanding and the impact of the tasks on their mathematical thinking and ways of working.

Students' views of the effects of the tasks on their understanding

The students were asked what they gained from the tasks, and in particular which types of tasks helped them gain conceptual understanding. Four of the five students chose unfamiliar tasks designed for this study in answer to this question. Student B referred to unfamiliar tasks in general:

Student B: The ones I haven't seen before, definitely... in those ones you have to like completely understand it to get the answer.

Student D referred to less procedural types of tasks:

Student D: When you weren't just procedural the whole way, when you just had to stop and be like ok what do I know about it, is it continuous, differential and all this.

The comments of some students indicate that to perform unfamiliar tasks they were forced to apply and find relationships between previously learned concepts. The quote below from Student A arose from her response when she was asked to compare two particular tasks, the first one familiar (evaluating limits) and the second one unfamiliar to the student (an example generation task). Her answer suggests that she has learned more from the unfamiliar problem.

Student A: So you're kind of bringing together what you know from other things whereas in Question 1 you kind of — you're told what you have to do. So you're literally just kind of following a procedure really...whereas for the second one you kind of actually are more thinking yourself...it is more difficult, ya, but it kind of helps you understand it better. You see the relationship between them.

Other students said that some of the designed tasks involved ‘actually explaining the process involved’ (Student C) and that this led to better understanding. Student B also acknowledged that she had to understand and apply previously learned knowledge to perform unfamiliar tasks:

Student B: you had to go back on what continuity means and then try and apply it to the different ones. So it's making us see like when something is continuous and when it wasn't.

Two students also spoke of the benefit of unfamiliar tasks for assessing their own understanding of concepts. For example, Student E when referring to an example generation task, stated she found it beneficial because

Student E: it kind of proves you understand it more.

Students' views of the impact of the tasks on their mathematical thinking and ways of working

The interviews give some insight into how the tasks assigned encourage or stimulate thinking practices and ways of working. Some interviewees described certain tasks, which they had identified as unfamiliar or non-procedural, as encouraging habits such as thinking, analysing, questioning or exploring patterns. Four of the five students interviewed (A, C, D, E) asserted that the unfamiliar tasks made them think more or think for themselves. Student D claimed that, whereas for familiar tasks she would “just like write” and “plough through”, the unfamiliar tasks “really make [her] think”.

Considering specific types of tasks, Student C said about a conjecturing task:

Student C: You have to think about it and then, it's not actually a procedure, it's about you analysing the pattern and stuff.

This student also commented on a task which involves evaluating a statement:

Student C: about whether is the statement true or false, analysing it, ya it gets you thinking more than just actually using the knowledge that you learned like.

Student B described how performing an analysing reasoning task prompted her to ask herself questions:

Student B: Ahm, because it makes you analyse the proof and ask yourself questions like why you do things like that. Whereas if you were just given the proof, the correct one, you just take it for granted that that was correct.

A number of the students (A, B, C) also mentioned that, when they encounter an unfamiliar task, they refer to the basic definitions or theorems on the course and think about what they know (in relation to the task) and how they can apply it. One student (A) explained that she approached an example generation exercise by breaking it down or taking it step-by-step but also “drawing on other things” that she knew and bringing them together. Student C described using the following techniques (sometimes in combination) when confronted with various unfamiliar tasks: sketching a graph, examining different cases, generating examples, generalising, working backwards. When speaking more generally about their study habits in relation to the Calculus module, Students C and D mentioned focussing on understanding the concepts and Student B claimed a lot of independent work is required.

DISCUSSION

Research literature on the transition from second to third level mathematics seems to agree on the requirement at university level for more relational and conceptual understanding and more flexibility in thinking or approaching mathematical problems in comparison to second level mathematics (for example, Clark & Lovric, 2008; De Guzman et al., 1998). The responses of the students interviewed show that they are aware of the different requirements and, moreover, most of them welcome the change in focus. Various authors have made recommendations about the type of tasks that should be assigned to undergraduate students in order to gain the required relational or conceptual understanding and flexibility (for example, Geuedet, 2008; Boesen et al., 2010). Though the students interviewed in the study reported here struggle with the unfamiliar tasks assigned to them, they find such tasks beneficial regarding the development of conceptual understanding and their learning more generally. All of the interviewees stated that some of the unfamiliar tasks encouraged them to think more, or to analyse or question the information given. Some interviewees explicitly described how unfamiliar tasks they encountered led them to connect ideas met previously. Furthermore, the comments of the students interviewed indicate that unfamiliar tasks may not only have the effect of stimulating the development of conceptual understanding, but also may have some potential to raise an awareness that more than instrumental understanding is required at university, thereby easing their transition to university practices.

While all the interviewees reported using the practices or ‘habits of mind’ (generating examples, generalising, visualising etc.) of mathematicians when specifically called on to do so by a particular task (an example generation or conjecturing task, say), one student, Student C, described drawing on such practices in a broader sense when confronted with an unfamiliar task. Given the assertion by Cuoco et al. (1996) that it is these practices which ‘give students the tools they will need in order to use, understand and even make the mathematics that does not yet exist’ (p.376), this is a very positive development.

However, it should be noted that some of the interviewed students also described significant advantages of familiar and/or procedural tasks on their learning and confidence. In practice, the sets of problems assigned to students in this project also contained procedural-type questions, to aid the development of procedural fluency (the “ability to carry out procedures flexibly, accurately, efficiently and appropriately” as described by the National Research Council, 2001, p116). In combination, these two types of tasks helped to address the first three end-goals of a first-year calculus course as described by Sofronas et al. (2011): the mastery of fundamental concepts and-or skills; the construction of connections and relationships between and among concepts and skills; the ability to use the ideas of calculus.

The data analysed here consists of self-reported views of what the students gained from the tasks assigned. The next step in this project is to conduct a series of task-based interviews to explore the practices engaged in by students as they attempt the tasks and to investigate progress in their understanding of particular mathematical concepts related to the tasks.

While developing conceptual understanding requires a suitable teaching and learning environment as well as attention to task design, our findings to date suggest that the inclusion of unfamiliar tasks is beneficial in helping students negotiate the secondary-tertiary transition in terms of the changes in the type of mathematics taught and the way in which mathematics is taught. Clark and Lovric (2009) mentioned that certain parameters, such as a student’s attitude, approach towards work and learning style, may have to be modified to successfully accomplish the transition. We suggest that the tasks assigned to students can be used as a vehicle through which these parameters might be changed.

STUDENTS' PERSONAL RELATIONSHIP WITH SERIES OF REAL NUMBERS AS A CONSEQUENCE OF TEACHING PRACTICES

Alejandro S. González-Martín

Université de Montréal

Infinite series of real numbers are a topic that students usually encounter in their first courses of Calculus, however this notion has not received much attention by research, and research has focused mostly on learning difficulties. Our research focuses on the teaching of series and on the consequences of institutional choices on students' learning. After having analysed textbooks and teaching practices, we conjectured the presence of some contract rules in the existing praxeologies to teach series which might have an impact on students' learning. The analyses of the responses to a questionnaire seems to indicate that institutional choices lead the students to learn series without being able to define what a series is, and without being able to identify any application of this notion.

INTRODUCTION

Infinite series of real numbers (*series* in what follows) have been at the heart of the development of Calculus and appear in the programs of the introductory Calculus courses in many countries together with the teaching of sequences, limits, derivatives, and integrals. Series have many applications within mathematics (such as the writing of numbers with infinite decimals, or the calculation of areas by means of rectangles), and also outside of the field of mathematics (as the modelling of situations such as the distribution of pollutants in the atmosphere, or the growing of interests in bank accounts), which may justify their position in Calculus courses.

In Canada, the organisation of education and official curricula is under the jurisdiction of each province. In Québec, compulsory education finishes at the age of 16. For students who wish to pursue university studies, the completion of two years of pre-university studies, called *collégial* is required. For students who want to pursue scientific or technical careers, Calculus is introduced during the *collégial* studies, and it is at this time that series first appear.

Our PhD research (González-Martín, 2006), about the learning of improper integrals, led us to conjecture that students' learning of series could be mostly based on routine aspects. As we discuss in the next section, literature led us to see that most of the scarce research about series has focused on their learning, but not on their teaching. For this reason, we decided to analyse how series are presented in *collégial* textbooks (González-Martín, Nardi & Biza, 2011), and to study how they are taught by *collégial* teachers (González-Martín, 2010), while adopting an anthropological approach (Chevallard, 1999) and acknowledging the key role that the *collégial* institution and its choices play in the learning of series. After our analyses, our

results led us to conjecture the existence of some *contract rules* [1] which might have an impact on students' personal relationship with series as a consequence of teaching practices. The purpose of this paper is to discuss our results regarding some of these *contract rules* and their impact on students' learning about series.

BACKGROUND

Research literature in mathematics education focusing on series is scarce. Regarding their teaching, series appear implicitly in Robert's (1982) work, where she states that inadequate conceptions of convergence of sequences found in university students in France could be, in part, due to the exercises used in teaching. More recently, Bagni (2000) identified two levels in the construction of a notion in someone's mind (the *operational* and the *structural levels*), and observed that this distinction is not usually considered in the teaching of series.

Other results focus on the learning of series, such as Kidron's (2002) who identifies some difficulties linked to series themselves (such as the use of the potential infinity, for instance), or the confusion between sequences and series. A more exhaustive summary of literature can be found in González-Martín et al. (2011).

As we are interested in the teaching of series and in some possible consequences linked to their teaching, we undertook a research program on different stages. For the first stage, we analysed a sample of 17 textbooks used in *collégial* studies in Québec over a period of 15 years: from 1993 to 2008 (González-Martín et al., 2011), paying special attention to the praxeologies (see next section) privileged by textbooks. Our main results can be summarised as follows:

- R1. Series are usually introduced through praxeologies which do not lead to a questioning about their applications or *raison d'être*. They do not seem to solve any specific problem.
- R2. Praxeologies tend to introduce series as a tool in order to later introduce functional series, but the importance of series *per se* is usually absent.
- R3. Praxeological organisations tend to ignore some of the main difficulties in learning series identified by research.
- R4. The vast majority of tasks concerning series are related to the application of convergence criteria, or to the application of algorithmic (or previously exemplified) procedures.

The second stage of the research consisted in analysing the use of textbooks that *collégial* teachers make, and whether through their practices they attempt to do something different from what is usually presented in the textbooks (González-Martín, 2010). This is, we tried to analyse whether there are important differences between the *knowledge to be taught* and the *knowledge actually taught*. Our interviews with five teachers revealed that they considered their textbook as

adequate for the teaching of series, and that their practices tended to mostly reproduce what was presented in their textbooks. We could even identify some *gaps* between their *didactic intentions* and their practices: for instance, some teachers said that during the teaching and learning of series it is important to feel that the arithmetic of infinity is different; however, in the tasks they privileged, it was not possible to see how these tasks could help their students to achieve this.

As a consequence of the results of these two stages, we conjectured the existence of some implicit *contract rules* in the teaching of series in the *collégial* institutions in Québec. For the purposes of this paper, we will only discuss the two following ones:

Rule 1: “To solve the questions about series that are given, their definition is not necessary”.

Rule 2: “Applications of series, inside or outside of mathematics, are not important”.

These two rules have been chosen for this paper because they are related to two main activities in mathematics: defining [2] and modelling. *Rule 1* could be a consequence of *R2* and *R4*; as series seem to be presented as a tool to introduce other notions, and as the tasks seem to be organised around the application of criteria, students might develop the idea that they do not need to be able to define series in any way, since this knowledge is not required to succeed in the tasks which are proposed. *Rule 2* could be a consequence of *R1* and *R4*; the praxeologies tend to introduce series as a notion which does not solve any particular problem and the focus is established on the application of convergence criteria, without giving any importance to the utility that knowing that a series converges or diverges could have. We believe that these contract rules participate in the characterisation of the institutional relationship of the *collégial* institution with series, which might have consequences for students’ personal relationship with series and for the learning of other notions. We do not advocate that being able to define series in some way, or knowing applications of series, are indicators of a *good* learning of series. Our intention is to better understand the personal relationship of the *collégial* students with series as a consequence of institutional practices.

To verify whether these rules have an impact on *collégial* students’ personal relationship with series, we created a sample of students and applied a questionnaire (for other examples of this type of work, see for instance Kouidri, 2009).

THEORETICAL FRAMEWORK

As we have said before, our research follows an anthropological approach (Chevallard, 1999), as we recognise the important role of institutional choices in the learning of mathematics, and the repercussions of these choices.

Chevallard’s (1999) anthropological theory attempts to achieve a better understanding of the choices made by an institution in order to organise the teaching of mathematical notions. This theory recognises that mathematical objects are not

absolute objects, but entities which arise from the practices of given institutions and that every human activity consists in completing a certain type of task. These practices can be described in terms of tasks, techniques used to complete the tasks, technologies which both justify and explain the techniques, and theories which include the given discourses. According to this theory, every human activity generates an organisation of tasks, techniques, technologies and theories which Chevallard designates as *praxeology*, or *praxeologic organisation*. A praxeological analysis allows us to characterise the institutional relationship with mathematical notions within given institutions. This institutional relationship is mainly forged through the exercises (or tasks), and not only through the theoretical explanations (Koudri, 2009). Praxeological analyses are useful to describe praxeological organisations, but also to identify the existence of (sometimes implicit) *contract rules*, which are rules that the institution fosters through its practices around a mathematical notion and which contribute to determine the institutional relationship with a mathematical notion. This institutional relationship and its *contract rules* play an important role in the development of the learners' personal relationship with the mathematical notions s/he learns within the institution.

In our case, our praxeological analysis of the teaching of series (both in textbooks and in teaching practices) led us to identify some praxeological organisations in the teaching of series (see González-Martín et al., 2011), and to identify some implicit *contract rules* which may have a direct impact on the development of the students' personal relationship with series.

METHODOLOGY

To verify the impact of the *contract rules* 1 and 2, among others, on the students' personal relationship with series, we created a sample of 32 students in their second year of *collégial* studies (where series are introduced) after the teaching of series had occurred (so all the usual contents about series had already been taught). These 32 students come from three different teachers, who we name teachers *A*, *B* and *C*. Our sample consists of 4 students from teacher *A* (referred to as students A1 to A4), 14 students from teacher *B* (referred to as students B1 to B14), and 14 students from teacher *C* (referred to as students C1 to C14).

We constructed a questionnaire with 10 questions, aiming to assess the students' learning about series, as well as to verify our conjectures about the impact of the *contract rules* on their learning. The questions were designed taking into account: 1) our results of the textbooks analysis; 2) our results of the teachers' interviews about how they teach series; 3) research literature about the learning of series. The questionnaires were administrated in May 2011 during one of the courses (approximately 55 minutes in duration), and the students participated voluntarily (the students who did not want to participate just did not attend the course on that day).

In this paper, we discuss the students' responses to the three following questions:

Question 1:

Define the notion of “numerical series” or “infinite sum”.

Question 3:

Name at least two different applications of series in the field of mathematics.

Question 4:

Name at least two different applications of series in a field different than mathematics.

For one of these applications, create a realistic problem whose resolution requires the use of series. Solve the problem.

In the next section, we present and comment on the results obtained to these three questions.

DATA ANALYSIS**Question 1**

The distribution of responses to this question is the following:

Correct definitions with her/his own words explicitly mentioning a sum or the addition of terms.	B4*, B13
“Let $\{a_n\}$ be a sequence, we write: $\sum_{n=1}^{\infty} a_n = a_1 + a_2 + a_3 + \dots$ ”	A1, A4 B1
“An infinite series has the form: $\sum_{k=1}^{+\infty} aK^{k-1}$. We multiply a constant by a number till infinity. We add all the terms.”	C11
Other definitions mentioning the necessity of defining an equation, or finding some logic among the terms. Some of these definitions illustrate confusion between sequences, series and other notions.	A2 B3, B12, B14 C3*, C4, C5, C8, C9, C12, C13, C14
Definitions showing some confusion between sequences and series.	B2, B6, B9 C1, C6*
Other incorrect definitions.	A3 B5, B7, B8, B10, B11 C2, C7, C10*

Table 1: Responses to Question 1

As we said before, the usual contents about series had already been taught, including the definition of series and the application of convergence tests. In spite of this, only five students (A1, A4, B1, B4, B13) provide definitions with no erroneous elements. However, mentioning that the sum could converge or diverge does not seem to be an important thing to mention for the students, as only the students marked with * mention this fact. Other students (particularly those from teacher C) seem to associate series with the existence of a formula or regularity, which might be a consequence of the praxeologies used. For many students, in their discourse, there seems to be some confusion between sequences and series, or in the use of some vocabulary: “it’s the sum of sequences” (B2), “infinite series, it’s series in which we add the terms indefinitely” (B6), “numerical series: a sequence of numbers having some logic. Infinite sum: when you add numbers infinitely” (C4)...

We also wish to highlight the fact that most of the students provided informal definitions in their own words, and only A1, A4 and B1 seemed to be able to provide a correct, symbolic definition, although none of them mentioned the possibility of the sum being finite or finite.

These responses seem to indicate that *Rule 1* is effective and that it has an important effect on many students’ learning, shaping their personal relationship with series. The praxeological organisation necessary to solve many tasks is usually structured around the application of known criteria (*R4*), therefore the students are not required to remember or to understand what a series is to apply these criteria.

Question 3

The distribution of responses to this question is the following:

No response or a rhetorical response (“good question”)	B10 C4, C9
I don’t know	A1, A2, A3, A4 B1, B8, B11 C1
“It’s too abstract. I just apply rules”	B11, B12
Helps to find some values (like e , π , $\ln x$, $\sin x$)	B4, B9, B13
Mention of some convergence criteria as applications	B5, B7
Helps to make approximations (to curves, in a calculator, or through Taylor polynomials)	B6, B12 C14
Helps to calculate areas	B8 C3, C10

Other	B2, B3, B14 C2, C5, C6, C7, C8, C11, C12, C13
-------	---

Table 2: Responses to Question 3

Our analysis of textbooks led us to state that textbooks seem to teach students to determine the convergence or the divergence of some series, but that this task has no utility or purpose (*R1*, *R2*) (González-Martín et al., 2011). The responses to this question seem to confirm our initial impressions as most students do not seem able to clearly state any mathematical applications of series. The students who are able to give some applications (like finding some values, or making approximations), do not seem to be able to give details about how series are used (so, probably, they just heard their teacher quickly mention some applications).

One application which appears in certain textbooks (modelling the distribution of medication in the blood) is vaguely remembered by just one student: “I am not sure, but we can use them to determine or to know the amount of medication present in the organism of a person” (B14).

We believe it is also significant that the four students of teacher *A* acknowledge not knowing any application. We can also see that almost all the students who mention the use of series to calculate some values, or to make approximations, are students from teacher *B*. In sum, the students’ responses lead us to believe that possibly, teacher *A* did not mention any application during his teaching while teacher *B* probably mentioned some applications without giving details, and finally, that teacher *C* made some links with integrals and Taylor polynomials.

The possible consequence of *Rule 2* is that students are unaware of the applications of series. Data seem to indicate that this consequence has occurred among the students in our sample, and the responses to question 4 seem to confirm this conjecture.

Question 4

The distribution of responses to this question is the following:

No response	B6, B10, B12 C7, C9, C10
I don’t know	A1, A2, A3, A4 B4, B9, B11, B13 C1, C4
Example of the ball which bounces indefinitely	C2, C8

Example of the ball which bounces indefinitely (developing some calculations)	C6, C11, C14
In Chemistry: “every second, half the number of molecules having reacted the second before, react...”	C3
“The digestion of a substance is made in a specific way. After one hour, half the substance is digested. Two hours later, only a quarter of the substance remains...”	B3
Pharmacy: “A medication which is taken every day. Calculate the amount of the medication in the body of a person in this context”.	B1
Besides mathematical applications, I don't know	B7 C5
Other	B2, B8, B14 C6, C12, C13

Table 3: Responses to Question 4

None of the students were able to create a realistic problem, to model it and to solve it using a series. As in the previous question, we observe some regularities in the responses: none of the students from teacher *A* can give a response; all of the students who mention the ball with infinite bounces are from teacher *C*; again, the example of the distribution of medication comes from a student from teacher *B*.

Just as the textbooks analysis and the teaching practices analysis suggested, applications of series to model some situations seem to be generally absent from praxeological organisations, which seems to strengthen the development of *Rule 2* and its impact on students' learning. Even if some students seem to be aware (in a vague way) of some applications (inside or outside of the field of mathematics), they do not seem to be able to further develop them or to give specific details, probably because tasks requiring them to do so are absent from the praxeologies privileged in the *collégial* institution.

FINAL REMARKS

In spite of the importance of series for the development of modern mathematics, the teaching of series in the *collégial* institution seems to reduce them to a set of criteria and algorithms used to solve tasks which do not seem to have any purpose (“once we know this series converges, what do we do with that knowledge?”).

The analysis of the praxeological organisation of the teaching of series both in the textbooks and in the teaching practices at the *collégial* level led us to conjecture the existence of some implicit *contract rules* having an impact on students' learning. Our

results seem to support our conjecture, meaning that students learn to solve some questions concerning the convergence or the divergence of given series, without:

- Clearly being able to state what a series is.
- Clearly knowing what utility solving this task could have.

Even if the definition of series appears in the textbooks (and usually this is the first encounter of students with series), and some textbooks present certain applications (in a very vague way), praxeological organisations do not seem to clearly place any importance on these elements. However, students are later required to construct other mathematical notions (like power series and Taylor polynomials) from a notion they are barely able to define, and one key mathematical activity (modelling) is completely absent from these practices.

We do not have the intention of making generalisations from our sample (32 students from three teachers). As we said before, the anthropological theory allows characterising the institutional relationship with mathematical notions within given institutions, which has a very important role in the shaping of the individuals' (as institutional subjects) personal relationship with these notions. Our analyses of textbooks and teachers practices led us to a characterisation of the existing praxeologies (and implicit *contract rules*) in the *collégial* institution to introduce series (González-Martín et al. 2011). This characterisation made us establish conjectures about the significance given to series within the institution, and guided us to design our questionnaire. Even if we do not have a representative sample of students, we can say that the analysis of their responses seems to give some strength to our conjectures about the impact of existing praxeologies on the development of the students' personal relationship with series.

Our paper discusses the responses to just three questions from our questionnaire. We expect to continue our analyses of the questionnaire and to provide a more detailed portrait of the learning achieved by students within the *collégial* institution, as well as to identify other *contract rules* that praxeologies might be developing and their impact on students' learning.

An awareness of the consequences of practices being privileged at the *collégial* level could be helpful in order to begin a discussion about how series are taught and whether the students' difficulties in learning series are taken into account in teaching practices and finally, the possible consequences of current practices. We hope that our results can lead to the development of more research focusing on the teaching and learning of series, as well as to stimulate a discussion among members of the teaching community at the post-secondary level about the practices which are privileged and their consequences in the learning achieved by the students.

NOTES

DIGITAL RESOURCES AND MATHEMATICS TEACHERS PROFESSIONAL DEVELOPMENT AT UNIVERSITY

Ghislaine Gueudet

CREAD, IUFM Bretagne UBO

For university mathematics as for other levels, a profusion of digital resources is available for teachers. This evolution impacts the teacher's practices, and contributes to teachers' professional development. Retaining here a focus on the interactions between teachers and resources, I study the use of digital resources for the teaching of mathematics at university, and how this use articulates with teachers' professional knowledge and its evolution. I also investigate the consequences of digital resources for teachers' collective work. I consider these issues, drawing on a case study concerning a mathematics lecturer working with computer science students.

TEACHER RESOURCES AND PROFESSIONAL DEVELOPMENT, IN THE UNIVERSITY CONTEXT

The profusion of digital resources for the teaching of mathematics is a well-known fact. Its consequences for teacher professional development have been, and are studied in a number of research works (Gueudet, Pepin & Trouche, 2012), in the context of primary and secondary school. This issue has not been studied at university yet.

We retain here the theoretical perspective of the documentational approach (Gueudet & Trouche, 2009). This approach considers that teachers interact with resources: textbooks, websites, software; but also students productions, discussions with colleagues. Teachers combine resources, design their own resources, set them up in class, modify them: we name this process the teachers' documentation work. It holds a central place, in teachers' professional activity. Interestingly, a recent work (Mesa & Griffiths, 2012) considers textbooks mediation of teaching at university, in mathematics. The authors identify several types of mediation, and observe that the use of textbooks by lecturers changes over time. The perspective adopted here is very similar, and textbooks are part of our study, which considers more generally all teaching resources. Drawing on the instrumental approach (Rabardel, 1995) we consider that teachers, along their interactions with resources, for a given teaching objective, develop a document: a mixed entity, associating resources and utilization schemes of these resources. This process is called documentational geneses. For the sake of brevity, we do not give here a detailed description of schemes. We retain that documents encompass resources and, in particular, professional knowledge, of different kinds: subject matter knowledge, pedagogical knowledge, but also, and this is essential in our study, pedagogical content knowledge, if we refer to Shulman's (1986) categories. The documents of a given teacher constitute a structured set,

his/her documentation system. This documentation system associates a resource system, and professional knowledge.

Teachers' professional knowledge evolves, along the use of resources. For example, using a piece of software can lead to evolutions of the teacher's knowledge, concerning this software, but more generally also concerning mathematics and their learning by students. Thus teachers' documentation work is central, for professional development; moreover, the interactions between teachers and digital resources are nowadays an essential aspect of this documentation work. We propose here to study teacher documentation at university, with a focus on the role of digital resources.

Our study takes place in France, where teacher education, at university level, is very limited. In most universities, short training programs are proposed to university teachers, to discover a new software in particular; but there is no in-service training program concerning pedagogical issues. In this context, I claim that teacher documentation work is the principal source of teacher professional development at university. I study here two main questions, related to this issue:

- How do university mathematics lecturers use digital resources, to reach their pedagogical objectives? How does this use articulate with their professional knowledge, and its evolution?
- Which evolutions of mathematics lecturers' work at university can arise from the use of digital resources, in particular concerning collective work?

My aim in this paper is not to provide complete answer to these general questions, but to propose possible answers, and to open directions for further research, through the study of a particular case.

STUDYING DOCUMENTATION WORK: METHODS

Studying documentation work means to consider long-term processes, that happen in several places: the classrooms, but also the teacher's office, or even his/her home. Interviewing the teacher, asking her/him about her/his use of resources and the evolutions of this use is essential, but not enough. An essential methodological tool, associated with documentation, is the collection of the teacher's resources (Gueudet, Pepin & Trouche, 2012): extract of the books, the websites she/he uses; the students' sheets he/she writes; e-mails exchanged with colleagues etc. During the interview, the researcher asks to investigate the teacher's computer, to see his/her cupboards, and all possible places where material resources are kept. This complete data collection process corresponds to an ethnographic approach, which requires an important mutual commitment of the teacher and the researcher. Naturally, the conditions of the research work do not always permit to reach such a commitment.

The data used here have been collected in the context of a European Research project, Hy-Sup (Burton *et al.*, 2011), aiming at studying the use at university of distant platforms. In the context of this project, I followed in 2010-2011 two mathematics

lecturers, who used in particular a Moodle platform for their teaching. I focus here on the case of one of these two lecturers, Peter.

I collected his resources, and met him for an interview that has been recorded and transcribed. This interview comprised several parts, concerning respectively: his working context and use of resources in general, digital resources in particular; a detailed presentation of his use of digital resources in the context of a precise course – he retained his linear algebra course –; the evolutions he retained of his own practice, linked with the use of digital resources.

The interview is firstly analysed by noting all the resources, and the agents (students, colleagues etc.) mentioned. Then I retain the teacher's comments about the use of each resource, in particular: his aims, for the use of a given resource; his expression of beliefs about the role of these resources in his teaching of mathematics; the mention of evolutions. All these elements are confronted with the main resources collected: for example, when the teacher declares using a textbook, the content of the book is confronted with the students' sheets designed by using this book.

A CASE STUDY

Peter has a PhD, about partial differential equations, obtained in 2001. Since 2001, he teaches at university; he obtained a position as full-time lecturer, and stopped his research activity. Peter teaches mathematics at a University Technological Institute, specialized in computer science, in France. These institutes, inserted in Universities, offer a two-years training with professional objectives. They deliver professional diploma after these two years; nevertheless, nowadays more than 80% of the successful students continue their studies afterwards, to graduate or even to obtain a Master degree.

The teaching of mathematics, in Peter's institute, is organised in several courses, each of them concerning a given mathematical topic (for example: “linear algebra”). Each course lasts 40 hours: 5 hours a week, over 8 weeks. One hour is the lecture; two hours are a paper-and-pencil tutorial; two hours take place in the computer laboratory, using a computer algebra system (CAS, in what follows) – namely Scilab.

All the material used for a course is available for the students on a Moodle platform. The students also upload their own productions with Scilab on this platform, for correction by the lecturers.

Peter's resource system: an overview

For the preparation of his courses, Peter uses classical mathematics textbooks, written for students of this level (for example, Ramis, Deschamps & Odoux, 1979). These were the textbooks he used himself as a student in mathematics. He also uses books about the history of mathematics (Hauchecorne & Surrateau, 1999).

Peter appreciates the use of technology – he used different software himself as a student, and developed this use as a lecturer. He can be considered as a technology enthusiast (Monaghan, 2004). He uses various software: Scilab, the CAS used in the

technological institute courses; LaTeX, to compose his students' sheets, and his courses; different software for composing web pages, and wikis; and Moodle. He also visits many websites: websites associated with given software, personal websites of colleagues, Wikipedia etc. Peter is an experienced lecturer; the courses he produced during the previous years are now central resources, in his documentation work.

His professional webpage (figure 1) gathers many of these resources, produced during previous years. The texts of his courses, exercises lists (ordinary mathematics exercises, or exercises for working on the computer), exam texts. It also proposes technical notices, about Scilab, or about non-mathematical tools, like wikis.

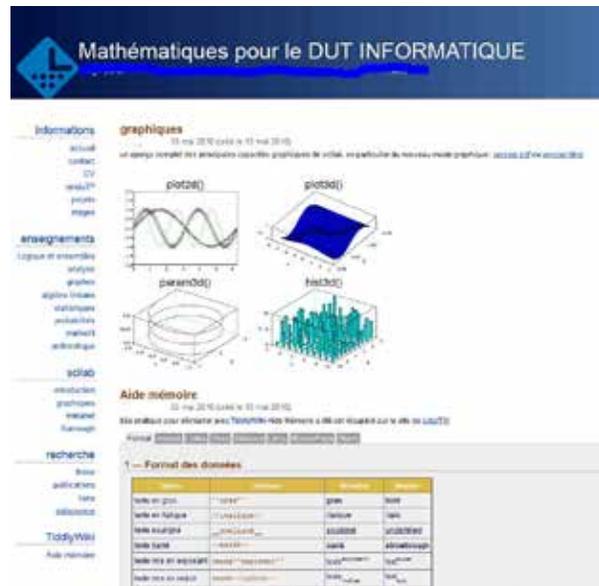

Figure 1. Peter's professional webpage.

Mathematics for computer science students, and use of digital resources

One difficulty, emphasized several times by Peter in his interview, is that his students are not specialized in mathematics. He mentions mainly two kinds of consequences of this fact: the students have limited mathematical skills; and they are not interested in theory, only in mathematics as a tool for computer science.

P: We adapt the content, because it is very complicated, for such students [...] They are students in computer science, mathematics is not their central subject.¹

Another difficulty of his teaching context, that he emphasizes, is the heterogeneity of his students' skills in mathematics. He has indeed students from several origins. Some of them come directly from secondary school; amongst those, some were specialized in mathematics (which means receiving 8 hours of mathematics courses each week in grade 12), and others not (which means only 4 hours of maths each week in grade 12,

¹ Our translation.

with a very technical content). Other students have spent one year at university before, possibly in mathematics major. Moreover, the students' aims can also be very different, between obtaining the two-year diploma, or trying to go further, to obtain a master degree. “We have a very broad spectrum of students”, declares Peter in his interview, describing all these possibilities.

Peter himself was a student in mathematics, specialized in a very theoretical research subject in partial differential equations. During his PhD, he gave courses at university for mathematics majors. Discovering this new teaching context, at the technological institute, was a important change for him, which raised professional questions. His answers to the interview, and the analysis of his resource system, indicate that he developed several kinds of solutions, linked with digital resources.

Scilab, supporting the learning of mathematics

Scilab holds a central place in Peter's resource system. One reason for this is that it contributes to answer to the professional questions mentioned above. Peter (together with his colleagues, at the technological institute) considers it as very important, for raising the students motivation, and helping their comprehension.

P: Programming the topics taught in maths gives a practical aspect [...] when they implement Gauss method, they appropriate it.

Peter considers that programming a mathematical method with a software helps to understand the mathematics. Research works about the use of CAS to teach mathematics, at the beginning of university (e.g. Weller *et al.*, 2003, Gyöngyösi *et al.*, 2011) indicate that such possibilities indeed exist, under certain conditions, since the software can also constitute a difficulty. Another important aspect, not mentioned in the interview but evidenced by Peter's resources (figure 1), is that he extensively uses the possibilities of visualization offered by Scilab.

Scilab also intervenes in the management of students' heterogeneity. Firstly, almost all the first year students discover Scilab, the differences existing in mathematics do not exist about this software. Moreover, Peter composes texts, for the Scilab sessions, which comprise a common, minimum basis; and many complements. Thus the high-achieving students have something to do, working by themselves on a computer; at the same time the lecturer can support students having more difficulties.

P: I see that in the computer lab session, a weak student, not motivated, and a good motivated student, their work is completely different, a 1 to 3 ratio.

Here the text proposed by the lecturer, and the computer with Scilab are combined resources, for the management of students' heterogeneity.

I asked Peter, about his use of Moodle for the same objective (he could, for example, propose to some of the students an out-of-class work). He does not use it for this objective, because he considers that most of the work in mathematics must be done in class, in particular for the students who have difficulties.

Raising students' motivation by using mathematics for computer science

Peter tries to present mathematics as a useful tool for computer science, in order to raise the students' interest. For example, the text of his linear algebra course finishes with the example of Google searching process: the notion of PageRank, and its links with vector spaces, and eigenvectors (figure 2).

En 1996 Larry Page et Sergey Brin, deux étudiants en doctorat à l'université de Stanford, eurent l'idée d'une nouvelle définition du PageRank : *“la pertinence d'une page web est proportionnelle à la somme des pertinence des pages qui pointent vers elle”*. Cette définition peut se traduire par un système d'équation linéaires dont les inconnues sont les pertinence des pages $x_k > 0, k = 1, 2, \dots$ et le coefficient de proportionnalité λ :

$$\forall i, \sum_{j \in P_i} x_j = \lambda x_i, \quad P_i = \{j \mid \text{la page } j \text{ pointe vers la page } i\} \quad (1)$$

En d'autre terme : *les PageRank forment un vecteur propre (de coordonnées positives) associé à une valeur propre (non-nulle) d'une matrice représentant les liens entre les pages web.*

Figure 2. Extract of Peter's linear algebra course, Google definition of PageRank²

Peter also proposes to his students to implement well-known algorithms – he calls it “real applications”. A “real application”, for him, is for example the RSA algorithm³, in cryptography; the students implement it, in the context of his arithmetic course.

Digital resources and evolving collective dimensions of teachers' work at university

Peter often works with his mathematics colleagues at the technological institute. For each course (e.g. “linear algebra”), a lecturer is responsible of the course. This lecturer gives the lecture; he/she builds the content of the lecture -the corresponding file is available on this lecturer's webpage, and on Moodle, for his/her colleagues and for the students. The texts of the tutorials and of Scilab sessions are usually collectively composed. Sometimes Peter also works with computer science colleagues, to propose and follow “students' projects” (for second year students; the students have to design a software, over six months).

Peter learned by himself to use various technologies, ranging from Scilab to Moodle. The university offers some technical training sessions, but they were proposed too late for Peter who trained himself before! He reads the software notices; but the most useful tool for him is always the “Frequently Asked Questions” pages. We consider

2 In 1996 Larry Page and Sergey Brin, two Stanford University PhD students, had an idea for a new definition of the PageRank: “the relevance of a web page is proportional to the sum of the relevance of webpages offering links to it”. This definition corresponds to a system of linear equations, whose unknowns are the relevance of pages $x_k > 0$, and the coefficient λ . [...] In other words: the PageRank constitutes an eigenvector (with positive coordinates) associated with an eigenvalue (non-zero) of a matrix representing the links between web pages.

3 RSA stands for Rivest, Shamir and Adleman, who first publicly described this coding algorithm in 1977.

this as a collective dimension: Peter's knowledge evolved, by reading the answers to questions raised by colleagues on these websites.

As mentioned above, on his webpage he proposes, for students and colleagues, technical notices, about the use of different software: Scilab, but also wiki tools. He works with his mathematics colleagues, in particular, for the use of new digital means.

P: My colleagues have started to use Scorn, to program multiple choice questionnaires... We can insert them in Moodle, for the assessment.

Peter's colleagues have learned to use a software, for building online tests in Moodle. Peter himself did not learn it yet, but he can use the questionnaires. Here the collective work is needed, because of technical difficulties, in discovering new software. Moreover, it will probably lead to a change in the students' assessment: instead of written tests, they will fill in online tests on the Moodle platform.

DISCUSSION

Initial research questions, and the case of Peter

Our first set of questions concerned the use of digital resources by mathematics lecturers to reach their pedagogical objectives, and its articulation with professional knowledge.

Peter's resource system comprises a large range of digital resources of different kinds. This means that these digital resources belong to documents, developed by Peter, which associate sets of resources and professional knowledge.

Scilab (considered here as a resource) is involved in several documents, developed by Peter, with the objective to teach university mathematics to computer science students. Along his use of Scilab, Peter developed professional knowledge, about the possible use of a CAS to support the learning of university mathematics, for students who have a low interest in theoretical issues. Working with CAS permits an approach of the mathematical concepts through practical tasks (Gyöngyösi *et al.*, 2011); this professional knowledge is part of the document he developed.

Scilab is also involved in another document, developed for an objective of management of the students' heterogeneity. Other resources intervene in this document: the computer lab naturally, and also the texts composed by Peter, with a core content, designed for all the students, and complements for gifted students. Professional knowledge, intervening in this document, is formulated by Peter in his interview as: “the students have very different skills, some of them can be very fast”; “if a high-achieving student finishes the task too early, he/she will disturb the other students in their work”. As noticed above, he does not use Moodle, for the same objective, because he considers useless to propose distant work to students who have difficulties. He developed this knowledge along his observation of students at the technological institute. A direct consequence is that Moodle is not inserted, for Peter, in a document for the management of heterogeneity.

In fact Moodle is mostly used as a place where students can find information about the courses schedule, and can upload their productions (for downloading, Peter's webpage already offers most of the files that the students can find on Moodle). We consider that Moodle is not really integrated yet in Peter's resource system. This situation can naturally evolve, in particular if Peter develops his use of the Scorn questionnaires designed by his colleagues.

Besides all these digital resources, surprisingly Peter's resource system comprises a mathematics textbook, published in 1979 – the textbook that his own lecturers used, when he was a student. This textbook is for him the reference, for the mathematical content of his courses; he uses it to build his courses texts, and complements it with “cultural information”, about the life of mathematicians, or the actuality of computer science. It leads to an important gap, between a theoretical course, and the practical applications proposed to the students. The use of these “old” resources, in some cases, can contribute to explain why university mathematics teaching can seem to be “congealed”- resources also yield a kind of inertia (this has been evidenced, for assessment texts at university, by Lebaud, 2009).

Our second set of questions concerned the evolutions of mathematics lecturers' work, with a focus on collaboration.

Peter works with his mathematics colleagues, and digital resources play an important part in this collaboration. The files designed for their teaching are exchanged, via e-mail, or using the webpages, or Moodle. Moreover, since the university does not propose teacher training, about new software, a mathematics lecturer who has learned how to use a particular software writes information, suggestions, offers texts on his/her webpage, for colleagues.

University teachers' resources and documentation: directions for research

The case of Peter is certainly very special. He is a technology enthusiast, teaching mathematics to computer science students; under these conditions, the importance of digital resources in his system is not surprising. Moreover, Peter has no research activity; this fact certainly impacts his resource system. Nevertheless, Peter's case informs us more generally about the use of resources by lecturers at university, and suggests directions for further research. We retain here questions about teaching resources, digital resources in particular, and about collective teachers' work.

University lecturers, like all teachers, use many resources to design their teaching. They use in particular textbooks; the work of Mesa & Griffiths (2012) identifies needs for further research on this topic, in particular about how teachers' use and students' use articulate, how textbooks articulate with lecture notes, how textbooks use evolves over time. All these issues are essential, I add here a fourth direction: How does teachers' textbook use articulate with their use of digital resources?

These digital resources deserve a specific study. Many researchers have already studied the use, at university, of specific software for mathematics, like CAS, or

visualization software. Nevertheless, it has mostly been considered in terms of students' learning. The integration of mathematical software by university lecturers, the professional development associated with it, has not been investigated yet. Moreover, the use by lecturers of digital resources like online exercises, distant platforms, and virtual learning environments is also a new, interesting direction. These resources open possibilities, in particular for assisting diversely able students with a diversity of tasks. Is this potential effectively used by the teachers, and if not, which kind of teacher education could foster and support this use?

Concerning collaborative work, in the case of France we can claim that lecturers' work is more collective at university than, for example, at secondary school. Lecturers have to work together, when a lecture is given to a large number of students, who will then follow tutorials in sub-groups. Teachers giving tutorials have to know the content of the lecture, to coordinate for the content of the tutorials etc. They also generally write the exam texts together. Digital resources have fostered these aspects of collaborative work: the lecturers can indeed easily exchange files, via e-mail, or on webpages. Which are the consequences, for teacher knowledge, of this collaborative work? Do university lecturers, working together, develop similar beliefs, ideas about their teaching?

Investigating the interactions between teachers and resources, at university, requires specific studies. These interactions are a major factor, for teachers' professional development, and studying them could enlighten specific features of university teacher's professional knowledge. Such research works could contribute to the design of resources, for the teaching of mathematics at university, and to propositions, for teacher education.

ON THE CONCEPT OF (HOMO)MORPHISM : A KEY NOTION IN THE LEARNING OF ABSTRACT ALGEBRA

Thomas Hausberger

Université Montpellier 2

This article is dedicated to the investigation of difficulties involved in the understanding of the homomorphism concept. It doesn't restrict to group-theory but on the contrary raises the issue of developing teaching strategies aiming at gaining access to structuralist thinking. Emphasis is put on epistemological analysis and its interaction with didactics in an attempt to make Abstract Algebra more accessible.

I. INTRODUCTION

In our context, Abstract Algebra means the discipline devoted to the study of algebraic structures, according to the new paradigm established after the publication of van der Waerden's textbook *Moderne Algebra* (1930):

This image of the discipline turned the conceptual hierarchy of classical algebra upside-down. Groups, fields, rings and other related concepts, appeared now at the main focus of interest, based on the implicit realization that all these concepts are, in fact, instances of a more general, underlying idea: the idea of an algebraic structure. The main task of algebra became, under this view, the elucidation of the properties of each of these structures, and of the relationships among them. Similar questions were now asked about all these concepts, and similar concepts and techniques were used, inasmuch as possible, to deal with those questions. The classical main tasks of algebra became now ancillary. The system of real numbers, the system of rational numbers, and the system of polynomials were studied as particular instances of certain algebraic structures, and what algebra has to say about them depended on what is known about the general structures they are instances of, rather than the other way round (Leo Cory, History of Algebra, Encyclopaedia Britannica Online, 2007).

Abstract algebra is taught in France at third-year University level. The situation reflects the international one and can be summarized by Leron and Dubinsky's (1995, p. 1) statement: *“The teaching of abstract algebra is a disaster, and this remains true almost independently of the quality of the lectures”*. If both students and experienced instructors generally agree upon this provocative claim, this shouldn't prevent us from investigating the nature of the obstacles and proposing alternative or complementary approaches (as Leron and Dubinsky did).

Our approach is based on an epistemological analysis of structuralist thinking (Hausberger 2012) with a view to introducing “meta” aspects in the teaching of abstract algebra. In other words, the goal is to build reflexive activities that can help students to make sense of this particular knowledge. This is justified by the identification, on an epistemological point of view, of the concepts involved as FUGS (formalizing, unifying, generalizing & simplifying) concepts (Robert 1987).

Obstacles regarding the built-up of teaching strategies, using traditional didactic tools such as Brousseau's "théorie des situations" (Brousseau 1986) or Douady's "dialectique outil-objet" (Douady 1986), can be analyzed as consequences of their epistemological nature as FUGS (Rogalski 1995). This approach has been conducted previously by Dorier, Robert, Robinet & Rogalski in the case of linear algebra (Dorier and al. 2000).

In Hausberger 2012, we underlined the fact that several levels of unification have to be distinguished in the context of algebraic structures: at level 1, a general theory applies to quite different objects sharing a common feature (for instance group theory), at level 2, the axiomatic presentation of structures is conducted in a uniform way (leading to structural questions and methods) and puts forward bridges between structures, at level 3, what has been previously a form (structures) is fully taken and studied as object in a superior level of organization (this is category theory or any other mathematical meta-theory of structures, the word "meta" being used here in a different context and with a slightly different meaning. Nevertheless, meta-theories and meta-activities meet in so far as they both introduce a reflexive point of view).

We made the assumption that meta activities of level 2 were worth being introduced to facilitate the access to modern structuralist expositions of algebraic structures. In the case of Linear Algebra, Dorier introduced in fact only meta of level 1. This is justified by the fact that a single structure is at play and that it is the first abstract structure that students encounter and theorize at University.

Moreover, unlike the impression conveyed by Cory in the previous quote, each structure has its own flavor. Indeed, it has its own history of problems, its own "typical objects". There certainly is a tension in modern mathematics related to the articulation of abstract formalism and intuition (requiring a more direct grasp of objects). This tension is acknowledged by philosophers and is also visible in manuals¹. This raises the following didactic issues and tasks:

–Find a right balance between formalizing and problem-solving involving more concrete objects.

–Think about strategies to gain access to structuralist thinking. This should be progressive: in this respect, the goals set in the teaching of group theory should be different from those regarding ring theory. We will make this statement more precise below.

In our view, the flavor of Linear Algebra resides in interrelating geometry and algebra (enlarging the notion of vector, vector space, or interpreting geometrically reduction theory) and its challenge is also to articulate computational and abstract theoretical aspects (for instance, matrices and linear applications). In group theory, the symmetric group is a paradigmatic example, classifying groups of small order is a very didactical moment and understanding the notion of isomorphism is fundamental to give access to the abstract group concept, thus accomplishing level 1. The

emphasis on group action is also fundamental to make the concept fully operational. Ring theory has quite an arithmetical flavor: extending the unique-prime-factorization theorem to rings of algebraic integers has proved to be a motivating force in history for the development of an abstract divisibility theory in which the concept of ideal plays a major role and the main objects to unify, on an elementary level, are numbers and polynomial rings. On the structuralist front, ring theory (being preceded by group theory) should be an opportunity to discuss structural aspects shared in the modern exposition of both theories: the construction of quotients, the concept of homomorphism as structure-preserving function, the isomorphism theorems as tools to compare objects, decomposition theorems into simple objects, characterization by universal properties, etc. These aspects would certainly benefit from being made more explicit through level 2 meta activities. It is nevertheless a real challenge and it remains conjectural whether it is feasible or not at third year University level.

This article will now focus on the (homo)morphism and isomorphism concepts which are central in abstract algebra. Students often confess that they lose tracks when homomorphisms come in the foreground after the introduction of isomorphism theorems. Previous didactic studies also report on this issue, for instance Nardi (2000) titles p. 179: “Episode 3: The first isomorphism theorem for groups as a container of compressed conceptual difficulties”. We will contribute by deepening the epistemological analysis on morphisms, extending the picture to isomorphism theorems for other structures and conceptions about morphisms in general. This corresponds to our general philosophy of attacking globally the issue of teaching abstract algebra through epistemological, didactic, cognitive studies of processes involved in structuralist thinking.

II. A FEW CASE STUDIES

Previous studies on groups

According to Leron, Hazzan & Zazkis (1995), “the very concept of isomorphism is but a formal expression of many general ideas about similarity and differences, most notably, the idea that two things which are different may be viewed as similar under an appropriate act of abstraction”. It corresponds to the vague (but crucial and intuitive) idea that two isomorphic groups are essentially the same (on the group-theoretic point of view) and part of the proposed didactic strategy is to help students make sense of it before getting engaged in the formalization of the isomorphism concept. Indeed, such a formalization requires the function concept and reasonable understanding of quantification, which adds further difficulties.

This point of view contrasts with the standard exposition in modern manuals, in which structuralist conceptions have been naturalized. Interestingly, it matches van der Waerden's (1930) who didactically took great care in motivating the introduction of new concepts. If isomorphisms derive formally from homomorphisms, it should be pointed out that isomorphisms come first epistemologically.

Nardi (2000) carries on the work by analyzing tutoring sessions dedicated to retrieving and proving the first isomorphism theorem:

Let $\Phi: G \rightarrow G'$ be a group homomorphism. If $K = \ker \Phi$ then $G/K \cong \text{Im } \Phi$. The isomorphism is constructed by setting $\psi(Kg) = \Phi(g)$.

She underlines that “the degree of complexity in a problem which requires a well-coordinated [linking ψ and Φ] manipulation of mappings between different sets is extremely high” and stresses the numerous “difficulties in the conceptualization of properties associated to the notion of mapping (homomorphic property, 1-1, onto, well-definedness)” as well as the high degree of abstraction involved in the definition of a mapping between the cosets of a subgroup and the elements of the group. Finally, she points out the impact of epistemological arguments that the tutor would put forward to motivate the newly introduced concepts. This certainly brings water to our mill.

Comparing objects through homomorphisms

Context. The following questions were asked to third year undergraduates as part of a mid-term examination for a second course in abstract algebra devoted to ring and field theory. The student is supposed to retrieve the statement and proof of a classical generalization of the first isomorphism theorem (in the ring context), which has been presented during the lectures as a **tool** for constructing homomorphisms from quotient rings (i.e. of type $A/I \rightarrow B$):

Let $f: A \rightarrow B$ be a ring homomorphism, I an ideal of A and $\pi: A \rightarrow A/I$. Then f “factorizes through A/I ” (i.e. there exists a homomorphism \bar{f} such that $f = \bar{f} \circ \pi$) if and only if $I \subset \ker f$.

The theorem is illustrated by the following commutative diagram:

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ \pi \downarrow & \searrow \bar{f} & \\ A/I & & \end{array}$$

Homomorphisms have been introduced as structure-preserving functions, emphasizing the condition $f(1) = 1$ ⁱⁱ. To facilitate the retrieval, the ring data has been denoted $(A, +, \cdot, 1)$. The general idea has been developed that **homomorphisms aim at “comparing” rings**: if $f: A \rightarrow B$ is bijective then A and B are “essentially the same” and can be identified. If it is only injective (1-1), then A can be identified with a subring of B and the kernel measures the defect of injectivity, if it is surjective (onto), then B can be identified with a quotient of A through the first isomorphism theorem. As an application of the generalized theorem, named explicitly “factorization theorem for ring homomorphisms”: $\mathbb{Z} \rightarrow$

$\mathbb{Z}/2\mathbb{Z}$ factors through $\mathbb{Z}/4\mathbb{Z}$ and induces an isomorphism $(\mathbb{Z}/4\mathbb{Z})/(\bar{2}) \cong \mathbb{Z}/2\mathbb{Z}$. The lecture then carried on with the third isomorphism theorem which generalizes such isomorphisms and is named “simplification theorem for quotients of

quotients". To summarize the didactic intent, the tool-object dialectic (Douady 1986) is at play and epistemological insight was given to connect the formalism with cognitive processes of comparison and identification.

Here are the questions:

1. Recall the factorization theorem for ring homomorphisms and give a proof.

2. Can $\mathbf{Z}/4\mathbf{Z}$ be identified with a subgroup of $\mathbf{Z}/8\mathbf{Z}$ (in other words, does $\mathbf{Z}/8\mathbf{Z}$ contain a subgroup isomorphic to $\mathbf{Z}/4\mathbf{Z}$)? Can $\mathbf{Z}/4\mathbf{Z}$ be identified with a subring of $\mathbf{Z}/8\mathbf{Z}$ (in other words, does it exist an injective homomorphism $\mathbf{Z}/4\mathbf{Z} \rightarrow \mathbf{Z}/8\mathbf{Z}$)? Can you construct a ring-homomorphism connecting $\mathbf{Z}/4\mathbf{Z}$ and $\mathbf{Z}/8\mathbf{Z}$? Can $\mathbf{Z}/4\mathbf{Z}$ be identified with a quotient ring of $\mathbf{Z}/8\mathbf{Z}$?

Results. Out of the 13 students who took the test, only 5 managed to retrieve successfully the statement of the theorem (question 1). The diagram was often reproduced, indicating that it played some role in the memorization process. 5 students didn't answer question 1 and among the others, common mistakes concerned the omission of the condition on the ideal, or an inversion of the inclusion. Indeed, the student can have control on this only if he has understood that elements of I are mapped to 0 because the diagram commutes. Yet, only 4 students gave an attempt to retrieve the proof: 2 of them successfully demonstrated that the condition is necessary but couldn't carry on so that a single student gave a complete proof. This is a bit surprising since it was emphasized during the lectures that the proof can be worked-out exactly as in the group context. Moreover, the difficulty of articulating ψ and ϕ identified by Nardi (2000) is greatly taken in charge didactically by the formulation: " f factorizes through the quotient and induces \bar{f} ". Even after completion of a first course in abstract algebra, the task of elucidating the properties that need to be checked (well-definedness, homomorphic property, 1-1, onto), thus reducing the problem to elementary tasks, is regarded as very complex by students.

A single student gave elements to answer question 2. He began by making the groups more explicit: $\mathbf{Z}/8\mathbf{Z} = \{\bar{0}, \bar{1}, \dots, \bar{7}\}$, $\mathbf{Z}/4\mathbf{Z} = \{\bar{0}, \bar{1}, \bar{2}, \bar{3}\}$ and argues that:

$G = \{\bar{0}, \bar{2}, \bar{4}, \bar{6}\}$ is a subgroup of $\mathbf{Z}/8\mathbf{Z}$ of order 4, therefore isomorphic to $\mathbf{Z}/4\mathbf{Z}$. The map $\phi: \mathbf{Z}/4\mathbf{Z} \rightarrow \mathbf{Z}/8\mathbf{Z}$, $\bar{0} \mapsto \bar{0}$, $\bar{1} \mapsto \bar{2}$, $\bar{2} \mapsto \bar{4}$, $\bar{3} \mapsto \bar{6}$ is an injective morphism of groups but not of rings since $\phi(\bar{1}) \neq \bar{1}$.

Although the student uses the same notation for elements of both quotients, he doesn't mix them and has the right intuition on how to construct the 1-1 group-homomorphism. The teacher would expect a more abstract reasoning: to find a subgroup isomorphic to $\mathbf{Z}/4\mathbf{Z}$ amounts to finding an element of order 4 in $\mathbf{Z}/8\mathbf{Z}$. The student doesn't justify that G is a group nor that it is cyclic because every subgroup of a cyclic group is also cyclic. It would be interesting to check him on isomorphism classes of groups of order 4. Finally, quantifiers are again handled with too little care: if ϕ is not a ring homomorphism, this doesn't imply such a homomorphism doesn't exist. For instance, the student could have argued that $\mathbf{Z}/8\mathbf{Z}$ has a unique subgroup of

order 4 or used the fact that the $\Phi(1)=1$ property completely determines Φ (which then isn't a homomorphism). The last part of the question remains unanswered and indicates that finding a map between two quotient rings is a conceptually hard task (and a bit tricky one since the arrow is reversed: $\mathbf{Z}/4\mathbf{Z} \leftarrow \mathbf{Z}/8\mathbf{Z}$), even if it consists in reproducing the reasoning made during the course on a very close example.

In fact, the two questions were asked before heavy use of the factorization theorem for rings was made during the tutoring sessions. The experiment shows that the test was premature even if the course was epistemologically-oriented and the students could rely on previously acquired conceptual knowledge (which remains very fragile). We will engage in further investigations of the difficulties in 2013 by asking the same questions during tutoring work. Nevertheless, this experiment already confirms that the homomorphism concept is much of an obstacle, even after the completion of a first course in abstract algebra devoted to group theory.

III. MORE EPISTEMOLOGICAL INSIGHT

By the way, what is a structure ?

Abstract Algebra teachers often speak about structures... but they never mathematically define any concept of structure! Let us explain this a priori abnormal phenomenon by giving a few details concerning the didactic transposition (Chevallard 1985) of the notion of structure.

In his attempt to give an historical account, Cory (1996) makes the distinction between “body of knowledge” and “image of knowledge”. Interestingly, the notion of structure takes its origin in the latter:

This textbook [*Moderne Algebra*] put forward a new image of the discipline that implied in itself a striking innovation: the structural image of algebra. In the forthcoming account, it is this specific, historically conditioned image of mathematical knowledge that will be considered as implicitly defining the idea of a mathematical structure (Cory 1996, p.8).

We won't comment on historical methodology, but it is certainly the combination of Noether's mathematical ideas (see below) and a didactic intent to expose the recent advances in algebra in a systematic and clear fashion, in an organized and integrated whole, that lead to the idea of structure. It remained implicit in so far as van der Waerden didn't give any comment, formal or non-formal, on what he meant by a 'structure'. Bourbaki, on the contrary, gave a formal-axiomatic elucidation of the concept of mathematical structure in the first book of his treatise '*Elements de mathématiques*' dedicated to set theory and published in the 1950s. In parallel, he promoted (Bourbaki 1948) the structural image of mathematics within the noosphere (Chevallard 1985). Yet, Bourbaki's definition did hardly play any role in the exposition: it only provided a general framework which in fact didn't prove to be mathematically functional (Cory 1996, p. 324, see also Mac Lane 1996), unlike category theory which is very advanced and a too hovering viewpoint for the present purpose. Therefore no definition at all is given in more recent manuals.

As a consequence, students are supposed to learn by themselves and by the examples what is meant by a structure whereas sentences like “a homomorphism is a structure-preserving function” is supposed to help them make sense of a homomorphism. Is that possible without any clarification on the notion of structure? The students certainly understand that when we talk about structures we refer to sets of axioms and we say that a mathematical object has a particular structure when these are fulfilled. This reflects the fact that the notion of structure is an outgrowth of the widespread use of the axiomatic method. In our view, meta-discourse on axiomatics together with activities devoted to building axiomatics and “playing” with the axioms would help students to make sense of them and memorize them. It is not straightforward to comprehend that axiomatics encode properties of mathematical objects which are analyzed abstractly as being made of elements connected by relations (therefore primitive terms of axiomatics are sets equipped with extra data encoding the relations such as laws of composition or binary relations). The abstract formalism (axioms and the language of set theory) is much of an obstacle and hides the simple ideas. Too little emphasis is made on the idea of relations: structure-preserving is synonymous with operation-preserving in contemporary manuals, unlike van der Waerden's (1930), in which examples are given of non-algebraic structures such as ordered sets when introducing the homomorphic property, defined as preserving relations. The idea of relation is also useful to understand quotients: making a quotient is equivalent to introducing more relations. This should help the students to interpret, for instance, the quotient $\mathbf{Z}[X]/(10X-1)$ as a ring isomorphic to the decimal numbers. We will need of course to engage in further didactical studies in order to support our conjectural claims regarding conceptions and teaching strategies.

Coming back to the epistemological investigation, the word 'structure' is used in fact in two more contexts with a different meaning, which may induce some confusion: we also want to identify the different isomorphism classes for a given structure and we say for instance that the abstract group-structure of $\mathbf{Z}/3\mathbf{Z}$ is that of a cyclic group of order 3. Finally, we call 'structure-theorem' a result describing the way an object can be reconstructed from simpler objects of the same type.

Noether's set-theoretic foundation of Algebra

We have already distinguished the concept of isomorphism as an equivalence relation from that of a function (with properties) which relies on the notion of homomorphism. The equivalence relation is in fact a crucial concept with regard to the process of abstraction, which often amounts to selecting common characteristics of objects being thus taken as equivalent. A classification is a description of the corresponding partition: for instance, group theory will classify groups of a given order. We will now focus on the latter conception of isomorphism: it is the heritage of Noether who developed

[...] what she called her set-theoretic foundations for algebra. This was not what we now call set theory. [...] Rather, her project was to get abstract algebra away from thinking about operations on elements, such as addition or multiplication of elements in groups or

rings. Her algebra would describe structures **in terms of selected subsets** (such as normal subgroups of groups) **and homomorphisms** (MacLarty, 2006, p. 188).

We pretend that Noether's new conceptual approach (characterized in the last sentence of the quote) is a **major epistemological difficulty** in the learning of abstract algebra. It is also the key to level-2 structuralism (referring to the introduction): this indeed allows a unified treatment of structures. It proved in history to be a major breakthrough leading to a complete rewriting of algebra (in terms of newly-forged concepts that emerged from the new methodology: noetherian rings, principle-ideal domains,...).

Dedekind's theory of ideals in which divisibility relation between (algebraic) integers were replaced by inclusion of ideals certainly contributed to the transition from an arithmetical conception of algebra to the set-theoretic conception. But Noether's chief tools were isomorphism theorems and she made it obvious that this applied for different kinds of structures. She considered only onto homomorphisms, denoted $M \sim \bar{M}$ (the functional notation $f: M \rightarrow \bar{M}$ comes from topology) and correlated them to distinguished classes of subsets through the first isomorphism theorem. As an illustration of the generality of the principle:

Ideals bear the same relation to ring homomorphisms as do normal subgroups to group homomorphisms. Let us start from the notion of homomorphism (van der Waerden, 1949, p. 51).

Homomorphisms or morphisms?

On forumsⁱⁱⁱ are taking place interesting discussions on the differences to be made between homomorphisms and morphisms. Some people argue that homomorphism is the old terminology and the shorter word should be adopted for pragmatic reasons. Others mention that morphisms come from category theory (which remains obscure to them). Finally, one of them argues that the difference between homomorphism and homeomorphism is clear, but not between homomorphism and morphism. This leads to a confrontation of two different definitions of a morphism in the context of topological spaces: open maps (preserving open sets) versus continuous maps. But this didn't allow to make the point underneath the morphism concept which derives from category theory and thus the difference to be made.

Indeed, the morphism concept is a relativization of the homomorphism concept as a structure-preserving function (which doesn't apply to morphisms in topology since they preserve open sets by *inverse* image): in a category, one is free to decide which maps are morphisms, these define the category together with a given type of objects. If morphisms tend to replace homomorphisms, beyond the pragmatic argument, it might be that algebra practitioners are implicitly assuming that they are working in a category.

IV. CONCLUDING REMARKS AND PERSPECTIVES

This study certainly contributes to break the illusion of transparency concerning the concept of homomorphism and the idea of a mathematical structure. It aims at reestablishing the rationale of this particular knowledge through the epistemological investigation of the concept and the engineering of epistemologically-oriented activities. In this spirit, a simple didactical situation has been given in part II. Unfortunately, it needs to be re-experimented in order to reveal its full potential. Meanwhile, we have engineered, on the basis of the epistemological analysis of the notion of structure presented in this paper, an activity dedicated to reflecting on the axiomatic method and the structuralist viewpoint in a simple context (“mini-theory”). We hope to report soon on the results of the pre-experimentation of this activity. On a more theoretical perspective, following Chevallard's idea that a “body of knowledge” is a complex of praxeologies (see for instance Chevallard 2002), we will need to track and analyze the “structuralist praxeologies” in order to support the idea, presented in part I of this paper, that there really is a “structuralist agenda” to meet in relation with the learning of abstract algebra. Finally, our analysis connects the transition problem that occurs at third year university level in relation to abstract algebra with epistemological transitions: the systematization of the axiomatic method, after Hilbert, and the transition, after Noether, from thinking about operations on elements to thinking in terms of selected subsets and homomorphisms. This analysis should be crossed with a didactical investigation of the transition problem: the analysis of praxeologies should again bring much light.

MATHEMATICAL ENCULTURATION – ARGUMENTATION AND PROOF AT THE TRANSITION FROM SCHOOL TO UNIVERSITY

Andrea Hoffkamp, Jörn Schnieder, Walther Paravicini

Humboldt-Universität zu Berlin

Universität zu Lübeck

Westfälische Wilhelms-Universität Münster

University students, especially in their first semesters, often lack specific mathematical learning and working techniques that are necessary to develop and apply mathematical notions, definitions, theorems and proofs. We consider this to be a key factor for problems arising in the secondary-tertiary transition in mathematics. Usually the foundations of mathematical proofs as well as questions of validity and justification are not an explicit aim of university teaching. In our approach we invoke philosophical aspects of epistemology. We show how our theoretical considerations lead to the development of a teaching design for the teaching and learning of mathematical reasoning, argumentation and proof, making the methodological foundations of mathematics explicit and accessible for students.

INTRODUCTION

Courses in mathematics at university level are often considered to be difficult. Unsatisfactory exam results and high drop-out rates seem to confirm this. Of course there are many reasons for this and the measures and projects to deal with it is also manifold. In Germany, for instance, a notable example is the council the “German Centre for Higher Mathematics Education” (<http://www.khdm.de>) that was founded in 2011, but there are also many projects like the already completed project SAiL-M (<http://www.sail-m.de>), in which one of the authors took part as a team member.

Many students fail because of their insufficient prerequisites, some just do not have the ability to work autonomously or do not have enough self-discipline to prepare and review lectures and exercise meetings efficiently. In fact “a shift between two institutional cultures happens when entering university” (Gueudet, 2008, p. 245). To attenuate the ruptures occurring at the transition to university most of the German universities have established so-called math-bridging courses for students who are about to begin first semester.

A lot of math-bridging courses at the secondary-tertiary transition are organized as blended learning scenarios aiming at the repetition of mathematical content and training exercises (e.g. the project <http://www.math-bridge.org>, Biehler et al., 2012). Within such courses mathematical learning and working strategies are mainly taught implicitly.

Talking about the secondary-tertiary transition, Gueudet (2008) named several related perspectives and issues. In our work we take an epistemological and didactical perspective, and we present a teaching design within our bridging course that focuses

on argumentation and mathematical proof. Unlike many other bridging courses at German universities, we do not (only) aim at the repetition of mathematical skills and knowledge mentioning superior concepts and working strategies more or less explicitly. But we have a strong focus on uncovering, discussing and training the methodological foundations of argumentation and proof. In our approach mathematical skills and contents are used as occasions and examples for the development and reflection of comprehensive strategies in an explicit and general way.

The secondary-tertiary transition concerning mathematical argumentation and proof is characterized as follows:

Mathematical argumentation and especially mathematical proving at school is only taught in an exemplary way (Douek, 1999). Bringing the meta-theoretical aspects of mathematical proofs that legitimate the employed methodological means up for discussion is not envisaged or reflected explicitly. We think that this is a key factor for transition from school to university, since

[...] proofs provided during lectures at university play a new role: they are central in the building of the university mathematical culture, because they indicate methods, and also what requires justification or what does not. (Gueudet, 2008, p. 247)

The present article is meant as a theoretical contribution to the described topic although we present a concrete teaching design illustrating and underpinning our theoretical approach. In fact, we consider the science of mathematics education to be a ‚design science‘ that

[...] presupposes a specific didactic approach that integrates different aspects into a coherent and comprehensive picture of mathematics teaching and learning and then transposing it to practical use in a constructive way. (Wittmann, 1995, p. 356)

In our article we focus on a learning activity exploring the epistemological aspects of mathematical proofs. In the next section we describe our *theoretical position* and give a *didactical analysis of the issue*. After that we shortly describe the *target audience, objectives and context* of our course. Following this, we present a learning scenario together with didactical and methodological comments (*mathematical reasoning and justification – learning scenario and didactical comments*). We close the article with a *summary and outlook on research questions guiding our future work*.

THEORETICAL POSITION AND DIDACTICAL PERSPECTIVE

One of the most important methodological principles of mathematics – and in fact of any science – is the principle of trans-subjective comprehensibility of its results. This means that there is a demand for the comprehensibility of the terminology and the notions, but also the duty to explain and justify its assertions. In particular, everybody – provided that she/he has the adequate prerequisites – should be able to check and understand mathematical assertions (at least this should be possible in principle) (Janich, 2002; Gatzemeier, 2005).

In other words, the main target of mathematical arguments and proofs is to convince ourselves or others of the truth of (mathematical) propositions that seem questionable or are uncertain (Thiel, 1973). In this sense the methods of mathematical proof could be considered as tools or as a guideline for the development of mathematical argumentations, and thus ensure the trans-subjective comprehensibility of scientific findings (Lorenzen, 1968).

Following the above epistemological and normative perspective of mathematical argumentation we are – at this point – only concerned with the minimum requirements for effective mathematical reasoning. Therefore, we abstract from special didactical differentiations between proofs as processes resp. proofs as products, or between (fully) formalized proofs resp. proofs “really performed” in textbooks (Duval, 1991; Douek, 1999). Moreover, we assume that our approach could lead to fruitful suggestions to close the gaps between the above differentiations in a theoretical and practical way.

What is our understanding of mathematical argumentation? Mathematical argumentation (as any argumentation) can be structured into the classical premise-inference-conclusion pattern written in linear form (Tetens, 2004). The verifiability of the conclusion is derived from certain propositions (premises). These do not require further justification or have to be accepted as having been justified already. In particular, the rules of inference are stated and justified explicitly. A mathematical argumentation that is modelled after this pattern can neither be accused of running into fruitless circular reasoning, nor of culminating in an infinite argumentative regress, nor of aborting the argumentation by appealing to a dogma, i.e., it does not lead into the notorious “Münchhausen-Trilemma” formulated by Hans Albert (1991).

The dialogical character of argumentation is a central idea. In some sense, it could be seen as a basis for the interpretation of (logical) implications. For a short overview from a didactical perspective we refer to Durand-Guerrier and Barrier (2007). Following this idea, logic does not deal with (everlasting) laws of verity (Frege, 2003), but logic is a means to create new knowledge from existing knowledge (Thiel, 1980).

Therefore, we want the students to critically discuss the ideal of trans-subjective comprehensibility as a minimum condition for mathematics as a science. The premises-inference-conclusion pattern should be recognized as a tool to reach this ideal. For this reason, we do not only want to teach some basic theoretical knowledge of argumentation and train the students to read and produce proofs basing on this pattern. In addition, we want the students to discuss these tools on a normative basis considering their usefulness to achieve the ideal of trans-subjective comprehensibility. The above logical pattern presented in a linear form has some didactical advantages in the sense of a didactical reduction.

The linear form is much easier to understand than the common Toulmin-scheme (as didactically analysed in Barrier, Mathé & Durand-Guerrier, 2009) or game theoretical

concepts (as presented in Vernant, 2007; Marion, 2006; Durand-Guerrier & Barrier, 2008), since we reduce the number of notions (warrants, backings etc.) and the number of dialogical rules. However, the main advantage is that, beginning with Euclid's "Elements", proofs in mathematical literature and lectures have a monologist form of argumentation by presenting a proof as a step-by-step construction. Their dialogical character weighing the pros and cons and showing the decisions taken is usually not obvious. In this sense, mathematical texts emphasize the product-aspect more than the process-aspect of proofs.

We believe that the normative discussion could enable the students to critically reflect general objectives of mathematics as a science and to recognize methodological decisions as being appropriate. At least, we hope that this could lead to higher motivation and autonomous learning following an ideal of continuous rationality as part of the "mathematical culture".

TARGET AUDIENCE, CONTEXT AND OBJECTIVES

The math-bridging course is designed for first semester students with mathematics as a major subject, but also for future math teachers. A first course integrating the presented learning scenario was held at the University of Education Ludwigsburg in October 2012. In Ludwigsburg, future teachers (primary school, secondary school up to grade 10 and special school) are educated and have to take a variety of math courses depending on their choice of study programme. Especially here we hope that our approach has a positive impact on the future teachers' *idea of mathematics* and hence on their teaching at school.

We expect the target audience to be very heterogeneous and differ widely in their mathematical competencies, learning motivation and general academic ability. Nevertheless, we want to achieve some common learning goals.

At school the students usually come in contact with mathematical proofs in an exemplary form - for instance when applying geometrical theorems about the congruence of triangles in their reasoning or when proving the irrationality of $\sqrt{2}$. In the "educational standards" for mathematics in Germany (KMK 2003) *mathematical reasoning* is one out of six mentioned competencies within mathematics education at school. With our learning scenario we want to build on this basic knowledge of the students and achieve the following learning objectives:

The students should

- analyze mathematical proofs considering the example of the *proof by contradiction* and understand as well as describe their deductive structure, and
- realize that completeness and deductive derivation are necessary criteria for mathematical proofs and adopt the ideal of the premises-inference-conclusion pattern as a reasonable means for mathematical argumentation.

MATHEMATICAL REASONING AND JUSTIFICATION – TEACHING DESIGN

The presented teaching design consists of three phases:

First, a lecture (*Phase 1: Information*) in which the students are provided with information about the basics of “naïve logic” and the method of “proof by contradiction”. Second, the first part of the exercise session in which mathematical proofs are analyzed and compared (*Phase 2: Cognition*). Third, the second part of the exercise session that provides an activity to think about argumentation and proof from a philosophical point of view (*Phase 3: Metacognition*). We will shortly describe each phase including didactical and methodological comments referring to our theoretical position.

Phase 1 (Lecture): In the first part of the lecture we introduce the usual logical operators including the quantifiers. Although we want formal interrelations to become transparent by discussing some logical riddles and parallels to everyday language, this part is organized in a stringent way and mainly directed and executed by the lecturer.

The second part of the lecture includes considerably more interaction with the audience. Here we analyze the “model” of a *proof by contradiction* by comparing two examples. First, we present an example of Cohors-Fresenborg and Kaune (2010, p. 31). Here, a judge reasons why a defendant is proved to be innocent following the scheme of a proof by contradiction in the following way:

Assuming that the defendant *is guilty* (here: robbed the bank). Then he would have been in A-town at 16:00 h. This means he could have been in B-town no earlier than 17:30 h, since you need at least 90 minutes for this distance. Since the bank in B-town was robbed at 17:00 h, this contradicts the given facts. Hence, the defendant has to be innocent.

Together with the audience we develop the following scheme of the proof:

Logical opposite of the claim \rightarrow conclusion from the first line \rightarrow conclusion from the second line \rightarrow fact \rightarrow conclusion (“a contradiction appears”) \rightarrow conclusion (“the claim is true”).

To obtain the pattern of a chain of deductions the students need to identify the premises and the implication steps. Moreover, this example allows resp. forces us to reflect on the character of mathematical propositions and leads us to the *law of the excluded middle* and the *law of non-contradiction* (Russell, 1912).

The second example is a proof of the infinity of the prime numbers as given by Euclid. The lecturer has cut the steps of the proof in lines and put the lines in a wrong order (*proof-jigsaw*). The audience is asked to find the right order and figure out the correspondences between the two examples. The results are collected by the lecturer.

Unlike many other bridging courses do, we do not aim at completeness in the sense that we try to communicate the complete range of methods of mathematical proofs. However, we have chosen the „proof by contradiction“ as being an exemplary

method. By choosing the above approach we hope to implicitly suggest that formal (naïve) logic is a technical means for the proper formulation of mathematical propositions and everyday statements.

Phase 2 (Cognition): The above scenario is taken up again in the exercise session in the afternoon, where *two more proof-jigsaws* of the proof of the infinity of primes are given, differing widely in their level of detail. One proof-jigsaw is a very brief version of the proof similar to the one in Aigner and Ziegler (2009). The other one is a very long and detailed version including a high level of formalization. The students form groups and are again asked to put the proof-lines into a meaningful order, while at the same time comparing and discussing all three given proofs for the infinity of the prime numbers. We hope that this creates some sort of provocation resp. irritation in the following sense: at school, mathematics is usually done by learning and applying “recipes”. Usually there is only one way of execution and the result can be right or wrong. The above scenario allows the discussion of three different forms of argumentations, providing an action-oriented and suggestive access to the main objective of the learning scenario: The students discover and reflect the structure of mathematical proofs as chains of deductions. But they also implicitly discover the dialogical character of mathematics as a science through considering a proof to be an attempt to convince another person of the truth of my own statement. This attempt depends on the mathematical background or context of the reader/producer of a proof.

The learning activity leads directly to a higher level of abstraction through the thought experiment “What if a mathematical proof could never be formulated completely?” In the end, the question “What are the basic rules a proof must follow to be convincing?” – a question of validity – could arise, leading to the last phase of our learning scenario.

Phase 3 (Metacognition): The last phase is directed by the questions: *How do I know that it is true?* or *What is a perfect proof?* For this activity it is important to create an atmosphere of discussion and reflection to gain various ideas of the participants. Therefore, we put the students together in groups providing them with only few – but accentuated – impulses. The students are provided with some further material leading them to the question of justification and validity as follows:

The Münchhausen-Trilemma

If we ask of any knowledge: "How do I know that it's true?", we may provide proof; yet that same question can be asked of the proof, and any subsequent proof. The Münchhausen Trilemma is that we have only three options when providing proof in this situation:

- The circular argument, in which theory and proof support each other (i.e. we repeat ourselves at some point)

- The regressive argument, in which each proof requires a further proof, ad infinitum (i.e. we just keep giving proofs, presumably forever)
- The axiomatic argument, which rests on accepted precepts (i.e. we reach some bedrock assumption or certainty)

The first two methods of reasoning are fundamentally weak, and because the Greek sceptics advocated deep questioning of all accepted values they refused to accept proofs of the third sort. The trilemma, then, is the decision among the three equally unsatisfying options.¹

The students are asked to work in groups on the following tasks: *Formulate connections between the proof-jigsaws and the Münchhausen-Trilemma text. Name characteristics of “a perfect proof”.*

The results of the groups are collected in the end. Using this method we hope to get a larger variety of ideas as well as to involve all the students in the discussion process by generating commitment for everybody. But especially we want to allow a first step towards the establishment of socio-mathematical norms “which means in this context, criteria shared by students and teachers to decide whether a proof is valid or not, what is a satisfactory explanation, etc.” (Gueudet, 2008, p. 243).

The didactical potential of this learning activity lies in the following:

Since most of the students have not thought about justification-theoretical aspects of mathematical proofs so far, this activity could create the awareness of the problem area. Therefore, we provide the students with three proofs that differ widely in the given details, which can be seen as an analogue to the “infinite regress” in the Münchhausen-Trilemma. We want the students to reflect their implicit convictions resulting from their previous mathematical experiences, and lead them to the question “*What is a perfect proof?*” in a suggestive way.

The reflection about the three options given in the Münchhausen-Trilemma could lead to the conviction that the premises-inference-conclusion pattern is a reasonable and adequate means for mathematical argumentation. But it also allows the recognition of “mathematical work“: Defined properties can be used without proof, whereas all other properties must be proved by only using the definitions. This is also mentioned by Duval (1991) who pointed out the importance of the awareness of the logical status of propositions when trying to understand a mathematical proof – especially the difference between premise, theorem, conclusion etc.

SUMMARY AND OUTLOOK

The aims of the math-bridging course we present in this paper are twofold: the development of basic mathematical skills and the explicit training of strategies for the

¹ The Münchhausen-Trilemma after H. Albert (1991). English formulation as in http://en.wikipedia.org/wiki/Münchhausen_Trilemma (14.9.2012)

learning of mathematics as a science. Our central method for teaching these learning strategies is to construct a teaching scenario that encourages the students to do two things. First, to implicitly apply these strategies in the course of an exercise. Second, to become aware of and to discuss their methodological status as norms or ideals that one should follow in order to justify knowledge as scientifically objective. As a concrete example, we outline a teaching scenario, including some comments on our didactical reasoning and teaching methods, that aims at clarifying the central inner- and meta-mathematical significance of deductive reasoning. This way, the students should not only value the importance of the concept of deductive reasoning in scientific mathematics, but also discuss the legitimacy of this concept as a helpful tool in reaching objective scientific knowledge in science in general.

In October 2012 a first bridging course integrating the above learning scenario was realized at the University of Education Ludwigsburg. This was meant as a first test of our approach and led us to further considerations and the formulation of research questions. In Ludwigsburg about 300 students took part in the bridging course. 150 of the students are future primary school and special school teachers who did not choose mathematics as a major subject, but will have to attend several mathematics courses. These students visited the lecture of one of the authors and a small part of these students took part in the exercise sessions conducted by her. Their attitude towards mathematics was mainly characterized by a procedural view of mathematics and by the fear of not managing the subject. Our experiences let us hope that our approach is practical and useful even with such an audience. Although the first realization is far from being empirically solid, we present some of the students' comments to give an impression of the students' "view of mathematics" after the bridging course:

"I got another view of mathematics in the sense that things are not just as they are, but that there is a reason for everything and one could ask for the reason. The children will also ask for reasons at school."

"I found it good to get motivated and to get another view of mathematics (questioning calculation rules: Why is it like that?)"

Therefore, we are confident that our approach could give the students "a new idea of mathematics" by initializing mathematical enculturation at the secondary-tertiary transition.

In the future we plan to develop further learning scenarios and a large pool of differentiated exercises for subsequent courses to allow the students to group themselves according to their individual needs. Another bridging course integrating our approach will be held at Humboldt-Universität zu Berlin in October 2013. For this course we will also implement assessment methods. Our future work will be guided by the following research questions:

- Will the "metacognitive" considerations lead to more comprehension concerning mathematical argumentation and proof and their relation to everyday language?

- Will our approach help the students not only to understand a proof as a product but to produce their own proofs?
- In which way is the students' view of mathematics as a science changed, and how does this change influence their learning of mathematics? E.g. will the students be enabled to work more autonomously on mathematical problems (including tasks that aim at argumentation, but also tasks to train skills)?

ACKNOWLEDGEMENTS

We thank Andreas Fest for the organization and collaborative realization of a math-bridging course at the University of Education Ludwigsburg.

DEVELOPMENT AND AWARENESS OF FUNCTION UNDERSTANDING IN FIRST YEAR UNIVERSITY STUDENTS

Olli Hyvärinen, Peter Hästö and Tero Vedenjuoksu [1]

Department of Mathematical Sciences, University of Oulu, Finland

This article presents results from a longitudinal study on the development of first year university students' function concept, and of their awareness of this development. We used questionnaires in the first and last quarter of the first year and had 38 students participating in both tests. We found that most students' function concept did develop, but many students did not notice the development. A small number of students had low proficiency with functions but high estimation of their proficiency; these students tended to show less development in their function concept.

INTRODUCTION

Too often our students complain that their mathematical training lacks relevance for their future careers as teachers, engineers, etc. Some student teachers value the mathematical component of their study as a personal intellectual pursuit of “real mathematics” before returning to “school mathematics”. We, on the other hand, see mathematics studies as an opportunity to enjoy challenging yourself with mathematical problems; to learn to value critical thinking and argumentation over dogma; and to observe your own development, as well as that of your peers. In short, to develop mathematical habits of mind, as Cuoco, Goldenberg and Mark (1996) put it.

Goulding, Hatch and Rodd (2003) investigated what British students actually carry with them from their bachelor's degrees to the teacher training (PGCE) in a retrospective study. Of the seven themes emerging from the students' responses, only two pertain to the issues mentioned in the previous paragraph; and within these categories many responses were actually negative, in that the students' views of mathematics had changed in undesirable directions (e.g., “for exams only”).

In 2010, we started a project to investigate whether standard pure mathematics courses do support the development also of concepts central to “school mathematics” and applications. We focus on the function concept in which the development is subtle and slow, and may go unnoticed to the students (Carlson, 1998). Further, it has been indicated as one of the central topics for mathematics teacher education in the *standards* endeavor (Conference Board of the Mathematical Sciences, 2001). Here we report our findings from the first year of follow-up.

BACKGROUND AND RESEARCH QUESTIONS

Several studies indicate difficulties when describing mathematical concepts in different, mathematically identical, ways (see, e.g., Even, 1998; Bayazit, 2011). Although most students can visualize simple functions by drawing their graphs, they often lack ability to link the graph and the algebraic representations of the function (Vinner &

Dreyfus, 1989). The intuitive notion of the function often relies on an explicit algebraic formulation (Breidenbach, Dubinsky, Hawks, & Nichols, 1992; Tall & Vinner, 1981). Functions and related notions are often treated as if they were only symbols and representations instead of proper mathematical objects (Eisenberg, 1991). We understand the function concept in the same way as Carlson (1998), see, e.g., Selden & Selden (1992) for a more detailed discussion.

Carlson (1998) found in a cross-sectional study that even A-students take a long time to acquire solid understanding of functions: second year undergraduate students still showed many flawed conceptions. The complexity of the concept and its slow development suggest that it might be quite likely that some or even most students fail to notice their developing function concept during their mathematics studies. This is especially problematic for student teachers since they then miss out on the opportunity to reflect on the difficulty of coming to terms with functions.

As far as we have been able to find out, there is little research about students' self-awareness of long-term development of mathematical concepts (for an exception, see Bjuland, 2004). In mathematics education, a typical time frame for reflection seems to be the solving of one problem (e.g. the "looking back" stage of Schoenfeld, 1992). Following Bjuland (2004), we see both long and short time frames as necessary for self-awareness: immediate and short-term reflection is needed to notice the different aspects of the concept whereas reflection over an extended period of time is needed to compare these observations at different points in time and thus become aware of the development. The scarcity of studies on long-term reflection in mathematics education led us to consider theories of reflection and metacognition in a more general context.

A general framework for addressing issues related to reflection and metacognition was proposed by Schraw and Moshman (1995). According to them, a person's *metacognitive theory* integrates metacognitive knowledge and experiences, and can be used to explain and predict his/her cognitive behavior. They argue that one aspect in which individuals' metacognitive theories differ is the extent to which they are explicit (i.e., the extent to which one is aware of possessing such a theory).

Schraw and Moshman (1995, p. 360) point out that explicit knowledge about your own cognition makes it possible to reflect on your performance and to use this information to modify your future performance and thinking. They also seem to imply that individuals' metacognitive theories gradually develop via awareness of changes and reflection on them.

In contrast, tacit theories are developed without conscious reflection, based on personal experience or adaptations from others, and therefore it can be difficult to notice and report one's own development to others. Since an individual with a tacit metacognitive theory is not readily aware of either the theory itself or evidence that supports or refutes it, it can be very difficult to change the theory even when the theory

is maladaptive and the individual is explicitly encouraged to do so. Further, the lack of conscious reflection might cause metacognitive knowledge and regulation to lack transferability between task-types. (Schraw & Moshman, 1995)

Since the development of the function concept is likely to be slow and subtle, students might not be aware of it. However, it is also possible that some students may not notice any development since there simply is none to notice. Hence we divide our research question in two:

1. Do students' function concepts develop during 1st year university studies?
2. Are students aware of this development?

METHODOLOGY

Instruments

We used two questionnaires, both based mainly on Carlson's tests (1998). Our first test consisted of A1, A5, A6, A7, A14, B3 and a modification of A13 in which the linear graph was replaced by a piecewise linear one. The second test consisted of A2b, B2, A6, A7, and A8. The tasks were:

A1. Express the diameter of a circle as a function of its area and sketch its graph.

A5. Does there exist a function all of whose values are equal to each other?

A6. Does there exist a function whose values for integer numbers are non-integer and whose value for non-integer numbers are integer?

A7. Does there exist a function which assigns to every number different from 0 its square and to 0 it assigns 1?

A8. The given graph (Figure 1) represents speed vs. time for two cars. (Assume the cars start from the same position and are traveling in the same direction.)

- a) State the relationship between the position of car A and car B at $t=1$ hr.
- b) State the relationship between the speed of car A and car B at $t=1$ hr.
- c) State the relationship between the acceleration of car A and car B at $t=1$ hr.
- d) What is the relative position of the cars during the time interval between $t=.75$ hr. and $t=1$ hr.?

B2. Assume $F(x)$ is any quadratic function. True or false: $F\left(\frac{x+y}{2}\right) < \frac{F(x)+F(y)}{2}$

A13. Suppose that the given graph (in test) of height as a function of volume as a bottle is filling with water. Sketch the shape of the bottle.

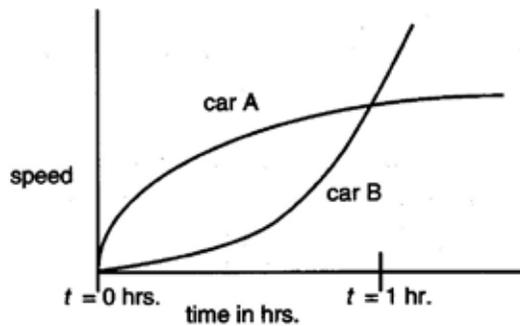

Figure 1. The graph from Task A8.

The questions had been translated into Finnish and tested by P. Hästö and M. Leinonen (unpublished). The tests were scored following Carlson's (1998) rubrics, and for A13 we developed our own rubrics. The number of tasks selected was dictated by time constraints, and the selection was based on our assessment of the relevance of tasks to the course in which the test was given, and on having sufficient variability in task types.

The second test also included six “self-awareness” claims which were answered on a five-point Likert scale and two other questions which are not analysed here. The claims were

- Q1. Examples of functions at the university are similar to those in high school.
- Q2. In high school it was clear to me what was meant by a function.
- Q3. It is (presently) clear to me what is meant by a function at the university.
- Q4. My understanding of functions has changed while at the university.
- Q5. I have pondered over my understanding of functions during my university studies.
- Q6. During my university studies there have appeared examples of functions contrary to my function concept.

It is, of course, clear that these questions will only provide a very sketchy picture of students' self-awareness and experience, which had to suffice for this pilot study.

Participants

The first test was administered in the second week of the first period in a class typically taken by first year students, both mathematics majors and other students with a math component (mainly physics and chemistry majors). The second test was administered in the first week of the fourth period (out of four) in an analysis class typically taken by first year majors and second or later year minors. Note that students did not follow any special courses on functions, only a standard university mathematics curriculum.

There were 98 participants in the first test and 64 in the second. Of these 38 participated in both tests. Two questions were repeated from the first to the second test; it should be noted that students got no feedback on the tests and solutions were also not distributed. A majority of these students are expected to become teachers, although the choice is not yet made.

RESULTS AND ANALYSIS

Our first observation is that students in our follow-up became significantly better at the tasks in the tests. Their scores in the two repeated tasks improved, on average, over 2.5 points (the maximum score being 5 points on each task). To compare the other tasks we use Carlson's Group 2 (A-students from a 2nd year calculus course) as a reference. In the first test our students' scores were consistently (and sometimes considerably) below the reference, whereas in the second test they exceeded the reference. This strongly suggests that there was on average much improvement in students' ability to answer these kinds of questions regarding functions.

Quantitative data reduction techniques, for instance concerning graphical and analytic components of the function concept, did not yield results.

To get a view on individual improvement, we cross-tabulated the sum of scores from the two tasks included in both our tests, displayed in Table 1. From the table we see that only three students got a lower score in the second test (in fact, all dropped from 1 to 0 points), while all others improved their score, many by more than 5 points.

1 st test/ points	2 nd test/points						Total
	0	2	4	5–7	9	10	
0	1	2	2	2	0	4	11
1–3	3	0	0	3	2	11	19
5–7					1	4	5
10						3	3
Total	4	2	2	5	3	22	38

Table 1. Number of students with given points in Tasks A6 and A7 of the two tests.

Based on the results in the two repeated tasks, we divided the students into three groups: LOW (less than 5 points in both tests), RISE (at least 5 point improvement between tests) and HIGH (at least 5 points in both tests). Three students belonged to none of these groups and are excluded from the next analysis. In other tasks the achievement level of the RISE group lied between the other two groups. In other words, they had not quite caught up with the HIGH group.

Group	<i>n</i>	Q1	Q2	Q3	Q4	Q5	Q6
LOW	8	.3	1.0	1.0	.3	1.0	-0.4
RISE	19	.3	.3	.8	1.0	.1	-0.3
HIGH	8	.0	.9	1.4	.8	.9	-1.3
Total	35	.2	.6	1.0	.8	.5	-0.5
All	64	.2	.6	1.1	.8	.5	-0.4

Table 2. Means of opinion scores. The shaded cells are discussed in more detail below.

For these three groups we calculated the means of the answers to the six questions mentioned on page 4. The results appear in Table 2. The answers were coded so that “strongly agree” has value 2 and “strongly disagree” -2 . From the table we see that there were no radical differences between the groups. In fact, in a one-way ANOVA even the biggest between-group difference, in Question 6, was only approaching statistical significance ($p = 0.085$).

Nevertheless, we combine indications from several answers to form a tentative conclusion, or, if you will, a hypothesis for further study. Q4 (change of understanding) is consistent with Q2 (high school) and Q3 (university) in that groups RISE and HIGH now rate their understanding higher than in high school, and correspondingly rate it as having changed more than group LOW.

Group HIGH has consistently higher view of their function understanding than group RISE, which is consistent with test scores. However, students in group LOW find that they have had a fairly clear understanding of functions from high school, which has not changed. It appears that these students have an erroneous and overly optimistic view of the adequacy of their function concept.

Question 5 (pondering) is somewhat of a dilemma: the group with the least pondering (RISE) has improved most drastically. Finally, Q6 (new examples) is consistent with the groups in that the consistently high-scoring individuals found fewer examples which did not fit into their conception of function. Surprisingly, across all students there was a tendency to disagree with the statement that they had encountered new types of functions at the university. This may be due to the inclusion of the technical term “function concept” in the question.

Qualitative analysis

Based on students’ responses to questions A5–7, we identified four students as major improvers and did a more thorough data-driven analysis of their answers. In the analysis we marked all interesting responses; since the data set was not large, all marked responses are presented.

Our first observation in the qualitative analysis of the two questionnaires was the obvious improvement in students’ understanding of “the language of functions”, as Carlson (1998) puts it. Initially the students demonstrated great difficulties in translating a verbal description of a function into algebraic notation: e.g., in task A5 one of them wrote “for example, $f(x): x = 2$ ”, and another one started to solve the equation $x - y = y - x$, and after a couple of steps concluded that $x = y$. Apparently these students understood neither what is meant by “the value of a function” nor the usual notation by which functions are defined. However, three of these students showed very little difficulty in algebraic manipulation while expressing the diameter of a circle as function of its area (the fourth one left it blank), but all of them neglected to sketch the graph.

It also seems that these students thought that all functions must be defined by a single algebraic formula. In task A7, two of the students simply wrote “ x^2 ” while two left it blank. In the second part none had difficulty in defining functions piece-wise.

Although there is little doubt about the students’ improved writing in a formal mathematical style, it is unclear to what extent this indicates improvements in students’ concept. For example, in the challenging task B2, one of the four students started the solution by defining $f(x) = x^2$ and then $f(y) = y^2$, as though the second did not follow from the first (a misconception also documented, e.g., by Sajka, 2003).

The difficulty in interpreting functional information from a given graph (rather than interpreting it literally) appears to be somewhat persistent. In Task 8 all the four students demonstrated very little difficulty in interpreting static graphical information (speed) or relatively standard dynamic information (acceleration), yet all of them failed in Task A8d, in which they were asked to describe the relative position of the two cars over a time interval. Although they noticed that the car A was driving faster than B for the whole time, they still concluded that B was catching up with A because B had accelerated so much whereas A had driven with nearly constant speed.

DISCUSSION

In answer to our first research question, we found that the function concept of most students does seem to improve. In particular, courses in pure mathematics then also support the education of student teachers and applied mathematicians. The answer to the second question, regarding students’ awareness, is more complicated. Let us elaborate on this.

Our results are consistent with Carlson’s study (1998). In our first test students had difficulties very similar to those in Carlson’s Group 1 (A-students from a college algebra course): they had problems understanding the language of functions, for instance when defining functions piecewise. In the second test, however, our students seemed to have the same kind of difficulties as Group 2 (A-students from a 2nd year calculus course), e.g., interpreting dynamic functional information over an interval. Interestingly, although many participants in our first test apparently thought that a function must be defined via a single algebraic formula, this was not the case in the second test; in contrast, Carlson’s Group 2 subjects had this misconception. We interpret this as meaning that our students were slightly more advanced in their general understanding of functions than Carlson’s Group 2 students.

Between the two tests most of the students had taken introductory courses on both abstract and linear algebra, and advanced calculus. In these courses functions appear mainly through definitions and further properties (bijectivity, linearity, etc.) whereas little explicit focus is placed on development of intuitions. Nevertheless, the quantitative analysis showed that students made great progress in function tasks. This means that students were able to improve their function language without explicit in-

struction. Unfortunately, we cannot say how much of the improved scores is due to conceptual change and how much is a consequence of adopting the formal language used at university.

The qualitative analysis showed that this progress was tenuous in the sense that there was a tendency to relapse into old ideas when facing non-standard tasks with high cognitive demand. Apparently, students had least difficulty in tasks requiring algebraic manipulation of quantities. This is probably due to the Finnish curriculum in which a considerable attention is paid to solving equations via algebraic manipulation. On the other hand, in many high schools there is passing mention also of more abstract notions of functions, so the best students may have picked it up there. This may explain why they did not find examples at the university to be beyond their function concept. Altogether, these observations are consistent with Carlson's (1998) finding that students do not use the newest tools in their conceptual arsenal proficiently.

Our tests did not uncover a graphical and analytical component in the sense that there would have been greater correlation within the groups of graphical and non-graphical tasks. This may be due to floor and ceiling effects in the task scores which led to skewed distributions; we found several nonlinear relationships between tasks where only students with 5/5 points on problem X got non-zero points on problem Y. This means that the difficulty range of the problems was not optimal. On the other hand, it seems that also in most other studies the graphical and analytical components are postulated rather than recovered from the data. Our observations of graphical components are limited to the qualitative analysis. Here our findings mirror Bayazit's (2011) results of students' limited abilities to shift from a graphical expression to algebraic expression, with most depending on algebraic expressions.

Some answers indicate that the concept of variable is also problematic. For instance, one student introduced a function by defining it for several variables ($f(x) = x^2$ and $f(y) = y^2$) instead of just once. We do not know to what extent our students' problems are due to deficiencies in such prerequisite concepts as that of the variable.

About a quarter of the participants performed poorly and did not improve their performance between the first and second test. Interestingly, these students on average had a high estimation of their understanding of functions — in fact, they estimated that the function concept had been clear in high school and had remained clear since then. If they do not come to terms with the need to develop their function concept, this might cause serious problems for their studies and possible teaching careers. From course grades and other feedback these students must know that their studies are not progressing as well as they should be. Therefore they seem to be misattributing this lack of progress to some other factors than a weak function concept. This suggests that they do not have effective means of checking their metacognitive theories against reality, which indicates a persistent tacit metacognitive theory.

A second group, consisting of more than half of the participants, improved between the tests. Moreover, this group realistically estimated their function concept as having been average and then having improved. Unfortunately, we only asked participants to rate the clarity of the concept in the second test. Thus we have only a retrospective estimation of what the students thought after high school. Do they rate the conceptual clarity as low because they now understand it better? Or is it the case that they were unsatisfied with their understanding at the beginning of the studies, and were thus more open to new influences? This remains a question for further study. A methodological short-coming is the selection of the group based on only one repeated task: this might have introduced some bias. This will be addressed in the next iteration of the study.

If the retrospective rating is accurate, then it might allow us to design a diagnostic test for the beginning of studies which detects students at risk of belonging to the LOW category as those with low performance and high estimation of their function concept. Alcock and Simpson (2004) found that this kind of profile (low performance and high confidence) is typical for some graphically oriented students. Whether there is such a link in our case also remains to be determined. Another open question is whether this profile is context specific, or whether the students follow the same path in all areas of mathematics.

The results of the first year of our study in general agreed with our expectations. Students' concepts improved and most said as much in the questionnaire. Whether this group contains a subgroup of improvers who do not notice the change is a question for future study. Almost a quarter of the students did not improve, and showed low self-awareness of their situation. This pilot study had both deficiencies and strengths. In future versions we will diversify the data collection to get a better picture of the groups tentatively identified in the analysis above.

MATHEMATICAL MEANING-MAKING AND ITS RELATION TO DESIGN OF TEACHING

Barbara Jaworski

Loughborough University, Mathematics Education Centre

This paper addresses the design of teaching to promote engineering students' conceptual understanding of mathematics, and its outcomes for mathematical meaning-making. Within a developmental research approach, inquiry-based tasks have been designed and evaluated, through the use of competencies proposed for their potential to promote conceptual learning. A sociocultural frame draws attention to interactions between different cultural elements to address challenges to teaching relating to student perspectives and the mathematical meanings they develop. The paper recognizes tensions between design of inquiry-based practice and the outcomes of that practice, and demonstrates the need for new research to address mathematical meanings of a student community within a sociocultural frame.

SETTING THE SCENE

In this paper I focus on the ESUM project (Jaworski & Matthews, 2011) in which an innovation in the teaching of a basic mathematics module to first year engineering students (n=48) was studied. The ESUM innovation involved design of teaching using inquiry-based tasks and small group activity within a GeoGebra environment. The goal of teaching development was to promote students' *conceptual* understanding of mathematics rather than understanding that is instrumental or procedural (Skemp, 1976; Hiebert, 1986). The etymology of "understanding" (understanding), as for example in comparison with the French word "comprendre" (taking together), is of interest. We have been challenged to declare what we mean by "understanding" or indeed by "conceptual understanding" and how we expect to recognise it. One finding from ESUM was the difficulty of discerning students' conceptual understanding, which we have expressed in terms of students' *mathematical meaning making*. We want to go beyond superficial indicators (like test or exam results) to find ways of revealing students' mathematical meanings. The focus of this paper is how to address this challenge. I consider a (draft) report from the SEFI (Société Européenne pour la Formation des Ingénieurs) Mathematics Working Group (2012) which recommends a *competence* approach (Niss, 2003). More precisely, this paper investigates the following research questions:

RQ1) *When a (developmental research) project seeks to enhance students' meaning making of mathematics, how can we gain insights to students' mathematical meanings?*

RQ2) *How can we characterise mathematical meaning making in ways which aid its creation? (In what ways can the SEFI/Niss competence framework aid characterisation?).*

To address these questions, I draw on findings from ESUM, using the SEFI framework to interrogate the design of inquiry-based tasks or questions, taking, as an example, the topic of *functions* which was a central topic in the mathematics module.

A literature search on innovative modes of teaching (in HE STEM-related subjects¹), showed that the use of inquiry-based approaches is often conceptualised within a *constructivist* theoretical frame (Abdulwahed et al, 2012). As such, learning is considered from individual cognitive perspectives, possibly with a social dimension (e.g., Ernest, 1991). In ESUM, research findings have pointed to tensions and contradictions between the design of teaching and students' perspectives on learning and teaching (Jaworski, Robinson, Matthews & Croft, 2012). This has required us to deal with complexity within differing cultures and within institutional constraints, for which a sociocultural theoretical frame makes more sense than a frame of individual cognition. Thus, we see mathematics knowledge growing in social settings through mediational processes and the use of tools such as inquiry-based tasks and approaches to teaching (Schmittau, 2003; Wertsch, 1991).

A DEVELOPMENTAL AND INQUIRY-BASED APPROACH

The ESUM study employed a developmental methodology, incorporating an inquiry-based approach, in which research both studied developmental practice and contributed to development (Jaworski, 2003). A team of three teacher-researchers (insiders) designed and taught the module, with continuous reflection and review leading to modifications during practice and new insights for the next year of teaching. A research assistant (outsider) collected data and analysed data together with the teaching team. Analyses informed future teaching.

The developmental methodology involving nested layers of inquiry (A, B & C with $A \subset B \subset C$) with students' learning of mathematics at the centre: *Inquiry in mathematics* (A) involves students in learning and understanding mathematics through inquiry. *Inquiry in developing mathematics teaching* (B), involves questioning teaching approaches and the design of teaching, to understand the basis of teaching decisions and ways of improving teaching for better learning outcomes. Inquiry in layer C inspects the other two levels to gain insights to the developmental processes in both layers, and their outcomes (Jaworski, 2006). When inquiry practices are instituted or promoted within a group, an outcome can be the formation of an *inquiry community*, which can be seen to have all the hallmarks of a *community of practice*, as designated by Wenger (1998), except in one major respect. In Wenger's terms, those involved in the community can be seen to have joint *engagement*, *enterprise* and *repertoire*; and their identities can be conceptualised as encompassing the use of *imagination* in charting personal trajectories of engagement, and *alignment* with the norms and expectations within the practice (Wenger, 1998).

¹ STEM – Science, Technology, Engineering and Mathematics. The ESUM project was funded through the Higher Education (HE) STEM programme by the *Royal Academy of Engineering*. Two case studies from the project can be found at <http://www.hestem.ac.uk/resources/case-studies>.

While it is impossible to be a part of a community of practice without aligning with its norms and expectations, one does not have to align uncritically. Uncritical alignment can result in perpetuation of practices which do not achieve the goals of practitioners – for example, alignment with certain forms of teaching practice, within a community of mathematics teaching, can result in student learning outcomes which are instrumental or procedural in nature, lacking conceptual depth (Skemp, 1976; Hiebert, 1986). So, alignment needs to be critical – critical alignment – in which (established) practices are subject to critical questioning by the practitioners who engage with them (Jaworski, 2006). In learning mathematics, with inquiry in the three layers A, B and C. critical alignment involves asking *why?* Why do we do things in certain ways: why this formula, why this procedure, why these relationships? Inquiry-based tasks and questions are designed to get student to address these *whys*.

LEVELS OF COMPETENCY IN MATHEMATICS AND IN TEACHING

I turn now to competence and competency and their relation to the design and use of inquiry-based questions and tasks to address the given research questions and the ESUM main goal regarding conceptual understanding. Niss writes:

Possessing mathematical competence means having knowledge of, understanding, doing and using mathematics and having a well-founded opinion about it, in a variety of situations and contexts where mathematics plays or can play a role (Niss, 2003 p.183)

A mathematical competency is a distinct major constituent in mathematical competence: eight competencies have been identified in two groups.

<i>The ability to ask and answer questions in and with mathematics</i>	<i>The ability to deal with mathematical language and tools</i>
1. Thinking mathematically	5. Representing mathematical entities
2. Reasoning mathematically	6. Handling mathematical symbols and formalism
3. Posing and solving mathematical problems	7. Communicating in, with and about mathematics
4. Modelling mathematically	8. Making use of aids and tools

Table 1: Mathematical competencies as expressed in SEFI (2012)

These competencies seems to have synergy with inquiry-based learning and what we aimed for in the ESUM project, and they offer starting points for design of tasks and evaluation of learning outcomes. Space here precludes a detailed account of each competency; I will rather clarify their meaning through application to task design. The authors emphasise three dimensions for specifying and measuring progress in learning with respect to competency: Degree of coverage: The extent to which the person masters the characteristic aspects of a competency; Radius of action: The contexts and situations in which a person can activate a competency and Technical level: How conceptually and technically advanced the entities and tools are with which the person can activate the competence. How to address these dimensions is an issue to consider.

TASK DESIGN AND ANALYSIS

When students emerge from schools and their A level² courses, we know that their mathematical learning has often been of an instrumental nature (e.g., Artigue, Batanero & Kent, 2007; Hernandez-Martinez et al. 2011). Thus, as part of the school culture, they know how to, for example, apply rules of differentiation and integration, but have little conceptual understanding of the nature of functions or of limiting processes. In both of these areas research has pointed to conceptual difficulties that students experience (e.g., Cornu, 1991; Even & Tirosh, 1995). So, the demands of design within the university course are to create tasks which engage students with mathematics, some of which is already familiar to them, in ways which take them beyond school practices and into a university culture in which it is hard to progress without deeper understandings.

The following two tasks (Table 1) were designed for these purposes. The first was used in a lecture at the beginning of our work on functions. In the second, the first part (a) was used in a lecture and the other parts (d-e) in a tutorial where students sat in groups of three or four each with a computer and access to GeoGebra software. In accord with design goals, and associated expectations of students' engagement, I have analysed the tasks in terms of the eight mathematical competencies (Table 1).

Analysis of Task 1 using the competencies

Task 1 (Table 2) was intended to open up discussion of functions. The lecturer offered the task and waited for students to write down two functions, meanwhile, walking round the lecture theatre and looking expectantly at students (and smiling, with eye contact) to encourage their engagement with the task.

	Task	Competencies
1	Think about what we mean by a <i>function</i> and write down two examples. Try to make them different examples.	1, 2, 5, 6, 7
2	In the topic area of real valued functions of one variable Consider the function $f(x) = x^2 + 2x$ (x is real)	
a)	Give an equation of a line that intersects the graph of this function (i) Twice (ii) Once (iii) Never (Adapted from Pilzer et al. 2003, p. 7)	1, 2, 3, 5, 6, 7
b)	If we have the function $f(x) = ax^2 + bx + c$. What can you say about lines which intersect this function twice?	1, 2, 7, (8)
c)	Write down equations for three straight lines and draw them in GeoGebra	1, 2, 5, 6, 7, 8
d)	Find a (quadratic) function such that the graph of the function cuts one of your lines <i>twice</i> , one of them <i>only once</i> , and the third <i>not at</i>	1, 2, 3, 7, 8

² A *level* courses means courses preparing students for “Advanced Level General Certificate of Education” a public examination qualifying students for study in Higher Education. These are high stakes examinations and schools are measured by their examination successes.

	<i>all</i> and show the result in GeoGebra.	
e)	Repeat for three <i>different</i> lines (what does it mean to be different?)	1,2,3,5,6,7,(8)

Table 2: Two tasks from ESUM, with associated competencies

The task is *open* in nature. Students could write down any example they could think of. Since most students had studied *A level* mathematics, they had certainly encountered the term “function” and used functions. So for most students the task was accessible. It encouraged them to *think* [1]. To write down the function they had to use symbolism to represent the function [5, 6]. I argue that in *writing down*, they were already starting to communicate, and, in deciding on *different* functions, to reason mathematically [7, 2]. After a suitable time, the lecturer, in plenary, asked students to offer one of the ‘functions’ they had written, and wrote these verbatim on the overhead projector. Initial contributions were made tentatively, the lecturer smiling encouragement and thanking the student, and many more then followed, thus overcoming some of the barriers to student contribution in a lecture. When a (long) list of offerings had been produced, the lecturer asked students to comment on the nature of what had been offered (importantly, a student who had offered any example was now anonymous). Some of the examples offered were as follows: $y=x+3$; $y=x^2$; $y=e^x$; $x+y=4$; $f(x)=x+1$. The majority were of the form “ $y=$ ”. When asked to comment on ‘difference’ some students mentioned linear functions versus quadratic functions, or exponential functions. Some queried $x+y=4$, stating that it is an *equation*, not a function. Very few used functional notation of the form ‘ $f(x)=$ ’. When the lecturer added to the list $y=5$ and $x=4$, students were adamant that these are not functions. Thus, communication occurred between students and the lecturer [7], and students offered explanations and reasons for why an item was a function or not [2]. Students could see alternative offerings from their peers. For the lecturer, students’ responses to the task provided insights to their current knowledge/thinking about functions, and allowed some immediate challenge – for example, “what is the difference between a *function* and an *equation*?”, “why do you think $y=5$ and $x=4$ are *not* functions?”

In Task 1, students had to produce their own examples, leading to engagement, questioning, discussion and *inquiry*. *Inquiry* could be seen in the questioning which resulted, in consideration of what is a function and what is not a function, and in the mode of engagement in the lecture: students were expected to contribute, think, reason, argue, not to take some things for granted, and to deal with uncertain situations (not everything will be presented as cut and dried, right or wrong). We can see this episode as the beginnings of creating an inquiry community. We see here some starting points in addressing RQ1, and a start to characterisation of understanding using the competencies (RQ2). We can ask how the three *dimensions* relating to competency can be used to evaluate students’ responses to the task.

Analysing Task 2 using the competencies

The first part of Task 2 (2a) was also presented in a lecture with a similar teaching approach to that described above. An analysis of this task suggests that:

- The function is easy to sketch for students who have reached A level in school – it is easy to see lines which cross it in the three conditions [5]
- Students have to talk to each other [7]
- They have to think about equations for their lines [1] [3] [6]
- They start to reason about the differences between the lines [2]
- They have to give feedback to the lecturer and others in the cohort [2, 7]

In the lecture, students were asked to write down the required equations and to discuss with a neighbour [1, 5, 6, 7]. After a short time, students' suggestions were written on the OHP by the lecturer. Some students offered equations of parallel horizontal lines, such as $y=1$, $y= -1$, and $y= -3$. Others offered non-horizontal lines. One question which arose was how one can know that a non-horizontal line will cross the graph (or not). This provided opportunity for discussion, with some students disagreeing with others as to which lines will cross or not cross [1, 2, 3]. Further graphical and algebraic activity resulted. GeoGebra allowed the possibility to experiment quickly changing coefficients in equations and scales on axes to gain insights into relationships. Some students were able to offer algebraic reasoning, but it was not certain that all were able to understand this [6].

Here the lecturer learns from students' responses and can consider how to plan differently for a future occasion, to give more time or not, to rearrange material or not. The lecturer also learned about interventions: where a question or explanation seemed to promote student engagement and where not; how to deal with incorrect assertions if no student offered a challenge. When students themselves offered a challenge, mathematical communication between students provided corresponding opportunities for learning. The lecturer became aware of actions which promoted or inhibited students from offering such challenges. More time could valuably have been spent on such activity, encouraging questions and explanations from students, but there was much further material to address in the lecture, and so not enough time to give to continuing the discussion. These are examples of contextual constraints.

Tasks for use in a tutorial

Parts b) to e) of Question 2) were addressed in a tutorial. Typically a tutorial was related to material addressed in a recent lecture. Often a sheet of questions was provided, some questions offered practice and support in relevant areas of mathematics; others were inquiry-based questions in which exploration, questioning, discussion and justification were encouraged. Question (2) is an example of the latter: 2b) requires students to generalise from (a), [competencies 1, 2, 7]; in 2c) students have to invent their own mathematical objects and use a technological tool [1, 2, 5, 6, 7, 8]; in 2d) they have to tackle an open-ended problem [1, 2, 3, 7, 8], and in 2e) they are required to generalise mathematically [1, 2, 3, 5, 6, 7]. In (b) and (c), use of GeoGebra can provide opportunities to visualize and to generate a range of possibilities for consideration. 2d) is seriously challenging – even with use of GeoGebra it is not simple to generate the function, analytical thinking is required. In

2e) the question about *what it means to be different* is designed to promote thinking at more general levels and encourages movement towards conjecture and proof.

In the tutorials, lecturer and a graduate assistant moved from group to group of students encouraging work on tasks and probing students' mathematical thinking. It became clear that different groups engaged very differently: some taking on the mathematical challenges and some seeking quick and easy solutions. GeoGebra was used variously as a graphical display (with a screen full of indistinguishable graphs), a source of quick/easy answers to questions, or as a help in tackling challenging questions. While tutor and assistant encouraged the latter, they were aware of the other uses. Although their questions encouraged a more meaningful, mathematically in-depth use, it could be seen, when the tutor left the group, that some students returned to other uses or were tempted to use social networking sites or engage with email. Critical alignment for the tutor is seen in how to promote deeper engagement when former school practice and current student cultures acted in other directions.

Data and Analysis

Data collected from these events included the lecturer's reflections: orally after a lecture or tutorial, and a written reflection each week addressing issues arising from the interpretation of teaching design in practice (critical alignment); the research assistant audio-recorded lectures and the oral reflections and kept observational notes from all events. After the end of the module (one semester) she and another colleague interviewed a selection of students. In addition, data was collected from student surveys and written project work. Data were analysed to address questions of students' engagement and their experiences of inquiry-based tasks and use of GeoGebra. Data from written project work showed that students were aware of ways in which GeoGebra could contribute to their understanding. However, the following two responses, from focus group interviews, are indicative of student attitudes.

- I found GeoGebra almost detrimental because it is akin to getting the question and then looking at the answer in the back of the book. I find I can understand the graph better if I take some values for x and some values for y , plot it, work it out then I understand it ... if you just type in some numbers and get a graph then you don't really see where it came from. (Focus group 1)
- Understanding maths – that was the point of Geogebra wasn't it? Just because I understand maths better doesn't mean I'll do better in the exam. I have done less past paper practice. (Focus group 2)

How *dimensions of competency* might interface with such findings is hard to see.

MAKING SENSE OF STUDENT UNDERSTANDING

In the above I have focused on analyses of *the design of teaching*, principally the design of inquiry-based tasks and an associated teaching approach to engage students with mathematics for conceptual understanding. I have used mathematical competencies to qualify or start to characterise 'conceptual understanding'. I have suggested that students' responses to this careful design have not been what we would ideally have liked; factors identified being institutional constraints, time,

students' school culture, students' social culture. Student remarks such as those quoted led us to characterise student responses as 'strategic' (Jaworski & Matthews, 2011). Students wanted the best possible grades and had clear ideas as to how this should be achieved; some of these ideas conflicted with the expectations of teaching, students expressed their own expectations on the nature of teaching (e.g., the teaching should focus more on graph *plotting*; there should be time given to practising past papers). Comments related to doing "better in the exam" suggested students valuing a more instrumental approach to understanding with a perception that a more in-depth understanding was unnecessary.

We are aware that the existence and nature of an exam (worth 60%), whose style had changed little from that before the innovation, was not exactly in the spirit of inquiry-based learning to encourage deeper understanding, although it might be seen to have synergy with dimensions of competency. We have considered replacing the exam with other forms of assessment, but institutional constraints have so far prevented this³. In written group project reports (worth 20%), understanding was demonstrated through responses to questions in which students had to pursue their own lines of inquiry and comment on the value of their use of GeoGebra. A typical response was:

As a group we looked at many different functions using GeoGebra and found that having a visual representation of graphs in front of us gave a better understanding of the functions and how they worked. In this project the ability to be able to see the graphs that were talked about helped us to spot patterns and trends that would have been impossible to spot without the use of GeoGebra." [Group F – project report]

However, observational data showed some students not engaging seriously with the more demanding questions in tutorials, and many attending more assiduously to the more routine exercises. It was clear that where groups were taking seriously the inquiry-based questions, discussion with the tutor proved encouraging and motivating. Unsurprisingly, groups which responded best in tutorials gained the higher marks in the assessed group project.

In the above I have commented briefly on some of the key findings from our ESUM analyses. They reveal important insights into the sociocultural factors influencing the implementation of project design and its outcomes for students. Nevertheless, the nature of mathematical understanding remains elusive. Analyses using the competency framework have supported our design of tasks; apparent synergy between principles of inquiry and competency reinforce confidence in our didactic design. However, our research questions above are only partially addressed. The competency-based task analysis offers a form of characterisation (2a). The sociocultural analyses allow us to frame some of the obstacles to deeper insights into students' understanding (e.g., students' perceptions demonstrated in project writing in comparison to their views expressed orally in interview). The competencies and

³ It is ironic that, in the exam at the end of the ESUM innovation, students' scores were on average 10% higher than those of previous cohorts. We are not able to link this directly to the innovation, since data was not available to compare intake grades with those of previous cohorts.

dimensions offer a framework for the design and evaluation of tests or examinations, but we believe this would give us little more than a summative evaluation of the sort we have already from exam and test scores, albeit perhaps more detailed and specific. RQ2 -- *How can we characterise understanding in ways which aid its creation?* – is only partially addressed, and perhaps we need a better-focused question. What is it, exactly, that we are trying to characterise? So far we have reinforced our design principles and the elusive nature of discerning students' mathematical understanding. We have juxtaposed design principles with sociocultural findings using activity theory to highlight inherent tensions or conflicts (Jaworski et al, 2012). Discerning tensions and conflicts is one step towards resolving them. Finding ways to characterise understanding is another. We still need to make the sociocultural findings active in our design so that we come closer to enabling the student understandings we seek. This requires us to go beyond competencies, while remaining aware of their contribution towards recognition of the mathematics for which we seek understanding. Since these are engineering students, discussion is taking place also with the engineering department.

A final consideration is methodology. We need to adapt our methodological approach with a deeper focus on mathematical meanings. The use of questions in lectures could be more focused towards revealing meanings; this would require the lecturer to pay more attention to generating student articulation of meanings which would be recorded and analysed within the sociocultural frame of the lecture community. We are designing further research to address these considerations.

INTEREST IN MATHEMATICS AND THE FIRST STEPS AT THE UNIVERSITY

Michael Liebendörfer, Reinhard Hochmuth

Leuphana Universität Lüneburg, Germany

Abstract: *First, we discuss interest in mathematics from a theoretical perspective. For this, we outline theory on interest and supplement it with reference to the specific context of the secondary-tertiary transition, constructing a specific theoretical perspective. We then use some interview data to demonstrate, how this perspective may help structuring practice reports and sketch an example for the interplay of the theoretical facets.*

Keywords: Interest, secondary-tertiary transition, self-determination theory

INTRODUCTION

Interest plays an important role in the experience and behaviour of students entering university, as numerous empirical studies have shown that interest (notwithstanding the way it was operationalized) is an influential factor in learning, being closely connected e.g. to the student's use of deep learning strategies, their effort and learning outcomes (Krapp, Schiefele, & Winteler, 1992). Such findings have not been replicated for the university, but can presumably be transferred from school. One might even speculate upon increasing influence at university, since students have more personal responsibility there (e.g. uninterested students might even not attend lectures). Therefore we believe it to be useful to learn more about interest, its structure and development, and present an approach to how to tackle this topic.

The study and thus our theoretical considerations refer to courses at the German mid-size university of Kassel where the mathematics is based on definition and proof from the beginning. The dropout rate is around 40-50 %.

THEORETICAL FOUNDATIONS

The context of the **secondary-tertiary gap** has many facets (see e.g. Gueudet, 2008). Personally, it often coincides with a new social situation and many more liberties and responsibilities. Much more than before, one may set goals for oneself. This is an opportunity to gain more autonomy, but may also lead to uncertainties. Then, the formal requirements of the study regulations are often taken as benchmarks, which unfortunately disregard important factors like learning goals, professional qualifications, the own vision of education and their contribution to science. These rather general issues are supplemented by some points which are specific to mathematics. Transition problems may be caused by a high degree of formalization, in which the focus is no longer given on calculations, but on proof (Tall, 2008). University mathematics requires skills (like language) which rarely correspond to the

expectations of the students, and which play an important role in the student experience and behaviour within this new system.

Our conception of **interest** is based on the theoretical framework provided by Krapp (Krapp, 1992). Here, interest is conceptualised as a person-object relation characterised by value commitment and positive emotional valences. Individual interest is perceived to be a disposition that associates the object of interest with positive emotions (experienced and expected in future) and a personal value. Interest differs from motivation in the specific object. This can be a real object, but also something imagined, as long as it is known to the subject and perceived as one object. It can be located at different levels, e.g. school mathematics and university mathematics may be considered, but also specific aspects like proof or issues like calculus. According to Krapp, we distinguish individual interest from situational interest, which means that an individual acts with a concrete object motivated by external stimuli. However, this interest action requires the locus of causality to be perceived in the person itself (cf. autonomy, below). Interest development can be characterised by three stages: introjection, when interest actions are conducted for reasons which have nothing to do with the object, identification when the object has a value besides the aims of the interest action, and integration, when interest is integrated in the concept of self and doesn't conflict with it.

An important background for the analysis of origins and influences on interest is **Self-Determination Theory** (SDT) (Deci & Ryan, 2000). SDT posits the three basic needs for (perceived) autonomy, competence and social relatedness. All three factors are important, maybe necessary, for the development of interest (Krapp, 2005). This leads us to the following questions: When is competence experienced? How is autonomy experienced and secured? In which contexts do students feel relatedness? The very personal view is stressed in (Hannula, 2001), where the author revealed a strong interplay of needs and their satisfaction, goals and beliefs in school context, emphasising, that “what students want, has a strong influence on their experiences”. Concerning university students, (Ward-Penny, Johnston-Wilder, & Lee, 2011) emphasised the importance of “students’ view of what constitutes success and achievement” for the developing identities, which can be different on seemingly similar trajectories.

Our emphasis is on individual interest, which also requires situational interest to be considered, as both are closely linked. In the last decades, individual interest in mathematics has not been tackled often in depth. A notable exception is (Bikner-Ahsbals, 1999) who investigated different facets of individual mathematics interest (like its history or cognitive problem solving). Recently, interest as outcome has received more attention, (e.g. Frenzel, Goetz, Pekrun, & Watt, 2010). In our work, we want to investigate interest in higher mathematics (HM), but also in school mathematics (SM), since it is assumed that the initial interest in HM and the attitude towards the subject are based on experiences and interest in school mathematics. The

third major theme is studying in general. From the theoretical perspective, we would not believe that interest in HM is present from the first day, since it would require HM to be known to the beginners. Even interest in SM doesn't need to be present, since there is a whole range of additional motives for going to university. An important aspect of our work is the question of how the new objects are perceived in the light of the facets of interest emphasised by the SDT, and of which opportunities of action, belonging to these objects, are realised in which context. In this way we hope to obtain evidence on how and why the development of interest is hampered or supported by some aspects of the context or typically appearing as partially habitualised behaviour and patterns of argument. Thus, we have to capture the context and the way the subject deals with the context to understand the interest. Here, it makes sense to use a theoretical approach that reflects the role of the basic needs and includes pragmatic and habitual aspects, as offered in (Grotlüschen, 2010).

We could not find much literature on interest development during the transition. (Daskalogianni & Simpson, 2002) describes that entering university is a critical point for interest in mathematics. The authors interviewed students in school and later at university. The students showed a substantial loss of interest in the first six weeks, based on a mismatch between their beliefs and the mathematics they encountered. Some could recover as they managed to rearrange their belief system, whereas others not. Kenneth's case was illustrated, as he was one of the first kind. Here, we offer an alternative interpretation based on the presented framework: If we distinguish SM from HM, then we might see the early interest as referring to SM, as the first interviews were held in school and the authors mention school mathematics in this context. However, a possibly later interest might refer to HM, which the interviewers had asked for ("Why do you think, that Further Maths is more difficult?"). It seems that the students differentiate the two objects, as Kenneth states: "it's really quite a lot different to A-Level Maths". The "loss" would then be caused by changing the considered object of interest and the individual insight that the two kinds of mathematics differ (even from expectations). Inappropriate student expectations are well known to university teachers and e.g. documented by (Hirst, Meacock, & Ralha, 2004) concerning the importance of proof or technology use. The "recovery" would then simply be a new genesis of interest, which apparently requires the right kind of beliefs and some time for development. The importance of the student's beliefs and their adjustment had already been stressed by the same authors in (Daskalogianni & Simpson, 2001). From the SDT perspective on interest genesis, this again raises the question of the above mentioned interaction of beliefs and need satisfaction.

THE EMPIRICAL PART

We apply our framework to data from a focus group discussion and a subsequent interview at the University of Kassel, Germany. There, the typical course includes 2 hours of lectures a week with some 100 students, and a 2h tutorial in smaller classes (10-20 students). Each week, the students get a sheet with about four tasks as

homework and have to hand-in their solutions. Successful participation (receiving at least 50% of the maximum score) is precondition for admittance to the exam.

The data is taken from a project where we investigate interest and its development in the first semester at university. In the study, we aim at reconstructing the subjective experience and behaviour, and want to relate it to interest. As a pilot study, we conducted a focus group since we believe that the more natural atmosphere of a group can help revealing student orientations and typical behaviour more directly. The participants were all taken from a lecture on linear algebra which normally is attended in the first semester (which was the case for two of the five students only). For about two hours we talked about transition problems and interest. The group discussion was audio-taped and transcribed. We first coded in an inductive way heading to different interests and related statements, and then recoded using theoretical categories emerging from SDT. All students agreed with anonymous scientific use of the data and were given the possibility to delete audio sequences. They reported very intense emotions concerning the homework assignment, like stress, anxiety and frustration. In their view, HM was quite different from SM. They also reported coping strategies like copying. We found that the students mostly didn't experience autonomy and competence. When asked about interest, they described themselves e.g. as "not uninterested" in HM, but couldn't specify this interest. It might be the case, that they had no interest in HM in the sense of Krapp, but didn't want to admit. As a disadvantage of the method, we couldn't easily ask for more details since the method requires the discussion to go on. Thus, we asked some students to come again for an interview (under the same ethical conditions), and it was a student we call Anna who decided to do so. The interview was based on her statements from the focus group and took about 60 minutes. It was again digitally recorded but not entirely transcribed. The analysis by the two authors was mainly done by discussion of the critical passages based on the theory sketched above.

Anna is an untypical case regarding the fact that her major subject is physics and also regarding her education biography. Anna dropped out of school before doing the Abitur (compares to UK's A-Levels) and went to schooling as chemical-technical assistant. She then decided to do her Abitur in evening classes. As a physics student, Anna attended the lectures on analysis in her first year, and those on linear algebra in the second year. (Mathematics majors usually attend them at the same time.) The focus group was conducted at the end of her 3rd semester; the interview was in her 4th semester. For us, her case was interesting since she reported mainly negative experiences, yet thought about switching major to mathematics, a seemingly contradicting behaviour. Other students also showed a discrepancy of interest in studying and interest in the subject. Anna's case, however, is a very clear one. Additionally, she spoke openly and reflected, although a self-report can only partly reveal her experience. We had first taped her talking in the more natural group and

then went into detail in the individual interview. But still, we have methodological limitations some of which are inherent to any retrospective research method.

The transition experience

At school, Anna has always had good maths teachers and felt interested in this subject. For her, doing mathematics was mostly doing calculations. When Anna came to university with a friend, they both had decided to study together. After presentations of different courses, they agreed to study physics, although it wasn't Anna's first choice. It was more important for her to not start studying on her own. When she and her friend couldn't solve tasks no. 3 & 4 of their homework assignments in the first (!) week, they looked for someone she calls "private tutor" who solved the tasks for them. In the focus group she described herself as "desperate" since she "completely failed". One might wonder why she didn't see the two solved tasks as a success or give herself another try, especially since we know that neither the teachers expect the students to solve all tasks, nor many students do so. We hypothesize that her definition of success is adopted from school, where she usually solved a higher percentage, she always knew what to do, and copying homework is quite common. The tutor offered Anna and her friend to also explain the solutions, but in most times, they refused. The following interview passage illustrates her expectations and her experience with the homework:

Anna: Well, we didn't understand the sheets at all. Well, yes, I think it was the first two tasks of the first sheet and there it stopped. And then I couldn't do it. Well I couldn't, I couldn't somehow handle the writing in mathematics, they have their own writing, e.g. that is sets, this and that, and I – I couldn't do this. I have never somehow worked on sets in school and thus it was difficult to read, what you want from the students. And therefore we were desperate and looked for a private tutor.

Interviewer: Was it new, this feeling that there is something you can't do in mathematics, that it is so unfamiliar?

Anna: Well yes, but I have – that is strange, but I have not really [related the sheets] to mathematics somehow – well I didn't really see them as mathematics. Well for me, that was something completely different. For me, mathematics had always meant calculating something, setting up something, and actually that's it. But not any strange proof. Maybe you have heard before a bit, that higher mathematics is something slightly different. But you have never really perceived what is really there.

Interviewer: That's exciting, what kind of mathematics would you have expected, can you describe this?

Anna: This is difficult now, because now I know what is to come. But if I – I do not know what I would have said if someone asked me when I was in school. (..) If someone had asked me, I don't know. Maybe – I think I would not have expected so many proofs. Well, calculations yes, also without using numbers, but simply just this general; but more

calculations are what I have thought. But what do calculations mean? Not silly replacement of variables, just setting up [equations], too. So, where does all this come from, e.g. we had proven in calculation methods [a course for physics students] why the volume of a sphere equals pi times r^2 – of a circle – and we have deduced it. And this is what I have thought, that we would do more things like this. But not, don't ask me, what we have done. But I have passed it!

For Anna, HM is very different from SM and she experiences many problems particularly in the theoretical parts of HM. Today, she still struggles with formalism and couldn't manage to adjust her beliefs on the nature of mathematics. (“How do they know 4-dimensional spaces exist?”) She describes mathematics as “understanding, seeing, calculating”. Although she failed at the two analysis exams and her exam on linear algebra (as well as some exams in physics) she still thinks she will manage her studies, albeit it will take her more time than usual. Anna's aims are dominated by achievement goals. In the interview, she often refers to exams, to the homework assignments and even to her CV. In contrast, she never talks about learning goals she would like to achieve, except for one statement on applications of mathematics (playing poker).

Basic needs

Anna experienced her first year as very stressful, and university didn't match her expectations. She couldn't solve the homework on her own and didn't pass the exam. Anyway, she managed to feel competent. Copying from her private tutor, she got the admittance for the exam (which is also valid the next years), what she calls a success. In addition, she learned some calculus techniques like integration by parts and feels competence in doing calculations (like she did in school). Concerning proof, she often didn't even understand the tasks, and showed no need to clarify this. Instead, she tries to fade-out or to dismiss such tasks (disvaluation of unaccessible tasks was also described in (Hannula, 2001)). She additionally excuses her problems by her education biography, often referring to her inferior prerequisites. Another explanation is the ‘fact’ that only gifted students can fully meet the requirements. Asked for feelings of success she reports that once she found a solution for a task in a book. This matches her goal orientation since it helps her receiving credits for her homework (but not achieving learning goals). When in the second semester she had success doing the homework with a colleague, she started solving the tasks without her private tutor. She reports she had learned how to deal with the symbols and now the tasks were more based on calculations. So, situational interest sometimes appeared when calculations were involved, at one point she even reported flow. Concerning autonomy, Anna felt forced to do the homework, but managed this by copying. Her own need for autonomy is strongly stressed:

Anna: “I don't surrender quickly, but if I don't understand it, then I won't do it. I won't sit down and do this for hours until I understand it. I won't do this for sure. I'm not proud of it, but yes...”

Unlike the other aspects, social relatedness is not a problem for her. She often mentions others (common decisions, work and experiences) and at no point reports feelings of unrelatedness. Anyway, the situation is unlikely to foster interest in HM.

Anna's interests

In both the interview and the group discussion, we couldn't find a statement of Anna that indicates interest in HM (such as positive emotions or valuations, see *Theoretical Foundations*), although we had explicitly asked for it. For instance, she couldn't name any topic of interest and also didn't want to learn the subject matter. This is consistent with our account of her SDT experience. However, rather than thinking about dropping out, in the focus group Anna had reported her thoughts about changing her major subject to mathematics, although her motives were unclear. In the interview, she said that she first wanted to see how physics is going, and since she has passed her last exam there, she sticks to physics, focussing on the more mathematical topics. We believe that her interest in studying mathematics has been preserved from the end of school. However, stressing this interest can also be an expression of an exit option from studying physics. Then it would be seen typical for a developing interest in studying physics (cf. Grotlüschen, 2010) and is an emphasis of autonomy. Concerning both study subjects, she reports that they are untypical for a woman but respected and important. From the SDT perspective, relatedness and perceived autonomy may be given, the latter restored by copying. The obvious lack of competence in mathematics needs not be necessarily an obstacle for Anna. First, she didn't experience it so much after she started copying and also when she repeated the 1st semester course. Second, she has the expectation that once she would start engaging more, she eventually would succeed: "I don't think that after years, when you do this, that you still don't understand it. I don't believe this."

The special case of proof

We chose the issue of proof because, although proof is the basic paradigm of university mathematics, Anna managed to study two years without acquiring a taste for proof. She starts with a special obstacle, since she sometimes struggles with language. Her parents presumably emigrated from Eastern Europe, which (besides her accent) sometimes causes phrasing problems. Again we take a passage from the transcript:

Anna: [...] and I liked calculating everything nicely, writing down everything nicely, yes. – And still, well I still like calculating, and when we have the calculation tasks, but proof, maybe, you don't really see how to do these proofs yet. Maybe that's why it still is. But if I talk about it with someone or so, everybody says it: 'Oh I hope there is no proof [in the exam]' or so.

Interviewer: Yes ok. Is it the same with you?

Anna: Yes. Proof is more difficult. Because, maybe you don't hm – have this learning effect for proof, because you have never had proven anything

this in school. Well, we only have, the only thing we maybe proved is for example hm, oh how do you call it, hm this derivatives, well

Interviewer: The derivation rules?

Anna: Exactly, we have proven these derivation rules. However, that is also nearly calculating. You have to put in [variables].

Anna had never proven anything in school and she shows no meta-knowledge on doing mathematics. Thus, it is not easy for her to feel success or to act autonomously. At no point, she reveals a need for proof, which fits her belief system: If mathematics is about having the right formulae and doing the right calculations, proving doesn't help. Proof is also problematic regarding her goal orientation. Her performance goals are not compatible with understanding proof, since proof seems to be different every time. She doesn't notice a learning effect, except for simple calculation-based proofs. So she is missing, e.g., knowledge on what can be learnt by exercising proof and typical heuristics. One might even speculate about the question, if the repeated refusal of proof might grow into a habit.

On this basis, the requirements of the SDT can hardly be fulfilled. Anna feels incompetent in two ways: She doesn't know how to solve a given proof problem, and very often she even doesn't understand the problem itself (also strongly restricting autonomy)! This becomes clear e.g. when she joyfully emphasised, that in the exam she could understand all tasks. Meanwhile, she has learned to do proofs built on calculations, like checking subspace axioms, but not more. Even typical induction proofs seem unfamiliar to her. Concerning the need for autonomy, she doesn't mention any positive aspect, but some negative ones relating to the homework assignments. Social relatedness appears in avoiding proof only ("everyone says it: I hope there is no proof [in the exam]"). Sharing the same problems with proof, the students can exchange experiences. In summary, proof is a case where the lack of autonomy and competence is large and Anna neither has a good coping strategy, nor can construct a different view for herself. Consequently, she avoids proof whenever possible. Obviously, she has no interest in proving.

CONCLUSION

In this paper, we present an approach to investigate interest in Higher Mathematics (HM) using the interest theory by Krapp and Self Determination Theory (SDT). To this purpose we distinguish different objects of interest, namely School Mathematics (SM), Higher Mathematics (HM) and studying mathematics. Relating this approach to the work of (Daskalogianni & Simpson, 2002) revealed a new perspective of interest genesis at university. We then used empirical data to check plausibility of this new perspective. In a group discussion we could see that the participating students had different views on SM and HM and a problematic competence and autonomy experience. For an application of SDT we invited one student (Anna) for an interview to explore her subjective experience, beliefs and goals, and relate it to her articulated interests. Anna couldn't manage to feel competence or autonomy

concerning proof within HM and didn't develop any interest in it. However, she could manage to keep her interest in studying alive by different strategies. Lack of perceived success on her homework assignments was compensated by a private tutor, which also restored autonomy. Lack of success in the exams was explained and excused by external factors. Besides situational interest, we see her individual interest in higher mathematics at the introjection stage, apart from identification with calculating, which form the only point in which she had success and thus feelings of competence.

The theoretical framework helped structuring the reports and identifying aspects which are presumably strongly connected to interest of different kinds. Her expectations and beliefs played a role in how she dealt with the new mathematics and her goal structure can help explaining her behaviour, both forming the basis for competence and autonomy experience. We could then observe that competence and autonomy were generated in different ways, sometimes leaving the promising ways behind. The conclusions are drawn from very few data, including problems of reliability of self-reports. Anyway, we believe our approach to be helpful to structure relevant aspects of interest development. It offered an explanation of contradictory interests in studying mathematics with respect to HM. In the on-going project, we want to apply the framework to a broader sample of first year students.

SHIFTS IN LANGUAGE, CULTURE AND PARADIGM: THE SUPERVISION AND TEACHING OF GRADUATE STUDENTS IN MATHEMATICS EDUCATION

Elena Nardi

University of East Anglia

A common case of a Masters or a doctoral student in mathematics education is that of a student doing so in a language other than their first, from a non-Western background and in a discipline other than that of their undergraduate studies. This student often needs a broadened understanding on how to read, converse, write and conduct research in largely unfamiliar ways. The intervention into the practices of post-graduate teaching and supervision that I describe here aims at fostering this broadened understanding and thus facilitating students' participation in the practices of the mathematics education research community. Here I exemplify the intervention through a brief discussion of an activity series designed to facilitate incoming students' engagement with the mathematics education research literature.

INTRODUCTION

In today's global and highly mobile educational community students arrive at their graduate studies often from different linguistic, cultural, pedagogical and scientific backgrounds. The case of an international student who embarks on study for a Masters or a doctorate in a language other than their first, from a non-Western background and in a discipline other than that of their undergraduate studies is quite common. This student needs a broadened understanding on how to read, converse, write and conduct research in academic environments that are unfamiliar in many ways.

The educational research literature has described this unfamiliarity as a key aspect of the post-graduate student learning experience; and the overcoming of this unfamiliarity as a key issue that the teaching and supervision of post-graduate students needs to address. The intervention into the teaching and learning practices of post-graduate teaching and supervision that I describe in this paper aims exactly at that: to facilitate students' gaining of aforementioned broadened understanding and thus facilitate their transition to post-graduate studies. In doing so I take cue from research in this area – some of which I summarise later in the paper – that calls for a reconceptualization of the Higher Education curriculum, pedagogy and assessment on this matter, and focus this small-scale trial, itself part of a plan for a larger study, on aspects of pedagogy.

Mathematics education, the discipline of my immediate expertise and the discipline within which the activity sets of the trial will be carried out, is a suitable Example Case discipline: mathematics education postgraduate students, especially those engaged in university-level mathematics education research, are likely to come from a background in mathematics. The shift from a Science to a Social Sciences milieu for these students is typically a very pronounced part of their transitional experience.

THE TRANSITION TO GRADUATE STUDIES: AIMS AND PRINCIPLES

Research into the challenges of the transition from undergraduate to postgraduate studies has been growing rapidly in recent years, often in connection with the move ‘from elite to mass higher education’ (Sharpham, 1993) or the ‘widening participation’ agenda that has been driving developments within Higher Education (HE) in several countries (e.g. <http://www.hefce.ac.uk/whatwedo/wp/> in the UK).

Often this research includes direct, self-reporting studies of students’ perceived needs and perceptions of effective supervisory practices (e.g. Egan, Stockley, Brouwer, Tripp and Stechyson, 2009; Pyhalto, Stubb and Lonka, 2009). Alongside a plethora of supervisory practice guides, much of this research tends to focus on generic issues. These include: interpersonal aspects of the relationship between supervisor and supervisee, accessibility and availability of the supervisor, academic compatibility, time management and expectations, etc. (e.g. Krauss and Ismail, 2010).

Findings concerning generic issues such as that ‘especially international students and those in soft¹ disciplines, require a personal and holistic style of supervision’ (Egan et al, 2009, p.337) are of utmost significance. However of at least equal gravity is the focus on practices that aim to foster skills and attitudes in postgraduate students which are *epistemologically* specific, namely specific to the discipline – in our case: mathematics education – they are coming into (Boaler, Ball and Even 2003). Attention on these is also part of a longer-term perspective on post-graduate studies as a stepping stone to a career in research (e.g. Shacham and Od-Cohen, 2009).

The project I describe in this paper aims to make a contribution in these respects (epistemologically specific, long-term) and builds on a relatively small body of work in this area – aptly summarised in (Boaler et al., 2003) and evident in several chapters in (Sierpiska and Kilpatrick, 1998; most explicitly in the chapter by Gione, p. 117 - 127). In what follows I outline the theoretical foundations on which the project is built.

Engaged pedagogy. As Pyhalto et al. (2009) identified there is ‘an urgent need for more effective means of fostering PhD students’ experience of active agency within scholarly communities’ (p221). Much in the spirit of Gunzenhauser and Gerstl-Pepin (2006), the teaching and supervision practices trialled in this project reflect the prioritising of ‘an engaged pedagogy, which represents a shift in emphasis from instrumental training in research methods to an approach in which students develop appreciation for complex possibilities’ (p.319).

¹ The authors include in this term the social sciences, of which mathematics education is widely perceived to be one. I acknowledge that this assumption is not universal; in fact it is a culturally dependent assumption. For example, in continental Europe, chairs in didactics of mathematics are usually located in science faculties, often alongside those in applied or pure mathematics. However, regardless of whether mathematics education research is carried out by researchers whose affiliation is in a mathematics, education or another department, the epistemological differences between the two fields are profound. For extended accounts of these see, for example, (Sierpiska and Kilpatrick, 1998, Part VI, p. 445-548) and (Nardi, 2008, Chapter 8, p. 257-292).

Cultural sensitivity. Particularly for those whose background was shaped away from where much of the educational research dominating the publication venues was conducted in (e.g. graduate students of non-Western backgrounds), they, ‘valued as knowing subjects, may enrich their investigations of educational problems and questions with epistemologies and theoretical perspectives that value their individual identities’ (p.319) and inform their emergent research plans. Away from a ‘dominant discourse’ that ‘appears to centre on what universities do to fit international students into their existing cultures’ (Turner and Robson, 2008, p. 70), the project I describe in this paper aims to contribute to what the 2007 UK Higher Education Academy Report (Caruana and Spurling, p. 64) outlines as a much needed shift from merely ‘awareness of difference’ to ‘valuing difference’ and integrating this valuing into pedagogical practice in substantive ways – in other words the shift from ‘symbolic’ to ‘transformative’ internationalization (ibid. p. 126).

Independence, creativity and critical thinking. These are often described (e.g. Adler and Adler, 2005) as marks of the emerging membership to the scholarly community: decisions on what to focus on, the move from appropriating to creating knowledge, the growth of an epistemological perspective (for Adler and Adler’s sociology students the ‘sociological eye’, p. 11); the flexibility of moving between immersion into the specificity of one’s own research to contributing to abstract theory; and so many other features of what Baker and Pifer (2011) call ‘transition to independence’ (p. 5).

So far I have set out the foundations of the project as being built around the principles of: engaged pedagogy and participation; cultural sensitivity; and, independence, creativity and critical thinking. The spirit of the intervention is captured well by DeVita and Case (2003, p. 393) who outline the role of the HE teacher as ‘helping students construct understandings that are progressively more mature and critical’. They thus propose ‘the pursuit of didactic strategies aimed at facilitating processes of self-enquiry, critical reflection, mutual dialogue and questioning’ that lead ‘to a more participative and student-centred approach’ in which students interact ‘with the content and with each other’ and are thus ‘exposed to multiple perspectives and foster cultural understanding’.

Within mathematics education, working towards membership of the scholarly community often implies a rethinking of epistemological beliefs – as evident in the experiences of mathematics educators and university mathematicians engaging with collaborative research (see, for example, (Nardi, 2008, p. 257-292), including a review of literature on this matter). This is even more acutely true for those who arrive in mathematics education postgraduate study from a purely mathematical background. In a nutshell, the area where a shift of epistemological belief often emerges as necessary is towards what has been called in the literature (e.g. Boaler et al., ibid., particularly p. 497-516) a less absolutist, more contextually bound, more relativist and multiplist perspective on what constitutes knowledge (in mathematics education) and how it is constructed and shared.

METHODS AND SAMPLE OF PROJECT ACTIVITY

The intervention in the teaching and supervisory practices I describe in this paper is designed, implemented and evaluated, in collaboration with post-graduate students in my institution. I do so in consultation with the relevant literature and through drawing on personal and professional experience that I have accumulated over 20 years of my own post-graduate studies and post-graduate supervision and teaching.

Key to this intervention is also my on-going work with colleagues from my institution, whose own background (mathematics, international), similarly to mine, is a valuable resource to this initiative. Involving colleagues is crucial also in that the ways in which supervisors work with students is naturally filtered through their own interpretations of these activities – and, of how these activities can be tailored to address their students’ specific needs. At the moment – for example, in the instances exemplified in this paper – the involvement of other supervisors is informal but a more systematic participation is envisaged for the larger study.

Furthermore, since the inception of the Research in Mathematics Education Group at UEA in 2003, the post-graduate student cohorts (on the Masters and doctoral programmes) have been steadily informing the formation of the practices and activities trialled in this project and exemplified in this paper. For example, of the 13 completed/current doctoral students of the Group, five come from a mathematics background (hold undergraduate degrees in mathematics) and 9 are non-UK students (EU: 2; non-EU: 7).

The intervention has been designed in the spirit of developmental research (e.g. Sierpiska and Kilpatrick, *ibid.*, chapter by Gravemeijer: p. 277-295). Sets of activities are trialled in the course of the current academic year’s post-graduate teaching and supervision. These aim to address key issues of the transition to post-graduate studies that I have observed as seminal over several years of experience. Realistically this small-scale intervention can only address some of these key issues. In subsequent phases of the project the list of issues to be addressed will be fine-tuned with further reading of the relevant literature and interviews with colleagues of analogous experience. I aim to carry out interviews with six HE teachers with substantial experience in post-graduate teaching and supervision (at UEA and elsewhere).

The activity sets address issues germane to the following three areas:

- *Engaging with Research Literature*
- *Forming the Conceptual/Theoretical Framework of a Research Project*
- *Choosing and Applying Data Analysis Methods.*

Data collected during the implementation and evaluation of the activities aim to:

- Describe and analyse the students’ participation in the activities.
- Explore how subsequent versions of the activities can be amended to address students’ needs more precisely and effectively.

The activity sets are trialled and evaluated with new cohorts of Masters and doctoral level students. These activities are fine-tuned versions of activities I already deploy – see example in Fig.1. I note that the treatment of issues germane to the clearly different needs of different groups of students (Masters and doctoral; British and international; mathematics and other backgrounds; with varying teaching or other professional experience) cannot be conflated into one single investigation. However, the profile of most participating students is such that a concurrent consideration of issues is often necessary, even potent. Any consideration of student data is alert to this variation of student profile and this variation of issues.

I trial these sets of activities during sessions of group and individual tutorials. In subsequent phases of the project the execution of the activities will be reported in field-notes produced by a collaborating doctoral student (not participating in the observed session) or me (drafted during the session and finalised immediately after).

Evaluation of the trialled activities takes place through evaluative questionnaires and interviews. The number of students who participate in the trials in 2012-13 is 6 (at either Masters or doctoral level). This participation is subsumed in the normal provision to the students. However, their written consent was obtained for using observations from the sessions, responses to the questionnaires and audio-recordings focused group discussions of their experiences of the intervention. Their participation in the evaluation phase was on a volunteering basis. Anonymity has been kept throughout, e.g. through the option to submit anonymised questionnaire responses and confidentiality secured through using pseudonyms in any quotations from the data.

An Example Activity: *Engaging with Mathematics Education Research Literature*

A post-graduate international student in mathematics education – or a student with a background in the *sciences* who arrives in the UK in order to complete post-graduate studies in the *social sciences* – is tasked with formidable challenges. Apart from carrying out their studies in a different language and learning the terminology of the field they are entering, this student faces novelty on several grounds. They would be required, for instance, to read the social sciences research literature that: is often *lengthier* than the research literature in the sciences; often uses a breadth of related, subtly *different but not equivalent terms* to describe similar phenomena; and, is typically rather more *open to multiple interpretations* than the bulk of scientific texts they are accustomed to.

This student is expected to identify, read, reflect upon, converse and write about this literature, often in a matter of months. In Figure 1 I sample some activities that I currently invite my Masters and doctoral students to participate in during the early months of their arrival. I then outline the empirical origins and rationale for each activity – in resonance with the observations on the type and scope of reading and writing that Boaler et al (ibid, particularly those on p.497-499 and p.512-513) highlight as pertinent in the transition to post-graduate studies in mathematics education.

The activities aim to facilitate incoming post-graduate mathematics education students' *Engaging with Research Literature* particularly in relation to:

- Searching: identifying relevant research literature
- Reading: critical reading of research literature
- Writing: reviewing research literature
- Conversing: presenting and discussing research literature

Of importance in the **outline of activities** below is to encourage students to draw upon the knowledge and experience they acquired in their own educational and cultural background and relate those to the reading of the novel research literature.

1. In an early session, students engage in a **discussion of various types of publications** (such as books, journal papers, reports, policy documents) and of their **status in research writing**. A significant part of this discussion is on the ways in which literature from the students' own educational and cultural context (often not published in English) relates to the (often English-dominated) literature that they are expected to engage with.
2. In the sessions that follow, the students are asked to prepare as follows:
 - a) **Read** pre-specified texts, typically book chapters or journal papers.
 - b) Produce/identify a piece of **writing** that illustrates how they relate their reading for the session with what they have read or experienced before. This can be a publication from their own cultural and educational context, or a short account of a mathematics teaching or learning experience that relates to the theme of the session.

This is their *Short Contribution I*.

- c) **Identify a journal paper** that matches the theme of the session from a particular journal, typically a leading journal in the field (such as *Educational Studies in Mathematics*).
- d) Write a short account of their chosen paper that provides
 - a summary of the paper,
 - their views on the paper, and,
 - how (if at all) the paper relates to their own research interests and plans.

This is their *Short Contribution II*.

3. In ensuing weeks the **range of sources** that the students are asked to draw on **broadens** (from one to several pre-specified journals, then non-pre-specified)
4. **Brief presentations of Short Contributions I and II** occur during the session.
5. Brief presentations are accompanied by **discussion** with the group.

Fig.1 **Example Activity Series on *Engaging with Research Literature***

Justifying Activities 1-5: *Empirical origins and rationale*

1. Discussion of *types of publications and their status in research writing.*

The early sessions of the MA in Mathematics Education are partly dedicated to what we call *The world of mathematics education research*. In these, types of mathematics education publications are discussed in terms of intended readership and distinguished as *academic* (e.g. a paper in *Educational Studies in Mathematics*; a peer-reviewed, research-based monograph/edited book/book chapter; a *PME Research Report* etc.), *professional* (e.g. a paper in *Mathematics Teaching*, the official journal of UK's ATM, Association of Teachers of Mathematics) and *policy related* (e.g. a government-commissioned report such as the UK's *Smith Report* on post-14 mathematics of 2004). Students are encouraged to consider this distinction in terms of types of publication they are familiar with. Mathematics graduates appear to be more familiar with undergraduate mathematics textbooks and, to some extent, with publications in mathematics journals. Many overseas students typically put forward influential governmental reports as examples of what they perceive a publication in mathematics education to be. All along, the students are asked to offer counterpart information about analogous or equivalent activity from within their own backgrounds.

The discussion is interspersed with sharing information about key conferences and symposia in mathematics education, national and international, and a brief historical account all the way back to 1908 and the establishment of ICMI. Through this discussion the students are invited to perceive the launch of their mathematics education post-graduate studies as inauguration into the scholarly community of mathematics education. I note that these sessions are also attended by incoming doctoral students who are expected to already hold a Masters qualification in (Mathematics) Education. The experience of these students, typically small but non-negligible, operates as a helpful bridge in these early discussions.

2. Reading pre-specified text and identify two related texts (insider, outsider)

As we launch into the thematic sessions of the MA programme, preparation for each session tends to be highly regimented (2a) but in tandem with the expectations that:

- the reading is embedded into own prior readings and experiences (2b, 'insider');
- the reading will be enriched with further readings (2c, 'outsider'); and,
- a rationale will be put forward for the choice of this further reading (2d).

(2b) and (2d) require of students to produce a small piece of writing for each session. Intertwined with the students' inauguration into the world of mathematics education research, these exercises aim to foster the perception that writing is paramount; and, acquiring the skill to write with the rigour and sophistication expected at this level is feasible through constant and regular practice. This applies equally to the mathematics graduates on the course (who may not have written in this 'genre' for a long time, if at all) and the non-UK students (who are writing in a language other than their own).

An example

The module *Introduction to Research in Mathematics Education*, attended by MA in Mathematics Education students as well as Year 1 doctoral students includes five sessions on key theoretical constructs used in mathematics education research. Two sessions are on developmental / cognitive approaches; and, three are on sociocultural, discursive and anthropological approaches). In the first of the sessions dedicated to developmental / cognitive approaches in (2a) the students were expected to read two seminal papers: Richard Skemp's 1976 *Mathematics Teaching* article on *Instrumental and Relational Understanding* and David Tall and Shlomo Vinner's 1981 *ESM* paper on *Concept image - Concept definition*. In (2b) one student, a recent mathematics graduate (international, non-EU) wrote a short account in which she recollected her first encounter with the concept of limit. As part of (2c) she brought along a *PME Research Report* on a study that used the *Concept-image, concept definition* construct to explore students' understanding of limits in a university of her country. And, in (2d) she commented on the use of the construct in her paper of choice and related this to her own emerging research plans for her dissertation.

Within (2a) the students are asked to read two texts (Skemp's, Tall and Vinner's) that appeared at a time when mathematics education was at a turning point of its growth into an academic discipline – research was largely influenced by educational and cognitive psychology and PME was being founded. Within (2c) the students are asked to identify research texts, from that era or thereafter, that report research which deploys these theoretical constructs. They are thus encouraged to find out the *scope* and *impact* of these works in the field.

3. Broadening the range of sources

As the thematic sessions of the MA programme continue to unfold, the instructions for preparing for (2b) and (2d) gradually broaden and relax. In order to facilitate, and accelerate, the students' familiarisation with key publication venues in the field, initially they are asked to prepare for (2d)

- through searching for journal papers in *Educational Studies in Mathematics*;
- then, in a few more journals (*Journal for Research in Mathematics Education*, *Journal of Mathematical Behaviour*, *For the Learning of Mathematics*);
- then, a list of about ten international, peer-reviewed journals held in the UEA library. By the end of the module the list has opened up to include practically most peer-reviewed published work in mathematics education research.

The rationale for the **presentations within (4)** (for non-UK students it is perfectly acceptable that, at least to start with, this can consist of *reading out* to the group their *Short Contributions*) and the **discussion within (5)** is analogous. These activities aim to foster an understanding of how paramount these ways of engagement are and how regular participation in these practices can facilitate the acquisition of presentation and discussion skills.

A CASE OF EXPERIENCING ACTIVITY SET 1-5: SOPHIA

Sophia is a 2012 mathematics graduate, international student (EU) and a non-native speaker of English. Throughout the Masters module in question (see *Example* above) her participation was positive and enthusiastic and this is reflected in her written evaluation of the experience of Activity Set 1-5. Sophia comments on the gradation **of difficulty of the tasks** within the Set and acknowledges some **value in this gradation** ('the tasks gradually became more difficult, but we also became more familiar with the way of working on them...'). She recognizes that 'the freedom to choose a paper (more practical or looking at different aspects of the focus of the lecture) made the topic more clear'. Adding to this **clarity** was the **supplementary role of her peers' more substantial teaching experience**: '... we could see the views or the thoughts that the other classmates had regarding the topic and the practice of those theories, as they were more experienced teachers and had different background from me...'. Finally she encapsulates how the **network of reading, writing, presenting and discussing tasks assisted her gradual adoption of skills and practices** that are bound to be crucial in subsequent parts of her studies:

'...coming from an environment where I didn't have to present anything in oral form, it was difficult for me to present a paper, even to express my thoughts on the readings, but with the way the tasks were designed, starting with reading something we wrote about the paper, and then slowly talking more about it in the group, and finally doing a presentations, made it easier'.

PROJECT PROSPECTS AND FURTHER WORK

As research in this area suggests (e.g. Pole, 1997; Boaler et al., *ibid*; Gione, *ibid*), there are issues in the training of graduate student supervisors and teachers that call for systematic investigation – what Boaler et al. identify as the search for an appropriate 'research curriculum' (p.518). As the bulk of my supervisory and teaching experience is in the discipline of research in mathematics education, this is the Example Case discipline of the intervention. I note however that the experiences and needs of students in this area are not untypical or substantially different to those of students in other areas, particularly those in transition from a science to a social sciences paradigm. I therefore see the potential of the project as transcending the disciplinary boundaries of mathematics education. I see this small-scale intervention as a precursor to a larger, longitudinal study that will include other institutions, involve a larger number of colleagues and extend the scope and range of the activity sets. The larger study will also allow the trial of the activities in several modification-and-improvement cycles.

ACKNOWLEDGEMENT

I extend my warmest thanks to Sarah Dufour (University of Montreal, Canada) for her invaluable assistance during her apprenticeship visit to the RME Group in 2011-12.

TRANSFORMATION OF STUDENTS' DISCOURSE ON THE THRESHOLD CONCEPT OF FUNCTION

Kerstin Pettersson, Erika Stadler and Torbjörn Tambour

Stockholm University

In this study of university students' discourse on the threshold concept of function, the aim was to examine what kind of changes of their mathematical discourse could be observed during a study year. Data was collected through interviews, questionnaires and observations during the students' first year of mathematics courses and was analyzed using the commognitive framework of Sfard. The result shows substantial differences in the students' discourse. The transformation of their discourse resulted in broader registers of words, mediators, narratives and routines. Students not transforming their discourse showed an unbalanced use of visual mediators and fewer connections between the interrelated features of the discourse.

THE THRESHOLD CONCEPT OF FUNCTION

For students who have recently entered university studies in mathematics the development of their mathematical conceptions seem to be a crucial issue (Thomas et al., 2012). Over the years, the meaning of mathematical understanding has shifted from focusing individual cognitive aspects to socio-cultural and situated perspective where the learning context and discursive elements are focused. Being aware of that the students do learn mathematics in a social setting, we have chosen to bring back focus on the relation between individual students and their understanding of mathematical concepts. More specifically, we are interested in novice university students' understanding of the mathematical concept of function. Limited understanding of the function concept has been shown to have an effect on the transition from secondary level to university (Thomas et al., 2012). Moreover, functions are used in all branches of mathematics and it is a concept that students encounter early during their school time. The first encounter with functions can be on a very informal and intuitive way but rather soon the students may work with functions as algebraic expressions and graphical representations. In university mathematics, students encounter a more formal definition. What distinguishes functions from other relations is that y in $y = f(x)$ is uniquely determined by x . The increasing abstraction and generality of functions may be one reason for that students' learning of the concept of function is troublesome (e.g. Artigue, Batanero, & Kent, 2007).

The notion *threshold concept* was introduced by Meyer and Land (2005) for initially troublesome concepts for which students' development of understanding of the concept involves a potential to transform the understanding not only of the concept, but also the understanding of the subject area where the concept is included. A threshold concept can be seen as a portal to a new and previously unreachable understanding. Meyer and Land characterized threshold concepts as initially troublesome, transformative, integrative and irreversible. To come to understand a

threshold concept is troublesome for the students, it is a threshold to cross over, but then their understanding gets transformed. Understanding a threshold concept will bring a significant shift in students' perception of the subject. The transformation may be sudden but it often occurs over a long period. Integrating prior understandings is part of the transformation and the understanding is irreversible; when it has been transformed to a new one, it will not be forgotten or unlearned without a big effort. There are several threshold concepts in mathematics e.g. limit, function, derivative and integral (Pettersson, 2011). However, studies of threshold concepts in mathematics are rare and there is also a need for more general discussions about the transformation process of students' understanding of threshold concepts (Scheja & Pettersson, 2010). In this paper we focus the threshold concept of function and the transformation of students' discourse on this concept.

THE COMMUNICATIVE PERSPECTIVE

The notion of threshold concepts provides a theoretical perspective on the character of students' learning of specific mathematical concepts that play a particularly important role for students' access to university mathematics (Pettersson, 2011). However, to study students' development of their understanding of threshold concepts, we also need a theoretical framework that focuses students' learning of mathematics from a more general point of view. Threshold concepts are often presented by mathematicians or in the literature with a significantly different discourse than that of the students. Thus, to study students' learning of threshold concepts in terms of discursive development is relevant; and we have chosen to use Sfard's commognitive perspective to analyse the students' development of their understanding of functions. That means, we define learners' development of understanding as development of their discourse, and to study this we look for transformations of the students' discourses. In our analysis, we will focus on the characteristics that make a mathematical discourse distinct from other kinds of discourses; *mathematical words*, *visual mediators*, *narratives and routines* (Sfard, 2007). According to Sfard discursive development of individuals can be studied by "identifying transformations in each of the four discursive characteristics" (p. 575).

A mathematical discourse implies the use of *mathematical words*. There are many words that students almost only meet in a mathematical classroom context, but there are also colloquial words that get another meaning when used in a mathematical discourse. The concept of function is in itself a mathematical word and the very core of the notion of threshold concepts is that the meaning of the mathematical word function dramatically changes when a student crosses the threshold. *Visual mediators*, such as symbolic artefacts and manipulatives, can be used as a cursor on the objects of communication. Graphs are used as visual mediators for functions and can be used to show features and behaviours of different functions. The crossing of a threshold may be recognized by identifying new ways of using visual mediators that are related to functions. *Narratives* are descriptions or accounts of objects. It is any written or spoken text that is used within the discourse and can be subject to

endorsement, i.e. narratives can be judged as true or false. In the interviews, the students make use of narratives to describe their conceptions of the function concept. *Routines* refer to repetitive patterns for actions and serve as important tools for the interlocutors to participate in any kind of mathematical discourse. Routines can be due to properties of mathematical objects. Concerning functions, a familiar routine from secondary level is to examine functions with tables of values and graphs.

We will use these four characteristics to analyse university students' gradual development of their mathematical discourse about mathematical functions. The research question is: What kind of changes of the students' mathematical discourse could be observed during the transformation of their understanding of the threshold concept of function?

METHOD

To capture the process of transformation of students' understanding of a threshold concept, a process that mostly is a development over a long period (Meyer & Land, 2005); the students have been observed during a study year. The students were student teachers at a Swedish university participating in mathematics courses. In total the study included 18 students, all the students that participated in the courses for prospective mathematics teachers in their second semester. These students also included a few students taking the courses a second time and one in-service teacher expanding her mathematical competence. In an earlier paper results connected to one student were reported (Pettersson, 2012). In the present paper four students, A, B, C and D, are presented. These four were chosen since they have participated in nearly all of the data collection occasions (only interview 3 is missing for C and interview 4 for A) and in that way have given a rich dataset. B and D were first year student teachers, A was an in-service teacher and C was taking the courses a second time. The four students participated in the same courses with the same lecturers.

During the first semester of their studies the students enrolled courses in general education and an introductory course in mathematics. The second semester the students participated in the courses 'Vectors and functions', 'History of mathematics', 'Geometry and combinatorics' and 'Calculus'. Data were collected through observations of lectures and tutorials in the two courses where functions are part of the syllabus. To get more specific data on the individual students' use of words, visual mediators, narratives and routines individual questionnaires and interviews were carried out. On three occasions questionnaires were distributed to the students in the tutorials. The two first questionnaires asked the students to explain what a function is and the third asked if given graphs (e.g. $y = 1/x$, the line $x = 2$, a discrete function) and algebraic expressions (e.g. $f(x) = x^2$ for $x \geq 0$; x for $x < 0$) represent functions. Individual interviews were conducted on four occasions with students who volunteered for interviews. The first three interviews used the student's answers in the questionnaire as a starting point. The fourth interview was conducted at the end of the next semester, five months after the third interview. During that semester the students were enrolled on courses in mathematics education, in

probability and statistics, and general teacher education courses. The interviews were semi-structured and the duration was about 30 minutes. They were conducted on a time chosen by the student, audio recorded and later transcribed in full. All students were informed about the research and participated voluntarily. None of the authors were involved in the teaching or examinations. The students were informed that the data would not be presented to course leaders and examiners in a manner that would reveal individual identities.

In the pre-calculus course ‘Vectors and functions’ polynomial and exponential functions were presented. At the end of the course there was a discussion about the definition of function. The definition given in the compendium reads as follows: “A function is a mapping that for all numbers x in a specified set maps the number to another number which is called the value of x for the function and is noted $f(x)$ ” (authors’ translation). In a lecture the students worked with an exercise, meant to practice reading of mathematical texts, where a more abstract definition of a function was given: “A function is a subset of the Cartesian product in which all elements x in the domain occur in exactly one pair (x, y) ” (authors’ translation). In the lecture this definition was discussed and the lecturer gave an example of a function with a domain consisting of five students and a codomain consisting of marks (A-F). The function was represented by the graph where marks are ordered to each of the students. The lecturer also pointed out that no rule or arithmetic formula was included in that example. In the course ‘Calculus’ a definition was given in the beginning of the book used: “A function is today understood as a rule or a process that in a well-defined and unique way remake (transform) some specified objects to new objects” (authors’ translation). However, there was no discussion about the definition of the function concept in the lectures or tutorials. An interpretation of the absence of a formal definition and a discussion may be that this was expected as already known by the students. During the course, the derivative was used to analyse functions with respect to extreme values. These analyses together with studies of asymptotes were used to draw graphs.

The qualitative analysis of the questionnaires, interview transcripts and observation notes was focused on the students’ ways of talking about their understanding of function. As mentioned above, according to Sfard (2007), the use of mathematical words, visual mediators, narratives and routines are characteristics of a mathematical discourse. To identify the transformation of the students’ mathematical discourse, we read and re-read the data searching for instances where changes in the discourse regarding these characteristics could be recognized and made records on the development of each student’s discourse on the concept of function.

RESULTS

The presentation of the results gives for each of the four students a review of the transforming of their discourse during the year.

Student A

Student A is a woman, about 35 years old. She is an in-service teacher studying math to get certified also as a mathematics teacher in secondary school. There was no fourth interview; at that time she was back to her work as a teacher. Student A used *mathematical words* already in the beginning of the semester. Her vocabulary was expanded during the semester and included correctly used formal words. In the first questionnaire she wrote that a function is “e.g. a variable a that depends on b ” and gave an example: “The prize of a taxi journey depends on how far (s) I go and how long time (t) it takes, $p=as+bt$ ”. We can notice the mathematical words ‘variable’ and ‘depend’ in her description of a function. As could be seen in the narratives below, during the semester she successively included more mathematical words.

She used formulas and graphs as *visual mediators*. The mediators seemed not to be crucial for her understanding, but are used in a convenient way. In the example above she used the formula for the prize as a visual mediator. In the second interview she spontaneously drew a graph with discrete domain, showing that she was comfortable with using graphs as illustrations. The *narratives* used in the beginning of the semester included everyday examples, such as presented above, but develop during the semester to formal expressions. In the middle of the semester she wrote in the questionnaire that for a function the key idea is “for every x there is a value y ”. She pointed out that the pairs (x, y) do not need to be connected and we can notice that the narrative at this time was more formal and included mathematical expressions such as ‘for every’. In the interview she said that she did not remember the definition but “it was something with exactly one.” During the semester the narratives she used changed from describing function as a rule to function as pairs. She told that her encounter with the abstract definition was important for this change. She talked about the change from functions as rules to accepting collections of points as functions, as an extension of her previous understanding. She used a narrative that is a reflection of the more abstract definition in the exercise earlier mentioned:

Then I thought like that you have one rule that somehow determines what is going to happen, that was my relation, and now it feels like, no, there doesn't have to be any relation at all, we just have to say that they come in pairs.

During the semester student A developed a *routine* for deciding if a graph or a formula represents a function or not. In the third questionnaire she answered correctly on which of the graphs and algebraic formulas that are functions. In the interview she gave a definition of function: “For every value x there is a value y , or in other words, one value x can only give one value y , if you put in one x you will get one y , you can't put in one x and get two y ”. She said she used this as a routine to decide if the curves are functions. She also repeated what she said in the second interview, it does not need to be a rule; if one x gives one y then it is a function.

Summing up the transformation of the discourse of student A we can notice that she from the beginning included several mathematical words and that the vocabulary was

extended during the semester. She used visual mediators in a convenient way. The narratives she used changed to more formal ones and she also developed a routine for deciding if a graph or a formula is a function or not.

Student B

Student B is a man, about 25 years old. Looking on the development of his discourse it could be said that he still, nine months after the first interview, was talking about functions nearly in the same way. During the whole study year he mainly used colloquial discourse and he included just a few *mathematical words*. In the first interview he, like student A, gave everyday examples as the prize of a taxi journey, but unlike her, student B did not use mathematical words in the examples. In the middle of the semester he used some mathematical words like ‘variable’ in his explanation of what a function is. At the end of the study year he said that a function is “like a connection, it is something that gives something, and maybe you could draw it graphically”, an example showing the absence of mathematical words.

Visual mediators, formulas and especially graphs, were important for student B all along the study year. In the first interview, he talked a lot about graphs and their interpretations. In the middle of the semester he said that he still mentally remains in the upper secondary school where, as he interpreted it, functions are regarded as graphs. In the end of the semester he talked about algebraic representations but still he also connected functions to graphs: “You feel a bit unsure, but if you can show something graphically then you feel that it is a function”. During the study year, the *narratives* did not include formal definitions. In the first questionnaire student B wrote that “from given data [a function] describe[s] a course of events depending on different factors”. In the middle of the semester traces from the more abstract definition, given in the exercise mentioned above, could be recognized but the content in that definition was not involved in the narratives. At that time he wrote:

I regard functions as a relation of dependence where e.g. y depends on x . This can be shown graphically, but not necessarily. A function can express and maybe predict processes from given data.

In the narratives given at the end of the semester we once again found a trace of the more abstract definition, but still it was not made clear and established. Student B referred to the lecturer: “He said that even if you just have dots it could be a function”. A semester later, in the fourth interview, student B still could not give any formal definition.

Student B did not use any *routine* for deciding if a curve is a function. In the third questionnaire he answered wrongly that all the graphs were functions. He said in the interview that he did not have any routine for checking if a graph represented a function or not. He had not recognized, or could not make use of, that to each x there needs to be exactly one y . However, during the study year he developed routines for algebraic manipulations; he talked about routines of algebraic manipulations to get the possibility to “see it in the formula”.

The development of the discourse of student B included just a small expansion of use of mathematical words. Visual mediators were used frequently in the discourse during the whole study year. The narratives started with everyday examples, slightly changed but never included formal definitions. He developed routines for algebraic manipulations but did not use any routine for deciding if a graph or an algebraic formula represents a function or not.

Student C

Student C is a woman, about 30 years old. She was taking the courses this semester a second time because she did not pass the first time. In the beginning of the semester she was really happy about participating in the course with this, from her point of view, good lecturer. She did not take part in the third interview. At that time, in the end of the semester, she was really upset and frustrated. She had not passed the examinations and felt that the teachers did not help her. She said that she did not manage to talk about mathematics at all. However, five months later, at the end of the next semester, she by herself said that she wanted to take part in an interview. The passing of some examinations had given her strong self-confidence.

In the beginning of the year student C mostly used a colloquial discourse and she just included some simple *mathematical words*. The vocabulary slightly expanded during the year but mathematical words were partly used in a wrong way. *Visual mediators* were frequently used by her from the start. In the first interview the notion $f(x)$ was what she first mentioned when asked about functions. She also talked several times about the system of co-ordinates and curves, but she did not use the word graph. In the middle of the semester she did not mention curves or system of co-ordinates; neither did she use the notion $f(x)$. It seemed as if she had lost the connection to visual mediators without coming to a good use of mathematical words and more formal narratives. However, at the end of the study year she again frequently used visual mediators. In the last interview, as in the first, she talked about the notion $f(x)$, system of co-ordinates and curves, but at this time she also used the word graph.

The *narratives* were mostly connected to visual mediators and no formal definition was given. In the first questionnaire she wrote:

A function describes a relationship between axes in a coordinate system and a line or a curve in the same co-ordinate system.

In the first interview she also talked about a function as a ratio between x and y . In the second questionnaire she wrote: “A function is an expression for conditions between values.” In the subsequent interview she could not mention any definition of function but remembered from the lecture: “...well, he said a very good definition a couple of lessons ago but I haven’t learnt it by heart so.” This is the only instance where a trace of the more abstract definition, given in the exercise mentioned above, could be found in her utterances. At the end of the study year she said that she now had matured in her understanding of mathematics and no longer was afraid of functions. But still she could not give any definition. She said that she did not grasp the key

aspect. She never got any *routine* for checking if a curve represents a function or not. From the third questionnaire we can conclude that she, at this time, had not recognized that for an application to be a function it is necessary that for each x there is exactly one y . She answered wrongly that $x = 2$ is a function and did not give any answer on discontinuous graphs. The justifications given were in a colloquial discourse and some of them incorrect.

Summing up the development of discourse during the study year we notice that student C slightly expanded her vocabulary. She frequently used visual mediators in the beginning and at the end of the year. The narratives started in everyday examples and never developed to formal ones. She did not develop any routine to decide if a graph or an algebraic expression represents a function or not.

Student D

Student D is a woman, about 35 years old. Before she started her teacher education she had been working as an economist. In the beginning of the year student D correctly included several *mathematical words* and her vocabulary was expanded during the year. She did not frequently include *visual mediators*, but when used it is in a convenient way. The *narratives* started with everyday examples and function as a rule and ended up with function as pairs without need for a rule. In the first interview she said that a function is a recipe. However, in her narratives she connected functions to everyday examples and did not give any algebraic examples. In the middle of the semester she talked about a new understanding of functions:

...what's new in my understanding of functions is that there doesn't have to be a rule that defines this relationship; sometimes there's just a relationship between two... chosen things.

She continued with a reference to the lecture where she encountered the more abstract definition: "... it could be a bit arbitrary like in the example with the marks". She said this example was an eye opener for her, but also that she still could not use it by herself. "I think I'm still like in between two understandings of this and I suppose I'm trying to find a way to put them together." She also pointed out that the important characteristic of a function is that for every x there is one single y . At the end of the first semester she said that now it is not the functions that are the problem: "...but the functions, I think they've suddenly become, well I don't know, a table, a platform". At the end of the study year she again talked about her encounter with the more abstract definition and how it opened her eyes for a new understanding. Student D got a *routine* for deciding if a graph represents a function or not. In the third questionnaire she answered correctly on all the graphs. She was using a vertical test checking that it was just one y for each x .

The discourse of student D included several mathematical words from the beginning and the vocabulary was extended during the semester. Visual mediators were used in a convenient way. The transformation of the discourse included changing the

narratives to more formal ones and developing a routine for deciding if a graph or a formula represents a function.

CONCLUSIONS AND DISCUSSION

The results show substantial differences in the transformation of the students' mathematical discourses. Student A and D developed their discourse on the threshold concept of function in several crucial ways. They expanded their use of mathematical words. They changed their narratives from everyday examples and function as a rule to function as pairs. The students' encounter with the more abstract definition seemed to be important for the transformation of their discourse. These students also got a routine for deciding if a curve represents a function. They used graphs and formulas in convenient ways and also connected routines and narratives to visual mediators. The other two students, B and C, did not transform their discourse in the same way. Through the whole study year they just used a few mathematical words. They frequently used visual mediators, predominantly curves in co-ordinate systems. The narratives were mainly connected to visual mediators and were given in colloquial vocabulary. No formal definition was included in the narratives and just traces of the more abstract definition could be found. These students did not have any routine for deciding if a curve represents a function or not.

The results show the complexity involved in developing the understanding of the threshold concept of function. For these four students it was important to expand their use of mathematical words. It seemed like the need of precision requires the use of mathematical words. Visual mediators are surely important for students' understandings, but it could be seen from the discursive development of these four students that it was not enough to base the narratives mainly in visual mediators. For two of the students, A and D, the encounter with the more abstract definition seemed to have had an important influence in the development towards a more formal level. When the students' view of a function as a rule developed to a view where functions are recognized as a set of pairs, they understood also discontinuous and discrete functions. It also helped these students to recognize the key idea that for each x there should be exactly one y .

Through this longitudinal study the complexity in coming to understand a threshold concept has been made visible. Since threshold concepts are crucial in students' development of their understanding of mathematics, it is important for university teachers to know how to support this transformation (Meyer & Land, 2005). An early development of solid conceptions may also make the transition from secondary level to university easier for the students (Thomas et al., 2012). The results of the study substantiate the importance of expanding the mathematical vocabulary and developing a balanced use of visual mediators and routines. Changing the discourse to include more formal narratives also supports the transforming of the understanding. Development related to all four features was needed for these four students to cross the threshold. Words, visual mediators, narratives and routines are interrelated features (Sfard, 2007) and the results indicate that students who

developed connections between them transformed their understanding in a crucial way. To raise the level of awareness among university teachers in mathematics, on the impact of discursive development, can be regarded as a didactical implication of our study and a reasonable way to support the transformation of students' understanding of threshold concepts.

VARIABILITY IN UNIVERSITY MATHEMATICS TEACHING: A TALE OF TWO INSTRUCTORS

Alon Pinto

Weizmann Institute of Science, Israel

This paper examines two lessons in an infinitesimal calculus course given by two instructors with different backgrounds and teaching agendas. The lessons were based on the same lesson plan but decisions the instructors made prior to class took the lessons in substantially different directions. Using Schoenfeld's framework for analysing decision-making processes we describe the resources, beliefs, attitudes and goals that guided and restricted the instructors. These findings provide an insight into the different agendas and considerations underlying the instructors' decisions and the subsequent course taken by their lessons. On the basis of this analysis we will reflect on the impact that background, teaching experience and orientations have on university mathematics teaching. This discussion is a contribution to the increased pedagogical awareness in university mathematics teaching.

INTRODUCTION

Students in university math courses are often divided into groups where the same curriculum is taught concurrently by different instructors. This is the case in a calculus course for first year math students at a leading university in Israel. Aside from the lectures, every week the students divide into small groups and attend a teacher assistant's (TA) lesson of their choice. These lessons are supposed to follow a lesson plan written according to the lecturers' needs and consequently the students are told they can attend any TA lesson because all the TAs teach more or less the same lesson. In this study we examine and compare two of these lessons given by two different TAs and based on the same lesson plan. These two lessons showed substantial differences that were in part a result of decisions each TA made while preparing for his lesson. These decisions are based on different interpretations of the lesson plan that led to the forming of different teaching goals and consequently to different adaptations of the lesson plan. The question this paper reflects upon is: *What led each of the TAs to interpret and implement the lesson plan in the way that he did.*

In recent years various members of the research community noted that there is a shortage of empirical research describing and analysing the practice of teaching mathematics at the university level. Speer et al. (2010) note that only little is known about what university math instructors do and think daily, in class and out, as they perform their teaching work. Weber (2004) states that most of the research that does exist in this topic consists of researchers' suggestions for improving pedagogy and that there are relatively few studies on how advanced mathematical courses are actually taught. In their survey, Speer et al. (2010) list (only) five empirical studies that analyze teaching practices at a sufficiently fine level of detail so that other

instructors and researchers can inspect and learn from the instructional choices and reasoning described therein. One of these studies focuses on the beliefs of a novice instructor of college mathematics and their influence on his instructional practices, particularly on his in-the-moment decisions in class (Speer, 2008). In-the-moment decisions of instructors were also the focus of the case studies described in (Hannah, Stewart, & Thomas, 2011) and (Paterson, Thomas, & Taylor, 2011) where Schoenfeld's theory on decision making processes (Schoenfeld, 2011) was used to describe and analyse decision processes that took place during math lectures.

In this study we continue this line of employing Schoenfeld's theory and analysing the resources, orientations and goals (ROG) underlying instructors' decisions. The contribution of this paper is twofold. First, it examines decisions that were made prior to the first TA lessons in the course and that are thus unaffected by many factors which normally influence classroom in-the-moment decisions. Second, we have in front of us decisions made in very similar conditions by two TAs with very different backgrounds: TA1 is a math graduate student with little teaching experience, while TA2 is a very experienced calculus instructor with a PhD in mathematics, who is not engaged in active research. Thus in this paper we do not only describe the effect of the TAs' agendas on their decisions, we also reflect on the impact of the TAs' background and teaching experience on their stated and inferred resources, beliefs, attitudes and teaching goals and consequently on the way their lessons evolved.

Another focus of this paper is the substantial gap between the intended and the implemented curriculums in the TA lessons. While there are many studies about such gaps in the context of primary and secondary math education (e.g. Even & Kvatinsky, 2010), here this phenomenon is examined in the context of university math education.

We shall not discuss here the mathematics that each TA made available to his students, and the impact of the findings of this paper on students' learning. These two important aspects of the TA lessons are the subject of an ongoing follow up study.

THEORETICAL FRAMEWORK

To analyse the decisions made by the TAs we will employ Schoenfeld's theory on in-the-moment decision making processes. Schoenfeld (2011) asserts that what people do is a function of their resources (intellectual, material, and contextual), orientations (their beliefs, values, biases, etc.) and goals (the conscious or unconscious aims they are trying to achieve). According to Schoenfeld these categories are both necessary and sufficient for understanding decision making. Necessary in the sense that if any of these categories is left out of an analysis then the analyst runs the risk of missing a key factor in the decision making process, and sufficient in the sense that every root cause of decision making can be found within these categories. Thus, in order to understand the considerations underlying the TAs' decisions, we should aim to uncover the explicit and implicit orientations and goals that guided each TA as well as the resources they had at their disposal while preparing for class. We retain that the analysis done here does not make use of the full strength of Schoenfeld's theory. The

theory addresses decision making processes and requires attending to the factors that shape the teacher's prioritizing and goal setting when potentially consequential unforeseen events arise. These factors are critical when dealing with in-the-moment decisions. However, the decisions we focus on are made prior to class, and are often planned, conscious and deliberate. We will therefore refer to the ROG categories as a framework that guides us where to look while analysing the TAs' decisions.

RESEARCH CONTEXT AND METHODS

This study focuses on the lessons of two TAs: TA1 is an exceptionally bright math graduate student. He has been teaching TA lessons for 4 years in various math courses and has taught calculus only once, 3 years prior to this study. TA2 has been the head TA of this course for more than a decade and he is a very experienced and a very popular calculus instructor. He has a PhD in mathematics but he has not been engaged in mathematical research for several years. A noteworthy fact is that TA1 is not only inexperienced as a calculus teacher but also as a calculus student since he taught himself calculus prior to his university studies and did not attend first year calculus courses as a student. The two lessons examined here were the first TA lessons in this course and revolved around the definition of the derivative that had been taught earlier in the lectures. The lesson plan for these lessons was prepared by a third TA according to the demands of the lecturers and under the supervision of TA2. The TAs in this course were expected to follow this plan but there was no supervision of its actual implementation during or after the TA lessons.

The author attended the lessons as a non-participant observer, audio recorded them and took notes. After each lesson the TAs reflected on their preparation for class. Each lesson was compared to the lesson plan and an initial analysis of the TAs' ROG was conducted by inferring from the TAs' actions in the classroom. Confirmation and expansion of this analysis was made in final interview with each of the TAs.

AN OVERVIEW OF THE TWO LESSONS

The lesson plan revolved around the following definition: *Suppose f is defined in a neighborhood of some point x_0 . Then we will say that f has a derivative a at x_0 if the limit $\lim_{x \rightarrow x_0} (f(x) - f(x_0)) / (x - x_0) = a$.* The plan had a theoretical part with several observations regarding the definition (e.g. differentiability implies continuity) and a practical part with three exercises, along with concise, formal, algebraic proofs:

- A. Find the derivative of the function $f(x) = \sqrt{5x+1}$ at $x_0 = 3$.
- B. Show that the function $f(x) = \text{sign}(x) \cdot x^2$ is differentiable at every point and find its derivative at $x_0 = 0$.
- C. Show that if f is differentiable at x_0 then $\lim_{h \rightarrow 0} (f(x_0 + h^2) - f(x_0)) / 3h = 0$.

The plan did not specify time allocation or any teaching/learning goals.

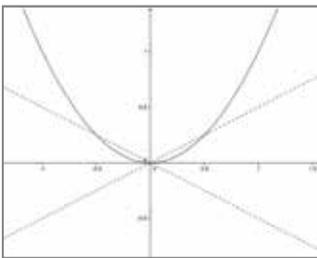

TA1's lesson

TA1 started his lesson by writing the definition of the derivative. Then TA1 stated that he would like to develop some intuition before getting into examples and departed from the lesson plan, initiating a teaching sequence that he designed. TA1 rewrote the definition in terms of epsilon and delta and with a few algebraic steps he obtained the following: *Suppose $f'(x_0) = a$ then for every $\varepsilon > 0$ there exists δ such that $0 < |x - x_0| < \delta$ implies $(a - \varepsilon)(x - x_0) + f(x_0) < f(x) < (a + \varepsilon)(x - x_0) + f(x_0)$.* TA1 then clarified to the students the geometric meaning of this statement:

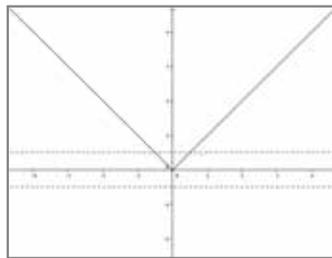

What we see is that if f is differentiable at x_0 then for any given epsilon the (graph of) f is bounded, in some neighbourhood of x_0 , from above and from below by two lines with slopes $a + \varepsilon$ and $a - \varepsilon$ crossing each other at the point $f(x_0)$. We are now ready to draw a picture.

At this point TA1 drew **Drawing1** and used it as a visualisation aid while repeating his previous explanation. He then noted that differentiability implies continuity:

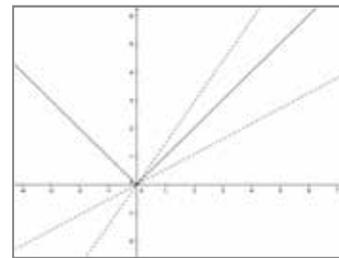

When I get closer to x_0 (TA1's finger slides on the graph towards $(x_0, f(x_0))$) the graph gets closer and closer to the point $f(x_0)$... I'm not giving here a full formal proof; I think that the fact that differentiability implies continuity is very clear from this drawing.

Drawing1

Drawing2

Drawing3

After this explanation TA1 suggested using the geometric interpretation to develop an intuition as to why the absolute value function is continuous but not differentiable at zero and for this purpose he drew **Drawing2** and **Drawing3**. After discussing with the students what can be seen through these drawings TA1 emphasized that this type of argumentation does not qualify as a formal proof. He set aside the geometric interpretation, wrote on the board a rigorous algebraic proof and concluded:

This is a formal proof. Note however that it actually repeats what we saw in the drawings.

This remark ended the sequence TA1 initiated and he continued to exercise B in the lesson plan. Again he stated that he would like start by developing some intuition. TA1 drew the graph of the function and discussed the notion of "gluing" functions together (in this case x^2 and $-x^2$) and how in some cases (e.g. the absolute value function) gluing differentiable functions yields a non-differentiable function. While addressing the differentiability of the function he introduced the notion of a "local property of a function" and invested a great amount of time discussing why the derivative is indeed a local property. This discussion continued until the end of the lesson and TA1 did not address exercises A or C.

TA2's lesson

TA2's lesson remained close to the lesson plan. Like TA1, TA2 started his lesson by writing the definition of the derivative, while constantly making stops to clarify the mathematical terms he used. Then TA2 advanced quickly through the observations listed in the first part of the lesson plan using them as a springboard for exercise A:

The fact that differentiability implies continuity tells us that if f is differentiable at x_0 then the limit of $(f(x) - f(x_0)) / (x - x_0)$ when $x \rightarrow x_0$ must be in the form $0/0$. Pay attention! This means this limit cannot be found using the arithmetic rules of limits! Let's see an example.

At this point TA2 wrote exercise A on the board, turned to the students and asked:

Is it a legitimate question? Why? Why is f defined in some neighbourhood of 3? How do we start? How shall we find the derivative? Pay attention - Whenever we learn a new concept we always start solving problems by going straight to the definition. Only after some time we start developing theorems that we can use instead of the definition.

After this introduction, TA2 wrote the limit according to the definition and simplified it to obtain: $\lim_{x \rightarrow 3} (\sqrt{5x+1} - \sqrt{5 \cdot 3 + 1}) / (x - 3) = \lim_{x \rightarrow 3} (\sqrt{5x+1} - 4) / (x - 3)$. He then commented:

The claim that the limit is of the form $0/0$ relied only on the fact that f is continuous at x_0 . Do you agree that f is continuous at 3? So this limit is of the form $0/0$. How do we overcome this uncertainty? Recall what we did before in similar situations.

TA1 then showed that $(\sqrt{5x+1} - 4) / (x - 3) = 5(x - 3) / ((x - 3)(\sqrt{5x+1} + 4))$, at which point he turned to the students and raised his voice:

A-ha! (Pointing at the two appearances of $(x - 3)$ at the right-hand side) This is the culprit responsible for the fact that both the numerator and denominator tend to zero! We can cancel these expressions $(x - 3)$ (which are not zero by definition) and now the limit becomes a simple exercise, since we can use the arithmetic laws of finite limits.

TA2 then continued to solve exercise B, again constantly reflecting on his actions. Unlike TA1, TA2 did not discuss the notion of the derivative as a local property. After exercise B TA2 temporarily left the course of the lesson plan telling the students that he would to review several concepts that were introduced in the lectures. After this review TA2 return to the plan, solved exercise C and concluded his lesson.

PREPARATIONS FOR CLASS

After their lessons the TAs described to the author their preparation for class. TA1 started by reading the lesson plan but after getting to the definition of the derivative he stopped and attempted to *try and make sense of the definition by playing with it and by drawing pictures*. This course of action has led to the geometric interpretation of the definition that TA1 considered interesting and valuable. He then decided to present this interpretation in class. TA1 explained that while reading the lesson plan he was asking in his mind questions like: *What do I find important and interesting in this topic? How do I approach this content? What would help me if I were in the place of my students?*

TA2's preparation was guided by different kind of questions. He explained that while reading the lesson plan he was thinking: *If I were a student, how would I see this topic? What might prove difficult for me? Where will I get confused?*

ANALYSIS

We now turn to describe and analyse some of the decisions the two TAs made.

Decisions

TA1 made on several occasions a conscious decision to deviate from lesson plan, for example when he initiated his original teaching sequence or when he ignored exercises A and C. By contrast, TA2 followed the lesson plan and restricted himself to content that had already been taught in the lectures, in what turned out to be a conscious decision on his part. A tacit decision of TA1 was to precede every rigorous proof with a visual intuition. TA2 did not develop any visual intuition in his lesson and presented to his students strictly rigorous proofs.

The interviews revealed several additional decisions. TA1 teaching was guided by a decision to concentrate on the theoretical aspects of the derivative on the expense of the applicative and procedural aspects. TA2 on the other hand made a decision to advance quickly through the theoretical part of the lesson plan and to concentrate on solving the exercises. TA1 saw in exercise B an opportunity for discussing the notion of the derivative as a local property. TA2 decided to use exercise A to emphasize to the students that the derivation is a property of a function at a point (rather than a property of a function as a whole). Below we expand on and analyse these decisions.

Resources

Both TAs had sound mathematical background and indubitable content knowledge and both relied on the lesson plan as a major resource. However, the TAs' reflections on their decisions uncovered additional resources that they had or lacked.

In his interview TA2 stated that in his opinion *the most significant element in preparation for class is the teaching experience*. Indeed, the rationale TA2 provided for his decisions indicated that his teaching experience played a central role as a resource of pedagogical content knowledge (Shulman, 1986). For example, knowledge of a potential learning obstacle has led TA2's to decide to highlight the notion that the derivative is a property of a function at a point (rather than of a function as a whole):

Students became accustomed over the years to differentiate functions as a whole. You start with $f(x)$ and differentiate it to obtain $f'(x)$. There is usually no mentioning of x_0 anywhere in the process! This approach often causes many difficulties for the students when they encounter functions which are not elementary. Thus it was very important for me to emphasize again and again that student are required to work with the definition, especially in the first exercise where most students would feel temptation to differentiate the function.

TA2's reliance on his experience as a resource was also evident in the rationale he provided for his decision to advance quickly to the second part of the lesson plan:

Keep in mind that in this particular lesson the students have just returned from a long semester break. For this reason I decided to get as quickly as possible to concrete examples, which I know are more effective than abstract theory for getting the students back on track.

In contrast, TA1's lessons were often based on what he himself perceived as interesting or challenging:

While preparing for the lesson I usually encounter something which makes me pause. It can be something I find interesting or maybe some difficulty I have with justifying a certain step in some argument. I often end up taking this something to class, thinking that if I found it interesting or if it got me confused then it would probably do the same to the students. I know it is naïve to think that I and the students would find the same things interesting or confusing, but the way I see it is an inevitable working assumption.

Later in the interview TA1 added that he cannot really say what students in his class need or want. These acknowledgments indicate that TA1's decisions were effected by his lack of pedagogical content knowledge.

Orientations

TA1's reflection on this decision uncovered also some of his beliefs and attitudes regarding how mathematics should be taught and communicated in the TA lessons:

The reason I opened the lesson with the geometric interpretation is that it is not standard. It is a good example of the things I'm drawn to. It is not just textual, it involves drawings and it requires a great amount of explanation. It is not something a student would get just by reading the lecture notes. I believe that the added value of the TA lessons does not lie in well-polished content but rather in the learning experience that it provides for the students.

An important factor in TA1's decisions is the image of the student he had in mind:

I wouldn't say that my teaching is directed at the brightest students but rather the hardest working students. I know there are students who prefer to learn in class just by writing everything that is on the board and then read their notes afterwards in the comfort of their homes or before the exam. I don't claim to provide very good service to these students.

Regarding his decision to focus on exercise B, TA1 expressed a dislike to exercises A and C, stating that he did not find them challenging or interesting:

In the lessons I prefer to focus on the more challenging exercises and let the students struggle with the simple exercises on their own. [...] I don't think students benefit much from seeing me just performing algebraic manipulations in front of them. I prefer solutions which represent some mathematic depth, like in exercise B where you have the notion of gluing functions together and the notion of a local property of a function.

Like TA1, TA2's decisions were also shaped by the image he had of his students. In his interview TA2 noted that his decisions often reflect an evaluation of what these students could not manage or could not understand on their own:

I believe I have a responsibility towards all my students, not just those few who will later become mathematicians. The home assignments can be very difficult. I remember myself

struggling with them for hours. I think this is a good thing. However, from my experience this can be a breaking point, especially for the weaker students. I believe that it is the responsibility of the TAs to support these students and to make sure they are not left behind.

Goals

TA1 reflection on the teaching sequence he designed uncovered an implicit goal:

I wanted the students to leave class with some intuition. The students probably heard in the lectures that the derivative is related to the slope of a tangent line to the graph. This is a nice intuition but there is a big gap between a tangent line, which is something you can draw or visualize, and the formal definition which express the derivative in terms of epsilon and delta. What I tried to do in this lesson is to narrow this gap.

Another goal can be inferred from TA1's actions in class: To model for his students the behaviour of a professional mathematician. This goal was confirmed in the interview, when TA1 reflected on the role and the goals of the TA lessons in general:

I think these lessons should develop the active aspects of learning. How do you approach a task? How do you start a proof? Often before I prove theorems in class I do some preparation. I tell the students that we should first gain some intuition, try and see the big picture of the proof. Same with definitions ... As mathematicians, we constantly take actions to gain intuition and one of the goals of these lessons is help students learn how to do that.

An implicit goal, which seems to have had great impact on TA1's decisions, became evident when TA1 reflected on how the TA lessons should complement the lectures:

The lectures are restricted to content which is complete, precise and true. There is an unwritten law that the students can prepare to the exams by reading the lectures notes. I believe that this law does not apply on the TA lessons and that I am obligated to provide the students with a meaningful added value. I want the students to have a different interaction with the content, a mathematical experience that cannot factor through a notebook.

TA2 also addressed the role and goals of TA lessons and their relation to the lectures:

Ideally every new mathematical concept or term introduced in the lectures would be accompanied by several examples. This is not the case and thus one of the main goals of the TA lessons, as I see it, is to review the content taught in the lectures and to give the students an opportunity to get a firm hold on it. [...] There are many things that students should hear more than once, preferably from different teachers with different perspectives and different terminologies. You cannot start to imagine how many times I have heard this "ahh" sound of understanding in class after repeating something that was already said in the lectures.

We note other explicit goals of TA2 already mentioned above: Improving students' capability to solve tasks, getting the students back on track after the long semester break, and emphasizing that formally the derivative is a property of a function at a point. The actions of TA2 in this lesson as well as other lessons suggest another goal which guided TA2: To model for the students the behaviour of an idealized student rather than the behaviour of an experienced mathematician. TA2 confirmed this goal.

SUMMARY AND DISCUSSION

There is a well-known myth stating that university math teaching is just a matter of accumulated experience, clear presentation skills and sound content knowledge. One may also speculate that within the community of professional mathematicians working side by side there cannot be much variability with respect to their resources, orientation and teaching goals. In fact, this assumption seems to be institutionalized by telling the students that all the TA lessons are roughly the same. This study not only challenges these assumptions but also highlights and analyses the differences between two instructors, both with sound mathematical background and indubitable teaching proficiency, implementing the same lesson plan. Using Schoenfeld's ROG framework we showed how different beliefs and attitudes, different goals and reliance on different resources resulted in two substantially different lessons.

A more specific contribution of this study refers to the ways in which the TAs' pedagogical content knowledge, or lack of it, affected the lessons. TA2 stated that his teaching experience was his most significant resource in preparation for lessons, highlighting the specific difficulties he expected from his students and ways of addressing them. For example, TA2's experience suggested that students will be better off with concrete examples and led him to decide to advance quickly through the theoretical part of the lesson plan. Similarly, TA2's decision to focus on the notion that the derivative is a property of a function at a point was his way to address what he considered a common mistake of students, and a potential learning obstacle. By contrast, TA1's lack of calculus teaching experience forced him to choose goals according to what he found interesting or difficult, led by his own introspective processes and by his aesthetics and values as a researcher trying to make sense of new concepts and ideas, designing teaching sequences accordingly. TA1 acknowledges that his perspective on the content may not necessarily coincide with the students' viewpoint or needs, but he sees it as his best possible approximation.

Paterson et al. (2011) suggested that lecturers who are research mathematicians bring different, at times conflicting, orientations into play. It is thus interesting to observe and compare the orientations of the two TAs, whose backgrounds represent these two identities. TA1 is first and foremost a researcher, and believes that it is in the best interests of his students that he will display before them the tools of the trade of a mathematician at work. At the same time TA2, who is first and foremost an instructor, believes that it is in the best interests of his students that he will model the behaviour of an idealized student and attend to their potential learning obstacles. TA1 directed his teaching at the mathematically oriented students, even though he acknowledged that by doing that he may not be providing good services to many of his students. TA2, on the other hands, felt a strong commitment to all his students and *not just those few who will later become mathematicians*, but he does so at the cost of not fully attending the needs of the brighter students in his class. While acknowledging these two identities as a potential source for conflicts regarding university math instruction, it is important to note that these two identities may also

combine in fruitful ways. In this sense, it would be interesting to study a collaboration between TA1 and TA2, or any other two instructors representing their distinct identities, and examine how and when do their different orientations conflict or synergize.

An interesting by-product of this study was the way it influenced the TAs themselves to reconsider their beliefs and attitudes, simply by having a chance to talk with an outside observer about their teaching. TA1 noted that after reflecting on his lesson and discussing it with the author, he has decided to routinely ask questions and initiate dialogues during class and thus obtain a better understanding of his students' viewpoint on the content. TA2 expressed his worries on whether his teaching has strayed too far in favor of the weaker students at the expense of the rest of the class and especially the brighter students. These outcomes suggest that the approach taken in this study, where instructors reflect on decisions they and other colleagues make under similar conditions, may be used in development programs to enhance teaching.

CONCEPTUAL UNDERSTANDING IN LINEAR ALGEBRA

- ANALYSIS OF MATHEMATICS STUDENTS' MENTAL STRUCTURES OF THE CONCEPT 'BASIS' -

Kathrin Schlarmann

University of Oldenburg, Germany

***Abstract.** In this paper I present the analysis of students' thinking processes and the reconstruction of their activated mental structure when they are dealing with a task. The analysing tool is based on Peirce's semiotics. The data is taken from clinical interviews, in which mathematics students were given tasks dealing with the concept of basis. The aim is to understand students' thinking processes and to reconstruct their activated mental structures.*

AIM OF THE PAPER

The theory of linear algebra is characterised by its high degree of interconnections between concepts. The concept of basis, for example, is connected to the concept of linear independence and the concept of a spanning set. Both are linked as defining conditions to basis (of course equivalent definitions that focus on one of these features are possible, too). These concepts refer to other concepts – linear combination and span – so that one can with good reason state that basis is a concept of higher order. Understanding the concept of basis implies that one has a high ability to connect ideas. As a complex theory linear algebra deals with concepts that have a wide significance. Furthermore several equivalences connect conceptual ideas.

The research question of this paper is as follows: Which individual mental structures of the concept basis can be reconstructed when students solve a particular task concerning this topic? When working on the challenging investigation task students will apply concepts they have learned before and in some cases students will broaden their conceptual ideas. Skemp (1973) explains that a mental structure is the “major instrument (...) for solving new problems, and for acquiring new knowledge” (p. 43). Before a person's mental structure can be reconstructed empirically, the thinking process should be analysed. In this paper, I describe the theoretical tool for analysing students' thinking processes and apply the tool via examples to data of students who are working on a task. Then, the analysed thinking processes are condensed in a net by focusing on the individual's mental structure of the concept of basis. Before doing so, I give a literature review of previous studies dealing with students' difficulties in advanced mathematics.

STUDENTS' DIFFICULTIES IN LINEAR ALGEBRA

Several studies are dealing with students' difficulties of the conceptual nature of linear algebra. Sierpinska (2000) states that concepts are not used precisely and are not well-conceived. Moreover, students struggle to interpret signs in definitions and to use them for the construction of contextual mental structures. Several researchers of the MAA-Notes (Carlson et al., 1997) report that their students are able to

reproduce procedures in known contexts successfully, but that they often fail to understand the meaning behind the procedures. Stewart and Thomas (2010) tie their study in with this aspect by trying out a framework for teaching the concept of basis (and other concepts) that emphasises the embodied aspect of basis. Their aim was to help students enrich their understanding. “The results of this study show that a number of the students tended to prefer to work procedurally“ (p. 186). Maracci (2008) shows that students conceived of linear combinations more as processes than as objects (in terms of Sfard’s process-object duality). Britton and Henderson (2009) described students’ difficulties in dealing with the concept of closure. Students struggled with applying the formal concept of a vector space to the algebraic notation in a task. Furthermore, many of the difficulties that students experience in linear algebra are presented in detail in Dorier (2000). These studies all highlight that students struggle with the conceptual nature of the complex theory of linear algebra.

MENTAL STRUCTURES AND UNDERSTANDING

Several authors describe levels of learners’ construction of concepts (hierarchical or otherwise) (e.g. Winter, 1983; Harel, 1997). All have in common that it is essential to connect single ideas for understanding a concept. This corresponds to psychological views (e.g. Skemp, 1973; Sweller, 2006). According to Skemp (1973), pairing single ideas with concepts by connecting them results in a construction of a new idea, which he calls a “relation” (p. 37). A “transformation” (p. 37) is applied to an idea and describes a function of the idea. The entire process of connecting and transforming ideas results in a construction of a complex mental structure. The mental structure includes ideas of concepts and theories. Concerning a concrete thinking process, only a part of the mental structure will be activated. A mental structure is known as “schema” (p. 39). Skemp (1973) defines understanding something as being able to assimilate it into an adequately mental schema. Understanding is subjective. I assume that an individual’s mental structure has to be actively constructed by the individual. Information given to him or her in the form of external representations needs to be constructed by the individual. “The study of structures themselves is an important part of mathematics; and the study of the ways in which they are built up, and function, is at the very core of the psychology of learning mathematics” (p. 39).

THEORETICAL TOOL – ASPECTS OF PEIRCE’S SEMIOTICS

The triadic sign model of Charles Sanders Peirce (1931-1935) is taken as a foundation to analyse thinking processes and mental structures by using an interpretative approach. The triadic sign model has been applied successfully as a tool for analysing processes by some researchers in mathematics education (e.g. Hoffmann, 2003; Presmeg, 2006; Schreiber, 2012; Bikner-Ahsbahs, 2006).

The triadic sign model of Peirce

Peirce describes the triadic sign model in the following way:

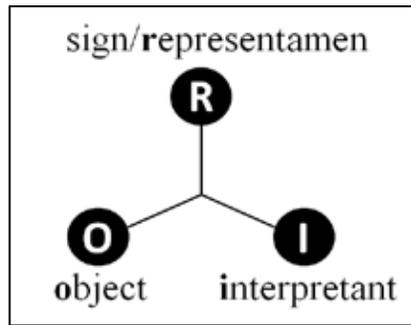

Figure 1: Triad of Peirce

“A sign, or representamen, is something which stands to somebody for something in some respect (...). It addresses somebody, that is, creates in the mind of that person an equivalent sign or perhaps a more developed sign. That sign which it creates I call the interpretant of the first sign. The sign stands for something, its object. It stands for this object not in all respects, but in reference to a sort of idea, which I have sometimes called the ground of representamen” (Peirce, CP 2.228).

According to Peirce, a sign is an external representation that is visible, hearable, or perceptible in some way. Peirce’s sign has a wide range of use. It can be, for example, a word, a task or any material thing. The interpretant describes an internal representation that is induced by the sign and can become explicit. Concerning the term object, Peirce differentiates between the ‘immediate’ and the ‘dynamic object’ (Hoffmann, 2005). The immediate object is to be understood as the object to which the interpretant of the sign refers. Thus, the immediate object describes a special view towards the sign. “Immediate objects are neither obvious nor visible, but they can be reconstructed (as hypotheses) and verified through further data” (Bikner-Ahsbahs, 2006, p. 163). Unlike the immediate object, the dynamic object would emerge after all possible interpretations of its sign. These interpretations do not depend on individual views. Thus, the dynamic object is kind of a limit-object.

The frame as a foundation of Peirce’s triad

Hoffmann (2005) describes the difference between a person working on a familiar sign and the same person working on a sign yet new to him. While interpreting a new sign, the focus is on the sign itself as problematic. While working on a familiar sign, persons “conflate them with the phenomenon itself” (Roth and Bowen, 2003, p. 468 as cited in Hoffmann, 2005, p. 35), as they possess “experience” (Hoffmann, 2005, p. 39) with the sign.

Hoffmann developed further the aspect of “ground of representamen” mentioned by Peirce (see quotation of Peirce above). He used the term “the general” (2005, p. 42, translated by the author) instead and explains that the general includes mentally or physically given concepts, theories, perceptions, habits, and skills of the interpreting person. The general is the foundation of Peirce’s triadic relation. Schreiber renamed the general as “frame” (Schreiber, 2012, p. 7). It influences individual construction of interpretants because “each individual creates interpretants against the background of his or her own subjective interpretation experiences and under a specific perspective” (Schreiber, 2012, p. 7). The interpretants depend on the individual’s activated frame. It is in this sense that Skemp’s approach of mental structures can be linked to Peirce’s theory. Mentally represented ideas of concepts and theories are included in the mental structure and belong to the frame in the triadic relation. The frame can be analysed by interpreting the students’ interpretants.

The chaining of single triads

The strength of Peirce's triadic model lies in describing processes in which new ideas are constructed. This construction is an ongoing process in which an interpretant of a sign becomes explicit and serves in turn as a sign of a further triad (Peirce, CP 2.303). Presmeg (2006) called this process "chaining" (p. 169). While Presmeg refers to linear processes of chaining, Schreiber reconstructed processes that are not always linear. In the processes that I have reconstructed, the interpretants often do not only refer to the previous sign, but to groups of triads that previously occurred.

METHODOLOGICAL TOOL

Sample and data collection

The sample of the whole study consists of 15 mathematics students, whereby in this paper I only look at two mathematics student, Peter and Mike, to exemplify the analysis. Peter and Mike took part in the lectures and tutorials of the linear algebra course in 2010/11, but had to take part again in 2011/12 (their third semester) because they failed the final examination. They participated voluntarily in an additional workshop (four sessions, main topics: vector spaces, basis).

The data was collected about four weeks after the final examination in 2012. This time was chosen because I was interested in the concepts Peter and Mike were able to retain for a longer period of time. In a face to face situation Peter was given a task in written form (fig. 2). He had unlimited time to work on this task by himself. So, this was an individual and active process of construction in which Peter shows on which conceptual aspects he focuses. The interviewer did not influence this part. After working on the task Peter was asked to explain his procedure to the interviewer. This was a kind of retrospective think aloud. Thereby, Peter reflects on his approaches and develops further ideas. In the rest of the interview Peter goes on solving the task. The interviewer's role is to animate the students to verbalise their thoughts. The intention is not to arrive at a solution as quickly as possible. Thus, a semi-structured clinical interview was used to obtain data. The same procedure was carried out with the student Mike. The written survey part of Peter and Mike took about ten minutes; the interviews took each about 20 minutes. The whole session was videotaped. The same procedure was undertaken with the students working on two other tasks concerning the concept of basis in other domains and representations, but this is not taken into account in this paper. Peter and Mike are chosen from the whole sample because their solving processes of only one task show different kinds of connections in the mental structures, and because their ways of solving offer a comparison.

A mathematical task and possible approaches

A task given to the students is shown in figure 2.

$U = \{(x, y, z) \in \mathbb{R}^3 \mid 2x = z\} \subset \mathbb{R}^3$ is given.

- Declare a basis of U .
- Describe in detail: How did you go on?

Figure 2: Mathematical task given to the students

In the following, approaches of ways of solving the task are briefly pointed out. An approach to solve the task is to choose a vector in U and complete it to a basis by focusing on linear independence. Another approach can focus on linear combination by separating $(x, y, 2x)$ according to variables. A starting point could also be to recognise the dimension of U and figure out the number of basis vectors. This could be done by noticing that the equation $2x=z$ geometrically describes a plane in \mathbb{R}^3 or by noticing that the condition $2x=z$ reduced \mathbb{R}^3 to dimension two. These are just examples or ideas; of course combinations of the ideas provide adequate approaches as well.

The task is particularly convenient for the reconstruction of mental structures because it complies with the following aspects: The task challenges the students to apply their knowledge conceptually, but also just deals with familiar aspects. The notation of the vector space U is typical and was used in lectures, tutorials, and in the workshop. The task offers various ways of solving. Several connections among ideas of concept can be applied. This is why every student should be able to get access to work on the task at all. There is not just one special idea that needs to be remembered. Moreover, a solution is not available by applying memorised calculations, but refers to conceptual ideas. To put it in a nutshell, the task is rich and simple at the same time.

DATA ANALYSIS AND RESULTS

In a first step, the students' thinking processes were analysed by using triads. Chains of triads arise from the whole analysis. They structure the students' ideas. The presented analysis consists of parts removed from the chains of triads. These examples show the reconstruction of conceptual aspects in a laudable fashion. In a second step, the chains become condensed. This process results in the reconstruction of the activated mental structures of the students, which are illustrated in a net. The focus is on conceptual understanding of the concept of basis.

In the original data, all vectors were written as column vectors. In the following I will use row vectors instead of column vectors because it saves space. In the following, the triads are consecutively numbered. T stands for triad, S for sign, I for interpretant and O for object.

The case of Peter

The first part of Peter's thinking process is analysed in table 1. The task is the sign (S1) in the first triad (see tab. 1). It causes the interpretant I1. The immediate object in triad 1 (see O1) is the aspect that basis vectors need to be characteristic of the subspace U . When Peter starts working on the task, he concentrates on the condition $2x = z$, which is given in U . He uses it when creating $(1,1,2)$ and $(2,0,4)$ as possible basis vectors.

T	S	I	O
1	task (see fig. 2)	Peter: “In U the condition $2x = z$ is given, and if I choose 1 for x then z must be 2 (writes: (1,1,2)). The same with the second vector (writes (2, ,4)).”	- $2x = z$ is important for finding a basis. - basis vectors need to fulfill $2x = z$
2	↙	Peter: (Completes (2, ,4) to (2,0,4)) “Basis vectors need to be linear independent. This is why I choose one here and zero there (points at second components in both created vectors).”	- linear independence of a set of basis vectors is an essential condition for a basis - effect of 0-component concerning linear independence
3	↙	Peter: “Because we are in the \mathbb{R}^3 (in this task) I need three basis vectors”	to be in the three dimensional space \Rightarrow number of basis vectors is three
4	↙	Peter: “The third must be linear independent, too.” Peter adds (1,2,2) to his set of basis vectors and immediately says: “This one is wrong because I can span it with the others.” He eliminates (1,2,2) from the set of basis vectors.	- The set consisting of (1,1,2); (2,0,4) and (1,2,2) is not a basis. (1,2,2) is not an element of Peter’s basis. - ‘not linear independent’ is used as being able to generate vectors from each other
5	↙	Peter: “I can span (1,2,2) with the other two vectors. If I multiply (1,1,2) by two, divide (2,0,4) by two and subtract this from this, I get this one.” (points at vectors)	generate vectors from each other by combining them linearly $\begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix} = 2 \cdot \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix} - \begin{pmatrix} 2 \\ 0 \\ 4 \end{pmatrix} : 2$

Table 1: Example of reconstructed triads from Peter’s thinking process

The interpretant I1 serves as a new sign (I1=S2), which is a part of the next triad. This sign S2 serves to create a next idea, the interpretant I2. The reconstruction of the immediate object O2 is based on I2. Peter focuses the feature of linear independence of a set of basis vectors. In I2 Peter gives an indication of a part of his concept of linear independence. He applies the concept of linear independence by using the effect of a vector component that is zero. In the following interpretant I3, Peter assumes (wrongly) the number of basis vectors to be three. He refers to one of the symbols \mathbb{R}^3 written in the task (which one is not clear at this point) and concludes that he needs three basis vectors. It could be possible that he associates the dimension like “to be in the three dimensional space means to have the dimension three”, and then concludes the number of basis vectors. The next interpretant is I4. Peter uses the ‘linear independence’-feature again, but refers to another facet than in I2: The possibility to generate a basis vector from the others. I5 makes clear that generating vectors from others means to combine them linearly. This brings him to reconsider his preliminary set of basis vectors.

In the next part I will (because of the limited space) describe how Peter overcomes the crucial point concerning the call for three basis vectors in a summary. Peter adds another third vector and recognises again that the set of basis is not linear

independent because a linear combination of the vectors is possible (T6). Then, he gets the idea that two basis vectors will suffice (T7). He establishes his idea by referring to different aspects: He reinterprets the subsigns $\in \mathbb{R}^3$ in the task, which mean that the vector is in \mathbb{R}^3 and then associates that U could be a plane for example, and that only two basis vectors are necessary to span planes (which are vector spaces) (T8). Thereby, he looks at U as an entity, for example a plane. Peter adds that a basis consisting of three vectors would always span the \mathbb{R}^3 (T9). He convinces himself that his basis consists of (1,1,2) and (2,0,4) by checking if he can span every vector of U with it. By combining them linearly, he focuses on relations among their components and on the structure among the elements of U (T10). Figure 3 shows Peter's activated mental structure when he is solving the task in figure 2. The focus is on the concept of basis because the task explicitly deals with this concept.

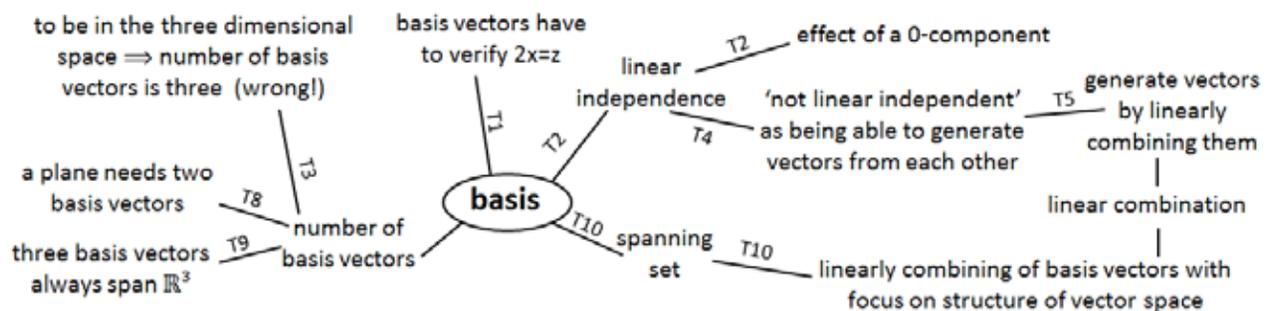

Figure 3: Reconstruction of Peter's activated mental structure

The inscriptions written at the connection lines declare the number of the triads from which the aspects result. Thus, the net offers a look at the order of the problem solving process and the conceptual priorities of Peter. In short, Peter focuses on linear independence, he argues by using aspects of the number of basis vectors, too, and convinces himself by referring to a basis as a spanning set. The connection lines based on linear independence (fig. 3) elucidate in which ways linear independence is applied in the context of the task. Peter refers to the concept of linear combination when he uses the feature of linear independence and the feature of spanning set. Thus, he uses the concept of linear combination flexibly to argue.

The case of Mike

In the following, I summarize the first part of Mike's thinking process (because of the limited space) and describe the second part in more detail by using triads. After reading the task, Mike mentions that a basis is a linear independent spanning set. In his work, he focuses on the part of the linear independence. He applies a relation between determinant and linear independence which he takes down as follows: " $\det(A) \neq 0 \Rightarrow$ linear independent" (T1). This relation implies A to be a $n \times n$ -matrix. In the context of Mike's idea A is a 3×3 -matrix consisting of three column vectors. By choosing the vectors he carefully considers that $2x=z$ is fulfilled (T2). Mike checks if a set of three vectors, which he assumes to be a possible basis of U , is linear independent. Mike applies the relation to four tries of vector sets consisting of (1,0,2),

(0,1,0), and a third varying vector (T3, T4, T5, T6). His focus is on the carrying out of the procedure. Mike does not find three linear independent vectors (of course). He does not conclude a reason why he will never find three linear independent vectors, but he says that two basis vectors, namely (1,0,2) and (0,1,0), will suffice. The interviewer asks Mike to check if the two vectors build a basis (S8). Then Mike continues with I8 (see tab. 2).

T	S	I	O
8	...	Mike: The function of basis vectors is „to span U. (...) So, I have to prove if my vectors are a spanning set.”	a basis needs to be a spanning set
9	↙	Mike: “I don’t know.” (He writes: $\text{span} \left(\begin{pmatrix} 1 \\ 0 \\ 2 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \right)$). “This is the span. I don’t know what can be spanned with it. That’s beyond me.”	- concretion of spanning set idea to the context by using span-notation - notation is not filled with meaning
10	↙	Interviewer: “Linear combination, do you remember this?”	idea of linear combination is offered
12	↙	Mike: “I heard about it. I think I should remember it, but I can’t write anything down.”	linear combination cannot be used in this context

Table 2: Example of reconstructed triads from Mike’s thinking process

Mike refers to the ‘spanning set’-feature of basis. In I9 Mike paraphrases I8 by using the symbolic notation of span. Moreover, he concretises his idea by inserting his own assumed basis vectors into the span notation. Mike cannot go on. It seems that the notation is not filled with meaning to him in this context. The interviewer offers the idea of linear combination in I10. I11 shows that Mike cannot associate ideas with this keyword.

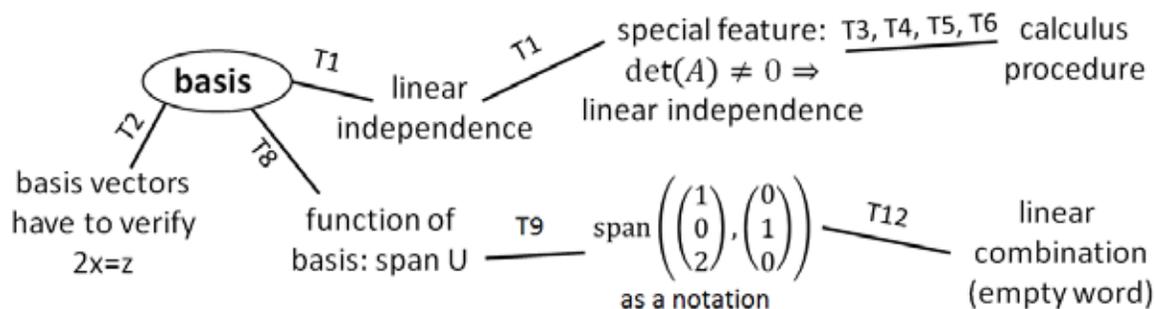

Figure 4: Reconstruction of Mike’s activated mental structure concerning basis

Figure 4 shows Mike’s activated mental structure in his process of solving the task. As well as Peter, Mike focuses on linear independence at first, but he concentrates his attention on another aspect, namely the calculation of the determinant to conclude linear independence. This is a special feature with a limited applicability. Concerning linear independence Peter refers to features that can be generalised like the aspect of zero components and the aspect of generating vectors from each other by using linear combination. This is why his activated connections are more substantial than the ones

in Mike's reconstructed mental structure. Later, Mike addresses the defining feature of a basis being a spanning set, just as Peter, too. However, Mike has problems in applying it. He cannot remember linear combination and cannot justify his set of vectors to be a basis of U .

FINAL REMARKS

In this paper I present my analysis based on the semiotic theory of Peirce. The analysing tool allows describing processes of problem solving in a structured and detailed way. Moreover the order in which conceptual aspects are activated is indicated. The processes are described by chaining triads. The chains serve as a foundation for the reconstruction of students' activated mental structures that are represented in a net.

Outlook: This procedure is carried out with 15 students and three tasks each that are dealing with the concept basis. I am interested in describing and understanding the students' thinking processes in detail. Furthermore, I plan to make up types of activated mental structures explicit. By comparing the mental structures, it will be interesting to have a look at the differences between the mental structures of successful students and those who are less successful.

APPROACHES TO LEARNING MATHEMATICS - DIFFERENCES BETWEEN BEGINNING AND EXPERIENCED UNIVERSITY STUDENTS

Erika Stadler¹, Samuel Bengmark², Hans Thunberg³ & Mikael Winberg⁴

¹Stockholm University, ²Chalmers University of Technology/University of Gothenburg, ³KTH Royal Institute of Technology & ⁴Umeå University

In this paper, we report an on-going quantitative study of students' transition from school to university mathematics. The study aims at examining differences between beginners and experienced students' approaches to learning mathematics. Students were given questionnaires in the beginning and at the end of their first year at university. The results were summarized with descriptive and inferential statistics. The results show that beginners rely heavily on the teacher, while experienced students re-orient themselves from the teacher to other kinds of mathematical resources, for example peers and Internet based resources.

INTRODUCTION

In this paper, we report the first part of an on-going quantitative study of mathematics students in transition between secondary and tertiary level. We focus their experiences of mathematics studies in secondary school and after one semester of university studies. In particular, we are interested in the changes that take place during the students' first courses in mathematics at the university. The aim of this study is to examine students' approaches to learning at the beginning of their mathematics studies at the university and after completing their first mathematics courses when they are more experienced as university students in mathematics. After a short report of previous research that is related to our study, we give an account for the conceptual framework that has been used in our study. The results from descriptive and inferential statistics are discussed in the final section of the paper.

Previous research

Despite extensive efforts to make the transitional phase from school to university mathematics easier, entering higher studies in mathematics still seems to cause problems for many students (Gueudet, 2008). Entering university studies in mathematics put new demands on novice students' adaptability, both to a partly new mathematical content and to a new learning environment (Wood, 2001). Previous experiences of mathematics education from secondary level can have a crucial impact on the transition, for example if the pace of study increases significantly or if the relation to the teacher changes (de Guzmán et al., 1998). This may call for changes of students' approaches to learning and view on knowledge (Perry, 1970), which seem to be a crucial step for students to successfully undertake the transition into university mathematics (Stadler, 2009). Attempts have been made to develop quantitative measuring instruments to find correlations between students' view of knowledge and their learning approaches (Kemper & Leung, 1998), as well as between students'

perception of changes when learning mathematics when entering university and their mathematics dispositions (Pampaka, Williams & Hutcheson, 2011). Also, the relation between affective variables, such as students' beliefs and self-conception, and students' success in the transitional phase from school to university mathematics have been examined, where a correlation between students' beliefs about mathematics and their approaches to learning has been shown (Liston & O'Donoghue, 2009).

In this study, we will focus on differences between beginners and more experienced mathematics students. Novice mathematics students at university have various experiences from mathematics teaching and learning from secondary level, which in turn influence their approaches to learning mathematics (Stadler, Bengmark, Thunberg & Winberg, 2012). Moreover, to have been subject to mathematics teaching is crucial for students' transformation from novice to expert mathematical problem solvers and their approaches to work mathematically (Schoenfeld, 1982). Consequently, we assume that students' approaches to learning are likely to change during the transition into university studies. The aim of our study is to examine students' approaches to learning mathematics with a focus on differences between beginners and experienced mathematics students at the university.

CONCEPTUAL FRAMEWORK

In this section, we present the concepts that we have chosen to use in our study to examine *students' approaches to learning mathematics*. In a qualitative study of students' transition from secondary to university mathematics, Stadler (2009) identified three concepts that describe students' approaches to learning mathematics.

The *mathematical learning objects* category refers to the students' view of the overall purpose of learning mathematics. It captures students' interpretation of what mathematics is and what learning mathematics is all about. Students' subject specific beliefs about learning and knowledge have been shown to strongly relate to their reasoning ability in the subject (Winberg & Berg, 2007). Perry's scheme (1970) describes stages of college students' intellectual and ethical development. It is regarded as a continuum between two views of knowledge and learning; from an absolute and transferable knowledge, which can be either right or wrong, to a relativistic view of knowledge, which is contextually dependent and where the students take responsibility for their learning. If university teachers teach mathematics in a way that corresponds to a higher level in the scheme, students can regard the teacher less useful (Stadler, 2009). Thus, from a student perspective, the transition brings about a need to re-orientate towards new and modified mathematical learning objects compared to secondary school.

Mathematical resources are objects and phenomena that students use to learn mathematics. Some examples are the textbook, the teacher, the peers, the students' pre-knowledge in mathematics and their logical thinking skills. For novice students in mathematics, modifications of the use of mathematical resources are an essential part of the transition (Stadler, 2009).

Students' actions as learners are closely related to their goals and aims of learning mathematics, are contextually dependent and may vary over time. Differences between mathematics teaching in secondary school and university call for new ways of approaching learning and actions to learn. A distinction can be made between independent and dependent actions as learners, where the former indicates that the students undertake actions they chose by themselves, whereas the latter means that even though students have intentions, they are not always able to undertake those actions by themselves that they find necessary to accomplish their intentions.

Choosing these concepts to examine students' approaches to learning is a methodological approach that combines qualitative and quantitative research methods. In the qualitative study, crucial aspects of learning mathematics for students in transition were identified. The quantitative study advances these positions by examining which aspects are more crucial than others, to what extent and for whom. For example, the qualitative study shows that the use of partly new mathematical resources and also the use of familiar mathematical resources in slightly new ways are important for mathematics students in transition (Stadler, 2009). The quantitative study gives supplementary information about to what extent new and other mathematical resources are used and by which category of students.

METHOD

We have developed a research instrument with two questionnaires consisting of 13 query themes (Table 1). The choice of themes was based on the conceptual framework of students' approaches to learning and their beliefs, motivation and self-concept regarding mathematics, as presented previously in the paper. The first questionnaire focused on the students' previous experiences of studying mathematics at secondary level and their expectations from mathematics studies at tertiary level. In the second questionnaire, almost the same questions were asked, but now with focus on their mathematics studies at university, after approximately one semester of mathematics courses.

In our study, we have chosen not to pose explicit questions about the students' mathematical knowledge. Instead, we have collected data about their previous grades from secondary level and study results on their initial mathematics courses at the university. To examine which *mathematical learning objects* the students are focusing on, we have examined students' orientations towards mathematics and the learning of mathematics (Stadler, 2009). Students' preferences about *mathematical resources*, known to be crucial for the transition, were captured by questions about their evaluation of different mathematical resources and behaviour in relation to these mathematical resources. Students' actions as learners involve the two other categories and are operationalized in questions about what the students actually do when they aim at different mathematical learning objects and use different mathematical resources.

Questionnaire 1	Questionnaire 2

Experiences of mathematics studies at university. 13. Experienced requirements to succeed with mathematics studies at university.

Table 1: Query themes in the questionnaires

Questions 3 to 13 were formulated as Likert scale questions with a five-step rating scale. For example, the initial questions about beliefs and attitudes towards mathematics and the learning of mathematics were formulated as follows:

11. Here are some questions about your views of mathematics and learning of mathematics.

	Strongly Disagree				Strongly Agree
a) It's easy for me to learn mathematics.	1	2	3	4	5
b) I can solve most exercises by myself.	1	2	3	4	5
⋮					
w) I learn new concepts by solving exercises.	1	2	3	4	5

The participating students came from different universities and various study programmes. However, in this report, we have chosen not to discriminate between specific groups of students (see Stadler et al., 2012). All students were chosen according to availability. In total, 146 students answered the first questionnaire while 134 students answered the second questionnaire. Both questionnaires were distributed to the same categories of students. The first questionnaire was handed out during mathematics lectures and in the first two weeks of the first semester of the study programme. The second questionnaire was handed out when the students had studied two university mathematics courses. Each questionnaire took 15-25 minutes to answer.

The quantitative data have been analysed using two methods. Firstly, we have used *descriptive statistics* to summarize data in order to describe the main features of the participating students and to be able to compare the results from the first and second questionnaire. Secondly, *inferential statistics* (discriminant analysis with PLS, PLS-DA, a regression extension of Principal Component Analysis) was used to describe the relative importance of questionnaire items for discriminating between the beginner and experienced student group, that is, to investigate the distinguishing features of these two groups of students. The data from the first questionnaire has been separately analysed and reported in a previous paper (Stadler et al., 2012).

RESULTS AND ANALYSIS

With the descriptive statistics, we focus on changes of students' characteristics as learners of mathematics. For each Likert scale question we have calculated the mean value for beginners and experienced students and used a two-sided t-test to investigate possible significant differences between the two groups of students. In the first questionnaire the students' previous experiences of mathematics studies at secondary level were examined (Stadler et al., 2012). According to the students, a typical mathematics lesson begun with the teacher giving a short introductory lecture, which lasted for 10-15 minutes. In the rest of the lesson, the students worked with textbook exercises. In the questionnaires, the beginner and the experienced students were asked about the importance of the following lesson activities for their learning of mathematics at secondary and university level respectively (Table 2).

	Beginner	Experienced	95% CI for difference	p
Lectures	4.24	3.99	[0.01; 0.49]	.04
Demonstration		4.36	[-0.34; 0.09]	.26
Individual work with exercises	4.28	3.99	[0.05; 0.53]	.02
Individual help from teacher	3.92	3.07	[0.55; 1.16]	.00
Exercises with peers	3.37	4.02	[-0.96; -0.35]	.00
Discussions with peers	3.20	4.13	[-1.21; -0.65]	.00
Internet based resources	0.94	2.56	[-1.93; -1.30]	.00

Table 2: Evaluation of lesson activities, query theme 3.

The beginners value two kinds of lesson activities as the most important, namely lectures and demonstrations from the teachers, and work with exercises. The focus seems to be on working with exercises with the support of a teacher. The experienced students give higher ranking to peers, while the main contribution from the lectures are demonstrations of how to solve exercises. The shift from relying on the teachers to the peers is in accordance with Stadler's findings that the students in transition are forced to an increased independency and autonomy (2009). Another difference between beginners and experienced students is the use of Internet based resources.

The students' valuation of the importance of various mathematical resources is shown in Table 3.

	Beginner	Experienced	95% CI for difference	p
Teacher	4.29	4.16	[-0.11; 0.36]	.29
Peers	3.74	4.23	[-0.73; -0.26]	.00
Textbook	4.05	4.22	[-0.38; 0.04]	.11
Previous tests	3.20	4.25	[-1.29; -0.82]	.00
Book of formulas	3.60	3.04	[0.28; 0.84]	.00
Calculator	3.43	2.14	[1.04; 1.52]	.00
Computer for calculations	1.33	2.42	[-1.32; -0.87]	.00
Internet based resources	1.34	2.56	[-1.45; -0.98]	.00

Table 3: Evaluation of mathematical resources, query theme 7.

The beginners' evaluation of mathematical resources are in tune with the mathematics education that they have experienced at secondary level; the teacher gives a short introduction, which is followed by individual work with textbook exercises where the students are allowed to use the book of formulae and graphic calculators as resources. The appraisal of mathematical resources changes in favour for previous examinations, peers, computers and Internet based resources when the students become more experienced. According to Stadler (2009) the teacher as a mathematical resource changes at the university. Instead of giving instructions of how to solve exercises, the focus is on general mathematical ideas. To novice students, the information from the teacher becomes less useful. However, examples, previous tests and the peers can still provide information and instructions of how to solve exercises.

The students' beliefs about what will be or are the most important things to do to succeed with their mathematics studies at the university are shown in Table 4.

	Beginner	Experienced	95% CI for difference	p
Attend all lectures	4.32	3.72	[0.37; 0.84]	.00
Study outside school	4.29	3.55	[0.50; 0.97]	.00
Do as the teacher tells you to	4.24	3.61	[0.40; 0.86]	.00
Study theory in the textbook	4.23	3.92	[0.09; 0.52]	.01
Solve many exercises	4.18	3.90	[0.05; 0.51]	.02
Attend all tutorials	4.14	3.86	[0.05; 0.53]	.02
Get help from the teacher	4.05	3.12	[0.67; 1.9]	.00
Get help from the peers	4.03	4.02	[-0.21; 0.23]	.93

Table 4: Valuation of study activities, query theme 13.

The experienced students value the importance of almost all study activities lower than the beginners. Our interpretation of these results is that as a beginner, the students are highly motivated, but do not know what to expect. It is difficult for the students to discern which study activities may be important. When the students become familiar with the university, they acquire a more relaxed approach to their

studies. Noteworthy is the decreasing importance of the teacher for the students' success in their studies and, in contrast to their expectations as beginners, the experienced students consider getting help from their peers as the single most important factor.

The students' actions as learners can be categorized as dependent or independent (Stadler, 2009). This is a crucial aspect of the transition because the students are to a greater extent forced to manage their studies on their own, relying more on their ability to read and learn and to use peers and resources on the Internet. Table 5 shows the differences between beginners' and experienced students' help seeking behaviour.

	Beginner	Experienced	95% CI for difference	p
Teacher	3.60	3.02	[0.35; 0.80]	.00
Peers	3.67	4.04	[-0.57; -0.16]	.00
Reading theory	3.61	3.81	[-0.42; 0.03]	.10
Solve examples	3.79	4.18	[-0.58; -0.19]	.00
Study notes from lectures	3.02	3.34	[-0.61; -0.02]	.04
Other peers' solutions	2.63	2.99	[-0.61; -0.12]	.00
Using the Internet	1.43	2.72	[-1.54; -1.04]	.00
Skip the exercise	2.33	2.56	[-0.43; -0.02]	.03

Table 5: Help seeking behaviour, query theme 4 and 6.

While students' help seeking from the teacher decreases, peers and the Internet are two interactive mathematical resources that increase in importance. The textbook, other notes and solutions of exercises are also available mathematical resources that can be used anywhere and anytime. Also, the intensity in the interaction between the teacher and the students usually decreases at the university (Stadler, 2009).

Unlike descriptive statistics, inferential statistics can be used to find correlation patterns between variables, and their relative importance for characterization of similarities and differences between groups of students. We have performed a PLS discriminant analysis, a regression extension of Principal Component Analysis, to further discern differences between beginners and experienced students. A model with three significant components was produced, describing 80% (R2) and predicting 72% (Q2) of the variation in group belongingness, using 22% of the total variation in the questionnaire items. However, as the first component was able to predict 65% of the variation in group belongingness and the second and last component 13% and 9%, respectively, only the first two components are presented in the loading plot (Figure 1). Items that are important for describing and predicting student group belonging are located far from the origin of the figure. This importance is also represented by the item's VIP (variable importance for prediction) value; i.e., the sum of each item's loadings on the components, weighted by the proportion of group belonging that is predicted by the respective component. This value is given for each of the items discussed below. Items that are close to each other in Figure 1 are

positively correlated with each other, while items located on opposite sides of a line through the origin are negatively correlated. In the same fashion, items that are close to the experienced group in Figure 1, in particular in the horizontal direction, describe features that are typical for the experienced students and atypical for the beginner students. The opposite is true for items that are close to the beginners group.

The interpretation of the loading plot and a VIP analysis revealed the most important features that discerned experienced students from beginners. Experienced students perceived a lower usefulness of calculator (item 7i; VIP 2.4), an increased value of internet-based resources to ask questions and find answers (7j; 2.2) and actual use of internet-based resources to seek information to support learning and problem solving in school (4g; 2.2, 3h; 2.2) as a calculating tool or task bank (7i; 2.1, 5e; 1.8). Internet based resources was also perceived valuable as general support (5f; 2.1) or problem solving assistance (6g; 2.0) when studying math outside school. However, the computer as a calculator was not considered as important for study success (13i; 1.3).

Furthermore, experienced students, to a greater extent than beginners, view peers as an important resource, for joint problem solving (9b; 2.1), discussion of theory and concepts (9e; 1.9) and question asking (9d; 1.9, 6b; 1.6) outside school. Getting help from the teacher (13l; 1.6, 3b; 1.3), as well as preparing well before going to the lectures (13a; 1.6), daily work with the course after school, doing what the teacher tells them (13e; 1.3), and attending all lectures (13b; 1.2) were considered less important for study success by experienced students than beginners.

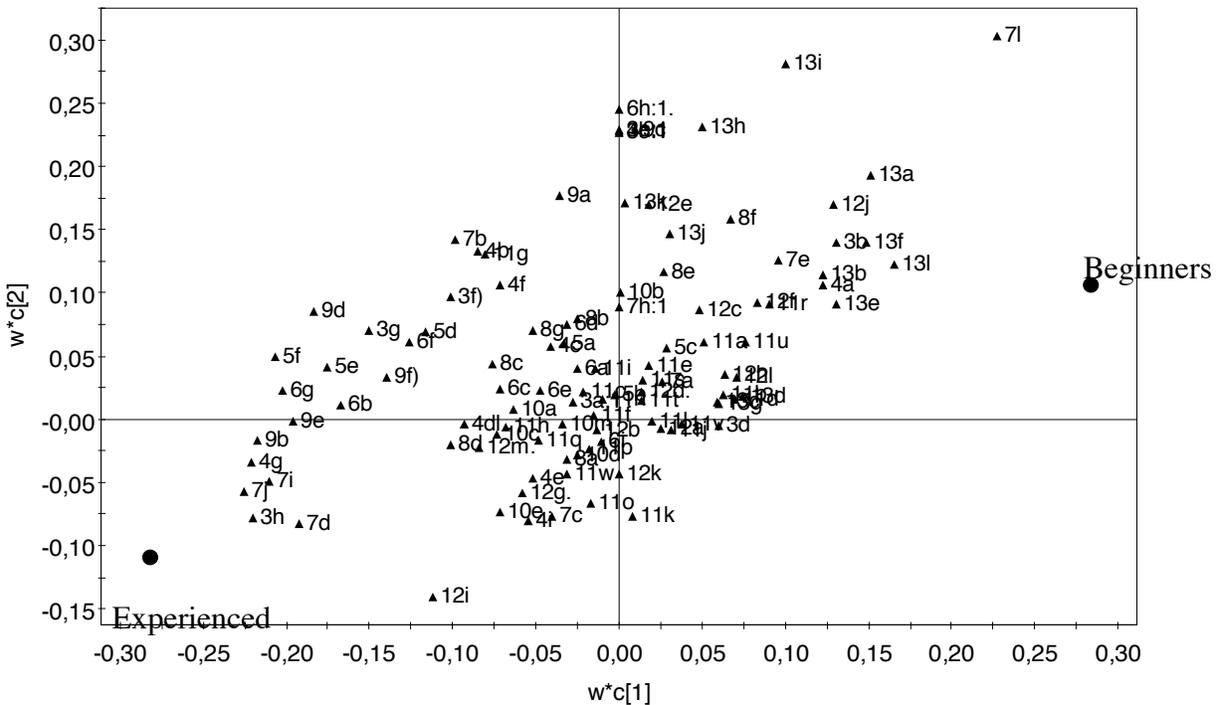

Figure 1: Loading plot from the PLS-DA, showing the relative importance of the questionnaire items to describe the distinguishing features of beginners and experienced students respectively.

The validation of the model was made through analysis of Hotellings T2 range, DmodX (distance to model), Response permutation testing, and Observation risk analysis. One student was outside the Hotelling 99% confidence interval. On deletion of this student, no substantial differences in the model occurred and it was decided the student should be included in the final model. No DModX outlier was detected. R^2 and Q^2 values were significantly lower than for the original model when group belonging values were permuted, meaning that the model's predictions were not spurious. No students had undue effect on the model, e.g. by being extreme in their responses to the questionnaire items and having large residuals when omitted and re-predicted into the model, built on the remaining students.

DISCUSSION AND CONCLUDING REMARKS

The aim of this study was to examine students' approaches to learning mathematics with a focus on differences between beginners and experienced mathematics students at the university. The results indicate that during the transition, the students' approaches to learning change. This may be due to the students' exposition to university teaching of mathematics (Schoenfeld, 1982) that may differ from their previous experiences of mathematics education from secondary level (de Guzmán et al., 1998). Shifting focus from the teacher to the peers can be interpreted as a way to adapt to a new learning environment, which is a crucial ingredient of the transition (Wood, 2001). The decreasing significance of the teacher may be due to limited availability of the teacher or that the university students found the explanations and help from the teacher less useful (Stadler, 2009). However, a higher value might have been predicted since the university teacher can be regarded as the best representative for the new epistemological beliefs and approaches to mathematics that the students have to adapt to in the transition. The decreasing valuation of teacher and the increasing valuation of peers may be interpreted as the students' attempt to handle the transition without changing their epistemological beliefs and approaches to mathematics.

Despite the complexity that the multifaceted transition implies for research in this area, our approach has rather been to take the complexity as a starting point and yield a result that shows which variables are the most crucial for students in transition. Previous studies have mainly adopted a bivariate approach to predict the outcome (Pampaka et al., 2011; Kemper & Leung, 1998), which limits the possibility to understand the impact of confounding variables and yields a lower predictability than multi-variate methods. In contrast to previous studies (Pampaka et al., 2011) we have also included questions about students' actions and behaviour so that we can correlate these with their performance and their beliefs and experiences.

Our results indicate important insights about students in transition. However, we are aware of the danger of jumping to too far-reaching conclusions. The sample is small and not representative. We also lack information about whether individual students have answered both the first and the second questionnaire. The results presented in this paper give an indication of what the crucial differences between beginners and

experienced mathematics students can be. Also, the results can be used as an indication of what to expect from a larger sample and how to design forthcoming studies.

STUDENTS' PERCEPTIONS OF HOW THEY LEARN BEST IN HIGHER EDUCATION MATHEMATICS COURSES

Svein Arne Sikko and Birgit Pepin

Sør-Trøndelag University College, Trondheim, Norway

This paper reports results from an on-going project investigating the transition from upper secondary to higher education mathematics. From a survey of students in their second year in higher education, we report the teaching and study methods from the first year which, according to the student survey, gave students the greatest dividends as learners of mathematics. Results show that work assignments and collaboration with fellow students in tutorial groups or informal groups were the methods students felt they learnt most from. Lectures were not perceived as equally important in the learning process, and ICT was perceived as having little importance for their learning. The implications of the results are discussed in the paper.

INTRODUCTION

The transition from secondary to higher education mathematics has been widely studied and it appears to be a difficult phase for many students (Gueudet, 2008). In addition to causing disappointment and distress for students personally, student failure and/or drop-out represent a significant financial loss for the university/college, a concern for teachers and a loss of potential for society as a whole (Gamache, 2002). It is said that students coming into higher education are more numerous and have more diverse backgrounds than previously, and they have different and often vague views of mathematics, its learning and its role in their future careers and lives (Kajander & Lovric, 2005). Students struggle with university studies because they have a distorted perception of what the acquisition of knowledge entails, and many students see knowledge as a collection of facts that can be absorbed passively (Gamache, 2002). Moreover, undergraduate mathematics does not yet seem to accommodate the diversity of its student body in its offerings and learning mode opportunities (Barton, Ell, Kensington-Miller, & Thomas, 2012).

In this study we investigate how students perceive their 'learning milieus', why and how students continue with mathematics and what could be reasons for dropping out. We examine how students develop their identity as mathematics learners, at transition and through their first year university mathematics, and how they perceive the 'use' of mathematics for their further studies and lives. In this paper we report the results from the second of two data points performed in the second year of the project. The question we ask is "Which forms of study did the students perceive as having learned most from in their first year of study?"

CONCEPTUAL FRAMEWORK

The larger study was conceptualised in collaboration with, and it is very similar to, the TransMaths project at the University of Manchester¹. The project's aim is to develop a deeper understanding of how student experiences of mathematics education practices may interact with various (identified) factors to shape students' development as learners of mathematics, their dispositions and their decision-making at this crucial time. Students experience difficulties at different stages, and they develop different strategies to make these transitions successful (e.g. Brown & Rodd, 2003). Wenger (1998) contends that learning involves both *practice* and *identity*, that is learning develops as students engage and participate in a particular 'world' and in a *practice*. At the same time institutional practices afford, or hinder, students developing a mathematical disposition and an identity (Boaler, 2002) that supports their engagement with mathematically oriented subjects. The on-going project studied students' identities in relation to their experiences of different mathematics learning-and-teaching practices.

The literature (e.g. Wingate, 2007) argues that at transition to university students are often expected to become 'independent learners', hence the importance of "learning to learn". In a previous article (Pepin, Lysø, & Sikko, 2012) we argued that the strategies for learning to learn mathematics were not adequately addressed in the higher educational institutions we studied, except in elementary teacher education, even though, according to our survey, this was just what students said they needed most.

In terms of learning-and-teaching practices, face-to-face lectures remain a standard component of most higher education mathematics courses, despite being widely criticised, and even with advances in information technology and access to the internet, and it is claimed that lectures often are, in practice, where students' learning starts (Pritchard, 2010). These criticisms relate to the lecture as a mode of teaching (mathematics) which promotes superficial learning and 'transmissive' teaching, an environment where 'right-and-wrong' answers are encouraged, amongst others. However, there is evidence that lectures, appropriately 'conducted', are likely to provide opportunities for student learning, for students to take responsibility for their own learning and to engage in activities that are conducive to collaborative learning (e.g. Barton et al., 2012).

Research (e.g. Crawford, Gordon, Nicholas, & Prosser, 1998) shows that students' views of mathematical learning and knowledge relate to their experiences of learning as a whole. This indicates the need for shifting lecturers' attention from just focussing on the mathematical content (and presentation of their course) to a more systemic view of the learning environment. For example, Schoenfeld (1998) proposes an environment that fosters "a community of sense-making in which exploring ideas is

¹ <http://www.education.manchester.ac.uk/research/centres/Ita/Itaresearch/transmaths/>

highly valued” (p.61). In his mathematical problem-solving courses teachers encourage students to conjecture and propose solutions where the validity and accuracy of the solutions are decided by the group. Barton et al.’s study (2012) shows that lectures are crucial in establishing new social norms (Yackel & Cobb, 1996) where the lecture goals are changed from ‘covering the content’ to ‘developing mathematical understanding’. This change includes active engagement of students where “students spend some time working in informal groups engaged in mathematical activity” (p.6). Hence the literature advocates student activity, collaborative learning and informal group work as having overall positive effects for the learning of mathematics, in the cognitive domain as well as the social and affective domain in higher education mathematics (e.g. Barton et al., 2012).

This change of focus is also supported by new technology. However more research is needed in this relatively new domain, and one could ask whether ‘technology would be helpful in fostering novice students’ autonomy by using appropriate online resources’ (Gueudet, 2008, p. 252). E-learning is now advocated in the secondary-tertiary transition in mathematics (e.g. Bardelle & Di Martino, 2012), for the purpose of transforming practice and hence learning. Advocates believe that it can transform thinking and attend to individual students’ needs for personalisation (of paths) and collaboration (in a single activity) (Bardelle & Di Martino, 2012).

RESEARCH DESIGN

The research design (of the whole project) was based on a theoretical framework of mixed methodology involving student longitudinal survey, student biographical interviews and case studies of practice; all at two data points (DP1 and DP2). The questionnaires were developed based on the Manchester examples, subsequently tested and calibrated for the Norwegian context (which included the validation of each question), and appropriately translated.

The data chosen for analysis reported in this article were the questionnaire/survey data from students at the following institutions: at City University (CU) the study was conducted with students in three different courses (Calculus 1 for civil engineers specializing in maths and physics; Basic Analysis; and, Mathematics for Applications). The Basic Analysis course was followed by students enrolled in the teacher programme in the sciences or mathematics, but also included students in various undergraduate programmes and a one-year mathematics programme. The Mathematics for Applications course is usually taken by students who need a somewhat less theoretically oriented mathematics course and focuses on applied mathematics. At River University College (RU), we conducted the survey in both the three-year engineering programme (RUE) and the teacher education (RUT) for years 1-10. RUE students from three different programmes were following the same math course. At DP 1 (autumn 2010) we collected questionnaires from 720 students (and interviewed a total of 49 students spread across the various programmes and courses -

see Pepin, Lysø, & Sikko, 2012). At DP 2 (autumn 2011/spring 2012) we collected 562 questionnaires.

The DP 2 Questionnaire had a total of 26 questions. In this paper we look at three of the questions, Question 16, Question 17 and Question 18. In Question 16 respondents were asked to consider 10 different statements regarding teaching and learning methods in the mathematics they experienced during their first year. For each of the statements they were asked to respond on a scale from 1 (Strongly disagree) to 5 (Strongly Agree). There was also an opportunity to check for Do not know / Not applicable. In Question 17, they were asked to give more detailed comments on which of the learning methods and study forms mentioned in Question 16 they believed they had benefited most from. In Question 18 they were asked to give reasons for possible non-attendance in lectures.

In order to develop deeper insights into students' experiences at transition from school to university mathematics education, the study applied robust methodological principles. These included:

- the principle of 'extended time' survey: in the case of the students, this involved following their development from their first weeks at university (DP1: case observations; individual student interviews; informal talks/interviews with lecturers) throughout their first year and into the second (DP2: as above);
- the principle of 'continuity': selected students were 'followed' inside sessions (e.g. lectures, tutorials) and outside these sessions (informal group discussions/sessions);
- the principle of 'seeing it through the student's eyes': when following the students and observing their 'work environments', data collection was conducted as far as possible through the 'lense' of the students' eyes and their work practices (e.g. observing them in lectures writing, listening, discussing with their peers, etc.);
- the principle of 'reflective investigation': this included discussing what they had written down, or submitted, or said before, in a reflective discussion.

In addition, and in order to counter threats to the validity of the data, and to further strengthen our rigorous data collection across different sites, the teams of researchers/investigators changed in the following ways: always one person was responsible for a particular case, but the second person changed from data point to data point. This allowed each investigator to see different cases 'in situ', and in turn to reflect on his/her own case and its students. In terms of ethics, we adhered to the code of conduct for surveys (observation and interviews) in Norway (NSD), which included student anonymity in questionnaires and voluntary 'opting-in' for interviews.

The methodology clearly has limitations, in particular our survey. Although we had two investigators at each data point, who both had experience with studies of this kind, and we had good rapport with the lecturers at the institutions, we were limited

in terms of time and capacity: it was clearly not possible to understand and research the full range of students' experiences. Our survey data also has limitations regarding the longitudinal aspect. At DP 2 all students present at the lecture where the survey was conducted was allowed to take part, regardless of their participation at DP 1. Combined with the option they had to remain unidentifiable, this accounts for the fact that only around 40% of the surveyed students at DP 1 were identified at DP 2. This also has implications for the significance of comparison of results at the two DPs. Hence, the results cannot be generalised across other sites in Norway, or other subject areas. The extensive nature of our investigations could however deepen our understanding of what students might experience when studying mathematics courses in the selected institutions.

THE FINDINGS

The 10 different statements in Question 16 can be divided into four different categories related to a) Lectures; b) Organized tutorials; c) Informal self-selected groups; and d) Use of computer programmes.

Questions about the benefits of lectures were measured with three statements which are summarized in Table 1.

	Mean	Standard deviation
I benefitted a lot from lectures in mathematics	3.75	1.06
I generally feel that lecturers responded to my needs in the mathematics courses	3.30	1.09
I was able to understand most of what was being taught in the lectures	3.41	1.01

Table 1: Benefit of lectures. 1) Strongly disagree, 2) Disagree, 3) Neutral, 4) Agree, 5) Strongly agree

There were some differences between the institutions. RUE students (3 year engineering programme) seemed to report most positively on their benefit from lectures, as 42% strongly agreed with the statement "I benefitted a lot from lectures in mathematics", and they also strongly agreed with the statement "I generally feel that lecturers responded to my needs in the mathematics courses" (20%). However, only 14% of students at CU strongly agreed with the former (and 22% at RUT, and 7-8% to the latter). When asked about understanding what is going on in lectures, the percentages were more equal: 14% of the RUT students; 11% of the engineering students; and 6% of the CU students strongly agree.

How the students felt they benefitted from organised tutorials and working with obligatory exercise hand-ins was also measured through three statements. Results can be seen in Table 2.

	Mean	Standard deviation
I learned a lot of mathematics by working with the obligatory hand-in exercises	4.12	0.97
I learned a lot of mathematics from working with my fellow students	4.04	0.94
I benefitted a lot from the tutorials with teacher assistants	3.41	1.19

Table 2: Benefit of organised tutorials. 1) Strongly disagree, 2) Disagree, 3) Neutral, 4) Agree, 5) Strongly agree

It is noticeable that the mean score on the statements about obligatory hand-ins and working collaboratively with fellow students were considerably higher than the score for lectures. It is also noticeable that the score for benefits of the tutorials with teaching assistants was much lower than the two others. The standard deviation was also much higher. A closer look at the data makes it clear that the RUT (teacher education programme) pulled the score down; in fact, as many as 41% of the RUT students checked “Don’t know” on this statement. In comparison, the “Don’t know” percentage was only 5% at CU and 9% at the RUE programme.

Even if working with obligatory exercise hand-ins was given a high score at all education programmes, CU students were those who saw this as most beneficial, as 90% agreed or strongly agreed to the statement “I learned a lot of mathematics by working with the obligatory hand-in exercises”. For RUC students the percentage was 78% and the percentage at RUE was 59%.

In addition to or parallel to the organised tutorials, students organised themselves in informal or self-governed groups (see Pepin, Lysø, & Sikko, 2012, p. 357). The benefits from working in such groups were measured with two statements (Table 3). The statement about working together with fellow students fits both in the category of organised tutorials and the category of informal group, and is therefore included twice.

	Mean	Standard deviation
I learned a lot of mathematics from working in informal groups with friends and colleagues	3.90	1.10
I learned a lot of mathematics from working with my fellow students	4.04	0.94

Table 3: Benefit from informal groups. 1) Strongly disagree, 2) Disagree, 3) Neutral, 4) Agree, 5) Strongly agree

RUE and RUT students agreed more with these statements than their peers at CU.

The benefits from working with computers appeared to be surprisingly small. The statement “I learned a lot of mathematics from working with different computer software” was given a mean score of 1.79; whereas the statement “I learned a lot of mathematics by communication on the LMS “It’s learning etc.” attained a mean score of 1.70. RUT and RUE students seemed to agree somewhat more with these statements, but across programmes and institutions it appears that computers did not add significantly to the students’ learning experiences.

It is interesting to note that the statement “I preferred the teaching at upper secondary school to the teaching last year at university/college” attained a relatively low score, the mean being 2.73. This indicates that the students did not want the higher education institutions to adapt more to the way teaching was conducted at school level. This can also be seen from the findings at Data Point 1 (see Pepin, Lysø, & Sikko, 2012), where it was found that students appreciated that they had to take more responsibility for their own learning at university.

The three statements that attained the highest mean scores were the following: (1) ‘I learned a lot of mathematics by working with the obligatory hand-in exercises’ - Mean 4.12; (2) ‘I learned a lot of mathematics from working with my fellow students’ - Mean 4.04; and (3) ‘I learned a lot of mathematics from working in informal groups with friends and colleagues’ - Mean 3.90. These results point unambiguously towards the fact that students perceive working in groups with hand-in exercises as meaningful activities for their learning. They gave statements concerning these much higher scores than statements about how much they learnt from attending lectures. In terms of references within the open comments, exercises, hand-ins and group work were mentioned 409 times.

DISCUSSION OF RESULTS

(1) The findings from the survey provide evidence for the claim that students perceive the most important learning to take place when they are working with the mathematics themselves, and in particular when they are working together with their colleagues in small groups. Comments from students at all three institutions support that. A student at CU claimed that he rarely went to lectures and that the “obligatory hand-in exercises ...these were my main tool for learning mathematics”. In terms of seeking help, the tutorials and informal group work appeared to provide the main support.

“I benefitted most from the tutorials, there one could ask and get help when you didn’t understand something.” (CU student 1).

“I benefitted a lot from working in a small group with fellow students. To get help, and giving help back to others, this helped me a lot in my learning.” (RUE student 1)

Although the participants in our survey came from different backgrounds (strong mathematics; engineering; teacher education), there were commonalities in their ‘discourse’ and survey answers, in the sense that students largely welcomed collective work and team-based learning. It appeared that they felt safe in these groups where they could ask questions, seek help from and provide help to others. This supports previous research findings (e.g. D’Souza & Wood, 2003) in terms of benefits of collaborative learning for the creation of an environment of active, involved and goal-directed learning. It also allowed students to exercise a sense of control on the tasks they had to perform and was likely to enhance self-management skills. It appeared that collaborative learning has an overall positive effect in the cognitive/mathematics learning domain, as well as the social (and possibly affective), domain in higher education mathematics (Bardelle & Di Martino 2012)

(2) Many students claimed that their learning outcome of lectures was low. Asking students about their reasons why they did not attend lectures, a common thread in answers from all students, regardless the institution, was that students felt that the pace of lectures was too fast. As the pace was too high, they could not follow the teachers’ explanations, and as a consequence they felt that they did not learn. Others claimed that they could not follow the lecture and take notes at the same time.

“I felt the lectures went along at too high a pace, and I really could not follow the teacher. I have never understood so little in mathematics” (CU student 5).

Even those who persisted in going to lectures found themselves at a loss with the mathematics - resilience was not the route to success in terms of learning.

“I attended all lectures, but I often had trouble understanding what was going on. Since then I have studied chemistry and I have had to use a lot of the maths from the maths course, but I soon found that I really had not understood the theories and the methods.” (CU student 4)

As lectures were typically held in large auditoria, students apparently had little opportunities for asking questions. Only when they prepared the lecture, did it seem to make sense and provided positive experiences.

“I attended the lectures, but I only benefitted from them when I had read about the subject prior to the lecture.” (RUT student 2)

We argue that what students perceived as most useful for their learning may be seen as threefold: (1) Lectures could be seen as the place where learning started, in the sense that this was the place where students gained knowledge about what they had to learn. (2) In organized tutorials students received help with their hand-in exercises, so this was where they were provided with ways on ‘how to solve’ the problems at hand and with ‘the answers’. (3) It was when working with their peers that students perceived that actual learning took place (likely through discussions and reflection).

For these students the social and socio-mathematical norms (Yackel & Cobb, 1996) of the lectures they experienced did not help them to understand and engage in the

mathematics. Lecturers would need to develop their pedagogic practice, e.g. in terms of more skilled questioning and more active student involvement, in order to offer a diversity of learning approaches for their large and diverse audiences. This may also change student perception of learning in and through lectures.

In conclusion we claim that students are clear about how they can learn best – and this is collaboratively and actively engaged. Not ‘remedial instruction’ (e.g. Gamache, 2002), but innovative practices, either face-to-face (e.g. Barton et al., 2012) or by using technology (e.g. Bardelle & Di Martino, 2012; Borba & Llinares, 2012), are likely to be beneficial for ‘re-invigorating’ large-group pedagogic practice, such as lectures, or individual/small group tuition.

ACKNOWLEDGEMENT

This study was supported by funds from Sør-Trøndelag University College, and we are also grateful to colleagues, especially Knut Ole Lysø, and students at both "River University College" and "City University".

UNDERGRADUATE STUDENTS' PERCEPTIONS OF THEMSELVES AS CAPABLE MATHEMATICS LEARNERS

Amanjot Toor and Joyce Mgombelo

Faculty of Education, Brock University, Canada

This exploratory study aimed to investigate how undergraduate mathematics students perceive themselves as capable mathematics learners and whether differences exist between male and female students' perceptions. A concurrent mixed method design was used in which quantitative and qualitative data were collected and analyzed separately. The findings from quantitative data suggest that gender differences exist with regard to participants' perceptions of their self-efficacy and their environment. Qualitative data analysis revealed that the participants describe their experiences of being a capable mathematics learner from two positions: from their direct experience and from their perceptions of ideal images of a capable mathematics learner.

Keywords: Post-Secondary Education, Gender, Mathematics, Identity, Perceptions

INTRODUCTION

Researchers have highlighted various aspects of the mathematics learning process and have presented it from a range of theoretical standpoints (Grootenboer et al., 2006). Recently, the notion of identity has been explored to bring an understanding of mathematics learning (Boaler & Greeno, 2000; Sfrad & Prusak, 2005). Learning mathematics involves the continuous development of a student's identity as capable mathematics learner. Identity can be defined as a perception of self in an academic environment that develops through relationships and experiences with peers, educators, family, and community, and an individual's own connections and meaning of mathematics in the broader context (Anderson, 2007; Solomon, 2007). Sfrad and Prusak (2005) refer to identity as the way in which one is defined by others and oneself.

Most of the studies on identity have focused on school mathematics learning. Current research has highlighted the importance of identity for understanding learning at an undergraduate mathematics level (Solomon, 2007). There is a need to recognize how mathematical identity contributes to the experiences and educational success of students at the undergraduate mathematics level. Undergraduate mathematics students' identity is essential to students' beliefs about themselves as capable mathematics learners and as potential mathematicians (Solomon, 2007). There is evidence from literature that gender plays a significant role on mathematical identity (Anderson, 2007; Solomon, 2007; O'Brien, 1999). This raises the question regarding whether male and female undergraduate students perceive their identity as capable mathematics learners differently. This study aimed at exploring how undergraduate mathematics students identify themselves as capable mathematics learners and whether gender differences

exist. The study was guided by the following questions: 1) What are undergraduate students' perceptions of capable mathematics learners? 2) What does it mean for undergraduate mathematics students to be a capable mathematics learner? 3) How do their perceptions of self-efficacy, the environment and four faces of identity compare with their meanings of a capable mathematics learner? And 4) Are there any gender differences?

CONCEPTUAL FRAMEWORK

Literature shows various factors that may contribute to one's self perception of as a capable mathematics learner. Most of the studies on mathematical identity have focused either on self-efficacy, primarily from psychological perspective, or on environment, mainly from a socio-cultural perspective (Grootenboer et al., 2006). Grootenboer et al., argued that the plurality of theoretical perspectives may provide a richer and more comprehensive understanding on the issues of identity in mathematics education. Like Grootenboer et al., this study looked at identity as a capable mathematics learner at the undergraduate mathematics level from the plurality of the three approaches: self-efficacy, environment, and four faces of a learner's identity (Figure 1). In this study, self-efficacy refers to the way in which one may perceive him/herself and may ask, *Am I a capable mathematics learner?* According to Bandura (1986), self-efficacy is learned and self-efficacy expectations are acquired through various sources. The essential source of self-efficacy is one's accomplishments where one's experience on given task will either increase or decrease one's self-efficacy connected to that task (Bandura, 1986). A second source, vicarious learning, can affect one's self-efficacy where one sees others (peers and classmates) succeed or fail on a given task, assessment, or in class. In observing the behavior, performance, grade, etc., of others an individual may reflect on their experiences and make meaning of its relevance in a new situation. Other sources of self-efficacy are verbal persuasion and emotional arousal. In verbal persuasion, beliefs about oneself are influenced by the messages conveyed by others (e.g., what others are telling me about my capability to learn mathematics). Emotional arousal refers to the stress and anxiety in a given task and its effect on self-efficacy.

According to O'Brien, Martinez-pons, and Kapala (1999) environmental factors may negatively affect self-perceived academic skills and career goals. Furthermore, Boaler and Greeno (2000) emphasize that identity is decisive in the belief that one can be a creative participant in mathematics as a social practice. Given this orientation, this study explored identity as a capable learner from the environment approach, where one's identity as a capable mathematics learner might be influenced by how others define him/her. For the purposes of this study, the environment refers to one's surroundings, which may compel one to question: *Do my peers, classmates, educators, etc. perceive me as a capable mathematics learner?* In addition, this study explores identity from Anderson's (2007) four faces: engagement, imagination/relativity, alignment, and

nature. Engagement face refers to the experience and active involvement of an individual with people within their environment/the world around them. Imagination/relativity face refers to the images one has of him/herself and of how mathematics fits into the broader experience of life. The third face of a learner's identity is alignment. This refers to how one aligns personal energies within given institutional boundaries and requirements in response to their imagination face of identity. Finally, the nature face of a learner's identity looks at the connection one makes of their natural characteristics, which one has no control over, such as sex, and is dependent on their relationships and broader social settings (2007). Anderson's (2007) conceptualization of identity in terms of four faces of learner's identity, might lead a student to ask: *Why should I learn this?*

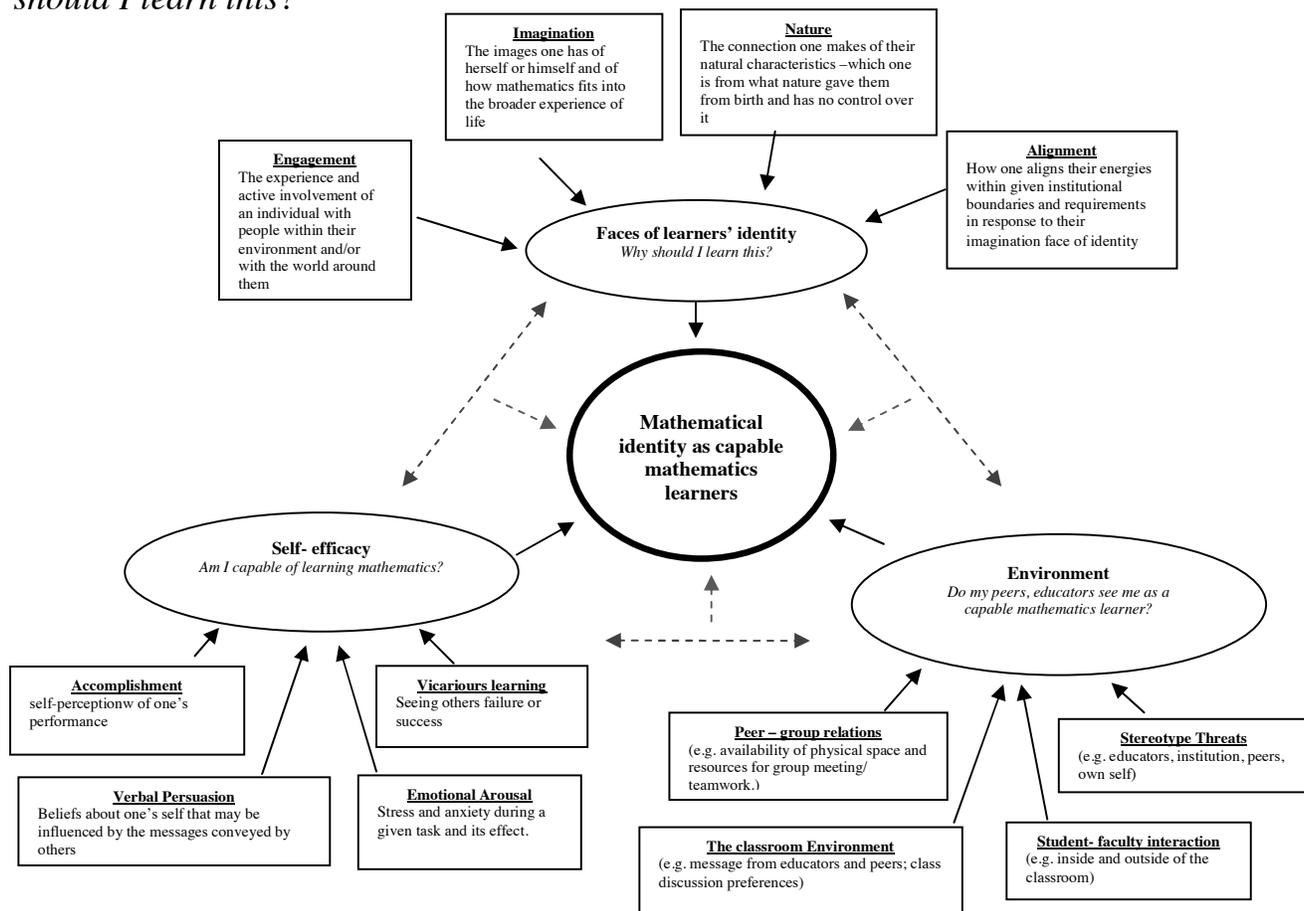

Figure 1: Conceptual framework: Mathematical identity as capable mathematics learners.

The figure has two levels. First, the bolded centre circle is influenced by the three approaches in the elliptic shape (Self-efficacy, Environment and faces of learners' identity). Each of the approaches are influenced by the sources/ factors/each face, represented within the rectangular shapes. However, in the second level, these approaches may have an impact upon each other, represented by the dotted bi-directional two-way arrow, which shows the possible relationship among the approaches.

METHODOLOGY

Both quantitative and qualitative methodological approaches were taken in this study. The two methods were not intended to serve as a contrast point to one another; rather each method was utilized for a different purpose. The quantitative method was utilized to get a snapshot of the ways in which undergraduate mathematics students see themselves as capable mathematics learners and whether gender differences exist. The purpose of the qualitative analysis was to provide an in-depth understanding of students' experiences at the undergraduate mathematics level influenced their perceptions of themselves as capable mathematics learners.

Quantitative data was collected from an online questionnaire. A total of 30 participants, 10 males and 20 females responded to the online questionnaire. These participants were comprised of undergraduate mathematics students majoring in mathematics and those enrolled in the concurrent mathematic education programme at a Canadian University. Of the 30 participants, four were in First Year, five in each of Second, Third and Fourth Year of undergraduate mathematics programme, and 11 in the "others" category (including graduates and students who were in the programmes for more than four years). Twenty-seven participants were from the honors programme (a 20 credits base programme) and three from the pass programme (a 15 credits base programme). The online questionnaire consisted of 24 statements where 10 statements related to self-efficacy, eight statements related to environment, and seven statements related to four faces of learners' identity. These statements utilized the 5-point likert scale and were designed using the three approaches of understanding mathematical identity as a capable mathematics learner (see Figure 1). Both parametric and non-parametric measures for descriptive statistics were used to analyze the data. Given the assigned rating of 1-5 of the Likert scale level, the means of response rate of each statement, along with corresponding standard deviations and associated modes, were calculated using SPSS software in terms of all the participants and, male and female participants. The Mann-Whitney U test was used to test significant gender differences at $p < 0.05$ level.

The qualitative data were obtained from individual semi structured interviews with three males and three females. The six participants were given the pseudonym of Adam, Brent, Craig, Andrea, Britney and Carole. Adam and Andrea are graduates of a mathematics undergraduate programme. Brent and Carole are in the last year of mathematics undergraduate programme. Craig is in his third year of undergraduate intermediate/senior concurrent education with mathematics as his first teachable. Britney has completed a junior/intermediate concurrent mathematics education programme. The questions for the interviews were designed using the three approaches of understanding mathematical identity as a capable mathematics learner (see Figure 1). The interview consisted of eight questions and took about 25-30 minutes. In the invitation letter sent out by email, the interested candidates were asked to fill out a form and reply through

email. The form asked for their name, gender, year of study, and contact information. Six participants volunteered for the interview component, which ensured a balanced sample to gender, and variation of their year of study. The data analysis followed John Creswell's (2008) general principals of qualitative data analysis. These procedures entailed preparing and organizing data, exploring data, describing emerging themes from the data, representing and reporting the findings, interpreting the data and, validating the accuracy and credibility of the results through prolonged engagement and persistent observation.

QUANTITATIVE FINDINGS

The results from quantitative data indicate that participants had strong perceptions of their self-efficacy, and strong perceptions of the influence of their environment. A majority of participants responded, 'Strongly agree'/'Agree' to the statements related to self-efficacy and environment. With respect to the four faces of a learner's identity, the results indicated that participants had strong perceptions regarding preferences for dispositions to nature face and strong perceptions of the influences of imagination face. A majority of participants responded, 'All of the time'/'Most of the time' to two out of three statements related to the nature face of a learner's identity. In relation to the imagination face, 76.6% of the participants responded 'Strongly agree'/'Agree' to the statement *Mathematics will help you further your career goals*.

		Rating				
		Strongly agree or all of the time	Agree Or most of the time	Neutral or some of the time	Disagree or few of the time	Strongly disagreed or never
Self- efficacy		25.7%	34.3%	18.7%	5.6%	0.7%
Environment		21.7%	37.0%	14.2%	5.8%	1.3%
Four faces of learners identity	Engagement	26.7%	33.3%	16.7%	3.3%	0.0%
	Imagination	63.3%	13.3%	3.3%	0.0%	0.0%
	Alignment	3.3%	26.7%	20.0%	23.3%	6.7%
	Nature	26.7%	23.3%	38.9%	11.1%	0.0%

Table 1: Average of Participants' Responses to the online questionnaire

Furthermore, the quantitative results show that there were significant gender differences in the perceptions with regards to the statement related to self-efficacy, *if someone oppose to your idea, you can find the means to prove your idea* ($p=0.003$), and a statement related to environment, *there is enough physical space available and mathematics resources in your institute for you to work by yourself* ($p=0.014$).

QUALITATIVE FINDINGS

Results from the qualitative data suggest two positions regardless of gender from which the participants described their experiences of being a capable mathematics learner: from direct experiences and from their ideal images of a capable mathematics learner. Within these two positions are the six emerged themes. These themes suggest that participants perceive themselves as capable mathematics learners at the undergraduate mathematics level: (a) when they contribute and fit in, (b) if they can teach others and others understand it, (c) when they have opportunities to interact with their peers, (d) when they are recognized by their professors, (e) if they have previous knowledge of the course content, and (g) if they fit in with their image of a capable mathematics learner.

Participants described their perceptions of their mathematical identity from their own, direct personal experiences. For example, in relation to the theme ‘when they contribute to and fit in the class’, Britney expressed:

I usually see what other students got...how other students did. So I try to compare myself with others and I try to see, well, okay if the rest of the class did bad ...okay, I guess we are all just bad together. If I see that I am on the lower end, I know something ...you know something is up like: I need to, myself, do something.

In relation to the theme, ‘if they can teach others and others understand it’ Craig stated:

For me, I learn a lot by teaching and so if and when I have a study group, I can maybe help out some of the other students that might struggle a little bit. And through that, I learn better. And because by teaching you sometimes have to think of it [problem] in different ways, and through thinking different ways you are learning yourself new ways, new techniques to do these problems.

For the theme, ‘when they have opportunities to interact with their peers’ Britney reflected on her experience as an undergraduate mathematics student and stated that it was important,

when I had support of friends who were able to basically be the professors for me. And they were the ones who were able to explain things in a different way, interpret it for me, give me concrete examples and spend the time, work with me, problem solve with me. Because I am not the type where I can just have a professor standing in front of me. They do their own thing on the board, and I don’t try out much in the class with them.

In relation to the theme, ‘when they are recognized by their professors’, Britney commented,

The professors would influence the course the most for me. If the professor can teach and they can actually...they take the time, and you know I feel respected in the class they’ll take the time to teach me something, then I would take their class, and I will struggle and I will try hard...

In relation to the theme, ‘if they have a previous knowledge of the course content’, when asked the question, *How do you see yourself succeeding in a course*, Craig responded,

Some courses I see that I might not do so well in and for that, it would be based on my prior experience with the course. So, for instance, when I went into the second year statistics, I knew that I would do well in the course because it is very much similar to the data management course.

In contrast to participants’ descriptions of their direct experiences of capable mathematics learners, in the second position, the participants used their ideal images to describe their experiences of capable mathematics learners. Participants described their experiences by giving definitions or characteristics of their ideal images, which they then compared with themselves. Carole’s response to the interview question demonstrates this way of perceiving. She said, “Once I am in the range on As ...that’s very happy...like for the outcome. But once I am not As but Bs and Cs, like which is lower... I start to question myself if I am doing my work...” Carole’s response shows that she perceives a capable mathematics learner to be someone whose grades are in the A range. However, if she does not measure up to her image of a capable mathematics learner, then she begins to question herself as a capable mathematics learner.

Britney also framed her perceptions relative to her ideal image of a capable mathematics learner. In her interview, she pointed out the importance of dialogue in mathematics classes for learning. She commented, “In mathematics courses there isn’t that much room for dialogue, and if there is dialogue it’s with the smartest students in the class and the professor. So I am kind of cut out of that part.” Britney noted that given a limited dialogue in mathematics courses, it would seem that the only dialogue that occurs is between “the smartest students in the class and the professor.” This situation provides her with an image of a capable mathematics learner as someone who dialogues with the professor in the class. She then compares herself with this image where she notes that she is “cut off” from the dialogue. This suggests that Britney perceived herself as a capable mathematics learner if she fits in with her image of those students who dialogue with the professor in the class. Further, in the same interview Britney revealed some other ways in which she perceived an image of a capable mathematics learner and how she compared herself with that image. She added:

I could tell that there were students who, somehow I guess, had a math gene in them but I didn’t, and they were the ones who could teach math at a higher level, understand at the higher level and do more mathematical things.

Here, in this response, Britney’s image of a capable mathematics learner is someone who is born with “a math gene.” Therefore, she sees herself as a capable mathematics learner if she fit in with her image of someone who has “math gene”.

Brent's response to how he sees himself as a mathematics student gives further indication of participants' ideal images of a capable mathematics learner. During the interview, Brent mentioned that right after high school he enrolled in a chemistry undergraduate programme. Due to his relationship with his professor in his First Year mathematics course, he decided to switch his undergraduate programme from chemistry to mathematics in his second year. The interview revealed how Brent negotiated his image of a capable mathematics learner in his undergraduate mathematics studies. He noted:

I didn't like that impression that everyone is like you are in math, you are nerdy. Well, like I am not...that is not necessarily the case. So I didn't like to associate myself with other math majors...like I guess because of that. So that didn't last too long....first I was like okay it really doesn't matter...I don't identify myself as a nerd so it doesn't matter...I can still talk to people and talk to them...so then now I am like, yeah, I guess I fit into the nerd category.

Brent's response indicates that he did not want to be perceived as a "nerd" by others just because he was an undergraduate mathematics student and hesitated from associating himself with the image of a "nerd". However, upon interacting with others, he realized that he fits with his ideal image of a capable mathematics learner, "nerd". In other words, he sees himself as a capable mathematics learner if and when this fit in with his image of a "nerd".

DISCUSSION OF RESULTS

The discussion of results is guided by the research questions and by the conceptual framework discussed earlier. The two positions and six themes, in which participants describe their experiences of being a capable mathematics learner, point to participants' perceptions and their meanings of a capable mathematics learner (research question 1 and 2). An attempt is made to weave together the results from both quantitative and qualitative data to discuss about how participants' perceptions of their mathematical identity in terms of self-efficacy, environment and four faces of a learner's identity compare to their meaning of being a capable mathematics learner (research question 3). The results from quantitative data pointed to the existence of gender differences. For example, results from qualitative data show that participants perceived themselves as capable mathematics learners if they can teach others and others understand it. They noted that teaching others provoked one to think of different ways of solving a mathematical problem and validated their own understanding of the concepts. These participants' perceptions and meaning of a capable mathematics learner might lead to their perceptions of self-efficacy in terms of verbal persuasion. In verbal persuasion, beliefs about oneself can be influenced by the messages conveyed by others (Brown, 1999). Further, teaching others may provide opportunities for participants to assess their confidence in their ability to succeed/accomplish a variety of tasks and problems. Being

able to teach others requires one's ability to deal with questions and different ways of thinking by their peers. Most of the participants strongly agreed/ agreed that *they are confident that they could deal efficiently with the unexpected* (70.0%), *they can solve most problems if they invest the necessary effort* (66.7%), *they can always manage to solve difficult problems if they try hard* (53.4%), and *they can find the means to prove their ideas if someone opposes their idea* (66.6%). This suggests that these participants might have strong perceptions of self-efficacy due tasks related to teaching others.

Results from qualitative data suggested that participants perceived themselves as capable mathematics learners when they contributed to and/or fit in the class. For participants, in order to see if one was a capable mathematics learner in terms of contributing to the class, one would assess their performance to see whether their grade is above or below the class average. This would then show, whether their performance is contributing positively or negatively to the class average, and consequently determine whether one is a capable mathematics learner. In regard to fitting in the class, participants assess their performance to see if it belongs to a majority or a minority of overall class performance. For instance, if majority of the class did not do well on a test and one's performance is part of the majority then one judges one's performance as not something to do with one's capability as a mathematics learner, but rather to do with other factors out of one's control. In contrast, if one's performance belonged to the minority that did not do well on a test then one saw oneself as not being a capable mathematics learner. Participants' perceptions of contributing to and fitting in the class might contribute to their perceptions of self-efficacy in terms accomplishment and vicarious learning as well as to their perceptions of their classroom environment in terms of their readiness to participate in class (Shunk & Pajares, 2004). For example, seeing oneself as contributing negatively or positively to the class average might lead one to feel worthy/unworthy or competent/incompetent (i.e. (not) a capable mathematics learner), which in turn might contribute to their timid or passive behaviour in class (Shunk & Pajares, 2004). Quantitative results suggested that the majority of participants (60%) agreed or strongly agreed that their participation in class depends on their comfort level in that class. Following these results from both quantitative and qualitative data, one might postulate that one of the contributors to one's feeling comfortable/uncomfortable to participate in class may well be their perceptions of contributing to and fitting in the class.

IMPLICATIONS

This study utilized a mixed method design and was conducted at one university. Hence, the implications of the study should be read not in terms of generalizability but of transferability to other cases (Creswell, 2008). The results suggest that the participants' perceptions of themselves as capable mathematics learners are influenced also by the perceptions held about them by their professor. Subsequently, while teaching/providing explanations, educators might benefit from taking undergraduate mathematics students'

understanding of mathematics into account, by spending the necessary time that a learner may require for clarification and by providing explanation for mathematics concepts in multiple ways. Furthermore, this study indicates that participants' learning experience deepens when they develop personal relationships with professors. Consequently, there is a need for educators to provide learners with a comfortable learning environment where both educators and other learners invite one another's ideas, and where an individual feels comfortable to pose questions and discover answers. Hence, educators should provide opportunities where undergraduate mathematics students have opportunities to interact with educators and other learners at the undergraduate mathematics level.

WHAT WE TALK ABOUT WHEN WE TALK ABOUT FUNCTIONS – CHARACTERISTICS OF THE FUNCTION CONCEPT IN THE DISCURSIVE PRACTICES OF THREE UNIVERSITY TEACHERS

Olov Viirman

Karlstad University & University of Gävle, Sweden

The study reported in the present paper forms part of an ongoing project regarding the teaching of functions in undergraduate courses at three Swedish universities. The theoretical framework underlying the project is Sfard's commognitive theory. In the present study, three lectures in calculus from two different universities are analysed, focusing on the characterizations of the function concept presented by the discursive practices of the teachers. All three teachers are found to make extensive use of the principle of variation, but differences are found for instance in the emphasis put on different realizations of functions, and on the role of domain and range. Also, according to the type of content of the lectures, differences between more process-oriented and more object-oriented discourses of functions can be seen.

INTRODUCTION

The teaching of mathematics at tertiary level has attracted growing interest within the research community over the last decade. However, studies of the actual teaching practices of university mathematics teachers remain relatively rare. My thesis project, focusing on the teaching practices of university teachers regarding the function concept, contributes to this area of research. The main part of the project, reports of which have been presented at PME 35 (Viirman 2011) and ICME 12 (Viirman 2012), aims at describing and categorising the discursive practices of the teachers regarding functions. The present paper, however, investigates how these discursive practices serve to characterize the function concept.

THEORETICAL FRAMEWORK

Underlying the project is the view of mathematics as a discursive activity. According to this view, mathematical objects are discursively constituted, and doing mathematics is engaging in mathematical discourse. Central to this approach is the commognitive theory of Sfard (2008). Taking the assumption “that *patterned, collective forms of distinctly human forms of doing are developmentally prior to the activities of the individual*” (ibid, p. 78, emph. in original) as a starting point, Sfard defines thinking as “an individualized version of (interpersonal) communicating” (ibid, p. 81). The notion of communication is thus central to commognitive theory, and it is used to define what Sfard means by discourse. Different types of communication are called discourses, and they can be distinguished through four characteristics: *word use*, *visual mediators*, *narratives* (sequences of utterances regarding objects and their relations, subject to endorsement or rejection within the discourse) and *routines* (repetitive patterns characteristic of the discourse) (ibid, pp. 133-135). The rules of discourse act on two different levels. Object-level rules regard

the properties of the objects of the discourse, while meta-level rules govern the actions of the discursants. A routine can thus be seen as a set of meta-rules describing a repetitive discursive action (ibid, p. 208). These discursive actions are also central to the notion of concept. From a commognitive standpoint, a concept is defined as a symbol together with its discursive uses (ibid, p. 111). How mathematical concepts are discursively characterised of course has great influence on what students might learn. Within the commognitive framework, learning is viewed as change in the individualized discourse. Learning can then take place on two levels, related to the levels of rules of discourse. Object-level learning is expressed through expansion of existing discourse, whereas meta-level learning involves changes in the meta-rules of the discourse (ibid, pp. 255-256). Central to meta-level learning is the notion of commognitive conflict, a term used to describe a situation where different discursants act according to different meta-rules. Most often, such conflict can be detected through the fact that different discursants endorse contradicting narratives.

Discussing the possibilities for learning afforded by teachers through their teaching practices, Runesson (2005) looks at dimensions of variation in the critical aspects of the object to be taught. She claims “that exposure to variation is critical for the possibility to learn, and that what is learned reflects the pattern of variation that was present in the learning situation.” (ibid, p. 72) Since these patterns of variation are made visible through routines in the teaching discourse, the notion of patterns of variation fits within the commognitive framework.

The question the study aims to answer is: How is the function concept characterized, on both object- and meta-level, by the discursive practices of the teachers?

PREVIOUS RESEARCH

The function concept has been widely studied within mathematics education research (see e.g. Harel & Dubinsky 1992). Much research has focused on student difficulties with the concept. Of relevance to the present paper is for instance Even (1998), illustrating how knowledge of different representations of functions is dependent on several other factors, for instance the context of the problem, and the ability to consider both the global and point-wise behavior of a function. Sfard’s (1991) notion of process-object duality, while not directly related to the function concept, has still been highly influential on later research on the topic. Research (e.g. Breidenbach, Dubinsky, Hawks & Nichols 1992; Viirman, Attorps & Tossavainen 2010) has shown that students mostly possess process conceptions of function, and that attaining a structural conception is very difficult for many students. The process-object duality is a critical aspect of meta-level learning regarding the function concept, as is the notion of arbitrariness (Even 1990) associated with a structural view of functions. Critical object-level aspects of the function concept highlighted in the literature are for instance the role of domain and range and defining rule in the definition (Breidenbach et al 1992), the importance of one-valuedness (Even 1990), and the different representations of functions – e.g. algebraic, graphic and numerical (Even 1998; Schwarz & Dreyfus 1995).

The teaching of mathematics at university level, while nowhere near as well-researched as the function concept, has still grown as a research field in later years. Studies of particular relevance for the present paper are for instance Pritchard (2010), arguing the continued relevance of lectures in university mathematics teaching, as well as Weber, Porter & Housman (2008), discussing the different roles examples play in conceptual understanding. There are also a number of studies focusing on the actual teaching practices of university mathematics teachers (e.g. Weber 2004; Wood, Joyce, Petocz & Rodd 2007). In Sweden, research on teaching at tertiary level is still rare. Apart from my own work (Viirman 2011, 2012) on the discursive practices of university mathematics teachers, one example is Bergsten (2007), using a case study of one calculus lecture on limits of functions to discuss aspects of quality in mathematics lectures.

METHOD

The empirical data in my project consists of video recordings of lectures and lessons given by teachers in first year mathematics courses at three Swedish universities – one large, internationally renowned; one more recently established; and one smaller, regional university. The participating teachers were chosen among those willing to participate, and giving relevant courses during the time available for data collection. A total of seven teachers participated in the study – four from the large university (labelled A1-A4), two from the younger (B1-B2) and one from the regional university (C1). The topics taught by the teachers included calculus, introductory algebra and linear algebra. The present paper focuses on the lectures covering calculus topics, limiting the number of teachers to three – A1, A4 and B1. Of these teachers, one is female (A1) and two male. All three are quite experienced teachers, having taught at tertiary level for more than 20 years. Two have doctoral degrees in mathematics, while the third (B1) was educated as an upper secondary school teacher. In all three cases, the courses were aimed at engineering students, and the lectures were given to fairly large groups, between 50 and 100 students. The topic of teacher A1 is an introduction to the function concept, part of a course preparatory for calculus, while teacher A4 covers continuity and teacher B1 the inverse trigonometric functions and their derivatives, both as parts of courses in single-variable calculus. In all three cases, the textbook used was Adams (2006).

For each of the three teachers, I have about two hours of videotaped lectures, which have been transcribed verbatim, speech as well as the writing on the board. The transcribed lectures were analysed, with the aim of distinguishing the discursive activities characterizing the teachers' respective discourses of functions, paying special attention to repetitive patterns (for more details, see Viirman 2012) and also patterns of variation regarding the critical aspects of the function concept mentioned in the previous section. I first analysed each lecture separately, and then compared them, searching for differences and similarities. I have intentionally chosen an outsider perspective, trying to view the unfolding discourse in as unbiased a way as possible. At the same time, I am of course making use of the fact that my

mathematical knowledge makes me an insider to the discourse. However, I have specifically tried to avoid making references to what is *not* present in the discourse, except in contrasting the teachers' discursive activities, or making comparisons with previous research.

RESULTS

Looking at the discursive practices of the three teachers in this study, we find that all three teachers use various patterns of variation, highlighting different aspects of the function concept. For instance, the examples used by teacher A1 when introducing the function concept make the various components of the definition visible through variation. The examples she uses are $f(x) = (x-1)^2 + 2$, $g(x) = \sqrt{x}$, and $h(x) = \sqrt{|x|}$, varying rule, domain and range, as well as indicating the connection between them. She then uses the example $x^2 + y^2 = 1$, using this as contrast, making the one-valuedness requirement visible. As seen in the following excerpt, she even uses the same defining formula while restricting the domain, to highlight the fact that all three parts of the definition are necessary (all excerpts are translated from Swedish by the author. Text within [square brackets] indicates writing on the board):

Teacher A1: [On the board two graphs are drawn: the function $f(x) = x^2$ defined on the intervals $[-1, 1]$ and $[-1, 2]$ respectively.]

And what I want to get at is that this proper definition of what a function is.

It is important that you state both the sets and the rule, not just the rule, really, because these are of course different functions, you can just look at them.

Later, when introducing trigonometric functions, she investigates the behaviour of the functions through variation of angles, periods and amplitudes. We can note, however, that all these functions are real-valued functions of one real variable, making the notion of arbitrariness of domain and range impossible to discern. In fact, with one exception, all examples of functions given by the three teachers are of this type. But since all data are taken from courses in single-variable calculus, where the general set-theoretic concept of function is not included in the syllabus, this is not very surprising. It should be mentioned that teacher A1, whose aim is to introduce the function concept, on a few occasions refers to a more general version, hinting that the elements of domain and range need not be numbers, and that the rule need not be given by a formula. However, as soon as she actually uses the concept, it is in the more restricted version, so it is fair to say that functions, as characterized by her teaching practices, are real-valued and defined on (some subset of) the reals.

Teacher B1, when introducing the inverse trigonometric functions, highlights the requirements for the existence of an inverse by varying the functions, as well as their domains, showing how too large a domain results in loss of injectivity:

Teacher B1: [the graph of $\sin(x)$ is drawn on the board]

You sense that we get a problem here, I think. Because you can't exactly say that this is everywhere increasing, nor that it is everywhere decreasing, and it simply must, it can't have much of an inverse, this one, because if we choose one y here.

[He marks a point on the y -axis, a short distance above the origin, and draws a line through the point parallel to the x -axis.]

There will be a whole lot of possible x s, right?

Student: You could define an interval.

Teacher B1: Yes, exactly!

He then goes on to show how different restrictions in domain need to be done for the different functions.

Teacher A4, finally, in a lecture on continuity, uses variation in function graphs to make the possible types of discontinuity visible. He draws a graph which is nice and continuous up to a certain point, marked by a dotted vertical line. He then says:

Teacher A4: Let's assume for example that the function is reasonable in this way, it might go there and then approach some line here.

What can happen when we approach this line from the other direction?
What possibilities do we have? And they turn out not to be very many.

He then asks the students to give suggestions, and together with them he constructs a catalogue of possibilities. He introduces further variation through describing the different cases both geometrically and analytically, through limits. He also indicates the importance of domain through variation, showing how a continuous function whose graph has a jump discontinuity can be made discontinuous through assigning it a value at the jump point. Later, when discussing one of the basic theorems about continuous functions, the boundedness theorem, he highlights the necessity of the conditions (continuous function on a closed, bounded interval) by removing them one at a time and presenting counterexamples. In conclusion, all three teachers use patterns of variation to characterize functions through rule, domain and range, with the domain and range subsets of the reals.

Regarding different realizations [1] of functions, for teacher A1 the algebraic realization of a function through a formula is given prominence. New functions are introduced as formulas, while for instance graphs are spoken of as pictures of the function, as in this typical example:

Teacher A1: [$f(x) = (x-1)^2 + 2$]

It is a function; it is the function x -squared that I move one step to the right and two steps upwards. Then we can for example draw it.

This pattern occurs nearly every time an example of a function is given. It can be found also in the practices of the other two teachers, but not to the same extent. Also,

for teacher A1, the graph is rarely used to gain knowledge of the function. For instance, when determining the range of the function in the excerpt above, she uses the formula to determine the minimum, instead of using the graph. For teacher B1, the formula is still central, but the graphical realization is not just seen as a picture, but as a means of gaining information about the function, as in the example above about the non-injectivity of the sine function. The relationship between graph and formula is also used, for instance to find the graph of the inverse given the graph of the function.

Teacher A4, finally, is less reliant on the algebraic presentation of function. In fact, he explicitly states the need for both the algebraic and the geometric view:

Teacher A4: [CONTINUITY.]

And that is a property that functions can have, which on the one hand has an arithmetical, algebraic way of expression through inequalities and equalities and so on, and a geometric way.

It is always reflected in what the graph of a function can look like.

He often introduces functions through graphs, as in the example of the classification of discontinuities described above. Of course he also uses formulas, but his more varied approach makes the connections between different realizations more visible. This is also achieved through his use of words. For instance teacher A1 speaks mainly in terms of “what does this function look like?”, giving the impression that the graph is just an illustration. Although teacher A4 occasionally expresses himself in this way, he generally speaks of “the graph of the function”, indicating that the graph is a realization in its own right.

On the meta-level, the move from viewing functions as processes on mathematical objects, to viewing them as mathematical objects in their own right, is known to be problematic for students. This duality is seen in various ways in the discourses of the teachers, and the distinction is not always made clear. For instance, all three teachers speak of functions as objects, which can for instance grow, be moved around or be split into smaller parts:

Teacher A1: It is the function x -squared which I move one step to the right and two steps upwards.

Teacher B1: There was a word collecting functions which are either just increasing, increasing, increasing or just decreasing, decreasing, decreasing.

Teacher A4: This function really approaches a whole lot of different points here, right.

Teacher A4: We have this function, this kind of patched-together function that consists of two pieces, and what I'm asking is: can you give a value for b such that f becomes continuous?

In their working with functions, however, distinct differences in the discursive practices of the teachers can be seen. Teacher A1 speaks of functions as objects performing processes on numbers:

Teacher A1: Well, it was all right putting in all real numbers here, all real numbers we can subtract one and take the square and then add two, and what comes out are also real numbers.

Teacher A1: Well, you can say that f itself is the machine, and A is the set of things you are allowed to put into the machine, and when you put a thing from A into the machine, then something comes out that is in B .

In the teaching of teacher A4, the transition from process to object is taken a step further. He often makes no distinction between the function and its values, but still doesn't treat the image as a totality, instead referring to it using metaphors of moving, like in the following example (concerning drawing the graph of the function

$$f(x) = \frac{1}{x-1} \text{):}$$

Teacher A4: What happens to this function when x is bigger than one?

(...)

It goes down, yes, and then it will wander here, and become bigger and bigger and bigger, and when we approach one, this one is still positive and really big.

This way of handling functions is also apparent in the example referred to above, about the classification of discontinuities:

Teacher A4: In what way can it go wrong when I come wandering here towards this line? One way is that I hit the line, there is a limit but it is the wrong limit. Is there something else?

Student: Oscillation.

Teacher A4: Yes, it could swing, right, so that we don't have a limit when we approach here, that is, that it starts getting the shivers here.

For teacher B1, finally, functions are treated very much like objects, where the global behaviour of the function affects invertibility, and where you can create new functions from old ones, for instance by restricting the domain, or by differentiation. He still speaks of the value of a function at a point, but the function as a process acting on numbers is no longer so prominent.

DISCUSSION

As mentioned above, the lectures of the teachers in the study cover different topics – the definition of function (teacher A1), continuity (teacher A4) and derivatives of the inverse trigonometric functions (teacher B1). These topics typically occur at different stages of a calculus course, with functions defined early, continuity introduced

somewhat later, and derivatives of inverse functions covered even later. This fits with the move towards a more objectified discourse observed in the teaching of the three teachers. Since I have no way of accessing what has occurred outside of the video-taped lectures, I can merely make conjectures about the effects of this. To validate these, I would have to observe the same teacher at different stages in the same course. However, even given these limitations in my data, it seems to me as if there is room for commognitive conflict here, with potential for meta-level learning for the students. Teacher A1 speaks of a function as an object performing a process, acting upon numbers. For teacher A4, however, the word ‘function’ signifies something slightly different. This can be seen in the way he sometimes conflates the function with its values, indicating a view of the function as a totality, comprising domain, range and rule. This description is given by teacher A1, but it isn’t apparent in her discursive practices the way it is for teacher A4. However, there is a slight tension in his lecture, seen for instance in the way he uses metaphors of movement, indicating a process view. It is known from previous research (Sfard 1991; Breidenbach et al 1992) that attaining a structural view of the function concept is difficult, and that such a view is rare even among university mathematics students (Viirman, Attorps & Tossavainen 2010). Making this tension more explicit might help the students change their own meta-rules.

On the object level, the role of rule, domain and range indicated by Breidenbach et al (2002) is central to the discourse of all three teachers, but as mentioned above it is characterized somewhat differently, where teachers A4 and B1 see them as an integrated whole, whereas teacher A1 speaks of domain and range more as necessary complements to the rule. Furthermore, research has shown that the use of multiple representations contributes to students’ conceptual understanding, and that the ability to move between different representations is dependent on other factors, like the use of a global or point-wise approach (Even 1998) or the use of different kinds of language (Wood et al 2007). In the teaching observed in the present study, the two main realizations of functions are formulas (algebraic) and graphs (geometric). The relation between these is made more or less explicit in the teaching, with teacher A1 mainly treating the graph as an illustration of the formula, and teacher A4 using graphs independently of formulas, to investigate the qualitative behaviour of functions. Also, teacher A1 mainly takes a point-wise view of functions, whereas teachers A4 and B1 use both point-wise and global approaches. It would appear as if teacher A1 is less successful in integrating the use of algebraic and geometric realizations, giving prominence to the algebraic language of formulas.

I also wish to discuss some observations regarding the use of examples. Weber, Porter & Housman (2008) consider two types of example usage in university mathematics teaching – worked examples and examples aimed at concept image building (see also Pritchard 2010). The teachers in the present study display both types in their teaching, but perhaps most interesting to discuss here is the use of examples to develop discursive objects through variation of critical features

(Runesson 2005). The way teacher A1 introduces the function concept through a series of examples (and non-examples), and the way teacher A4 develops the notion of discontinuity at a point through a systematic use of examples are cases in point.

Finally, I want to mention one topic of further study suggested by my data. This paper has focused on the function concept, but a very interesting aspect of the discursive practices of the teachers in the study concerns how their views of mathematics as a more general practice are made visible. The scope of this paper is too limited for me to be able to present such an analysis here, but this is planned as the topic of a future publication.

NOTES

1. Within the commognitive framework, Sfard (2008, p. 155) uses the term ‘realization’ rather than ‘representation’, signifying the fact that the realization and the signifier being realized belong to the same ontological category.

THE TRANSITION FROM UNIVERSITY TO HIGH SCHOOL AND THE CASE OF EXPONENTIAL FUNCTIONS

Carl Winsløw

University of Copenhagen

University mathematics programmes cater, in various ways, to future teachers of mathematics. The gap between the university contents and methods on one hand, and on the other hand secondary school mathematics, is investigated in studies of how students experience the beginnings of university mathematics programmes. Here we consider the gap as it appears at the other end of the students' experience at university, as they try to relate their new mathematical knowledge to contents and methods in secondary school teaching. The main points of the paper are to introduce a theoretical model to analyse the changes in relation to mathematical knowledge which may be operated at that point, and to show its use on a significant example (the construction of exponents or, more generally, of the exponential function).

AN DOUBLE TRANSITION PROBLEM

Most research on university mathematics education has been devoted to the study of the specific challenges students face at the beginning of a study programme with a strong or exclusive mathematical component (see Gueudet, 2008 for a review of such research, as well as several papers in the CERME7 version of this working group). These challenges are *institutional transition problems* since they arise as students change institution, and several challenges appear to be related to major differences between emphases and methods of teaching in high school and university. At the opposite end of the university programme, the students face another type of institutional transition, namely that from academic mathematics to various professions. In this paper we explore the nature of this second kind of institutional transition, and we also discuss how a mathematics programme may seek to “smoothen” it in view of the profession of secondary mathematics teacher.

Already Klein (1908, p. 1) observed that students taking this direction may face a “double discontinuity” as they move from high school to university, then back again:

At the beginning of his studies, the young student is faced with problems that in no way remind him of the [mathematical] things he worked with in school; naturally he then forgets these matters quickly and thoroughly. If he becomes a teacher after having finished his studies, he must suddenly teach this time honoured elementary mathematics in a school like fashion; and as he cannot by himself see the connection between this task and university mathematics (...) his university studies become just a more or less pleasant memory which has no influence on his teaching. (Translated by the author)

Indeed in many countries, secondary school teachers receive their mathematical education in study programmes geared towards academic “pure” mathematics. The second discontinuity or gap, from university mathematics to secondary school mathematics, appears as a problem to the extent the students' outcome from the

programme does not function as a resource for teaching mathematics at the secondary level. While there is extensive research on how teachers experience the transition from teacher education into teaching practice (see e.g. Winsløw, 2009, for an overview), there remains a practical need for systematic didactical research on how standard undergraduate mathematics is, or could be, developed in view of facilitating its use by students in inquiries related directly to high school mathematics.

This problem is clearly at the borderline between research on mathematics teacher education and research on university mathematics education. But it is of relevance to the latter for at least two reasons: university mathematics programmes often include courses specifically designed to treat elementary mathematics “from a higher viewpoint”, as Klein (1908) put it in his book title; and also one may speculate that the two “smoothing problems” might usefully be approached together.

In this paper, we present a new theoretical model of the second transition, with a concrete case to illustrate it. We first introduce the institutional context in which we have considered the problem (a capstone course). Then we explain the theoretical model in order to situate this somewhat arbitrary context within the general problem of institutional transition and the corresponding changes in relation to mathematical knowledge. Finally, we explore a case which is both illustrative and important in its own right, namely the work with exponential functions in a capstone course.

We emphasize that the primary aim of this paper is to present the problem (of transition from U to HS) and our theoretical model of it, while the case serves to illustrate both through a concrete didactic design, its premises, and some observations of its effects. The case is not an empirical study; it helps to substantiate the model.

CAPSTONE COURSES AND THEIR COUSINS

Universities operate with different traditions and methods across the world. In American colleges and universities, there is a long standing tradition of “senior year programs”, which include the so-called “capstone courses”:

The capstone course typically is defined as a crowning course or experience coming at the end of a sequence of courses with the specific objective of integrating a body of relatively fragmented knowledge into a unified whole. As a rite of passage, this course provides an experience through which undergraduate students both look back over their undergraduate curriculum in an effort to make sense of that experience and look forward to a life by building on that experience (Durel, 1993, 223).

In mathematics programmes, capstone courses are not always aimed at preparing students to a life as mathematics teacher, but many are, as evidenced by the offer of text books such as Usiskin, Peressini, Machisotto and Stanley (2003) or Sultan and Artzt (2011). These texts contain exposition and exercises related to critical areas of secondary mathematics such as trigonometry, number systems or plane geometry, but from the “higher viewpoint” of academic mathematics, just as in Klein’s (1908) treatise which had similar goals (for its time). In fact, a related feature of the German

Stoffdidaktik (content didactics) tradition is to make use of academic mathematics in the development and study of secondary school mathematics. One could mention also the *concours* system, a kind of preservice teacher examination in France and other Romance countries, as an example of transition measures of this kind which are more or less integral parts of the university curriculum within a discipline.

Our context

At the University of Copenhagen, almost all mathematics courses focus on inducing students into the methods and theory of the academic disciplines in question. Only a minority (~40%) of the students become teachers, and many students are undecided about career plans during most of their study. Even the options to specialize in the history or didactics of mathematics (at the master level) are aiming to develop familiarity with research and its methods, rather than professional skills as a teacher.

It should be noted here that to become a high school teacher in Denmark, one needs to study two disciplines, normally a major (for 3-4 years) and a minor (1½-2 years). Students who do a minor in mathematics get to study the first parts of the bachelor programme in mathematics, including abstract algebra, analysis and differential geometry. For some of these students, that material appears both relatively advanced and rather disconnected from what they perceive as relevant to teach mathematics in high school. Then, a few years ago, a course on “Mathematics in a teaching context” (UVmat) was introduced as an option at the bachelor level, primarily in view of students who take mathematics as a minor (but open to others interested in teaching). In recent years it was co-taught by the author and a colleague; in the version of 2011-2012 it was based on Sultan & Artzt (2011). The course has gradually adopted the idea of serving as a capstone course with the following aims:

- Identifying and filling serious gaps in the students’ knowledge of select areas high school mathematics which remain after taking more advanced courses;
- Treating selected topics – mainly from high school analysis and algebra – but from “from a higher viewpoint” (cf. Klein, 1908), in an attempt to illustrate how the material learned in university can serve also when working with more elementary topics in view of teaching.

To sharpen the meaning of these points further, we introduce some elements of the anthropological theory of didactics as well as a more general model of the double transition mentioned in the introduction.

THEORETICAL MODEL

It is a basic contention in the anthropological theory of didactics (Chevallard, 1991, 206-207) that the relation of an individual to an object o of knowledge is strongly conditioned by the institution I in which this object of knowledge lives. For a didactic analysis, we usually consider the individual as occupying a position p within the institution, for instance as a first year student, and study the relation $R_I(p,o)$ of this position in the institution to o , where the subscript stresses that p and o depend on I .

This abstraction is by no means artificial. In fact, data may inform us, with more or less precision, about the relation of smaller number of student to the practice and theory related to Taylor series, or a similar object of knowledge o that of course must be more precisely delimited. But our real aim is usually more general, such as investigating the relation to o of first year students in the University of Copenhagen – or perhaps a generic university of a similar kind.

Such a relation can, indeed, exhibit many variations, which are not exhausted by simple measures of “mastery” of target knowledge. The relation involves also, for example, the *status* assigned to o with respect to other knowledge objects, which may depend highly on p and therefore also on the institution I . For instance, to Spanish high school students, *limits* of functions may end up with an exclusive and marginal status as a formal preliminary to defining *derivatives* of a function (Barbé et al., 2005). Another important variable in the relation is the *modality of access* which I enables p to have to o , for instance, solving exercises, study of a textbook, autonomous inquiry etc.

To model the “objects of knowledge”, Chevallard (1999) introduced the notion of *praxeology* (do read Barbé et al., 2005 if you are unfamiliar with this). In this model, an object of knowledge o is modeled as praxeologies which consist of two related parts: *practical knowledge* (abbreviated P) such as a method to estimate the error of a given Taylor approximation of a given function, at a given point; and *theoretical knowledge* T , such as a way to explain and justify P . In fact, the knowledge object o which we consider may be formed by a whole collection of praxeologies (P, T) .

When considering the double transition outlined in the previous section we are actually investigating transitions of the type $R_{HS}(s,o) \rightarrow R_U(\sigma,\omega) \rightarrow R_{HS}(t,o)$ where the institutions are that of a more or less well defined high school (HS) and university U ; also, s and σ refer to more or less delimited positions as student in these institutions, and t to the position as teacher in HS . Finally o and ω are knowledge objects of a more or less comparable nature. Chevallard (1991) developed the notion of didactic transposition to explain how a knowledge object is transformed in view of enabling students in an institution such as U or HS to establish relations with it; an important case is the transposition of praxeologies ω developed and taught at universities into praxeologies o taught in schools. The second transition above is, clearly, of another nature, and takes place at another pace; still, the success of the didactic transposition certainly depends on the relation $R_{HS}(t,o)$ and this, in turn, relies in part on a past relation $R_U(\sigma,\omega)$ with the transposed object ω , and with teachers now in position t after having been in the position σ .

In capstone courses, we focus on students in position σ and consider how $R_U(\sigma,\omega)$ could be developed in view of a future situation of the students in a position t , and we try to prepare bridges between relations of type $R_U(\sigma,\omega)$ and a more or less hypothetical relation of type $R_{HS}(t,o)$. As a matter of fact, the relation may not be hypothetical at all. Due to an increasing shortage of graduates to fill positions in

Danish HS, some of the students in UVmat are already part time high school teachers. This clearly is a special situation worth particular attention as these students are already experiential in some of the challenges transitions of type $R_U(\sigma, \omega) \rightarrow R_{HS}(t, o)$ which are our topic here. However, we do not focus on this situation here.

CASE STUDY: EXPONENTS AND EXPONENTIAL FUNCTIONS

We now consider, as knowledge object o , the approaches to exponents a^b currently or potentially found in Danish high school (HS), and we consider the set of knowledge objects ω more or less close to o , which are taught in the bachelor programme in mathematics at the University of Copenhagen (U). Our focus is on how a capstone course such as UVmat may contribute to (and draw on) $R_U(\sigma, \omega)$ in order to prepare the transition to the relation $R_{HS}(t, o)$.

High school approaches to exponentiation

There is a certain variation in the approaches to exponentiation found in text books and, conceivably, therefore in the relation students and teachers in *HS* will develop to o . Most textbooks define a^x for rational x , using more or less elaborate justifications of the formula $a^{m/n} = \sqrt[n]{a^m}$ based on the definitions of $a^{1/n}$ and a^n . Given that real numbers and limits are not rigorously treated in HS, the variation lies in how the books explain the passage to real exponents. Here are some typical examples:

The power is calculated by approximating the exponent by a finite decimal number. How many decimals you include depend on the required accuracy (Timm & Svendsen, 2005, 26; translated from Danish by the author)

In Chapter 3 we saw how to calculate powers where the exponent is integer and positive, 0, integer and negative, and rational (fraction). Strictly speaking we have not explained the meaning of a symbol like $7^{\sqrt{3}}$ but we assume CAS will take care of this. (Carstensen, Frandsen & Studsgaard, 2006, 82; translated from Danish by the author)

It is also possible to extend the notion of power to the case of arbitrary exponents like for example π and $\sqrt{11}$ but it will take us too far to do that here (Brydensholt & Ebbesen, 28; translated from Danish by the author)

After this, all books operate with exponential functions as functions defined on \mathbb{R} . There is nothing surprising about this and one should not overestimate the impact on $R_{HS}(s, o)$ of the differences like the above. Judging from informal questioning at lectures over the past few years, few students recall the definition of powers with rational exponents, and even less wondered how to define a^x properly and in general.

Exponentiation in the mandatory bachelor curriculum

All texts used in U simply *assume* the existence of exponential functions as part of the prerequisites from HS. Students are also assumed to know certain basic properties of exponential functions, such as continuity, derivatives and other specific rules, like $a^{x+y} = a^x a^y$ for $a \geq 0$ and x, y real. Exponential functions appear frequently in the first courses on calculus and analysis – for instance, in examples of calculating Taylor

series, as solutions to differential equations, as building blocks in functions of several variables and complex functions, as a tool to study complex numbers (polar form) or functions, etc. Briefly speaking, in $R_U(\sigma, \omega)$ the meaning and basic properties of a^x (for real a, x) are certainly available, but they are neither questioned nor explained.

Exponentiation in UVmat

There are several classical ways to approach the construction of a^x for $a > 0$ and x real, some of which are elegant but out of reach in the first year of HS when this object is first encountered. In UVMat, it is a specific point to develop $R_U(\sigma, \omega)$ so as to know and relate five of these, based on

- (1) “Direct” construction, starting with the case $x \in \mathbb{N}$ and extending first to \mathbb{Q} , then to \mathbb{R} ;
- (2) The inverse function to \log_e , itself constructed via $\log_e(x) = \int_1^x \frac{dt}{t}$;
- (3) The initial value problem $dy/dx = y$, $y(0) = 1$;
- (4) The functional equation or “property” $f(x+y) = f(x)f(y)$;
- (5) The power series $\sum_{n=0}^{\infty} \frac{x^n}{n!}$.

Here, (4) can be used to show uniqueness of a certain form, detailed in the next subsection, while existence must be based on other methods. We notice that (1) is similar to the brief explanations found in o (first year) as explained above, but it still relies on deeper properties of \mathbb{R} that are may be identified in ω but not in o , while (2)-(5) are all entirely beyond the scope of o .

Indeed, giving a complete account of (1) is somewhat challenging even based on $R_U(\sigma, \omega)$. The textbook by Sultan and Artzt (2011, pp. 242-250) provides such an explanation up to rational exponents. For the last step, it provides an insufficient “proof” while acknowledging that “there are some serious issues with this, and to get into all of them would be beyond the scope of this book” (p. 250). The serious issues concern the equation $\lim a^{q_n} = a^{\lim q_n}$ for a sequence (q_n) of rational numbers, assumed in the proof with no warranty even of the existence of the first limit and its independence of a choice of sequence (q_n) tending to a given real number. While one may argue that this could be sufficient for a high school teacher, $R_U(\sigma, \omega)$ can be developed to give a complete explanation by making use of the following property of \mathbb{R} , taught in first year and equivalent to the completeness property : every ascending sequence of real numbers with an upper bound, has a limit.

From a didactic viewpoint, the real challenge lies of course in the effective extension of $R_U(\sigma, \omega)$ and its possible consequences for $R_{HS}(t, o)$. In a recent version of the course (2011), we chose to present (1), (2) and (5) in lectures, while leaving the approaches (3) and (4), and the links between them, to an exercise. We now take a closer look at the tasks left to students and the outcomes.

Students' turn

The 25 students worked on the following exercise (part of a weekly assignment for group work; translated from Danish and slightly rephrased to be self-contained):

- Show that if a function $f : \mathbb{R} \rightarrow \mathbb{R}$ satisfies $f(x+y) = f(x)f(y)$ for all $x, y \in \mathbb{R}$ then $f(0) = 1$ or f is the zero function. Give a (non-zero) example of such a function.
- Show that if a function as in a) is differentiable in 0, then it is differentiable on all of \mathbb{R} . [Hint: look at $(f(x+h)-f(x))/h$ for $h \neq 0$.] What is the derivative of f ?
- You know from calculus that the initial value problem $dy/dx = ky$, $y(0) = 1$ has the unique solution $y = e^{kx}$. Use this together with the results obtained in a) and b) to provide a characterization of exponential functions.

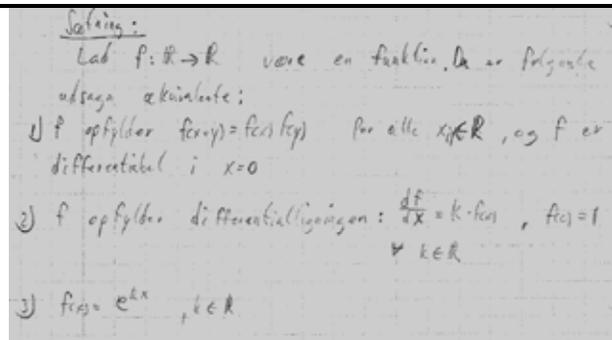

The point in b) is that the condition implies that f' exists and equals $f'(0) \cdot f$ in all cases. It is the *existence* of a solution, mentioned in c), which the “real meat” of the result assumed, as a special case of Picard’s theorem which is treated in first year calculus. The uniqueness, which is the main point here, is quite easy to prove.

The first questions are technical questions and most groups were able to solve them on their own, with a few minor lapses like forgetting the case $f = 0$ in b). However, the third point proved to be challenging for almost all groups. The challenge seems to be the word “characterization” and also to link the form e^{kx} to the notation a^x privileged by the text book. In fact, the theoretical point of view involved with recognizing and formulating a “theorem” is not frequently required from students in $R_U(\sigma, \omega)$ at least in the work prior to UVmat. On the other hand, with the result recalled from calculus and the results proved before, there is – from a technical point of view – a small step to realize and prove that a function f is an exponential function (i.e. $f(x) = a^x$ for some $a \geq 0$) if and only if f is differentiable at 0 and satisfies $f(x+y) = f(x)f(y)$ for all $x, y \in \mathbb{R}$. Of course there are other possible formulations, and in this case we made a point of leaving the formulation open so that alternatives could appear (in fact they did). For instance, the term “exponential functions” could be defined as including the zero function, or not.

The students have access to supervision during their work, and many needed help to even get started on part c) of the task. Looking closer at students’ final formulations of theorems, we find a number of shortcomings that are of a more logical nature. Here is one example (translation to the left, the original in Danish to the right):

Theorem: Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be a function. Then the following propositions are equivalent:

- f satisfies $f(x+y) = f(x)f(y)$ for all $x, y \in \mathbb{R}$ and f is differentiable at $x = 0$
- f satisfies the differential equation $df/dx = k \cdot f(x)$, $f(0) = 1$
 $\forall k \in \mathbb{R}$
- $f(x) = e^{kx}$, $k \in \mathbb{R}$

For instance, we note the strange appearance of the letter k in part 2) and 3). In 2) an existential quantifier (\exists) would be more relevant than the universal (\forall), while in 3), the unspecified status of the letter k is just as problematic. On the other hand, it appears from the students' proof that these points are really mainly of a formal nature. Indeed, many students produced essentially sound proofs despite occasional lacks of clarity in their statements, as above. For these students, we can focus on the formal features of mathematical expression which are, of course, of special importance to $R_{HS}(t,o)$ regardless of the piece of knowledge o involved, as the teacher should not only be able to express formal relations with a variation of formality while retaining basic correctness, but should also be capable of assessing less correct ones.

For other groups of students – representing roughly a quarter of the 25 students – there appear to be real challenges even in the parts of the reasoning that are completely within the kind of arguments that appear in HS text books. As an example, one group did not only formulate a “Theorem” which is formally incorrect, but also provided a proof that is flawed from the first lines, as the following excerpt (translated into English) shows:

Theorem: An arbitrary function $f : \mathbb{R} \rightarrow \mathbb{R}$ which is differentiable in $f(0)$ and satisfies $f(x+y) = f(x)f(y), f(0) \neq 0$ for all $x, y \in \mathbb{R}$, is of the form e^{kx}

Proof: A function f satisfying $f(x+y) = f(x)f(y)$ could be the exponential function. We therefore let $f(x) = e^{kx}, f(y) = e^{ky}$ in the rest of the proof. (...) f also satisfies $f(0) = 1$ since this is well known for the exponential function and can be easily seen by:

$$\text{If } y = -x \Rightarrow f(x-x) = e^{k(x-x)} = e^{k \cdot 0} = 1 \neq 0$$

(...) [*The group goes on to show, by a lengthy calculation repeating parts of the argument from b) in the special case $f(x) = e^{kx}$, that f satisfies the differential equation $df/dx = kf$. They conclude as follows]*

From Picard's theorem we know that for all real numbers k there is one and only one solution to $dy/dx = ky$ satisfying $y(0) = 1$. As we have shown the exponential function satisfies this we know that the exponential function is the only one satisfying this, and the theorem is proved.

For students who produce “proofs” like this one, even formulating autonomously a proof within the core contents of o is likely to be a serious challenge, and one could say that the task c) is perhaps missing the level at which they need to improve their relation to basic HS knowledge. Fortunately, UVmat also offers many much simpler tasks and discussions, focusing more directly on o , such as a) and b), which in fact were solved almost perfectly by all groups, including those who failed on c).

PERSPECTIVES AND CONCLUSION

All of the five approaches (1)-(5) involve technical work that is to some extent beyond $R_{HS}(s,o)$; and as power series are not treated in HS, (5) is perhaps of less importance to $R_{HS}(t,o)$. The other four can strengthen $R_{HS}(t,o)$ in the sense of providing extensions or alternatives to standard presentations. In fact, the above tasks do not go beyond the formal boundaries of the HS curriculum which does include a

formal definition of derivative as well as simple differential equations. The main point is to supply $R_U(\sigma, \omega)$ with an alertness to the non-triviality of o from a mathematical point of view, which could certainly be relevant to $R_{HS}(t, o)$; it could, , be achieved just by working on (1). However, to include alternatives such as (2), (3) and (4), which are strongly related to more advanced parts of the HS curriculum, is clearly of merit to $R_{HS}(t, o)$ as well. For instance, a rigorous approach to integrals has been part of the HS curriculum and might become part of it again, with the increasing use of computer algebra systems to take care of calculations; and then (2) would be a reasonable and elegant way to make up for the shortcomings of o based on (1), including the ease with which fundamental properties of exponential functions may be derived using this construction.

It is interesting to reflect on the difficulty which students had with c) even after solving a) and b) correctly. This exemplifies a phenomenon which we have noticed also in regular, semi-advanced analysis courses, namely a transition which occurs *within* U , and not as a result of changing institution. These transitions have to do with the kind of relation $R_U(\sigma, \omega)$ students need to develop to a university situated mathematical praxeology ω . In the terminology of Winsløw (2008), the transition is said to be of type I when theory is to be used and operated with by students; it is said to be of type II when tasks require students to autonomously develop theory.

In a) and b) students are faced with relative precise tasks, which – although they do involve the theoretical level of ω – can be carried using familiar techniques (operations with the definition of derivative etc.). However, in c) the task is to formulate and prove a “characterization of exponential functions”; it is less “precise” and students have no familiar technique to solve it.. This kind of task is indeed relevant to the position $R_{HS}(t, o)$ of a teacher relative to a piece of knowledge o , such as explaining the sense in which a property (to be precisely defined, as part of the task!) characterizes a class of mathematical objects (equally to be defined). Thus, while the relation $R_U(\sigma, \omega)$ necessary to solve a) and b) is already different from $R_{HS}(s, o)$, this is not so much due to a difference between o and ω , but because of the fact that theory (definitions, proof based on limit operations) has to be drawn upon by σ but usually not by s . On the other hand, going from b) to c) represents an instance of the transition $R_U(\sigma, \omega) \rightarrow R_U^*(\sigma, \omega)$ where the asterisk indicates autonomy with respect to the theoretical level of ω ; notice that this is a transition of type II in the sense of Winsløw (2008). Typically, we find that $R_U^*(\sigma, \omega)$ is more relevant for a “mature” teacher relation $R_{HS}(t, o)$ than $R_U(\sigma, \omega)$. While a capstone course may have other agendas as well, this is an important point in many of the tasks proposed to students in UVmat, the main difference from other mathematics courses in the programme being that ω remains elementary and close to a corresponding o in HS.

By way of conclusion, we hypothesize that in general, the second institutional transition $R_U(\sigma, \omega) \rightarrow R_{HS}(t, o)$, as referred to in the introduction, is not only very different from the first institutional transition $R_{HS}(s, o) \rightarrow R_U(\sigma, \omega)$, it is also closely

linked to transitions of type II within the university programme (in the above notation, $R_U(\sigma, \omega) \rightarrow R_U^*(\sigma, \omega)$). These are in general very hard to accomplish (cf. Winsløw, 2008). The aim of a capstone course could be – among other things – to achieve it, not in general, but for as selection of mathematical praxeologies ω close (if not identical) to praxeologies o which are, or could be, developed in high school. In short, a capstone course could strive deliberately to get students started in autonomous work with theoretical parts of the mathematical praxeologies ω that are most directly related to school mathematics praxeologies o .

TEACHING AND LEARNING COMPLEX NUMBERS IN THE BEGINNING OF THE UNIVERSITY COURSE

Martine De Vleeschouwer (1), Ghislaine Gueudet (2), Marrie-Pierre Lebaud (3)

(1) Didactical Unit of Mathematics, University of Namur (2) CREAD, IUFM of Britain UBO (3) University of Rennes 1

This contribution relates to the secondary-tertiary transition and to the new flexibility requirements (changes of frames or registers...). We especially study the teaching and learning of complex numbers, at the beginning of the university course. First, we present experimental teachings using the online basis of exercises WIMS [1], to work on different representations of complex numbers (Rennes, France). Secondly, we analyse students' productions working on complex numbers inside a geometrical frame (Namur, Belgium). It seems that students willingly move from a geometrical to an algebraic frame, but the choice of the most appropriate one remains a challenge.

COMPLEX NUMBERS AND TRANSITION

Different transition forms take place at the entrance of the university course (Gueudet, 2008). There is a clear need for greater flexibility and greater autonomy for the students to change from one frame to another (Douady, 2008), from one register to another (Duval, 1995)... As far as complex numbers are concerned these requirements are crystal clear. A complex number can be represented under its algebraic, trigonometric or even exponential form. It also has various interpretations in the geometrical frame, where it can be associated with a point, or with a vector, or as a transformation within a plane. Different studies point out difficulties associated with these requirements of flexibility, particularly with respect to geometric representations (Panaoura et al., 2006). We consider that they require specific teaching.

Our research questions are then: which teaching devices need to be set up in order to assist students to learn complex numbers, according to the above flexibility requirements? Why choose an on-line device to help students to learn complex numbers? Which strategies are used by students to carry out a task involving complex numbers in a geometric frame? Which difficulties do the students meet in performing such a task?

To answer these questions, the poster first presents two experimental teaching approaches put in place in Rennes (France): a face to face teaching on complex numbers given at the beginning of the year, and an online course prepared by a team of IREM (Research Institute on the Teaching of Mathematics), associated with some specific exercises available on the web server WIMS[1]. WIMS can propose exercises focusing on the technical aspects, as well as exercises requiring transfer from one register to another (like « complex shot », Figure 1). The choice of this

online platform enables to meet two specificities of the work at university: acceleration of didactic time and greater availability of knowledge.

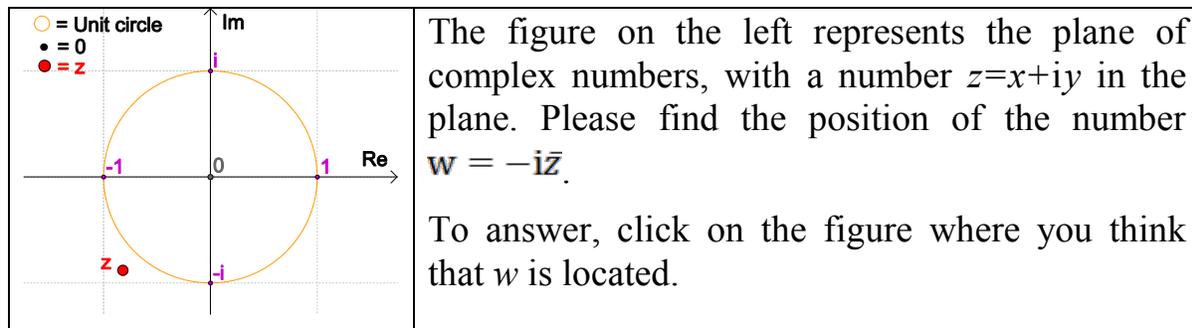

Figure 1: Example of a “Complex shot” task – WIMS (Vandebrouck 2006)

Secondly, the poster presents a brief analysis of students' productions (Namur, Belgium) working on a task involving complex numbers in a geometric frame (exercise of a « complex shot » task). We have noticed that, for example, even if the geometrical frame is sufficient to solve the problem (by the addition of vectors for example), many students convert the problem under algebraic form, which requires more calculations and sometimes approximations. The poster presents extracts of several students' copies. It seems that students willingly move from a geometrical to an algebraic frame, but the choice of the most appropriate one remains a challenge.

OPEN ACCESS MATHS TEXTBOOK: STUDENTS' PERSPECTIVE

Irene Mary Duranczyk

University of Minnesota

Student perceptions (attitudes, behaviours, beliefs) regarding the use of an open source text were collected through pre- and post- surveys and student journals before and after major assignments and tests. This paper highlights student's characteristics related to their attitudes towards open access text/materials, course outcomes, and service learning projects.

RESEARCH QUESTION

What are students' attitudes, behaviours and beliefs regarding the use of published vs. open access textbooks for a maths course? What is the impact of the use of an open access textbook on student learning (self-reported)?

CONTEXT OF THE STUDY

Engaging non-STEM (science, technology, engineering, or maths) major students in an undergraduate maths course can be daunting. Students may be taking the class to check off a graduation requirement. Interest in the class may simply be passing a maths course and not "learning" maths. On many occasions students may not even purchase the \$100 - \$140 dollar text book. The cost of students' textbooks has increased faster than inflation (Office of Program Policy & Government Accountability, 2008, April).

Evidence of student engagement in learning has been linked to the use of open textbooks (Doering, Pereira, & Kuechler, 2010; Petrides, Jimes, Middleton-Detzner, Waling & Weiss, 2011). Open textbooks were found to support inquiry-based, interactive learning and pedagogy in a series of studies by Baker, Theirstein, Fletcher, Kaur, and Emmons (2009) and Hilton and Laman (2012). The hybrid introductory statistics course that is the subject of this paper was revamped with the purpose of: (a) using a free open access book with open access applets for exploring statistical content/concept; (b) infusing a social justice theme (Atweh, Forgasz, & Nebres, 2001; Solomon, 2009); (c) using Microsoft Excel with shareware add-ins for statistical analysis; and (d) requiring students to participate service learning with a non-governmental or non-profit organization in the design, implementation and analysis of data important to the service agency (Hadlock, 2005). The on-campus sessions were conducted within a computer classroom. The off-campus sessions were conducted utilizing Moodle and engaging with service agencies. Given the choice, 11 students selected an open source text and 9 students selected a traditional text.

RESULTS

The quantitative and qualitative data collected revealed the following: (a) A statically difference on the post survey between open source ($M=1.6$, $SD=.70$) and

traditional ($M=2.5$, $SD=.76$) text students on the question: I believe that digital resources did increase my understanding of the course content; $t(14.56)=-2.6$, $p=.021$. (Scale: 1=strongly agree to 4=strongly disagree); (b) A statically difference on the post survey between open source ($M=1.4$, $SD=.52$) and traditional ($M=2.25$, $SD=.46$) text students on the question: I believe that open access textbooks provided the same level of quality as a traditional published print textbook; $t(15.74)=-3.68$, $p=.002$. (Scale: 1=strongly agree to 4=strongly disagree); (c) Reflective comments by students frequently reported on the value and challenge of service learning and infrequently commented on the value of an open source or traditional text; (d) More consistency in students' response to "use of learning materials several times a week" with the open access vs. traditional text; (e) More non-white (60% non-w vs. 40% w) students, more first-year students and more female (65% f vs. 35% m) students chose the open access over the traditional text; and (f) No statistical differences between the groups in attendance, grades, or overall course academic performance.

STUDENTS' PERSONAL WORK

A CASE STUDY: BUSINESS SCHOOL PREPARATORY CLASSES

Lynn Farah

LDAR - Université Paris Diderot (France)

The poster displays the skeleton of an ongoing research study pertaining to students' personal work in the learning of mathematics at an undergraduate level. It presents the tools used to explore students' personal work, and focuses on the main results found through the analysis of the data collected for students enrolled in three different tracks of business school preparatory classes (CPGE).

Keywords: mathematics learning, student personal work, CPGE

DESCRIPTION OF POSTER CONTENT

Section 1- Research Background

The study targets students enrolled in specific French higher-education institutions (*classes préparatoires aux grandes écoles de commerce* - CPGE). It focuses on the development of students of these institutions over one year, with regard to their acquired knowledge and methods, as well as the factors influencing this learning process.

Section 2- Research Questions and Rationale

- What are the forms of study expected by the teachers, and what are the study gestures exhibited by “successful” students on their own initiative, in addition to those that are taught, as opposed to those who fail?
- How does the personal work of the students evolve throughout a preparatory year, in terms of quantity, modalities, and acquired knowledge and methods? What factors influence this learning process?
- What is the impact of the institutional context on the personal work of students? What is the impact of social relationships on student work, in particular the relationships that are built between the students and those with the teachers?

We attempt to answer the above questions while focusing on two main aspects of the students' activities: problem solving and studying math lessons. We hope that this would help us understand how the work that is carried out, or not, by the students contributes to the difficulties which they face. The institutional context plays a major role in this study, hence the choice of the CPGE. These institutions are known for their selectivity and supportive culture, which favours student collaboration and close follow-up by teachers, in a relatively rigid high-school-like system. In fact, students enrolled in these institutions seem to be achieving better results than those in regular universities, where failure during the first years seems to be a serious widespread problem particularly in France. These institutions are viewed both in terms of the

constraints they weigh on students and the resources they offer them, hence they constitute a rich and interesting field of study and observation.

Section 3- Theoretical Framework

The theoretical framework is still in the process of elaboration. This study comes as a continuation of the work of Castela (2011) on this topic. Hence, it is possible to include certain elements of the Anthropological Theory of the Didactic: first to consider the institutional dimension while analyzing the activities of students, who are subjects of particular institutions, which impose on them ways of doing and thinking; and second to account for the knowledge which is necessary for mathematics learning while emphasizing the idea that this type of knowledge is not taught, it is rather constructed by the students themselves. As for the cognitive dimension, other more psycho-social frameworks, yet to be defined, will be used.

Section 4- Data Collection

The study uses a combination of quantitative and qualitative methods which allow close follow up of several volunteer students throughout the year. So far, extensive data has been collected about teachers' practices and expectations, as well as student work habits, through several informal discussions, classroom observations and extensive email communication. In addition, three questionnaires have been designed, pilot-tested and filled out by the students of three different branches (S scientific, E economics and T technology) from four preparatory business schools involved in the study. They all include similar items organized into six categories, which were mainly inspired from prior research on the topic (general work habits, inside the classroom, taking notes, studying the lesson, solving exercises, evaluation of work and results), but contrast two moments of mathematics learning during a student's path (pre/post type): end of high school and end of first year of a preparatory class. The last phase of the study which has started in February 2013 is more clinical. It includes interviews with several volunteer students, one last questionnaire, and videotapes of student group work sessions.

Section 5- Some Results (until end of January 2013)

The focus of this section is on the data collected from the questionnaires. The main objective is to compare the results of the pre/post questionnaires in order to identify common ways of student work, and how these evolve throughout this first year of preparatory classes, in the particular context of these institutions.

THE FIRST ACADEMIC YEAR – STEPS ON THE WAY TO MATHEMATICS

Tanja Hamann, Stephan Kreuzkam, Jürgen Sander, Barbara Schmidt-Thieme, Jan-Hendrik de Wiljes

Universität Hildesheim, Germany

To enable students who are becoming math teachers to provide a process related image of their subject in the future, they need to be made familiar with the subject's methods and – probably even more vital – they need a positive attitude towards mathematics. To this end, a program for the first academic year consisting of several measures, each of them complementary to the others, has been designed at the University of Hildesheim. Studies have been and will be conducted to evaluate the accomplishment of our goal. In this poster the program is presented and discussed.

STARTING SITUATION

Over the past decades there has been growing complaint about increasing problems of first year math students, including larger gaps between school and university with regard to subject-specific skills. Consequently, questions of supporting academic starters have become topic of research within the last few years (proceedings of conference about courses for mathematic newcomers are to be released soon, [2]). For beginners studying mathematics to become school teachers, additional aspects occur, there is on the one hand lack of motivation to do university math whilst on the other there are specific needs for this group of students. German curricula include the teaching of process related competencies such as problem solving, presenting and mathematical communication (as laid down e.g. in [4]), thus students aiming for being a teacher e.g. need to acquire the ability to communicate mathematics on very different levels. Further information on subject-specific requirements for math teachers can be found e.g. in [1].

INTRODUCTION OF THE PROGRAM

Within the frame of the new approach to the first academic year for those studying mathematics to become a teacher for primary or secondary school at the University of Hildesheim, modules were developed in order to help the students in being more successful and gaining a clearer view of their subject during their first two semesters. These should support math students taking their first steps at university towards subject-specific methods.

A preliminary two-week course focussed on repeating fundamental basics of school mathematics and a scholastic assessment test before the beginning of academic studies are the first two steps on the way. Those were evaluated in [3]. The third

module is a weekly “tutorial-market” during the first semester, which gives students the opportunity for self-reliant group work on mathematical tasks and problems with assistance from lecturers and tutors if necessary. Within this arrangement students will be given the opportunity to communicate about mathematical contents and methods of problem solving. The fourth step, evaluated in ([5]), is a joint three-day study trip (“Mathe-Hütte”) in the second semester where students work independently and literature-based in small groups on a mathematical subject. On the third day they present their findings to the other participants in the course of a poster session, thus getting an opportunity to communicate and present mathematical contents to others – skills particularly crucial for a school teacher. In order to support students assessing their own proficiency and approach towards mathematics after the first stage of their studies, there is a fifth and final step: a mathematical talk in which lecturers and students meet to discuss the students’ abilities and attitudes. This talk completes the first academic year.

PERSPECTIVE

Further research has been initiated to evaluate the program with respect to the goal formulated in the introduction. Particular questions are whether the program helps to bridge the gap between school and university math and if it increases the teacher-specific skills in mathematics.

ENHANCING BASIC SKILLS IN MODERN INTRODUCTORY ENGINEERING MATHEMATICS WITH HIGH IT INTEGRATION

Karsten Schmidt and Peter M. Hussmann

Dept. of Mathematics/LearningLab DTU, Technical University of Denmark

At a technical university, the freshmen meet technical textbooks and instructions that require mastery of basic pre-university mathematical skills. In this project we are testing these skills, and propose a curriculum redesign for introductory mathematics aimed for bridging the gaps. Mathematics 1 at the Technical University of Denmark (DTU), a course with high IT and Maple integration, now opens with a four-week paper and pencil course in complex numbers and functions. Since this topic is essential for the subsequent instruction in linear algebra and differential equations, we claim that this is a forward-looking and motivating method.

INTRODUCTION

Many research questions within the relation between mathematics and ICT is following this template: How can we in a paper and pencil teaching environment remedy the observed problem X by a dedicated and delimited use of the software programme Y. In this project the scenario is upside down. The large introductory two-semester course in mathematics (Math1) at DTU has since many years been in the frontline of the pedagogical-didactical development within teaching and learning mathematics at university level, especially regarding the integration of ICT (Markvorsen and Schmidt, 2012). Of special relevance here is that the advanced CAS-software program Maple for more than 10 years has been a fully integrated part of the course. As a response to the well-known worry of *the black box effect*, we introduced rules of thumb for a cautious CAS use in 2007-2010 (Schmidt, Rattleff and Hussmann, 2010). Recently, the CAS debate has been replicated at DTU, but now also as a high school-to-university-transition problem. It has been claimed that the widespread use of CAS in Danish high schools has caused a lack of basic mathematical skills, and that consequently many students are unable to follow the reasoning behind introductory technical textbooks (internal DTU paper, 2011). To counter this new challenge we have redesigned the first semester of the course.

CURRICULUM REDESIGN AND INQUIRY DESIGN

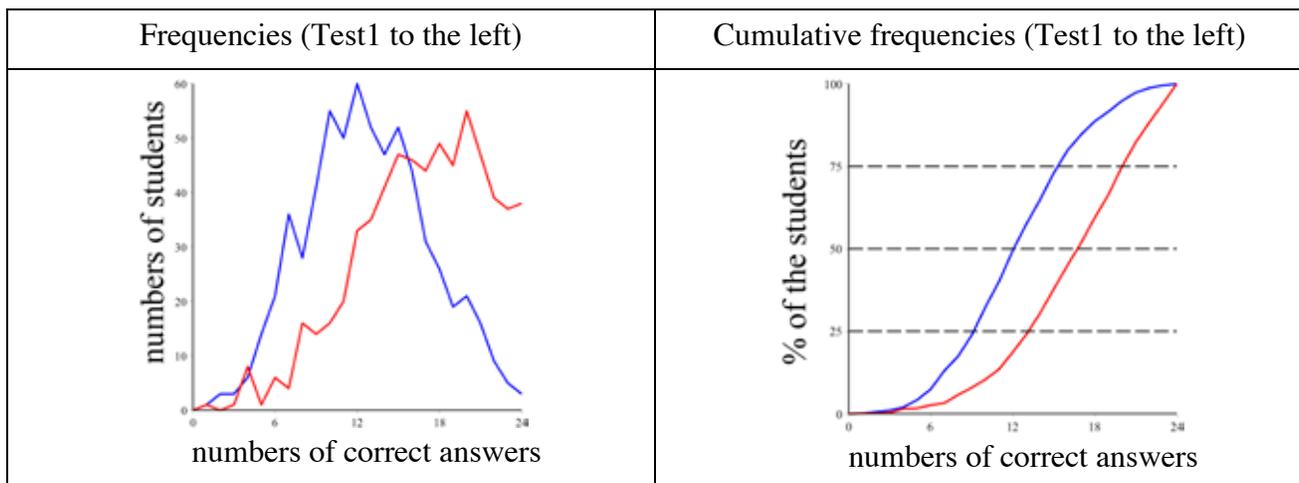

In 2012 we redesigned Math 1, so that it now opens with a four-week paper and pencil sub-course in complex numbers and simple complex functions. It includes precisely what is needed for linear algebra and the subsequent presentation of (systems of) linear differential equations in a frame of linear transformations between spaces of functions. But to be able to cope with complex numbers and functions the students need to deepen their understanding of (or learn for the first time!) a big range of pre-university topics from parenthesis, fractions and equations to

elementary real functions and differentiation rules. We claim that this method to enhance the basic skills is more motivating and efficient than a traditional and back-looking repair/brush up course in high school topics.

The **inquiry data** consists of the following components: 1) At the very first day of the math course the students were assigned a 30 minute test in real numbers and elementary real functions (Test1). 2) After the end of the four-week sub-course the students received the same 30 minute test with small parameter-changes (Test2). 3) One week after Test2 the students were asked to answer an electronic questionnaire (EQ) about their experiences of the four-week complex number course.

SOME RESULTS AND CONCLUSIONS

In Test1 the students had in average 12.7 correct answers out of 24 (simple) questions. This indicates a lack of basic skills. As a majority of the students were unsatisfied with their performance and at the same time a vast majority found it highly relevant for “a new-coming engineering student” to be able to answer the questions (EQ), we conclude that the new course design is a motivating factor. The figure below shows that there in general was a significant progress from Test1 to Test2. We underline that the students’ individual progress was very different.

USING “IRDO” MODEL TO IDENTIFY ERRORS MADE BY STUDENTS IN DIFFERENTIAL EQUATIONS EXAMS

Younes Karimi Fardinpour, Zahra Gooya

Shahid Beheshti University, Tehran, Iran

Y_Karimi@sbu.ac.ir

In this action research report, we investigated the errors made by students in their Differential Equations (DE) exams and classified them in order to develop a model that describes the causes of students' low scores as a result of those errors. Knowing the causes would help the lecturer to be more cautious about the roots of students' errors and it would also allow the researchers to help students overcome their errors and enhance their understanding about DE problems. This could improve students' abilities to perform better on their DE exams and develop their self-confidence too. In this study, four types of errors were identified as Identifying, Recalling, Doing and Overlooking (IRDO).

This paper reports on the results of a PhD study of the first author that has several phases. Here we report on the preliminary findings of the first phase of the pilot study. Literature review on teaching and learning of Differential Equations (DE) helped us to realize that teaching and learning of the DE goes much beyond memorizing a set of rules, algorithms, and procedures to solve a set of routine problems. For instance, the DEs could be studied through the use of graphical, numerical and contextual systems of representations as well.

Research studies have investigated the ways in which university students understand DE concepts and become skilful in solving related problems (Arslan, 2010; Camacho-Machín, Perdomo-Díaz & Santos-Trigo, 2012; Kwon, 2005, 2002). The research findings are useful for educators and researches in this field and help them to learn more about new approaches on teaching and learning of DE. However, students' performances in DE exams have not been the subject of much scrutiny. Specifically, students' errors in DE tasks and the causes of these errors have not been investigated so far. Thus, identifying and categorising the errors could help the educators to implement the appropriate teaching strategies that might be useful for students to improve their performances in DE problems.

This study aims to contribute in the categorisation of the errors in DE tasks. To do this, the study focused on students' exam papers. The authors, firstly, tried to understand the roots of the students' errors based on the evidences of their responses on the exam papers; then they categorised these errors accordingly; and, finally, they put together these categorisations in order to generalise into a model for identifying errors that students might make while dealing with DE tasks. For example, some students were not able to realize that $x(1-x)y'' + \frac{1}{2}(x+1)y' - \frac{1}{2}y = 0$ is not a

“Second Order Exact DE” and it is not a “Second Order Cauchy–Euler” either, but it is a “Second Order Homogeneous Linear Equations with non-Constant Coefficients” instead. When students study DEs, they need to learn to look at a DE and classify it into one of the above three groups. The reason is that the techniques for solving differential equations in each group are common within that group. Our study showed that the “Identifying” errors usually happen, when students fail to distinguish between different classifications of DEs; namely “First Order”, “Second Order”, “Linear vs. Non-linear”, “Homogeneous vs. Non-homogeneous”, etc. Further, “Identifying errors” happen when students are not able to identify specific kind of DEs such as “Separable”, “Exact”, “Bernoulli”, “Cauchy–Euler”, “Abel's formula”, “Riccati”, etc. Additionally, we named “Recalling” errors the cases in which students fail to use an easier solution techniques; “Doing” errors the usually mathematical errors when students work out a mathematical expression; and “Overviewing” errors when students do not pay attention on overviewing their work and identifying potential mistakes. These four types of errors comprise the elements of the IRDO (Identifying, Recalling, Doing, Overviewing) model of students’ errors in DE tasks.

Throughout the DE course that the first author taught, he witnessed the benefits of introducing the IRDO model to the class and using it to help students to improve their performance in the exams. Additionally the IRDO model enhanced the mathematical communication in class and allowed the lecturer to assist the students to have better control in the exam questions; to organize more efficient their work; and, consequently, to improve their exam scores.

INTRODUCTION TO THE PAPERS AND POSTERS OF WG15: TECHNOLOGIES AND RESOURCES IN MATHEMATICS EDUCATION

Jana Trgalová¹, Mirko Maracci², Giorgos Psycharis³, Hans-Georg Weigand⁴

¹University of Lyon 1, France, ²University of Pavia, Italy,

³University of Athens, Greece, ⁴Wuerzburg University, Germany

Technologies in mathematics education have been a topic of a working group since the CERME 1999. The last two conferences confirmed the relevance of considering information and communication technology (ICT) in mathematics education within a range of various resources, such as software, hand-held devices, online classroom activities, but also more traditional geometry tools or textbooks. A number of important issues related to the design of technologies and resources and their use by students, teachers and teacher educators emerged from discussions within the working group at the previous conferences, such as the importance of coping with a strong interconnectedness of mathematical and technological knowledge in student-tool interactions, or the necessity of including the users' feedback in the ICT and resource design processes (Trgalová, Fuglestad, Maracci, Weigand, 2011). Concerning teacher education questions appeared about the complexity of ICT and resource integration in teachers' practices due to a double instrumental genesis, both personal and professional one (Haspekian, 2011). The idea of teachers' communities, sharing resources and practices in using ICT, emerged as a powerful means to favour teachers' professional development (Wenger, 1998; Jaworski, 2005). These issues require further theoretical and methodological developments.

The call for contributions proposed to deepen these issues in the following three themes: (1) Design and use of technologies and resources, (2) students' learning with technologies and resources, and (3) technologies, resources and teachers' professional development. The group work combined plenary sessions where common issues were discussed, such as theoretical frameworks used in the field of ICT in math education or conceptualization of mathematics with ICT, and parallel sessions addressing various topics, such as software design, task design, teachers' professional development toward the ICT integration, or reports of empirical studies of ICT use. In what follows, we give a brief overview of the working group and the discussions within it, and we outline a few perspectives for the next conference.

WORKING GROUP IN A FEW NUMBERS

The group involved 44 participants from 15 countries: Brazil, Czech Republic, Denmark, France, Germany, Greece, Iceland, Ireland, Israel, Italy, Mexico, Norway, Sweden, Turkey, and United Kingdom. The 27 accepted papers and 6 posters were distributed according to the three themes as follows:

(1) Design and use of technologies and resources	4 papers	
(2) Students' learning with technologies and resources	13 papers	3 posters
(3) Technologies, resources and teachers' professional development	10 papers	3 posters

Table 1: Distribution of papers and posters in the three themes.

REPORT OF THE WORKING GROUP DISCUSSIONS

In spite of several attempts toward building an integrative theoretical framework allowing to address the issues of ICT in math education (e.g. EU project ReMath, Artigue & Mariotti, to appear), the discussions within the WG15 highlighted a *variety of theoretical approaches* used, such as constructionism (*Kynigos & Moustaki*), theory of didactic situations (*Joubert*), instrumental approach (*Misfeld*), variation theory (*Attorps et al.*). *Abboud-Blanchard & Vandebrouck* proposed a new theoretical frame for studying the teachers' professional development, which integrates some of these theories, and *Tabach* developed a general framework to describe instrumental orchestration. Necessity of networking of theories appeared as an issue. Suggestions on how to proceed were formulated: look at the same set of data with the lens of different frameworks or analyse a given instrumented task from different theoretical viewpoints.

Particular importance was given to *software* and *task design*. *Lagrange & Psycharis* explored the potential of a learning environment and *Mackrell et al.* designed tasks for a specific environment, both studies drawing on two complementary theoretical frames. *Libbrecht & Kortenkamp* highlighted the importance of metadata in the design of learning activities and *Libbrecht & Zimmermann* brought forward didactical design patterns that can impact software construction processes. *Pilet et al.* designed a piece of software allowing teachers to automatically generate exercises for differentiated instruction adapted to learning needs of various students' groups. Task design was explored by *Robová & Vondrová* in relation with the integration of netbooks in math classes. *Müller* proposed an instrument, drawn from history of mathematics, allowing to document changes in the type of tasks proposed in technology environment.

A number of contributions addressed the issue of *teacher professional development*. They described and analysed various means of teacher development, formal (e.g., *Akkoç; Santos-Trigo et al.; Sollervall*) or informal (*Trgalová & Jahn*), in presence (*Balgalmis et al., Dullius*) or on-line (*Fredriksen; Gravina et al.*). The efficiency of these different means need to be evaluated, and for this, specific methodologies have to be developed. The participants raised a need for a model allowing to analyze the evolution of teachers' practices related to the ICT use. *Clark-Wilson* identified perturbations when teachers use technology due to discontinuities within teachers' knowledge which she calls "hiccups".

Students' learning of mathematical concepts with specific software was discussed in numerous papers. Students' conceptualisation processes with dynamic geometry were explored by *Henning & Hoffkamp* (the concept of limit), *Kilic* (elementary geometry), *Kaya et al.* (transformational geometry) and *Pettersson* (linear functions). The use of CAS and handheld calculators was investigated by *Persson* (development of problem solving skills with TI-Nspire), *Rieß & Greefrath* (lower achieving students' learning of functions with CAS-calculator), *Storfossen* (primary school mathematics with graphic calculator) and *Grønbaek* (use of professional CAS to teach upper secondary mathematics). *Weigand* explored the interplay between mental, digital and paper representations in a CAS environment in tests and examinations.

A general issue of a ***capitalisation of research results*** was raised in the light of an important number of research studies on ICT in mathematic education. First steps toward this was done by *Bray* who provided an overview of recent technological interventions in mathematics education and examined the educational affordances of the technology, and *Scheffer* who proposed a survey of research conducted by undergraduate, master and doctoral students, aimed at promoting reflections about the ICT integration.

CONCLUDING REMARKS AND PERSPECTIVES

The papers and posters presented and discussed within the group show a big variety of research topics, theoretical and methodological approaches, which is undoubtedly a sign of a richness of this scientific domain. However, the feeling is that the research presented in these contributions is rather local, focusing on a particular aspect of teaching and/or learning mathematics, rather short-term, not allowing to draw general conclusions about the benefits of ICT in mathematics education, and quite often conducted in controlled, laboratory conditions.

Thus, the participants expressed a need to know more about the “real” use of ICT in mathematics classrooms and outside, but also why ICT is not used. Long-term studies focusing on “ordinary” teachers and “ordinary” classrooms are necessary to explore the impact of the ICT use on students' performances and on teachers' practices. Such studies require developing specific methodologies enabling to assess the effectiveness of ICT in learning processes.

Moreover, research working toward a definition of recommendations or guidelines for teachers suggesting how to use efficiently ICT is missing. For this, surveys of international comparative studies highlighting best practices with ICT use could/should be conducted.

Little or no studies focus on how mathematics as a school subject matter is impacted by the ICT use. We know since many years that computers can perform complex calculations and that educational software provides multiple representations offering reliable visualisations of mathematical concepts. But some “old” questions are still

CONCLUDING REMARKS AND PERSPECTIVES

The papers and posters presented and discussed within the group show a big variety of research topics, theoretical and methodological approaches, which is undoubtedly a sign of a richness of this scientific domain. However, the feeling is that the research presented in these contributions is rather local, focusing on a particular aspect of teaching and/or learning mathematics, rather short-term, not allowing to draw general conclusions about the benefits of ICT in mathematics education, and quite often conducted in controlled, laboratory conditions.

Thus, the participants expressed a need to know more about the “real” use of ICT in mathematics classrooms and outside, but also why ICT is not used. Long-term studies focusing on “ordinary” teachers and “ordinary” classrooms are necessary to explore the impact of the ICT use on students' performances and on teachers' practices. Such studies require developing specific methodologies enabling to assess the effectiveness of ICT in learning processes.

Moreover, research working toward a definition of recommendations or guidelines for teachers suggesting how to use efficiently ICT is missing. For this, surveys of international comparative studies highlighting best practices with ICT use could/should be conducted.

Little or no studies focus on how mathematics as a school subject matter is impacted by the ICT use. We know since many years that computers can perform complex calculations and that educational software provides multiple representations offering reliable visualisations of mathematical concepts. But some “old” questions are still

present and valid: Do we still need to teach and learn the same mathematics as before the rise of technology? How can we define the educational added value of ICT use for the learning of mathematics given the explosion of new tools and functionalities provided in technology-rich environments? How can we connect the mathematics embedded within particular ICT tools and curricular mathematics?

In addition, there are emerging research themes in education which are still underrepresented in CERME: the design and use of innovative technologies such as Web 2.0 or mobile technologies, or the design and use of technologies and resources for learners with special educational needs.

Clearly, these concerns could define a research agenda for the coming years. On a CERME working group scale, especially the following two tasks can be carried out:

- Working towards common understanding of theoretical constructs and research vocabulary used in various national contexts. This can be done for example by organizing during the sessions a group work on the analysis of concrete material (e.g. a task, an ICT tool, a set of data) from different theoretical perspectives;
- Working towards capitalising research outcomes, especially from previous technology working groups at CERME conferences. Each contribution to the working group should draw, when relevant, on the results of studies presented at previous conferences.

GENESES OF TECHNOLOGY USES: A THEORETICAL MODEL TO STUDY THE DEVELOPMENT OF TEACHERS' PRACTICES IN TECHNOLOGY ENVIRONMENTS

Maha Abboud-Blanchard, Fabrice Vandebrouck

LDAR, University Paris Diderot & UCP, France

This paper introduces and discusses a new frame aiming to describe and characterize the evolutions of teachers' practices related to technology uses. Articulating several theoretical developments of Activity Theory enables us to conceive a model to interpret the evolutions in terms of "geneses of technology uses". We consider these geneses as movements which articulate three levels of organization of practices related to the temporality of actions and to the goals/motives of the activity: a micro level, a local level and a macro level.

Research studying mathematics teachers' practices when using technology were very fruitful in the two last decades. Authors investigated this field by using diverse theoretical frames. In the European sphere, Monaghan used the Saxe cultural model (Monaghan, 2004) to study the emergent goals of teachers in ordinary technology-based lessons. Ruthven (2007) introduced five key components structuring the classroom practices in the context of technology uses. Drijvers et al. (2010) develops Trouche's concept of instrumental orchestrations (2004), by defining several type of orchestrations in the technology-rich mathematics classroom. Even if these studies have considered some evolutions in teachers' practices, they have not adopted a theoretical perspective to investigate it.

We conducted two studies of teachers practices, carried out on the long term. The main common issue of these studies was to observe the teacher's activity in classroom and its impact on the students' learning. At a methodological level, we have particularly analyzed students' tasks, teachers' options regarding these tasks and the corresponding management of students' work on these tasks. The first research (Abboud-Blanchard, Cazes & Vandebrouck 2007, Abboud-Blanchard & Cazes 2012) dealt with specific tools, called here Electronic Exercises Bases (EEB). These are software applications that mainly consist of classified exercises with an associated environment. The research provided a set of data about thirty teachers over 3 years. The analysis was both qualitative and quantitative, and related to: lessons preparations, class observations and answers to questionnaires and interviews. The second research (Abboud-Blanchard & Lenfant-Courblin 2009, Abboud-Blanchard et al. 2008) investigated the first professional uses of technology by pre-service mathematics teachers in order to understand the conditions in which these uses take place. The data was of two types: professional dissertations about using technology in classroom and interviews carried out with them at the end of their first year of teaching practice. The analysis enabled an exploration of the uses of technology in two phases of the teacher's work, which are preparation work and

classroom work. The analysis carried out within these two research studies led us to question the evolutions of teachers' practices and to conceptualize them by constructing a *model of geneses of technology uses*. This construct articulates several theoretical frames deriving from Activity Theory, mainly the instrumental approach and the double approach of teachers' practices. The aim of this paper is not to provide a detailed presentation of our studies but rather to introduce our model and to show how it can give meaning to the observed evolutions.

In the first section, we present the fundamentals of our frame starting from elements related to Activity Theory (AT). We introduce "geneses of technology uses" as movements which articulate three levels of organization of practices. In sections 2 and 3, we describe these movements between the levels and give examples to illustrate our purpose.

THEORETICAL CONSIDERATIONS

Activity Theory takes the object-oriented-artifact-mediated-collective activity system as its unit of analysis, thus bridging the gulf between the individual subject and the societal structure (Engestrom, 1999). In this paper, AT enables us to study mathematics teachers' technology uses, by considering the unit of the context of the teaching activity, while being particularly sensitive to the mediations between the subjects (teachers) and the object of their activity (the students and their mathematical work). However, we address AT from a cognitive individual perspective, taking into account the context surrounding the teacher's activity.

More precisely, we use the concepts of AT in the context of French research, as developed within the field of ergonomic psychology (*i.e.* cognitive ergonomics) (Leplat 1997). This development highlighted the fundamental distinctions between, on the one hand, subject and situation and on the other hand, task and activity. Within this French approach, the activity of the subject is indeed developed in situ. The task corresponds to the goal the subject must achieve, taking into account a double system of determinants which relate to the subject or the situation. The development of AT within cognitive ergonomics research brought Verillon and Rabardel (1995) to introduce the Instrumental Approach (IA) which distinguishes artifact and instrument, the artifact being on the situation's side and the instrument on the subject's side. IA consists, for a given subject, in a process (instrumental genesis) of appropriation and transformation of a given artifact, in order to accomplish a given task, within a variety of context uses and a same class of situations. IA was then developed in the field of French mathematics education by Artigue (2002), Guin and Trouche (2002) and Lagrange (2005).

In our work, we articulate the cognitive individual perspective of AT with the cognitive aspects of the ergonomic approach. This allows introducing a developmental approach not specifically highlighted in the AT, which enables us to characterize the evolutions of teachers' technology uses that we call *geneses of*

technology uses. In particular, we consider that geneses of technology uses *encompass* instrumental genesis of specific artifacts. Indeed, the instrumental approach, applied to the teacher, does not deal with the practices as a whole. It does not take into account the context surrounding the teaching activity, neither the connection between teachers' instrumental geneses and students' activities, which are key elements that we aim to investigate in our work. This fact leads us to articulate the above concepts of AT with the double didactic and ergonomic approach of the teaching practices (Robert and Rogalski 2005, Robert 2012).

The double approach adapts AT to the teaching of mathematics in school situation. It aims at the study of the teacher's practices starting from the study of various forms of his/her activity in class and for the class. It introduces five components of teaching practices. The didactical components, cognitive and mediative, translate recurring choices in the activity of teachers that are related to the activity of students. The cognitive component translates choices related to the design and organization of tasks for the students. The mediative component translates choices during sessions related to the management of students' work on the tasks and interactions through verbal communication. The ergonomic components complete the former and are related to the professional context of teaching. Personal, institutional and social components respectively translate the personal (beliefs, knowledge and experience) determinants and the determinants related to the teaching situation (social constraints, curricula...).

The double approach postulates the stability of practices. This stability is, at the same time, a postulate, in the double approach, and a result of a set of research work relating to the teaching practices, with or without technology (see for example Vandebrouck (ed.) 2008). In our study, we consider that AT takes into account, in a global way, for the study of the geneses of technology uses, the complex articulation between stability of practices and evolutions of the activity in situ.

To achieve a degree of stability concerning the evolutions of the activity, we introduce three levels of organization of practices (Abboud-Blanchard & Vandebrouck 2012). These levels are related on the one hand to the temporality of the action and on the other hand to the goal/motives of the activity:

- The micro level is about "automatisms", for example elementary gestures of the teacher for the preparation of lessons' management. One can bring this micro level closer to the short-term of the action and the level of the operations within the AT (Galperine 1966, Léontiev 1978). However, the construction of the micro level of teaching practices (constitution of the actions' schemes or the operations' schemes (Vergnaud, 1982) can be done only over the long-term of the action.
- The local level refers to everyday actions, where co-exist preparations and improvisations; the level of the adaptation of the teacher to the students' work.

The goals of the teacher's activity are basically related here to management's issues and to teacher-students interactions. Studying this level allows to better understand what precise activities the students could have developed, related to the task, the teacher's discourse and help and also the nature of the students' work.

- The global level refers to scenarios, preparations, assessments... It can be reached by studying the motives of the teacher's planning of his/her teaching project. Some of these motives may explicitly occur after a reflective view on the action already accomplished.

We consider that a teacher who begins using a technological tool does not have sufficient "automatisms" and routines related to this use, neither a holistic view on the organization of a coherent teaching approach that integrates this tool. In response to this unfamiliar "overload situation" at the local level, several phenomena would take place:

Figure 1: the three phenomena modelizing the geneses of technology uses

- a first phenomenon reflects the way that the teacher makes use of his/her 'traditional' paper-and-pencil practices for the context of technology uses: the micro level of practices supporting the local level. We describe this phenomenon in the second section;
- two other phenomena are involved in the geneses of technology uses. We interpret these as « *movements* » going from the local level of practices towards both the global level and the micro level. We describe in the third section these movements and their articulation with the IA.

FROM THE MICRO LEVEL TO THE LOCAL LEVEL

A teacher's first session in the classroom using a new tool reveals phenomena that lead the teacher to manage his/her session at the local level within an « improvisation mode ». Even if the session is well-prepared, some difficulties occur that relate to classroom management. It seems that the teacher bases his/her management on his/her traditional practice, which allows him/her to better deal with the technology session at the local level. In other words, it seems that the automatic regulation of

teaching practice at the micro level allows the teacher to cope with difficulties emerging during the technology based session at the local level.

For instance, a teacher using EEB provides different help to her students depending on whether they are more or less in difficulty. She gives more procedural help if the student is really in trouble (reinforcing one method) and she provides more constructive help (giving other possible methods...) if the student is more comfortable with the task - Robert (2012) distinguishes teachers' procedural and constructive help for the students: procedural help allows students to perform their mathematical tasks and a constructive help promotes more directly the students' constructive activity. However, during the interview post-observation, it appears that the teacher is not aware of this differentiated practice. This can be related to a characteristic of the mediative component of her practice.

Nevertheless, the use of such micro level of "automatisms" does not ensure efficiency at the local level. For instance, a teacher gives the same individual help to each student, as he does usually during traditional setting with the whole class group, considering that students may be at the same level of task resolution. Therefore some students do not succeed to overcome their difficulties even after the teacher's help. Indeed this help is not adapted to their personal resolution trajectory. For other students, the teacher answers questions they have not yet asked.

Thus, faced with difficulties at the local level, some teachers feel the need to build new specific practices with technology, while others tend to reduce the role of technology within their teaching. As an example of this last case, the students of a beginning teacher had not understood the task during a technology based session. The teacher realizes only at the end of the session that the students were really in trouble with the technological aspects of the task. This observation led her to give a posteriori explanation, during a traditional session, in order to be sure that the task is correctly understood by students, without although considering changes of the technological aspects of the task.

MOVEMENTS STARTING FROM THE LOCAL LEVEL

The phenomenon described in the previous section concerns teachers performing classroom activities in order to manage the classroom on the short term; whereas geneses of technology uses are mainly related to developments at the medium and long-term of the action. Our analysis reveals an evolution of the whole teaching project, including the uses of technologies, starting from their uses at the local level. We interpret this evolution as a movement from the local level of practices to the global level. In parallel, there is a development of technology uses at the micro level entailed by frequent uses at the local level.

Towards the global level

The main movement seems to be an evolution of scenarios. It concerns what we might call, referring to the double approach, the cognitive component of the geneses of use. There is a new balance between traditional sessions and technology sessions, between collective work and individual phases of students' activity or between old and new mathematical knowledge in students' activity.

As an illustration of this type of evolutions, we note that all our studies mentioned above emphasize that teachers promote quickly the use of 'paper notes' within the students' activity involving technology. For instance, teachers using EEB insist that students use a sheet to keep notes and some of them promote use of a specific notebook devoted to technology sessions. This use of paper evidences is an aspect of the integration at the long-term of technology activity within ordinary activities of students.

Another aspect of this movement is the fact that some teachers evolve towards a systematic implementation of collective moments such as phases of institutionalization at the end of technology sessions. When observed, these collective phases are often based on the use by the teacher of students' written notes. This observation shows particularly the articulation with the above evolution and the relative complexity of the movement. However, the nature of the technological tool or the kind of technology session can lead in some cases to opposite phenomena. For instance, we observe the complete absence of such phases at the end of training sessions with EEB. These sessions seem to be too individualized and too heterogeneous to permit such collective moments.

This movement, from local to global level, explains some difficulties for the integration of technology within ordinary practices as a consequence of the stability of practices. Indeed, for some teachers, established practices at the global level are incompatible with such a development of practices.

Towards the micro level

In this paragraph, we deal with the development of technology uses at the micro level, starting from their uses at the local level of practices. This development is particularly related to teachers' instrumental genesis of specific artifacts. Indeed, the identification of schemes of uses which characterize instrumental geneses is related to both the micro level and the local level of practices, i.e. during the process, the teachers builds operations schemes of use of the artifact as well as actions schemes. However, in the model we provide, the identification of schemes is not a central issue. We rather examine the evolution of technology uses through the lens of teachers' practices dealing with students' activities. Moreover, Abboud-Blanchard and Lagrange (2006) have shown that there exist two dimensions in instrumental genesis of teachers: the personal dimension and the professional dimension.

Understanding geneses of technology uses as a whole, needs to consider these two dimensions.

Personal instrumental genesis concerns teachers' activity with technology for their personal uses, as well as for teaching preparation. For instance, a beginning teacher was meeting dynamic geometry for the first time. Starting from a position of apprehension ("*it is something that scared me*"), she firstly evolved with the development of some practices related to the preparation phase. She used dynamic geometry to draw geometric figures to be integrated in students' worksheets. Then, she developed some practices in which she feels confident without however really reflect on the educational aspects of practices with this technology: a whole class video projection, where students are simple spectators of "technological images".

Professional instrumental genesis concerns both the personal appropriation by the teacher of the software in order to be efficient when using it with students and the actual use in classroom. For instance, an experimented teacher using EEB for the second year, has felt the need to master all the functionalities of this technological tool in order to be able to better adapt his assistance to students for each given exercise. He developed three types of actions to manage the students' activity in computer room. When he arrives to help a student, he first tries to understand the path of the student by questioning him/her, secondly he provides the appropriate help and finally he gives advices enabling the student to pursue his work without the presence of the teacher.

In both these cases, what teachers experienced at the local level, led them to develop micro actions which might enrich their routines when using technologies. Moreover, such development sometimes goes further and impact traditional practices involving both mathematical tasks and classroom management. For instance, a teacher who uses spreadsheet in both private and professional sphere on regular bases has improved her way of introducing algebra. She built new tasks, not necessarily using spreadsheet but although inspired by her instrumentation of spreadsheet. In addition, when performing algebraic tasks, she authorizes students to have tinkering procedures as they would have done with the spreadsheet.

DISCUSSION

The frame that we presented in this paper aims to describe and characterize the evolutions of teachers' practices in their connections with students' activity. The instrumental approach, applied to the teacher, goes also in this direction but does not however deal with the practices as a whole (as we explained above).

We think that our model can better grasp the complexity of the emergence in situ and evolution at the middle and long term of teachers' practices related to technology-based mathematics lessons. It articulates three levels of the organization of practices, and it opens to new meaning for these complexity and evolution. The variety and multiplicity of uses at the local level leads to:

- developments at the global level, mainly evolutions of teaching projects and scenarios, which go beyond the instrumental geneses of specific artifacts;
- developments at the micro level, i.e. the teacher developing new “automatisms” related to the use of technology in the classroom. These automatisms concern of course the schemes of uses of specific artifacts but can also concern other types of automatisms about mathematics tasks or class management.

Moreover, the model also leads to new meaning for the somehow observed stability of practices in technology based environments. Indeed, the stability of teaching practices seems to result in “automatisms” at the micro level scaffolding the local daily practices. It seems to prevent some teachers who have difficulties to manage technology sessions at a local level from creating new “automatisms” specific to technology at the micro level or seeking to change globally their practices. The micro level of ordinary practices (not involving technology) could thus act as a barrier to the integration of new tools.

In the double approach, the stability of practices is based theoretically on the consistency between the five components of practices: cognitive, mediative, personal, institutional and social. In our studies we have identified geneses of technology uses related mainly to cognitive (tasks and scenarios) and meditative components (class management) of teachers’ practices. We also investigated the determinants of these geneses, related to personal, social and institutional components (Abboud-Blanchard & Vandebrouck, 2012). In this short paper, we chose only to consider the geneses of technology uses through the lens of the two didactical components, in order to better exemplify the dynamic phenomena between the three levels of practices, in the “real technology-classroom life”.

Finally, the model draws originally on features of the double approach of practices, yet it enriches this general frame by adding a dynamic modeling of the practices’ development. Hence, we wonder if it can be generalized to the evolution of any given practice (not specifically addressing technology uses).

PRE-SERVICE MATHEMATICS TEACHERS' PRACTICE OF QUESTIONING IN COMPUTER LEARNING ENVIRONMENTS¹

Hatice Akkoç

Marmara University, TURKEY

This paper focuses on a specific aspect of formative assessment, namely questioning. Given that computers have gained widespread use in learning and teaching, specific attention should be made when organising formative assessment in computer learning environments (CLE's). A course was designed aiming to develop knowledge and skills of questioning in CLE's for the purpose of formative assessment. This case study investigates how a pre-service mathematics teacher used questioning in the classroom to introduce the derivative concept using Geogebra and Graphic Calculus software. The findings indicated that the course provided a guideline for pre-service mathematics teachers in planning and using effective questioning in CLE's.

INTRODUCTION

Assessment plays an integral role in teaching. However, as Heritage (2007) point out, assessment and teaching have been traditionally seen as reciprocal activities as a result of measurement concerns such as high-stakes accountability of testing. Many researchers mention that good practice yields from a recognition of both summative and formative purposes of assessment and use them accordingly (Dwyer, 1998).

Despite its importance for learning and teaching, assessment has not been a main focus of teacher training courses. Furthermore, administrators “also lack training in assessment and therefore do not have the skills to support the development of assessment competencies” (Heritage, 2007, p. 4). Dwyer (1998) mentions that, courses on evaluation of learning have been disappearing from teacher education programs. However, she claims that it is well understood by experienced teachers and assessment is well targeted in many professional development programmes for in-service teachers (Danielson, 1996 as cited in Dwyer, 1998).

Given that computers have gained widespread use in learning and teaching, specific attention should be made when organising assessment in computer learning environments (CLE's). A successful integration of technology into instruction requires an integration of technology into assessment. On the other hand, there is little research on how to organise assessment as an integral part of teaching in computer learning environments (Kissane *et al.*, 1996).

Considering the need to incorporate assessment component into pre-service teacher education programs and the importance of integration of technology into instruction as suggested by the relevant literature, we designed a course for pre-service

¹ This study is part of a project (#107K531) funded by TUBITAK (The Scientific and Technological Research Council of Turkey).

mathematics teachers, which aims to develop their assessment skills as a component of TPCK. This paper focuses on how a pre-service teacher developed the knowledge and skills of formative assessment in computer learning environments. Particular attention is given to questioning which occur during classroom assessment.

THEORETICAL FRAMEWORK

In teacher education research, assessment has been considered as an important component of teachers' knowledge of pedagogy. After Shulman (1986) suggested pedagogical content knowledge (PCK) as a separate domain of teacher knowledge, many researchers such as Tamir (1988) defined assessment as a component of PCK. Pierson (1999) and Mishra & Koehler (2006) has added the technology component to PCK framework and defined Technological Pedagogical Content Knowledge (TPCK) framework. Although, in the literature, the components of the TPCK framework have been defined as parallel to the components of PCK framework, assessment as a component of TPCK has not been sufficiently dealt with.

The theoretical perspective of this study is situated within the distinction between summative and formative purposes of assessment. Summative assessment is used for the purpose of grading or certifying students. On the other hand, formative assessment intends "to monitor student progress during instruction to identify the students' learning successes and failures so that adjustments in instruction and learning can be made" (Gronlund, 2006, p. 6). There is research evidence of the extraordinary effectiveness of formative assessment (Black & Wiliam, 1998). Despite its importance, most pre-service teachers use assessment for summative purposes while a minority uses for formative purposes (Volante & Fazio, 2007). There are various aspects of formative assessment: uses of tests to diagnose what students have already known or using the evaluation of homework in decision making for the next lesson and classroom assessment which occurs in the classroom on a daily basis. Among those, researchers point out classroom assessment as an area of difficulty which is encountered by pre-service teachers (Mavrommatis, 1997).

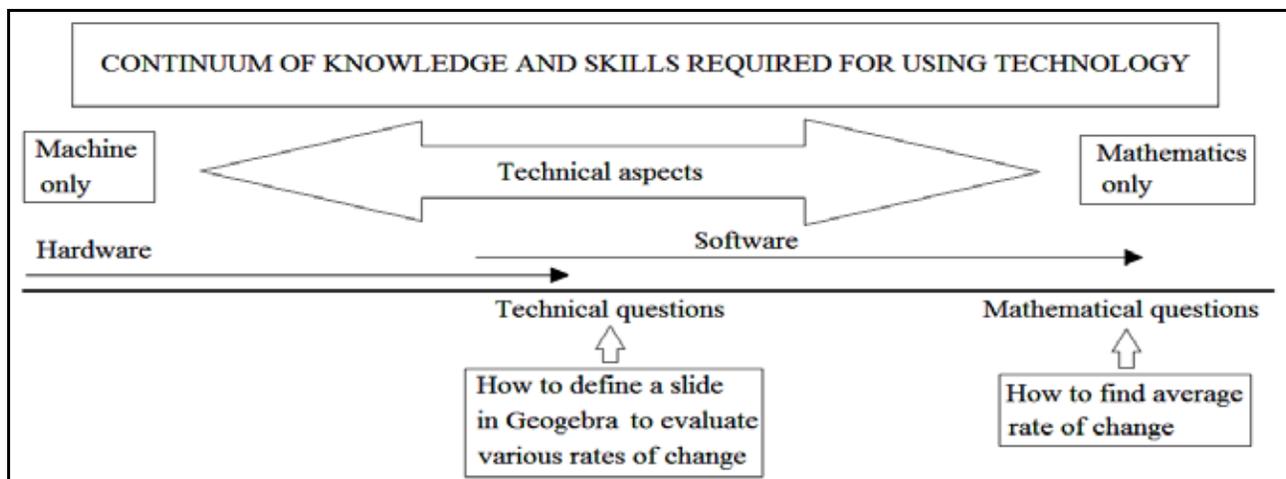

Classroom assessment refers to the processes of collecting information and making interpretations and decisions based on this information on a daily basis in order to improve teaching and learning (Airasian, 1991 as cited in Mavrommatis, 1997). In that process, questioning is an important information-gathering technique by which teachers can monitor student learning. Airasian & Jones (1993) claim that pre-service teachers are not given adequate training in developing questioning strategies and, indeed, that some receive no training at all. Therefore, questioning that can facilitate formative assessment for the purpose of learning should receive more attention in the preparation of teachers.

Given that computers have gained widespread use in learning and teaching, specific attention should be made to questioning in CLE's. Therefore, this study focuses on the design of a course aiming to develop knowledge and skills of questioning in

CLE's for the purpose of formative assessment. To analyse pre-service teachers' questioning, Pierce & Stacey's (2004) framework is adopted. Their framework identifies the main characteristics of students' interactions with CAS technology. They specify aspects of effective use of CAS which they suggest to adopt to other mathematical software tools. Using a CAS in particular or any other software in general to do mathematics requires both traditional mathematical knowledge (which could be constructed through the use of paper and pencil methods as part of a lesson in CLE) and knowledge of the machine. These two requires a constant interplay which Pierce & Stacey (2004) defined as *technical aspect* of effective use of technology which could be described as the knowledge and skills related to the software rather than the hardware of the machine. It is where mathematics meets machine (e.g. fluent use of software syntax, ability to systematically change representation or interpreting the software output) as mentioned by Pierce & Stacey (2004).

In the framework, two types of questions will be distinguished. The first is *mathematical questions* which aim to assess what Pierce & Stacey (2004) call traditional mathematical knowledge. The second will be called *technical questions* which attend to technical aspects of using technology. Although questions in this category seem to focus on what the software perform, there is a constant interplay of mathematical knowledge and knowledge about the technology (See Figure 1).

Figure 1: Continuum of knowledge and skills required for using questioning in CLE's

The aim of this paper is to explore what kinds of issues come into question in CLE's in terms of questioning for formative purposes. In this respect we formulate the following research question: "How do pre-service mathematics teachers use mathematical and technical questions for formative purposes in CLE's?"

COURSE DESIGN

In a wider context, this study is part of a research project for which we designed a course guided by TPCK framework. In this paper, the description of the course is restricted to its assessment component. An eight-hour workshop was conducted on

assessment. During the first phase, which we call PCK workshop, general information on assessment, its integral relationship with learning and teaching, and examples of summative and formative assessment was given. This is followed by activities during which forty pre-service teachers worked in groups. In the first activity, pre-service teachers were asked to specify objectives of a lesson which introduces the concepts such as function and derivative. They presented their objectives to their peers and discussed each group's objectives in an interactive way. For the second activity, they designed lesson activities to achieve their objectives. As they began to structure their activities, they were asked to prepare questions to provoke student thinking for the purpose of attaining their lesson objectives. The aims of such questioning in a lesson were explained in relation to classroom assessment for formative purposes. At the next phase, which we call technological knowledge (TK) workshop, pre-service teachers learnt how to use computer software and did hands-on-activities in a computer lab in groups of twenty. They used Graphic Calculus, Geogebra, Probability Explorer, Excel and Cabri Geometry software. This phase focused on the technical knowledge of the software. The last phase, which we call TPCCK workshop, focused on the pedagogy of using technology with specific attention given to the assessment component. Focusing on the content, that is function and derivative, pre-service teachers were asked to re-consider their lesson activities and how to attend to assessment of their lessons. They also practiced various computer based assessment tools such as dynamic worksheets of Geogebra and Inspiration software for making concept maps. During this phase, we focused on the following questions with regard to assessment in general and questioning in computer learning environments in particular:

- How would assessment and evaluation techniques/tools change when concepts such as function and derivative are taught using technological tools?
- How can technology be used for summative/formative assessment to achieve lesson objectives which you specified for the lessons for function and derivative concepts?

Questions above were discussed with pre-service teachers during the workshops considering a specific lesson objective as shown below:

Let us consider the following lesson objective:

- Students will be able to express derivative at a point as instantaneous rate of change.

To assess whether this objective is achieved by students, ask questions with the following purposes:

- What kinds of questions could be asked during a lesson in CLE's for summative/formative purposes to promote thinking in accordance with lesson objectives?

Table 1: Points of discussion concerning questioning during the workshop

Following this, workshops focused on classroom assessment in CLE's and how to evaluate students' understanding when they use technology. We emphasised that the nature of probing questions will be changed as a result of change of media in the classroom. Pre-service teachers were encouraged to ask questions on what were performed by the software and their mathematical meanings to promote purposeful use of technology.

METHODOLOGY AND CONTEXT OF THE STUDY

This study is part of a research project which aims to develop a programme for pre-service mathematics teachers guided by TPCCK framework. The research has been carried out in a mathematics teacher education program in a state university in Istanbul, Turkey.

Following the TPCCK workshop which was explained in detail above, pre-service teachers were asked to prepare lesson plans which introduced the concepts of function and derivative at a point as the first part of the program. In these lesson plans, they were also asked to explain what kinds of assessment they plan for their lessons. Ten pre-service teachers taught these lessons as part of micro-teaching activities and discussed their assessment approaches with their peers. This way, pre-service teachers had the chance to put their knowledge of assessment into practice. In the second part of the program, pre-service teachers planned and conducted their own workshops of TPCCK on various mathematical concepts such as limit, continuity, integral, probability and radian and did micro-teaching activities.

For the current exploratory study, a case study was conducted to investigate a pre-service mathematics teacher's practice of questioning for the purpose of formative assessment in CLE's. The pre-service teacher, Güven, is male and twenty-two years old. He completed mathematics courses which lasted for three and a half years and started to take education and mathematics education courses. The data was collected during "Mathematics Teaching Methods II" and "Instructional Technologies and Material Development" course. Pre-service teachers participated in the program were asked to prepare a lesson plan with detailed teaching notes to introduce the concepts of function and derivative and they were interviewed on their lesson preparations. Semi-structured interviews, which included a section on how assessment is planned, were conducted. In addition to that, pre-service teacher's lesson and his reflections at the end of the lesson were video-taped. This paper focuses on the analysis of Güven's lesson plan, verbatim transcripts of his interview on the preparation of his lesson plan, and video of his micro-teaching lesson on derivative.

FINDINGS

In this section, findings will be presented in two sub-sections. The first sub-section focuses on how Güven planned to use questioning for formative purposes in his second lesson plan on derivative at a point which he prepared after the TPCCK

workshop. In the second sub-section, findings from the analysis of Güven's lesson will be presented with excerpts demonstrating his questioning in the classroom.

Güven's planning for questioning

Güven included the following problem in his lesson plan to start his lesson:

Engineers who design car templates are working on the highest velocity that the template is going to reach after two seconds. They evaluated the distance during the first five minutes and they represent it with the function $f(x) = x^2$.

During the interview, he mentioned that he chose this problem to create a cognitive disequilibrium. He also added that he would use a lot questioning to start a discussion on the problem in the classroom.

Güven's lesson plan draft included two sub-sections on assessment: assessment during the lesson and assessment at the end of the lesson. Güven wrote a few questions to be asked during the lesson for two different purposes: diagnostic purposes and formative purposes. For formative purposes, he mentioned that he would check whether students (that is their peers) had learnt what he intended to teach using these questions. Some of these questions in his plan were specific to the software he used, namely Geogebra and Graphic Calculus. One example of these is the following: "How does Graphic Calculus calculate the values for rate of change? Find one of these values with paper and pencil". During the interview he said the following:

Güven: The formative questions that I prepared were related to the activities that were performed on the computer. Students (his peers) performed these activities by looking at the computer and making calculations.

As can be seen from the question in his lesson plan and excerpts above, Güven purposefully planned for formative assessment. The question above can be considered as a technical question since it requires both the knowledge of how to evaluate the values of rates of change and the knowledge of the software.

Güven's practice of questioning

In practice, Güven used a lot of questioning for formative purposes during his micro-teaching lesson which he taught to his peers. Below, a detailed account of his questioning approach during his lesson is presented. Strength and weaknesses of his pedagogical approach to using mathematical and technical questioning will be discussed below.

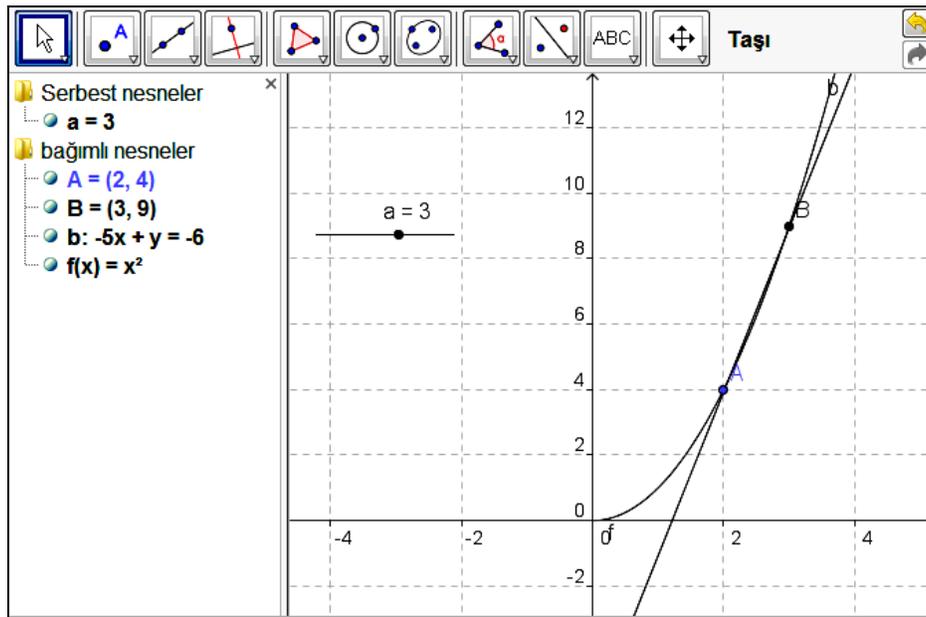

In the computer lab his peers were in front of the computers in pairs. Güven started his lesson with the problem above. After asking questions about velocity and instantaneous velocity to assess their prior knowledge, Güven asked his peers to find the average velocity in the first two seconds which is $[f(2)-f(0)]/(2-0)=2$. Following this mathematical question, he asked how to represent the average velocity using

Geogebra software which is a technical question. At this point, it should be mentioned that this question can be either solved graphically (finding the slope of the tangent line in the equation of the tangent) or numerically using spreadsheet view. Instead of letting his peers to chose the representation to find the average velocity, he preferred to explain it on the graph using Geogebra. He then asked how to represent the average value on the graph by plotting two points on the graph which is again a technical question:

Güven: Did we specify two points, both (2,4) and (0,0). Are these, change in y divided by change in x ? Let us check it again using Geogebra. But how?

He then mentioned that he would define rate of change using "slide" feature of Geogebra. Although he asked technical questions about how to do it, he immediately demonstrated it in a step by step manner without waiting for the class to do it in front of their own computers.

Figure 2: Geogebra activity used by Güven to explain graphical meaning of derivative

After obtaining the graph as shown in Figure 2 above, he asked the following questions to help his peers discover the relationship between average velocity and the slope of the chord:

Güven: What else can velocity between A and B be equal to? Let's think about it on the graph. Let's draw a chord from A to B . What would velocity be equal to in terms of the chord?

Student: Rate of change, slope

Güven: Well, we can draw a straight line through two points using Geogebra.

After that point he went back to the problem he asked in the beginning of the lesson and asked his peers to find the highest velocity in the first two seconds:

- Güven: We chose two points for the average velocity. How can we find the velocity at a point? For instance, let's move your slide in Geogebra.
- Student: We can't find it. It becomes undefined.
- Güven: How did you choose the points to approach? Where does the point A approach to?
- Student: To the point B .
- Güven: When the points are on B it's undefined. Let's see it on the table.

As can be seen from the excerpts above, Güven asked questions to help his peers find the instantaneous velocity and told them to move the slide. In other words, using the slide feature of the software he wanted them to interpret the outcomes of the software and find instantaneous velocity. Therefore, his questions above can be considered as technical questions where the slide feature of Geogebra interplays with the knowledge of instantaneous velocity.

After that point, he focused on the table as well graph to explain the instantaneous velocity. To do that, he used the spreadsheet view of Geogebra and evaluated $\Delta y/\Delta x$ and asked his peers to interpret different values obtained on the table by moving the slide:

- Güven: (Pointing out slide a). Is "a" at 0? Let's trace this point on the slide and see what happens in the table. What happened now? Let's interpret these values (He moved around the class, observed what everybody did in front of their computers and helped them when they needed).
- Student: When does the point A approach to the point B, it's $\Delta y/\Delta x$
- Güven: Well, what would be the velocity of the car template at 2? What is your guess?

As can be seen from the excerpts above, Güven used technical questions which focus on the outcomes on the screen and promotes an understanding of instantaneous velocity. After getting the answer for instantaneous velocity, Güven went back to the geometrical meaning of it and asked his peers to find out where the chord approaches to. After getting "tangent" as the answer, he focused on the relationship between velocity and tangent with the following question:

- Güven: Fatih, could you find a relationship between the velocity at the 2nd second and the tangent? I'm asking this question to everybody.

After that, he used the properties of the slide in Geogebra to get closer points by changing the increment from 1 to 0.1:

- Güven: It becomes 3.99. OK. Is this enough for you?...Can we get closer values?

After that, Güven asked his peers to start Graphic Calculus software and to find out how the software calculate the rate of change ($\Delta y/\Delta x$) for smaller Δx . Some of the pre-service teachers mentioned that it approached to 4 when Δx is very small.

Güven: 0.0001 and this gives us 4. Can the slope be equal to 4?

Student: It can't be.

At this point he mentioned about the limitations of the software and that the slope of the chord can never be equal to 4 but the software makes an approximation. He then questioned the idea of limit and explained the mathematical definition of derivative at a point. To do that, Güven asked questions to promote an intuitive understanding of limit using the software and moved to the mathematical definition of derivative as the limit of rates of change.

DISCUSSION

Findings above indicated some strength and weaknesses of the pre-service teacher in integrating technology into his formative assessment practice. Güven was successful at asking technical questions which have two purposes. First of all, he focused on technical aspects and how the software perform certain tasks e.g. how to get smaller values of rate of change using the slide feature of Geogebra. Second, Güven used these questions to focus on the mathematical meaning behind what is observed on the computer screen e.g. the rate of change being 3.99 as the increment of the slide becomes 0.1, in other words, the idea of limit. At this point, Güven used a lot questions to promote an intuitive understanding of limit and its relationship with instantaneous velocity. In that sense, it can be claimed that his technical questions successfully focused on the interaction between technical and mathematical aspects. More importantly, interview data indicated his awareness of using the technical questions to promote an understanding of derivative.

Although Güven used extensive questioning during his lesson, he had some pedagogical weaknesses. For example, he did not give enough time to his peers to interpret the outcomes of the software and discover mathematical ideas. He performed some of the tasks by himself in a step by step manner which might yield to loosing the purpose of the task and dismiss the potential interplay between technical and mathematical aspects.

The study had some implications concerning the courses designed for pre-service mathematics teachers. As mentioned in the literature, assessment in general and assessment in CLE's in particular have not been a main focus of teacher training courses (Dywer, 1998; Heritage, 2007). This study aimed to help pre-service teachers equip with the required knowledge of formative assessment in CLE's. The workshops focused on how to use questions during a lesson in CLE's and pre-service teachers were encouraged to ask questions on what were performed by the software and their mathematical meanings to promote purposeful use of technology. The

workshop was effective in the sense that it provided a guideline for pre-service teachers to use questioning in CLE's.

This study has also implications at a theoretical level. Theoretical framework adapted from Pierce & Stacey (2004) provided a theoretical lens to analyse questioning practice for formative purposes in CLE's. For a further study, this framework could also be used to guide the programs for pre-service or in-service teachers in terms of how to use questioning in CLE's.

TEACHING INVERSE FUNCTIONS AT TERTIARY LEVEL

Iiris Attorps, Kjell Björk, Mirko Radic and Olov Viirman

University of Gävle, Sweden

This study is a part of an ongoing research that attempts to explain the relationship between the teachers' instructional practise and students' learning in the context of functions and function inverses. The question in this paper is how the use of technology as a pedagogical tool may contribute to the understanding of the inverse function concept. An engineering student group ($n = 17$) was taught functions and inverse functions with the assistance of GeoGebra. In our theoretical framework we apply Variation theory together with the theory of Concept image and Concept definition. The data were gathered by doing a pre and post test concerning inverse functions. Our experiment revealed that students' concept images in the post test were more developed compared with the results in the pre test.

Keywords: Concept definition, Concept image, Inverse functions, Technology, Variation theory

INTRODUCTION

The function concept is a central but difficult topic in mathematics and therefore it has received considerable attention in mathematics education (Akkus, Hand & Seymour, 2008; Ponce, 2007). Strong understanding of the concept of function is crucial for any student hoping to understand calculus, which is a critical course for the prospective teachers, engineers, and mathematicians.

Functions have different faces, and to make students aware of that is a pedagogical challenge for teachers in mathematics. A number of studies have been conducted concerning students' understanding of the functions at the tertiary level, confirming a frequent inconsistency in students' conceptions of function and the definition of function (e.g., Thomas, 2003; Thompson, 1994; Vinner & Dreyfus, 1989). Vinner and Dreyfus (1989) conducted one study, showing that tertiary students during a course in calculus, even when the students were able to correctly formulate the definition of function, could not apply the definition of function successfully.

Even (1992) conducted an investigation of prospective secondary math teachers' understanding of inverse functions. She found that many students conceptualized a function inverse using the notion of 'undoing'. "Undoing' is an informal meaning of inverse function which captures the essence of the definition" (ibid., p. 557).

Bayazit and Gray (2004) investigated student learning of function inverses from two teachers, Ahmet and Mehmet. Ahmet focused his instruction on the idea of inverse "undoing" operations, whereas Mehmet on algorithmic and procedural skills (Bayazit & Gray, 2004). Students were given pre test and post test to evaluate their understanding about inverse functions before and after the classroom instruction.

Results from the post test indicated that more students from the class of Ahmet were able to answer a question regarding the domain and range of inverse functions correctly using verbal explanation. In Ahmet's class 25% of the students chose to take a global approach in reflecting the function across the line $y = x$, while no students in Mehmet's class used this method. The authors conclude that in order to grasp the concept of inverse function, students would be given the opportunities to experience conceptually focused tasks (Bayazit & Gray, 2004, p. 109).

Can technology as a pedagogical tool help students to understand different faces of the concept of the inverse function? Technology is becoming increasingly used at teaching of university mathematics but there are still few studies which have examined technology-assisted teaching at the university level, even though university mathematics teaching has been changing quickly during the past two decades (Attorps et al., 2011; Lavicza, 2006; 2007; Zimmermann, 1991).

THEORETICAL FRAMEWORK

In our study we apply two theoretical frameworks, the Variation theory and the theory of Concept image and Concept definition. We consider these two theoretical frameworks to be complementary. The theoretical constructs of concept image and concept definition have proven to be a useful analytical tool for nearly three decades (Tall & Vinner, 1981). According to Vinner (1991) and Tall (1999), each mathematical concept is associated with concept definition and concept image. The concept definition can be stipulated as a definition assigned to a given concept. The concept image, on the other hand, is a nonverbal representation of any individuals understanding of a concept. It includes the "visual representations, the mental pictures, the impressions and the experiences associated with the concept name" (Vinner, 1991, p. 68). We agree with Vinner in believing that many mathematics instructors generally would imagine that their students' concept image is growing out of a delivered concept definition in class and normally supplied with a textbook definition. In our study, it is our strong belief that by using the GeoGebra software, we have affected the student's concept image of functions and function inverses.

Another interesting framework in our study is Variation theory. Teaching and learning research has found that ways of experiencing something are essential to what learning takes place (Shulman, 1986). Marton & Booth (1997) stated that qualitatively changed ways of experiencing something is the most advanced form of learning. If we can describe learning as coming to experience something in a changed way, we should also acknowledge that experiencing something must require the ability to discern this new way of seeing the experience. Central in Variation theory is an assumption that variation is needed to discern aspects of object of learning not previously distinguished by learners. According to this theory the most powerful factor concerning students' learning is how the object of learning is

handled in a teaching situation. Marton et al. (2004, p. 16) have identified four patterns of variation in a learning object: contrast, generalization, separation and fusion. They are described as follows:

Contrast: ... in order to experience something, a person must experience something else to compare it with.

Generalization: ... in order to fully understand what “three” is, we must also experience varying appearances of “three”...”

Separation: In order to experience a certain aspect of something, and in order to separate this aspect from other aspects, it must vary while other aspects remain invariant.

Fusion: If there are several critical aspects that the learner has to take into consideration at the same time, they must all be experienced simultaneously.

According to Leung (2003), these patterns of variation create opportunities for the students to understand the underlying formal abstract concept. In order to generate the patterns of variation, we use the dynamical nature of the GeoGebra software, which has the “ability to visually make explicit the implicit dynamism of ‘thinking about’ mathematical, in particular geometrical, concepts” (Leung, 2003).

THE PURPOSE OF THE STUDY

The aim of this study is to investigate if the technology-assisted teaching of functions and function inverses at the university level can contribute to the development of engineering students’ understanding of the concept of function and function inverse. The study investigates the following research questions:

- 1) How can the patterns of variation be visualized by using GeoGebra when teaching the concept of function and function inverse?
- 2) Which qualitative differences between the students’ concept image of the concepts function and function inverse could be distinguished in pre and post test results?

METHOD AND DESIGN OF THE STUDY

The study took place during one teaching session in mathematics at a Swedish university. A total of 17 students were involved. They were all students at the engineering program, studying the course Calculus in one variable. The data were gathered by analysing the teaching sequences during the lecture and by doing a pre and post test. In the analysis of the test results we started by making an easy quantitative overview. Then we continued with a qualitative analysis of the outcomes of the students’ answers.

The pre and post test

The test contained five questions, including both conceptual and procedural ones. Students had maximum 30 minutes to do the test. It was not allowed to use any technical facilities. In this paper we focus on the following three questions:

1. How would you explain if someone asks you: What do you mean by the concept of function? You may like to explain by drawing a picture.
2. How would you explain if someone asks you: What do you mean by the concept of inverse function? You may like to explain by drawing a picture.
3. How would you explain if someone asks you: What do you think are necessary conditions for a function to have an inverse? You may like to explain by drawing a picture.

In order to categorize the answers to the questions above based on their quality, we coded the answers as following: no explanation, incorrect explanation, acceptable explanation, good explanation and excellent explanation.

RESULTS

We used the pre test results as a starting point to design our lecture. In order to create different teaching sequences that could encourage students to discern varying aspects of the object of learning, we applied the ideas of the variation theory in the context of the free dynamic mathematics software GeoGebra.

Teaching sequences

Teaching sequences were implemented in an ordinary lecture with a teacher manipulating the computer and students observing the screen. In the first application of GeoGebra (Figure 1), we visualize, by using dynamically the vertical test, that the graph is a function (the most left picture in Figure 1). By applying the horizontal test, also dynamically, on this function we can see that it doesn't possess an inverse (the picture in the middle in Figure 1). However, by shrinking and moving the domain of the function we can find an interval where the function is invertible.

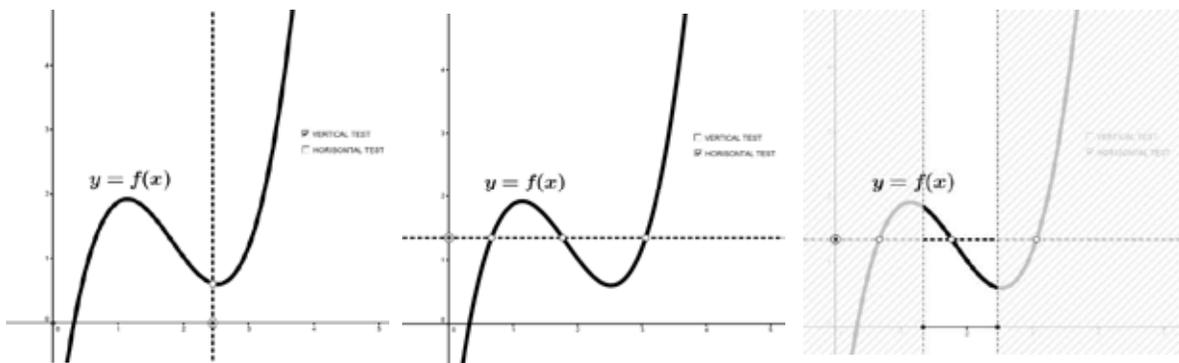

Figure 1: The domain of the function whose graph passes the vertical test has to be adjusted in order to make the graph to pass the horizontal test.

In order to experience the pattern of variation, *generalization*, i.e. to experience that the vertical test works in all positions for the given function, in Figure 1 (the left picture) we moved the vertical line through several points in the domain of the function. In the teaching sequences related to Figure 1 (the middle picture), the students were given opportunities to experience a *contrast*, i.e., to discern that the horizontal test both works and for some points doesn't work on the same graph depending on the position of the horizontal test line. In the right picture in Figure 1, we illustrated the pattern of variation called *separation* by changing both the length and the position of the interval representing the domain of the function. In this way the students were given the opportunity to experience one of the necessary conditions for a function to have an inverse, namely, being strictly monotonic.

The second example (Figure 2) should help the students to understand how to plot a given invertible function and its inverse in the same coordinate system. We use here the dynamical nature of GeoGebra to show how an arbitrary point on the function graph is reflected in the line $y = x$.

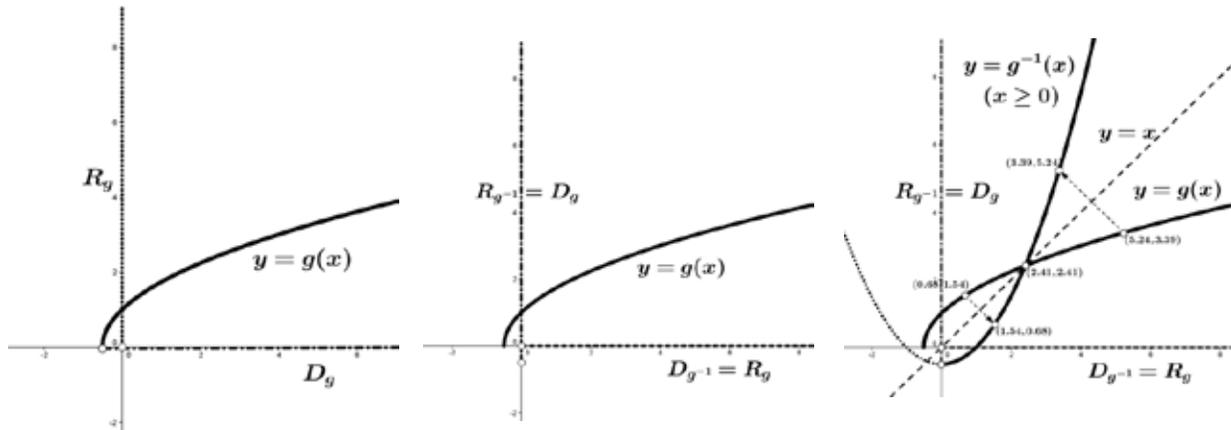

Figure 2: Plotting the graph of function $g(x)$ and its inverse $g^{-1}(x)$.

The teaching sequence illustrated by Figure 2 should help the students to understand how to plot a given invertible function and its inverse in the same coordinate system. They were given the opportunity to experience the pattern of variation – *fusion*. The critical aspects that they could discern simultaneously were the following three: reflecting of the function graph through the line $y = x$, in the corresponding points x - and y -coordinates switching the positions and observing that the domain of the inverse must be restricted.

In the third presentation (Figure 3) we wanted to illustrate an informal conception of inverse function, “undoing”, which captures the essence of the definition.

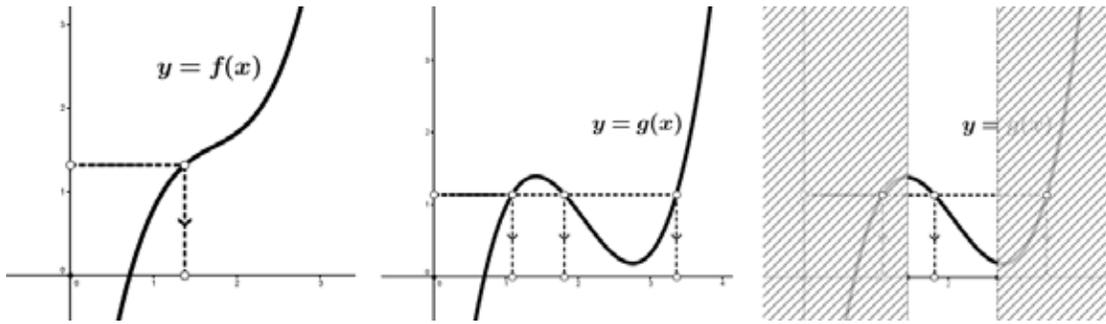

Figure 3: Illustrating of the “undoing” process.

In Figure 3 we wanted to illustrate the concept of “undoing”. In the first two pictures to the left we created the opportunity for students to experience the pattern of variation – *contrast*. In the third picture to the right we separated the crucial condition concerning the existence of the inverse, namely, strictly monotonicity of a function connected to the informal notion “undoing”.

Qualitative differences distinguished in pre and post test results

The Geogebra lecture began with a brief review of the concept of function, familiar to students from previous mathematics courses.

Figure 4 shows an overview of how students responded to the questions in the pre and post tests according to our criteria described in the Methods section.

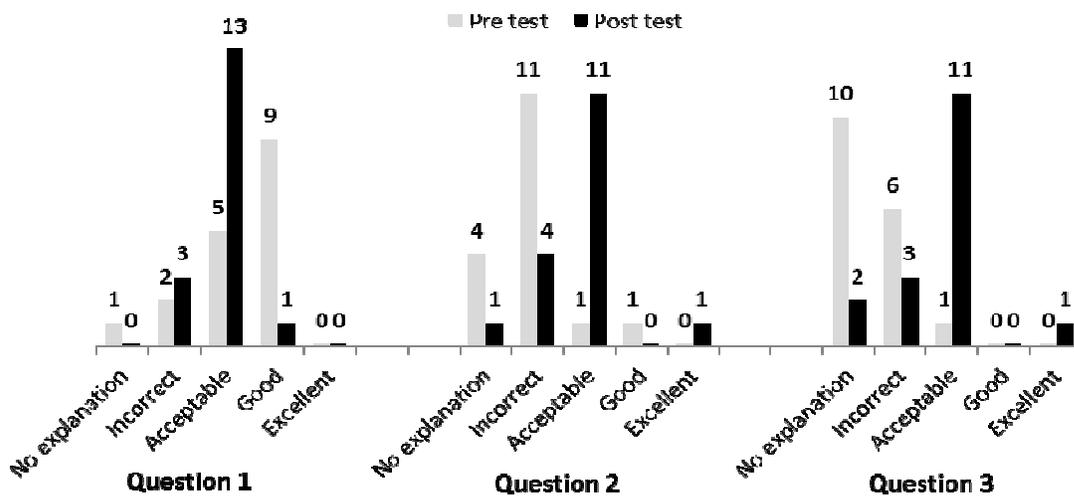

Figure 4: Students’ pre and post test responses to the test questions.

In order to find qualitative differences between pre and post test results we selected six students’ responses to analyse the changes in their concept image more deeply.

The first question in our test focused on the perceptions students had about the function concept. It turned out that we could not notice any direct qualitative differences between pre and post test results. The students already had adequate pre knowledge of this notion.

The second question in our test centered on the students’ conceptions of inverse functions. When we analysed the students’ responses in the pre and post tests we

noticed qualitative differences in their concept image. Some of the students responded in the pre test as follows:

Student 1: The inverse function is a function that is undoing another function.

Student 2: It is a reflection of a function

Student 3: It is a mirror function

Student 4:

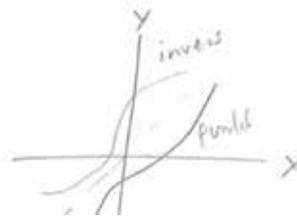

In the post test the same students' conception was:

Student 1: The inverse function is a function that is undoing another function or taking back an original function. If I take the starting value x , expose it to a function to form a final product y , so I can take this final product y , expose it to the inverse of the first function and get x that was my start value.

Student 2: An inverse function reflects the function in the line $x = y$

Student 3: För varje y -värde finns bara ett x -värde och speglar en funktion kring $x=y$

Student 3 says: For each value y is only one value x and reflects a function around $x = y$

Student 4: Det är själva avspeglingen av funktionen

Student 4 says: It is the reflection in itself of the function

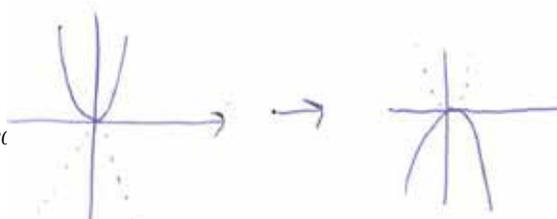

The students' pre and post test responses to the second question reveal that they (S2, S3, S4) often have an intuitive conception about inverse functions as some kind of mirroring. However they often lack the full comprehension of why and where the mirroring should be performed. The results above also show that one of the students (S1) became able to completely explain the notion "undoing".

The third question in our test focused on conditions that must be satisfied for a function to have an inverse. Some of the students responded in the pre test as follows:

Student 1: No explanations.

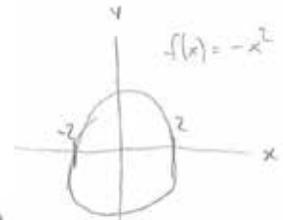

Student 2: What is required is that the function is really a function and it must be symmetric.

Student 5: That you should come back to

the original position and that it is “vice versa”.

Student 6: A function can only have one value on y and x axis because otherwise you cannot come back to the same place again.

In the post test the same students responded this way:

Student 1: One value x must correspond to one value y and one value y should correspond to one value x. If one draws a function in a coordinate system the graph of the function is neither to cut an imagined horizontal line more than once, nor to cut an imagined vertical line more than once.

Student 2: Each value x should only have one value y, and each value y will only have one value x.

Student 5: One horizontal line and one vertical line will only be allowed to have one intersection in the graph.

Student 6: There should be only one value x and one value y on the graph. In the figure there is both an inverse and a function.

Unlike the poor pre test responses, the students' answers in post test show that most of the students after the lecture could give a rather good explanation about the conditions that are necessary for a function to have an inverse.

DISCUSSION

Patterns of variation i.e. generalization, contrast, separation and fusion create learning space for the students to understand the underlying formal abstract concept.

According to Leung (2003), when engaging in mathematical activities or reasoning, one often tries to comprehend abstract concepts by some kind of mental visualization of conceptual objects in hope to discern patterns of variation.

By continuously moving the vertical line through several points we could present the general idea of function in terms of “vertical line test” (generalization). In the similar way we created opportunities for students to experience a contrast by using the standard horizontal line test on a given function. We moved the horizontal line continuously so that students could experience the contrast between functions having an inverse and functions not having an inverse by simply counting the number of intersection points (one or more). We illustrated separation by changing the length and the position of the interval representing the domain of the function, one at a time. In this way the students were given the opportunity to experience one of the

necessary conditions for a function to have an inverse, namely being strictly monotonic. In order to get the students to experience fusion several critical aspects could be illustrated simultaneously for instance by reflecting the function graph through the line $y = x$.

Analyzing the pre and post test results we could notice that the students' concept image of the inverse function had developed. For example, they were able after the lecture to explain why and where the mirroring should be performed. Furthermore, they were able to completely explain the meaning of "undoing". We could also notice that most of the students after the lecture could give a satisfactory explanation about the conditions that are necessary for a function to have an inverse.

As already mentioned, this study is a part of an ongoing research that attempts to explain the relationship between the teachers' instructional practise and students' learning in the context of functions and function inverses. Our ambition in the future research is to further explore already collected data which also involve the pre and post test results for a control group, as well as qualitative results from the final exam.

REACTIONS OF PRE-SERVICE ELEMENTARY TEACHERS' TO IMPLEMENTING TECHNOLOGY BASED MATHEMATICS LESSONS

Esra Balgalmis*, Kathryn G. Shafer**, Erdinc Cakiroglu*

* Middle East Technical University, Turkey, ** Ball State University, USA

The results reported in this paper focus on the reactions of three pre-service elementary mathematics teachers (PSTs) after designing and implementing three GeoGebra lessons. The analysis of the data revealed that focusing on the mathematical concept more than technology and using technology when it is really necessary were the basic criteria for effective technology based lesson. PSTs defined GeoGebra as a tool that assisted them to promote students' learning and a helper for students to discover features of mathematical concepts. Pre-knowledge of students, classroom management and time management are important components of successful lesson implementation. The PSTs reported increased self-confidence and valued having a mentor to help them reflect on their lesson implementation.

Keywords: *Mathematics Teacher Education, Integrating Technology in Mathematics, GeoGebra*

INTRODUCTION

Educational technologies have become a significant part of the teaching and learning process in Turkey. The current elementary mathematics curriculum developed by the Ministry of National Education (MoNE) in Turkey emphasizes using technology effectively in teaching to provide students the opportunity for expressive mathematics teaching (MoNE, 2009). Dynamic technology-supported instruction presents an opportunity to enhance mathematical reasoning. For instance, with the help of dynamic geometry software, students explore various conjectures by constructing geometric shapes and making connections between them (MONE, 2009). In order to be an effective teacher, pre-service teachers need to learn fundamental concepts, knowledge, skills, and attitudes for applying technology in educational settings (NETS•T, 2008). It is our claim that the field experience is a crucial element in the development of TPACK. The purpose of this report is to examine three pre-service teachers' (PSTs) reactions to implementing three technology-based mathematics lessons in the context of a field experience.

LITERATURE REVIEW

Technology plays an ever-increasing role in the lives of elementary school students. Dynamic software packages, such as GeoGebra and Geometer's Sketchpad are vital in raising student awareness, challenging their conceptual understanding and motivating the synthesis of mathematical notions (Hollebrands, 2007; Kaput &

Thompson, 1994; Peressini & Knuth, 2005). Construction of mathematical objects, creating models and conducting interactive explorations are available via GeoGebra by dragging objects, tracing points, changing parameters and measuring objects.

According to the National Council for Accreditation of Teacher Education standards (NCATE, 2002), the new professional teacher who graduates from a department of education should be able to integrate technology into instruction to effectively enhance student learning. To achieve the technological goals stated by NCATE, teachers have to be prepared for their new roles in a technological environment (Thompson & Kersaint, 2002). To design and structure learning environments, researchers have suggested that teacher educators need to integrate technology into their teaching and their technology integration should go well beyond teaching technical skills (Kim & Baylor, 2008). Therefore, many teacher training programs and professional development initiatives integrate technology, with educational aims, into the courses to develop pre-service teachers' knowledge of technology (Koehler & Mishra, 2005; Katic, 2007).

Examples of undergraduate courses intended to promote Technological, Pedagogical, and Content Knowledge (TPACK) are found in (Kersaint, 2007; Ozgun-Koca et al., 2009/2010; Powers & Blubaugh, 2005). These three courses share a few common characteristics. All of the courses include activities that focus primarily on pedagogical and content-related tasks. For example, PSTs engaged in technological training, and then they examined the activities by discussing how and when to use appropriate technology in mathematics instruction. A second way in which the three courses are similar is that they include student-centred teaching methods such as guided discovery (Powers & Blubaugh, 2005), collaborative teaching (Kersaint, 2007) and inquiry-based learning with open-ended questioning (Ozgun-Koca et al., 2009/2010). Microteaching is found in the methods course developed by Ozgun-Koca et al. By providing these types of experiences, PSTs are challenged to reorganize their subject matter knowledge and use educational technology on the development of that subject itself (Niess, 2005).

FRAMEWORK

Teacher training courses should provide PSTs a rich technological environment to develop TPACK. Unfortunately, it is our experience that most pre-service teachers are unable to integrate what they learn in teacher education programs into their future teaching practice. Consider balancing the technological/pedagogical training with experiences of classroom observation, implication and reflection. A methodology used to support the development of TPACK is found in the Situated Technology Integration (SiTI) model (Hur, Cullen & Brush, 2010). It is the authors' opinion that the recommendations found in this model are well crafted due to the focus on didactical modeling, tool use, and skill practice. The SiTI model includes aspects of TPACK that occur within a broader classroom context. An emphasis on technology

implementation in the classroom is emphasized in the guidelines (italics were added by the authors). Three out of five SiTI guidelines were used to frame this study.

SiTI Guidelines:

- **Provide concrete experiences:** To assist pre-service teachers in understanding the relationship between theory and practice, various examples and concrete experiences should be provided.
- **Assist in application:** To help pre-service teachers apply knowledge learned in real situations, opportunities to observe expert teacher's classrooms and chances to utilize knowledge in actual classrooms should be included.
- **Develop Technological Pedagogical and Content Knowledge:** To successfully integrate technology into their future classes, pre-service teachers should be called on to develop plans to use their technological knowledge in a meaningful way in relation to their content and classroom teaching knowledge. (p. 167)

To position these guidelines in their teacher preparation program, Hur, Cullen and Brush (2010) developed a three-phased approach (preparation, exploration and implementation). They readily acknowledge difficulties in providing pre-service teachers with a field experience as part of a mathematics methods course. These three guidelines provide information about the role of the teacher educator in pre-service teacher field experiences.

METHODOLOGY

The Elementary Mathematics Education Teacher Program is an undergraduate program of the Department of Elementary Education in the Faculty of Education at Middle East Technical University (METU) in Ankara. The population for the study were elementary mathematics majors who had taken ELE 430 and were enrolled in ELE 435 (the course descriptions follow).

ELE 430 – Exploring Geometry with Dynamic Geometry Applications (Spring 2011): Introduction to Geogebra software with emphasis on technical and pedagogical skills needed to teach geometry in grades 6-8.

ELE 435 – School Experience (Fall 2012): Introduction to grade 6-8 learning environment through classroom observations, and planning and implementation of a learning-centered activity.

During the ELE 430 course, pre-service teachers were not only presented with the features of GeoGebra software program, but also with how they can support students' mathematical understanding via this program. The instruction provided was aligned with the SiTI guideline recommendation to **provide concrete experiences**. An example used by the instructor was "Activity Exterior Angles of Polygons" [1]. The goal of the activity was to explore this topic within the dynamic geometry

environment. In this activity, an exterior angle of a polygon was formed by a side and an extension of an adjacent side. PSTs were guided to create the dynamic sketches. In the first sketch, PSTs created and used a slider to resize a triangle. They discussed the sum of the exterior angles of a triangle. They observed that changes in the angle measures did not affect the sum of the exterior angles.

In the class sessions, the instructor's primary role was to facilitate discussion by asking PSTs pedagogical questions. She also asked them to answer and ask new questions about the activity. There were two types of pedagogical questions. The first type of questions asked PSTs to discuss the mathematical reasoning they encountered when constructing figures in GeoGebra. Some examples of the first type of questions are: *Why is it important to construct this object first? Can you show us your thoughts by constructing via GeoGebra? How can you represent your thinking? Is there any other way to construct this activity? What would you do if...?* After finishing the activity, the instructor asked a second type of questions. These questions required that the PSTs discuss implementation of the geometrical activity in an actual classroom environment. Some examples of the second type of questions are: *How might this activity be useful for you as a teacher with your students? What kind of "what if" questions can you ask students on this task to facilitate their learning? Do you think the use of this sketch can somehow change the learning environment? Which difficulties do you think can be encountered when conducting this activity?*

A total of sixteen PSTs had taken ELE 430, and from this group, eight were enrolled in the ELE 435. Six of the eight PSTs agreed to participate in the study and three of these participants were chosen as subjects for the post hoc case study analysis; Meltem, Pelin, and Ali (pseudonyms). Meltem exhibited an especially strong knowledge of technology, Pelin showed substantial change in the success of implementation from the first to the third and Ali showed a strong technological knowledge but claimed not to feel the need to use technology to teach mathematics unless it was required. These three PSTs were chosen by a purposeful sampling method because this sampling strategy provides access to people who will provide rich information about the research question (Creswell, 2007). A small stipend was paid to all six of the student volunteers.

Three limitations that can affect the generalizability of the reported results include:

- The population of students accepted into the teaching program at the METU is inherently biased. These students possess strong content knowledge;
- Researcher bias is possible because the lead author was a mentor to the PSTs;
- A case study methodology was used. The results that follow focus specifically on the data gathered in the final interview (completed January 2012).

DATA ANALYSIS AND RESULTS

To analyse the final interview data, the researcher's focus was especially on the **assist in application** and **develop TPACK** guidelines of the SiTI Model. The PSTs had developed and implemented their plans in actual classrooms. The purpose of the final interview questions was to promote and document reflection on their experience. The 50-minute interviews were transcribed and translated into English by the researcher in order to collaborate with an associate professor from the USA. From each transcript, significant sentences directly related to the interview questions were identified. For example, the 18th question was about time: Because of using educational technology in your teaching, did you have any problems in terms of time management?

A total of 21 theme items emerged and were numbered as they arose. Sorting the theme items into nine distinct categories followed this analysis. While analysing the data, an associate professor experienced with qualitative research and analysis, reviewed the data, validated the emerging themes and collaborated in the assignment of categories. In what follows, each of the identified categories is followed by two to four theme items and selected quotes (with time stamps) from the interviews.

The first category, **Content Criterion**, is important because it indicates that the PSTs were focused on mathematics content and not just on technology. The PSTs stated that to integrate educational technology into mathematics education there should be some criterions to follow. The three theme items that emerged related to content criterion to teach a geometrical concept via GeoGebra were:

- Use technology when it is really necessary,
- To implement lesson in computer lab or classroom environment make a decision based on the lesson objectives,
- Focus on one concept; focus on concepts not technology.

I think, we should use technology when it is necessary to teach a geometrical concept. We need to focus on one objective; otherwise, as we see from my implementation, it makes students confused. [Ali.13:25-14:00]

Ali was referring to his third lesson implementation where he taught three objectives related to factorization. That lesson covered greatest common factor, factoring by grouping and factoring quadratic polynomials. His GeoGebra activity was constructed to teach factorization of quadratic polynomials. He reported during the interview that some of the students appeared to be confused because of learning three objectives in a single lesson and had some difficulties to focus on a GeoGebra activity at the end of the lesson.

Time management is the second category identified. PSTs stated that, if there is no technical problem, educational technology helps teacher use time economically. The two theme items categorized as time management were:

- Technology helps PST use time economically,
- Have a back up plan in case of any technical problems.

I think when we use technology in math education, it provides time saving. [Ali.14:03-14:27]

All the time we need to have a plan B in case of any technical or other problems. [Pelin.35:20-35:51]

In some cases, the technology saved time. For example, in Meltem's first implementation she was able to demonstrate how to make a triangle with the same area by dragging one of the vertex points of the polygon (instead of drawing on the board for each situation). In other cases, technology problems wasted class time. In Pelin's third implementation, the electricity cut off and she couldn't project the screen onto the board. Nevertheless, her laptop battery was full and she displayed the GeoGebra file via laptop screen by grouping students into the three parts.

Classroom Management is the third category. PSTs said that educational technology makes classroom management harder. The two theme items that came out related to classroom management were:

- Technical problems make classroom management harder,
- Following students is more difficult in technology-based classroom.

Most of the classroom management problems arose from technical problems. [Ali.12:15-12:24]

To follow students at the same time is more difficult when I was using GeoGebra. [Meltem.13:05-13:34]

The fourth and fifth categories that generated strong reaction and appeared in each of the interviews were named **Tool Use**. PSTs defined educational technology as a tool for teachers and students separately in order to have effective teaching and learning. **For Teachers**, technology is a tool to promote students' learning. The two theme items that came out related to tool use for teachers were:

- Technology is a tool to help teachers support their students reasoning,
- Technology gives opportunity for teacher to implement student-centered lesson (Problem solving, questioning).

It is a really helpful tool for mathematics teachers if they want to make students discover geometric objects. One of the GeoGebra features that can be used was hiding objects. It gives an opportunity for teachers to hide something and let students discover ... teacher can show the objects step-by-step to confirm students reasoning. [Ali.24:25-25:20]

For Students, technology is a tool to help them learn easier. The theme items were:

- Technology is a tool 1) used for discovering features of geometrical concepts, 2) to help students transfer their mathematical knowledge, 3) used for testing students' answers,

- With the help of technology, students learn geometrical rules conceptually without memorizing.

GeoGebra helps students to observe and discover features of geometric concepts... GeoGebra can help students make abstract concepts concrete. [Ali.23:30-24:22]

As you observed in my third implementation, students could transfer their knowledge, they learned in previous lesson, to another problem situation while drawing a circle when only three points to pass through are given. [Meltem.16:52-17:20]

For example, in Ali's third implementation, he modelled algebra tiles via GeoGebra and taught factoring quadratic expressions. With the help of GeoGebra, students could visualize $2x^2 + 5x + 2$ and its factors. Another example is from Meltem. In her second implementation, she asked the students to find the circumcenter of a dynamic triangle first by dragging a point (that was connected to the three vertices). This was followed by an exploration of the use of the perpendicular bisectors of each side of the triangle to find the circumcenter of the given triangle. In Meltem's third implementation, she asked students to create a circle when only three points to pass through were given. In the second step of the activity, a few of the students made a connection with the previous lesson and found the correct solution for the problem (this was observed in the video tape of this lesson).

The sixth category that also generated strong reaction when it appeared in each of the interviews was named **Implementation**. During the interviews, PSTs reported contributions of the implementation experience to their future teaching. For example, they reported an increase in confidence in teaching and predicting what students might ask. The theme items that related to implementation were:

- The more they implement lessons in a real classroom context, the more the PSTs have self-confidence in teaching,
- The more implementations in real classroom contexts, the more PSTs interpret what will happen in the lesson,
- The more implementation in real classroom contexts, the more the PSTs see their weaknesses,
- Personal reaction to lesson implementations.

The more we have teaching experiences in real classrooms, the more we have knowledge about students' reactions.... As a teacher, I feel more comfortable in real classroom environment now. [Meltem.34:57-35:20]

In the third implementation I could predict what kind of questions students will ask me, about the task. [Ali.08:30-08:45]

Luckily all of the class activities that I implemented in real classroom context were really close to what I imagine while designing... Normally I thought that I could not implement what I planned, since I am looking for ideal students that have mathematical content knowledge very deeply as a pre-knowledge and they will answer whatever I asked to them related to content [Meltem.04:09-04.30]

There is an improvement in my opinion. My best implementation was the last one. [Ali.05:41-05.52]

The seventh category was **Recommendations**. The last question of the interview was: do you have any recommendation about training teachers in terms of using technology? PSTs gave recommendations to the teacher training programs. The four remaining theme items that came out related to recommendation were:

- Teacher training programs should have more technology courses,
- Integrate technology into methods course,
- PSTs should improve their techno pedagogical skills before graduation,
- PSTs need more lesson plan implementations in real classroom contexts to have more experiences before graduation.

There should be more obligatory courses about educational technology in our national teacher training programs. [Pelin.46:04-46:20].

Teacher training programs need to integrate technology into method course [Ali.35:37-35:48].

I need more experiences in real classroom context before graduation [Ali.35:03-35:21].

Two remaining categories were identified by one theme item each;

- Need to know student's pre-knowledge,
- Mentoring is helpful to improve lesson plan.

The need to know students' **Prior Knowledge** appeared in each of the interviews. All three of the PSTs commented on the impact of not having a good understanding of the students' knowledge when designing and implementing a lesson.

Therefore, just because I didn't know students' pre-knowledge, my lesson implementation was not effective. Without any reasoning, they answered the questions. It was not a challenging activity for them. [Ali.04:49-05:15]

We need to have information about students' pre-knowledge to prepare effective lesson plan. [Pelin.33:57-34:06]

The last category that emerged was **Mentoring**. While it was not anticipated, this category is in alignment with the SiTI guideline "assist in implementation." The PSTs commented on the feedback and advice offered by the researcher in her role as a mentor.

While I was creating GeoGebra activities, I took your opinions about in which part of the lesson I need to use that activity ... Based on our discussion during the interviews I made some changes in my lesson plan. [Ali.05:54-06.15]

DISCUSSION AND CONCLUSION

The purpose of this report is to examine three pre-service teachers' (PSTs) reactions to implementing three technology-based mathematics lessons in the context of a field experience. Three of the five the SiTI Guidelines provided a framework for the PSTs

coursework and the additional field experience that participation in this study provided. The overarching goal of developing the PST's TPACK can be observed in five of the categories identified in the final interviews. Issues that emerged with regard to classroom management and time management could be considered technological pedagogical knowledge (TPK). Issues that emerged with regard to content criterion and tool use (teacher and student) could be considered as technological content knowledge constructs. Pre-knowledge could be considered as necessary to a teacher's pedagogical content knowledge, which for these PSTs affected the overall success of their lesson implementation. What is interesting is that the PSTs did not specifically reflect on the technological aspects of their lesson implementation. This might be due to the questions asked in the interview or to the PST's past experience with regard to using GeoGebra and/or preparing the files used in the lessons.

The remaining two categories provide important information about the field experience as a whole. The PSTs valued the implementation experience, recommended that this type of experience be included in a teacher education program, and reported positively on the role of the mentor.

NOTES

HOW TEACHERS LEARN TO USE COMPLEX NEW TECHNOLOGIES IN SECONDARY MATHEMATICS CLASSROOMS - THE NOTION OF THE HICCUP

Alison Clark-Wilson

Institute of Education, University of London, UK

This paper reports the outcomes of a longitudinal doctoral study which sought to illuminate the process through which secondary mathematics teachers learned to use a complex new multi-representational technology, the TI-Nspire handheld and software. The research examined the trajectories of fifteen teachers, with a focus on the pedagogical approaches that privileged the exploration of mathematical variance and invariance. Analysis of the data reveals the importance of the notion of the ‘hiccup’; that is the perturbation experienced by teachers during lessons stimulated by their use of the technology, which illuminates discontinuities within teachers’ knowledge.

Keywords: Classrooms, Handheld technology, Hiccup, Mathematics, Teachers.

INTRODUCTION

Most studies concerning the appropriation of technological tools within mathematics classrooms have been approached from the students’ perspectives and far less is known about teachers’ epistemological developments, i.e. the process through which their mathematical, pedagogical and technical knowledge develops over time as a result of their use of mathematical digital technologies. The opportunity provided by a funded project in which a group of English secondary school teachers were introduced to the TI-Nspire handheld and software environment provided the context for this study. For the teachers, this involved both learning about the affordances of the new technology and then devising teaching activities and approaches that utilised these affordances in ways that had educational legitimacy in their classroom settings. The outcomes of these classroom activities led to the development of ‘instrument utilisation schemes’, which provided the platform from which to observe and evidence teacher learning (Verillon & Rabardel, 1995).

The TI-Nspire handheld and software is described throughout this paper as a ‘multi-representational technological’ tool as it is an environment which incorporates numeric, syntactic, geometric and graphical applications that can be dynamically linked through the definition of variables. These variables can either be defined by the user or captured from existing objects within an application and hence the multi-representational technology (MRT) offered a new condition for organising teachers’ actions.

THEORETICAL FRAMEWORK

The research was underpinned by Verillon and Rabardel's theory of instrumented activity, which seeks to explain the process through which humans interact with technological tools (Verillon & Rabardel, 1995). Their 'triad of instrumented activity' was adapted for the context of the study, resulting in the diagram shown in Figure 1 below. Consequently, the instrument (in a Vygotskian sense) incorporated the use of the MRT, the subject was considered to be 'teachers as learners' and the object was 'teachers' learning about the teaching and learning of mathematics through the exploration of mathematical variance and invariance'.

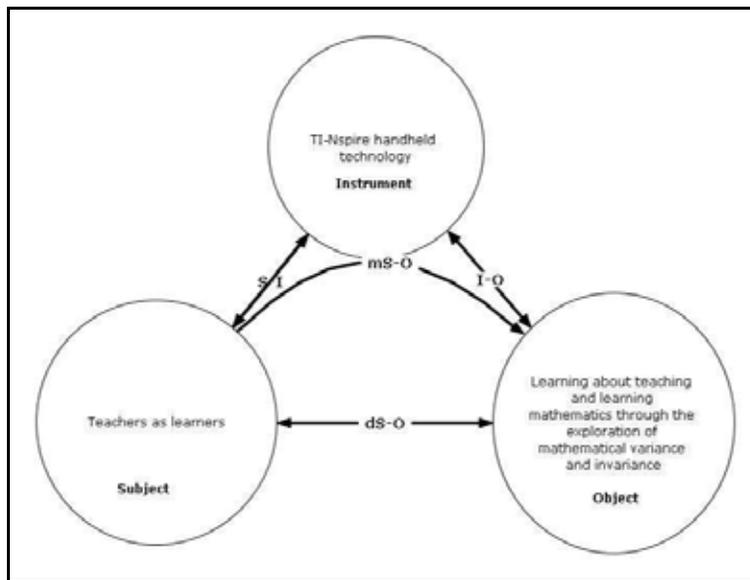

Figure 1: The adapted triad characteristic of Instrumented Activity Situations. The arrows indicate the interactions between Subject and Instrument (S-I), Instrument and Object (I-O) and, in the case of the Subject and the Object, the direct interaction (dS-O) and the mediated interaction (mS-O) (Verillon & Rabardel, 1995).

The research was also influenced by three key themes from the literature, which concerned: the appropriation of technological tools and the role this plays in teachers' subject and pedagogic knowledge development (Guin & Trouche, 1999; Pierce & Stacey, 2009; Ruthven & Hennessy, 2002; Stacey, 2008); the development of representation systems for mathematics (Kaput, 1986, 1989; Mason, 1996) and the interpretations of knowledge and the processes involved in mathematics teachers' professional learning (Polanyi, 1966; Rowland, Huckstep, & Thwaites, 2005; Shulman, 1986).

RESEARCH METHODOLOGY

As a researcher, I adopted the perspective that reality is socially constructed and I sought to privilege the voices, actions and meanings of the teachers as the main data sources and ensure the reliability of the study through a robust and

systematic process of data analysis leading to a valid set of conclusions. (See Clark-Wilson (2008b) for more detail). The research was carried out in two phases, (Jul 2007 – Nov 2008 and Apr – Dec 2009) and, in each of these phases, a group of teachers was selected and a series of methodological tools developed to capture rich evidence of their use of the technology in classrooms to enable the aims of the study to be realised. Hence this was a situated exploratory study in which the unit of analysis was (secondary mathematics teachers + mathematics + activity design) that sought to expand the discourse on teachers' appropriation of technology tools; that is how they adapt and mould the tool for their own use. The research lens was trained on the trajectory of the teachers' interpretations of variance and invariance.

Phase one of the study

During the first phase, fifteen teachers were introduced to the technology and encouraged to develop activities for the classroom, which they then trialled with their students and reported the outcomes of these trials to the study. The teachers reported a total of sixty-six activities and the research data comprised: teacher questionnaires, which included a mandatory detailed lesson evaluation; teachers' lesson plans, pupil resources and software files; and teachers' presentations during project meetings. The data analysis of the first phase of the study (using Nvivo8) revealed the trends in the teachers' interpretations of variance and invariance and the emergence of nine different instrument utilisation schemes (IUS), within their 'intended' lesson activities. As these lessons were not observed, it cannot be assumed that they correspond to the students' actual utilisation schemes.

Instrument utilisation scheme (IUS)	Frequency of use (n=66)
IUS1: Vary a numeric or syntactic input and use the instrument's functionality to observe the resulting output in numeric, syntactic, tabular or graphical form.	37
IUS2: From a given set of static geometric objects, make measurements and tabulate data to explore variance and invariance within the measured data in numeric and tabular forms.	4
IUS3: Vary the position of an object (by dragging) that has been constructed in accordance with a conventional mathematical constraint and observe the resulting changes. (Use another representational form to add insight to or justify/prove any invariant properties).	13
IUS4: Vary a numeric input and drag an object within a related mathematical environment and observe the resulting visual output.	2
IUS5: Vary a numeric or syntactic input and use the instrument's functionality to observe the resulting output in numeric, syntactic,	8

Instrument utilisation scheme (IUS)	Frequency of use (n=66)
tabular or graphical form. Use another representational form to add insight/justify/prove any invariant properties.	
IUS6: Vary the position of an object that has previously been defined syntactically (by dragging) to satisfy a specified mathematical condition.	1
IUS7: Construct a graphical and geometric scenario and then vary the position of geometric objects by dragging to satisfy a specified mathematical condition. Input syntactically to observe invariant properties.	1
IUS8: (Construct a geometric scenario and then) vary the position of objects (by dragging) and automatically capture measured data. Use the numeric, syntactic, graphical and tabular forms to explore, justify (and prove) invariant properties.	2
IUS9: (Construct a graphical or geometric scenario and then) vary the position of a geometric object by dragging to observe the resulting changes. Save measurements as variables and test conjectures using a syntactic form.	3

Table 1: Summary of the instrument utilisation schemes in the lesson activities designed by the teachers (n=66)

There were three outcomes of the first phase of the study: a clearer understanding of the ways that the teachers used the multi-representational environment to emphasise different conceptions of variance and invariance; the identification of the teachers who would become the subjects of the research in its second phase; and the emergence of my interest in the instances in the classroom where the teachers were perturbed (in an epistemological sense) as a result of using the MRT with their students. I use the word epistemological to mean that the teachers underlying knowledge in relation to mathematics, technology and pedagogy was being reviewed and reorganised as a direct result of their classroom experiences with the technology.

Phase two of the study

The second phase involved the focused case studies of two teachers, Tim and Eleanor, who had demonstrated the desired attributes (technical competency and a diversity of IUS) and had adopted pedagogical approaches that placed the students' mathematical experiences at the centre of the classroom environment. As this phase of the study aimed to elicit the nature and process of the teachers' learning through a close observation of them in their classrooms, the research methodology used in phase one was developed further to include audio-recorded lesson observations and interviews.

In addition, the opportunity for the teachers to use TI-Nspire Navigator technology in their classrooms resulted in additional data such as students' files, handheld screens and screen capture views being collected, providing an unanticipated additional rich resource for the study.

In all, eight of Tim's lessons and six of Eleanor's lessons were observed and, as previously, the data was imported as a synchronised set into Nvivo 8 software, which facilitated the 'replaying' of the lesson in the fullest sense. The analysis of each set of lesson data led to the development of a detailed, accurate and complete lesson narrative, by a broad analysis of the lesson that utilised Stacey et al's 'pedagogical map' (Stacey, 2008) and the emergence of the 'hiccup' as an organising principle.

HOW DO TEACHERS LEARN TO USE COMPLEX TECHNOLOGIES? – THE EMERGENCE OF THE 'HICCUP'

As I began to observe the teachers in their classrooms, my attention was increasingly shifted towards the existence, and opportunity to analyse, what I refer to throughout the study as lesson 'hiccups'. These were the perturbations experienced by the teachers during the lesson, triggered by the use of the technology that seemed to illuminate discontinuities in their knowledge and offer opportunities for the teachers' epistemological development within the domain of the study. They were highly observable events as they often caused the teacher to hesitate or pause, before responding in some way. At the time of the study, the teachers were not aware of the concept of the hiccup as I would refer to them as 'surprises' or 'unanticipated moments'.

For example, the Nvivo coding summary for one of Tim's classroom activities is shown in Figure 2.

Name	
	TP6 Hiccup1 - Difficulties over identification of dynamic objects
	TP6 Hiccup2 - Students' mis-interpretations of task - 'different way around'
	TP6 Hiccup3 - Instrumentation (T) 'your c has gone off the screen'
	TP6 Hiccup4 - Instrumentation (S) - grabbing and dragging
	TP6 Hiccup5 - Jump from MRT task to trad paper and pencil problem

Figure 2: Tim's coded hiccups for the activity 'Pythagoras exploration'.

The analysis of all of the lesson data enabled all of the hiccups to be identified and there were sixty-six in total. A constant comparison method, led to the definition of seven categories of 'trigger'. These are detailed later in the paper. What follows immediately is a detailed description on one particular hiccup and a justification of why its occurrence provided evidence for the teacher's epistemological development.

An example of a hiccup and its relationship to Tim's situated learning

In the lesson activity 'Pythagoras exploration', Tim had designed an activity in which his students were dragging the vertices of a geometric construction and it

was his intention that the students would conclude that when the triangle was dragged such that it appeared to be right-angled, the areas Tim had defined as a and b would sum to the area he had defined as c .

The initial screen that the students encountered is shown in Figure 3.

What follows is the detailed analysis of one of these hiccups (coded TP6 Hiccup2 from Figure 2), and an articulation of how this event may have contributed towards Tim's situated learning during and soon after the lesson.

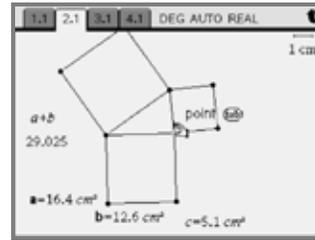

Figure 3: The students' opening view of the task

This hiccup was observed during a point in the lesson when Tim was clearly reflecting deeply on the students' contributions to the shared learning space and 'thinking on his feet' with respect to responding to these. It coincided with his observation of an unanticipated student response. The chosen hiccup came about when a student had found a correct situation for the task, that is the two smaller squares' areas summed to give the area of the larger square, but the situation did not meet Tim's activity constraint of $a + b = c$.

Tim commented about this in his personal written reflection after the lesson,

One student had created a triangle for which $a+b$ did not equal c , but (I think) $a+c=b$. This was also right angled. This was an interesting case because it demonstrated that the 'order' did not matter... when the sum of the smaller squares equalled that of the larger square, then the triangle became right angled.

Tim revised the TI-Nspire file after the lesson, providing some convincing evidence of his learning as a result of the use of the MRT. Tim gives an insight into his learning through his suggestions as to how he thought that some of these perceived difficulties might be overcome by some amendments to the original file (see Figure 4).

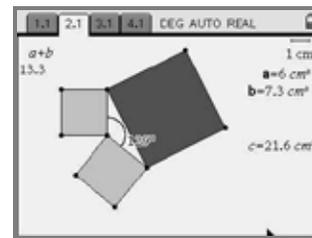

Figure 4: Tim's revised MRT file for the task

The squares whose areas were previously represented by 'a' and 'b' have been lightly shaded and the square represented by the area measurement 'c' has been darkly shaded. Tim also added an angle measurement for the angle that is opposite the side that was intended to represent the hypotenuse.

Both of these amendments to the original file suggest that Tim wanted to direct the students' attentions more explicitly to the important representational features. He wanted to enable the students to connect the relevant squares to their area measurements and 'notice' more explicitly the condition that when the condition for the areas was met, the angle opposite the hypotenuse would be

(close to) a right angle. This seemed to suggest that Tim was still trying to overcome the inherent difficulty when using mathematical software concerning the display of measured and calculated values in the hope that students would achieve an example where the areas were equal and the measured angle showed ninety degrees. This seemed to suggest a conflict with his earlier willingness to try to encourage his students to accept an element of mathematical tolerance when working with technology with respect to the concept of equality.

CATEGORIES OF HICCUPS

The research concluded that the teachers were engaged in substantial situated learning, prompted by their experiences of lesson hiccups. In this sense the hiccups are an epistemological phenomenon as they are the manifestation of a rupture in the fabric of the teacher's knowledge. The seven categories of hiccups are detailed below alongside a brief exemplification from the research data.

1. Aspects of the initial activity design

Hiccups in this category were attributed to aspects of the teacher's choice of initial examples, the sequencing of the examples, the methods for identifying and discussing objects displayed on the MRT or unfamiliar pedagogical approaches. The hiccup described previously within Tim's lesson is an example of this type as the lack of any on-screen labelling made it difficult for the students to interpret the initial instructions for the task.

2. Interpreting the mathematical generality under scrutiny

This category concerned the acts of relating specific cases to the wider generality under observation, the appreciation of the permissible range of responses that satisfy the generality or failing to notice the generality at all.

Figure 5: The students' handheld screens displayed publicly during the plenary.

For example, in a lesson designed and taught by Eleanor, the large set in functions that the students were asked to plot within the MRT led to diverse set of screens on which it was difficult for the students to notice the generality that was common to the functions that had all been transformed by a ‘sideways shift’ of $\pm a$ (Fig. 5).

3. Unanticipated student responses as a result of using the MRT

There were several instances where the response from the student differed from that which the teacher had anticipated in his or her original design, leading to occurrences of hiccups. For example, the students’ prior understanding was below the teacher’s expectation, the students’ interpretations of the activity objectives differed from that of the teachers or the students developed their own instrument utilisation schemes for the activity.

For example, in a lesson created by Eleanor, in which she has asked her students to construct linear functions through the given co-ordinate point (3, 6), one of the students produced the screen in Figure 6.

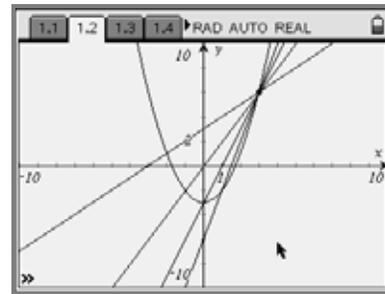

Figure 6: Emily’s response to the task

4. Perturbations experienced by students as a result of the representational outputs of the MRT

A number of observed hiccups resulted from the students responses to a particular syntactic or geometric output or their doubt of the ‘authority’ of the syntactic output from the MRT.

An example of this is shown in Figure 7 where Tim was required to make sense of a student’s response to a task in which the student had questioned the output of the MRT.

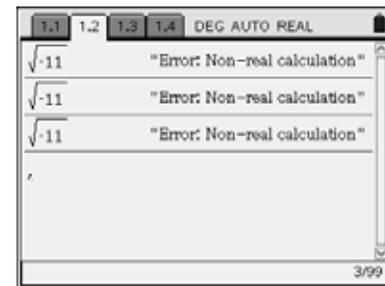

Figure 7: A student’s screen in which he repeats his entry to the MRT.

5. Instrumentation issues experienced by students when making inputs to the MRT and whilst actively engaging with the MRT

The hiccups within this category resonate with much of the research concerning students’ uses of complex technologies and they were related to: entering numeric and syntactic data; plotting free coordinate points; grabbing and dragging dynamic objects; organising on-screen objects; navigating between application windows; enquiries about new instrumentation and the accidental deletion of objects.

6. Instrumentation issue experienced by one teacher whilst actively engaging with the MRT

The high level of experience and confidence of the two teachers with the MRT most probably accounts for the low incidence of hiccups relating to their own instrumentation issues. In this case, the teacher ‘forgot’ how to reveal the function table at a key point in one activity.

7. Unavoidable technical issues

The teachers were using prototype classroom network technology which did result in some equipment failures during some lessons. Although these occurrences were definitely classed as hiccups, they were considered to be outside of the domain of the research study.

CONCLUSIONS

The evidence from the study strongly supports the thesis that teachers were engaged in substantial situated learning, which was prompted by their experiences of lesson hiccups, as they designed and evaluated activities using the MRT. These activity designs privileged explorations of variance and invariance in some way and most also involved multiple mathematical representations. In this sense the hiccup is considered to be an epistemological phenomenon, that is, a rupture in the fabric of the teacher’s knowledge. All of these hiccups provided opportunities for the teachers to at least interrogate, if not develop their knowledge. It is not suggested that all hiccups would lead to a clear learning outcome for the teachers. However, the research evidence from my study is rich with examples of how individual hiccups (and combinations of hiccups) have prompted the teachers to rethink the subtle aspects of their activity designs evidencing them to be learning sites for the teachers. The discussions within the CERME conference working group raised a number of interesting questions such as: how the concept of the hiccup might be incorporated into the design of professional development for teachers? and, if so, whether the theory should be introduced first or whether teachers should need to be allowed to experience them first? Other questions related to how the notion of the hiccup might be incorporated into existing theories about teacher knowledge development and whether the teacher’s experience might be an important factor.

ACKNOWLEDGEMENT: The data collection carried out during Phase One of the study (and part of the data collection in Phase Two) was funded by Texas Instruments within two evaluation research projects.

MATHEMATICS TEACHING ON THE WEB FOR STUDENT TEACHERS: ACTION RESEARCH IN PRACTICE

Helge Fredriksen

University of Nordland

The article summarises experiences gained through my practice as web-based pedagogue in mathematics at the University of Nordland (Norway)'s teacher-training institute. It has been my wish to make continuous improvements to my practice and I present two of the most important improvements that I investigated on the basis of practical action research. Data collected from students' feedback indicates that video lectures produced by filming whiteboard teaching yields a greater educational result than so-called screen video of a slideshow run on a PC. In addition, we present and discuss significant findings regarding the use of Skype in web-based teaching.

INTRODUCTION

The purpose of this article is twofold. Firstly, I wish to describe some of my findings in respect of the new web-based maths teaching in the teacher education at the University of Nordland. I then wish to present some suggestions for possible initiatives against the background of empirical observations collected during my first term of web-based teaching.

My professional background is as university lecturer in mathematics. During the spring term 2011 I taught the first class of student teachers at the University of Nordland in statistical analysis, basic geometry and probability calculation in a web-based version. In addition to the web-based classes, this teaching has been held in equivalent classes on campus. The goal of the web-based program is to enable a flexible form of tuition in which the bulk of the teaching per se is conducted over the internet instead of face to face, as was the case in the old general teacher-training program. One of the primary intentions is that the university to a greater extent should accommodate the students' desire for freedom from a teaching form that entails constraints on time and place. Traditional campus-based tuition forces the student to be present at the time and place in which lectures and group seminars are held. By putting lectures out as video clips on an established web address, as well as arranging web-based meetings with voice and webcam, an attempt has been made to liberate participants from location-bound tuition. The video clips are accessible 24 hours a day so that the student in principle can view them whenever it is convenient and on any suitable medium that has a modern web browser installed. The idea is that this provides far more students with an opportunity to complete teacher training – primarily those who for one reason or another are unable to move to Bodø during the period of study.

I believe that it may be of interest to others who are involved with web-based tuition in general, and web-based maths teaching in particular, that I share these experiences.

Issue to be examined

In the course of this article I will address the following questions through action research (Schmuck, 1997), without arriving at definitive answers: What form of lecturing in mathematics using films published on the web has the better learning potential? Are there lessons to be learned about being present online as a math tutor in a web-based learning environment?

THEORY AND METHOD

Theoretical basis

What makes action research attractive as a theoretical backdrop for the survey is that it gives the researchers a more participatory role in their own research. It is not only permitted but even encouraged to be both a participant in the experiment that is being carried out, as well as to carry out research on it. The expression “experiment with” rather than “experiment upon” can be an expression of the general philosophy behind this scientific theory (Schmuck, 1997). The criticism often expressed by traditionalists is that such an approach will produce problems in terms of repeatability and objectivity. It may be replied that even with a traditional socio-scientific approach it is often impossible to guarantee an adequate degree of objectivity. The results that are presented are often derived from issues and interpretations of results that are not necessarily repeatable. One can also view action research as a systematic means of describing or interpreting personal interaction with the practice field, often entailing a quest for “improvements” after one or more actions have been carried out (Coghlan & Brannick, 2001).

In the methodology section of this article we will look more closely at our own approach to this general way of viewing action research. In particular we will attempt to employ it to challenge our own practices within web-based pedagogy.

The concept of web-based pedagogy

Web-based pedagogy can be viewed as one of the building blocks in a web-based education, in which the pedagogic interaction between teacher and student takes place via a data network as opposed to face-to-face contact in a teaching room. The term “web-based teaching” can perhaps be understood as a more general concept of which the actual web pedagogy forms one of the parts, alongside other elements such as how the courses are adapted to the internet, which attendance requirements should be for a web student as opposed to a campus student, etc. In this study I will deal particularly with one aspect of the pedagogic part: *how changes in presentation form used in the online lectures on the internet changed the perception quality of the students.*

Maths teaching for student teachers

For student teachers one wishes especially to promote a type of mathematics of a more practice-related and didactic variety than is found in other higher education. Teacher training is primarily a professional study that should be firmly rooted in

practice (Eraut, 1994). How can mathematical connections form a didactic backdrop for a teaching program? Different teaching theories, amongst which social constructivism (Bråthen, 1996) is perhaps the most prominent today, should shine through in the teaching.

Method

In this article I have chosen to employ a responsive action research form in which I collect data in advance of the actions in order to be able to form an instantaneous picture of how my own practice is working. This forms a basis on which to determine adequate measures, often with contributions from others such as the year coordinator and colleagues. These had a central role in the assessment stage in terms of making decisions about which initiatives to include in the action.

All in all, I have adapted the familiar action-research cycle to my own research in the following manner (Fig. 1):

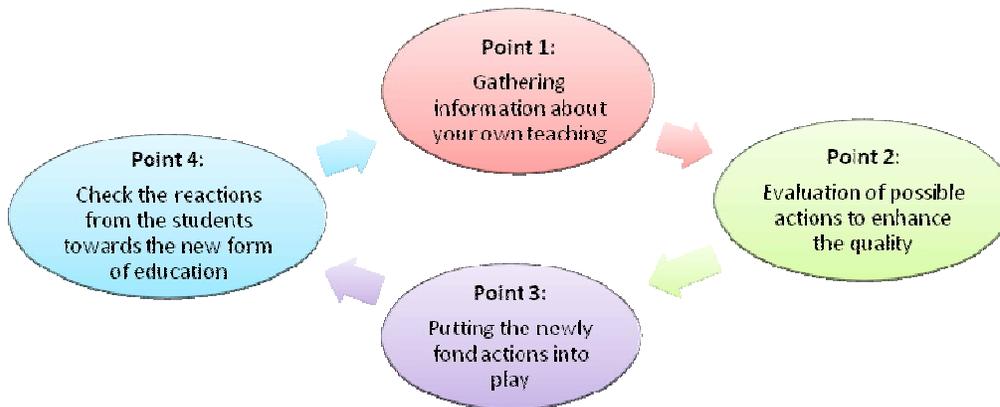

Figure 1: Action-research cycle in personal teaching practices

The purpose of action research

The concept of web-based education contains, naturally, no detailed definition of how the pedagogic scheme should function with regard to each individual course. It is naturally up to each individual web tutor to find his preferred way of doing this, according to the available resources and the terms of reference that are set by administrators, the director of studies and others (Paulsen, 2001). There does however exist some principal guidelines for the setup and construction of web-based education. In the background paper from Europace (2001) for instance, there is given a division in pedagogical principles, functions and variables in their theory of online pedagogy, and it highlights the importance of a teacher attaining the role of a support person for the learner.

In light of this, the goal of the research can be stated as: A search for the form or forms of web-pedagogic mathematics program that provides the best possible learning outcome for student teachers.

Actions

The actual actions will be dealt with in point 3, where I employ the new teaching reform. I have chosen to highlight two actions in particular, even though I undertook many minor adjustments to the teaching program which will not be described here:

1. Turning from static slide-show-based teaching to filming whiteboard presentations.
2. Using Skype for assistance in solving mathematical tasks.

In addition to these primary actions I constantly made small adjustments involving, for instance, the use of technical aids and how the material was presented.

Data in the survey

Data collection is built on concrete responses from students regarding how they perceived the different teaching forms used in the courses that I held. More precisely, I issued a simple question regarding this form in an e-mail. There were only 10 students attending this course, from which I received 7 replies. See the section “Results and discussion” for more details about the question asked and some representative samples of responses.

Description of electronic aids

To understand the pedagogic context in which the web study has been carried out I have chosen to include a presentation of the technical environments that were tested during this one term, as well as some lessons drawn from their use. This is in order to understand more easily the backdrop for the chosen actions. In terms of action research this description will be involved in points 1 and 2 described in Figure 1.

Camptasia Studio is a computer program that provides the teacher with the opportunity to combine a Power Point slideshow with sound/video of the lecturer which can be edited and put out on the internet for the students. Many lecturers at the University of Nordland, including myself, use this program to record lectures which in turn usually is uploaded on the virtual learning environment (VLE) “Fronter”.

Fronter is the VLE used by all students and staff at the Faculty of Professional Studies in the University of Nordland at Bodø. The platform offers a common structure with functionality for document sharing, news wheel, submissions and forum. As much of the teaching in a web and practice-based study is carried out over the internet, a VLE is the most natural portal for making teaching material accessible.

In addition to the purely static one-way communication involved in Fronter, I have also attempted to persuade the students to use the forum in Fronter for presenting their questions. In practice, however, it was difficult to motivate students to use the specially-designed forums to any great extent. We have not had time to investigate all the reasons for this, but we believe that one of the reasons is that it takes “many clicks” to find out whether there is any activity in a particular forum. I believe that a learning portal such as Fronter should incorporate means of notification using media

such as email, RSS and social network. In addition, I believe that editing of mathematical text must soon be taken seriously in such portals. At the moment, only poor-quality formula editors are available. In addition, support for LaTeX should be investigated in order to simplify entering formulae without having to resort to massive clicking in a Word-like WYSIWIG (“What You See Is What You Get”) editor.

The use of GeoGebra provides web teachers with many opportunities to demonstrate principles and analysis within geometry and function teaching. We used GeoGebra to demonstrate theorems such as Thale’s proposition by making screencasts in Camptasia Studio together with voice recording. The screencast combined with GeoGebra provides an opportunity to make dynamic geometric constructions, something that is not possible to put directly into Power Point without inserting film clips. In addition, the constructions are very precise and it is possible to demonstrate to the students how this important learning resource can be used.

As an extension of this it is possible to imagine the use of this tool in internet meetings, if it were possible to share one’s own desktop with the students. If concrete problems are brought up in which the students are struggling in geometry, solutions for these can be shown very effectively to everyone in the internet meeting by demonstrating the construction live, with everyone following. In this way one can attain a virtual blackboard teaching in geometry. Conferencing programs such as Skype offer just such a system of sharing the desktop that can make this possible.

Skype is a type of computer program that enables real-time communication in speech, text and image. If logged in, contact between different participants in a learning community can occur spontaneously. The service is free of charge, apart from the conference section.

This program is particularly straightforward to use in a web-based teaching context as it is not necessary to keep attention on the program itself all the time, as is the case for instance when using a chat function in a web browser, because when someone wishes to take contact, the user’s attention is drawn by means of sound/notification.

In a social-constructivist view of teaching, it is clear that a direct exchange of opinion and a joint problem solving will have a fairly central part in teaching math as well as in other subjects (Barron & Darling-Hammond, 2008). To my experience, the discipline is usually regarded so abstract that students can quickly find themselves frustrated by “getting stuck” in their own understanding of it. Regular contact with other students and with the teacher can be regarded as an essential part of mathematics study for teachers (Lampert et al., 2010). Skype can be a good alternative in this respect since it is easy to contact other students and teachers who are online in order to get help.

It was observed that individual students who did not often speak out in a normal classroom situation found it easier to do so when using Skype. Email may also seem more formal than Skype, which assumes a more chat-like form.

PREPARING AND PERFORMING THE ACTIONS

Students' reactions after two months of internet tuition in Camptasia

Between the two physical meetings of the web-based class a period of eleven weeks elapsed. During that period, new lectures and teaching on statistical methodology recorded with the help of Camptasia Studio were regularly issued, along with accompanying assignments and guidance with the help of NTR Meeting. The whole statistical analysis syllabus was gone through before the first meeting and we were very anxious to hear the students' reactions. Up until then there had been a more or less one-way pedagogic transmission of the syllabus.

The first hour with the group after the meeting was used for a repetition of the greater part of the syllabus that had been gone through on the internet. After this session we received feedback such as "I learned more during these two hours with you and the blackboard than by watching all the online lectures combined".

Why was this the case? A great deal of time had been spent in making an entire lecture series on statistical methods, in which emphasis was placed on using illustrations to simplify understanding of the fundamental concepts. The slideshow on which the online lectures were based was also made available so that the students could look at it in their own time as well as watching the actual video, optionally pausing/stopping/rewinding it.

The students pointed out that the material had too high a threshold to be put out on the internet. Analytical statistics was a topic of which few of them had any experience in advance and it required a good deal of assimilation time to understand all the new concepts that were introduced during the course. The students also pointed out that they had few "pegs to hang the material on". The perception of having learned a great deal during the blackboard teaching could well have been the result of a subconscious maturing that had taken place in the period leading up to the meeting.

In addition to the material on statistical analysis we had also put out some lectures on geometry. For these, films of demonstrations, prepared with GeoGebra on an office PC, were used, with an explanatory voice recorded in parallel. These lectures were given a better reception. Reactions received suggested that "the only thing we managed to follow was the practical material on GeoGebra, because then we could see things done step by step".

Another issue highlighted in students' feedback was that one had been too little accessible as a teacher. The communication was too much in one direction and the sessions using NTR Meeting were only partially successful: the sound/picture was too poor and the use of time too little flexible.

Planning a new teaching form

Some hints had also been given during the course that the chosen teaching pattern was not entirely suited to the fairly heavy statistics material. We reviewed some web-

based lectures that were produced by another institution (NKI) which combined filming of blackboard-based lectures, simple statistical attempts and slides. Short and simple lectures demonstrated with actions and words what the statistical formulae entailed. Even though the material's level of difficulty was far lower (descriptive statistics) and filming the lectures demanded a great deal of preparation and resources, there were ideas to be gained here. It seemed rather alarming that one required a cameraman to actively zoom in on formulas written up on the board, as well as that the final result contained edited-in film clips from other presentations of the material. The resources demanded by this type of arrangement clearly exceeded those available to me.

We were however interested in how others had designed web-based teaching in mathematics and conducted internet searches about this. I then found via YouTube a commercial resource from the American firm Classmate. This showed how a teacher, just through filming a static section of a whiteboard, was able to show mathematical procedures in a very understandable manner. I had the idea to try out the same thing. With a film camera mounted on a tripod I found out that this was possible without the help of an assistant, in other words, with far less planning and use of resources.

In order to accommodate the students over the second issue – a greater degree of presence – we decided to begin to use Skype far more actively. Skype has the opportunity to publicise accessibility by setting one's status in the program. If actively used, this can give an efficient way for students to know about your virtual availability for consultation.

The actions themselves

Having completed the whole syllabus before and during the final session, we only had the repetition lectures to try out the new lecture form. When the camera and external microphone were rigged up it was possible to concentrate fully on just the pedagogic conduct of the lecture. Personally I found this much simpler as a teaching method than using Camptasia. The reason for this may be that the teaching took place in a more familiar context, in front of a board.

In addition, as intended, we set up the use of Skype. Accessibility was ensured on the occasions when it was possible to help the students with problem solving. This led to a number of enquiries, either in the form of groups of students taking contact or of individual contact.

RESULTS AND DISCUSSION

Students' reactions to the actions, as well as follow-up assessments

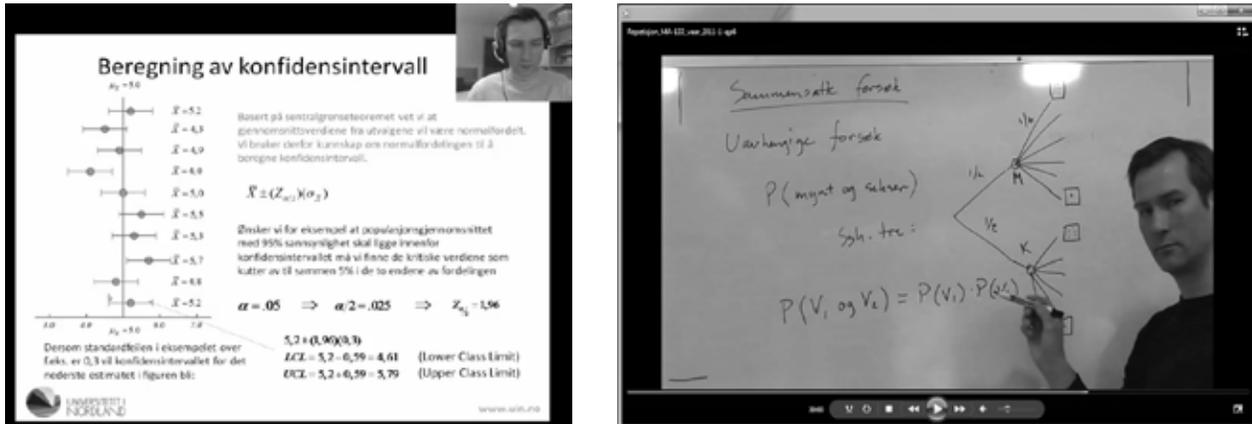

Figure 2: Web-lecture before and after the action. On the left the Camptasia studio recording, on the right, filming my own lecture.

Following the one repetition lecture that we had time to hold for the students we got in touch to ask for reactions to the new lecture form. We asked the students to draw a comparison between the previous form, with the Power Point presentation, and the new filming of the blackboard-based teaching. We did not use a questionnaire but instead sent out an email to which all the web-based students were asked to respond. The text was as follows:

I am working on writing up the web-pedagogic concepts of NP 5-10, and in this connection wonder whether I could have your opinion about the new form of web lecture, involving filming of the whiteboard, which I demonstrated in the last repetition lecture. Your opinions can contribute to shaping the future layout of the maths teaching in the NP classes. Are there other things that you feel could improve the web-pedagogy?

As one can see, the investigation is very loose in its form; there were not enough time to present and analyse a detailed questionnaire on how and why the new teaching approach had improved the learning. In all, the email was sent to ten internet students who had followed the course. I received seven replies. The reactions were unanimously positive. One of the students says:

Hi Helge! The last web lecture with the whiteboard worked well (...) I believe at any rate that this method of conducting web-based teaching is better than Powerpoint lectures (...) I think, by the way, that the sessions in which you used Geogebra were very good. The fixed times on Skype are a good idea.

Another wrote:

Hi Helge! I liked the whiteboard presentation a great deal and would be very glad to have this type of web-based lecture in future. It becomes immediately easier to grasp and one gets concrete examples for comparison.

Regrettably, there was no time for an in-depth study on how this change in lecturing affected the students learning outcome and quality, I only recorded the unambiguous positive response on my single-question e-mail survey. I see of little point in using tools like Grounded Theory to extract meaning from these data due to the small amount of text in the feedback from the students.

Skype also worked very well in the sessions we had with the students. We believe that using Skype creates a more synchronised presence on the net. The dynamic contact list with availability status creates a proximity to the student that is not achieved to the same extent via more asynchronous media such as Fronter.

Justification in mathematics-didactics research

Raymond Duval has researched the characteristics of the cognitive processes on which a good learning process in mathematics is based. In his article “A cognitive analysis of problems of comprehension in a learning of mathematics” (Duval, 2006) he highlights the term “transformations between representations”. In terms of mathematical objects, it is important for learning to at least achieve two types of cognitive representations of these. In geometry for example, one representation can be geometric, i.e. consisting of a picture (a right-angled triangle, for instance) and the other can be numerical showing the numerical relationship among the sides of the triangle (the property of Pythagoras, for instance). Duval believes that the essential prerequisite for learning is the transformation between these systems; in other words, to understand a mathematical object the purely formal symbolic representation is not sufficient but must be supplemented by an understanding of how the object is significant in other contexts.

Using the whiteboard as a learning tool as compared to a static slideshow, it is my opinion that this kind of representation dynamics is easier accomplished with a whiteboard. As the teacher explains verbally, she/he can sketch the connections, draw a graph, make a diagram or a figure, etc., to illustrate how a mathematical object will behave in different circumstances. There is also evidence that teacher’s gestures can be a rather critical ingredient in the mediation of mathematical concepts and relations (Alibali & Nathan, 2011). All these various “analogue tools” that can be used for meaningful mathematical teaching are clearly not available in the static slideshow context.

SUMMARY

On the basis of students’ feedback we can gain an indication that the action led to a clear improvement of my own web pedagogy. Naturally, critical comments are possible in relation to such a conclusion. For instance, there may arise a more or less conscious desire to appear positive towards me in order to increase their chances of a better grade at the end of the course. Another critical comment to the final result may be that the nature of the actions themselves leads to a positive attitude:

- Modern humans often have a positive image of change, at least in areas in which problems exist. The saying “in need of a change” is a significant one.
- The simple fact that one has attempted to address a problem may in itself be enough to ensure that the students have a positive reaction.

Also, one could raise critical remarks as to if such a small number of participants in a survey could lead to a definite conclusion.

Even if purely objectively we cannot say that this sort of change in web pedagogy will lead to a significantly improved learning process, it is possible, on the basis both of a theoretical consideration of maths learning (Duval, 2006) and of the unanimously positive public response, to assume that ground has been gained.

CONTINUING PROFESSIONAL DEVELOPMENT AND DIGITAL MEDIA IN MATHEMATICS EDUCATION

Maria Alice Gravina, Marina Menna Baretto, Marcia Notare

Instituto de Matemática, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

This paper presents the results of a study in a continuing professional program for mathematics teachers that had as main objective the integration of digital media in their teaching practices. The program was offered in a distance education modality. The didactic material was designed taking into account cognitive aspects that can transform the digital media into a powerful math learning tool. The analysis the didactic material is based on the semiotic potential of an artifact and the analysis of the learning process makes reference to the instrumental genesis theory.

INTRODUCTION

Studies on mathematics teaching and learning in digital environments have been developed since Papert's work (the turtle geometry in the 80's). Since then, a considerable development of theories has happened (Gueudet & Trouche, 2010). One important subject focus has been the technology potential to enhance the cognitive process in mathematics learning (Moreno-Armella, Hegedus, & Kaput, 2008).

However, the integration of technologies in the practice of mathematics teachers has been happening very slowly, as reported in different studies. This is because a considerable amount of teachers has graduated prior to the widespread dissemination of digital media. Therefore, it is understandable that they prefer to keep away from practices that make use of digital media. As a result, programs of continuing professional development are necessary to overcome the absence of digital resources in mathematics classrooms.

In this paper we present the results of a study in a continuing professional program for mathematics teachers offered by Mathematics Institute at Federal University of Rio Grande do Sul (UFRGS/Brazil). The "Mathematics, Digital Media and Didactic (MDMD)" is a distance education program that had its first version in the period 2009-2011. Its main objective is to prepare mathematics teachers for using digital media in their classrooms. We will outline the program design and analyze the teaching and learning process in its first course. This course had focus on dynamic geometry software.

Our study is based upon theories developed to understand the complex process of integrating technologies into teaching practices. The idea of semiotic potential of an artifact (Bartolini Bussi & Mariotti, 2008), associated with the theory of registers of representation (Duval, 2008), helps to understand the mathematics learning process.

The theory of instrumental genesis helps to explain the dialectic between conceptual and technical work accomplished by the teachers in their first experience with dynamic geometry (Artigue, 2002; Trouche, 2004).

SEMIOTICS REPRESENTATION, DIGITAL MEDIA AND THE LEARNING OF MATHEMATICS

The theory of registers of representation emphasizes the importance of systems of representation in the learning of mathematics (Duval, 2006). Duval makes clear that the systems used in mathematics not only convey concepts and ideas, but they also have operating rules that allow to perform processes that lead to new concepts and ideas – those are the registers of semiotic representation. The concept of transformation highlights the mathematical process that occurs within a register (a treatment) or that occurs between registers (a conversion). The coordination of registers creates mathematical comprehension and enlarges cognitive abilities.

Digital media enlarge the possibilities of registers of representation. Indeed, nowadays there are a number of dynamic representations that can be manipulated directly on the computer screen. Different registers are synchronized - text, graphs, figures, equations and also metaphorical objects – offering different aspects of the mathematical object. This makes the digital tools powerful in the development of cognitive abilities for the learning of mathematics (Moreno-Armella et al., 2008).

However, digital systems of representation might not be enough to ensure the learning of mathematics (Bartolini Bussi & Mariotti, 2008). According to these two authors, the learning process depends on the design of didactic situations that can provoke the development of utilization schemes that convey mathematical ideas – in a vygotskian perspective, a digital system of representation is an artifact to support and develop the mathematical reasoning. But the authors say that “*the link between artifacts and signs is easily recognized, yet what needs to be emphasized and better explained is the link between signs and the content to be mediated* (p. 752)”.

We also rely upon the theory of instrumentation that explains the dialectic between conceptual and technical work when using a digital artifact (Artigue, 2002; Trouche, 2004). The differentiation between artifact and instrument is clear in this theory: an instrument is a mixed entity that involves an artifact and cognitive schemes of utilization. In this theory, the development of cognitive schemes related to software is called instrumental genesis. On the one hand, this development depends on the subject’s actions towards the artifact (the instrumentalization process). On the other hand, it depends on the subject’s actions that are provoked by the feedback of the artifact (the instrumentation process).

The interesting expression *toolforthoughts*, coined by Clinton and Shaffer (2006), highlights that subjects and artifacts (as digital systems of representation) can interact in an action and reaction process that produces cognitive attitudes towards new knowledge. In this paper we will use the expression *toolforthoughts* as

synonymous of *instrument*, because it conveys better the notion of “a tool to think with”.

The theories helped us to understand that teachers need to experience their own *instrumental genesis* prior applying digital media resource as *toolforthoughts* in their classrooms. So the didactic material was designed to provoke their instrumental genesis. The experience with the teachers showed that they need to be supported by professional development programs in new practices in order to think creatively about a curriculum that integrates the digital media. We look at these issues in this paper.

THE DESIGN OF HYPERTEXT WITH INTERACTIVE ANIMATIONS

The program MDMD was designed to prepare teachers to use different mathematics software in their classes. Particular attention was given to the software semiotic potential and to the process that makes an artifact become a *toolforthoughts*. The courses' contents emphasized the mathematics concepts and technical skills required to use a particular software. Pedagogical strategies were also presented.

The design of the didactical material focused on the role of the registers of representation, as well as on the utilization scheme to be developed in the learning process. Knowing beforehand the semiotic potential of the software, we prepared activities requiring utilization schemes related to transformations of registers, especially the conversions. For instance, activities using discursive and geometric registers were planned through geometric constructions with GeoGebra. Real variable functions activities requiring conversions from geometric register to algebraic one were also prepared with GeoGebra. An interesting conversion from geometric to algebraic register was proposed with software GrafEq – the goal is to produce geometric shapes using algebraic registers.

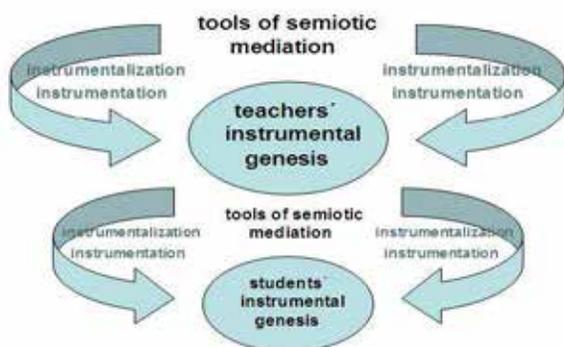

Figure 1: Cascade of instrumental genesis processes

The Program predicted a *cascade of instrumental genesis processes* represented in Figure 1. The activities, designed according to the principles of theory of semiotic mediation, were organized to provoke teachers' instrumental genesis and it was expected that the same material would be used by them to promote a similar instrumental genesis process in their classrooms. This cascade idea is supported by

the theory of documentation (Gueudet & Trouche, 2010); the theory highlights the important role of the resources used by teachers while preparing a topic to be taught.

Each course used its own website and focused on different software. The websites have a similar design in order to make the navigation easier (Figure 2). In the left frame there are modules and each one is divided in sub menus: (i) objective - gives the answer to the question “what we are going to study in this lesson?”; (ii) contents – presents the mathematics contents and the didactic background theories; (iii) activities – brings the activities to be developed; (iv) resources – presents tutorials for the software to be used; (v) complements - suggests additional material to enhance the contents and media used in the module. We will discuss a specific course of the program, Digital Media I, which emphasizes GeoGebra as a math learning tool. As undergraduate courses in Brazil, even nowadays, still do not prepare teachers for integrating digital media in their teaching (Jover, 2008), the website was designed to provoke the instrumental genesis in dynamic geometry environments. The main purpose was to provoke the utilization schemes in order to properly explore dynamic geometry, especially the “drag action” scheme.

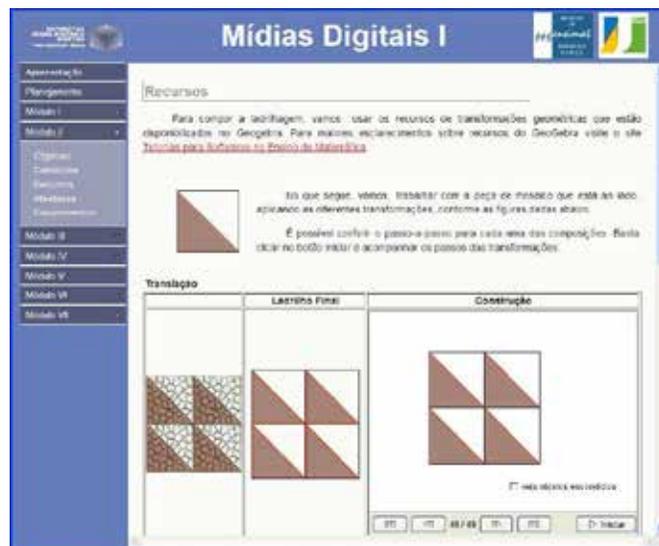

Figure 2: one of the course website interfaces. In the detail, the submenus objective, contents, resources, activities and compliments.

The theme of the module I and II is mosaics and tiling patterns and the module III is about geometric modelling. We are going to observe the instrumental genesis process through the work realized in those three modules. The whole site material can be seen at <http://www.ufrgs.br>, at the link ‘Disciplines’.

In module I the teachers are invited to observe different mosaics in their everyday life and produce a similar one with GeoGebra. A simple construction like this is not easy for beginners in dynamic geometry. The site offers interactive animations that explain how to produce mosaics and the construction procedure can be followed step-by-step in the user's learning pace. The module II focuses on the geometric transformations: the task is to produce different tiling patterns using the same mosaic

but different transformations (reflection, rotation, translation). As in the mosaic activity, interactive animations are available to help the beginners.

In module III, geometry is explored through modelling. Now the task is to produce a virtual model of an everyday-life mechanism – as a fan, a car piston, a hydraulic jack or a scale. Some virtual models that can be manipulated are available in the submenu *Contents*. Interactive animations and the protocol of construction that will help in the understanding of the construction procedures are presented in the submenu *Resources*.

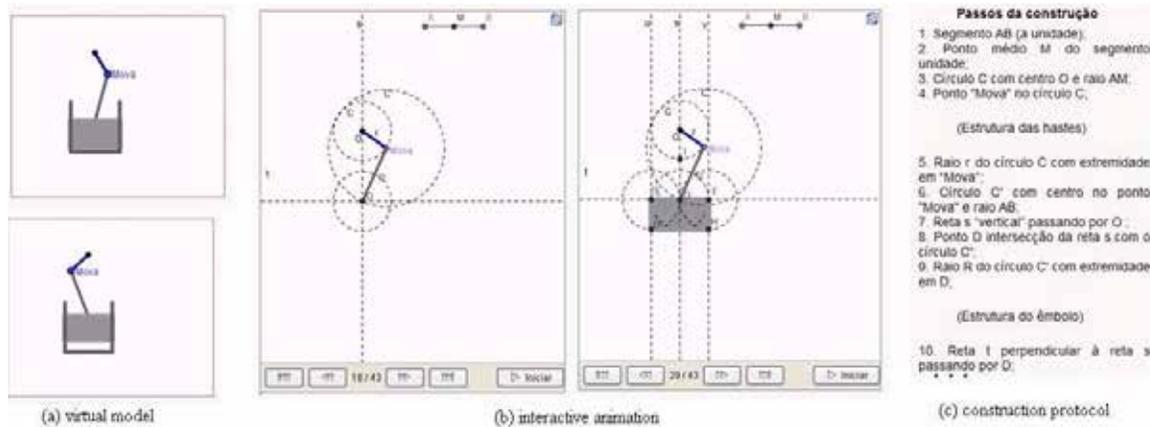

Figure 3: different registers of the model piston in the website.

Figure 3 illustrates the resources available in module III related to the model "piston": (a) shows two instances of the virtual model; (b) shows two different moments of the interactive animation of the construction; (c) shows the construction protocol.

The material offers different registers of the model to be learned. The virtual model can be manipulated (the "drag" of the blue point produces the piston movement) and the dynamic geometric register might be enough to proceed with the construction. Otherwise, the user can observe the step-by-step construction using the interactive animation and, at the same time, manipulate the model. If this second geometric register is still not enough to proceed with the construction, the user can read the discursive register.

One of the characteristics of the interactive animations is the navigation bar allowing going back and forth in the geometric construction. If necessary the user can also change the steps speed. Those two features make the interactive animation adaptable to different learning rhythms, which is an important aspect to be considered in the process of *instrumental genesis*. The teachers learned to use GeoGebra in the distance education program MDMD using those resources which were organized in a website.

A TEACHER LEARNING TO USE THE SOFTWARE GEOGEBRA

One hundred and eighty teachers attended the course and were accompanied by a professor and seven tutors. Teachers were distributed in seven cities in the state of Rio Grande do Sul, forming groups between 15 and 30 participants. A tutor, under the supervision of the professor, supported each group. The didactic material used was the website “Media I” presented in the previous section. Guidelines for the activity to be performed were posted weekly in the virtual environment Moodle. The teachers published their production in a Moodle Database consisting of a GeoGebra file and a text about the difficulties and the progress during the week. The interactions between groups and tutors happened in a Moodle Forum.

As most teachers had no knowledge of dynamic geometry software, it was interesting to observe their instrumental genesis process. In what follows we will analyze the process experienced by one teacher. Through the production presented in the three first modules of the course, we will bring evidences of the instrumentation and instrumentalization processes that were experienced by the teacher. The analysis uses the material that she posted weekly on Moodle. In her first attempts to produce the mosaic activity, proposed in module I, she says:

I did not know the software, so I had great difficulty.... I made several attempts because I was not having success to move the vertices of the mosaic without any deformation in shape.... I felt that it is needed a specific training with GeoGebra, so that we can explore constructions and then get the desired results.

When the teacher talks about the need of specific training to explore the software to accomplish the construction, she stresses the importance of recognizing the potential of the software (the instrumentalization process). When she refers to the need of practice with the software to obtain a figure in dynamic geometry, one can see a manifestation towards the development of utilization scheme (the instrumentation process). The tutor’s comment shows that the teacher is still developing the utilization schemes:

I realized that you explored the software quite a lot and you've already done a nice job ... still there is a problem with the construction related to the figure stability ... but this is common to most of those who are dealing for the first time with dynamic geometry... congratulations for the many construction attempts.

It was observed that the interactive animations of mosaics, available in the website, had an important role in the awareness of the two aspects of the instrumental genesis. The mosaic activity provoked an evolution of attitudes: in the beginning the teacher talks about things she does not know and difficulties with GeoGebra. She explores the software menus and makes many essays of construction – we would say that she is developing the utilization schemes that will transform the artifact into an instrument.

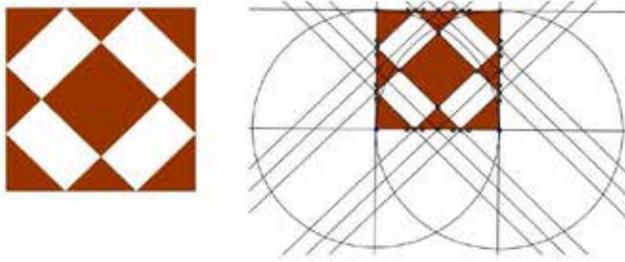

Fig 4: The mosaic produced by the teacher

Figure 4 shows her final mosaic and the geometric procedure. The square, made with perpendicular lines and compass, is a dynamic figure; for decoration she used several times the menu “midpoint” instead of the efficient menu of transformations available in GeoGebra – after constructing the first white rectangle, the others can be done through rotation. The teacher’s action indicates an instrumentation process in progress.

In the tiling pattern activity of module II, the tutor observed that the teacher did not make so many attempts as before. She was quite confident to produce a tiling pattern in dynamic geometry. Figure 5 indicates: a) the tiling pattern produced; b) the construction procedure; c) the basic elements of the pattern. At the end of the activity the teacher says:

As mentioned in the previous task, I did not know the software ... It was still very hard to carry out the new activity ... For reaching to the end of the task I spent several hours in front of GeoGebra... I am very concerned about the time that will be necessary to perform the next tasks.... I need to learn how to get the desired result faster ... I did my best at this moment.

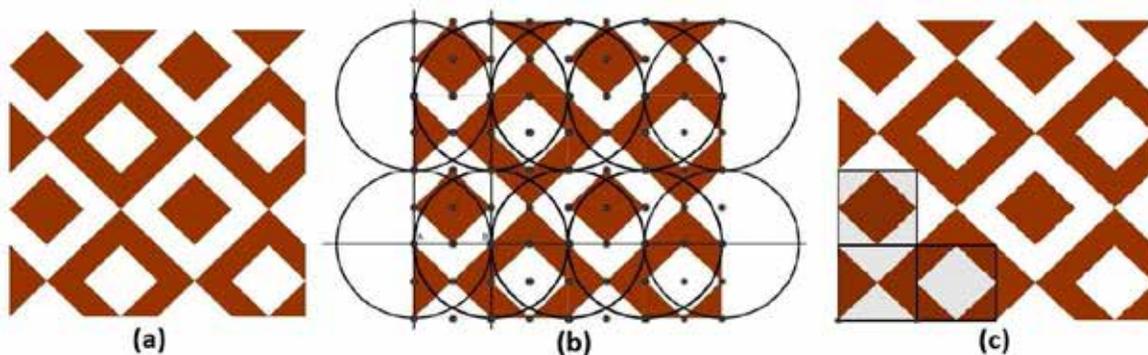

Figure 5: The tiling pattern produced by the teacher

The teacher advanced in her instrumentation process – the figure was made stable under “dragging” without the need of many attempts. However, it is possible to observe that the utilization schemes related to geometric transformations are still quite incipient even though this was the utilization scheme to be developed through the activity. The central reflection transformation was the only one present in the construction protocol and it was applied only to points. The tutor’s comment is:

As I have mentioned, you already have understood the spirit of dynamic geometry. In the construction of the tiling pattern I noticed the frequent use of the reflections, which is very interesting. I invite you to explore other geometric transformations in the task that is coming.

The construction procedure, illustrated in Figure 5b, still shows several circles, lines and segment midpoints - the construction has about 250 steps. In fact the teacher “spent several hours in front of GeoGebra” to accomplish the task and we would say that she was not yet using GeoGebra as a powerful tool for thoughts. She did not pay attention to the basic shapes that are highlighted in Figure 5c. With those shapes and using the geometric transformations (rotation, translation, reflection) it would be possible “to get the desired result faster” (a comment made by the teacher herself).

In the modelling activity of module III, the teacher produced a virtual blind window (Figure 6). The construction required more mastery of the GeoGebra menus. To obtain the “open-close” virtual movement, a point on a circle arc was used and the corresponding radius was the initial segment of one of the blue parallelograms. The reflection transformation was used in different moments to produce a second copy of the articulated blind window. In this third activity the teacher reveals a progressive recognition of the GeoGebra potential and also shows more confidence with the schemes of utilization.

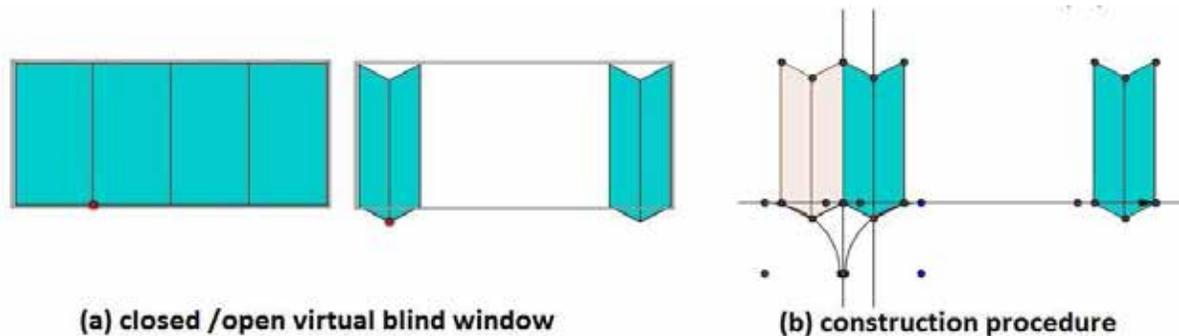

Figure 6: The geometric modelling activity of the teacher

The teacher’s production and her interactions with the tutor illustrates that simple geometry activities can be a source of difficulty for those who are starting a process of instrumental genesis. Artigue (2002) points out that the instrumental genesis involves the interweaving of mathematical knowledge and technical abilities to use the software features. In fact, it was observed that some of the teacher’s difficulties were related to the ability of using GeoGebra features, but she also had difficulties with the geometry knowledge required in the activities. In the whole group, similarly, we observed that the processes of instrumentalization and instrumentation happened completely intertwined with the geometry content. For instance, it took time for teachers to feel confident with the use of the geometric transformation menu and the main reason was the lack of knowledge, since geometric transformation is not a school subject in Brazil.

CONCLUSIONS

The analysis of the production of one of the teachers following the first course of the Program MMDD shows that the *instrumental genesis* is a complex process. As a general remark we would say that the process that will transform an artifact into *toolfortoughts* depends on many experiments. As a whole group, teachers did many experiments with GeoGebra and after two months, they carried out teaching experiments in their classrooms, as part of the course activities. Even though teachers had experienced their instrumental genesis (in fact, the instrumental genesis is always a process in progress), the use of GeoGebra that they did with their students was still quite modest. But even so, they spoke enthusiastically about the new teaching experience. One teacher said that “in the first meeting my students explored the GeoGebra tools... then they started the construction of polygons that do not deform, with motivation, interest and cooperation... they were very excited”; another one said that “the activities carried out with my students were special... I felt satisfaction and delight of the students with their geometric constructions”. The teachers’ experiments were not enough to evidence a cascade of instrumental genesis processes, as had been predicted in the design of the Program.

We might say that for the happening of such a *cascade*, a new perspective about the teaching and learning of mathematics must be also envisioned by teachers during their instrumentalization and instrumentation processes. Besides attention to the instrumental genesis process, professional development programs also need to pay attention to what could be called the genesis of a digital pedagogy. The teachers’ experiments with their students showed us that to think creatively about a school curriculum that integrates *toolfortoughts* is not an easy task. One important research issue to be addressed is: “how can the digital technology transform the school curriculum?”

DEVELOPING AN INTUITIVE CONCEPT OF LIMIT WHEN APPROACHING THE DERIVATIVE FUNCTION

André Henning and Andrea Hoffkamp

Humboldt-Universität zu Berlin

The central idea of calculus is the concept of limit. German secondary school curricula claim to introduce the concept of limit in an intuitive way refraining from a rigorous mathematical definition. However, it is unclear what can be regarded as a “good intuitive basis”. After the discussion of typical student problems we present a DGS-based activity to support the introduction of the derivative function fostering a dynamic concept of limit. Aside from the step from derivation as a local phenomenon to the global view of the derivative function we also show how the activity can be used to visualize and talk about the variety of limit processes.

Keywords: conceptualization processes, DGS, interactive learning activity, concept of limit, teaching and learning of calculus

INTRODUCTION AND RATIONALE

The problems of contemporary calculus courses at secondary school mainly result from the tension between learning or teaching of routines and the development of a structural understanding of the underlying concepts (Tall 1996, p. 306).

In fact this problem exists since the introduction of calculus to German school curricula: for example Toeplitz (1928) urges to remove calculus from school if teachers are not able to bring out more than the teaching of mere routines.

The fundamental concepts of calculus (e.g. the concept of limits, derivation and integration) are mathematically advanced. Therefore teachers are always required to make didactical decisions about what to teach in a visual-intuitive way and what to teach in a mathematically rigorous way.

For example the secondary school curriculum in Berlin, Germany, explicitly demands an intuitive or propaedeutic approach to calculus concepts at the end of grade 10. This is established through introducing a special “Modul” called “Describing change with functions” (Jugend und Sport Senatsverwaltung für Bildung, 2006a). In this context Hoffkamp designed and investigated several DGS-based activities to support such a qualitative approach (Hoffkamp, 2009, 2011), which could lead to a sustainable intuitive basis of certain calculus concepts.

Considering the central role of the concept of limit within calculus, the described situation needs particular attention. On the one hand the Berlin secondary school curriculum for grade 11 mentions that the concept of limit can only be taught in a propaedeutic way since the necessary exact notions (series, convergence tests) are not available to the students. On the other hand, the teachers are required to

introduce the derivative as limit of the difference quotient (Jugend und Sport Senatsverwaltung für Bildung, 2006b).

Sfard (1991) describes the process of mathematical concept formation. Starting with operational conceptions (e.g. functions as computational processes, rational numbers as results of division of integers) structural conceptions (e.g. function as set of ordered pairs, rational numbers as pairs of integers) develop, the latter leading to the establishment of abstract objects.

Fischbein (1989) offers another perspective on the issue of intuitive approaches as well as the process of mathematical concept formation. He describes how, during the process of mathematical abstraction, mental models of the abstract concepts develop in the learners mind. According to him these intuitive models, tacitly or not, influence the way we conduct mathematical reasoning processes. These tacit models are one reason for the difficulties students are facing in the process of learning mathematics. He suggests allowing the students to consciously analyze the influence of those tacit models and in this way to allow them to avoid the development of misconceptions.

Taking the above into account means to realize the necessity of a profound intuitive basis or cognitive root (Tall, 2006) for the limit concept that could lead to the development of an object view of the derivative. Cognitive roots as described by Tall (2006) are not mathematical foundations but approaches that build “on concepts which have the dual role of being familiar to the students and also provide the basis for later mathematical development” (Tall, 2006). According to him they require a combination of empirical research and mathematical knowledge in order to find them. In our opinion, DGS appears to be a good means in this context, therefore we present an activity using DGS-based interactive visualizations fostering a dynamic idea of limits and leading to an object view of derivation.

In the following we will describe the conceptual change approach and the potential of DGS-based activities. We will give an example of an activity that is related to our rationale. After that we will present our research questions and the results of a video-study.

Spontaneous conceptions of limit and conceptual change

The above considerations conform to a genetic view of learning as described by Wagenschein (1992). Especially for the process of conceptualization, a theoretical perspective like the conceptual change approach is helpful to design activities like the one described in this article, and to understand the students’ learning processes. The conceptual change approach itself is a genetic learning theory. A description can be found in Verschaffel and Vosniadou (2004). Conceptual change does not mean to switch from one concept to another by replacing the old concept by a better new one. It is the process of reintegration and reorganization of cognitive structures in order to

develop mental conceptions and to activate the appropriate conceptions dependent on given contexts (Verschaffel & Vosniadou 2004, p. 448).

For the process of conceptualization it is important to know about the students' spontaneous conceptions and to build on them. In fact the students' spontaneous conceptions can be considered a learning opportunity and a starting point for further development by dealing with them explicitly (Prediger 2004).

Therefore we tried to find out about the students' spontaneous conceptions of limits. We asked students at the end of grade 10 and 11 to write a letter to an imaginary "clueless" friend explaining the mathematical notion of limit. We present two excerpts from letters here. One student wrote:

The limit is the outermost value of a number range. For example if one says "all numbers from one to five" then one and five are limits.

Another student wrote:

Considering the graph of a function over a large interval one can observe that some functions come closer and closer to a certain value. The function tends only to this value, without drifting away again. However, the function does not reach or exceed it.

The first excerpt shows that the student considers limits as bounds of intervals and formulates a static conception of limit. The second excerpt reflects the student's experiences with limits in connection with asymptotic behaviour. Although the student formulates a dynamic conception of limit, his conception is not elaborated since limit processes seem to be always "monotonous" and limits "cannot be reached or exceeded".

These observations are confirmed by the work of Cornu (1991) who described typical spontaneous conceptions of limits. In fact all limiting processes like the concepts of continuity, differentiation or integration contain similar cognitive problems: To overcome or integrate the spontaneous conceptions in the learner's individual concept.

THE USE OF DGS-BASED ACTIVITIES

As already mentioned we think that DGS is a good means to establish an intuitive basis of the concept of limit. With respect to the mentioned spontaneous conceptions and the conceptual change approach, DGS-based activities could not only help to develop a dynamic view of limit and limit processes, but also help to develop a more elaborated conception of limit by visualizing the variety of limit processes. Therefore we combine interactive visualizations with special tasks stimulating verbalization and exploration processes. Especially the role of verbalization as a mediator between the representations and the students' mental concepts when working with interactive visualizations was pointed out in the work of Hoffkamp (2011) and based on Janvier's work (1978).

Which role of the computer do we focus on? At first, we benefit from the various possibilities of visualizing mathematical concepts. Therefore, we make use of the possibility to visualize a holistic representation in contrast to a linear order of mathematical content (see also Sfard 1991). Moreover we add interaction to enable learners to explore the interactive activities without negative consequences.

While giving the opportunity for exploration we use the computer to “restrict the actions of learners and thus help them to develop appropriate mental models of representation” (Kortenkamp 2007, p. 148). In this sense visualizations play a heuristic role and can be used before exact mathematical notions or concepts are available.

THE ACTIVITY “TOWARDS THE DERIVATIVE FUNCTION”

In the following we present a DGS-based learning activity. It introduces the derivative function as an object and its relation to the original function. This activity is meant to be exemplary. It shows how conceptualization processes in the context of the concept of limit can be supported by using special DGS-based activities. Our idea of using the difference quotient and its extension by continuity for an object-based approach to obtaining the derivative function has already been mentioned by Mueller and Forster (2003) quoting Yerushalmy and Schwartz (1999). However, they did not explicate the full didactic potential of this approach and did not use the dynamic approach towards limit that can be fostered by a DGS-based activity.

The two focal points for our activity are emphasizing the difference quotient and permitting a look on various limit processes that constitute the analytical step. The difference quotient is not only a (theory generating) precursor for the differential quotient and the derivative (the way it is often used in schools). It is the concept that has a direct relation to reality through the concept of average change (of speed etc.). Therefore it is evident for students and is thus worth taking a closer look at.

The activity is meant to be used when the derivative of a function at a certain value is already known to the students. However, the students have no elaborate limit concept so far. This is usually the case at the start of grade 11 in secondary schools. The derivative function, however, is not known to the students yet. The way from a local (derivative at a point) view on derivation towards a more global, object based view (derivative function) shall be supported, while several limit processes get examined on the way. This is in line with our idea of broadening the view on limits as well as bringing about an object view on the derivative function.

The activity can be found at

<http://www2.mathematik.hu-berlin.de/~hoffkamp/Material/ableitungsfunktion.html>.

Description of the activity and didactical analysis

The activity consists of three separate worksheets or tasks. It is very rich concerning mathematical concepts. We will however only describe and didactically analyze selected parts that have a direct relation to the presented results and aims of this article. Figure 1 gives a general idea of what one of the tasks looks like. The text above the applet gives an introduction to the task. The text next to the applet poses special questions and tasks that also ask students to verbalize their thoughts and observations and are meant to help the students go through the conceptual change process we intend to initiate. This also relates to Fischbein. Verbalization makes tacit models and intuitive concepts accessible to a conscious process of reflection.

The tasks are consecutive. Different predetermined functions f can be chosen in every task to make sure there is not just one but many graphs available. The restriction on predetermined functions allows a broadening of the view while at the same time focusing on certain sustainable examples (see also Kortenkamp, 2007). The functions were chosen as examples of certain classes of functions - symmetric and non-symmetric, polynomial and trigonometric functions and in tasks 2 and 3 also the (at the origin) non-differentiable absolute value function.

Figure 1: General overview of a worksheet.

The first task takes up the so far local ideas of the derivative at a point and differential quotient as the limit of the difference quotient. In the second task a first object view on the derivative function is reached. Also the limit process observed is changed. The third task introduces yet another variation of the limit process while the object view on the derivative function remains in focus.

The first Applet (see figure 2) offers a process view on the functions we will take an object view on in tasks 2 and 3. For three fixed values of h the term $\frac{f(x+h) - f(x)}{h}$ (the difference quotient) is evaluated at a certain x -coordinate. The x -coordinate can be changed by dragging the big red point on the x -axis. The point $\left(x \mid \frac{f(x+h) - f(x)}{h}\right)$ is always printed in blue. The students already know the difference quotient. So far they only evaluated it for a single fixed value of x and varying values of h to gain the derivative at a point. If tracing is activated one gets a trace of the

resulting points which forms the graph of the function g with $g(x) = \frac{f(x+h) - f(x)}{h}$ (for fixed h). This way we have a point wise (process) view of the construction of the graph. We change between processes by varying h . The resulting function becomes a better approximation of the derivative function for smaller values of h .

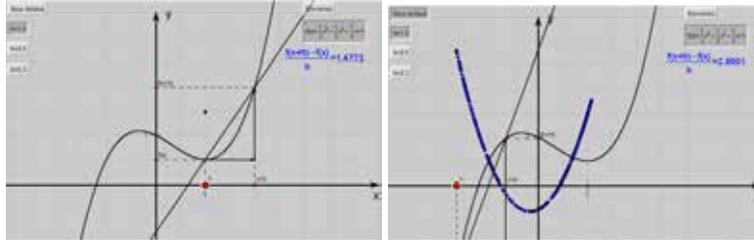

Figure 2: Applet 1 without and with tracing within the first task.

The second and third applets are pretty similar in their construction, which is why only one of the two is pictured here in figure 3. They both show graphs of functions that can be manipulated. In applet 2 there is only one function namely g with $g(x) = \frac{f(x+h) - f(x)}{h}$. In addition to that applet 3 also visualizes the function k with $k(x) = \frac{f(x+h) - f(x-h)}{2h}$.

Switching over to applet 2 we have a new situation. The function that developed as the result of a process (of changing the x value) in applet 1 now exists as a single entity. We evaluate the difference quotient for all values of x simultaneously now (note that this is not the difference quotient function as that would be $g_x(h) = \frac{f(x+h) - f(x)}{h}$ for a fixed value of x). At the same time we no longer have fixed values of h but can change those using a slider. If the value of h is changed, the graph of g moves as a whole. The students observe a family of curves that converges to a limit function. According to Sfard (1991) working with families of curves or equations with parameters is already a step towards reification. Limit becomes something more dynamic in this context as the students observe and describe the limit process that leads to the derivative function for differentiable f .

The third applet is aimed at the development of a more elaborated conception of limit. In contrast to task 2 we now take a look at not only one but two different limit processes. We show that different limit processes can lead to the same limit. The idea is to prevent or change a very restricted view on limits as could be seen in the student letters described above. An object view on the functions involved is necessary now.

One observed object is the function g , already known from task 2, the other is the above mentioned function k with $k(x) = \frac{f(x+h) - f(x-h)}{2h}$. k represents a symmetric differential quotient. It has some interesting characteristics. For example, if f is a symmetric function, k has a local extremum where f' has a local extremum for any given value of h . For g this is obviously not the case. The students are asked to

describe and compare the functions g and k and to explain their observation geometrically (by using secants) and algebraically (by comparing both forms of difference quotients). One other observation is that k converges faster to f' than g . Therefore the symmetric difference quotient is better for numerical computations. For polynomial functions this can even be proved with students. The students may discover that convergence is not always the same and that different processes may converge at different speeds.

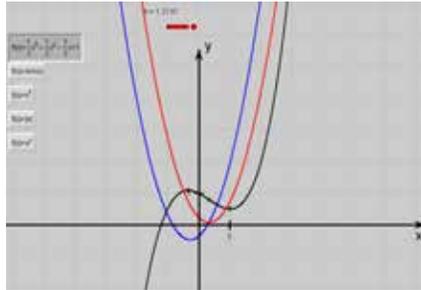

Figure 3: Applet 3 within the third task.

METHODOLOGY AND RESEARCH QUESTIONS

A first video study was conducted in August 2012. The two authors acted as researchers and teachers respectively. The activity was introduced in an 11th grade advanced course in mathematics. Students were video-taped during their work with the activity. The students' worksheets were collected for further study. Classroom interaction was noted by one of the authors while the other lead the course in classroom discussion and students' presentation of their results.

Our analysis of the collected data is led by the following research questions:

In what way can a dynamic-visual approach as depicted in this paper support the development of a sustainable conception of limit and related mathematical concepts?

What conceptions of limit do students develop if confronted with activities as the one presented?

What spontaneous conceptions can be uncovered through analysis of students' work and how can they be used as learning opportunities?

FINDINGS

One of the tasks for the first applet was "In which cases is the value of the difference quotient positive, negative and when is it equal to zero? Explain the geometric meaning of a positive/negative value or a value equal to zero." Many students answered in the way of "Positive if the graph increases; Zero if the central point of $x+h$ and x is similar to the local maximum; Negative if the graph decreases." Their reasoning however is only possible through the analytical step; the core achievement of school analysis. From a mathematical point of view, what we see here is a misconception: the difference quotient is interpreted as the differential quotient. The

students spontaneously assumed linearity. For linear functions the slope of any secant equals that of the tangent in any point of the graph. Therefore we may infer the behaviour of linear functions from the slope of any secant. In general, this is no longer true for non-linear functions, so the slope concept of the secant needs to be evolved to that of the tangent. The students' spontaneous conception of linearity became apparent and could be productively and explicitly used directly within the classroom in order to emphasize the fundamental difference between the difference quotient and the differential quotient. The second part of the students' answer was taken up in class discussion to develop Rolle's theorem starting in an informal way.

If we take another look at the above excerpt, we make another interesting discovery. The task was taken up again in later class discussion. It led to a theorem of monotonicity. What became apparent here is that mathematical logic and quantification constitute an important obstacle for students. It was difficult for them to express that the function is not increasing or decreasing for every x between x and $x+h$ but that there is at least one x with an increasing tangent.

The third applet offered a view on different limit processes that lead to the same limit. The students were asked to verify that the usual difference quotient and the symmetric one tend to the same limit. Or rather that the limit of the two series of secant-slope-functions actually is the derivative function. It was very hard for the students to verify any of this geometrically, which sheds light on the fact that geometric representations need to be focused on more, and the geometric meaning of the limit process when approaching the differential quotient should be made more explicit in a dynamic way. However, the students were able to compute the limit for certain values of h and this way convinced themselves that the symmetric difference quotient actually leads to the same limit as the usual one. To give an example of what they did, we present the work of one of the videotaped students. He said:

“We are not supposed to know, what function this is, but if we let h go to zero in this task, we shall only show, that it becomes roughly the same. They should move towards each other now... [uses the slider to let h go to zero]... Because it does not matter if we have plus zero or minus zero here or two times zero.”

He used the dynamic possibilities of the applet to support his assumption and realized that when he made h very small, the two graphs were almost indistinguishable. Finally he computed (in a longer way, but essentially)

$\lim_{h \rightarrow 0} \frac{(1+h)^2 - 1^2}{h} = 2 = \lim_{h \rightarrow 0} \frac{(1+h)^2 - (1-h)^2}{2h}$ to convince himself and the other students that his earlier observation was true. This way the students became aware of the fact that there is a variety of comparable limit processes leading to the same limit. The insight into the necessity of proving their assumption was directly evoked by the use of the dynamic possibilities provided through the applet.

CONCLUSIONS

The presented observations give an insight into the polymorphism of possibilities within the described individual cases and may raise one's awareness for the perception of specific students' conceptions and the own didactical action.

We are also confident that activities like the above are valuable means in the conceptualization process and may serve as cognitive roots respectively as an intuitive basis, as can be seen in our study. They allow the development of a dynamic conception of limit that appears to be a good cognitive root. Additionally, when using the applet there can be a clearer focus on the analytical step as a core achievement of analysis.

We have seen that a qualitative-empirical analysis as depicted in our paper can give impulses for further didactical and mathematical analyses. The search for appropriate cognitive roots necessitates further inquiries into the nature of such roots. More work in the field of ICT-based concepts and activities, also in the way of mathematics education as a design science (Wittmann 1995), is necessary here.

ACKNOWLEDGEMENTS

This work was partly supported by Deutsche Telekom Stiftung and Humboldt-ProMINT-Kolleg. We also wish to thank Robert Bartz and Dr. Sabiene Zänker for their constructive remarks from a teacher's point of view.

A FRAMEWORK FOR EXAMINING STUDENT LEARNING OF MATHEMATICS: TASKS USING TECHNOLOGY

Marie Joubert

University of Nottingham

This paper, taken directly from the author's doctoral thesis, (Joubert, 2007) develops a theoretical and methodological framing for examining student learning in the context of mathematics classrooms where computers are used. The framing, drawing particularly on the Brousseau' theory of didactic situations (1997), takes into account not only the student interactions with the environment but also the crucial role played by the feedback from the computer. This approach focuses on the processes in which the students are engaged and suggests the sorts of interactions that might provide evidence of student mathematical learning. The paper concludes with a section which analyses an episode of student mathematical activity using this framing.

Keywords: modes of production, computer, feedback, task, graphing

BACKGROUND AND CONTEXT

Mathematical activity, like all human activity, is mediated by tools, which include not only symbol systems, mental representations, algorithms and representational systems (such as functions and co-ordinate graphs) but also physical tools such as pen and paper, calculators, measuring devices and so on. Computers can be seen as a particularly interesting tool because of their 'intrinsically cognitive character' (Balacheff & Kaput, 1996, p. 469). For some software used in the teaching and learning of mathematics, the implication is that, to a greater or lesser extent, the software can perform mathematical processes (or 'do the mathematics') (Hoyles & Noss, 2003; Sutherland, 2007) for the user. For example, in traditional mathematics classrooms producing a bar chart from a set of data is seen as a valid mathematical activity, but a data handling package is able to 'do' this mathematics (as described by Ruthven and Hennessey (2002)). This has important implications for the design of classroom mathematical tasks.

A second important characteristic of software, related to its cognitive character, is the fact that software provides feedback for the user;

'The interaction between a learner and a computer is based on a symbolic interpretation and computation of the learner input, and the feedback of the environment is provided in the proper register...' (Balacheff & Kaput, 1996, p. 470).

This feedback, together with the ability of the software to 'do the mathematics' as described above, are perhaps the most compelling reasons for seeking to understand the way these tools are used in ordinary classrooms.

The current literature focuses more on teachers' perceptions of the actual use of computers in mathematics classrooms (Monaghan, 2004; Ruthven & Hennessey,

2002) than on the student processes (Lagrange et al., 2003). However, as Tall (1995) argued over fifteen years ago, there is a need to focus our attention on the students' thinking processes in situations where computers have become established in classrooms, to find out 'what is *really* happening under the surface' (p 11, italics in original). It seems that this research agenda has still not been fully met (Lagrange et al., 2003) and that there is still a need to develop a detailed understanding of the students' mathematical activity and learning in these authentic situations.

The data analysed in this paper is taken from a study which aimed to address this research agenda. The study aimed to contribute to the body of research conducted in a naturalistic research paradigm with a particular interest in the use of computer software in mathematics teaching and learning. The paper provides a theoretical and methodological framing for the observation of student interactions in these contexts with the overall aims of a) establishing an understanding of the relationship between observable student mathematical activity and their mathematical learning and b) understanding the role of the computer. It lays out the framing in detail and then provides an example to demonstrate how it has been used.

THEORETICAL FRAMING

To theorise the classroom situation, the paper draws on the *theory of didactic situations* (Brousseau, 1997) which identifies the 'didactical contract' between teachers and students and is based on detailed observations of authentic mathematics classroom settings. (This is explained in detail in my doctoral thesis (Joubert, 2007)). Brousseau uses the notion of the *milieu*; 'everything that acts on the student or that she acts on' (p 9) to describe these settings. It is through interacting with the *milieu* and with the tools of the *milieu* (including the task set for them by the teacher) that the students engage with classroom mathematics. The student interactions can be conceptualised as a 'dialogue' between the student (or group of students) and the feedback from the *milieu* (Brousseau, 1997). The feedback from the *milieu* can take many forms; for example verbal feedback from other students and the teacher, an outcome of a game or a graph produced by computer software. The importance of feedback should not be underestimated; as pointed out by Balacheff (1990) :

'The pupils' behaviour and the type of control the pupils exert on the solution they produce strongly depends on the feedback given during the situation. If there is no feedback, then the pupils' cognitive activity is different from what it could be in a situation in which the falsity of the solution could have serious consequences' (p. 260).

Student activity and mathematical learning

Brousseau (1997) uses the notion of 'modes of production' to describe the different types of dialectic interactions between students and the *milieu*; he suggests that as they work through a mathematical task, they will engage in all or some of the dialectics of action, formulation and validation.

Brousseau (1997) describes a dialectic of **action** as the student constructing an initial solution to the problem straight away, informed by her current knowledge. He explains that, in dialectics of action, students use ‘implicit models’, making decisions based on rules and relationships of which they may not yet be conscious; he suggests that the strategies the student uses ‘are, in a way, propositions confirmed or invalidated by experimentation in a sort of dialogue with the situation’ (p. 9).

It is possible that *all* dialectics between the student and the *milieu* in a given didactical situation are dialectics of action; if, for example, the student knows what to do and how to do it in order to complete the task. This would mean that, although she completes the task, she does not need to extend her mathematical knowledge or understanding to do so; ‘simple familiarity, even active familiarity ... never suffices to provoke a mathematization’ (Brousseau, 1997, p. 211).

There may be an argument that, in some cases of situations of action, the feedback from the *milieu* seems to have little or no role. For example, in a lesson where the student works through a set of examples, it could be that the only feedback they receive is when the teacher reads out the answers. However, as Brousseau argues, the student can be seen to be anticipating the results of her strategies, and in this sense the *milieu* provides feedback, which can perhaps be seen as unrequested and as expected; it does not require the student to adapt her strategies. On the other hand, feedback may occur from time to time as the student works. For example, students may use self-checking methods such as multiplying out factorised functions. In these cases, the dialectical nature of the student interactions is clearer, and the feedback from the *milieu* can be seen as requested and as ‘a positive or negative sanction relative to her action’ (Brousseau, 1997). A negative sanction might prompt the students to formulate new strategies, but it may also result in a sort of ‘guessing’ behaviour, where they simply try something different but do not use the feedback to inform the guess.

Dialectics of **formulation** occur when students meet a difficulty or problem as they engage in mathematical activity; Brousseau explains that when a solution to a problem is inappropriate, the situation should feed back to the students in some way, perhaps by providing a new situation. That means that the student may become conscious of her strategies and begin to make suggestions. Brousseau includes in this category ‘classifying orders, questions etc...’ (p. 61). He goes on to say that in these communications students do not ‘expect to be contradicted or called upon to verify ... information’ (p 61). In making these formulations the students construct and acquire explicit models and language, which, as Christiansen and Walther (1986) argue, serves to make the learner conscious of strategies: ‘actions become conscious for the learner’ (p. 268).

In the discussion above (‘Action’), the possibility of trial and error cycles of student behaviour was proposed. In these trial and error dialectics, the role of the feedback was seen to be only to inform the student that the strategy she had tried was incorrect. However, depending on the nature of the problem, it is possible that the feedback

may also provide some clue for the student about how to improve her strategy and she may formulate a new strategy; this approach can be seen as ‘trial and improvement’ or ‘trial and refinement’ approach (Sutherland, 2007).

Both action and formulation involve manipulating ‘moves in the game’ or mathematical objects; **validation** however involves manipulating ‘statements about the moves’ (Sierpinska, 2000, p. 6). Validation therefore takes place when an interaction intentionally includes an element of proof, theorem or explanation and is treated thus by the interaction partner (or interlocutor) ‘this means that the interlocutor must be able to provide feedback...’ (Brousseau, 1997, p. 16). Brousseau argues that this interaction should be seen as a dialectic because of the presence of the interlocutor. Examples of dialectics of validation include justification (perhaps of a procedure, a word, a language or a model), organising theoretical notions, ‘axiomization’ (ibid., p. 216), and developing proofs.

Brousseau, while suggesting that all three modes of production are ‘expected from students’, (ibid., p. 62) argues that it is through situations of validation that genuine mathematical activities take place in the classroom. There seems to be general agreement with this within mathematics education (for example, see Lakatos, Worrall, & Zahar, 1976; Romberg & Kaput, 1999).

Brousseau suggests that situations of validation do not occur very often and are unlikely to occur spontaneously and it is probable that validation will not take place unless it is explicitly called for.

A final comment in this section about validation concerns the role of feedback. The implication from Brousseau’s ‘interlocutor’ (above) is that this interlocutor provides feedback. It is in discussion with this interlocutor that the individual develops his or her arguments; it is unlikely that feedback will come from any source in the *milieu* other than classmates or the teacher because of the need to convince someone else.

METHODOLOGICAL FRAMING

The focus of the investigation was on what takes place in authentic classrooms. The implication is that the classroom situations should reflect, as far as possible, the everyday practice of teachers and students; teachers should teach and students should react as they normally do, all the teachers’ teaching decisions are their own; the choice of topic, software, approach and task. One possible constraint required by the research was that the students should work in small groups or pairs so that interactions between them (what they said and did) could be observed. This constraint is not a major concern; it is common for students to work in pairs in computer rooms.

The teachers taking part in the study were asked to choose one small group of students as a ‘focus group’; the request was that they chose a group whom they perceived to be of average attainment and who might be expected to talk as they worked (to provide verbal data). When the students worked on the task the teacher set, this focus group was observed.

Collecting and analysing data

The focus on processes required the researcher to be able to see and hear what the students did and said as they engaged with the activity, and these were captured on video. Screen activity was recorded using software which ‘grabbed’ the screen automatically every 30 seconds.

The perspective adopted uses the interactions between students and the setting or *milieu* (in other words, the dialectics) as the unit of analysis, and pays attention to the ‘flux of ongoing activity’ (Nardi, 1996). However, also as argued above, each interaction is situated in time, and related to all the other interactions taking place as the students work. The implication of this point of view is that, to make sense of interactions, it is necessary to understand the unfolding, or narrative, of all these interactions.

Creating the narrative

The interactions were coded using a scheme derived from the theoretical arguments developed above; to represent the type of student mathematical interactions (action, formulation, validation). These dialectics provide a useful way to investigate the data; mathematical thinking and acting requires all three, and the degree to which each is present will provide an initial understanding of the students’ mathematical learning as it relates to the feedback from the *milieu*. Further interactions (technical and other) were also represented. In order to create a narrative, the coded interactions were placed on a timeline.

Figure 1 below shows part of a timeline and explains how the interactions are represented. On the left are the six categories, and on the right is part of a coded timeline. The section of coded timeline shows when interactions occur in relation to others and the length of each block is directly proportional to the length of time the interaction lasts. This part of the timeline begins with a formulation, which is followed by an action, some computer feedback, another formulation, a technical interaction and one ‘other’ interaction. It does not include any validation interactions.

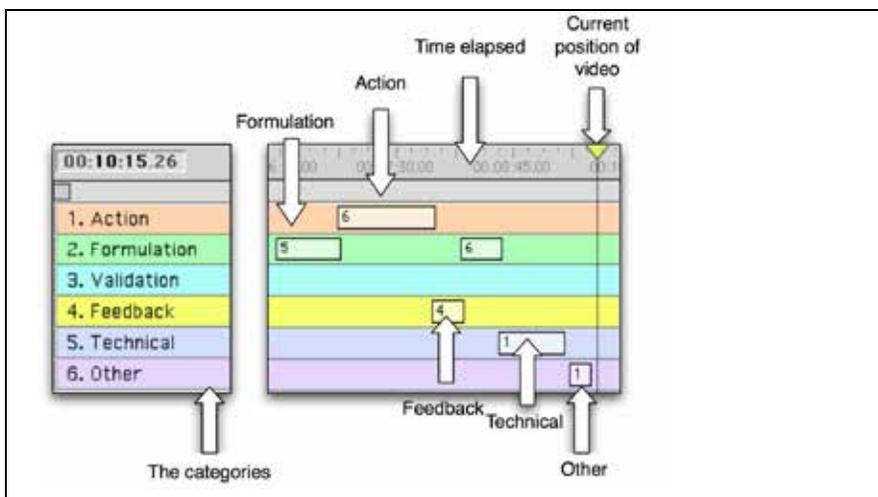

Figure 1: Explains the layout and elements of the timeline

GRAPHS WITH AUTOGRAPH

The data discussed below was taken from one of a series of five lessons for 14 to 15 year olds. From the class of approximately 25 students, the teacher chose a focus group of three girls; Claire, Alice and Charlotte. (These names are pseudonyms).

According to the teacher, the overall aim of the five lessons was for the students to develop an understanding of the relationship between the algebraic and graphical forms of quadratic functions of the form $y = x^2 + bx + c$, where b and c are integers. (The initial interview with the students established that they knew that these graphs would be ‘u-shaped’ but they had no experience of constructing the graphs by hand.) In some lessons, the software *Autograph*¹ was used to produce graphs of quadratic functions. Some of the lessons took place in the classroom, and some in a computer room. The first of these lessons is analysed below.

The task for this lesson, set out on a worksheet handed out to the students, was to use *Autograph* to create graphs of quadratic functions and then to sketch the graphs onto a paper-based worksheet. The teacher’s stated aim (both to the researcher and the students) for the lesson was for the students to ‘...notice the intercepts’ [*with the axes, but this is implicit*]. (It is argued in the thesis (Joubert, 2007) that the task is unambitious and is unlikely to lead to significant student learning. However, the methodological approach adopted in the study was non-interventionist, and the researcher had no influence on the task chosen by the teacher (perhaps, retrospectively, mistakenly).

The worksheet consisted of six similar questions, in which students were given an equation, such as $y = x^2 - 6x + 8$ (which the students had already factorised for homework as $y = (x - 2)(x - 4)$).

The students began by turning on the computer and starting *Autograph*. This technical interaction is the first on the timeline (see Figure 2 below). They opened the *Enter Equation* dialogue box and typed in the first function $y = x^2 - 6x + 8$. This action is the next interaction on the timeline. The students went on to complete the question, and Figure 2 below summarises the activity taking place as the students worked on this question.

The timeline shows the various coded interactions. The zigzag (black line) traces the computer activity, and the feedback interactions represent the computer outputs and the students’ reactions to these.

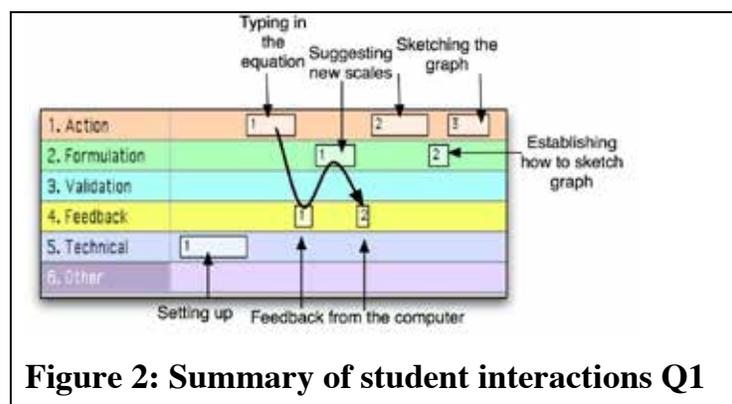

Figure 2: Summary of student interactions Q1

This analysis begins to unpick the student interactions with the *milieu*; there are three action dialectics, two formulation dialectics and two feedback dialectics. As will be seen below, the first formulation dialectic is promoted by the computer feedback. It is perhaps unsurprising that there are no dialectics of validation as these were not demanded by the task. However, the dialectics of formulation, and in particular the relationship of these to the computer feedback, are worth exploring.

The first formulation dialectic occurs in response to the computer feedback, an on-screen graph (see Figure 3 below). Alice remarked:

Can we see it all? Can we change the axes?

Without further discussion, she clicked on the Axes > Edit Axes menu commands. This opened a dialogue box which allowed the students to enter values for x and y 'max' and 'min' values. Claire suggested the changes needed:

(Points to the y minimum) Change this one to minus two and *(points to the y maximum)* that one to, say, eight. *(Points to the x minimum)* And this one to minus two and, yeah, that will do.

The second graph (see Figure 4) shows the computer feedback after this change. One of the students commented:

That's better, OK now we can draw that.

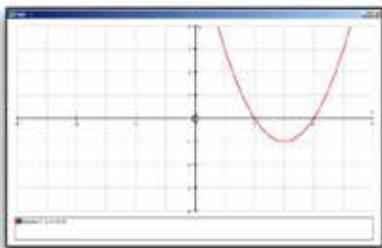

Figure 3: First graph, Q1

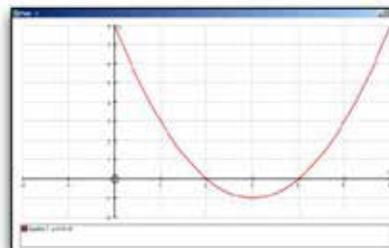

Figure 4: Second graph, Q1

The students then went on to sketch the graph on their worksheets. The second formulation was an unremarkable discussion about how to sketch the graph.

The first point to note about this student activity is that the students did not seem to find any difficulty in using the software. There was no discussion between them about how to create the graph or how to make changes to the scales on the axes. The first computer output was a graph page with the graph of the function drawn on it. However, as Alice's comment indicates, the students wanted to change it. The reason, it seems, was that the y -intercept could not be seen. Alice's reaction suggests that the feedback was unexpected, and in response to this unexpected feedback the students changed the graph page.

The students did not discuss the changes, and there is no way of knowing the basis for their decisions. However, it is likely that it was based on the visual appearance of the graph on the page because of Alice's reference to not being able to 'see it all'.

In the remainder of the lesson, the students followed much the same pattern of activity. In general, they tended to type in the equation of the graph, then adjust the graph page by guessing maximum and minimum values (as above) based largely on the appearance of the graph. Only in one case did they sketch the graph on paper before entering the equation into the software (see below).

Two dialectics of validation took place. The first occurred as the students attempted the fourth question. The teacher had encouraged them to sketch the graph first, and then to try it out on the computer but they found a mistake in the worksheet; whereas they had been asked to solve the quadratic equation $x^2 - 8x + 15 = 0$ by factorisation, they had then been asked to sketch the graph corresponding to $y = x^2 - 8x - 15$ and in the dialectic of validation the students explained (neither very clearly nor very confidently) why the y-intercept could not be -15. After some further actions and discussion they called the teacher and pointed out the mistake. The teacher asked how they found the mistake. In response one of the students suggested:

We worked out that it would cut the axes there and there (*pointing at predicted intercepts on the screen*) because those numbers are the same as those (*pointing at the zeroes on the sheet*).

Through her questioning, the teacher had drawn out a justification (second dialectic of validation), by encouraging the students to articulate what they had noticed. However, she did not question **why** the roots correspond to the intercepts, and it seems that both she and the students were concentrating on the visual connections between the algebraic and graphical forms of the function, rather than drawing on the theoretical notions underpinning this connection. Further, it seems that the teacher was relying on the computer to draw out connections by concentrating on noticing rather than explaining.

It could perhaps be expected that the students, having made the connection explicit, might use their understanding to adjust the graph page in further questions, or to sketch the graph before entering it on the computer. Their approach began as follows:

Alice: OK let's do the next one then.

Claire: What, draw it before?

Alice: No, I'm not doing that – too much hassle.

As the dialogue indicates, it seems that they preferred a trial and improvement approach rather than a more theoretical approach. Their talk indicates that they were deliberately choosing this approach, even though they knew that it was likely that the graph page would need to be changed later (by entering new maximum and minimum values for the visible parts of the page).

In the second dialectic of validation, one of the students justified her choice of scales to the others. Once again, however, she referred to the factorised equation but did not attempt to explain why the factors were related to the roots.

Overall student learning

The brief analysis above suggests that there was some student learning as evidenced by the presence of dialectics of action, formulation and validation. However, it seems that many of the dialectics of formulation were visually based, and were prompted by the computer feedback. The students used a trial and improvement strategy based on the visual appearance of the graph, but there is evidence that on several occasions they made the connections to the equation (initially suggested by the teacher). However, they chose to return to the former approach in later questions. Although they connected the numbers in the equation to the graph but there was no attempt to explain why the connection existed. There is some evidence of mathematical learning, in terms of the theoretical framework used, but the students never explained the connections they found and their learning can be seen as relatively superficial.

CONCLUSIONS

Space has not allowed a detailed analysis of the entire lesson, or of the place of this lesson within the series of five lessons concerned with the topic, but the example has served to demonstrate the use of the chosen framework. This analysis has, however, suggested that to complete the task the students were not required to engage in dialectics of validation, and it was primarily the teacher's intervention that prompted one of the two dialectics of validation observed. The difficulty, perhaps, lies in a confusion related to the role of the computer, which does the mathematical work of creating the graph, and the question then is, what mathematics will the students do? Further, although the feedback from the computer prompted dialectics of formulation, it appears that it was easier for the students to guess the changes needed and to try these out than to adopt any systematic predictive trial and improvement strategies.

The study overall set out to understand the use of computers in authentic classroom situations; the analysis above has confirmed the importance of understanding the role of the computer. It particular it has emphasised the importance of having a clear idea of the mathematics the computer will do and the mathematics the students will do, and of how feedback can be used so that tasks take advantage of the computer's potential to provoke situations of validation as well as action and formulation.

THE EFFECTS OF INTERACTIVE WHITEBOARDS ON TEACHING TRANSFORMATIONAL GEOMETRY WITH DYNAMIC MATHEMATICS SOFTWARE

Gürcan KAYA, Veysel AKÇAKIN, Mehmet BULUT

Gazi University, Turkey

The studies about the determining the effects of using Interactive whiteboard (IWB) have gained importance since the installation of IWB in almost every school by government funded project “FATİH” in Turkey. The purpose of this paper is to share some ideas about an experience of teaching transformational geometry with dynamic mathematics software on interactive whiteboards. The participants of this study were 31 tenth grade students of one of the public high school in Ankara. There were 16 students in experimental group and 15 students in control group. A test was developed to assess students’ transformational geometry achievements, which included translation, reflection and rotation tasks. The effects of IWB are also investigated by qualitative and quantitative analysis.

Key words: Interactive whiteboard, dynamic computer software, geogebra, geometry, transformations.

INTRODUCTION

The qualifications asked for from people have changed in line with the needs of our era and thus individual profile aimed to be created has also changed. It is aimed not to raise individuals who do memorize the information word by word but to raise individuals who can reach at the information s/he needs and who can use this information and synthesize it. In order to raise individuals having the required qualifications, it is necessary for them to pass through good education process. Including new technologies in education and training institutions will provide easiness to address learning needs of the individuals. These qualified individuals can discover fundamental concepts and use knowledge which they need. To educate individuals with the desired qualifications, it is important to integrate the new developing technology to education. New technology like interactive whiteboards (IWB) can help individuals to discover and use knowledge.

Recently, the use of new technologies becomes more and more widespread in teaching and learning environments (Tate, 2002). Thus, there is the need of further research aiming to investigate the effects of the use of these technologies in teaching and learning environments. Similarly, NCTM (2000) emphasizes the use of new technologies in mathematics education, and it has been reported that using new technologies in mathematics education can enhance the learning of students. Using technology in mathematics education can help students to focus on mathematical ideas, make sense of them and solve problems whose solution would be impossible without using technological tools. It can also enhance students’ learning by giving them chance to discover further level (Van de Walle, Karp & Bay-Williams, 2010).

“One can make easy drawings, make measurements, and drag elements of a drawing while those elements maintain the dependency relations that exist based on the initial construction in the environment by using dynamic computer software (DCS) programs” (Hollebrands, 2007). Dragging which is called “real-time transformation” is one of the most defining features of DCS programs. There are several DCS programs, but it can be said that Geogebra is one of the most popular and widespread. It is popular not only because its development is always in progress but also because it is a freeware software. Thus in this study geogebra was chosen as a DCS program.

The touch-sensitive board allows users to interact directly with applications without having to be physically at the computer which is projecting the image onto the board (Beeland, 2002). In this context, IWBs give teachers the opportunity to interact with teaching materials in every time during the teaching sequence by its increased functionality. This increased functionality introduces substantial benefits to teachers in the sense of flexibility and variety compared to video projector (Haldane, 2010). The use of IWBs is increasing day by day in education because of the benefits and innovations it brings to teaching and learning process. In Turkey, IWBs are going to be delivered to four thousand schools, and were given to several schools along with FATİH project. So it can be said that the IWB will supersede the classical white board with this project.

Several researches were carried out to examine the effect of IWB in teaching and learning process (Beauchamp & Parkinson, 2005; Kennewell, 2001). It was found that IWB enhances students’ motivation and interest towards learning. IWB also expands interaction between students, meets the wide range of student needs through the use of multimedia and varied presentation of ideas. By using IWB, students can answer easily such questions like ‘Can you explain?’ ‘Why?’ that asked students to clarify points in their mind and to help them to enhance their own learning (Glover & Miller, 2002). But the use of the full potential of the IWBs in teaching and learning process depends on how the instructors use them. In researches it was found that if instructors use the IWBs without considering the interactivity features of IWBs, and use it just for writing and drawing like the classical board, the IWB use will make no difference in teaching and learning process (Glover & Miller, 2002). Teacher and researchers can benefit from this research on using the IWBs that will be installed to almost every school by government funded project FATİH in Turkey.

IWB involves three modalities of learning: visual, auditory and tactile (Beeland, 2002). Stimulating the one or more sense can provide effective learning and also by this way, students make sense of concepts and ideas. On the basis of Becta’s (2003) analysis, the main research findings for general benefits of IWB has been summarized

- Versatility, with applications for all ages across the curriculum
- Increases teaching time by allowing teachers to present web-based and other resources more efficiently.

- Provides more opportunities for interaction and discussion in the classroom especially compared to other ICT.
- Increases enjoyment of lessons for both students and teachers through more varied and dynamic use of resources with associated gains in motivation.

IWBs are effective educational tools, which provide dynamic learning environment for students. These dynamic learning environments can help students develop positive attitude towards learning. IWBs have been being used in some countries (e.g. England, USA; Canada; Brazil, Portugal). Thus there are many researches about the effectiveness of IWBs (Beeland, 2002; Glover & Miller, 2002; Beauchamp & Parkinson, 2005). However, there is little research in Turkey. Therefore, we aimed to investigate the effects of using IWB in mathematics classrooms.

The purpose of this study was to determine the effect of the use of the IWB as an instructional tool on student academic achievement. In particular, the following research question was investigated:

Does the use of Geogebra via IWB as an instructional tool affect students' academic achievement on transformational geometry?

METHODOLOGY

The participants of this study were 31 tenth grade students of one of the public high schools in Ankara in the second semester of 2011-2012. There were 16 students in experimental group and 15 students in control group. Data were collected through eleven open ended questions about transformational geometry. Translation, reflection and rotation were chosen from tenth grade geometry curriculum. Posttest-only control group design quasi-experimental research model was used in this study (Fraenkel & Wallen, 2008). While preparing activities, Turkish national geometry curriculum and common core standards were considered. In the Turkish curriculum, the educational gains are "Students can do translation; rotation and their composition on the coordinate plane." and "Students can do reflection and glide reflection on the plane". In the common core, the standard is "Given a geometric figure and a rotation, reflection, or translation, draw the transformed figure using, e.g., graph paper, tracing paper, or geometry software. Specify a sequence of transformations that will carry a given figure onto another." The same activities were used in both groups. During teaching process, dynamic mathematics software GeoGebra is used via IWB. In the teaching process constructive, collaborative and interactive learning strategies were used. It wasn't used any technology in the control group. One of the activities used with IWB in the experimental group and its' classical board version used in control group is presented below (Figure 1). During this activity, worksheets including rotation tasks, grid papers were used and students were asked to fill the worksheet. It was intended to make clear the relation between the translated shape and the vector by changing translation vectors dynamically and interactively on IWB. It was asked to students to find the relation between the coordinates of translated shape and untransformed shape of triangle and to explain the rule mathematically that students

asked to find. All the students' inferences are discussed with class. In the control group, unlike IWB, the same activities were done traditionally only by drawing shapes without changing dynamically or interactively anything on the classical board. A test was developed to assess students' transformational geometry achievements, which included translation, reflection and rotation problems by consulting experts. The test involved 11 open ended questions. The developed test was applied to both experimental and control groups as post-test. The study was carried on for 4 weeks. Experimental and control groups were matched with the analysis of geometry scores of the last semester. The developed test was also applied as pre-test to experimental group. Data were gathered through participants' written responses. Quantitative data is analysed with non-parametric statistics Mann-Whitney U, Wilcoxon rank test and qualitative data were cleaned, coded and analysed. Students' responses in the pre-test and post-test were grouped, summarized and analysed using a content-based analysis approach to gather qualitative data. Students' responses were coded in three categories: "Completely wrong", "Completely true" and "partially true". The qualitative result was consistent with the quantitative results. Percentages of each response the students gave were computed. Frequencies and percentages were displayed in tables.

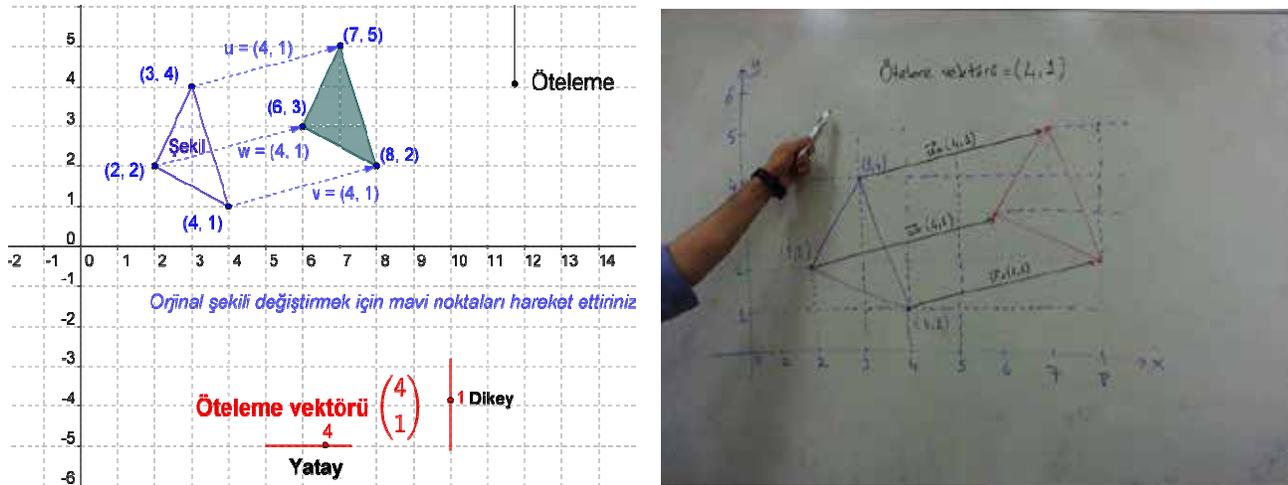

Figure 1: The Same Activity on IWB and Classical Board

RESULTS

In this section we show the results of the comparison between the achievements in the post-test of the experimental group and of the control group, and of the comparison between the achievements in the pre-test and in the post-test of the experimental group. Also some qualitative results of students' responses are shown. Three of eleven questions' analysis is shown because of limitation of the pages. The results were analyzed according to learning objectives about transformational geometry.

Groups	N	Mean rank	Sum of Ranks	U	p
Control group	15	14.47	217.00	97.000	.363
Experimental group	16	17.44	279.00		

* $p < .05$

Table 1 The results of comparing geometry academic scores of last semester with Mann-Whitney U Test

It is seen in Table 1 that average rank of geometry academic scores in last semester of the students in the experimental group is 17.44, while the average rank of score for the control group is 14.47. According to Mann Whitney U Test which was conducted to experimental and control groups students' geometry academic scores of last semester, it is observed that there is not a statistically significant difference between the geometry academic scores in last semester of the students ($U=97.000$; $p=.363 > .05$). According to this result, it can be said that these groups are appropriate to be chosen as control and experimental groups before the treatment.

Groups	N	Mean rank	Sum of Ranks	U	p
Control group	16	9.50	152.00	16.000	.000
Experimental group	16	23.50	376.00		

* $p < .05$

Table 2 The results of comparing post-test academic achievement test scores with Mann-Whitney U Test

It is seen in Table 2 that average rank of post-test scores of the students in the experimental group is 23.50, while the average rank of score for the control group is 9.50. According to Mann Whitney U Test which was conducted to experimental and control groups students' post test scores, it is observed that there is a statistically significant difference between the academic achievement test scores of the students in favour of the experimental group ($U=16.000$; $p=.000 < .05$). According to this result, it can be said that the students, who have been taught with the IWB, understand better than students who have not been taught with the IWB.

Post-test-pre-test	N	Mean Rank	Sum of Ranks	z	p
Negative Ranks	0	.00	.00	-3.519*	.000
Positive Ranks	16	8.50	136.00		
Ties	0				

*Based on negative ranks

Table 3 The result of comparing pre-test and post-test with Wilcoxon test

A Wilcoxon test was conducted to evaluate whether students showed greater success. The results indicated a significant difference, $z=-3.519$. $p < .01$. The mean of the ranks

in favour of pre-test was .00, while the mean of the ranks in favour of the post test was 8.50. First learning objective is doing translations, rotations and their composition on two-dimensional figures using coordinates. Second learning objective is doing reflection, glide reflection on plane.

Question 1	Pre-Test	Pre-test (%)	Post-Test	Post-Test (%)
Correct Ans.	2	12.5	12	75
Wrong Ans.	13	81.25	3	18.75
Partially Correct Ans.	1	6.25	1	6.25

Table 4: The Change of the Students' Performances Related to Question 1b

In question 1, students were supposed to rotate $\triangle ABC$ 90° around origin. While 12.5% of students give correct answers to Question 1, 81.25% of them gave wrong answers and 6.25% of student made some mistakes but the answers were not completely wrong. After the treatment the rate of students that gave correct answers increased to 75%, and the rate of wrong answers decreased to 18.75% in the post-test. On the other hand partially correct answers remained same. The most common mistake done by the students in question 1 is rotating around wrong point. Most of the students rotate the shape around the corner A of the triangle. After the treatment with IWB some students corrected their answers as shown below.

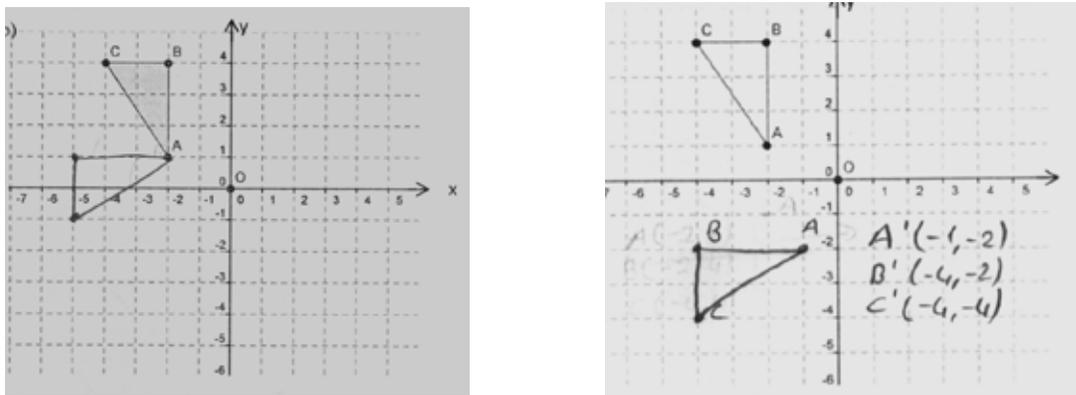

Figure 2: Example of pretest and posttest response of a student for question 1

Question 3	Pre-Test	Pre-test (%)	Post-Test	Post-Test (%)
Correct Ans.	0	0	4	25
Wrong Ans.	16	100	2	12.5
Partially Correct Ans.	0	0	10	62.5

Table 6: The Change of the Students' Performances Related to Question 3

In question 3, the shape below on the left was obtained by rotating $\triangle ABC$ with particular and constant angle. Students were asked to find the rotating angle in option

a, the coordinates of point F in option b and the angle \widehat{EOB} in option c. In pre-test all the students answered fourth question wrong and any of the students didn't even try to draw a line to obtain answer. After implementing the teaching process with the IWB, the correct answer rate increased to 25% and the wrong answer rate decreased to 12.5% and the rate of the partially correct answers were 62.5%. Most of the students answered the question similarly with using formula. In partially correct answers, most of the students could find the rotating angle in option a and the angle \widehat{EOB} in option c. But only four of the participants could use the formula correctly in option b. A precise correct answer is displayed below on the right and the shape of the question 3 is displayed on the left.

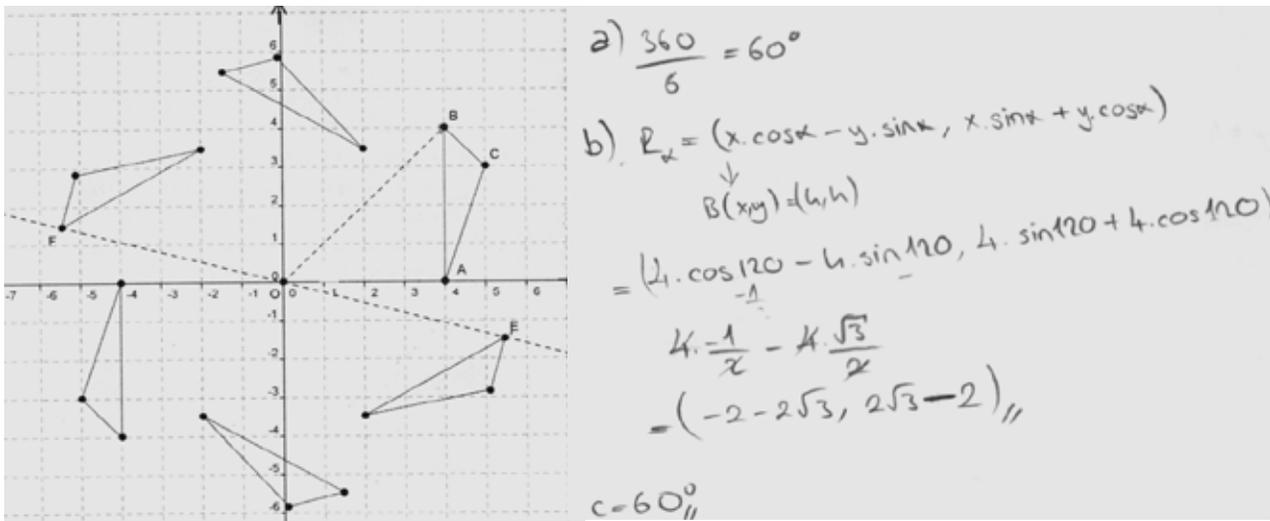

Figure 3: An example of posttest response of a student for question 3

Question 4	Pre-Test	Pre-test (%)	Post-Test	Post-Test (%)
Correct Ans.	3	18.75	10	62.5
Wrong Ans.	10	62.5	1	6.25
Partially Correct Ans.	3	18.75	5	31.25

Table 7: The Change of the Students' Performances Related to Question 4

In question 4, students were asked to obtain $\triangle A''B''C''$ by just reflecting $\triangle ABC$. Question 4 in pre-test was answered correctly by 18.75% of students and it was answered wrong by 62.5% of students. After the treatment, the rate of correct answers of Question 4 increased to 62.5% and the rate of wrong answers decreased to 6.25% in post-test. In pre-test most of the students couldn't reflect $\triangle ABC$ to obtain $\triangle A''B''C''$. After the teaching process most of them do the reflection correctly. There is a correct answer below.

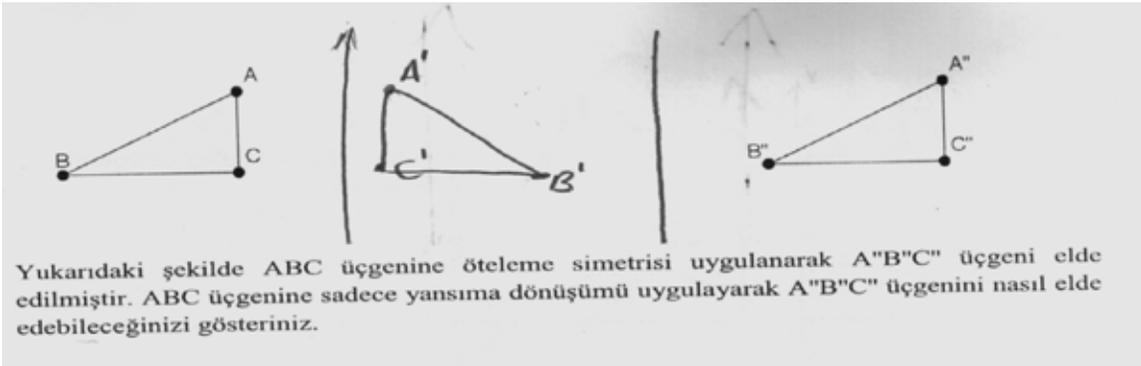

Figure 4: Example of pretest and posttest response of a student for question 4

CONCLUSIONS

The purpose of this study was to provide a view of the impact that using Geogebra with IWB has on academic achievement in transformational geometry. Understanding the concept of transformation is an important topic for students. Because patterns can be described with opportunities that geometric transformations provide. It also helps students make generalizations, and develop spatial competencies (Yanık, 2011). The improvements in the post test can be caused by both IWB and Geogebra. Effective using of software by teachers makes the lesson more efficient. The IWBs cannot facilitate or enhance anything about students' learning just by standing in front of the class and by being used as a classical whiteboard (Glover & Miler 2002). Necessarily it is to be used with software and method. Thus the effectiveness of IWBs depends on how the instructor uses it and with which software the instructor uses. Therefore the interaction between the IWB, software and method cannot be completely isolated and cannot be separated from each other. Two groups can be chosen, using projector in one and using IWB in other, to distinguish the interaction between them but it can be only partially.

It can be said that effective using of interactive whiteboards (e.g. with geogebra or other DGS program) can be used to increase student academic achievement during the learning process. Because IWB supports three modalities of learning: visual, auditory and tactile and it allows interacting with learning contents for students (Beeland, 2002). Thus, stimulating more senses the use of IWBs can provide effective learning and, by this way, students can retain longer what they learnt. Teaching and modeling transformational geometry via classical board is a difficult process (Harkness, 2005; Harper, 2003). Therefore students can understand transformational geometry better with the visual and unique features of IWB like drag and drop, manipulating images easily on the board. However software design by itself cannot provide opportunities automatically for effective learning (Wood & Ashfield, 2008). By controlling the software on IWB can offer to read display easily and offer an opportunity for a teacher to control the material by his hands. Thus, the pace of the lesson can be enhanced by the teachers' personality and dynamism by using IWB.

There is a statistically significant difference between the pre-test and post-test results of the experimental group in favour of the post-test. The post-test results were significantly higher in experimental group in comparison to control group. This result is consistent with the researches of Flacknoe and Thomson (2000), Swan, Kratcoski, Schenker and Hooft (2010), Zittle (2004), Dhindsa and Emran (2006), and BECTA (2007). Also there was an increase in corrects answers between the pre-test and post-test in favour of the post-test. Moreover, in the post test students tried to respond the task with more visually than the pre-test. This study cannot exactly figure out how IWBs affect students' mathematics achievement so sustained studies should be done about the pedagogy of IWBs. For this purpose, further researches can be carried out on designing appropriate materials and developing adequate software to enhance the efficiency of IWB.

THE EFFECTS OF DYNAMIC GEOMETRY SOFTWARE ON LEARNING GEOMETRY

Hulya Kilic

Yeditepe University, Turkey

The aim of this paper is to present the findings of a pilot study which was designed to collect data about the effects of using dynamic geometry software in the tenth grade geometry lessons on the students' geometric thinking, geometry achievement and ability of doing proofs in geometry. It was a quasi- experimental study in which treatment groups were given dynamic geometry activities during the geometry lessons. The findings revealed that the students' scores from geometric thinking test and proof test increased significantly with respect to the students' who did not experience those activities.

Keywords: dynamic geometry, geometric thinking, problem solving, proof skills

INTRODUCTION

Geometry is “a complex interconnected network of concepts, ways of reasoning, and representation systems that is used to conceptualize and analyze physical and imaged spatial environments” (Battista, 2007, p.843). Thus, learning geometry entails visualization and construction of images of geometric concepts and making appropriate relationships between the concepts. Van Hiele also identified visualization as an indicator of one's geometric thinking level. He noted that visualization is the first level of geometric thinking such that everybody should possess accurate concept images to attain higher levels of geometric thinking (Battista, 2007). Research findings show that students fail in geometry because they have difficulty in visualization of geometric concepts such that they are unable to analyze geometry problems and draw appropriate figures for the problem (Clements & Battista, 1992; Healy & Hoyles, 1999; Yerushalmy & Chazan, 1993). The conceptualization of visual objects, in other words having a valid matching of concept image and concept definition in mind (Vinner & Dreyfus, 1989), is vital to understand geometry (Battista, 2007). Therefore, teacher-oriented teaching strategies are not effective enough to help students understand geometry and improve their geometric thinking and proof skills (Reiss, Heinze, Renkl, & Gross, 2008).

Improvement in information technologies arise questions about how to use those technologies for educational purposes and how they affect students' understanding and learning. It is noted that using technology for educational purposes increase students' motivation for learning, helps for understanding and gives opportunity for repetition of the subject matter (Healy & Hoyles, 1999; Knuth & Hartmann, 2005). The studies indicated that although students can solve algebraic problems by following some algorithms they have difficulties solving problems including images

and shapes (Healy & Hoyles, 1999). Because dynamic software enables students to observe the properties and the relationships by drawing figures and manipulating them easily, it has potential to decrease such problems (ibid.). Indeed, the studies investigating the effective ways of teaching geometry suggest that dynamic geometry software (DGS) helps students visualize geometric concepts and understand geometric rules, generalizations and relationships between the concepts (Healy & Hoyles, 1999; Jones, 2000; Marrades & Gutierrez, 2000). Hence, using DGS in geometry lessons may be effective in terms of increasing students' geometry achievement and developing their geometric thinking and problem solving skills.

DGS not only contributes to the development of geometric thinking and problem solving skills but also facilitates understanding and proving hypotheses and conjectures (Jones, 2000). Doing proofs entails making a good plan for proof and following it by justifying each step (Heinze, Cheng, Ufer, Lin, & Reiss, 2008) and similar pattern is required when doing constructions with DGS (Scher, 2005). For instance, to construct a square with DGS students cannot just draw equal segments and connect them together but they need to use the idea of perpendicular lines, right angles and transformations. As students engage in fundamental constructions with DGS, the better they appreciate the fact that they have to follow an order to make constructions correctly. However, the studies about the effects of DGS on students' proof skills are limited, more research are needed to support that relationship (Hollebrands, Laborde, & Straesser, 2008).

Although the effectiveness of using DGS on learning geometry was investigated by many scholars, most of them were limited in terms of sample size, context, investigated variables, way of integrating DGS into geometry lessons or data collection tools. Still, there is a need for large-scale experimental studies supported by both quantitative and qualitative data (Battista, 2007). Therefore, the aim of this study was to investigate the effects of using DGS on students' geometric thinking, geometry achievement and proof skills. However, the results presented in this paper emerged from the pilot study of that large-scale investigation.

METHODOLOGY

In this pilot study, quasi-experimental research design was used to investigate the effects of using DGS on the tenth grade students' geometric thinking, problem solving and proving skills. It was conducted in the second term of 2011-2012 academic year in Turkish high schools.

Sample

A total of 227 students from 6 schools which are administered by the same foundation participated in this study. In these schools, the teachers follow the same yearly plan and they use the same or quite similar teaching materials. The schools were assigned into groups in terms of their preference. Three of the schools preferred to be in the experiment group and two of the schools preferred to be in the control

group. In one school, one of the tenth grade classes was assigned to the experiment group and the other class was assigned to the control group. Then 145 students were in experiment group and 82 students in the control group. However, because not all students were available during the testing days some of the data was lost. Furthermore, in two experiment schools all DGS activities were completed but in the others they were not. Therefore, the data analyzed for this paper is based on 12 students from the experiment group who experienced all DGS activities and took all the pretests and posttests and 37 students who took all the tests from the control group.

Data collection

In both experiment and control schools geometry is taught three hours per week. Five DGS activities were determined in line with geometry curriculum and they were applied during the geometry lessons in the experiment group. Because the activities were aligned with the objectives of the geometry lesson, the teachers did not fall behind their schedule. However, they assigned more homework problems to their students for exercise because in the control group, the teachers had time to give more paper-pencil exercises to the students during the lesson.

Before the study, the teachers in the experiment group were given a workshop about how to use DGS and how to apply the activities. They were provided a worksheet (manual) for each activity and they used these manuals for their students as well. In the experiment group, the teachers used the computer laboratory only for the activities and used their regular classrooms otherwise. The activities were about triangle inequality, angle bisectors, medians and perpendiculars, transformations and Euclid, Menelaus, Ceva and Carnot theorems. Geometers' Sketchpad Program (GSP) was used as dynamic software. The students were given three types of tests, namely Geometric Thinking Test (GTT), Geometry Achievement Test (GAT) and Geometry Proof Test (GPT) prior to and at the end of the study. The tests consisted of questions related to triangles and transformations which were covered during the second term in the curriculum. The items in all tests were in supply type form such that students were expected to solve the questions and explain and/or justify their answers. GTT test consisted of seven items such that the items were written in the line of first four levels of van Hiele's geometric thinking levels (recognition, analysis, order, deduction and rigor) and Driscoll's (2007) geometric habits of mind (reasoning with relationships, generalizing geometric ideas, investigating invariants and balancing exploration and reflection). By GTT, it was aimed to measure students' knowledge of geometric concepts (how they describe given concepts), ability to interpret the relationships in geometric constructions and ability to transfer their knowledge into application and make inferences. GAT consisted of ten items such that they were chosen from the 10th grade geometry textbooks and it was aimed to measure students' geometric knowledge. GPT consisted of six items such that they were the proofs recommended to be covered in the curriculum. It was aimed to measure

students' proof skills (i.e., choose an appropriate type of proof, make a plan to use it, write conjectures and justify them). Although during the pilot study qualitative data was not collected, for the main study qualitative data in terms of interviews and videotapes will be collected.

Data analysis

The test results were analyzed by using statistical analysis software. For the content validity of the tests, a specification table was prepared. In addition, for the GTT items van Hiele's and Driscoll's (2007) ideas for geometric thinking were taken into account. The tests content validity was agreed by one academician and three experienced geometry teachers. The tests concurrent validity was also checked. For the reliability test-retest reliability analysis was held. Furthermore, rubrics for each test were prepared for scoring and the interrater reliability was checked.

RESULTS

The content validity of the tests was agreed by one academician and three experienced geometry teachers. For the concurrent validity the correlation between each test was found. Then, for the pretest the correlation between GTT and GAT was .63 ($p=.000$), GTT and GPT was .38 ($p=.001$) and GAT and GPT was .51 ($p=.000$). For the posttest the correlations were as follows: .50 ($p=.000$), .38 ($p=.000$), and .47 ($p=.000$), respectively. Test-retest reliability was sought and Pearson's r for GTT, GAT and GPT tests calculated as .56 ($p=.000$), .67 ($p=.000$) and .68 ($p=.000$), respectively. The tests were out of 100 points. Two academicians rated the tests. The interrater reliability for GTT was .96, for GAT was .98 and for GPT was 1.00.

The descriptive statistics about the tests are given in Table 1.

	Experiment Group					Control Group				
	N	Min.	Max.	Mean	SD	N	Min.	Max.	Mean	SD
GTTPre	12	7	55	30.08	14.34	37	7	67	39.73	14.50
GTTPost	12	22	63	43.42	14.59	37	7	81	44.70	19.89
GATPre	12	0	33	9.25	10.50	37	0	47	16.68	13.14
GATPost	12	0	48	21.17	11.51	37	0	82	31.27	23.51
GPTPre	12	0	13	3.17	4.99	37	0	60	15.73	14.97
GPTPost	12	0	20	7.92	5.42	37	0	45	12.11	12.20

Table 1: The descriptive statistics about GTT, GAT and GPT

The pretest results for each group were compared. There were no statistical difference between GTT ($t_{47, .05}=2.007$, $p=.050$) and GAT ($t_{47, .05}=1.778$, $p=.082$) but there was significant difference between GPT ($t_{47, .05}=4.405$, $p=.000$). The posttest comparisons showed that there were no significant difference between the groups in terms of GTT, GAT and GPT results ($t_{47, .05}=.206$, $p=.838$, $t_{47, .05}=1.982$, $p=.055$, and

$t_{47, .05}=1.639$, $p=.109$ respectively). The pretest and posttest results for each group were compared. For experiment group significant differences were obtained in terms of all types of tests but for control group there was significant difference in terms of geometry achievement. For the experiment group the following t-scores were obtained for each test: For GTT, $t_{11, .05}=2.945$, $p=.013$, for GAT, $t_{11, .05}=3.856$, $p=.003$, and for GPT, $t_{11, .05}=2.844$, $p=.016$. Because the number of participants taken into account was small, Wilcoxon Signed Ranked Test was also applied for the experiment group. The findings were aligned with t-test results such that for GTT, $z=-2.432$, $p=.015$, for GAT, $z=-2.701$, $p=.007$, and for GPT, $z=-2.174$, $p=.030$. For the control group the following t-scores were obtained for each test: For GTT, $t_{36, .05}=2.025$, $p=.050$, for GAT, $t_{36, .05}=5.562$, $p=.000$, and for GPT, $t_{36, .05}=1.980$, $p=.055$. The following results were obtained from Wilcoxon Signed Ranked Test: GTT, $z=-1.753$, $p=.080$, for GAT, $z=-4.275$, $p=.000$, and for GPT, $z=-2.021$, $p=.043$. Except GPT, t-test and Wilcoxon test results were compatible in the control group.

The items for each test were analyzed. The maximum points for each item in GTT were 30, 9, 9, 8, 12, 12 and 20, respectively. In the first item of GTT the students were asked to write the definitions of fifteen geometric concepts including line, angle, median, incenter of a triangle, translation and reflection axis. In the second item, the students were asked to explain the relationships between the sides of a triangle (triangle inequality). In the third and the fourth items they were asked whether given information is enough to construct a triangle and find the measures of its sides and angles. The fifth question was about transformations and in the sixth question they were asked to distinguish congruent triangles among the given set of triangles. Finally, in the seventh item the students were given four different descriptions of geometric figures and they were asked to draw them by using appropriate labels and symbols. For instance, students were asked to draw a triangle ABC such that $|AB|=|AC|$ and the intersection of angle bisector of the angle A and the median of the line segment AC is P. In the figure 1, two examples from the students work are given. For the group taken into consideration, nobody deserved full credit for the first, the second, and the seventh items in GTT. Furthermore, although the credits for each question differed in GTT, the results showed that the weighted mean for the second item was the lowest (2.80 out of 6 points) while the weighted mean for the last item was the highest (11.41 out of 20 points).

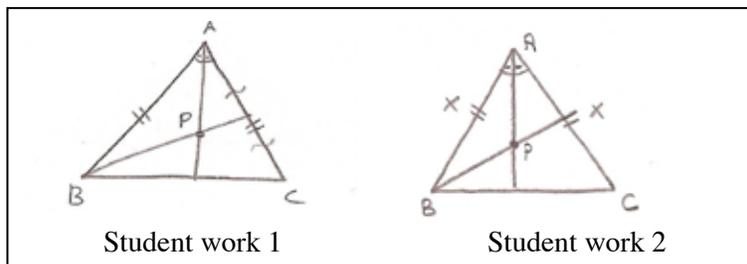

Figure 1: Typical student answers to the construction item of GTT.

In GAT, all items were worth 10 points. The test items were about triangle inequality, angle bisector, median, Pythagorean, Euclid and Menalaus theorems, congruency, similarity, area, and transformations. In GAT, there were students who received full credit from the items. However the mean of the tenth item (transformations) was the lowest (1.73 out of 10 points) and the mean of the sixth item (similarity) was the highest (5.61 out of 10 points). In the sixth item the students were given the following problem: *As shown in the picture, a bridge will be built up over a river. The segment \overline{BD} represents the bridge and $\overline{AE} \perp \overline{AB}$ and $\overline{CE} \perp \overline{CD}$. Use the given information in the figure and find the length of the bridge.* In the figure 2, a typical student answer is given.

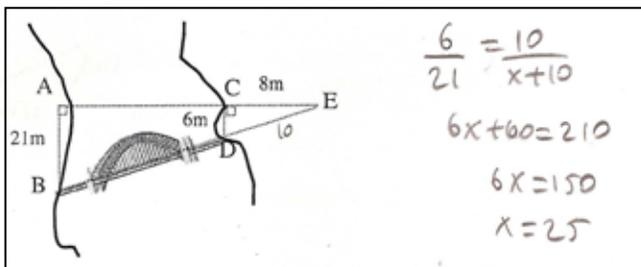

Figure 2: Typical student answer to the sixth item of GAT

In GPT, the third and the sixth questions were out of 20 points while others were out of 15 points. In the first item of GPT, the students were asked to prove that an exterior angle of a triangle equals to the sum of nonadjacent interior angles. The other items were about proving angle-side relationship in a triangle, area of a triangle, Sinus theorem, Carnot's theorem and Euclidean theorems, respectively. In GPT test the mean of the items were generally low but the first item had the highest mean (6.53 out of 15 points) and there were students who got full credit from the first and the sixth items.

DISCUSSION

The aim of this pilot study was to determine the reliability and validity of data collection tools and effectiveness of GSP activities. The data analyzed in this paper was based on 49 students who took all pretests and posttests. The mean scores of the tests and test items provide some information about the students' geometric thinking, geometry achievement and proof skills. It was apparent that students' geometric thinking levels, geometry achievement and proof skills were low.

Although comparing the means of the test items may provide information about the students' weaknesses and strengths in geometry, such inferences should be supported by some qualitative data in terms of structured interviews or other tests. In this pilot study, qualitative data was not collected but a detailed analysis of students' responses for each item is likely to provide some concrete data about students' geometric knowledge, geometric thinking and proof skills. Although such detailed

analysis is not the scope of this paper, an instance from GTT is noteworthy to be discussed. In GTT, the seventh item in which the students were asked to draw geometric figures by using information given about them had the highest weighted mean. In the first item, the students were asked to write the definitions of some geometric concepts. Although some of the students failed to provide complete and valid definitions for the geometric concepts in the first item, they were able to use those concepts to make some of the constructions in the seventh item. For instance, when they were asked to define angle bisector, some of them wrote “it divides an angle in two” or “it is a segment that divides an angle in two equal parts”. In the seventh item, there were descriptions in which angle bisector could be considered as a line segment and those students used appropriate symbols to indicate that the line segment was the angle bisector. Hence they received full credit from that construction if other parts of it were valid. However, they failed to draw another figure in the same item because they failed to extend the angle bisector, that is, they did not know that angle bisector is a ray not a line segment. Therefore, having higher mean score with respect to other items may not be an indicator of students’ ability to analyze geometric figures and definitions. Furthermore, this instance supported the importance of the consistency between concept image and concept definition (Vinner & Dreyfus, 1989). In this case, the students probably wrote the definitions of the concepts in terms of their images in their mind. However, DGS provides opportunities to eliminate such students’ misconceptions because the images and tools in DGS are compatible with their mathematical definitions such that an angle bisector is drawn as a ray or a line. Then, experiencing constructions with DGS may enable students to define geometric concepts correctly.

Furthermore, the mean scores of some of the items in GTT and GPT indicated that students’ proof skills were low. In the most cases, the students who attempted to prove the given statements gave examples to show that it worked rather than proving them deductively. One of the reasons for poor skills in proving is probably the fact that teachers did not spend enough time for proof activities. Therefore, students did not know much about how to prove theorems and they skipped most of the items in GPT. Since deduction is one of the levels in geometric thinking, for the main study, teachers will be encouraged to cover some of the proofs in the curriculum. GAT scores revealed that students do not know geometric concepts and relationships and they have difficulties to understand transformations. However, since DGS enables students to manipulate geometric figures and do transformations, more practice with DGS may help students understand and visualize transformations. Thus, higher scores from GAT may be obtained during the main study.

Because only posttest comparison was not enough, the pretests and posttests within the group were compared. The results revealed that there was significant increase in terms of students’ geometric thinking, geometry achievement and proof skills. These effects of DGS are also supported in the literature (e.g., Jones, 2000; Marrades &

Gutierrez, 2000). This result was noteworthy because although improvement in skills requires more practice and longer time, even five GSP activities created such a difference for the experiment group. Therefore, ten GSP activities which were planned for the main study will be likely to create such difference between the groups. However, because not all students took all types of tests during the administration of the posttests, the majority of data was lost. Furthermore, some teachers in the experiment group could not do all GSP applications, thus the data from those schools was excluded for this paper. Therefore, the number of students who experienced all GSP activities and who took all the tests was low. This was the limitation of the study. For the main study, there will be ten GSP activities and they will be done throughout the academic year. The exam weeks will be determined for each group and students will be encouraged to participate in the tests and do their best. Therefore, the completion of all activities and minor loss in data is aimed to achieve.

The values obtained for the reliability and validity of the tests were acceptable for supply-type teacher made tests (Miller, Linn, & Gronlund, 2009). It indicates that these tests can be used for the main study for the next academic year. However, the test may be revised for the main study for several reasons. First, the mean scores for GPT were quite low with respect to other tests. This was compatible with findings of many studies about students' proof skills (e.g., Clements & Battista, 1992; Stylianides, 2008). Although there was statistically significant increase in the GPT scores in the experiment group, the GPT may not be considered as a single test for the main study such that some of the items may be replaced with the items in GTT and proofs may be asked during the interviews. Second, some items in each test were aiming to measure the same or similar learning outcomes. Those items may be excluded or replaced with other items. For instance, the second, the third and the fourth items in GTT, which required from students to explain an identity or a rule and justify their reasoning, were aimed to measure the fourth van Hiele's geometric thinking level. Therefore, integrating some of the items from GPT into GTT may not cause any loss in terms of content validity of the tests. Similarly, the items with the lowest mean scores will be changed in GAT. Briefly, the tests will be revised for the main study although the values for reliability and validity were at acceptable levels.

In this study, the homogeneity of the groups was not satisfied because the assignment of the schools into the experiment and control groups were based on their choice due to some administrative reasons, and the pretests were administered after forming the groups. In fact, students' mathematics achievement in two of the control schools was higher than the achievement of the students' in two of the experiment schools. Therefore, comparing each group's posttests did not provide valid information about the differences between groups. For the main study, some demographic information about the students and the schools will be collected prior to the study and the pretests will be administered before assigning groups as

experimental or control. If possible, the classes will be assigned into groups rather than the schools to achieve homogeneity between the groups. Furthermore, since national curriculum is applied in Turkey and free textbooks are distributed for all subjects and grade levels, the teachers should cover the same content by using more or less the same teaching materials and activities. Therefore, the teacher as a threatening factor for the external validity of the study was at minimum, but it should be controlled. For the main study, the lesson plans and all teaching materials will be requested from both experiment and control teachers prior to and during the study and they will be asked to change anything that is seen as a threat for the external validity. Moreover, in the experiment group, as it was done for the pilot study, each DGS application manual will be provided to the teachers and a two-day workshop about the activities will be given before the study. Thus, the homogeneity in terms of application of DGS activities will be satisfied.

ON-LINE DISCUSSIONS ABOUT EMERGING MATHEMATICAL IDEAS

Chronis Kynigos, Foteini Moustaki

Educational Technology Lab, School of Philosophy, Department of Pedagogy

Collaborative knowledge-building within an on-line community of learners has for several years been at the core of several studies both for the CSCL and the technology-enhanced exploratory learning approaches. In the Metafora Project, Exploratory Learning Environments (ELEs) are combined with CSCL tools, all in one web Platform. In this paper, we study how the students' meaning making processes were shaped by their on-line discussions in the Platform as they interact with a half-baked microworld. As the Project moves further from the social aspects of learning and touches socio-metacognitive ones, the focus shifts to how on-line learners learn how to learn with and from each other. Thus, we attempt to also study if and how students' meaning making processes are influenced by learning to learn together aspects that come forward as they share and discuss their ideas.

EXPLORATORY LEARNING AND CSCL ENVIRONMENTS

The idea of discussing and sharing artefacts within a community of users through emails, fora or repositories (and nowadays through Web2.0 tools), has long been an issue for technology-enhanced exploratory learning (Resnick, 1996). One of the explicit attempts to develop specific technologies to support social aspects of exploratory learning was made some years ago through a “WebLabs” Project (Mor et al., 2006). At this Project, Noss and Hoyles studied groups of students as they collaborated through a web-based system that allowed them not only to share their experiences in a textual form, but also to co-construct and share models embedding mathematical and programming ideas. Apart from the exploratory activities in which the students engaged in their attempt to make sense of “how does this model work”, emphasis was also given to the social interactions among the members of the community and the ways these interactions shaped mutually constructed artefacts. In this case (as in others before), math meaning making was viewed as a process also taking place when students shared and discussed their ideas, argued about the validity of their models, reflected and redesigned their constructions, while working together in groups. Collaborative “knowledge-building in communities” (Bereiter, 2002) has also been at the core of studies regarding the use of computer supported collaborative learning (CSCL) environments. Stahl (2009) at the Virtual Math Teams (VMT) Project studied small groups of students meeting in chat rooms to discuss on-line about their ideas as they worked with complex math problems. The design of the system also included a shared whiteboard, a wiki for the common artefacts and a portal for social networking. The Project focused on the students’ “knowledge-building” processes as a result of their in-group interactions (which they termed as

“group cognition”), while working with this system. The social practices emerging as the students worked together were considered to be crucial not only for making sense of what they were jointly doing, but also for making sense of how to work together as a group. Thus, the effective collaboration was defined as the one in which the students not only “produced knowledge artefacts” to give to the broader community, but also the one in which each member made sure that everyone in the group understood and progressed as they should.

In this paper we discuss our attempts (in a 'Meta-fora' project) to study students' math meaning-making as they worked in groups with one of the system's Exploratory Learning Environments (microworlds) which were integrated with a CSCL tool in an on-line Platform (Mavrikis et al., 2012). The microworld in question, called the “Twisted Rectangle” (TwR), was designed as half-baked for the students to make changes to (Kynigos, 2007). The CSCL tool was a well known discussion-argumentation tool called 'LASAD' (Dragon et al., in press). The TwR is a 3d Turtle Geometry programmable microworld that is based on a buggy procedure given to the students to figure out how to fix. The task is to make the procedure construct a parametric rectangle which swivels in space as one of its sides swivels on a plane vertical to the opposite side. The procedure given to the students is pedagogically engineered to be buggy (half baked) in the sense that it is incomplete, challenging students to deconstruct it and make sense of the math behind the reasons for its buggy behaviour. These microworlds have been perceived as 'boundary objects' (Kynigos, 2007), i.e. questionable and improvable objects engaging members of communities in meaning making emerging from the joint de-bugging effort. Thus, they may operate as a tool around which the members of the community structure their activities. In this case, meaning generation processes are considered to emerge and be shaped both by the students' mathematical activity as they interact with the half-baked microworld and their social activity as they discuss on how to make it work, change and customize it. LASAD, in our study, is the tool that allows on-line communication and collaboration among the members of the community.

The Project, however, brings a new strand to integrating ELEs with CSCL tools as it views computer-supported learning in groups as a complex task that requires from students -as they collaborate- to also become aware of elements considered to be important for successful learning in collectives and to learn how to put those elements in use (Wegerif & Yang, 2011). Thus, the group members need to be able to show distributed leadership, plan and coordinate the tasks to be carried out, motivate one another, ensure everybody engages, reflect on the quality of the work through peer reviewing and reflect on the overall progress of the groupwork (Wegerif et al., 2012). All those elements constitute the key components of the “learning to learn together – L2L2” pedagogical approach adopted by the Project.

In this paper, we put emphasis on how the students' math activity was shaped as they interacted with the TwR: a) by their need to explicitly articulate their own ideas so as

to share them through a discussion tool and b) by the ideas brought at the table by the other group members. Moving between on-line group discussions and microworld actions, we sought to identify manifestations of L2L2 skills such as organizing and coordinating the work so as to proceed as a group, discussing and evaluate findings from others, reflecting on own findings.

THE DIGITAL TOOLS

The “3d Math” Authoring Tool (<http://etl.ppp.uoa.gr/malt>) is a programmable constructionist environment (Harel & Papert, 1991) that allows the creation, exploration and dynamic manipulation of 3d geometrical objects through the use of Variation Tools (Kynigos & Psycharis, 2003). Building and manipulating geometrical objects in 3d Math is not restricted to solely looking at the 3d world from static 2d views. A Camera Controller gives students the affordance to navigate around, inside and through their constructions, offering the potential for new ways of visualizing 3d space and conceptualizing mathematical notions, especially ones related to stereometry (Moustaki & Kynigos, 2011). We view 3d Math as an authoring tool for developing half-baked microworlds, such as the TwR (Figure 1).

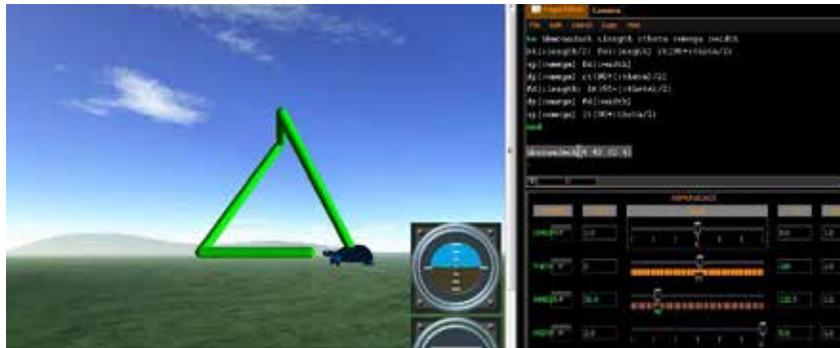

Figure 1: The Twisted Rectangle half-baked microworld in 3d Math

Being a web-based environment, 3d Math is fully embedded in the Metafora System (Dragon et al., submitted), an on-line software platform that offers a set of Exploratory Learning Environments (microworlds) as well as shared workspaces that allow communication among individuals or groups of students. One of those shared workspaces is the LASAD Discussion and Argumentation Tool. The users place in LASAD’s UI text boxes with their ideas (we call those “contributions”) and link them with existing ones, forming in this way a kind of a structured discussion map (Fig. 4). To further tag each contribution with respect to its content (e.g. as “a suggestion” or as “a claim”), a dropdown list is available for each text box. LASAD is designed to function as a tool in which the students may discuss, argue, negotiate their ideas and as a reflection space as it depicts how the group discussions evolved.

RESEARCH DESIGN AND METHODOLOGY

Our research approach was based on the idea of studying learning in authentic settings through “design experiments” (Cobb et al., 2003). “Design experiments” aim

to contribute to the development of grounded theories on “how learning works” and intent to shed light on relationships between the material designed for the experiment (usually innovative technological artefacts having added pedagogical value) and the learning processes within a specific implementation context.

The study described in this paper took place in a Secondary Vocational Education School in a small island near Athens (1st Vocational High School of Salamina) with four 10th grade students (15 years old). The students worked together for 8 hours (2 sessions) in two types of social orchestrations: all four of them as members of just one Group in face to face meetings, and divided in two Subgroups of two members each when working on-line with the microworld and the LASAD Discussion Tool. The researchers adopting a “participant observation” methodology chose not to intervene in the experimentation to give out specific instructions or to provide the “correct answer” to the students on how to address the challenge and proceed. They preferred to pose meaningful -often intriguing- questions at certain time points, so as to encourage students to continue their explorations, elaborate more on their thoughts, share and discuss their ideas collaborating with the other students. The researchers in this study had a dual role as they also acted as the class teachers.

Tools and Tasks

Phase 1: Making one side double the other

For this Phase of the Study, we designed in 3d Math the “L” letter microworld (Figure 2a). This was meant to be a preparatory activity for the TwR work which required rather difficult concepts for these students such as consecutive projections on a plane and trigonometrical relations. So this preliminary task, the students were given a 4-line Logo program to construct the letter 'L', including two variables (one for each of the “L”'s sides).

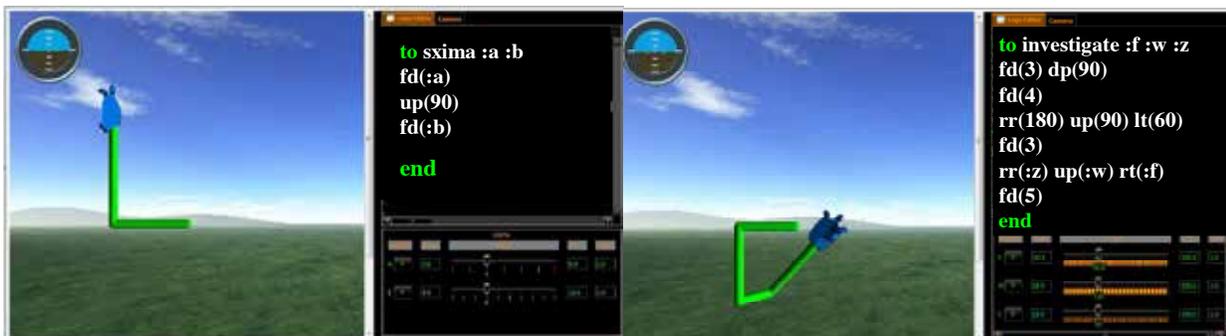

Figure 2a and 2b: The microworlds for Phases 1 and 2

The shape can be dynamically manipulated using the Variation Tool, which allows attributing sequential values to those two variables. The challenge that the students had to address working in two Subgroups (Subgroup A and Subgroup B) was to “make the vertical line be twice as long as the horizontal one”, so that the “L” shape changes proportionally as one letter-shape.

Phase 2: Closing an open shape

For the Main Phase of the Study the students worked with the TwR buggy procedure. The task was to construct a skewed quadrilateral as one of its segments swivels along a plane vertical to the one in which the original rectangle belongs. In this version of the TwR, the figure depicted is purposefully not a closed shape, but an open one, as the end of one of the rectangle sides is not attached to the rest of the shape (Figure 2b). The students working in two Subgroups of two students each (Subgroup A and Subgroup B), were asked to try to “make the shape close”. Since, we didn’t intend to provide an answer on how to work with variables to do so, but ask them to discuss any ideas within their Subgroup and with the other Subgroup, we had prepared a discussion space in LASAD in which the two Subgroups could meet and share their findings as they explored this issue within the TwR microworld.

DATA COLLECTION-METHOD OF ANALYSIS

A screen-capture software (HyperCam2) was used to record students’ interactions the Metafora Tools together with their verbal interactions. Since previous work with 3d Math had shown an extensive use of gestures as means to explain and communicate turtle movements and turns, a Camera was added to record students’ hand and body movements. The corpus data is completed by the students’ LASAD maps and the Researchers’ Fields notes. The video-recorded data from the screen-capture software were verbatim transcribed, while the rest of the data were used for providing additional details. In analysing the data, we searched for verbal exchanges between the students and interactions with 3d Math and through LASAD that indicated that learning to learn together aspects were brought forth as they students attempted to address the challenge when working with the half-baked microworld.

RESULTS

The episodes of this section are selected so as to highlight the students’ interactions at the Main Phase of the experimentations and describe: 1) their discussions within their Subgroup as they explored the idea that less variables than the ones that appeared on the Logo program were needed so as to close the “TwR” and 2) their discussion with the other Subgroup in LASAD around this same issue.

We focus, however, on how the students’ mathematical activity was fuelled by these discussions and specifically by: a) the fact that they needed to articulate their own ideas in LASAD and explain them to the other Subgroup as clear as possible and b) the fact that they are receiving an idea from the other Subgroup which they needed to try out and decide on its feasibility and usefulness in the process of closing the “TwR”. In these instantiations, we also look for manifestation of L2L2 elements

Subgroup’s B idea: One of the values is redundant

The students of Subgroup B, in their attempt to close the TwR, manipulate the three

sliders of the Variation Tool. Through this action, they attribute each time different values to the three variables of Logo program that generates the figure on screen.

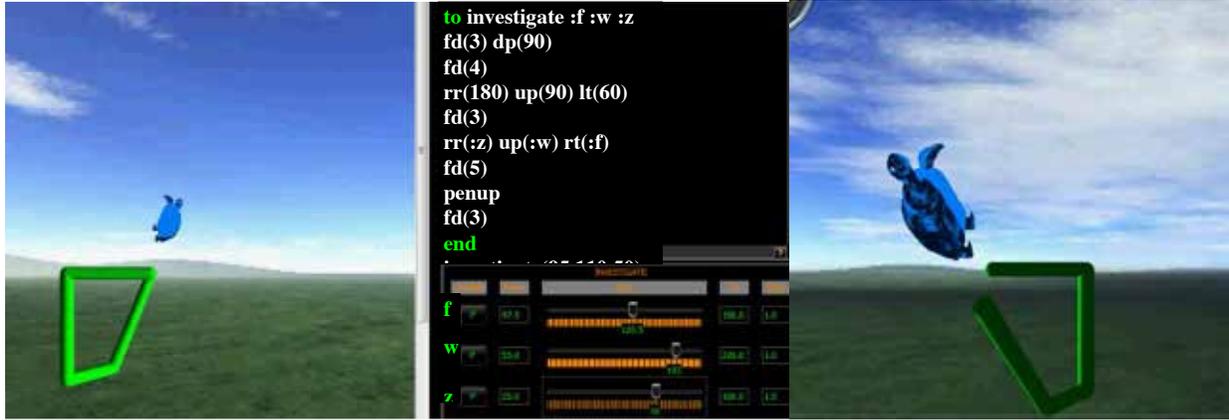

Figure 3: Attempting to close the figure for $f=126.5$, $w=193$ and $z=78$

As multiple times they have almost closed the figure, but haven't really managed to do so yet (Figure 3), the students come up with the idea that *one of the values is probably not needed for closing the figure* and thus they should manipulate only the sliders corresponding to the other two. As they believe this could bring the Group closer to achieving the common goal, they share this idea with Subgroup A through their LASAD discussion map.

S3: I believe that one should go.... It's..... how do we say that? Redundant?

S4: Redundant... We may remove the one line [refers to the slider's numberline]

S3: [Types in LASAD]...have just two values, because may be the one is redundant and makes the shape becoming larger. A suggestion.

Having entered their contribution in LASAD (Contribution no 2 – Figure 3), the students of Subgroup B move back to the microworld in an attempt to solidify the idea of “removing one of the values”. Being quite focused on the manipulation of the sliders for closing the figure, the students find it easier to eliminate the effect the third value has on their figure, by simply placing the third slider's pointer on the zero value. Their explorations from this point on, move to a more specific level as for what needs to be done (“have a value equal to 0”, instead of “removing it”) and share the results of these explorations with Subgroup A by entering a “Claim” in their discussion map (Contribution no 4 – Figure 3).

S3: [manipulates one slider at the time] This one should go. Because with this one you can do that and with this one you can make it come closer. I believe this one is redundant.

R2: So you say this is redundant. How should we make sure? What should we do?

S3: Let's make it 0.[change slider value]

S4: Now it is almost closed

S3: Let's go to the camera. Ahh!! [Laughters – it's not closed] I know what we'll do

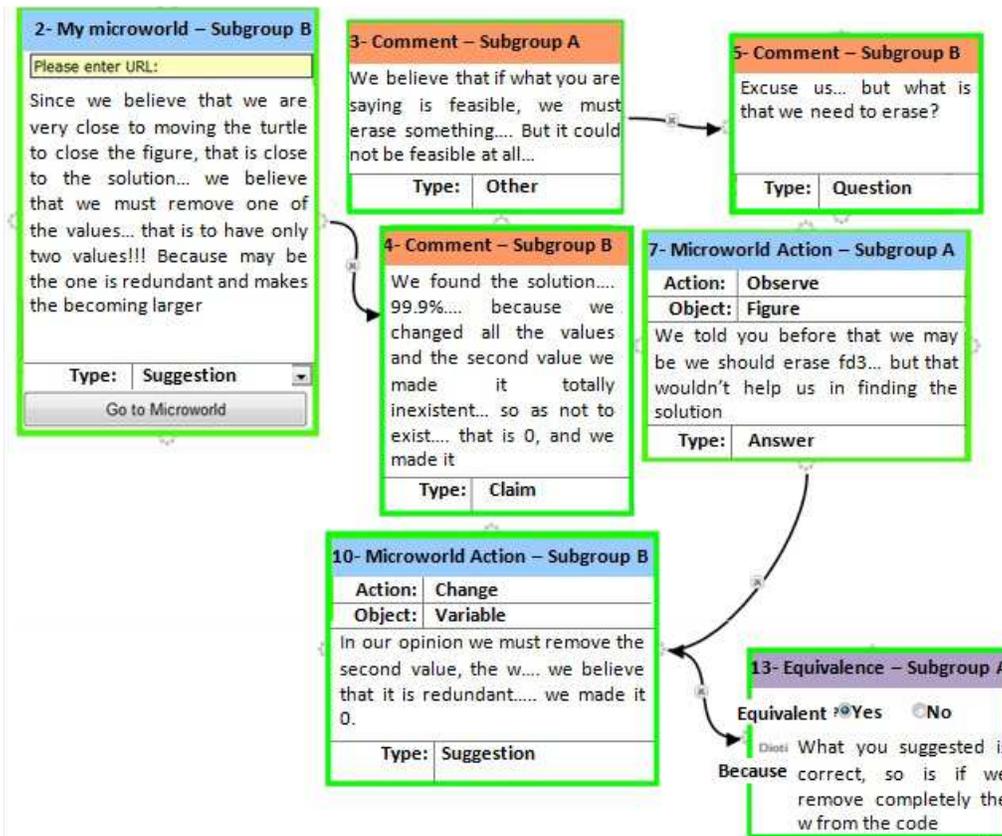

Figure 4: The LASAD map Subgroup A and B use to discuss their ideas on how to close the shape (translated in English)

Subgroup's A idea: Erasing a variable

After reading Subgroup's B contribution (no 2) about “removing one of the values”, the students of Subgroup A move to their microworld to explore if this idea is feasible. However, it seems that while trying to give an answer to Subgroup's B suggestion, they come up with another idea as for how to make two instead of three variables have an effect on the figure they are trying to close.

R3: What do you suggest to do?

S1: Let's try to erase something from here... [the Logo code]

R3: What do you suggest to erase?

S1: A letter to start with... a letter... one of the commands.[they explore which variable/command controls which turtle movement]

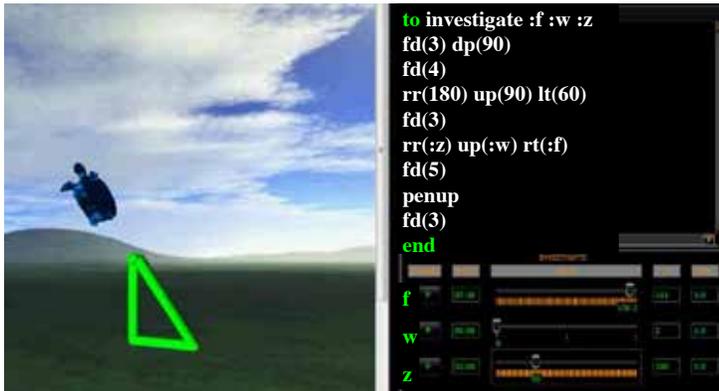

S2: Just tell them what is that WE believe and then we will try answering them. But I still don't know what answer to give them...

These students are less focused on the way the manipulation of the sliders affects the figure and pay more attention to the Logo program and to the way each Logo command corresponds to specific turtle's moves and turns that construct the 3d figure. Thus, they perceive the “removing one of the values” strategy proposed from Subgroup B as one to be implemented in the Logo Editor and interpret it as an

“erasing something” action (Contribution no 3 – Figure 4). As the Logo command for the TwR’s side that the students attempt to attach to the rest of the shape contains variables instead of constant values, the students of Subgroup A go further with their assumption and explain the need to “remove a value” as a need to erase a “letter” (a variable) from the Logo program or a whole command that encompasses a variable. However, as they don’t feel confident about their answer, they choose not to expose this new idea to its full extent to Subgroup B. As a result, the students of Subgroup B, post one more contribution (Contribution no 5) demanding from the Subgroup A students to explain what needs to be erased.

Subgroup’s B idea revisited: Make one variable’s value equal to zero

Just few moments before that, the same students posted the results of their

explorations as they had already revisited their initial idea of one value being redundant and suggest making one value equal to zero (Contribution no 4). However, they omit in their Contribution that the variable to which they gave the zero value was the “w” variable. Realizing that the reason for the misunderstanding is the fact that

they hadn’t efficiently explained to others how to implement their idea, they insert a “Microworld action” contribution (Contribution no 10 – Figure 4) that offers more details as for which “Action” to be carried out (“change”) and for which microworld object needs to be manipulated (“variable”).

Subgroup A: Evaluating both ideas

The students of Subgroup A, coming to view the symbolic representation (Logo program), the dynamic Variation Tool and the figure graphically generated on screen as three interconnected representations, validate the idea Subgroup B offers as an equivalent to their own and insert Contribution no 13.

- S1: “In our opinion we need to remove a variable”.... Ahhhh..... we agree!!!!
- S2: The “w”? [the “w” variable]
- S1: Yes the “w”, yes... because we also said that it should be the “w”...
- S2: Yes! Because it was the “w” that just rolled the turtle!!!
- S1: Yes... I’ll tell them that we also found that it’s “w”.
- S2: “f” and “z” are more important. They make it [the turtle] go up, right and left
- S1: So should we tell them that we agree?
- S2: It’s the same if we totally remove “w” or we make it zero.

DISCUSSION

The students of Subgroups A and B were both given the TwR half-baked microworld and were asked to figure out the math required to close the figure. The Subgroups worked independently with the microworld but shared an on-line mutual workspace in LASAD in which they discussed their ideas on how to achieve their common goal as one Group. Taking a close look at the students' activity, we tried to identify how meaning generation processes while working with the microworld were shaped by their social activity as they discussed both within their Subgroup and with the other Subgroup on how to make the figure close. Furthermore, looking at the students' moves between on-line discussions and microworld, we sought to identify specific L2L2 elements that may have influenced the students' meaning generation processes.

Our findings indicate that the interactions in the dialogue carried out between the Subgroups in the LASAD tool enhanced their awareness of involvement with math meanings and the ways in which these evolved. This dialogue was sustained by the fact that the students constantly moved between their discussion map and their microworld, trying out ideas and making them objects of discussion and reflection both for themselves and for other Subgroup students in LASAD. Each time a new idea was proposed by a Subgroup by means of sending a new version of the code or proposing variable values as potential solutions, the members of the other one tried it out so as to evaluate and check it for its usability with respect to the Group's goal.

At the same time, the members of the Subgroup initially suggesting the idea, revisited it and come to reflect on it so as to make it more explicit for the others, exemplifying the original idea and offering new insights on how to implement it. Reflecting on both approaches (their own and the one offered by the other Subgroup students), the two Subgroups came to put all ideas suggested not only under peer assessment processes but also under self-assessment processes. Moreover, Subgroup A, being proactive, used the feedback and experience from the other Subgroup's explorations and taking control of their understanding as a Group, decided that the two ideas were equivalent (Contribution no 13).

Meaning generation, in this case, was also fuelled by the fact that the students evaluated and monitored the progress they made as a Group towards the common goal. They assessed specific learning outcomes as important for the Group's understanding and re-organised their activities accordingly. All these L2L2 elements appeared to play a specific role in students' further explorations with 3d Math and discussions in LASAD. The outcomes of this small-scale pilot study were used to design the main study which was implemented with the participation of 10 9th grade students for 26 school hours.

EXPLORING THE POTENTIAL OF COMPUTER ENVIRONMENTS FOR THE TEACHING AND LEARNING OF FUNCTIONS: A DOUBLE ANALYSIS FROM TWO TRADITIONS OF RESEARCH

Jean-Baptiste Lagrange

Giorgos Psycharis

University Paris Diderot, France

University of Athens, Greece

In this paper we aim to address the potential of computational environments offering integrated geometrical and algebraic representations for the teaching and learning of functions. We follow a ‘double analysis’ method to analyse learning situations of an experiment that took place in the French context through the lens of the original research tradition (Theory of Didactical Situations) and an ‘alien’ one (Constructionism). The analysis indicates that this method enhances our efficiency to capture aspects of research traditions which influence knowledge concerning the nature of learning situations for functions with computers.

INTRODUCTION

The notion of function occupies a central role in a wide range of mathematical topics, but engaging students in functional thinking is known as a demanding task. We note issues identified by research in relation to students’ difficulties in understanding function as covariation (Carlson et al., 2002) and dealing with algebraic symbolism (e.g. distinguishing between independent dependent and variables, Thompson, 1994). The development of new modes of representation within specially designed technological tools has generated further interest as regards their potential to deal with the above mentioned difficulties. One of the prime affordances of such tools is the multiple linked representations designed with the aim of providing some sort of combination of Dynamic Geometry Systems (DGS) and algebraic multirepresentation, possibly including Computer Algebra Systems (CAS) (Mackrell, 2011). In this study we are especially sensible to the possibility offered by particular computational environments to connect the notion of function to dependencies and covariations between geometrical objects. Existing research indicates that geometrical situations in DGS can be a fruitful context to challenge students’ intuitions and ideas about covariation and functional dependency come into play (Falcade et al., 2007). In addition, problem solving by way of algebraic modeling of geometrical dependencies, which includes also sensual experience of these dependencies, can provide a basis for students’ understanding of the idea of function provided that students can work flexibly between the geometrical and symbolic settings (Lagrange & Minh, 2010). Here we report research aiming at shedding light on the potential of computational environments offering interconnected algebraic and geometrical representations to facilitate students’ making of links between the qualitative experience of dependencies in the

geometrical context and the algebraic notion of function. Yet, it seems difficult to really appreciate this potential, since it is needed to take into account the visions provided by specific theoretical frameworks in technology enhanced mathematics, and because of the fragmented character of these frameworks (Artigue, 2009). Here we consider fragmentation as resulting from the existence of different research traditions. By research tradition, we do not mean only a reference to a theoretical framework, but also all the research practice built jointly with a framework: reflection on a practice gives theoretical elements for a framework, and, in return, practice, constituted by design, observation and interpretation, is affected by the framework. While compartmentalized research traditions participate into fragmentation, we assume that different research traditions can be confronted and in some sense articulated in order to address a particular question, the potential of computer environments for the teaching and learning of functions. Testing this hypothesis is the general aim of this study.

Our choice here is to consider two research traditions, both dealing with functions and software, but different in many other aspects. One involves *Casyopée*, a piece of software that offers a dynamic geometry window connected to a symbolic environment specifically designed to support students' work on functions (Lagrange, 2005). *Casyopée*'s design and experimentations occurred in a French context shaped by didactical theoretical frameworks and epistemological considerations. We focus here on a framework preeminent in the French context: the Theory of Didactical Situations (TDS) (Brousseau, 1997). The other research tradition involves *Turtleworlds*, a piece of geometrical construction software which combines symbolic notation (Logo) with dynamic manipulation of variable values (Kynigos, 2004). The design and the research on the use of *Turtleworlds* is inspired by Constructionism (Papert, 1980) and have been carried out in the Greek context. Constructionism and TDS share a common focus on the design of learning situations through devices – such as the “milieu”- providing affordances for interaction and knowledge construction. Our assumption is that divergent views of the two traditions on the contribution of milieu (e.g. the design and analysis of a session, the nature of the constructed knowledge and its relation to the official knowledge) provide a complementary way to address the potential of computational environments for the teaching and learning of functions.

We drew on data from two concrete teaching experiments taking place in France and Greece respectively. We consider here the teaching experiment designed and implemented with *Casyopée* in the French context. We carry out “double analysis” of this experiment by way of TDS (a priori and a posteriori analyses) and Constructionism in order to be able to tackle under an “integrated” perspective (in the sense of Prediger et al., 2008) the following question: what new insight about the potential of computer environments offering integrated geometrical and algebraic representations for the teaching and learning of function might be gained from the

double analysis of research studies carried out in different national and didactic contexts? Prior joint research experience in cross-analysing teaching experiments with use of digital tools for function (project ReMath [1]) revealed that misunderstanding rooted in divergent views of functions and distinctive theoretical orientations could be addressed at two levels: one is the economy of learning situations, to which we refer in this paper, and the other is the process of conceptualisation of functions by students. Thus, the links between the issues involved in our research focus here are as follows: investigating the potential of computational environments for the teaching and learning of functions raises the issue of fragmentation of theoretical frameworks in the field of technology enhanced mathematics; in order to explore such fragmentation at the level of research traditions we adopt methods (such as double analysis) and theoretical tools (such as the economy of learning situations) that promote a deeper focus on the design, implementation and analysis of teaching experiments realised in different contexts.

THE ECONOMY OF LEARNING SITUATIONS

The notion of “economy” of learning situations helps to address the role of the many different components intervening in the classroom progression of knowledge: students, teacher, but also various artefacts which can be material (e.g. blackboard, disposition of the room) or not (e.g. tasks, rules, systems of notation, language). According to Hoyles, Lagrange and Noss (2006, p. 301): “... a learning situation has an economy, that is a specific organization of classroom components, and technology brings changes and specificities in this economy ...”.

Theory of Didactical Situations (TDS)

Brousseau (1997) presents TDS as a way to model mathematical situations in a learning context. In this model, a central notion is the “milieu”, a device which justifies the use of knowledge objectively to solve a given problem. Student’s acting on the “milieu” provokes feedback calling for modifying or adjusting action. Learning thus results from the student’s adaptation to an antagonist “milieu”. Teaching consists in organising these constraints and keeping optimal the conditions of the interaction. TDS considers didactical situations designed in a way that the desired outcome can be obtained only by applying the knowledge aimed at in the situation. Researchers who refer to TDS in order to consider interactions with digital environments (e.g. Cerulli et al., 2008) propose to think of technological learning environments as means to provide students with an antagonistic milieu, offering tasks and feedbacks adequate for the knowledge at stake, under the condition that situations of use are based on a suitable a priori analysis.

Constructionism

Constructionism incorporates and builds upon constructivism's connotation of learning as "building knowledge structures" through progressive internalization of actions, in a context where students are consciously engaged in constructing (or

de/re-constructing) physical and virtual models of situations on the computer (e.g. geometrical figures, simulations, animations): the notion of construction refers both to the ‘external’ product of students’ activity as well as to the process by which students come to develop more formal understandings of ideas and relationships (Papert, 1980). The constructionist paradigm attributes special emphasis on students’ construction of meanings when using mathematics to construct their own models during individual and collective 'bricolage' with digital artefacts, i.e. continual reshaping of digital artefacts by the students in order to complete specific tasks.

CASYOPÉE

Casyopée deals with various representations of functions. It provides a symbolic window (Fig. 1, left) with tools to work with functions in the three registers: numeric, graphic and symbolic. Casyopée also includes a dynamic geometry window (Fig. 2, right) linked to the symbolic window. The geometric window allows defining independent magnitudes (implying free points) and also dependant ones that can be expressions involving distances, x -coordinates or y -coordinates. Couples of magnitudes that are in functional dependency can be exported to the symbolic window and define a function, likely to be treated with all the available tools; this can be done automatically, a functionality that was expected to help students in modeling dependencies, and that we will refer to as “automatic modeling” below.

THE EXPERIMENT

The design of a session

The classroom session analysed in this paper was the fifth of a series of sessions in the ReMath project following three sessions by which students get familiar with the symbolic window, and one in which they were introduced to the dynamic geometry window and to problems about areas. A series of tasks was conceived in which the students had to make a choice of the independent variable as a key step to get an algebraic model of a geometric dependency, in order to solve the following problem: *ABCD being a rectangle, what can be the position of a point M in order that the area of the triangle BMC is one third of the area of rectangle ABCD (Fig. 1, right)?*

The sides of rectangle were parametric ($AD=a$ and $AB=b$) in order to ensure generality and a discussion on the fact that the solution does not depend on a . The solution is that the points satisfying the condition belong to one of two straight lines parallel to (BC) crossing (AB) respectively in M_0 and M_1 such that $BM_0=BM_1=2AB/3=2b/3$. It is possible to reach this solution geometrically, but the way the problem was proposed to students (in coordinate geometry) and their lack of knowledge in geometry, oriented towards using a function as a model of the variable area. Five successive tasks were then proposed to the students: (1) Build the figure in the dynamic geometry window, M being a free point in the plane (2) Create a geometric calculation for the area of $ABCD$, and moving M , conjecture positions of

M for which the area of BMC is one third of the area of the rectangle (3) Choose an adequate independent variable to get a model of the geometric function of the area of BMC (4) Use Casyopée's "automatic modeling" to get the definition of a function in the algebraic window (5) Use the algebraic window to get algebraic solutions, and then interpret these solutions in the dynamic geometry window.

Instructions were given in order that the side AB was parallel to the y axis, and the side BC to the x axis. So in task 3 the students had the choice to select for independent variable some length involving the point M or coordinates of M , but only calculations depending univocally of the y coordinate of M could be adequate variables. It was expected that students would observe that moving horizontally the point M does not change the area, and connect this observation with the fact that xM is not an adequate independent variable. After a user selects an independent and a dependent variable, Casyopée gives some feedback on whether it is possible to create a function with these data. Together with the observation of values of the variables when moving point M , this feedback was expected to create a milieu helping students understand the statute of variables in a function modeling a dependency.

A-priori analysis

For solving task 3, lengths involving M cannot be chosen as independent variables because they depend on the two coordinates. x_M can be an independent variable, but, as mentioned above, a change of x_M does not affect the value of the area of the rectangle. The version of Casyopée, still in development at that time, calculated a formula involving y_M , but after that refused to create a function. y_M is a suitable variable and the function calculated by Casyopée is $x \rightarrow a \times \frac{\sqrt{(x-b)^2}}{2}$. It was expected that the identifier x for the independent variable could be confusing for students. Casyopée offers other identifiers, but it was not likely that students will use this feature. In the preceding session, the independent variable was a length on the y axis, and the teacher insisted that this length could be labelled x in the function. After creating the function, the students could work in the familiar symbolic window to solve an equation. If y_M has been chosen as a variable, the equation is $\frac{ax|x-b|}{2} = \frac{axb}{3}$ but it can be different if the student chooses another variable; for instance $y_B - y_M$ is a possible choice and the equation is then $\frac{ax|x|}{2} = \frac{axb}{3}$. Another difficulty was expected to emerge from the fact that Casyopée displays the solution in the non-simplified form $\frac{\sqrt{(x-b)^2}}{2}$, thus students had to interpret the two solutions in x as two values of y_M and to connect it to the geometric solution.

Data

The situation has been implemented in a 90-minute session in two classes. Data consisted of recordings of students' work via screen capture software, observers' field notes and students' written assignment. Below we present briefly the work of a pair (Elina and Chloé).

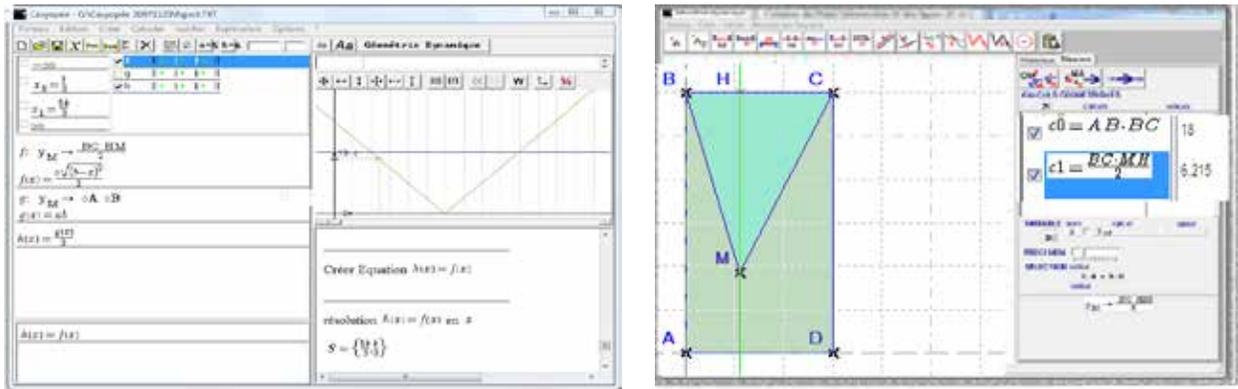

Fig. 1: Casyopée: The symbolic window and graphic tab (left) and the dynamic geometrical window and the geometric calculation tab (right).

The work of Elina and Chloé

In the first 20 minutes students built the rectangle, created a geometric calculation for the area of it and created a free point M initially in the plane and after some dialogue on a vertical side $[AB]$. By moving M on $[AB]$ and evaluating numerically this area (considering the numerical values of the a and b parameters) for about 10 minutes, the students found a solution without taking numerical information of the software. They commented “This is good, this is one third of $[AB]$ ” and wrote their solution. After the teacher’s prompt that M is in the plane, the students explored the figure again looking for a single position of M , but now on the perpendicular bisector of $[BC]$ without using values of the area of MBC calculated by Casyopée.

Then Elina proposed to create a function, but Chloé stressed that an independent variable had to be chosen first. Thus they returned to the text of the given problem and tried to identify the requested variables. Reading the message after trying the constant measure AB , they moved M to this segment. Trying BM , Chloé commented: “here we cannot create the variable”. After that, they tried $x_B - x_M$ and $y_B - y_M$, reading the message of Casyopée (“the variable depends on M , it is defined over $]-\infty, +\infty[$ ”) but not creating the variable. At 50mn, the teacher told them to choose a variable and they chose x_M . Then they defined the function: $x_M \rightarrow AB \times BC$ and got a function $x \rightarrow a \times b$ in the symbolic window. After that, they defined the function $x_M \rightarrow \frac{MH \times BC}{2}$. As indicated in the a priori analysis, Casyopée calculated a formula involving y_M , but after that, refused to create a function. At 65mn, they had to recreate the figure because of a technical problem and Chloé realized that the triangle area was constant and equal to one third of the rectangle area for every position of M on a certain horizontal line. They commented “it is always one third... then the y -coordinate is what is important”. Surprisingly they again chose the variable x_M and got the same feedback as before. At 70mn, the teacher told them to test the variable y_M as indicated in the text of the problem. Casyopée indicated ($-\infty, +\infty$) for the domain. They were not happy and tried to find a way to redefine this domain into $[0;3]$. Giving up, they defined the function by way of “automatic modeling” and

it was accepted by Casyopée. They tried a graphical resolution, but they were confused by the graphical window and needed to get help by the teacher. He showed them how Casyopée offers a dynamic link between a trace on the graph and the free point from which the function is built. The students observed that when they moved M horizontally in the geometry window, the trace does not move (Fig. 1, right).

The written report prepared by Elina and Chloé was divided in two parts: Dynamic geometry and Casyopée (i.e. the symbolic window). In the first one they describe their exploration for calculating the areas for the values $a=3$ and $b=6$ to the parameters: “in our case, the area of BMC must be 6. Thus we move M in order that the value displayed is 6. We see that there are two positions of M and only the y -coordinate has an influence on the area, the x -coordinate does not change the area”. As for their work in the symbolic window they write: “we chose the variable x_M ” [2]. And then “we draw the functions $y_M \rightarrow AB \times BC$ and $y_M \rightarrow \frac{MH \times BC}{2}$ ”, copying the formula given by Casyopée and not mentioning the domain. They copy also the equation and the two solutions. They conclude: “To satisfy the condition, the y -coordinate of M should be $y_M=5b/3$ or $y_M=b/3$ ”. About the difficulties encountered, the students mention: “Finding that only y has an influence on the area of BMC , and then choosing y_M as an independent variable”.

THE ECONOMY OF LEARNING SITUATIONS: A DOUBLE ANALYSIS

A posteriori analysis from a TDS perspective

The situation was certainly productive in the sense that students could grasp the necessity of choosing an adequate independent variable in order that Casyopée will be able to express a function, but they were far from giving an algebraic signification relatively to this necessity and to the other algebraic objects involved, like for instance the parameters. Casyopée’s feedback was generally not well understood. Eventually, it conflicted with students’ views, for instance relatively to the domain. It happened that the teacher had to intervene to help going forward in the task. He tended to offer more than a technical help to students, steering them towards steps of the solution and then breaking the intended adidacticity. This was also the case in other Casyopée experiments conducted in ReMath. Thus, the influence of the provided feedback seems to be less productive than expected as regards the students’ attempts to identify key steps in their mathematical work. Relatively to the question at stake of how students could appropriate the choice of the independent variable, as well as other functionalities already encountered in the preceding sessions, and through this appropriation progress in their understanding of functions, the appreciation is then mixed: the milieu highlights actions that students can identify as steps in the solution; then students are “pushed” towards these actions; however, this does not guarantee that they acquire an appropriate understanding of these actions.

Analysis from a constructionist perspective

The issue of design was mainly materialised through the preparation of a milieu facilitating - in constructionist terms- meaning generation for function as covariation. The reported episode reveals students' diverse views of the symbolic forms provided by the tool and difficulties to relate their selection of variables to the mathematical concept of function. To analyze this divergence, we refer to *two gaps at the level of design* and try to connect it to constructionism: one has to do with the design of the environment and, in particular, *the nature of the provided feedback* and the second with *the teacher's role*. As for the first, the level of design of Casyopée at that time did not provide students with opportunities to take some actions in relation to the provided feedback. Thus, we see that students could not experiment directly with notation in Casyopée. The correct symbolic form in mathematical terms appears as a 'closed' answer pre-supposing in some way students' understanding of the standard algebraic symbolism of functional dependencies. A constructionist view on design should stress that further development of meaning generation can be facilitated if students have at their disposal a mechanism to manipulate so as to take further action based on the provided feedback (i.e. to 'do something' with the tool). Learning activity within constructionist computational media very often consists of students' engagement in debugging intentionally designed 'buggy' behaviors of objects. These objects operate as means to challenge productive meaning generation and provoke further interpretations and actions by students. Thus, constructionism should emphasize the *expressiveness* of computational environments as a design principle, i.e. design based on the use of dynamic representations that make algebraic symbols and relationships more concrete and meaningful for the students through the ability to express mathematical ideas possibly in ways that may diverge from standard mathematics (see for example the idea of *autoexpression*, which privileges the role of a programming language as a mechanism to control objects by expressing explicitly the relationships between them, Noss et al., 1997). The second point has to do with the role of the teacher. In the episode we can see that the teacher seems to be reluctant to intervene and does it only when he realizes that the students face strong problems in coping with the provided functionalities and integrating them in their activity. In a constructionist perspective, in contrast, teacher's interactions are more participatory from the teachers' side and more strategic in encouraging students to elaborate emergent ideas and generalisations.

DISCUSSION

The motivations underlying the Casyopée experiment meet at a general level those involved for the use of multirepresentational, DGS and CAS software. Its specificity is that it focuses on key points of the transition from function in a DGS to symbolic functions, aiming to facilitate students' access to symbolic forms. The task in the experiment is to find a solution of a problem. It can be explored in geometrical settings, but can be really achieved only after the transition to symbolic functions.

The milieu is then inspired by TDS, the task being challenging and the transition being conceived as a non obvious step. Feedbacks are prepared in the software in order to ensure that interaction will actually put the aimed knowledge at stake, TDS rely on an a priori analysis and uses an a posteriori analysis to compare actual procedures of students to the a priori expected procedures to bring evidence that the milieu is adequate for the targeted knowledge. That is what it was aimed in the Casyopée experiment. However, as indicated above the appreciation is mixed: the interaction seems to produce effects in terms of action in the environment, but not to really make sense for the students. The constructionist interpretation points to an important fact: Casyopée is a mathematical tool, and most of the feedback it provides supposes algebraic knowledge, or coordination between geometry and algebra, that is precisely at stake. In this vein, constructionist analysis brings to the fore issues of tool design emphasising the importance of design choices allowing students' meaningful use of the available infrastructure by forging connections between students' action and tool formalism. The interventions of the teacher constitute a point of common interest in the double analysis. They are seen by constructionism as participatory and strategic in enhancing students' exploratory activity. In contrast, TDS cares for adidacticity that could be broken in these interventions, by way of "Topaze" effects. However, in the Casyopée experiment, it happens that total adidacticity would have led the students to an impasse.

Constructionist and TDS analyses of learning situations in the Casyopée experiment in part converge when they consider a milieu and in part diverge because they have different conceptions of this milieu. TDS analysis is oriented towards evaluating the reproducibility of situations of learning aiming a given knowledge, and constructionist analysis towards identifying occurrences of progression of meaning. However, this "double analysis" is clearly deeper and helps to look at the economy of learning situations about functions with computers as a particularly complex question. On the one hand, the multiplicity of interconnected representations of functions, of students' possible actions on these, as well as of students' understanding of these representations and actions is an obstacle to the possibility of a controlled milieu, and of adidacticity consistent with TDS. On the other hand, relying exclusively on uncontrolled meaning generation would question the extent to which connections can be made between knowledge built by interacting with the milieu ("knowing") and the standard mathematical knowledge ("knowledge").

NOTES

1. "Representing Mathematics with Digital Media", 6th FP, IST-4-26751-STP, 2005-2009 (<http://remath.cti.gr>)
2. Actually, xM was the label of the button allowing choosing a variable, which explains why the students mention this label, while being aware of yM being the right choice. This label changed in subsequent versions of Casyopée. The design decision at the time was to implement key actions at Casyopée's interface by way of buttons like in DGS. The difficulty was to find icons that could accurately represent the nature of the action.

THE ROLE OF METADATA IN THE DESIGN OF EDUCATIONAL ACTIVITIES

Paul Libbrecht, Ulrich Kortenkamp

Didactics of Mathematics, CERMAT, Martin-Luther-University of Halle-Wittenberg

How can dynamic geometry documents be shared? There exist several repositories of learning resources where this can be done. Each repository has its own specificities. In the process of understanding how dynamic geometry resources are selected and shared, preparing for the Open Discovery Space federation [1], we attempt to describe the role of the metadata for the potential users of the learning resources: what purposes it serves, and when it is useful or not. We do this based on the log-books of actual maths teachers of the i2geo platform whose experience and professional practice of teaching sets particular utility of the metadata: how they find the resources, assess the resources' qualities, and evaluate the cost of possibly needed adaptations: all depends on the practice.

INTRODUCTION: METADATA IN EACH CONTEXT

Metadata is understood to be the data about data – a fairly generic concept, probably as general as the notion of a *resource*. Our basic concern in this paper is learning resources: electronic information sets, which can be used by an educator or learner to support their teaching or learning processes. More precisely, we are interested in the information that is encoded in repositories besides the resources itself: the metadata.

Multiple repositories of learning resources exist, including LeMill (lemill.net), i2geo (i2geo.net), Curriki (curriki.org), Merlot (merlot.org), Agrega (agrega.educacion.es), each with its specificity: for example, Curriki allows to search by educational levels for sections of ages, while Merlot does not allow such a search, and Agrega supports search by the exact educational levels (of Spain). Each of these repositories was created with a target population and a target set of learning resources in mind; based on these, the toolset and the metadata structure [2] were chosen. However, the impact of these choices of metadata schema and tool sets on the day-to-day practice of teachers is little explored. In this paper we aim at qualifying the role of the metadata in the teachers' usage practice based on log-books of actual mathematics teachers. The differences between the learning resource repositories above make it so that it is easier to search for resources for a given educational level using Agrega or Curriki than using Merlot or generic web search engines (such as Google): in the two latter cases, only words can express the query and they do so quite ambiguously when one considers simple examples such as the word *quatrième* representing two different ages depending on the country one is living in.

This paper aims at inspecting the explorative processes of the selection of learning resources. The usage of learning resources by teachers, as well as the social and professional development that follows this usage, have been studied in such works as

the book of Gueudet, Pepin and Trouche (2012), but they assume that the resources are already found and study their impact on the teaching. In this paper, we study the selection process (searching, choosing, evaluating) preceding the use that seems to be little explored. The utility of the information that is displayed to the educators so as to decide on the re-use the relevance of a learning resource should be measured with a look to the professional life of teachers: we contend that re-using learning resources can help the teachers introduce innovative learning practices and support the usage of software in classroom. This paper does not discuss this hypothesis, but the question: Which information should a sharing environment display for each resource so as to trigger re-use? Differently said: What exchange vocabulary can be used between producers and recipients of learning resources?

While Ha Lee et al. (2013) investigate the role of the metadata fields of video games for the usages of different type of *personas*, we investigate the role of the fields of metadata based on the log-book of teachers preparing their mathematics courses.

Definitions

The *learning resources* we are interested in are any form of a digital artefact that is ready to be used by educators or learners to support the teaching and learning process. Learning resources can be found in published works such as textbooks or their supplementary materials, they can be found in the portfolio of the experience of each teacher, or they can be found in sharing platforms. The concept of “learning resource,” which is equivalent to that of a “learning object” (Wiley, 2000), is used by all current *Open Educational Resources* repositories. These repositories create a context, which allows the learning resources to be found and, later on, to be re-used.

For this paper, we shall call *metadata* of a learning resource in a given environment any information recorded directly about a learning resource that is not included inside the learning resource itself. Thus, metadata includes a description or a caption, annotations indicating the target educational level or an instructional type or a snapshot of the learning resource. Partially standardized formats exist to encode metadata (LOM, DC-ED, LRMI) and may help the exchange between different platforms (container websites). Metadata records are generally split in sections such as: general, authorship, rights, pedagogical metadata, and technical metadata. Beyond the metadata, one often calls *paradata* the set of data about a learning resource that has been recorded following a particular view or usage of the resource. This includes ranking statements, records of how many students have succeeded, or comments on the resource. While paradata is not exactly metadata (and it often lies in separate places than metadata), it may often serve the same role.

Although our investigations have a potential of application beyond teachers of mathematics in Europe, they are our focus: tools, resources, and annotations vocabulary in our study are designed for them and by them. The paper first informs about the objectives of this research: the design of the Open Discovery Space

platform. It then describes the principles the i2geo log-books approach which constitutes our experimental basis. Then it presents the roles of the metadata, computer-wise and didactic-wise. These roles are then instantiated in an interpretation of the log-books. General remarks form the conclusion.

OPEN DISCOVERY SPACE

The research described here is intended as a basis of the platform design process of the Open Discovery Space portal. This portal will be the result of the EU project of the same name, a broad project gathering 52 institutions across Europe and about 20 learning resources repositories in many subjects, including mathematics.

Open Discovery Space will federate multiple existing learning resources repositories already on the web. Among others, the i2geo platform (i2geo.net, Kortenkamp et al. 2009), the Cosmos portal (cosmosportal.eu), open-science-repository (openscienceresources.eu), organic edu-net (organic-edunet.eu), or edu-tube-plus (edu-tube-plus.info). A more detailed overview is made by Megalou et al. (2012).

This federation will be enriched by a social network, by students' delivery tools which should empower teachers to re-use learning resources including features as far as the analytics services that allow to know if and how learners have used the resources, and by optional extension-servers which support a deep integration into the school infrastructures. Open Discovery Space is a EU project running from April 2012 to March 2015; as of this writing, its design is being articulated.

The platform design process includes the elaboration of a vision of the usage of the portal in the design of educational activities for secondary school. The vision is to be complemented by scenario (or lesson plan) templates, which will support teachers in the application of alternative didactical approaches. The project gathers technology enhanced learning specialists in the field of science (notably biology and physics), language learning, and mathematics. It aims at serving the complete range of stakeholders involved in secondary school life.

In order to describe concrete scenarios of usages of the Open Discovery Space portal, user stories have been written and the design process of teaching activities using the expected platform is being sketched: this is where the learning resources sharing platform is expected to be used, and thus where metadata becomes important.

To understand this process, reports of the experience with other platforms are gathered. In this paper, the log-books of usages of the i2geo platform are discussed.

THE I2GEO LOG-BOOKS OF THE RESOURCING PROCESS

During the Inter2geo project (which ran between 2007 and 2010, see Kortenkamp, 2009), a team of active teachers attached to the INRP in Lyon (France) decided to gather to discuss and attempt the usage of the i2geo platform and to report about it. This effort was lead by Jana Trgalová and Sophie Soury Lavergne. The objective of

this report was to help to guide the elaboration of the platform so as to make it useful for the work of teachers. Log-books [3] were filled tracing the discoveries made and the expectations felt. These log-books are all dated and sometimes represent the i2geo platform in a very preliminary state. Many of the issues have been dealt with in the meantime, be it on the platform level or on the level of resources. Moreover, some of the log-books mention resources which have been changed in the meantime. These log-books however should be read with the perspective of informing how these platform usages have an impact relevant to these teachers' teaching activities.

We shall review several of these log-books. They all involved a simple *resourcing process*: start with a need for a future teaching occasion, formulate search queries, skim through each of the probable results, identify the useful ones, try each of them, file a quality evaluation, attempt in class, file another quality evaluation.

THE ROLES OF METADATA

In this section, we describe the roles that we propose the metadata can have in the software activities of a learning resources sharing platform. We differentiate the technological functions and the didactical functions.

Technological functions of metadata

We are interested in the following functions that a computer program can perform with metadata within the activities around learning:

DISPLAY: When a person browses a learning resource within a collection of resources, metadata is presented. Parts of the metadata can then be read or seen by humans; this can help to recognise a resource. Good examples of rendered metadata include the title and description, the media-type (typically as an icon), and the educational level. The display can also include paradata.

SEARCH or FILTER: Using several retrieval methods, it is possible to find the resources that match particular metadata values. This includes browsing taxonomy and clicking the links or entering a text and showing its matches. The information of the metadata is the basic search ingredient. Search engines generally apply multiple levels of matching between queries and resources so that the results list appears to be sorted by *relevance*: e.g. a word found in the title is more important than in the description or a resource, a didactical function (e.g. reference, handout, demonstration...) matching a query in the metadata of a resource that only has one such function is more important than such a function in a resource that has dozens of such functions.

RECOMMEND: Based on recommendation algorithms, automatic searches can lead to suggestions of learning resources for users. Recommendation is similar to searching, but the search criteria are given by the software and search is usually not initiated by the user, but by the platform itself.

INPUT: A user that contributes a learning resource, and one who updates it, has the possibility to input or modify most of the metadata.

Didactical Functions of Metadata

Such basic functions as above help an educator to perform a number of actions that are useful for his or her teaching preparation and implementation process.

SELECT: Within a *resourcing* process, teachers routinely seek learning resources that could support their teaching. This generally involves cycles of search, preview, trial, and refinements until something applicable for their objectives and conditions is found. Selection involves an elaborate dialectic activity between the usage of search tools, the observation (and thus evaluation) of the displayed metadata, the available (or missing) resources, the attempts of usage, and the refinements of the search.

PUBLISH: When users feel that a learning resource would be valuable to contribute so that others can take advantage of it, a basic record of metadata is populated with information that the user considers to be useful. Doing this he or she has an idea how to present the source so that it will be displayed adequately and that expected search queries will show it.

ADAPT: Finding the right resource is most commonly an imperfect quest which needs a complementary adaptation process. For example, one needs to adapt wording, the technical conditions of use (e.g. make PDF out of Word, find the exact link, package into a different format, cut irrelevant pieces...). The cost of adaptation is generally compared to the benefit of re-use as discussed in Libbrecht (2011).

ORGANIZE: Course planning and resource publishing often require the resources to be grouped and labelled. This activity allows a collection of content to be presented along a structure that is practical to get an overview (for example a thematic grouping, or a lesson plan).

DEPLOY: When it is time to get to the classroom, a publishing process happens: a print, the creation of a resource in the learning management system, an indication on the blackboard, an assignment... These processes can end in the classroom (for in-class activities) or later. This is generally the time when the learning resource is ready for the students' use (e.g. when an interactive exercise is properly linked so that most learners will be able to just click and start it).

RATE: During the usage of the resource, and during the selection process, a constant critical eye is exercised. The output of this critical eye is a judgement of the quality that is published, typically, on the sharing platforms. Various forms of rating exist, from simple star-based judgements to elaborate multi-dimensional questionnaires such as that of i2geo (Trgalová et al. 2011). This creates paradata.

SUGGEST: A more general form of than rating, suggesting is commonly done in social networks of teachers and learners (for example via Facebook or Twitter). It

involves transmitting the information about a learning resource from one person to another (or several). The suggestion should invite the recipient to explore the learning resource by formulating characteristics that are relevant for him/her. This can be done via email, for example, exchanging a URL and indicating or summarising the particularly interesting metadata facets.

THE ROLE OF METADATA REPORTED IN LOG-BOOKS

The roles we have described above appear in the INRP-log-books mentioned above. They show which metadata property and function has when led to a decision. We will summarize the analysis for several of these log-books below.

Triangular Inequality: Perfect but...

Log-book: [JdB-inegalite-triangulaire.pdf](#).

Our teacher searches interactive geometry resources about the triangular inequality (*inégalité triangulaire*). No concept is registered for this, so he searches for these words and finds a page-full of search results.

Because some resources have these words inside the title, they are listed earlier. The teacher reads the metadata excerpts of the search results: a bit of the description, the ranking... (see Figure 1 for an example). Based on the title and the descriptions, the annotated level and topics, and the didactical functions, he can select a resource that seems appropriate: [inégalité triangulaire](#) [4]. This teacher has decided on this resource because of its title which matches exactly the expectations.

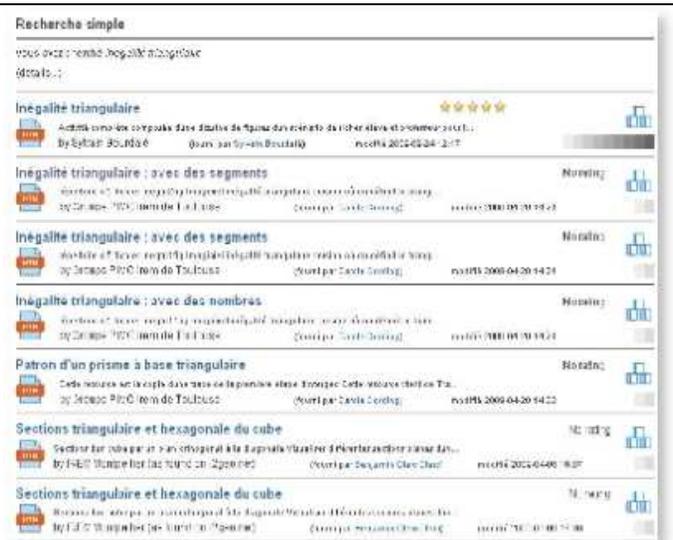

Figure 1: Excerpt of a list of resources

In this case, it is a linked page, which contains students' and teachers' sheets as well as 9 interactive exercises. Our teacher can test individual parts of the resource, making sure it is ready to try for the students. Thanks to the teacher sheet, he can plan that this activity will take two course-hours in lab and can book the rooms accordingly. He skips a part so as to save time. The second sheet is the starting sheet. During the course, he realises that some of the computers are missing a classical requirement (Java, Flash). Moreover, that day had a very low network bandwidth. Both of these technical issues lead to a loss of time of 15 minutes (of 50). The teacher notes that this resource is perfect, and he rates it highly, but he notes that he would wish his usage to be a bit different and that, since he cannot adjust the resources, he only can tell the students to follow things differently.

Metadata fields used: all that is displayed in the search results and in the resources' info (title, description, levels, instructional function).

Actions: done: select, deploy, rate; wished: adapt, organise.

One the most important criteria this teacher sets forth and has successfully encountered is the completeness of the didactical details (teacher's sheet, students' sheets, time estimates...). To our knowledge, no metadata structure encodes this completeness.

Corresponding Angles: Too Coarse Resources

Log-book: [JdB-angle.pdf](#)

Our teacher searches for *angle* using the search tool available then: a plain text search tool similar to that found on Curriki. She wishes to find resources allowing students to infer the relationship between parallelism and corresponding angles. As is usual with plain text search (Fig. 2), the result includes multiple unrelated results; only two seem to be closely related. She then tries to search for the occurrences of the plural word *angles*, which

Figure 2: Search for “angle”

gives unrelated results. For these two, she looks deeper, opens the resource view and the linked URLs. These URLs are large collections of resources (Fig. 3), such that inspecting each of them takes much time. One of the resources she finds in this big collection matches exactly in theme (Fig. 4) but the pedagogical approach bothers her: she wants the students to discover the relationship between the angle equality and the parallelism themselves but that interactive construction fixes the parallelism at start. At the end, she creates a new resource [Angles correspondants](#) [5] which corresponds to her intents. She expects to use it as a demonstration tool in classroom.

Metadata used: title, description, authors. Missing the use of a more precise topic.

Actions: done: select, deploy, publish, rate; wished: adapt.

Remarks: This log-book is a classical story of *poor metadata*: the topic our teacher expected is a relatively precise topic, a topic that needs two words hence is difficult to search for with precision. As a result, our teacher uses more general terms and has to sort through a pile of irrelevant resources which she can easily identify thanks to titles (such as the set of resources about the trigonometry).

She then meets another widespread issue for the central role of the learning resources platform (to make available learning resources findable to many): granularity.

Because the resource that is contributed is a broad collection encompassing multiple objects (Fig. 3), it cannot be finely annotated with topics and educational levels. Moreover, the description of each resource and the resources' content is not indexed. This is the reason why the best-practice guidelines of i2geo propose alternatives (Mercat et al., 2009).

Finally, one should note that the resourcing process is also made of simple *visits*: our teacher has created her resource at the end, which is less expensive for her than, for example, requesting the installation of new software.

That creation has been clearly supported by the resources that she has viewed before. A *dark re-use*, as coined by Wiley (2009), has happened.

Exponential: Cross-lingual topic search

Log-book: [JdB-fctexp-euler.pdf](#)

Our teacher intends to find supporting material for the introduction of the exponential function applying the Euler method. First she searches for the *exponential function* topic.

This search finds the resources that have been annotated with that concept. She only finds two resources, only one is interesting ([Exponentialfunktionen \[6\]](#)) but it is in German (Fig. 5). Nonetheless, she attempts it and tries to understand it but grasping it enough from the geometric aspects alone was impossible, she gave up.

Figure 5. Two resources responding to the search for “exponential function”

She then searches in plain text in several attempts. At the beginning, the results list is big and full of unrelated results (because such words as functions are very common and words that match fuzzily are also included). Finally, she finds how to search for a “phrase” putting quotes around it. The resources she finds are, however, insufficient. She then uses a generic web search engine, Google, and operates the same resourcing process. She finds the tenth result to be appropriate. This resource fits her needs, she is easily able to deploy it to her students and adapt it as needed. She contributes it on i2geo ([Introduction... \[7\]](#)).

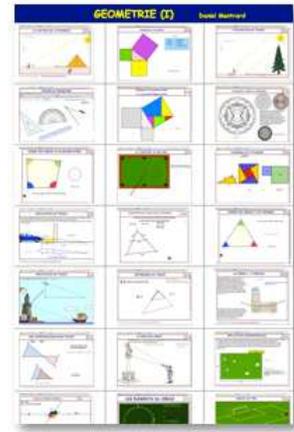

Figure 3. A collection of resources

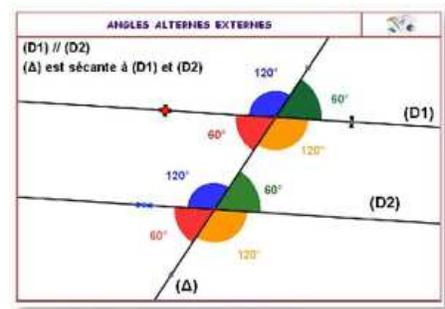

Figure 4: Resource chosen by the teacher

Metadata: topic, title, description (displayed, searched, input)

Actions: done: select, adapt, publish, deploy, rate.

It should be noted that the topic annotation is a very precise search ingredient: it allows to search with almost no error but often misses some resources which have not been tagged appropriately. Similarly the query for “fonction exponentielle” (as a phrase) is much more precise and misses results which, for example, do not contain this exact phrase. Such an ambiguity is recurrent and not fully solvable unless a considerable effort is made into polishing the annotations of the resources, for example by supporting is encoding by applying suggestions based on text analysis.

CONCLUSIONS

In this paper, we have proposed a coarse model of computer functions and of didactical functions of metadata. We have applied this model to the log-books reporting early activity of the i2geo platform successfully: the resourcing process described there is entirely dependent on the quality of the metadata records.

These log-books have shown the tricky role of the metadata: when read, it must be expressive enough for resources to be easily identifiable, still it must be easy to input. They also have shown that the criteria to choose a given resource to be applied in a teaching situation include all fields of the metadata that can be searched or displayed; these fields also include the didactical facets of the resource (in particular, the available documentation) and the compatibility to the technical environment.

These log-books have also shown a premise of the metadata that is often forgotten: its goal is to form a catalogue, and this catalogue should be informative. If a search result shows information that does not allow recognising the resources contents, it is likely to require extensive manual skim through all the results. This implies that a person that inputs a good metadata is one that knows the available content well.

This study has also shown a role of metadata which is completely different than that of enabling the *automatic assembly of learning resources* (as expressed in early visions such as those quoted in Wiley (2001)): the metadata display forms a step in the selection process, where the teachers’ expertise plays an important role.

Finally, these log-books have shown us interconnections between select, publish, adapt, and deploy actions: all teachers' log books demonstrate that previous actions have influenced the next ones, even if they were a selection that lead to a rejection.

NOTES

DIDACTICAL DESIGN PATTERNS FOR THE APPLICATIONS OF SOFTWARE TOOLS

Paul Libbrecht*, Marc Zimmermann**

*) Mathematics Didactics, Martin Luther University of Halle

**) University of Education Ludwigsburg

We report on didactical design patterns for mathematics education with a special focus on the impact on the software construction process. We describe how such short texts, in the first instance developed for educators, can also be used by developers of learning software. We claim that such an application supports a more effective usage of the tools, thus raises their quality.

The paper presents one of the design patterns in details, Representation-on-Demand, and illustrates its applications through several tools.

INTRODUCTION

Numerous software learning tools have appeared in the last ten years. Just as technology found its way into society (personal computers, mobile phones, tablets,...), technology found its way into the learning places. But what is the best way to learn with learning software? This question has not been solved till now. Learning software is not yet commonplace in daily school lessons or at university lectures, even though there are many well developed learning tools.

In the authors' experience, from the view of university education, many students still prefer working with pencil and paper. On the one hand using technology and learning tools is a new concept to the students. Before working on a task they have to learn to handle the program. Therefore it seems faster for them to get a solution by hand. On the other hand, students argue that in the end the exams also have to be done by hand. Using learning software makes no sense, because no matter what, you have to work on a task with pencil and paper to prepare for the exam. Additionally, students in teacher education argue that these programs are not going to be used in school, therefore there is no need to use them. As a result, for many students the learning tools do not connect to the learning behaviour.

Hence, learning tools, which we shall understand as any software that helps learning, have to be designed so that students will use them. They have to follow the learning behaviour of the students. We claim that learning tools could be enriched, by using the same patterns that are used by teachers and educators. In this paper, we propose the dissemination of short texts describing patterns in the learning processes.

The didactical design patterns are the focus of this paper. They form a collection of short and readable texts, which members outside the (mathematics) pedagogy

community can exploit. We are particularly interested in the applications of the didactical design patterns to the learning tools' development and documentation: we observed that the language to describe the learning tools may lack the concepts of the mathematics pedagogy and may sometimes be far from the users' day to day tasks.

A common language is needed for the technology enhanced learning and the mathematics pedagogy research and practice communities to understand each other. This has been noted by Noss (2009) who stresses the importance of interdisciplinarity for the field of technology enhanced learning. A few initiatives are emerging to help summarizing the branch in the form of encyclopedic knowledge. Among others, on the computer science side, the TEL Thesaurus (<http://tel-thesaurus.net/>) and the interaction-design foundation (<http://interaction-design.org/>) are both present, and on the mathematics education side, one finds MaDiPedia (<http://madipedia.de/>) or the ReMath scenarios (<http://remath.cti.gr/>).

The didactical design patterns we present here are a form of common language with a different perspective than the works above: they depict recurrent schemes which are backed by literature in pedagogy. Their *usage* by software designers or teachers should be simple and backed by a sufficient vocabulary that enables ease of discussion. We attempt to document possible application processes in the software construction and documentation.

Our contribution connects the three themes of the working group: it contributes to the design and use of technologies by proposing patterns to raise the quality of the learning experience (theme 1.1). It also provides means to raise the impact of the use of the technologies in their learning (theme 2.1). Finally, it proposes patterns that support best practices in using the technologies (theme 3.3).

OUTLINE: This paper first introduces the principles behind didactical design patterns and the concepts they relate to. It then describes *Representation on Demand*, the central pattern of this paper. Two of its exemplary implementations are then described. In the conclusion, future research directions are outlined.

DIDACTICAL DESIGN PATTERNS

In general, design patterns were first described in the subject of architecture by Alexander (Alexander., Ishikawa, & Silverstein, 1977). Even there, they were used long times before. The issue of design patterns was to give a general solution for recurring problems when constructing buildings. This approach was adopted in the 90s by computer scientists (Gamma, Helm, Johnson, & Vlissides, 1995) for recurring problems they encountered when writing programs, e.g. algorithm or programme concepts, which are used in many programs. For these, the design patterns are still used today in these fields. Therefore, design patterns are used to describe possibilities to solve challenges [1] on pedagogical or didactical [2] problems. This does not mean, that they are an instruction that says, after doing this all is fine. They

provide (theoretical grounded) hints and outlooks in which way the challenges can be solved.

To describe these kinds of challenges with a possible solution as a pattern in education is not new. The “Pedagogical Patterns Project” (Bergin et al., 2012; www.pedagogicalpatterns.org) contains a lot of very broad patterns relating to pedagogy. Vogel and Wippermann (2004) as well as Niegemann and Niegemann (2008) introduced didactical design patterns as a possibility to document didactical knowledge. The advantages of patterns are that they provide named short and repeatable approaches to a (pedagogical) problem. Thus, they are easy to read, understand, and thus to use by everyone, especially teachers to optimize learning scenarios and processes.

Figure 1 depicts how patterns are situated to other texts in terms of their applicability, didactical diversity (the diversity of situations it can be employed in), and their coverage (how many dimensions does it take in account).

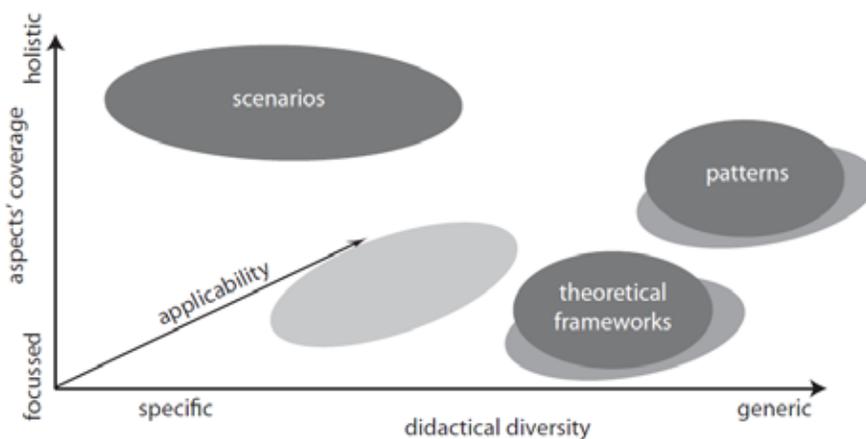

Figure 1: Localisation of didactical design patterns, compared to learning scenarios.

In contrast to the pedagogical patterns (c.f. Bergin et al., 2012), which describe challenges in learning scenarios in a very broad way, e.g. students should be active while learning (p. 17, *ibid.*), didactical design patterns described in this paper are somewhat more precise to the learning process. Didactical design patterns differentiate themselves from learning scenarios in that they are abstract and describe a more general situation. They more focus on didactical principles in learning scenarios, e.g. when does a learner need to get a hint on a problem (Zimmermann, Herding, & Bescherer, 2013). The patterns are the work of the SAiL-M project (Semi-automatic Analysis of individual Learning-processes in Mathematics). They all are available on the web at www.sail-m.de and at sail-m.i2geo.net. The availability of their text as simple web-pages with a short title, a direct URL, and under an open content license makes them considerably easier to mention in electronic communication, a fact of growing importance.

There are different and various styles to describe didactical design patterns the patterns developed in the project (Bescherer & Spannagel, 2009; Bescherer, Spannagel, & Müller, 2008) follow a structure made up of the following ingredients:

- **challenge/motivation** (problem): The issue intended to be solved is introduced.
- **forces**: Factors influencing the described problem and, therefore, no easy solution is possible.
- **solution**: One (general) recommendation is formulated.
- **rationale**: Theoretical reasoning on which the possible solution is based on. It helps readers to dig out justifications of particular aspects.
- **examples**: Precise situations where the pattern has been successfully used.
- **related patterns**: Connection to patterns that are relevant when applying this one.

DIDACTICAL DESIGN PATTERNS IN SOFTWARE DEVELOPMENT

As well as in school, didactical design patterns can be used in the development process of learning tools. Didactical design patterns can be interesting because they represents a compact set of guidelines for several types of applications, which focuses on the essential aspects of the learning processes. Software developers are left free to use them when creating a tool but should always be aware of an environment where the pattern can take place.

For example it is important in a learning process to get hints and/or feedback and learning tools often provide them. But the hints that are given by the tools should not reveal the whole solution at once. They have to be given in different levels of detail and have to be individual to the learner's problems. This is an approach a human tutor normally applies when helping students working on tasks. Hence learning tools should also provide hints and feedback at different levels and provide them when the learner demands it. The Hint on Demand Pattern (Zimmermann, Herding, & Bescherer, 2013) describes how this didactical approach can be implemented in learning tools.

Another question is, when the help or technical support should be given to the learner. Giving the help beforehand, because there are problems where learners normally get stuck, is disadvantageous, just as giving it in the time a mistake occurs. The Help on Demand pattern (Bescherer & Spannagel, 2009) describes that help should be given just in time and when the learner actively demands it.

THE REPRESENTATION ON DEMAND PATTERN

The didactical design pattern Representation on Demand gives advices to educators as well as learning tools developers to get the highest possible impact of learning. Most learning requires forms of representation such as written symbols or diagrams. For that reason, in lectures, lessons or even learning tools, multiple representations

of the same (mathematical) objects should be provided. How this problem can be solved is described in the following didactical design pattern.

<p>CHALLENGE / MOTIVATION (PROBLEM)</p>	<p>Contents, e.g. in mathematics, can be represented in many and different ways. For example, functions, in mathematical contexts, can be represented by algebraic terms, graphs, arrow-set-diagrams or a value table. E-learning tools only provide representations of the content, which fit to the context or the exercise. But learners are mainly on their own when working with e-learning tools, therefore the tool should offer more or all representations that the learner needs.</p> <p>With regard to theories of information reception, every learner should have the possibility to choose his/her best known and most comprehensible representation of the content according to their learning style. Only this way it is ensured that the learning potential is applicable.</p>
<p>FORCES</p>	<p>Offering all possible representations of a content to learners, e.g. in a lecture, costs a large amount of time. Usually, this time is not available or other contents have to be eliminated. Additionally, not all representations are needed. In many cases one or two representations are sufficient, and additional representations of the same content are boring for the learners.</p> <p>Multiple accesses to a topic are not always beneficial to all learners. In particular, the weak learners or students at the early learning stages get confused and overburdened by too many representations. Different descriptions of content require different approaches and perceptions, and therefore flexible handling of them.</p> <p>In computer tools displaying all of the representations of content would take too much working load and would take away “the view on the essential”. The GUI of a computer program would be too crowded and would move the main focus to the background. Users first have to get familiar with all of the representations, before he/she can start working or learning.</p>
<p>SOLUTION</p>	<p>In lectures one rarely has time to introduce more than two representations of a concept. One would, otherwise, lose too much time or having lectures only for showing representations. However, lecturers should provide two representation formats which are commonly used in the literature. Nonetheless, additional</p>

	<p>representations can be outsourced to bulletin boards or Learning Management Systems (LMS) and offered to students when needed. The learners can access these representations of content on demand.</p> <p>In computer learning scenarios or e-learning tools you can implement different kinds of representations. Beside the most commonly used presentation formats, the learner can enable additional representations when needed. In addition, the learner can try some of the yet “new” or unknown representations to obtain a new access to the content.</p>
RATIONALE	<p>When learning new content, several representations are often met. “Representations are any thing that stands for something else” (Schnotz, 1994). Manuals for technical products provide representations just as school content does. By connecting more representation formats of content the information level can increase (Kaput, 1989). Multiple representations can complement one another (Ainsworth, 1999) and contribute to a deeper comprehension.</p> <p>Different people need different representations concerning learning a new content (Vester, 1998; Bruner, 1968). As results of research on learning behaviours, learning contents should be presented with different representations for every type of learner. Hence, it can be ensured that the student can learn and assimilate the content optimally.</p> <p>The cognitive load-theory of Chandler and Sweller (1991) suggests that the working memory of our brain is limited. New information is first stored and processed in the working memory, and afterwards transferred to the long-term memory. Too many representations of content will overload the working memory and there is no space left for the learning content.</p>
EXAMPLES	See following section “Actual Applications providing representation on demand”.
RELATED PATTERN	Hint On Demand (Zimmermann, Herding, & Bescherer, 2013); Technology On Demand; Feedback On Demand (Bescherer & Spannagel, 2009)

Table 1: The representation on demand pattern

ACTUAL LEARNING TOOLS APPLYING REPRESENTATION ON DEMAND

Primarily, the didactical design pattern Representation on Demand was made to make learning for students easier by providing multiple representations of the contents of the lecture. For example, students can get additional materials through a learning management system (LMS) or in their weekly recitation groups, which contain a form of representation of a similar context to the lecture. Also, learning programs can be provided this way to show another perspective on the content.

Furthermore, learning tools can support the students learning if they follow the concepts of the didactical design pattern Representation on Demand. The learning tool has a chance to honour the learners' needs and demands by orientating on the patterns. Learning tools would feature more than one form of representations of the learning content but only make supplementary representations available if the students demand it.

The project SAiL-M (Semi-automatic Analysis of individual Learning-processes in Mathematics) has investigated applications on the didactical design patterns to the development and evaluation of the learning tools in teacher education in Germany from 2008 to 2012. The project has not only pointed out patterns (e.g. Bescherer & Spannagel, 2009; Bescherer, Spannagel, & Müller, 2008; Zimmermann, Herding, & Bescherer, 2013, also available on www.sail-m.de), it has applied them in an exemplary manner in the development of several learning tools and has evaluated the applicability of the patterns for them.

With the e-learning tool ColProof-M (Bescherer, Herding, Kortenkamp, Müller, & Zimmermann, 2012) students can verify simple geometric proofs, e.g. Thales' Theorem. The learner has to arrange a set of given logical propositions, and to state why each proposition is valid (fig. 2). On the one hand, the propositions are given in (mathematical) short notation as well as in plain texts. That means that those weak students can also work on the proof even if they do not feel confident with the mathematical notation. On the other hand, the students have the possibility to display the statement they have to prove via the dynamic geometry software (DGS) Cinderella (Richter-Gebert & Kortenkamp, 2012). Additionally, elements corresponding to the chosen proposition are highlighted. Every type of learner can select their way of representation when working on the task, using (short) mathematical notations or geometric manipulations.

SQUIGGLE-M (Fest, Hiob, & Hoffkamp, 2011) is a learning tool for the concepts and the properties of functions, also developed in the SAiL-M project. The software consists of several open learning laboratories. Each of them outlines a property of a function illustrated by one or more interactive forms of representations of the function. These representations also employ the DGS Cinderella. In some laboratories the function is represented as a term, a graph and a diagram (fig. 2), thus

the learner can switch between these representations and get them connected or just choose the preferred representation.

CONCLUSION

Several other didactical design patterns have been contributed within the SAIL-M project, most related to the usage of computer based learning tools. We refer to www.sail-m.de/sail-m/Patterns. Among others, Hints on Demand and Feedback on Demand are patterns that lie in the centre of the semi-automatic-analysis principles that have launched the project. They have been implemented in several learning tools which are run within a learning analytics architecture (Libbrecht et al., 2012). The Feedback on Demand pattern is implemented by a contact-teacher feature in the learning tools; feedback can be provided by the teacher because he can view the previous steps of the learning processes before responding.

This paper is a small contribution towards a greater visibility of the mathematics didactics to a broader public. The didactical design patterns we have outlined in this paper offer a simple and readable view of outcomes of the research in mathematics education. Their interpretation may support the software design process: the patterns may be embodied in user stories, their vocabulary may support the designation of software components or processes in as an interaction diagram. Examples of such

user stories can be read at http://www.sail-m.de/sail-m/MoveIt-M_en but more research is needed into generalizing the application processes.

The contribution of this paper is, at the same time, an invitation for the mathematics education community to employ the format of didactical design patterns to describe mechanisms of the learning process as it appears to be appropriate to support the software construction process.

ACKNOWLEDGEMENTS

This work has been partially funded by the Ministry of Education and Research of Germany under the SAiL-M project and by the European Union's ICT-PSP under the project OpenDiscoverySpace <http://www.opendiscoveryspace.eu/>.

NOTES

1. In this article, we replace the name problem by the name challenge, because in pedagogy there is never one problem which occurs in the same way and which can be solved in the same way all the time. Instead, when challenges occur, they have to be solved with respect to the persons and context.
2. The German idea of didactics (Didaktik) means the science of learning and teaching of a specific subject i.e. didactics of mathematics or didactics of foreign languages. This definition is more specific than the general concept of pedagogy. In German, as in many of continental Europe's language, the negative connotation of didactics is absent.

THEORY OF DIDACTICAL SITUATIONS AND INSTRUMENTAL GENESIS FOR THE DESIGN OF A CABRI ELEM BOOK

Kate Mackrell

Institute of Education, University of London, UK

Michela Maschietto

Università degli Studi di Modena e Reggio Emilia, Italy

Sophie Soury-Lavergne

Institut Français de l'Éducation, ENS Lyon, France

The contributions of two theoretical frameworks (Theory of Didactic Situations and Instrumental Genesis) to the design of a sequence of tasks in the Cabri Elem environment, where task and technology design are closely linked, are shown. Considering the potential for instrumental genesis as a theory of technology design reveals a fundamental difficulty in dealing with representations. It is hence suggested that the role of the artefact be broadened to include environments, tools, and entities.

INTRODUCTION

The first part of this paper consists of a summary of some aspects of our ICMI-22 submission on task design, in which we analyzed a particular sequence of tasks created using Cabri Elem in order to illustrate the interconnections between the affordances of the technology and the ability to implement particular didactic principles. Our choice of theoretical frameworks to use for this analysis was based on an analysis of tasks conducted as part of the Intergeo project (Trgalova, Soury-Lavergne & Jahn, 2011), which used Brousseau's theory of didactical situations (TDS) (Brousseau, 1998) together with instrumental genesis (IG) (Trouche, 2005).

In part 2 we begin a study of instrumental genesis as a theory of task/technology design with the aim of both creating greater links between TDS and IG and enabling IG to become a more effective framework for design.

PART 1: TECHNOLOGY AND TASK DESIGN

Cabri Elem technology was created to serve the needs of primary students and also to enable the creation of “applets” in order to support teachers to engage more confidently with technology (Laborde and Laborde, 2011). It is a task design environment in which “activity books” consisting of a succession of pages incorporating a sequence of tasks may be created, and a more restrictive task performance environment in which activity books may be used by teachers and students. Cabri Elem has the affordances of earlier Cabri technology for direct manipulation of geometrical objects and numbers, together with additional features such as 3D models and tools. A major difference between Cabri Elem technology and other dynamic geometry software, and also other generic technology, such as graphical calculators, CAS or spreadsheets is that the user interface of the task performance environment is under the control of

the activity book designer, who must decide which objects (tool icons, images, text, geometric figures, etc.) to arrange on initially empty pages, and who may program control actions on these objects. Creating an activity book hence involves issues of both task and technology design.

The theory of didactic situations

In this theory (Brousseau, 1998), knowledge is a property of a system constituted by a subject and a “milieu” in interaction. Learning occurs through this interaction: the subject acts within and receives feedback from the milieu. Technology, or the part of technology relevant to the mathematics concerned, may form part of the milieu, and the milieu related to a student changes as student knowledge, both technical and mathematical, develops. With a learning task in a technology environment, the author determines the possible milieu and hence the potential for learning by creating all the elements the student will deal with: the objects the student will manipulate, the possibilities of actions on these objects and the feedback provided by the environment.

Key aspects of a didactical situation are the mathematical problem and the choice of didactical variable values to set for the task, where the task involves learning objectives and the mathematical problem. The teacher assumes that achieving the task will cause the student to learn. The goal of a task, whether teacher or student determined, should be clear, together with criteria for success or failure. A task is performed by concrete and conceptual student actions, with the existence of a space of uncertainty and freedom for the subject about appropriate action and strategy. This contrasts with the common dynamic geometry tasks such as “drag this point and observe” where the student has no choice of action and is uncertain about what is relevant to observe. The task corresponds to phases of the didactical situation and is related to different values of a set of didactical variables. Didactical variables are parameters of the situation, with values that affect solution strategies. The effects can be of three kinds: (i) a change in the validity of a strategy, where a strategy that produces a correct answer with a certain value of a didactical variable will produce an incorrect answer with another value, (ii) a change in the cost of the strategy (for example counting elements one by one is efficient for a small number but much more costly for a larger number) (iii) the impossibility of using the strategy. A combination of the different didactical variable values contributes to the task definition. The learning situation is a choice of different tasks that lead the students to construct the appropriate strategy. Thus task design will consist, for a part, in identifying the didactical variables of the situation and then choosing the succession of appropriate combinations of didactical variable values.

Instrumental genesis

Learning situations involving the use of technology may be modeled as instrument-mediated activity situations (Rabardel, 2002), wherein the subject acts upon an object either directly or with the mediation of an instrument, which consists of an artefact together with the subject’s utilization schemes. Instrumental genesis (IG) is the main

aspect of instrument-mediated activity situations to be considered in the literature, and is the process by which instruments are developed from artefacts, through instrumentation (the development of utilization schemes) and instrumentalization (using the artefact for new purposes). Instrumental genesis, originating in ergonomics (Rabardel, 2002), is well established as part of the instrumental approach (Artigue, 2002) dealing with the integration of technology in the mathematics classroom, but also, being derived from the work both of Vygotsky and of Piaget (Rabardel, 2002), has links to socio-cultural approaches and, less explicitly, to constructivist approaches and constructionism.

An issue with instrument-mediated activity situations is that the “*object*” can be interpreted either as the goal of activity, consistent with the activity theory of Leontiev (Kaptelinin & Nardi, 2006, p. 59), or as the “*thing*”, not necessarily concrete, upon which the subject acts, which is the main sense in which Rabardel (2002) uses the word (e.g identifying object with wallpaper and ceiling (p. 43)). In considering learning tasks in technology environments, the *object-as-goal-of-activity* and the *object-as-thing-acted-on* are both of importance. We will refer to the former by the word *goal* and to the latter by the phrase. Note that the *object-as-thing-acted-on* will vary as the subject’s actions change; nothing is intrinsically an *object-as-thing-acted-on*. We will use the word object without italics to refer to entities that may become *objects-as-things-acted-on* during the course of the activity: this is consistent with the way it has been used in describing TDS above.

The Cabri Elem Task

We will now look at an activity book and discuss the links between this sequence of tasks and the theoretical frameworks from which the tasks were generated. The “Target” activity book addresses the French primary school level CE1 (7 year old students) and the *goal* for the teacher is for students to learn about the representation of numbers using place value notation. The idea arose from comparing counters on a scoreboard, where the value of the counter depends on its position on the board, with the way that the value of a digit depends on its position in a written number. It was designed by a team of ten researchers (including two of the authors of this paper), teacher educators and teachers involved in a French national project [1] whose purpose is to create resources for the teaching of mathematics in kindergarten and primary school.

The process of creating the activity book involved elaborating the milieu by choosing appropriate objects, possible actions and resultant feedback. In our example, the objects are essentially the scoreboard with three different regions, the counters, the target number and the score, as shown below.

Figure 1. Title page and a task page from the “Target” activity book

The actions on the objects are simple: dragging the counters, clicking on a button to reset counters and get a new target number or to get an evaluation.

Didactical variables played an important role in the task design process. Some were identified a priori, while others emerged during the design process as the authors became more aware of what aspects of the situation could be changed. Once a potential variable was identified, an analysis of the ways in which this variable could be changed produced a better understanding of the possible tasks and their consequences. It also enabled the creation of strategy feedback.

Three kinds of feedback were essential to the activity book design. Evaluation feedback is related to the achievement of the task or part of the task. Strategy feedback aims to support the student in the course of task resolution, like scaffolding (Wood et al., 1976). It is a response to the strategy used by the student. The authors needed to identify (i) configurations of objects that were typical of a strategy and hence enabled a diagnosis and (ii) new objects or actions that could be provided to help the student without changing the nature of the task. Such feedback could consist of help messages, or a graphic enlightening of contradictory elements. Another possibility is to modify the values of didactical variables in order to make the student aware of the current strategy limitations. Direct manipulation feedback is the response of the environment to student action, and may serve the function of either of the previous types of feedback.

The first page of the resultant activity book, shown in Figure 2, is a title page. In page 2, the main objects are presented. The student may interact with these objects, by dragging counters to different positions on the scoreboard and noticing how this affects the score. This is dynamically calculated: one, ten and one hundred for each counter in the green outside region, the purple intermediate region and the orange central region respectively. The aim of the page is to give time for instrumentation to both teachers and students. They can explore interactions with the objects that will constitute the milieu without the constraints of a particular task. It also contains a reset button which, when clicked, replaces counters in their initial positions, and a button which allows students to move on to the next page.

The changing score is direct manipulation feedback that shows students not only the effect of their action, but also that action on one object (moving a counter to a different region) will affect another object (the score). The score is always displayed in some pages, but displayed only after a specific sequence of actions in other pages.

On page 3 the student first receives evaluation feedback. A specific task is given: to reach a score equal to a target number, randomly generated between 1 and 999 (see Figure 1). Clicking on the reset button now in addition generates a new target number. Another new action is that the student may, in addition to comparing whether the score matches the scoreboard, click on a new button for evaluation feedback: a red frowning face if the answer is wrong, and a yellow smiling face if the answer is correct. In case of failure, the student can continue to drag counters and ask for a new evaluation: a new smiley will appear to the right of the previous one. It is important that new feedback is only generated at the student's request: otherwise a trial and error strategy not stemming from mathematical considerations could lead to success.

From page 4 to 7 students are no longer given the direct manipulation feedback of seeing the score. They hence need to take into account the value of the counters in the different regions of the scoreboard to determine the score. "Score" was identified a priori as a possible didactical variable, with two values: visible or hidden.

In page 5, the number of counters is reduced so that, if the target number is over 27, a strategy that consists in placing counters only in the green units region will fail. A strategy which takes into account that a single counter can have another value than 1, i.e. using the inside regions of the scoreboard, is necessary. Therefore, another potential didactical variable is identified: the number of available counters, with two values, $3 \times 9 = 27$ and > 27 . In page 6, the target number is a multiple of ten, between 10 and 990. As there are enough counters to either leave the green region empty or to fill it with multiples of ten counters, a change of strategy is not necessary. In page 7, however, a single counter is fixed in the green region. Therefore, new strategies are required, involving the placement of a multiple of ten counters into the units region of the scoreboard. The "fixed counter" didactical variable is identified, with four values: no fixed counters, or fixed counters in the units, tens, or hundreds region.

Page 8 contains input boxes for the student to enter the values of a counter in each region of the scoreboard. The aim of this task is to summarize the key idea of the activity book, i.e. that the value of a counter depends on the scoreboard region.

Other pages of the activity book are not devoted to student tasks. The first page is a title page showing an iconic representation of some of the main objects. Pages 9 and 10 contain commentaries for teachers, reporting the main aspect of the task, the evolution between pages, possible student strategies, and also the solution. The didactical variable analysis helps to determine what information is useful.

Trialing the Activity Book

This occurred in spring 2012 in two primary school classes: CE1 with the version presented here and CP (six year old students) with a version where the target number size was limited to 99. Teachers used the activity book as one resource for learning about place value and instrumentalized the book by printing pages to construct related paper and pencil tasks. They were enthusiastic about student engagement, mathematical reasoning and the evolution of strategies, but raised a number of issues.

It was expected that the strong metaphor between the task situation and real scoreboard situations would both provide a meaningful context and minimize the need for instrumentation. Students expected, however, that moving a counter would require tossing it in some way and were initially uncertain about how to do this using the software. Teachers also proposed that instrumentation would be enhanced by modifying page 2 to include a target number chosen either by the teacher according to the constraints of the class, or chosen by students in order to challenge each other.

Some students used the target number update not only to get a new number after finding a previous target but also, unexpectedly, to get a number they knew they were able to deal with, showing the ability to diagnose their level of expertise. This is an example of students' instrumentalization that has led the designers to modify the task in two ways: to provoke the task achievement for each target number, but also, in some pages, to enable the students to choose the target number. The possibility for students to adapt part of the task to their level of expertise is a new, generalizable element in activity book design.

The number of available counters was not a didactical variable for most CE1 students, who used each region of the scoreboard and limited the number of counters they needed to drag. Many of them did not notice the reduced number of counters on page 5 and were surprised to apparently have to solve the same task again. However, for many of the younger CP students who used only the units region of the scoreboard the number of available counters was indeed a didactical variable. The status of page 5 will hence be changed in further developments of the book. Instead of being automatically displayed to CE1 students, it will only be displayed as necessary, i.e. if the unit region is repeatedly filled with many more than 10 counters. The strategy feedback, resulting from our analysis in terms of didactic variables, will consist in reducing the number of counters to better fit the sum of digits of the target number and choosing a target number over 50.

Discussion

Both TDS and IG provide a useful lens to explore aspects of the design of the task. However, according to Prediger *et al.* (2008), there is not an integration between the two theories in our above analysis, but rather a coordination: for example student instrumentalization (described by IG) will affect solving strategies, and hence the milieu and the learning, as described by TDS. Identification of possible instrumental geneses should hence contribute to an a priori analysis in the framework of the TDS. A further issue is that technology design issues, crucial in the Cabri Elem environment, are not readily addressed within TDS.

PART 2: INSTRUMENTAL GENESIS TO DESIGN TECHNOLOGY

In this part, we will first address the potential for IG as a theory of technology design, and then show how an extension to the role of the artefact may both resolve some of the issues in its use in technology design and enable further integration with TDS.

In the field of human-computer interaction, IG is already recognised as a theory for the design of technology (Kaptelinin & Nardi, 2006). General design principles are that artefacts should be designed for efficient transformation into instruments through enabling flexible user modification and through taking into account the real needs of users while appropriating the artefact. It also explores user contribution to design, particularly through instrumentalization. An example of a design principle from Rabardel's (2002) analysis is that in a professional situation action should be easy, safe and reliable, but in a learning situation, action might be constrained in order to promote learning. This has connections to the use of constraint in TDS and is relevant in analyzing the types of action and feedback that should be enabled.

For fifteen years, IG studies concerning technology in the classroom have produced analyses of constraints and possibilities, that could provide a base for a constructive critique of the technologies being used. However, IG in mathematics education has primarily been used to describe the use of existing technologies and to contribute to the design of tasks, by using their constraints to promote student learning (e.g. Fuglestad, 2007, using spreadsheets). It was mainly used to analyze complex environments, like CAS on the TI-92 (Lagrange, 1999), where researchers had no control over the technology. Thus IG has not been much used to explore how such technology might be designed. For instance, Lagrange (2011) discusses the design of Casyopée with no connection to a framework that he was one of the first to use (Lagrange, 1999), and CERME 7 reports on the design and development of new technologies do not mention IG. An interesting exception is the current constructionist exploration of the significance of instrumentalization in design (Healy & Kynigos, 2010).

A means for connecting IG and technology design can be found in a list of artefact affordances that are perceived to enhance instrumentation: to constitute exploration spaces, mediate between formal and informal, provide executable representations, offer dynamic manipulation, evoke interplay between private and public expression and generate interdependent representations (Kynigos *et al.* 2007).

However, the model of the instrument-mediated activity situation has a major shortcoming: the *object-as-thing-acted-on* is typically taken as being independent of the instrumented artefact that mediates the action. Hence, with the focus on the development of the instrument, the *object-as-thing-acted-on* is not problematized. This is appropriate in the ergonomic context in which the model was developed, where typically the subject is construed as a worker using a machine to create or manipulate a product. It is also appropriate at the level of analysis of the teacher-as-subject, whose activity is directed toward the students rather than toward the technological artefact; the entire artefact is part of an instrument used in achieving the *goal* of facilitating student understanding of a particular concept. However, for the student-as-subject the *goal* is given by a task that involves using instruments to interact with objects that are screen representations - and both the means to perform the action and the *objects-as-things-acted-upon* are contained within the same technological artefact.

We will hence consider a technological artefact which provides representations (such as on a screen) as consisting of an environment within which are the means of action and also the objects which are acted upon. The need to consider the environment has been raised both by Hegedus *et al.* (2007) and Trouche (2005). The environment also gives feedback as to the way objects change through interaction.

There is a link to the TDS concept of milieu: milieu is the share of the environment that has a mathematical signification for the student. The counters, target and feedback within the “Target” activity book environment are clearly parts of the milieu, while the button to click to move to the next page is not. Note that the environment provided by an artefact does not constitute the entire environment within which student action takes place. Aspects of the wider environment may form part of the milieu, while aspects of the artefact environment may not be part of the milieu.

Identifying the object, the means of action and the feedback provided as distinct within IG clearly connects the theory more closely to TDS. A question is whether the unique contribution of IG, that of genesis (loosely considered as developing cognitive schemes in order to more effectively meet the goals of the activity) can usefully be applied to the artefact environment and objects as well as to potential instruments. We will address this question by again considering the “Target” activity book.

One aspect of “environmental genesis” is the ability to navigate to different parts of the environment, as required to be able to move between pages in the activity book. The title page contains text and images aimed at enabling the student to connect to a familiar activity in a real-world environment: other aspects of environmental genesis might be assimilating the environment to previously encountered environments and developing expectations as to the task and the type of actions relevant to the task.

Objects have a number of roles in the activity book, with different associated geneses. Objects which are icons (such as the reset button) provide a means of action: clicking on such an object will cause a particular action to occur. This action does not affect the icon itself. The “genesis” of such an object is instrumental. A second type of object (such as the counters) may be manipulated directly by means of an instrument (such as dragging) with feedback resulting. Objects (such as the score) cannot be manipulated directly but give feedback as to the result of actions on other objects. Interpreting such feedback requires some form of “meaning” genesis. In contrast to icons, the counters and score will not immediately be experienced as a means of action. But such as these may be linked to form both instruments for action and at the same time representations of mathematical concepts.

During the course of using the activity book, the student progressively develops the instrument of “using counters and target together to change the score” (instrumental genesis). By doing so, the student develops the understanding of the way in which the counters, target and score together constitute a means of action on the representation of a number in place value notation and also develops an understanding of the place value representation of the score.

It should also be noted that the development of the counters, target and score instrument and understanding is specifically facilitated through forcing student strategies to evolve via different types of feedback and changes in the values of different didactical variables: perhaps a consideration of feedback and didactic variables could also form a more prominent part of instrumental genesis in general.

CONCLUSION

In part 1 of this paper we have shown that two theoretical frameworks, TDS and IG, even though coordinated rather than integrated, contributed effectively to the design of a sequence of tasks in the Cabri Elem environment where task and technology design are closely related.

In part 2, it was shown that a technology such as a computer is not only an artefact to be instrumented, but consists of an environment which contains objects, such as representations, which are acted upon and can become means of action. This enables closer links with the TDS concept of milieu, containing the objects which the student will manipulate, as well as the possibilities for action on these objects, when they generate a mathematical meaning.

Consideration of the geneses of the environment and of objects has also been shown to be useful in analyzing the original task and the learning outcomes.

Representation is a major concern in the use of technology in teaching mathematics. Expanding the focus of IG from potential instruments to include objects such as mathematical representations will enable useful links to be made.

The distinction is also important for the designer. Potential instruments have design considerations such as accessibility, whereas representations have different considerations, such as their appearance, behaviour and the feedback given when they are manipulated.

In most software there is much more scope for creating and designing the representations with which students will interact than creating and designing the tools which they will use; this expansion may also be empowering for many teachers and researchers who would like to more actively engage with the design of technology in mathematics education.

INSTRUMENTAL GENESIS IN GEOGEBRA BASED BOARD GAME DESIGN

Morten Misfeldt

Aalborg University

In this paper I address the use of digital tools (GeoGebra) in primary school children's open-ended design activities. I discuss how open-ended transdisciplinary design activities can support the development of instrumented techniques, by considering the extent that pupils address mathematical knowledge in their work with GeoGebra. Furthermore, I evaluate how the pupils relate their work with GeoGebra and mathematics to fellow pupils and real life situations. The results show that pupils' consider development of board games as meaningful mathematical activity, and that they develop digital design skills with GeoGebra. Additionally, during the design phase the pupils consider the potential use of their board game by classmates.

DIGITAL TOOLS IN PRIMARY EDUCATION

The use of digital technologies, such as symbolic calculators, computer algebra systems, and dynamic geometry systems are changing teaching and learning of mathematics at different levels of the educational system. These tools lead to new didactical possibilities and create new challenges as well (Borba & Villarreal, 2005; Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010; Guin, Ruthven, & Trouche, 2005; Kaput & Balacheff, 1996). Most research on the possibilities and pitfalls with digital tools for teaching mathematics deal with students at the secondary and tertiary level, but recent research suggests dynamic geometry tools are relevant at the primary level as well (Sinclair & Moss, 2012). Furthermore, curricular development in several countries suggests that Information and Communication Technology (ICT) should be included in the primary level curriculum (for example, its use in Norway cf., Saabye, 2008). Hence, trends in research and curriculum development suggest it is relevant to investigate possibilities and problems using dynamic geometry tools in primary education.

Innovation and technological development drives a substantial part of the economy, and the application of mathematical concepts, models and methods to the developing cultural artefacts are of increasing importance. Such development calls for a more entrepreneurial attitude to the interplay between mathematics and technology in educational settings. This entrepreneurial approach has been addressed by relating education more directly to innovative disciplines (Rangnes, 2011; Shaffer, 2006), and, with the use of robotics and programming languages (Resnick, 2012).

In this paper I will investigate what kind of mathematics learning occurs in a case where pupils in primary and middle school use GeoGebra to design their own mathematical board game. The analysis is based on the instrumental approach (Guin, Ruthven, & Trouche, 2005), and focuses on three aspects of the pupils work designing games with GeoGebra: 1) The degree to which GeoGebra is appropriated to

fulfil the students own need, 2) the pupils use of GeoGebra for investigating and describing mathematical concepts, and 3) whether or not the pupils consider their work designing games as authentic in the sense that it relates to a future use situation where someone is playing the game.

GAME DESIGN AS A MATHEMATICAL ACTIVITY

The empirical basis of the current paper is a pilot project for the project *Creative Digital Mathematics*. The main project introduces GeoGebra to primary school teachers by supporting their collaborative development of digital teaching materials for open-ended work with GeoGebra. The purpose of the pilot was to develop and test a format for creating such learning materials (called ‘crushers’), as well as obtaining a better understanding of possible student learning when using such collaboratively authored material.

The pilot project has been running between March 2011 and November 2011, and been through two cycles of design and intervention (grade five = age 11 and grade three = age 9). In both cases this intervention was the first time these pupils used powerful mathematical tools in their mathematics class. In each intervention, the pupils developed their own board game using the tool GeoGebra. GeoGebra is a dynamic mathematical software that provides a close connection between symbolic manipulation, visualisation capabilities, and dynamic changeability of geometrical constructions. In this project GeoGebra was mainly used for its geometric capabilities, and less for dynamic and algebraic capabilities.

The involved teachers collaboratively authored the teaching material, while I provided additional inspiration and technical assistance. The tasks are simple instructions inviting pupils to use GeoGebra for a number of aesthetic and mathematical activities. A translation of the first and simplest scenario (“the fraction crusher” – designed for grade five.) can be found at the following url: <https://sites.google.com/site/fractioncrusher/fractions>, and the second scenario (“the multiplication crusher”, Figure 1) can be found in Danish at the following url: <https://sites.google.com/site/spilfabrikken/>.

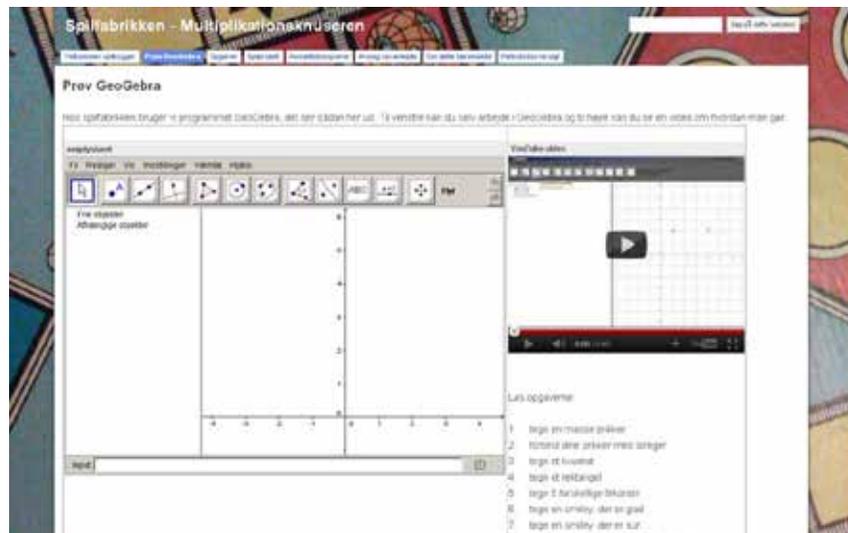

Figure 1: Screenshot from “multiplication crusher” with tasks (text field, bottom left), video-introduction (top left) and an embedded GeoGebra workspace

The board game design activity was an important part of the teaching material. The pupils made their visual layout of the board in GeoGebra, they were writing rules for the game, printing the game, and trying to play it with their classmates.

THEORETICAL FRAMEWORK

The intervention and research design is guided by two concerns with relates to different theoretical frameworks. The first concern relates to the didactical use of transdisciplinary, open-ended, and entrepreneurial practices that simulate professional activities, and the second concern deals with the use of digital mathematical tools in the classroom. The analysis that I present is based on the instrumental approach, and relates to the second concern. However, I briefly present the theoretical foundation relating to the first concern.

Shaffer has developed the concept *epistemic frame* to describe students learning in simulated work life situations. He describes an epistemic frame as a combination of values, knowledge, skills, and identity that people have when they are competent in such a work life situation (Shaffer, 2006). This suggests he views student’s activities in light of professional skills, knowledge and values, and considers students learning as a result of adopting a certain epistemic frame.

The term *microworld* was first used by Papert (1980) to describe how the Logo software could reform primary and lower secondary mathematics education. Papert’s approach was to use pupil’s creative and aesthetic work, in a computer-based environment, as means to develop their skills in mathematics. He suggests that the combination of Logo’s focus on computational procedures and geometric (aesthetic) output allows students to learn mathematics in interaction with computers when they are working to obtain their own goals. It is an important part of Papert’s approach to teaching with technology that pupils produce (digital) artifacts as part of their learning process.

Kaput and Balacheff (1996) describes a mathematical microworld as a combination of a set of primitive objects and procedures that constitutes a formal system, as well as a domain phenomenology that determines the feedback that students receive from their on-screen work. In a GeoGebra environment the primitives are for example geometrical concepts such as lines, polygons, and circles, while the domain phenomenology relates to the dynamic aspect of geometric constructions, such as the dragging mode, as well as the consistent use of multiple representations.

Students appropriation of digital tools for solving mathematical tasks has been described within the instrumental approach to mathematics education (Guin, Ruthven, & Trouche, 2005). The instrumental approach builds an activity theory framework and views computational artifacts as mediating between user and goal (Rabardel & Bourmaud, 2003); additionally, use situations is seen as continuations of

the design of the tool used. Hence, a pupil's goal directed activity is shaped by his use of a tool (this process is often referred to as *instrumentation*); simultaneously, the goal directed activity of the pupil reshapes the tool (this process is often referred to as *instrumentalization*) (Rabardel & Bourmaud, 2003, page 673). In order to relate the appropriation of tools in goal directed activities to learning of mathematics Luc Truche (in Guin, Ruthven, & Trouche, 2005, p.149), referring to Vergnaud (1996), introduces the concept of scheme as consisting of both a conceptual and a competence oriented aspect. Hence we can investigate the schemes in students' instrumented activity by studying the conceptual entities and involved competencies. However, such conceptual entities can be difficult to see empirically; hence, I will apply two more concepts from the instrumental approach. A distinction between *epistemic mediations* and *pragmatic mediations* (Guin, Ruthven, & Trouche, 2005; Rabardel & Bourmaud, 2003). Epistemic mediations relate to knowledge (Rabardel and Bourmaud uses the example of a microscope, and Lagrange (in Guin, Ruthven, & Trouche, 2005, ch. 5), refers to experimental uses of computers), and pragmatic mediations relate to action (Rabardel and Bourmaud uses the example of a hammer, Lagrange (in Guin, Ruthven, & Trouche, 2005, ch. 5) refers to the mathematical technique of "pushing buttons"). And finally I take from Rabardel and Bourmaud (p. 669) a sensitivity towards the *orientation* of the mediation. Instrumented mediations can be directed towards (a combination of) the object of an activity (the solution of a task) other subjects (classmates, the teacher) and oneself (as a reflective or heuristic process). Hence my theoretical framework consists of the concepts: *instrumental genesis* as consisting of *instrumentation and instrumentalization*, the concepts of *epistemic* and *pragmatic mediations* as well as a sensitivity towards the *orientation* of an instrumented mediation.

RESEARCH QUESTION

The research question that I address in this paper is:

How can the use of GeoGebra in pupils board game design activity, support pupils instrumental genesis with GeoGebra?

Furthermore, I will investigate *the types of mediations* that GeoGebra serves to the pupils:

To whom are these mediations directed? To fellow pupils? The teacher? or Towards fulfilling the task?

Are GeoGebra used for epistemic mediations, and what knowledge is involved?

Are GeoGebra used as a pragmatic mediation and towards what actions?

These questions are guided by two hypotheses. The *first hypothesis* suggests the nature of GeoGebra as a mathematical microworld will support pupils use of it for epistemic mediations. The *second hypothesis* infers that engaging in open-ended

design activities allows GeoGebra to act as a mediating artefact towards other subjects and not only towards solving specific tasks.

METHODS AND PROCEDURES

The methodology is design based, in the sense that we have been dedicated to an iterative approach and to the application of theoretically based analysis of learning goals and envisioned learning trajectory, as well as to the collection of empirical evidence (Cobb & Gravemeijer, 2008). The first game design scenario, the “fraction crusher”, was developed with the mathematics supervisor from the partner school in the project, and used for a weekly ICT class that this supervisor taught together with a first language teacher. The intention of this intervention was to test the idea of board game design with GeoGebra as a mathematical activity among children in grade five. The data from this intervention consisted of the students’ productions as well as reflections from the two teachers and the researcher who participated in some of the lessons.

The second scenario, the “multiplication crusher”, was developed together with the mathematics supervisor of the school and two teachers in grade three who tested the design in their classes. The intention of this intervention was to further understand the mathematical learning potentials in board game design with GeoGebra in grade three and to test if the idea of using board game design scenarios and the “crusher” format would work with different teachers. The data consisted of minutes from meetings between the teachers, supervisor, and researcher as well as field notes and pictures from the researcher’s participation in a total of 11 lessons in the two classes (six in one class and five in the other class). Both classes’ spent 10 lessons working with the scenario. Furthermore, a research student conducted four in depth interviews with pupils participating in the “fraction crusher” and four interviews with pupils participating in the “multiplication crusher” (Rosenkvist, 2012).

DATA

In both interventions the pupils worked in pairs. All the (pairs of) pupils developed a game with a mathematical theme. For some of the pupils the mathematical theme was very weak, whereas for others mathematics was used very explicit in the game. The pupils accepted designing board games as a meaningful activity. The involved teachers found the pupils engagement and developed competence with GeoGebra as positive and valuable aspects of the intervention.

The interviews (Rosenkvist, 2012, p. 142-143, here shown in translated form) show that the pupils considered their work as mathematical work. Furthermore, the interviews revealed that the work they did in the interventions were very different from the normal mathematics lessons. The pupils in general felt that the GeoGebra classes were much freer, building more on their own ideas than normal classroom activities.

The following quote describes how one pupil experienced the relation between the activities in the intervention and mathematics:

Interviewer: What mathematics have you used when you made your game. Have you used math to do that?

Pupil: Yes, we have used mathematics. We have created the shapes of the game, we needed to make some shapes.

Interviewer: What kind of shapes?

Pupil: Mostly squares, we have also made some circles and some pentagons.

Interviewer: Have you used any other mathematics than shapes?

Pupil: Yes, we have also used calculations actually, when you landed on a field, then you might need to solve a task.

This example shows the two types of reasons that the pupils gave for considering their game design work as mathematical work. First, the use of GeoGebra for creating visual layout enforced the pupils to design through mathematical shapes, and hence to connect to mathematical concepts. Second, the task of creating a mathematical game did influence the students' design related discussions. The pupil in the transcript describes calculation tasks as a natural part of their gameplay. And from looking at the resulting games it is clear that adding tasks is a typical strategy for including mathematics in the gameplay.

Figure 2, provides two examples of the pupils' game-designs. In both examples the students are working in pairs designing a mathematical board game. In the first example the pupils are working with GeoGebra and in the second the pupils are working with pencil and paper to design their game before implementing it in GeoGebra.

In the first example the two students designed a game where you move around on tiles (the small circles), in different "worlds" (the larger circles and the corners). They point to a part of the board and say, "this is a multiplication world, here you have to solve three multiplication calculations and then you can fly on to the next world – which is an addition world."

In the other example two students sketched an initial game design with pencil and paper. They explain that in their game you have to throw a dice in order to get to a field; some of these fields have a multiplication task attached. If you land on such a field (for example, 5×5), the other player should count to ten while you calculate and say the result, and if you get it right, you can go on, otherwise the turn is given to the next player.

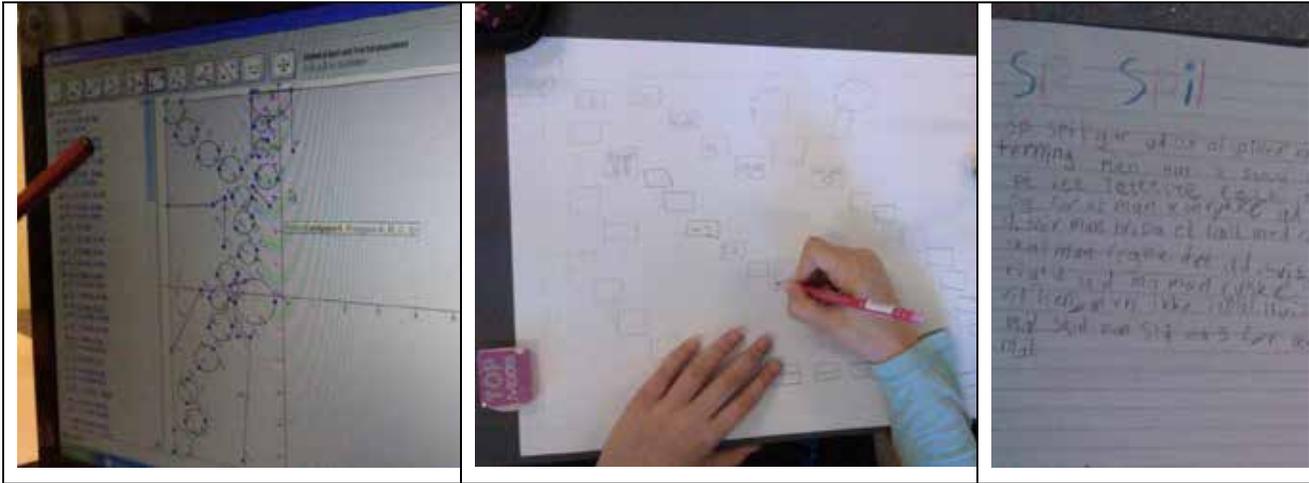

Figure 2 from left: (1) Two pupils have made a game where you move between different mathematical worlds. (2) Pencil and paper activities also play a role for some pupils; here pupils are sketching a game board, later to be drawn in GeoGebra. (3) Writing rules for the game.

This example shows another aspect of the pupils' activities; they write rules for the game. The rules written by the two pupils reads (translated from Danish): "The purpose of SP Game is that player number one throws a dice three times, and if you throw a '4' you can move to the nearest next field. When get to a field with a multiplication calculation, you should do the calculation right and then you can move all over the game board but not into the target zone. If you are next to the target zone you have to throw 5 with the dice in order to get into the target."

ANALYSIS

In this section I will analyze the presented data in order to answer the research questions.

The main research question of whether or not the board game design activity, supports instrumental genesis with GeoGebra, can easily be answered with a yes. All pupils were somehow able to use GeoGebra for something after the intervention. This observation is not entirely trivial. It could have been (but was not) the case that the software was too complicated or inappropriate to the age group or the task. However, it is contestable if the mere application of GeoGebra to a visual layout task can in any way be viewed as an activity that relates to the teaching of mathematics. Two aspects do suggest that this could be the case: First, the pupils were also doing a number of simple mathematics tasks with the software. We do not have data describing the development in the students' mathematical performance, but both observations and teachers' evaluation suggest that the pupils learned to use GeoGebra to visualise mathematical concepts and solve mathematical tasks. Hence, it is reasonable to conclude that the combination of board game design activity and mathematical tasks allowed the pupils to develop instrumented techniques with GeoGebra, which related to mathematical goals. Second, during the interviews the pupils described that the use of GeoGebra for developing the visual layout of the board game, forced them to

reflect on aspects of mathematics. The piece of transcription provided in the data section is typical in the sense that the respondent points to the mathematical shapes as the way in which the software made the pupils design work more mathematical. This can be viewed as a process of instrumentation and seen as a result of choosing to work with GeoGebra rather than any other visual layout tool.

The makers of GeoGebra most likely have not considered the type of visual layout activity that the pupils engaged in when designing games. Therefore, the pupils often needed to find ways to make GeoGebra “do” various things such as change colour, fill figures completely, and remove points for aesthetic reasons. This can be viewed as a waste of time and as an example of a bad choice of software for the task. However, these activities also give the students an experience of appropriating a tool to their own need. Such an experience with instrumentalization can be of potential value to the pupils later since it suggests that mathematical tools are open-ended and can be appropriated to different situations in school and life. As an example, some of the fifth grade students on their own initiative chose to use GeoGebra as a part of an assignment in an English class where an illustration was needed (and proudly announced it to the mathematics teacher afterwards). In that sense data suggest strong signs of the process of instrumental genesis with GeoGebra as a result of the intervention.

It is arguable to what extent we see GeoGebra used for epistemic mediations in the board game design activity. The observed dialogue among the pupils and the questions posed to the teachers, were mainly of a pragmatic nature. By wanting the software to support the development of specific visual layouts, the involved mathematical concepts were not object of investigation in their own right. They were used to get GeoGebra to do what the pupils wanted. However one aspect of the game design can be viewed as a mediation of a more epistemic nature. Many of the pupils included mathematical tasks in their game. The SP game in figure 2 shows one example. When developing these tasks some of the pupils were explicit in their discussion about what a difficult mathematics problem is, and how such problems could make their game easy or hard. However, GeoGebra was not used as a mediating artefact in these discussions.

GeoGebra was used for epistemic mediations by some pupils in some of the mathematical tasks that were done as a part of the intervention before and after the board game design. The tasks that dealt with visualizing mathematical concepts task, such as, “Make a drawing, which compares $\frac{2}{3}$ and $\frac{3}{5}$: Which fraction is the largest? Draw $\frac{1}{2}$, $\frac{5}{6}$, $\frac{2}{4}$, $\frac{6}{8}$, $\frac{1}{5}$, $\frac{3}{4}$, $\frac{4}{6}$, $\frac{2}{10}$ ” seemed to allow epistemic mediations.

When analysing the orientation of the use of GeoGebra as a mediating artefact, the situation of future use of the pupils’ game became apparent. While the pupils’ identification with professional designers was weaker than expected, their relation to the idea of their classmates playing their game was strong. In that sense the board game design did constitute mediation towards others. This mediation often did have

explicit mathematical aspects because it included posing mathematical challenges as part of the gameplay, and because the appropriation of GeoGebra to create a functioning and aesthetic layout did involved working with geometrical concepts.

CONCLUSION

In this paper I have presented an analysis of how an open-ended design activity can support instrumental genesis with GeoGebra. The analysis suggests that board game design tasks support instrumental genesis, and allows GeoGebra to mediate to fellow students. Most use of GeoGebra as a mediating artefact for board game design can be characterized as pragmatic rather than epistemic mediation. We can conclude that board game design can be a way to introduce strong tools into mathematics teaching and learning in primary school. Such activities might lead to easy adoption of GeoGebra, familiarity with appropriating GeoGebra for different tasks, a positive attitude to mathematics among the pupils, and a re-scoping of primary level mathematics in direction where the discipline play a part in constructing cultural artefacts. However the fact that the pupils in the interventions reported here, mainly used GeoGebra for pragmatic mediations, suggests that open ended design tasks might not be well suited for as the students main activity, and should be complemented with activities that addresses the use of GeoGebra for epistemic mediation.

A PROBLEM-SOLVING EXPERIMENT WITH TI-NSPIRE

Per-Eskil Persson

Malmö University, Sweden

This paper focuses on a problem-solving experiment which was an important part of a study of how students and teachers use laptops in their classes with TI-Nspire CAS technology and software, with or without concomitant use of handheld devices. Of particular interest has been the use of this technology for improving students' mathematical learning, problem-solving methods and deeper understanding of mathematics. Eight classes of students in theoretical programmes at upper secondary level in Sweden had continuous access to TI-Nspire CAS in mathematics during a whole semester. They used the software, and in some classes handhelds, during a whole course and also implemented the national test for the course on their laptops.

Keywords: CAS, classroom practice, problem-solving, TI-Nspire, upper secondary

INTRODUCTION

Calculators as well as computer software have been used for some time in mathematics classrooms. Calculators have changed over the years, from basic calculators to graphing ones, and now advanced calculators working with computer algebra systems (CAS) that include dynamic graphs and geometry. Simultaneously, computers have changed from being large and rather rare in mathematics education into smaller, mobile units (laptops) that can more easily be used in instruction. At the same time, software has changed from mathematics programs for specific tasks to ones which are much more flexible. One such software for laptops is TI-Nspire, which can be used with or without CAS. It also can be combined with handheld units in a teaching and learning system and thus is possible to use in a variety of ways.

The data for this paper comes from a larger study of how students and teachers from 8 classes used TI-Nspire technology in classroom work in a regular mathematics course at upper secondary level. In total, 133 students and 11 teachers participated in the larger study. Two of the classes took their first course (Ma A) and six of them their second course (Ma B). The mathematics in both these courses included different aspects of algebra and functions. In this paper, I focus on the results of one of the methods used in the study; a problem-solving experiment in which the students were given a longer task with several parts, of which the use of algebra and functions was central. Some examples of students' solutions and reflections after working with the tasks are presented, along with a discussion of the implications of this experiment. The complete report of the whole study is given in Persson (2011).

THEORETICAL FRAMEWORK

Balling (2003) distinguishes between the use of software and calculators as *calculating tools*, *teaching tools* and *learning tools*. When they are used mainly for facilitating calculations, they function as calculating tools. When the teacher takes advantage of their possibilities to illustrate and show important features of concepts and methods, they are used as teaching tools. Finally, when students use them for exploring mathematical objects, to discover concept features and to solve problems, they have the role of learning tools.

A tool can develop into a useful *instrument* in a learning process called instrumental genesis (Guin & Trouche, 1999), which has two closely interconnected components; *instrumentalization*, directed toward the artefact, and *instrumentation*, directed toward the subject, the student. To utilise the affordances of these processes requires time and effort from the user. He/she must develop skills for recognizing the tasks in which the instrument can be used and then must perform these tasks with the tool. For this, the user must develop instrumented action schemes that consist of a technical part and a mental part (Guin & Trouche, 1999). In the present research project, TI-Nspire CAS calculators together with the emulating computer software constitutes the physical parts of the instrumentation process. It is important to realise that an instrumentation process occurs for each of Balling's (2003) aspects of a tool. For each individual student the pace of the process also varies between these aspects.

The term *resources* is used to emphasize the variety of artefacts that can be considered: a textbook, a piece of software, a student's worksheet, a discussion, etc. (Gueudet & Trouche, 2009). A resource is never isolated; it belongs to a set of resources. When the process of genesis takes place, a document is produced. The teacher and the students build schemes about the utilization of a set of resources for the same class of situations, across a variety of contexts. This process is called *documentational genesis* and also demands time and effort from the users (Gueudet & Trouche, 2009).

The TI-Nspire environment has been studied for example by Artigue and Bardini (2009). They list why this type of technology is considered novel and special, including: its nature; its file organizing and navigation system; its dynamic connection between graphical and geometrical environments and lists/spread sheets; as well as its possibilities to create variables that can be used in any of the pages and applications within an activity. Aldon (2010) has studied the use of TI-Nspire calculators, and assumes that the calculator is both a tool allowing calculation and representation of mathematical objects but also an element of students' and teachers' sets of resources (Gueudet & Trouche, 2009). As a digital resource, these handheld calculators possess the main functions required for documentary production.

Weigand and Bichler (2009) also have researched the use of calculators, and formulated some interesting questions for research, such as:

- When working with new technologies, polarisation occurs in that some students benefit greatly from symbolic calculators use, whereas for other students, symbolic calculator (SC) use inhibits performance or even decreases performance. Are there ways to get all students convinced of the benefits of the SC?
- The reasons for non-use of the calculator are on the one hand the uncertainty of students regarding technical handling of the unit and on the other hand a lack of knowledge regarding use of the unit in a way which is appropriate for the particular problem. Is there a correlation between these two aspects?
- The responses of the students confirm that familiarity with the new tool requires a very long process of getting used to it. It is surprising that it took almost a year to establish familiarity with this tool for students to use it in an adequate way. After one year of SC use, confidence in and familiarity with the SC grow. However there is still a large group of students who experience technical difficulties when operating the SC. Will there be ways to shorten this period of adjustment? (pp. 1199-1200)

AIMS OF THE STUDY

The larger study considered the teachers' and students' perspectives as well as the cognitive and affective outcomes. In particular, the ways this technology was used according to Balling's (2003) classification and the levels of students' development in the instrumentalisation process were the focus. The two specific questions addressed in this paper are:

1. What skills in using TI-Nspire technology for problem-solving and in exploring mathematical tasks do the students show after working with it for a significant period of time?
2. What examples can be found of how the instrumental and the documentational geneses have developed during the project?

The first question was partly researched through the problem-solving experiment which is described here, and the second through comparing the results with what the students were able to perform at the beginning of the study.

Interviews with students (2 from each class) had been made near the start of the study, and the end of the study both students and teachers were given separate questionnaires. Directly after the problem-solving experiment, focus groups of students were interviewed about what they had experienced working with the different tasks. Some of their responses will be presented below along with the results from their solutions to the problems.

THE PROBLEM-SOLVING TASKS

The students were presented with problems that were constructed on three levels. The first level involved the students doing ordinary calculations and/or readings graphs. The next level involved some more complicated calculations that required the students to compare different answers and make decisions. At the final level, an exploratory task was given to the students who had to write their answers in plain text. The intention was to create tasks that were close to Balling's (2003) three types of technology use – calculating tools, teaching tools and learning tools.

The problem provided to Ma A classes was solved by the two classes taking their first course (27 students). It was called “Holiday cabin” and described three holiday companies with different fee policies:

- “Stugbyar AB” takes a basic fee of 1250 kr and then 100 kr more per day.
- “Semestersol” takes no basic fee, but has higher cost per day, 250 kr.
- “Strandängen” has a fee per week, no matter how many days you stay during the week. The price for the first week is 1500 kr, but you can stay another week for 950 kr, and after that 950 kr for each week or part thereof.

The students first calculated the fee for specific time-periods (3 days, a whole week and 10 days) and determined which alternative was the most favourable for each period of time. Then they were asked to represent the fee policies with functions and graphs, and finally they had to sort out which company had the smallest fee for all possible time-periods. They were also asked to explain why it is difficult to represent the fee policy of "Strandängen" with a function. A special interest in the study was to observe how the students handled this within the platform. This type of function, a "staircase"-function, was not specifically addressed in the syllables for the course. In the final task, the students' ability to make an overview of a rather complicated problem and to communicate this was tested.

The problem for Ma B was solved by six classes (96 students). It was called “Intersection points” and was based on two functions, one quadratic and one linear that intersected ($f_1(x) = x^2 + 1$ and $f_2(x) = 2x + 4$). These were initially provided through the Graph application. First the students were asked to read and note the points of intersection; then the constant term of the linear function was altered so that there was no intersection and they had to comment on what happened. Secondly, the students had to find out what the constant term in the linear function (instead of 4) was in order to get two, one or no intersections (see figure 1). Thirdly, they were asked to solve a non-linear system of equations that exactly reflected the graphs in the first part (the students were supposed to discover this). Finally a parameter m was introduced in the linear function for the constant term, and they were asked to solve the system again and explained why this general solution created two, one or no solutions for the system:

$$\begin{cases} x^2 - y = -1 \\ 2x - y = -m \end{cases}, \text{ with the solutions } \begin{cases} x = -\sqrt{m} + 1 \\ y = m - 2\sqrt{m} + 2 \end{cases} \text{ or } \begin{cases} x = \sqrt{m} + 1 \\ y = m + 2\sqrt{m} + 2 \end{cases}$$

The students were asked to reflect on the two general solutions and explain why these created different types of solutions for varying values of m . Using parameters in equation solving and explaining the outcomes is not a part of the syllables for the course, and a special interest in the study was to see how the students would interpret this new experience.

The screenshot shows the TI-Nspire CAS Student Software interface. On the left, a graphing window displays two intersecting lines and a parabola. The parabola is labeled $f_1(x) = x^2 + 1$ and the line is labeled $f_2(x) = 2x + 4$. The intersection points are marked with green dots. Below the graph, there are several text-based questions in Swedish, numbered 1 through 4, asking for the coordinates of the intersection points and how they change as the function $f_2(x)$ is modified. On the right, a larger text window contains the problem instructions in Swedish, starting with 'Skärningspunkter mellan grafer.' and listing three tasks related to finding intersection points for different values of m in the function $y = 2x + m$.

Figure 1: The first part of the problem for the Ma B students, concerning intersection points between graphs.

The problems, with all the instructions, were given to the students by means of the special TI-Nspire-files called tns-files. The students were asked to work individually with the tasks in the classroom. They also had to work within the given file and to present all their solutions in the Notes application within the file. The tns-files were then handed in, identified with the students' names. During the whole experiment the students' work with the task was observed by the researcher.

SOME RESULTS

The observation of the classes showed that they handled TI-Nspire as a tool in a mainly productive way, both through calculators and on laptops. Some features of the technology were new for them, but in most cases they coped very well with these. The difficulties seemed to lie more with the mathematics that the students had to engage with in the problems, and this was connected to the students' general

mathematical abilities. Their problem-solving skills with TI-Nspire were generally good, with only a few exceptions. Many also managed to give good answers to the more difficult parts of the problems. The analysis of the files that were handed in was built on an 'a priori' analysis of the mathematical structure of the problems, and on the anticipated possible ways to solve them. It also included the types of sub-tools that could be used in the problem-solving process, and the representations the students worked with. With these, students' versatility in using the technology as a tool within the three classified types could be established. In the final analysis of each student's file also 'post priori' considerations were used, such as the quality of the students' answers, how they communicated these and in what ways they showed signs of mathematical reflection. Each file was taken through the analysing process several times in order to secure the validity of the results, which are shown in table 1.

	Calculating tool	Teaching tool	Learning tool
Ma A (n = 27)	24	21	10
Ma B (n = 96)	93	83	57
Total (n = 123)	117 (95 %)	104 (85 %)	67 (54 %)

Table 1: Results of the problem-solving experiment, classified according to Balling's (2003) definitions.

The methods used by the students in the solving process varied. Some worked more with algebraic methods, using the CAS application, others more with graphic solutions. For example, some students demonstrated that they can manipulate graphs directly by dragging them up and down. Others instead worked with the equations for the functions and made changes in them, either in the entry line or in the formula inside the diagram. Some Ma B-students were familiar with the way equation systems were entered in CAS and could combine with the Solve-command. Others used more indirect methods. Most of the Ma A-students were quite unfamiliar with broken functions, especially the way these are possible to handle within TI-Nspire. These differences can be explained by the way that the teachers involved had, or rather had not, let the students work with this type of functions and objects in TI-Nspire during the study.

The problem for Ma A did not demand much use of CAS, but the one for Ma B did. Some students had specific difficulties, and asked for help with some of the practical components involved in using it. Some students also thought that the solution they got to the equation system with the parameter was 'weird' and therefore probably wrong. Data from the focus group provided further details about this:

Ma A:

Male student 1: It was things that we've done before.

Male student 2: Things that we knew, nothing particularly new.

Interviewer: Was the software well suited for working with such a problem?

Male student 2: I think CAS is great for this kind of task.

Female student: The first two questions were not so difficult, but the third one was pretty tricky. But we have had similar questions.

Interviewer: It seemed as if you were a little inexperienced at reading the intersections of the graphs?

Female/Male students: Mmm. We had not done that so much before. And it was difficult with "Strandängen" [the staircase function].

Ma B:

Female student 1: It was pretty similar to what we usually get in math books.

Female student 2: And sometimes we get ... and we will work in pairs. And you probably get one of those sent to the calculator.

Female student: We have not used this 'solve' in systems of equations before, but we have made it algebraically by hand.

Female student: The exercise was not so difficult in itself, but we do not usually do such exercises.

Interviewer: Can you mention something specific that was an obstacle for you?

Female student: Exercise 6, the penultimate. That kind of task we have not had. Like having an m besides x and y.

Nevertheless, most of the students had no substantial difficulties working with CAS. In analysing the solutions, having access to the calculations that the students had made in the Calculator application in the tns-files, gave extra information. Most students had usually not thought of deleting their mistakes, so it was possible to follow their ways to a solution. In Fig. 2, two examples of students' calculations are shown.

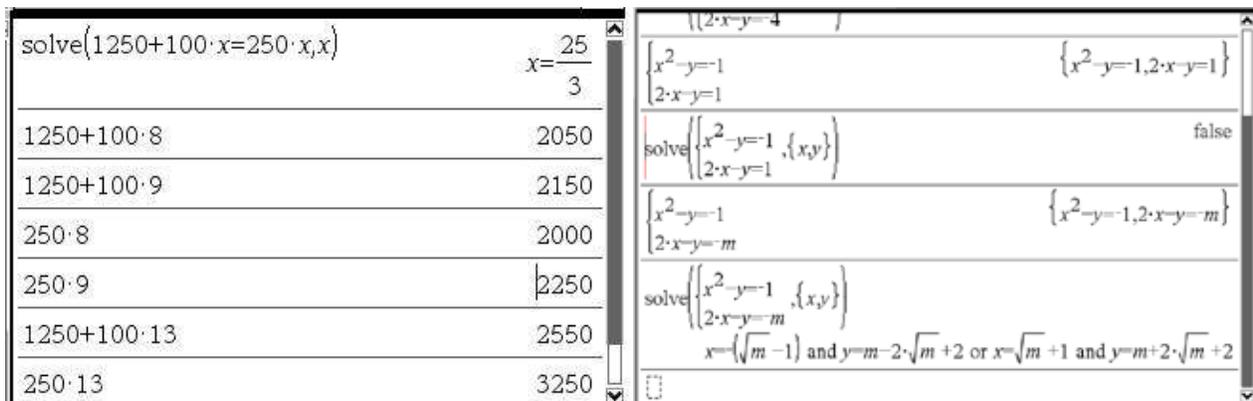

Figure 2: Excerpts from two students' tns-files (CAS application). The problem for Ma A is given on the left and for Ma B on the right.

Writing text within TI-Nspire seemed to cause problems for many students, especially those with handheld units. They were generally not used to do so within the system. The written answers to the different tasks were with a few exceptions very short, using mostly symbolic mathematical expressions and very few words (Figure 3). When asked about this, the students explained that it was hard for them to write, for example because the keyboard was small. There was, however, one exception. In one of the Ma A-classes, the method of distributing tasks through tns-files and for the students to hand in their solutions using written text was a common daily procedure. For this class, which used laptops, writing text represented no obstacles.

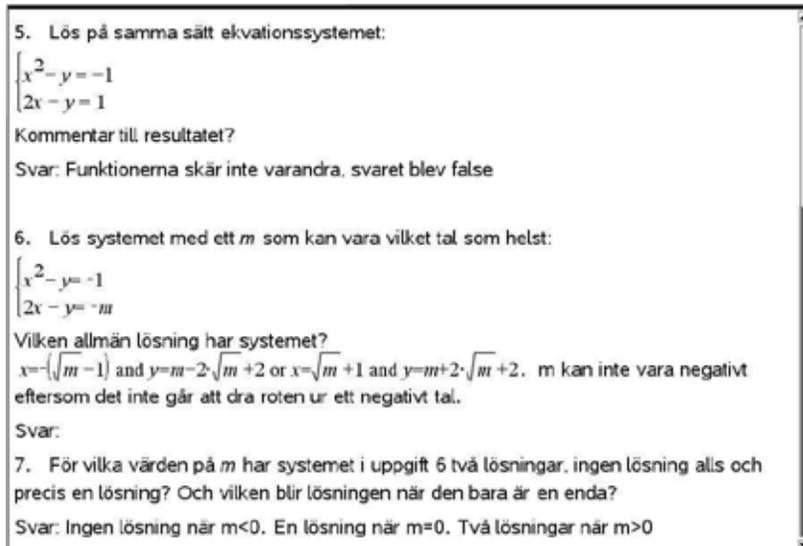

Figure 3: Example of from a Ma B student's solution with a rather short text. The translated answers to the questions are: 5. The functions do not intersect; the answer was "false". 6. $x = -(\sqrt{m} - 1)$ and $y = m - 2 \cdot \sqrt{m} + 2$ or $x = \sqrt{m} + 1$ and $y = m + 2 \cdot \sqrt{m} + 2$. m cannot be negative since you cannot take the square root of a negative number. 7. No solution when $m < 0$. One solution when $m = 0$. Two solutions when $m > 0$.

Laptops are normally not allowed when students sit the Swedish national tests, something that the students in the project had to do at least once. Thus special permission to use laptops for research purposes was applied for at the Swedish National Agency for Education. Permission was granted on two main conditions: First, any communication between students or through the Internet was forbidden, and second, unwanted files that could be used for cheating should not be accessible. Only TI-Nspire software was allowed for the students to use. These conditions were met by the teachers, and laptops were successfully used during the tests at the end of each of the courses, Ma A and Ma B. This showed that it is possible for students to complete the national tests using laptops. If this is implemented at a larger scale in the Swedish school system, solutions like turning off the Internet during the test or creating special 'test clients' for the laptops with USB memories will be possible.

DISCUSSION AND CONCLUSION

Several students had in their first interview explained how difficult and complicated TI-Nspire seemed the first time they used it. It contained so many ‘things’ that they hardly knew where to begin. However, most of the students also answered that after a short period of time, when they had become familiar with the software and/or the handhelds, it did not seem so complicated. During the project, the students’ versatility in using the technology had progressed substantially. Many of the difficulties they saw in the beginning disappeared, although even at the end of the study there still were a few students who had significant problems with the use of the software or the handhelds. In the teacher’s questionnaire 9 out of the 11 teachers answered that some students continued to have difficulties with the use of TI-Nspire, although most students had made progress in their ways of working with it. Five teachers also answered that some students enjoyed exploring TI-Nspire in order to find new functions, and they often shared what they found with other students and sometimes also with the teacher.

Teacher: But then there are some students who understand a little quicker and can show the others. So suddenly you have a whole staff that is helping. And it's good for you to have that.

The ways in which students documented their work with tasks and problems showed very little progress during the project. To some degree this was due to the fact the teachers rarely used the possibilities to work with files with many pages or pictures, and that the students did not use the Notes application in TI-Nspire to really document their work or to hand in solutions to tasks, with the exception of one class mentioned above, for which it was a fairly common procedure.

The problem-solving experiment, and the reflections made by the students in the focus groups afterward, showed that the students could use the technology as a tool in their classroom work, but also that there were possibilities for taking these uses further. If the students had been given longer problem-solving tasks to work with, they could have been able to solve even more difficult problems. They could also have become more used to writing longer answers to the tasks, where they could give more explicit arguments for why their solutions were valid and perhaps also present proofs. In the new Swedish curriculum, two *abilities* are especially emphasised; ability to make argumentations and proofs, and ability to communicate. This type of technology and software could be of assistance in the learning process.

Students in the study showed significant progress in the instrumental genesis and also to some extent the documentational one. Nevertheless, a much more complicated process is required, and the results suggest that this may take a long time, maybe several years. It is difficult to insert technology as an organic part of the resources of a "document" (Guedet & Trouche, 2009) which represent whole work sessions or lessons in mathematics. However, even here a certain development was

observed, and there were signs of a continuation of the process involving the TI-Nspire for both teachers and students, at a higher level.

Perhaps the most important result of this study is how TI-Nspire has been used in regular education in upper secondary courses. The various possibilities (Artigue & Bardini, 2009), of a technical, mathematical and conceptual nature, had the opportunity to appear in this longitudinal study taken over several months. It was interesting to be informed about the students' experiences and opinions of the technology. The technology was seen as contributing to speed and accuracy as well as providing a variety of forms of representation. It is also obvious that CAS represents a difficulty, especially for low-performing students, and simultaneously has an incredibly powerful potential in mathematics education. Only a few students are able to take full advantage of this potential, even though most of them can use CAS in a satisfactory way. Experiences from the use in the national tests were also positive. The barriers that existed for the use of laptops could be effectively eliminated, and this shows that it is possible to perform one of the sections of each national test with laptops as aids.

This paper presents research developed in the multidisciplinary PépiMep project (supported by the Ile de France region) which consists in transferring diagnosis and differentiation resources into the Sésamath platform, very much used by mathematics teachers in middle school in France. The research is based on the potentialities of the diagnosis software Pépite, which establishes an individual cognitive profile of the students in elementary algebra. We designed an interface to allow teachers to generate automatically exercises for differentiated instruction courses adapted to the learning needs of various groups of their classes.

Keywords: diagnosis and learning, differentiated instruction course in algebra, ICT, elementary algebra.

INTRODUCTION

Effectively helping students in the classroom with appropriate learning material is a difficult task for teachers. To make every student progress, they need detailed diagnosis about individual students’ learning. But, simultaneously, teachers also need to manage the whole classroom by proposing differentiated activities adapted to groups of learners with close competences in algebra or who require the same teaching strategy. Our hypothesis is that software tools can help teachers to do that. This paper addresses theme 2, “students’ learning with technologies”, of the Working Group 15 and the question of the impact of using technologies on students’ learning in the field of elementary algebra at the end of compulsory education in France (16 years).

Our research concerns the development and the use of online resources for diagnosis and differentiated learning. It takes place into the *Pépite* and *Lingot* projects, two multidisciplinary projects in Information and Communication Technology (ICT) (Delozanne et al., 2010). Based on a multidimensional analysis of algebraic activity (Grugeon, 1997), the *Pépite* software is a diagnosis tool which generates automatic multi-criteria assessments of students’ competences in school algebra (Delozanne et al., 2008). Furthermore, it also shows the principal characteristics of students’ activity in algebra which constitutes their cognitive profile.

This paper deals with the transfer and the integration of the diagnosis *Pépite* within the online databank *LaboMep*, developed by the French maths teachers association

Sésamath. The success of the *LaboMep* platform shows that such online resources may answer the teachers' needs. More precisely, from the potentialities of the diagnosis software *Pépité*, which establishes individual cognitive profiles of the students in elementary algebra, our goal is to design an interface to automatically index exercises for differentiated instruction courses in algebra adapted to the learning needs of various groups of a class. We deal with two research questions. On the mathematics education side: how can we automatically generate exercises of differentiated instruction courses proposed to students according to their diagnosis assessment about the learning objectives aimed at by the teacher? On the collaborative work side: how can the collaborative work between IT specialists and mathematics education researchers make possible the creation of an operational model to index a database of exercises that allows you to automatically produce differentiated instruction courses adapted to students' learning needs?

After clarifying some theoretical and methodological elements for the diagnosis, we will discuss the design of differentiated instruction courses. We will explain the principle of indexing exercises databases that allow for the automatic generation of instruction courses.

THEORETICAL AND METHODOLOGICAL ELEMENTS

Assessment

Diagnosis assessment is an important part of teachers' practice. But this term is used to refer to several types of assessment. Ketterlin-Geller and Yavonoff (2009) identify two practices within diagnosis assessment that use students' procedures and errors as their basis for analysis: analyses of students' answers to specialized tests and cognitive diagnosis assessments using standardized and psychometric models. In both cases, the objective is a local study of students' misconceptions. The diagnosis developed through the *Lingot* project aims to create an overall and multidimensional analysis of students' knowledge and abilities in algebra. It doesn't use psychometric models. It doesn't rely more on the conversation theory whose fundamental idea is that learning occurs through conversations between students which serve to make knowledge explicit (Scott, 2001). It is based on an epistemological study of elementary algebra from cognitive and anthropological approaches which enables to predict students' learning needs.

Assessment and epistemological references

Grugeon (1997) defined a model of algebraic competence at the end of compulsory education. It is the foundation of an epistemological reference to guide the design of an appropriate diagnosis (Artigue et al., 2001). This approach allows one to categorize tasks for a diagnosis test – problems of generalisation and proof, traditional arithmetical problems, problems where algebra appears as a modelling

tool, algebraic and functional problems – and to structure the different aspects of the multidimensional analysis of students' activities in elementary algebra.

From an international synthesis of research related to the learning of algebra, Kieran (2007) proposed the GTG model of conceptualizing algebraic activities which differentiates three complementary aspects: (1) *Generative activities* involve the production of expressions or formulas or equations or identities (2) *Transformational activities* involve the usage of transformational rules (factorizing, expansion of products, rules for solving equations and inequalities, etc.) (3) *Global/meta-level activities* involve the mobilization and usage of the algebraic tool to solve different types of problems (modeling, generalization, proof). This model will be used to create student working groups composed of students who can work on tasks with the same learning goals.

Assessment and Anthropological Theory of the Didactic (ATD)

The ATD theory takes into account the institutional context of education. It proposes an epistemological model in which all human activity is to accomplish a task of some type of tasks with some technique. The technology of the technique is intended to provide justification for the technique and the praxeology's theory supposed to justify the technology itself. We postulate that assessment should locate the personal relationship of students with algebra in solving diagnosis tasks, and technological elements involved in their resolution compared to those expected, taking into account praxeologies to teach (curriculum, textbooks) and praxeologies taught (teaching practice) (Chevallard, 1999). The linking between epistemological references and institutional praxeologies in algebra allows one to identify learning needs often ignored by the institution and often implicit in the curriculum and textbooks (Bosch, Fonseca, & Gascon, 2004, Castela, 2008). For Chevallard, “assessment will focus, by practical necessity, for each student, on a sample of all types of tasks constituting referred praxeological organizations”. Diagnosis tasks are thus characterized by a type of tasks, the complexity of algebraic objects involved, the level of involvement of tasks in the resolution.

Collaborative Work

An iterative process between educational researchers, computer scientists, teachers and trainers allowed to design and to test prototypes that implement the diagnosis in order to favor its evolution. There were four iterations to test the different versions of diagnosis (El-Kechai et al., 2011). Our research approach is a bottom-up one informed by educational theory and field studies. In previous work (iteration 1), we started from a paper and pencil diagnosis tool grounded on mathematical educational research and empirical studies. Then (iteration 2), we automated it in a first prototype, also called *Pépité*, and tested by dozens of teachers and hundreds of students in different school settings (Delozanne et al., 2005). In more recent work (iteration 3), we implemented *Pépinère* that generalizes the first tool to create a

framework for authoring similar diagnosis tools, offering configurable parameters and options (Delozanne et al., 2008). From 2010 (iteration 4), with the *PépiMep* project, we deployed the *Pépité* diagnosis tool on the *LaboMep* platform developed by *Sésamath*. For each iteration, we started with a didactic model and we defined a formal model for the implementation of the prototype. After, we tested prototypes with teachers or researchers (coding exercises, terms used in the interface to present the assessment, interface to index exercises) and, if necessary, we proposed an evolution of the prototype. Particularly, we tested the interface with teachers to adapt the terms used (type of tasks) with those of the curriculum and the mathematics textbooks (abilities).

FROM ASSESSMENT TO DIFFERENTIATED INSTRUCTION COURSES

We now present the principal elements taken into account to define the differentiated instruction courses related to the diagnosis assessment which supports the indexation of exercises.

Assessment and stereotypes

The diagnosis test included in the *Pépité* software implemented in *LaboMep* is composed of 10 diagnosis tasks (27 items), which cover the range of algebraic problems: exercises involving creating mathematical representations of problems in order to generalize, create a model, complete a proof, or write an appropriate equation (7 items); exercises covering techniques of algebraic calculation (8 items); or exercises in recognition (19 items). The diagnosis tasks may be multiple-choice or open-ended questions (Grugeon et al., 2012). Responses to the items of the diagnosis test are not only analyzed in terms of success or failure and mistakes. They are also coded according to properties and justifications used repeatedly, corresponding to institutionally recognized technologies, which highlight a coherent set of techniques (correct or incorrect) built within the institution. The main characteristics of a student's cognitive profile, considered relatively to its grade level, are automatically calculated by *Pépité* through a transversal analysis that codes the student's responses to the 10 diagnosis tasks.

The above model provides a description of the cognitive profile of each student. However, teachers need to use the diagnosis to form groups of students who require the same proposals of teaching to manage the whole classroom. We defined cognitive stereotypes in elementary algebra (Delozanne et al., 2010) as sets of equivalent profiles that can be considered close enough that students can work with the same learning goal tasks. The stereotypes model has three components: Usage of Algebra for solving problems (coded UA); flexibility in translating different types of representations (geometric figures, graphical representations, natural language) into algebraic expressions and vice versa (coded TA); ability and adaptability in the various uses of algebraic calculations (coded CA). For each of the three components, a scale with different technological levels has been identified, along with appropriate

criteria for each level (Delozanne et al., 2005). For example, for the component CA, we distinguished three technological levels according to the types of manipulation and associated justifications: (CA level 1) expected technology taking into account the structure of expressions and their equivalence, (CA level 2) technology only supported on syntax rules, (CA level 3) technology without operational priority leading to concatenation rules and false linearity.

Stereotypes and differentiated instruction course

We postulate that stereotype definition in elementary algebra is an important step in comparison with categories (good, average, low) commonly used by teachers regarding the design and the implementation of differentiation strategies. Indeed, *PépiMep* automatically calculates groups of students who have close profiles in algebra (Grugeon et al., 2012). Figure 1 shows (on the left) the cognitive profile of a 9th grade student with (on the right) the groups of students (A strong, B or C weak).

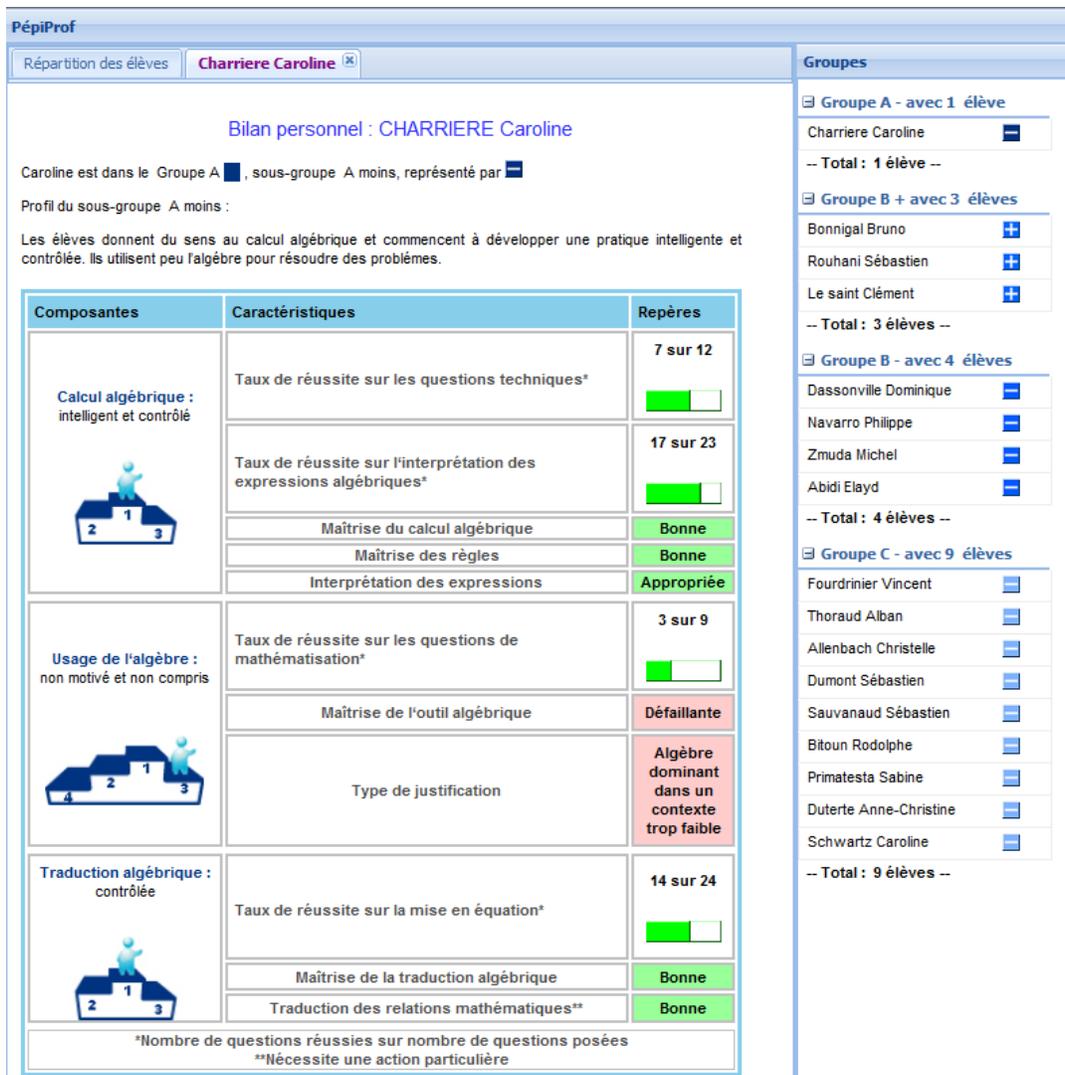

Figure 1: Personal cognitive profile of a 9th grade student

This model allows one to identify target learning needs often ignored by the institution. These are essential common learning issues to work on by all the students of a classroom: particularly, the need to produce general expressions to prove the equivalence of calculation programs, the dialectic numerical / algebraic, the double aspect, procedural / structural of an object, the equivalence of expressions (Pilet 2012). To define a differentiated instruction course, for a given mathematical topic, at a grade level, at a time of education, we identified issues of common learning for the class (presented above), i.e., the tasks involving types of tasks to work on. For a given purpose, we assigned tasks to each group, tasks that are associated with variables related to the technological level involved. An example of a differentiated instruction course is proposed in Grugeon (2012). This design also supports the indexation of the exercise database.

INDEXATION OF AN EXERCISE DATABASE

Our indexation is structured by ability. This choice can appear in opposition with the ATD theory briefly exposed previously, which organizes assessment like the personal relationship of students with algebra in solving diagnosis tasks, and technological elements involved in their resolution. This choice from the necessity to take into account the teachers' working context: they need exercises categorized by abilities in accordance with the curriculum and the mathematics textbooks. An ability refers to a kind of task to which is attached the targeted technology.

We developed an interface for the data capture relative to every exercise of the exercise database. For each exercise, our indexation takes into account: identification parameters (identifying in the database, title of the exercise), the school level for which the exercise is intended (7th grade, 8th grade, 9th grade and 10th grade), the targeted ability (detailed below), the mathematical domain concerned (literal calculation), the input and output objects (numbers, algebraic expressions...), the task complexity (detailed below), the input and output frame.

More precisely, the targeted ability is composed of three elements: relevant components (UA, TA or CA), main abilities for each component (see table 1), elementary abilities for each main ability (see table 2). The task complexity, as in a PISA test, is related to the level of proposed tasks described by Castela (2008): EL elementary, CS conceptual simple, MP multi-step, CX complex.

Component UA

- 0 – Conjecture that calculation programs or literal expressions are equal or not
- 1 – Produce a literal expression or formula for solving a problem
- 2 – Put in equation and solve a problem
- 3 – Demonstrate (calculation rules, properties, identities) or prove that calculation programs or literal expressions are equal or not
- 4 – Expressing a variable according to a formula in another

Component TA

- 5 – Translate a literal expression, a calculation program...
- 6 – Graph a function (linear or affine), the solutions of inequality or of system
- 7 – Recognize an object
- 8 – Read on a graph

Component CA

- 9 – Calculate
- 10 – Test equality
- 11 – Reduce a simple polynomial expression
- 12 – Develop a simple polynomial expression
- 13 - Factorize a simple polynomial expression
- 14 – Know the remarkable identities
- 15 – Transform equalities
- 16 – Recognize the structure
- 17 – Choose the most suitable form of an expression
- 18 – Solve equality or inequality or system
- 19 – Determine the algebraic expression of a linear or affine function from data
- 20 – Identify a calculation error and correct

Table 1: Main abilities table

9 – Calculate	9.1 calculate the value of a literal expression giving numerical values in the variables
	9.2 calculate a numerical expression using a rewrite
	9.3 calculate a numerical expression by using the remarkable identities
	9.4 calculate the result of a calculation program for a number
	9.5 calculate the value of a literal expression knowing a numerical relation linking variables
	9.6 calculate the image of a number by a function

Table 2: Elementary abilities for main ability 9 “calculate”

For example, exercise 578 (see figure 2) is relevant for component CA.

<p style="text-align: center;">- Calculer astucieusement</p> <p>Question N°1 : Calcule astucieusement.</p> <p>Je te conseille l'utilisation d'un brouillon pour effectuer les calculs intermédiaires.</p> <p>$A = 37 \times 101$</p> <p>A = <input type="text"/></p> <p style="text-align: center;">Valider</p>	<p>Calculate cleverly.</p> <p>I recommend you the use of a draft to make the intermediate calculations.</p> <p style="color: #008000;">Validate</p>
---	---

Figure 2: Exercise 578

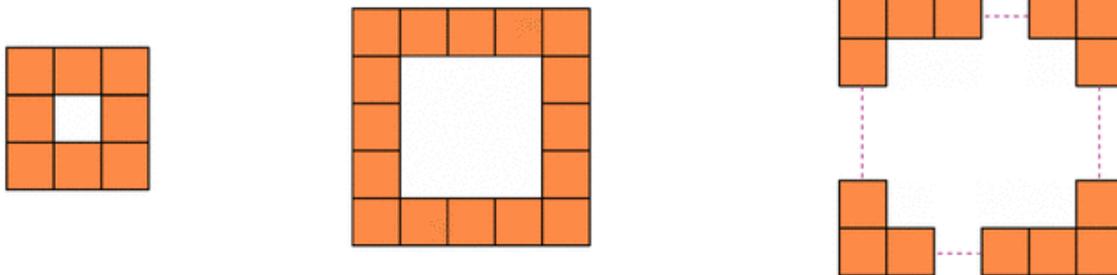

Three main abilities are worked on in this exercise: 9 calculate (9.2 calculate a numerical expression using a rewrite (*for example* $101=100+1$)); 12 develop a simple polynomial expression (12.1 develop an expression by using the simple distributivity of multiplication on addition). In particular, the question of rewriting the expression convened in ability 9.2, is not often highlighted in class to carry out the calculation successfully.

EXAMPLE OF AUTOMATIC GENERATION OF A DIFFERENTIATED INSTRUCTION COURSE

The automatic generation of differentiated courses uses *LaboMep* exercises indexed by main abilities and elementary abilities. From the common learning objective selected by the teacher for all students in the class, a list of abilities to work on is proposed. In addition, the teacher proposes differentiated exercises for each group by changing the choice of expressions. We now present an instruction course having for objective: working on the role of algebra to solve generalization problems. This instruction course includes hidden abilities corresponding to learning needs ignored by the institution. More precisely, if generalization problems are discussed in classes, equivalence of calculation programs is very merely worked on.

This course leans on the lined square exercise (see figure 3), a generalization problem, which aims at proving that several calculation programs are equivalent. This problem consists in establishing algebraic expressions that allow one to calculate the number of square units colored with a figure built on the model below, whatever the number of square on the side of the white square is. Writing algebraic expressions involves operating priorities. It includes several steps: determine the number of squares colored for definite values of the number of squares on the side of the square, produce a mathematical expression, compare calculation programs.

We consider a white square surrounded with square units colored as on figures below. The objective is to calculate the number of square units colored.

- 1) If the white square has a side of 3 units, calculate the number of square units colored.
- 2) Same question with the white square with sides 4 units.
- 3) Same question with the white square with sides 8 units.
- 4) Same question with the white square with sides 100 units. Hint: indicate first the calculation process.
- 5) Write a formula which gives the number of square units colored according to the number of square units on the side of the white square.
- 6) Compare your formula with those found by your classmates. What can you say about these formulae?

Figure 3: The lined square exercise

In this exercise, algebraic expressions are objects with which you can make calculations replacing letters with numbers. How can we show that two calculation programs are equivalent? This is possible using calculation rules that guarantee the equivalence of calculation programs that translate expressions. Algebraic identities,

such as simple distributivity, that students need to admit, are involved. The articulation between the procedural and structural aspects of an expression is merely worked on in the classroom. In this course, with the objective “prove that calculation programs are equivalent”, students in groups B and C (weak), worked with the lined square exercise which led to first degree expressions: $N=4n+4$; $N=4(n+1)$; $N=2(n+2)+2n$; $N=4(n+2)-4$. The students in group A (strong) worked with a similar problem but with a different pattern which involves a second degree expression.

CONCLUSION [1] AND FUTURE WORK

We have described research on a diagnosis tool, developed in research laboratories, and transferred to *LaboMep*, an ICT platform mainly used by mathematics teachers at the secondary school level. The diagnosis tool allows the teacher to have, for every student, a very precise profile concerning their skills in elementary algebra. By using an indexation of the considered domain, the software automatically proposes, to groups of students identified as having close profiles, a differentiated instruction course adapted to their competences. This automation of the differentiated instruction course was made possible by the crossed successive enrichment of the underlying didactic model and the IT model. Using ICT leads to rethink the teaching resources not only for the students but also for the teachers, so two Ph. D. projects are in progress: Julia Pilet's thesis is interested in profits for the students while the thesis of Soraya Bedja studies the integration of the software in teaching practices.

Future research consists in honing the role played by abilities. What is the impact of the choice of abilities on the course automatically proposed by the software? What is the role played by abilities in the link with the activity of the teacher in his classroom? Can we specify an ontology in elementary algebra? Indeed, this question of the choice of abilities is at the heart of the problem of the transferability of our research in a wider mathematical domain, even in other mathematical domains.

RESULTS ON THE FUNCTION CONCEPT OF LOWER ACHIEVING STUDENTS USING HANDHELD CAS-CALCULATORS IN A LONG-TERM STUDY

Michael Rieß and Gilbert Greefrath

University of Münster, Germany

Long-term studies of students using a handheld CAS-calculator encourage the hope that the gain of lower achieving students using digital tools is above average. The German CASI-project takes advantage of the three-tier school system to examine and evaluate the long-term use of handheld CAS-Calculators by lower achieving students in the 9th and 10th grade. The findings presented in this paper result from the pre-, post- and follow-up-test for the teaching unit on quadratic functions and equations which took place at the beginning, after approximately one third and near the end of 10th grade. The students had one year of experience using digital tools and already passed the tests on linear functions and equation systems. The theoretical framework for the test-design was based on the translation skills for functions.

INTRODUCTION

Functions have always been in the focus of research when the impact of digital tools on students' school achievements is evaluated. Especially, because

the graphing calculator affords the user both the ability to create equations, tables, and graphs quickly and the facility to move among the representations rapidly (Hollar & Norwood, 1999)

there is special expectation of a handheld CAS-calculator to particularly foster the translation skills (Swan, 1982) between different representations of functions [1] in students. Indeed, Weigand and Bichler (2010) were able to observe an improvement regarding the transition between graph and equation of a function. Therefore this subject matter is an obvious starting point when focusing on the results of lower achieving students using digital tools.

O'Callaghan found

that the CIA [2] students had a better knowledge of the individual components of modelling, interpreting, and translating as well as a better overall understanding of the function concept

supporting the idea of digital tools helping students to work on realistic problems involving functions. Schwarz and Hershkowitz (1999) claim

that more students learning functions in the interactive environment than in a traditional environment had rich function concept images

and the result of a meta-study by Barzel (2012) states that conceptual knowledge in general can be fostered by using CAS. This is why there seems to be reason to hope,

the students would be able to do better when working on examination tasks involving situational descriptions of functions and the corresponding translation skills.

The German School System

The findings presented in this paper emerged from a project which took place in Germany and in order to judge the meaning of the results some knowledge about the German school system is necessary. There are four types of secondary schools in Germany which all start at 5th grade.

The students who show the highest academic abilities in primary school attend the Gymnasium. They graduate to the German Abitur in 12th grade [3], which is comparable to British A-levels and qualifies to study at a university.

The students showing moderate academic abilities in primary school attend the Realschule until 10th grade and then choose between switching to the Gymnasium or other higher schools to get the Abitur or a similar degree and starting an apprenticeship. If they do switch to the Gymnasium they graduate after 13 years of schooling since they have to start over in 10th grade.

The students who show low academic abilities in primary school attend the Hauptschule and most likely start an apprenticeship after 10th grade even though there are possibilities to switch schools and reach Abitur or similar degrees like the students who attended the Realschule. In some German states Hauptschule and Realschule are replaced by a new integrated type of school.

The fourth type of school is the Gesamtschule which incorporates all of the three other types. This is done by differentiation through special courses on various academic levels in each grade; some students learning at Gymnasium-level others at Hauptschule-level.

Studies concerning Students using handheld CAS-Calculators

Some empirical studies regarding the usage of handheld CAS-calculators have been undertaken in Germany. In particular the CALIMERO-Project in Lower Saxony and the M³-Project in Bavaria have to be named. In Lower Saxony handheld CAS-calculators are employed at the Gymnasium from Grades 7 to 10 and up to the Abitur. The Bavarian study examined students at the end of the Gymnasium (Bruder & Ingelmann, 2009, Weigand & Bichler, 2010).

Since all major empirical studies on the usage of digital tools in mathematics education in Germany took place at the Gymnasium it is particularly interesting to note that while the overall test results of students using handheld CAS-calculators did at least not fall off in quality (Barzel, 2005) especially lower achieving students benefited from the use of handheld CAS-Calculators. The increase in school achievement found in this group of students was significantly greater than the average (Ingelmann & Bruder, 2007). Weigand and Bichler (2010) stated, that in the 10th grade particularly the weaker students may benefit from the use of digital tools.

International meta-studies even observe substantially better test results in classes using digital tools (Hembree & Dessart, 1986, Ellington, 2003). The results presented in the introduction give reason that the research on even lower-achieving students should be started with a closer look on their performance when solving tasks involving functions and translation skills.

THE CASI-PROJECT

The Project Computer Algebra Systems used in lower secondary schools (CASI-Project) examines the long-term use of handheld CAS-calculators at the German Realschule respectively courses of the same academic level at the Gesamtschule. It aims to support, test, and examine the use of digital tools by students taught in 9th and 10th grade. The focus lies on the design and evaluation of educational concepts for the use of handheld CAS-calculators regarding these by definition lower achieving students. Another part of the project concept is the aim to encourage and support diverse use of digital tools. The intent is to use the handheld CAS-calculator not only to calculate, but also to experiment, visualise, create algebraic models and control (Greefrath 2010).

The examined sample of students consists of 10 project classes at 5 different schools in North Rhine-Westphalia with 10 different project teachers who voluntarily signed up for the project without knowing which students they would be teaching except for their grade for obvious reasons. These 10 project classes were then equipped with ClassPad handheld CAS-Calculators. Aside from the loose planning of certain special content areas described below at project teacher meetings and the possibility to call for technical support at any time, the researchers did not influence the teachers' work. Additionally, the six parallel classes at the same schools serve as a control group.

Test Design

To achieve the goals specified in the paragraph above, several different research methods have been employed. During the 2 year duration of the project five content areas (linear functions and equation systems, Pythagoras theorem, circles and the number p , quadratic functions and equations, mathematic growth) were chosen to be of special interest and the educational concept of these is jointly planned and carried out by all project teachers and includes the definition of competencies the students are meant to achieve with digital tools, but also without any technological support at all. These study projects have been monitored using a pre-/post-test design as well as qualitative studies on mathematical test tasks and solution structure or strategies. Aside from mathematical tests, questionnaires on the students' opinions about digital tools and mathematics as well as journals of the teachers about the actual usage of the ClassPad during the lessons are evaluated.

The results presented in this paper follow from tests on the teaching unit on quadratic functions and focus on the quantitative side. These tests consist of two parts: While

working on the first part of the test, students are not allowed to use any technology at all. The first task in this part is to solve two equations or equation systems to test for the algebraic abilities of the student. The second task involves drawing graphs of linear or quadratic functions and reading off zeroes or intersection points.

Question 1. A candle burns down. At this moment, it's height is 9 cm high. It shortens by one half cm per 10 minutes. Draw a graph into the given coordinate system that represents this situation.

Question 2. A stone drops from the top of a tower which is 12 m high. After one half second, it has dropped 1.25 m, after one second 5 m and after one and a half second 11.25 m. Draw a graph which assigns the elapsed time to the height of the falling stone over the ground.

Figure 1: Example questions for translation from situation to graph

After finishing this part, the students have to pass the first part to the teacher in order to be allowed to use their calculators to solve the following examination questions. In fact most of these tasks are solvable with little to no technological help and would be classified “tasks with optional or neutral benefit from digital tools” according to the scale introduced by Brown (2003). The questions have been designed to be parallel in matters of the involved translation skills after Swan (1982) – some examples for the translation between situation and graph from different tests being shown in fig. 1. As already pointed out in the introduction, emphasis was placed on the translation skills including situations. The translation skills taken into account for the tests’ design are underlined in table 1.

From \ To	Situations	Tables of data	Graphs	Algebraic Expressions
Situations	---	measuring	<u>sketching</u>	descriptive modelling
Tables of data	reading	---	plotting	fitting
Graphs	<u>interpreting</u>	<u>reading off</u>	---	curve fitting
Algebraic Expressions	<u>formula recognition</u>	<u>tabulating or computing</u>	<u>curve sketching</u>	---

Table 1: Translation Skills (Swan 1982)

The lack of translations to algebraic equations takes the low age and therefore low experience in designing algebraic expressions into account. Also there might be some “curve fitting” and “fitting” involved due to the tabular design of the corresponding task (see fig. 3 for details), but the other direction is most likely the more important one.

The tests take place in the second year of the CASI-project. At that time the students attend the 10th grade and the chosen teaching unit takes place several weeks after the summer break. The pre-test occurs right before the subject changes to quadratic functions and with no repetition happening before. The post-test concludes the teaching unit and can optionally also be taken as written exam. The follow-up-test takes place about 3 month after the post-test without any kind of repetition.

RESULTS

The results presented in this chapter have to be sorted by the number of students involved in the analysis. This unfortunate premise is due to organizational problems with not-returning tests and decreasing numbers when working only with those students participating in all tests.

Therefore the results will be given in two sub-paragraphs. The first one will work with the data of all students who participated in all three tests to give the main impression and provide results in the most rigid form available. This first sub-paragraph will show an effect visible in the follow-up-test. To include the results of a substantially higher percentage of project and control group students and focus on the findings regarding the follow-up-test the second one will include the students who participated in the follow-up-test and at least one test of the other two. The combination of the results in this form proved to be the most accurate way to look at a larger number of students without flawing the results and also provide the more rigid view on the data.

Results of the students participating in all tests

The overall results of this group of students are presented in fig. 2. The analysis includes the data of 131 project students and 67 students of the control group.

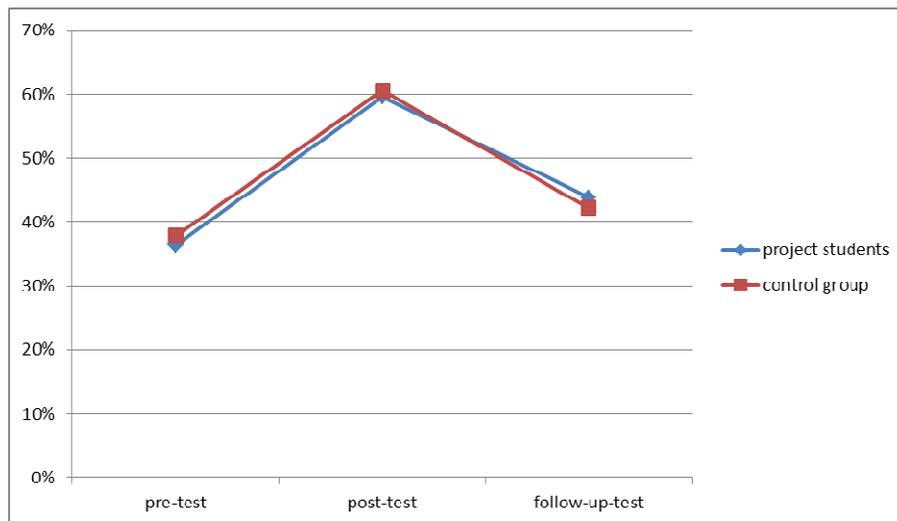

Figure 2: Test-results of the students participating in all three tests

The results show the usual peak at the post-test and then fall off until they reach a slightly higher level in the follow-up-test than in the pre-test. The small differences between the two groups are not significant, but the fact that the project students achieved a higher test-result only in the follow-up-test qualifies for a more detailed analysis of this special part. When analysing the examination questions on their own, mostly there are no significant differences between the project students and the control group. The few significant distinctions between these groups are summarised in the next paragraph.

There is a significant better result of the control group in the pre-test examination question on the translation from graph to situational description, $t(89.3)=-2.779$, $p<.02$, $r=-0.226$. In the post-test the control group has a significantly better outcome in an examination question where they had to read off values of graphs and insert modified versions of these graphs into the same coordinate system, $t(169)=-2.297$, $p<.03$, $r=-0.161$. The follow-up-test shows a significant advantage of the project students over the control group when solving tasks similar to the one shown in fig 3, $t(196)=2.453$, $p<.02$, $r=0.171$.

Question 7. Draw lines to connect the graphs with the corresponding algebraic expression. Then draw lines to connect the functional equation with the intersection of the graph defined by this equation and the corresponding axis intercept.

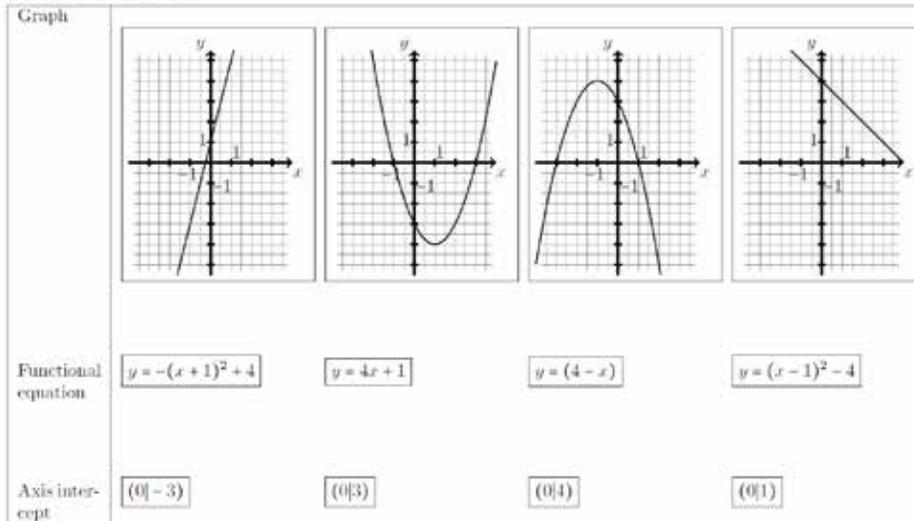

Figure 3: Example examination question from the follow-up-test

There are multiple translations involved in this examination question. Mainly they involve the translations between graphs and algebraic equations and algebraic equations and points on the graph which can be considered as a certain type of tables of data.

Results from the students participating in the follow-up-test

The results of the students who participated in both tests give ground to the assumption that a closer look on the results of the follow-up-test can lead to a better insight. So in this paragraph the students' total is defined by the participation in the follow-up-test and at least one of the other two tests in order to eliminate students for whom there is no data on their long-term progress. Admittedly, this way of looking at the data may be problematic when it comes to generalizations, but the strong tendencies found in the results of these larger set of students give some hint of explanation for the larger picture. Participation in either pre- or post-test and the follow-up-test still guarantees the students' participation over more than 3 month such that the students are familiar with project material and the way the parallel tasks are designed. Fig. 4 summarises the results in the three tests.

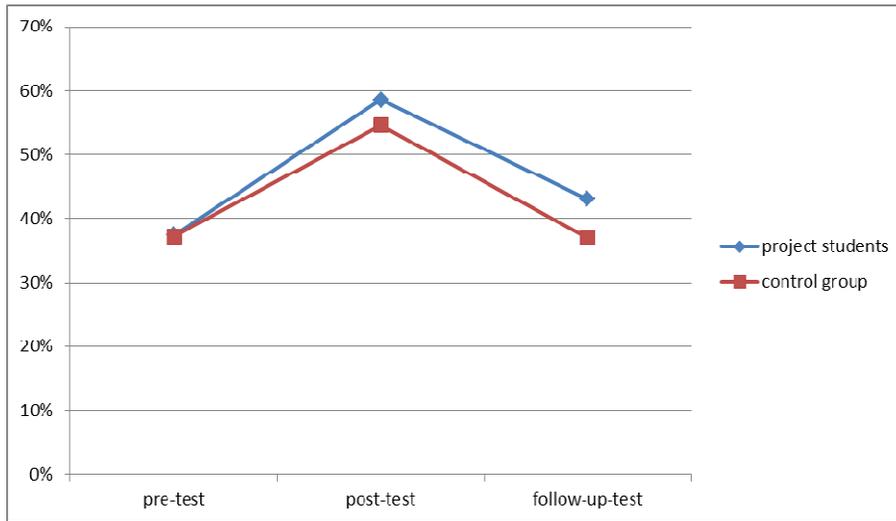

Figure 4: Results of the students participating in the follow-up-test

Both curves show the usual peak at the post-test's result, but there are more differences between the groups. The project students and the control group already differ significantly in the post-test and that gap gets bigger in the follow-up-test. The exact data is summarised in table 2.

	pre-test	post-test	follow-up-test
N (project stud.)	161	152	182
N (control group)	74	90	97
M (project stud.)	37%	59%	43%
M (control group)	37%	55%	37%
SD (project stud.)	15%	13%	13%
SD (control group)	16%	16%	15%
t	0.104	2.029	3.48
df	233	240	277
p	.917	.05	.001
r	0.007	0.137	0.204

Table 2: T-test results and effect size for the three tests

So there is no statistical difference at all in the pre-test, a significant difference with a small effect size in the post-test and a highly significant advantage of the project students over the control group with a small to medium effect size in the follow-up-test. A closer look at the examination questions yields the following findings [4].

The significant advantage of the control group when translating from the graph of a function to a situational description in the pre-test is still visible, $t(233)=2.294$, $p<.03$, $r=-0.155$, but equals out in the post-test and turns to a significantly better

result of the project students in the follow-up-test, $t(277)=2.11$, $p<.4$, $r=0.125$. Additionally, there are still better results of the project students visible when solving examination questions of the type shown in fig. 3 with small effect sizes in the pre- and post-test and medium effect size in the follow-up-test. Table 3 contains the t-tests' results on these tasks.

	M (PS)	M (CG)	SD (PS)	SD (CG)	t	df	p	r
pre-test	59%	48%	34%	36%	2.294	233	.03	0.148
post-test	91%	84%	19%	23%	2.342	157	.02	0.157
follow-up-test	83%	64%	26%	33%	4.917	161	.001	0.301

Table 3: Results of the examination question of the type shown in fig. 2 [5].

The project students' results ($M=45\%$, $SD=32\%$) also significantly exceed the control group's results ($M=35\%$, $SD=30\%$) in the post-test examination questions on drawing functions and reading off values without any technological help, $t(240)=2.699$, $p<.01$, $r=0.171$. Furthermore there is a difference (project students: $M=54\%$, $SD=30\%$; control group: $M=46\%$, $SD=29\%$) in solving equations by hand, $t(277)=2.073$, $p<.04$, $r=0.123$.

CONCLUSION

Conducting a project on the use of handheld CAS-calculators at the German Realschule takes the research on digital tools to a class of students which has not been taken into account yet. It has been unclear whether students of this age and academic ability would be able to profit from technology at all or perhaps even be hindered by the necessity to learn the language of the computer in addition to everything else. The lessons during the CASI-project were conducted by interested but otherwise normal teachers and in spite of advice and planning of certain aspects for the special subject matters mentioned above in no way influenced by the researchers.

The results presented in this article regarding the students who participated in all three tests show that the test results under these circumstances do at least not fall off in comparison to the control group. This is valid for the tasks where all technical help was allowed as well as for the examination questions which have to be solved by hand only. The few significant differences regarding isolated examination questions cannot be observed in the corresponding parallel tasks and – with the exception of the task displayed in fig. 3 – do not show a tendency to be anything more than statistical artefacts.

Widening the pool of students by allowing students with only two written tests – as long as the follow-up-test is included – to enter the analysis leads to some additional findings. The project students achieve significantly higher results in the post- and follow-up-test with the effect even increasing towards the later test showing that

mathematical knowledge is conserved better. This might partly be caused by the fact that the project students were able to use the handheld CAS-calculator to help solving the task shown in fig. 3 which is an examination question where there can really be a benefit from the use of digital tools. Even if this is the case it still shows the students' ability to autonomously use the digital tool for their benefit showing their progress in terms of instrumental genesis. (Guin & Trouche, 1999)

The results of the examination questions addressing translation skills which include translations with situational descriptions do not show any special advantage or disadvantage of either group of students. So there is no evidence to the assumption the richer conceptual images of the project students have an effect on these isolated tasks.

Additionally the abilities of the students to work on certain basic tasks without any technological help are at least conserved. This result was reached only by agreeing on certain competencies which are to be achieved and without the teachers being mandated by the project supervisors to train these skills with any special program. Students from the project group even had the tendency to be a bit better than the control group in these tasks.

A direct comparison of the effects observed in this project with the effects found by Ingelmann and Bruder (2007) as well as Weigand and Bichler (2010) examining students at the Gymnasium is difficult due to the different ages of the students and other ways the subject matters are addressed. The lack of improvement in examination questions addressing translation skills might be caused by the less abstract way of teaching functions at the Realschule. The main tendency of the results however is in line with the findings of these previous studies.

NOTES

1. See table 1 for a complete list of these translation skills as presented in (Swan, 1982).
2. CIA = Computer-Intensive Algebra
3. This has been subject to change quite often during the past ten years. Abitur after 12th grade is true for North Rhine-Westphalia at the moment, but this might also be about to change.
4. Only results with significance $p < .05$ are reported.
5. PS=project students, CG=control group.

PUPILS' ROLE AND TYPES OF TASKS IN ONE-TO-ONE COMPUTING IN MATHEMATICS TEACHING

Jarmila Robová*, Nad'a Vondrová**

Charles University in Prague, *Fac. of Math. and Physics, **Fac. of Education

The article presents results of data analysis of 11 mathematics lessons (29 episodes) in which netbooks were used within one-to-one computing. The research questions were: What are the types of tasks solved with the support of netbooks? What is the pupil's role in teaching in which netbooks are used (i.e., how does he/she participate in the solution to the task using the netbook)? The result of a qualitative analysis is a classification of tasks and of pupils' participation in the solution to tasks using netbooks (examples are provided). It was found out that traditional school types of tasks and a pupil as a user prevail. It ties with other research and points to the key role of developing teachers' technological pedagogical content knowledge.

Keywords: netbooks, one-to-one computing, pupils' participation, task types

INTRODUCTION

A relatively new type of ICT integration in the teaching of mathematics consists of so called digital classes in which each pupil has his/her own laptop with installed electronic textbooks and software for school and home work (one-to-one computing). Classrooms are equipped with a data projector, an interactive whiteboard and internet connection. There are many studies about one-to-one computing, however, only a few concern mathematics. For example, a study in a Grade 3 class has shown that the integration of laptops into the learning environment is a very complex process and that the key role is played by teachers (Neumajer, 2009). While the teachers welcomed the possibility of work with laptops at the beginning, they more or less impeded their more intensive use. Teachers mostly used laptops as a substitute for usual didactic means within a traditional frame of teaching. Similarly, Billington (2011) who investigated the teaching of mathematics at an upper secondary school concludes that laptops were mostly used within the curriculum – tasks could have been solved without them. Laptops strengthened the existing way of teaching rather than changed the teaching practice.

Freiman et al. (2011) describe a project in which Grade 7 and 8 pupils were equipped with laptops for use in several subjects. The authors conclude that “laptops in and of themselves may not automatically lead to better results on standardized tests, but rather create opportunities to enrich learning with more open-ended, constructive, collaborative, reflective, and cognitively complex learning tasks” (p. 136).

Vondrová & Jančařík (2012) analysed videorecordings of 15 primary mathematics lessons with netbooks and conclude that the episodes with netbooks concerned mostly revision and practice tasks and the teachers' explaining a new topic; tasks

leading to the creation of knowledge by pupils were not seen. The “netbooks were utilised for activities easily accomplished without them (such as reading a text)” and “except for the applets in which pupils can work at their own pace and can often choose the level of difficulty, we did not witness any incidence of the teacher asking pupils to work on different tasks”.

One-to-one computing is a rare phenomenon in the Czech Republic. There are local projects with netbooks which usually aim to enhance pupils’ motivation, engagement in mathematics and knowledge, to promote individualized learning, to use more complex tasks which are difficult without ICT, etc. This paper aims to see, broadly speaking, whether this expectation has been fulfilled in one such project.

THEORETICAL BACKGROUND

It is generally accepted that the key elements influencing pupils’ learning of mathematics are tasks and the way the tasks are implemented in lessons – in this implementation, an active role of the pupil in developing knowledge is usually stressed. For example, the concept of *opportunity to learn*, seen as the single most important predictor of pupils’ achievement, is defined as the “circumstances that allow students to engage in and spend time on academic tasks such as working on problems, exploring situations and gathering data, listening to explanations, reading texts, or conjecturing and justifying” (Kilpatrick et al., 2001, p. 333). It includes “considerations of students’ entry knowledge, the nature and purpose of the tasks and activities, the likelihood of engagement, and so on” (Hiebert & Grouws, 2007, p. 379). Hiebert & Grouws (2007) point out that the teaching in which pupils are *struggling* with important mathematics leads to conceptual understanding. By struggling, they mean pupils expending “effort to make sense of mathematics, to figure something out that is not immediately apparent”.

The tasks and their implementation is a matter of concern in teaching with PCs, too:

This is where the big issue is – the nature of the tasks and how they are presented to students. These should enable the student to experiment, investigate and draw conclusions. Students need to have access to the computer in the class, and the activities proposed should be rich enough and appropriate to promote learning. (Amado, 2011, p. 2150)

Thus, we are concerned with the way tasks are implemented in the digital class and what role pupils have in their solutions using netbooks – how engaged they are, if they struggle in the above sense or if they are invited to struggle at all.

There is a growing body of research focused on the types of mathematical tasks set in digital classes. One typology concerns the role technology plays in the solutions to the tasks (Böhm et al., 2004):

- Tasks where the use of PC and software is of little or no help; the solution is faster by-hand.

- Tasks that are solved faster or even trivialised by PC.
- Tasks testing the ability of using PC and software.
- Tasks starting from traditional ones that are extended to PC tasks (e.g., by including formal parameters or using realistic data).
- Tasks difficult, time consuming or impossible to solve without PC.

Another classification is introduced by Assude (2007): tasks of developing: instrumental knowledge and skills, mathematical knowledge and skills, relations between instrumental and mathematical knowledge and skills.

Zbiek et al. (2007) distinguish *technical* and *conceptual mathematical activity*. The former includes geometric construction and measurement, numerical computation, algebraic manipulation, graphing, translation between notation systems, solving equations, creating diagrams, etc. The latter involves understanding, communicating, and using mathematical connections, structures, and relationships, defining, conjecturing, generalizing, abstracting, etc. The authors stress that neither type of activity is more mathematically meaningful than the other.

Another point of view Zbiek et al. (2007) introduce is that of the initiator and maintainer of the activity. They distinguish *exploratory* and *expressive activity*. In the former, pupils are asked a question and given a procedure to carry out by the teacher; e.g., one type is “guided” exploration in which the pupils’ goal is to produce a predetermined result chosen by the teacher. In the latter type of activity, pupils decide which procedures to use; they attempt to answer a question of their choosing with their choice of process. Zbiek et al. stress that “the nature of students’ exploratory or expressive work depends on both the task and the activity” (p. 1181).

Finally, Zbiek et al. (2007) distinguish between the use of technology as *amplifier* and as *reorganiser*. The former accepts the goals of the current curriculum and works to achieve those goals better. The latter changes the goals of the curriculum by replacing some things, adding others, and reordering still others.

To sum up, PCs seem to provide a good opportunity to use rich activities in such a way that pupils struggle in the above sense; however, this opportunity is not often fulfilled. For example, the meta-study *The ICT Impact Report* (European Schoolnet, 2006) states: “Teachers’ use of ICT for communication with and between pupils is still in its infancy. ICT is underexploited to create learning environments where students are more actively engaged in the creation of knowledge rather than just being passive consumers.” Laborde et al. (2006), investigating the use of Cabri, conclude that teachers use it within a static geometric curriculum, i.e., traditional content and methods, and thus do not make use of educational powers of ICT.

Research has shown that also within ICT teaching, the key role of what is learned and how it is done is played by the teacher (e.g., Lozano & Trigueros, 2007; Fuglestad, 2005). Mishra & Koehler (2006) develop a model of the types of

knowledge teachers need to teach with ICT. *Technology Knowledge* involves the skills required to operate technologies. *Technological Content Knowledge* is knowledge about the relationship between technology and content, i.e., how the content can be changed by the application of technology. *Technological Pedagogical Knowledge* is “knowledge of the existence, components, and capabilities of various technologies as they are used in teaching and learning settings, and conversely, knowing how teaching might change as the result of using particular technologies”. The central part of the model is *Technological Pedagogical Content Knowledge* (TPCK) which “requires an understanding of the representation of concepts using technologies; pedagogical techniques that use technologies in constructive ways to teach content; knowledge of what makes concepts difficult or easy to learn and how technology can help redress some of the problems that students face; knowledge of students’ prior knowledge and theories of epistemology; and knowledge of how technologies can be used to build on existing knowledge and to develop new epistemologies or strengthen old ones” (p. 1029).

METHODOLOGY

In 2009, Grade 6 pupils in three classes in different schools were given one netbook each. The netbooks have been used in several subjects including Mathematics. The three teachers whose lessons are available to us were young, with several years of teaching experience. A publishing house that publishes, among other, e-textbooks provided them with training which concerned Technology Knowledge (use of netbooks, the interactive whiteboard, pupils’ and teacher’s software), Technological Content Knowledge (the use of the e-textbook, which includes multimedia, hyperlinks, e-tasks, etc., the use of dynamic geometry software, etc.) and partly Technological Pedagogical Knowledge (the way pupils can work in pairs, at the interactive whiteboard, how to create and use interactive exercises on the board and in netbooks). The teachers were rather passive during the training; they were not required to prepare digital material themselves. In other words, they were expected to develop their TPCK themselves while they were teaching. At the beginning of the project, their attitude towards ICT was positive and they believed in its potential benefits for pupils’ learning.

We have revisited some of the data used for Vondrová and Jančařík’s work (2012) and analysed them from the following perspectives:

1. What are the types of tasks which are solved with the support of netbooks?
2. What is the pupil’s role when netbooks are used in the lessons? How does he/she participate in the solution to the task with the help of the netbook?

The data consist of videorecordings of 11 lessons, in which netbooks have been used, in Grade 6 and 7 in three schools. The videorecordings were made by us or the school provided us with them. The camera was typically static, at the back of the classroom recording the whole class and zooming in on the teacher and/or the

whiteboard from time to time. The videorecordings come from different parts of the school year. At the time of our first observations, the teachers had had about half a year experience with using netbooks in their teaching. Thus, they already possessed necessary Technical Knowledge and their pupils had had an opportunity to familiarize themselves with netbooks and the software.

The analysis of videorecordings started by distinguishing episodes with netbooks, spanning 5 to 20 minutes (Tab. 1). By an episode, we mean a part of the lesson where one task was used. The episodes were coded in terms of the type of task used and the pupil's engagement in the solution to the task with the help of the netbook. We were only concerned with the part of the solution to the task which was done on the netbook, mostly disregarding the paper and pencil solution in the coding stage.

The coding was based on the above types of tasks but we also used techniques of grounded theory for coding the new emerging aspects of the tasks and their implementation. The coding stage resulted in a list of codes which were organised into two categories – pupils' engagement and types of tasks.

	Grade 6		Grade 7	
	No. of lessons	No. of episodes	No. of lessons	No. of episodes
Teacher X	3	3 / 5 / 3	1	4
Teacher Y	2	1 / 1	2	4 / 3
Teacher Z	2	3 / 1	1	1

Table 1: Number of lessons and episodes with netbooks

As an example, we will present the coding of three episodes from one lesson.

Grade 6, February 2011. Topic: Practical use of volume and surface area of cuboids.

Episode 1: Each pupil works on the internet with an interactive exercise to practise calculations of volumes and surface areas of cuboids. First, they recognise cuboids from among different solids which have sizes of edges given and record calculated volumes and surface areas in the box provided on the screen. The applet returns an immediate feedback whether the result is correct or not.

Codes: *Pupil as a user* (works according to instructions on the website), *Traditional school task* (distinguishing solids, calculating volume and surface area), *Technical mathematical activity* (numerical computations), *Netbook as amplifier*.

Episode 2: The teacher has sent the pupils a Smart Notebook presentation by wifi, the same presentation is open on the interactive whiteboard. The presentation shows some objects such as a house, a box, an aquarium and the pupils' task is to assign a box with dimensions $a \times b \times c$ to each object; that is, they should estimate measures of real objects and use units such as dm, cm and m correctly.

Codes: *Pupil as a user* (works according to instructions), *Traditional school task* (estimation of lengths, understanding units of measures), *Computer oriented tasks*

(namely, practising the dragging tool in Smart Notebook), *Technical mathematical activity* (estimation of dimensions, conversion of units), *Netbook as amplifier*.

Episode 3: Another task in the same presentation as used in Episode 2. The task is to calculate the height of water in an aquarium if we know its volume and dimensions of the bottom. The teacher asks the pupils to use the pen in Smart Notebook and colour edges of the bottom base in the pre-drawn cuboid. Next, they should use the blue pen to record the water level – lower than the upper base of the cuboid. Some pupils cannot do it and wait for the teacher to do it on the interactive whiteboard. The cuboid is then moved away and the pupils draw vertical edges according to the teacher’s instructions and they can “see” a cuboid again: “a cuboid of water in the aquarium”. The teacher refers to an analogical task solved earlier.

Codes: *Pupil as a user* (works according to the instruction), *Traditional school task* (calculating the height of the cuboid when the volume and measures of the base are given), *Computer oriented tasks* (namely, practising tools – coloured pens, deleting an object), partially *Mixed task* – the solution is supported by visualization (a picture of an aquarium – water “makes” a cuboid), *Technical mathematics activity* (calculation of volume), *Netbook as amplifier* (visualization of ordinary mathematics situation), *Exploratory activity* (“finding” a cuboid of water).

RESULTS

The first focus of the analysis was on the **types of tasks** which were assigned in the lessons and for which netbooks were used. Two aspects were followed: whether tasks were used for the development of knowledge and skills connected to mastering the netbook or mathematics, and whether the netbook with its software helped in the solution to tasks. Four types of tasks have been distinguished:

- *traditional school tasks* which can easily be solved without netbooks and for which netbooks only replaced paper-and-pencil techniques; netbooks were of no help or they only made the solution faster (13 episodes); the episodes included technical mathematical activities and 3 also conceptual activities; 1 episode included an exploratory activity.
- *computer oriented tasks* which developed computer skills through solving a mathematical task (8 episodes); all included technical mathematical activity and 3 conceptual activity, too; 1 episode was with an exploratory activity.
- *mixed tasks* for which the netbook and its software markedly simplified the solution or made it more illustrative, understandable (2 episodes); both consisted of a technical mathematical activity and exploratory activity, one included a conceptual activity, too.

To make the classification complete, we add one more type of tasks which did not occur in our data and which we, in view with Böhm et al. (2004), see as an ultimate goal of teaching with ICT:

- *computer tasks* which would not be possible without the support of the netbook; e.g., the algorithm is too complicated, the task is too numerically demanding, ICT mediates new insights, etc.

Thirteen episodes were not classified in terms of the task used. In 11, the pupils only read an assignment on the screen and did not use the netbook for the solution at all, in 1 episode they searched the internet for the word election and in another one they used the notebook for sending the teacher their homework by wifi. We did not witness any use of netbooks as reorganisers neither any expressive activity.

When solving tasks using netbooks, naturally the technical aspect plays a role. Thus it is quite difficult to distinguish which type of tasks of the proposed classification was the primary one, whether mathematically or technologically oriented. For example, in one of the episodes pupils look for the least common multiple of three different numbers. They use tables in Excel in which they are to generate multiples of the numbers. The teacher soon finds out that some pupils fill in the numbers manually and thus goes on to explain the solution in terms of technology – how to make the table with multiples in Excel automatically. The same problem with Excel appeared in the same class a month before this episode. A potentially *computer task* has become a *computer oriented task*.

The second focus of the analysis was on the type of **pupils' participation in the solution to the task with the help of netbooks**. The following classification has emerged in our data:

- *a pupil as a spectator* – pupils only observed what was going on on the screen of the netbook, they did not use any tools available on the netbooks (1 episode).
- *a pupil as a user* – pupils worked on the netbook according to the instructions of the teacher or the textbook, e.g., substituted numbers into the teacher's Smart Notebook presentation, used a mathematical applet for practising algorithms; we could say that the netbook substituted a worksheet with tasks to be completed but with a possibility of feedback (11 episodes); all episodes concerned technical mathematical activities and the netbook was used as an amplifier; one episode was classified as an exploratory activity and one as a conceptual activity.
- *a pupil as an active user* – the netbook was an important tool for pupils, they used its software to look for solutions to the task by, e.g., geometric constructions, computations, graphing, etc., or by looking for relationships, experimenting and making deductions; the netbook helped in the solution (4 episodes); the task was set by the teacher, who, through the choice of software, usually determined the solving methods, but the pupils could also make their own choices; all episodes were coded as amplifiers, 2 episodes as exploratory activities and 3 combined technical mathematical and conceptual activities.

Again, to make the classification complete, we suggest one more type of pupils' role which was not observed in our data:

- *a pupil as an independent and active user* – pupils use the netbook purposely to develop their knowledge and skills; if we paraphrase Amado (2011), the netbook is their partner in the learning process, “enabling [them] to achieve some knowledge that would otherwise be very difficult or even impossible”.

In most episodes, the pupils' work was controlled by the teacher; the pupils were rather passive even in potentially computer tasks. Let us consider one episode in which the centre of the circumscribed circle of a triangle is looked for. The task is as follows: *Find a place for a feed depot for deer which has the same distance from three given feeding-racks which make a triangle.* Several pupils make some drawings in their paper exercise books and hypothesise that it will be a centre of gravity. One pupil makes drawings on the interactive whiteboard. The teacher says that it is not the solution and asks the pupil at the board to refute the hypothesis by using a figure in GeoGebra. The other pupils are asked to “try yourselves that it will not work”. The teacher's instruction is not clear, only several pupils work with netbooks, the others look at the board. The hypothesis is refuted. The teacher goes on by giving hints towards the intersection of axes of sides. He asks one pupil to show this solution on a whiteboard using construction tools. The other pupils should make constructions into their exercise books. The situation potentially *a pupil as an active user* was classified as *a pupil as a user* as the teacher took a complete control of the situation. A potentially *mixed task* has become a *traditional school task*.

There were only 4 incidents of *a pupil as an active user*. For example, in one of them the teacher sent his own Smart Notebook presentation to the pupils in which a task was given: *There is an ancient temple with columns 60 m apart. We are to relocate the columns so that they are 45 m apart. Which ones will stay?* There is a picture of the temple and columns which can be moved by dragging. The teacher asks pupils to model the situation. The pupils experiment, relocate the columns by dragging, use the ruler on the screen to measure the distances. Not all the pupils find the solution. The teacher uses the problem to formulate the concept of the least common multiple. Smart Notebook was used for the visualisation of a mathematical situation and for experimentation and discovery of the solution. The teacher prepared a task and appropriate means of visualisation which determined the pupils' solving method.

CONCLUSIONS

The above four types of tasks can be combined with the four pupils' roles; e.g., we saw examples of computer oriented tasks in which pupils were users and active users. In a few episodes, types of tasks from the literature review were seen. Let us now take into account the *potential* of the four types of pupils' role. Netbooks as amplifiers as well as technical mathematical and conceptual activities could occur in all types of roles except for *the pupil as a spectator*. An expressive and exploratory

activity as well as netbooks as reorganisers will not occur in *the pupil as a spectator* either as the netbook is not used for the solution at all. An exploratory activity can appear in *the pupil as a user* and *active user* while the expressive activity would tie with *the pupil as an active user* and *an independent and active user*. More data is needed in order to see whether this potential is fulfilled in practice.

The prevalence of traditional tasks and the pupil's role as a user or spectator in the episodes with netbooks tie with results of some other research focusing on ICT tools (Billington, 2011, Neumajer, 2009, European Schoolnet, 2006). It can be caused by the teacher's fear of sudden teaching situations (Laborde et al., 2006) or it can be related to the teacher's little experience with the ICT tools (6 to 12 months in our study). Providing teachers with technology and technological content knowledge is not enough. It is necessary that their TPCCK is explicitly developed (see, e.g., Mishra & Koehler, 2006). The teachers go through stages. For example, when integrating Cabri in their teaching, the teachers begin with the use of software as a visual amplifier and end with creating tasks for pupils in which software plays a key role (Laborde, 2001). It might be interesting to see how the situation will develop for our teachers – pupils in the observed classes are in Grade 9 now and thus we plan to analyse data from Grades 8 and 9 to see whether there has been any progress.

Our study has its limitation in terms of data. More lessons or a series of lessons of one teacher would be desirable. The episodes were analysed in terms of an “average” pupil's participation. Borders between types of tasks and between types of pupils' participation in their implementation are somewhat blurred. Still, we believe that the study uncovered some aspects of real teaching with netbooks if teachers are not supported in professional training.

USING DYNAMIC SOFTWARE TO FOSTER PROSPECTIVE TEACHERS' PROBLEM SOLVING INQUIRY

Manuel Santos-Trigo

Matías Camacho-Machín

Mar Moreno-Moreno

Cinvestav-IPN-México, University of La Laguna-Spain, University of Lleida-Spain

Mathematical tasks are essential components that help prospective and practicing teachers to develop mathematics and didactic knowledge. What type of reasoning do problem solvers exhibit when they use a dynamic software to solve textbook tasks? We document the extent to which the use of the tool can offer prospective and in-service teachers the opportunity to construct and explore a task's dynamic model where visual, empirical, and geometric reasoning complement and enhance formal approaches. As a result of our research, it was evident that the use of the tool not only offers novel ways to think of the tasks, but also the nature of routine problems can be transformed into a series of nonroutine activities.

INTRODUCTION

There is an agreement within the mathematics education community that the use of technology plays an important role in the students' learning of mathematics. However, the extent to which teachers develop the experiences that allow them to recognize and incorporate the systematic use of the tools in their actual practice continues to be an important theme in teachers education programs. One way for prospective and inservice teachers to know the potential associated with the use of a particular tool is to get them involved in problem solving experiences that enhance the use of tools in solving and discussing routine problems found in regular textbooks (Santos-Trigo & Camacho-Machín, 2009). This report is part of a wider research project that aims to analyse and document the use of digital technology in teachers' education and students' learning. One essential phase during the development of the project was to characterize what ways of reasoning and problem solving strategies emerge when routine tasks such as those that appear in textbooks are approached through the use of digital tools. In this study, we focus on analyzing the problem solving sessions developed within a community formed by mathematicians, mathematics educators and prospective and inservice high school teachers which aimed to characterize and discuss ways of thinking and reasoning that the members of the community showed while using a dynamic software (Geogebra) to represent, explore, and solve a set of textbook problems. Thus, the research question that oriented our inquiry was:

- *What are the features of mathematical thinking and reasoning that distinguish and characterize a problem solving approach that relies on the use of dynamic software to deal with routine or textbook problems?*

CONCEPTUAL FRAMEWORK

To frame the study, we rely on two complementary approaches to explain ways for people to take decisions during the development of their activities. Specifically, we recognize that teachers take several important decisions during the preparation and development of their mathematical lessons. These involve the selection of problems, the introduction and discussions of concepts, ways to organize or structure learning activities, and ways to answer, evaluate, and orient students' comments and participation. How do teachers support and carry out choices and decisions related to the framing and development of a mathematical lesson? Schoenfeld (2011) proposes a framework to characterize and interpret ways in which people in different domains engage in, and develop practices associated with such domains or fields. "People's decisions making in well practiced, knowledge-intensive domains can be fully characterized as a function of their orientations, resources, and goals" (p. 182). Kahneman (2011) identifies two systems to account for or explain the decisions and choices that people make: "System 1 operates automatically and quickly, with little or no effort and no sense of voluntary control. System 2 allocates attention to the effortful mental activities that demand it, including complex computations. The operations of System 2 are often associated with the subjective experience of agency, choice, and concentration (p. 20). Hence, it becomes important to document the extent to which the opportunities and experiences that prospective teachers develop and encounter in their education influence the development of their practices.

How do teachers construct their orientations or beliefs, dispositions, values and resources to pursue their goals? What is the role of teachers' initial preparation and experience to achieve instructional goals that are consistent with mathematical practices? To delve into the teachers' preparation implies to recognize that there are multiple paths or programs and traditions to prepare prospective teachers around the world. In some cases, the faculty of education and the mathematics departments jointly share the responsibility to prepare teachers; other programs are part of a school or institutions (*e.g.*, normal schools) dedicated exclusively to the education of teachers. Both teaching models recognize the need and importance for teachers to develop the mathematical and didactic knowledge that can help them structure and implement proper conditions for students to learn the subject. However, the extent to which prospective and in-service teachers develop the mathematical sophistication needed to structure a sound mathematical lesson, to interpret students' ideas or comments and guide their learning has recently been questioned and generating an ongoing debate.

Even (2011) states that the assumption that "advanced mathematics studies would enhance teachers' knowledge of mathematics, which in turn will contributed to the quality of classroom instruction" needs to be reexamined in terms of what means for

teachers to have adequate subject-matter knowledge to become an expert teacher and how a teacher can develop and use that knowledge in her teaching.

Many practicing teachers, for different reasons, have not learned some of the content they are now required to teach, or they have not learned it in ways that enable them to teach what is now required. ... Teachers need support if the goal of mathematical proficiency for all is to be reached. The demands this makes on teacher educators and the enterprise of teacher education are substantial, and often under-appreciated (Adler, et al., 2005, p. 361).

To shed light on the role of advanced mathematical knowledge in teachers' classroom decisions, Zazkis and Mamolo (2011) provide examples where teachers' awareness of that knowledge becomes useful to orient the development of a lesson. They use the construct *horizon knowledge* to refer to “teachers’ advanced mathematical knowledge which allow them a “higher” stance and broader view of the horizon with respect to specific features of the subject itself (inner horizon) and with respect to the major disciplinary ideas and structures...occupying the word in which the object exist (outer horizon)” (p. 10). For instance, they describe a class event where Mrs. White asked her Grade 3 students to count the number of triangles formed by drawing segments from each vertex of a regular pentagon to the other vertices. When students provided their answers (32, 27), Mrs. White noticed that both were wrong and her recognition was based on using a mathematical result she had studied in her university course of algebra. Thus, Zazkis and Mamolo suggest that it is important for teachers to take advance mathematics courses in order to wide their mathematical horizon and to use that knowledge during the development of their teaching practices.

The ways in which prospective teachers study mathematics courses play a crucial role in developing resources and contents to be used in their teaching. That is, it is not sufficient for prospective teachers to take advance courses; but they also need to reflect on ways to connect mathematical results with other problems or situations. In this context, the systematic use of diverse digital tools can provide prospective teachers with the opportunity to enhance and extend problem-solving approaches that involve the use of paper and pencil. For instance, with the use of a dynamic software they can construct models of mathematical problems where objects or elements can be moved within the model to observe patterns of parameters that emerge as a result of moving those objects. In this context, it becomes important for prospective and practicing high school teachers to work and discuss ways in which the use of the tool helps them transform some routine problems into a set of activities that fosters mathematical reflection and connections between concepts. These problem-solving experiences are useful for teachers to explore, extend, and discuss mathematical concepts that later will shape their ways to frame and implement problem solving activities in their classrooms.

THE CONTEXT, PARTICIPANTS AND METHODS

Our research group formed by two mathematics educators, two mathematicians, and six high school prospective (three) and in-service teachers (three), has focused its agenda on analysing the types of reform that teachers' educational programs need to consider in order to incorporate the systematic use of digital technology to develop both mathematics and didactical knowledge. Our initial literature review allowed us to recognize that there is scant information on the characterization of ways of reasoning that subjects or learners can construct as a result of using a particular tool and how the use of several tools can help them enhance their problem solving approaches. That is, teachers need information regarding what types of representations and explorations of tasks or problems can be constructed with the use of a particular tools and the kind of arguments, including visual and empirical, that can be used to develop mathematical understanding and to support tasks solutions.

Our point of departure was to work on mathematics problems that appear in textbooks with the use of dynamic software and discuss them, within the group, features of mathematical reasoning that characterize and are consistent with this approach. Thus, we focus on contrasting the software approach that involves visualizing and supporting mathematical results through the use of empirical and geometric arguments with the analytic approach that relies on the use of algebra to identify mathematical relations. In this process, the software properties are helpful in visualizing the behaviour of particular parameters or relations without making explicit the algebraic model. We contend that while the use of the dynamic tool demands that problem solver think of the problem in terms of properties and their geometric meaning to construct a dynamic model; the analytic approach asks the problem solver to represent and explore the problem through an algebraic model.

The problem solving sessions and the unit of analysis. The group sessions were first developed through four three-hours meetings where we initially worked on a set of textbook problems and discussed, within the group, the role that the use of the software played in representing, exploring, and solving each problem. During each meeting one or two of the members of the group presented a task and possible ways to represent it through the dynamic software to the group. At this stage, the rest of the group got involved in open discussions that included asking for clarification issues, concept explanation or proposing other ways to approach the task. Later, we continued the group discussion via online conferences. In this report, **the unit of analysis** is the group's work exhibited while working on, and discussing the textbook problems. We do not intend to describe in detail the contribution of each group member to the solution; instead, we focus on what the group as a whole agreed and identified as important ideas associated with the problem solving process. To illustrate the common mathematical features that emerged during the solution process, we relied on a set of textbook tasks that appears at the end of unit that

involves the study of perimeters and areas of triangles. It is important to mention that the initial task was to analyse the list of problems in terms of concepts involved and possible strategies needed to approach each problem.

We found that the format and wording of the textbook problems, in general, asked to find a particular answer to each problem and there was little opportunity for learners to think of multiple approaches or go beyond the asked solution. Here, we regrouped the problems and identified those that could be extended and connected with key mathematical ideas.

An Initial Prompt

Two textbook problems in which students are asked to find areas and perimeters of particular triangles were slightly changed and posed as:

a. Draw two triangles that share one side AB (base) and whose third vertex lies on a line that is parallel to segment AB . By observing the figure, do those triangles have the same area/perimeter (explain)? With the use of the software, observe what happens to the area and perimeter values of the triangles when the third vertex is moved along line L .

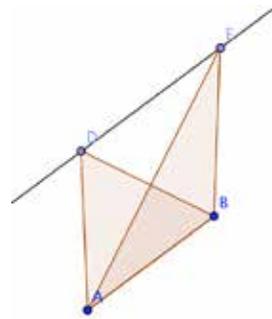

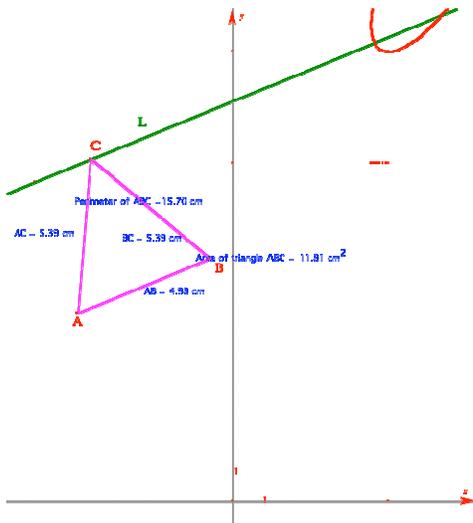

Figure 1: What happens to the triangle's area when point C is moved along line L?

b. Can you construct three triangles that share a common side (base) and also the same perimeter?

The group discussion of the tasks was framed around two problem-solving principles:

- All tasks are conceptualized as opportunities for learners to connect or extend initial statements.
- Solving the tasks involves looking for different ways to represent, explore and solve them and contrasting mathematical qualities associated with the solution process.

For example, during the process of dealing with the first task, the representation shown in Figure 2 was generated and it became a source of introducing several concepts into the discussion.

What happens the triangles' area and perimeters when point C is moved along line L? How can you graph the area and perimeter behaviours? Is it possible to identify a position where the triangle ABC reaches its minimum perimeter? How can we prove it?

Figure 3: Graphic representation of the perimeter and area of generated triangles.

During the discussion, it was recognized that the use of the dynamic software, became important to move objects within the representation and to quantify particular parameters (side, area, perimeter, angles, etc.) embedded in the representation and observe their behaviour. The use of the tool also allows the problem solver to graph particular functions or relations without defining the algebraic model explicitly. For example, the graph of the variation of perimeter as a function of the length of side AC and the corresponding perimeter as point C is moved along line L. Here, conjecture emerged:

From all triangles that are formed by moving point C along line L, the triangle with minimum perimeter is located when point C is the intersection of line L and the perpendicular bisector of AB. That is when triangle ABC is isosceles.

Other concepts that were addressed while discussing this task include:

- The concept of height of a triangle and the calculation of the area.
- The concept of variation (graph of perimeter) and constant function.
- The concept of perpendicular bisector and its relation to the perimeter variation.
- The concept of infinity (how many triangles can be generated while moving point C along L?)
- The use of the Cartesian system and ways to support conjectures.

Comment: Thinking of this type of task in terms of paper and pencil approach often leads learners to use a formula (triangle area, in this case) to conclude that the area of two triangles that share the same base and height is the same. However, with the use of the tool, the dynamic model of the task offers the problem solver the opportunity to observe invariances or parameters behaviours that often become a set of conjectures that needs to be supported mathematically. The visual representation and empirical data associate with the parameters' behaviours were important to formulate

conjectures that later needed to be proved or rejected. In addition, dragging points or objects within the configuration provided useful information to focus the group's attention on key elements or properties that help us construct arguments to support those conjectures.

The first task also provided the context to address problem b). The idea was to construct a family of triangles with a common base and the same fixed perimeter. With the use of the software, Figures 3 and 4 represent two ways to explore the problem:

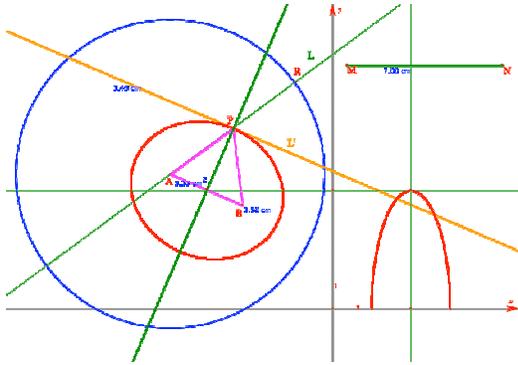

Figure 3: Drawing the condition through the perpendicular bisector

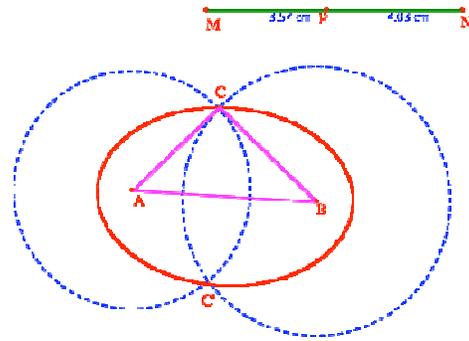

Figure 4: Another way to explore the problem

What is the locus of point C when point P is moved along segment MN?

In Figure 3, segment AB represents the common triangle side and segment MN the sum of the other sides of the triangle. That is, the perimeter of triangle ABC is the sum of segment AB and segment MN. Point A is the centre of a circle with radius segment MN and AR is a line passing by R (which is any point on that circle). L' is the perpendicular bisector of segment BR which intersects line AR at point P. The locus of point P when point R is moved along the circle determines the set of points that are the candidates to locate the vertex C to form a family of triangles with a fixed perimeter. Indeed, the locus is an ellipse since $PB = PR$ (definition of perpendicular bisector) and AR is the radius of a circle. Figure 4 represents another way to explore the same problem: Segment AB is the common side and MN is the sum of the other two sides of the triangle. P is a point on segment MN. Two circles are drawn: One with centre point A and radius MP and other with centre at point B and radius PN. These circles intersect each other at points C and C'. The locus of point C when point P is moved along segment MN is an ellipse and each point on this locus determines and becomes the third vertex of triangle ABC with fixed perimeter. Thus, Figures 4 and 5 were two dynamic models used to represent the problem and the source to discuss:

- The relationship between the common side AB and the sum of the other sides (segment MN). That is, when can the triangle be drawn? (the triangle's inequality).

- Definition and properties of the locus (ellipse).
- The area variation of the family of generated triangles. Again, the intersection point of perpendicular bisector of segment AB and the perpendicular bisector of segment BR determines the vertex C where triangle ABC gets its maximum area (Figure 3).
- Connections that emerge while moving point B out of the circle (Figure 5). It is observed that locus becomes a hyperbola.

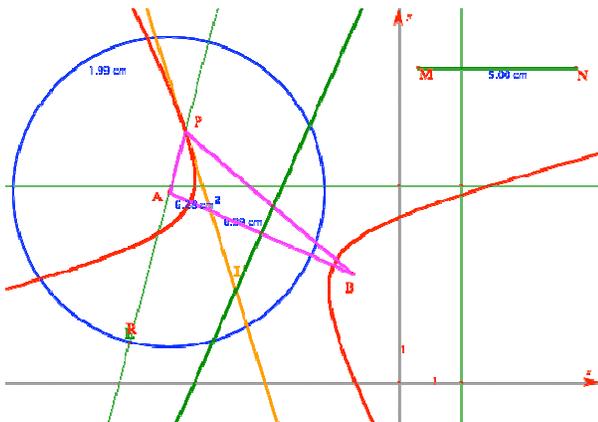

Figure 5: when point B is moved outside the circle, the locus is a hyperbola.

Comment: A main teachers' instructional goal is to encourage their students to extend and connect the contents they study with other ideas and situations. There is evidence that the task dynamic model exploration allows the problem solver to relate contents that in a traditional curriculum appear in different units. For example, the second task that asked for the construction of three triangles with the same perimeter became a platform to generate the conic sections that appear in an entire course of analytic geometry. In addition, the area behaviour of the family of triangle generated in figure 4 was analysed graphically to determine the triangle that reaches the maximum area. That is, the use of the tools offers problem solvers the opportunity to relate and connect concepts and themes that emerge as a result of moving objects within the representation or configuration of the task.

DISCUSSION AND REFLECTIONS

In retrospective, we recognize that the problem solving process involved while working on the tasks show several features of the type of reasoning and mathematical thinking that emerge as a result of approaching the tasks with the use of dynamic software. It was observed that there are several strategies and ways to think of and explore the problems that are associated with the use of the tool. Dragging objects within the model is a key strategy to identify and explore mathematical relations. The controlled movement of objects demands that problem solvers develop a set of heuristic that are crucial to explore and analyze the behaviors of objects relations. For example, drawing circles or extending segments to move lines on the plane or points along lines are strategies associated with the movement of the model. Assuming the problem as solved is a key heuristic that is enhanced

with the use of technology. Here, by analyzing elements associated with the solution, problem solvers can obtain useful information to explore the problem dynamically. In addition, finding loci of particular objects not only becomes important to identify patterns of behavior of some parameters in the model; but also the same loci are tools to find mathematical relations. There is evidence that the use of computational technology (a dynamic software) can offer learners the possibility of transforming some routine problems, found in regular textbooks, into a set of tasks where they can exhibit and contrast different ways of reasoning about the problem that involve visual, empirical, and formal approaches. In this context, the use of dynamics tools plays an important role for conceptualizing the tasks as an opportunity for learners to engage into an inquiring or inquisitive process that goes beyond reporting a particular solution. For example, the dynamic models of the two tasks become a platform to explore not only different forms to represent emerging relations; but also ways to extend and connect the initial statement of the tasks. In this process, it is possible to generate graphic behaviour of particular relations (perimeter variation and locus of particular objects) without defining the algebraic model. In addition, concepts like perpendicular bisector and loci of points became relevant to explain and justify those relations. In general terms, the use of the tool offers problem solvers the opportunity to examine graphically relations that later can be explored and contrasted algebraically. In this context, the use of the tool complements or extends mathematical reflection that learners engage in algebraic approaches. Discussing the tasks and the use of dynamic software throughout the problem solving sessions provided us, as a research group, important information to think of possible routes for teachers to frame and implement problem solving activities in the classroom. Our current project goal is to include more high school teachers in our group and to work on their own textbook problems in order to discuss ways in which the use of technology can help them orient their teaching practices. By reflecting on main issues addressed in the initial research question, we learned that:

- a) Many of the routine problems or exercises that appear in textbooks could be transformed, with the use of the tool, in a series of activities to engage learners in problem solving experiences. Thus, teachers do not need to think of a set of sophisticated problems to use the tool in problem solving approaches.
- b) Problem solvers or learners can develop certain experience in the use of the tool by experimenting and discussing strategies that involve moving or dragging objects within the representation, finding loci of particular objects, quantifying attributes such as areas, lengths, perimeters, and by contrasting other learners' approaches to the problems.
- c) The discussion of concepts and ways used to represent and explore the tasks became crucial to relate, integrate and extend the initial contents associated with the tasks. In this process, there is also an opportunity to review and

extend some of the concepts or themes that appear while dealing with the tasks.

- d) Working on the routine tasks with the use of the tools helped us design worksheets that can be used to orient teachers in the process of transforming the tasks into a platform to formulate conjectures and ways to explore and support them.

CONCLUDING REMARKS

In responding the research question posed initially, we argue about the importance for researchers and in-service teachers to work and discuss within a community what the use of the tool enhances in terms of ways of representing, exploring, solving and extending routine mathematical tasks. As a result, typical tasks found in textbooks offers a point of departure to construct dynamic models or tasks in which problem solvers can identify and explore not only different mathematical routes (contrasted with algebraic approaches) but also possible didactic ways to emphasize the coordinated use of empirical, visual, and graphic approaches.

THRESHOLD CONSTRUCTS INSTRUMENTING TEACHERS' ORCHESTRATION OF AN INQUIRY WITH GEOGEBRA

Håkan Sollervall

Halmstad University and Linnaeus University

In this paper we investigate how to efficiently empower teachers to implement and orchestrate a mathematical learning activity supported by digital technologies. The particular learning activity in this study is intended to facilitate learners' transition from the Pythagorean Theorem to the distance formula and the equation of a circle. The activity comprises structured and guided inquiries involving laptops with GeoGebra and traditional resources. It has been tested with 38 upper secondary students and two mathematics teachers. Our results indicate that a singular discussion with the teachers, based on the researcher's prospective analysis of the activity with main focus on threshold constructs and self-regulating skills, suffices to support the teachers' implementation and orchestration of the activity.

INTRODUCTION

There is not only an abundance of digital technologies available in society, but also an abundance of research about learning mathematics with technologies. Still, research and current teaching practices do not seem to provide sufficient guidance on how to efficiently and systematically integrate digital technologies in mathematics education (Drijvers, 2012). However, numerous efforts in design-based research provide examples of singular good practices that serve as inspiration and proofs of existence that technologies can significantly enhance the teaching and learning of mathematics (Hegedus and Moreno-Armella, 2009; Sollervall and Milrad, 2012; Drijvers, 2012). The issue of scaling up innovations is being increasingly attended to by the mathematics education research community (e.g., Jo Boaler, plenary session at PME-NA 2012; Hegedus and Lesh, 2008). Several authors have recognized that research needs to address systemic issues at macro-level as well as how to efficiently implement classroom innovations at micro-level (e.g., Hegedus and Lesh, 2008).

In the current effort, we will address the implementation of a mathematical learning activity at micro-level, involving two teachers and 38 students in the beginning of their second year at the Natural Sciences Programme in upper secondary school.

Moving beyond teacher-driven improvement of their current practices, as addressed by Lesson Studies and Learning Studies (Lo, Marton, Pang, and Pong, 2004), we have in several research efforts applied a research-driven approach where researchers with complementing domains of expertise engage in the collaborative design of innovative mathematical learning activities supported by digital technologies

(Sollervall and Milrad, 2012). In order to fully exploit the opportunities for learning that are afforded by digital technologies, we have chosen to let the participating researchers with technological expertise be responsible for communicating the affordances of these technologies to the members of the research team. Rather than involving teachers at the level of technologies, we have designed prototypical activities that are presented to and adjusted by the teachers before implementation (Sollervall and Milrad, 2012). Because of the technical complexity in some of these prototypical activities, we have engaged expertise also in the implementation phase.

In the current research effort, we are making use of a stable, commonly used, and readily accessible interactive software, namely GeoGebra, that allows the teachers to be in charge of implementing the activity with their students. The three tasks in the activity are presented and discussed during a meeting on the day before implementation, with focus on mathematical constructs and possible teacher interventions that may be crucial for the students' successful completion of the tasks. The teachers propose additional possible obstacles that are discussed and addressed through alterations of the activity. Within the limited scope of this paper, it is not possible to address all aspects of the learning activity in detail. Instead, we will present the activity in a similar way that it was presented to the teachers, although this implies a superficial treatment of some of the theoretical underpinnings for the activity.

The activity blends students' constructions in GeoGebra and traditional work with pen and paper. The development of the activity is framed by the methodology of design-based research that allows us to attend not only to traditional outcome evaluation but also development of learning activities and prospective (a priori) analysis of hypothetical outcomes (Cobb, Confrey, diSessa, Lehrer and Schauble, 2003). The development phase involves negotiations of a preliminary activity with a prospective analysis based on hypothetical learning trajectories (HLT: Drijvers, 2003; Sollervall and Milrad, 2012). Another key aspect of design-based research is its cyclic character that allows adjusting and improving a preliminary activity (Drijvers, 2003). The version presented in this paper is in its second iteration. The first version was implemented with three first-year secondary students in May, 2012. The evaluation of this implementation resulted in minor alterations of the technical instructions and a decision to involve laptops instead of an interactive whiteboard. The latter decision was mainly due to an ambition to implement the second iteration of the activity in a whole class setting.

Furthermore, a restructuring was made by sequencing the first two tasks according to the involved mathematical processes – defining, representing, generalizing, and justifying – and the corresponding actions on the products of these processes, following the Processes and Actions framework (Zbiek, Heid, and Blume, 2012). These four processes, as well as other theoretical constructs, were used in our discussions with the teachers. In this paper, we investigate the issues addressed in these discussions and how they influence the implementation of the activity.

RESEARCH OBJECTIVES AND RESEARCH QUESTIONS

This paper addresses the implementation of an inquiry-based learning activity, intended to facilitate mathematical processes and actions related to upper secondary students' transition from the Pythagorean Theorem to the distance formula and the equation of a circle. Students engaging in the activity are challenged to create several threshold constructs – as external (physical) or internal (mental) constructs – that serve a crucial role in promoting their continued mathematical inquiry.

Our research questions are:

- How are threshold constructs and self-regulating skills addressed in the discussions between the researcher and the teachers?
- How do the problems that students encounter during the implemented activity relate to the threshold constructs and self-regulating skills?

In the next section, we discuss the notion of threshold construct as a local version of threshold concepts (Meyer and Land, 2005). We also address the notion of inquiry and the self-regulating skills that facilitate successfully completing an inquiry.

THEORETICAL AND METHODOLOGICAL CONSIDERATIONS

From a teacher perspective, it is essential to identify and address the threshold concepts that facilitate learning in a specific subject area. An example is the threshold concept 'limit' in Calculus. In general, threshold concepts can be seen as 'conceptual gateways' that lead to previously inaccessible ways of thinking about something (Meyer and Land, 2005). In this study, we will attend to threshold concepts that are localized to the learning trajectories for a specific activity focusing on learning coordinate geometry and specifically the distance formula. We refer to these local and specific threshold concepts as *threshold constructs* for the activity. In Figure 3 (left pane) the triangle PAB serves as a threshold construct (when the distance formula is not yet available) that together with the coordinates $(x,4)$ of the point B affords constructing the algebraic expressions x and $y - 4$, respectively, for the catheti of PAB. Such threshold constructs may be identified either in a prospective analysis as hypothetical constructs or actual constructs that during the implemented activity serve a crucial role in facilitating a student's learning trajectory. Since the threshold constructs are situated within a specific activity, they need to be empirically tested, updated and refined in an iterative research process that can be smoothly integrated within the methodology of design-based research.

The activity that will be presented in the next section is comprised of structured and guided inquiries (Herron, 1971) where the students have primary ownership and initiative. Inquiry-based learning challenges the students' self-regulation regarding cognition, motivation, behavior, and context, in corresponding phases of self-regulation: forethought, planning, and activation (cognition); monitoring (motivation); control (behavior); reaction and reflection (context) (Schunk, 2005).

In this paper, we will investigate if (and, if so, how) the teachers' interventions address scaffolding these phases of self-regulation or if they address other issues, with focus on the threshold constructs.

THE ACTIVITY AS PRESENTED TO THE TEACHERS

A meeting between the researcher and the two teachers (and a third teacher) took place in the afternoon on August 29, 2012, the day before implementation. Before the meeting, the teachers had received a preliminary printed version of the student instructions. These instructions consisted of a cover page with general information, seven pages with task instructions, and a brief two page manual to GeoGebra.

The first two tasks were presented as structured inquiries, while the third task was a less structured so called guided inquiry with no suggested sequence of steps for solving the task (Herron, 1971). The teachers were informed that self-regulated inquiries impose a substantial cognitive load on the students, which implies a need for the students to consolidate their experiences in order to process and retain what they have just learned (Kirschner, Sweller, and Clark, 2006). We decided to address this issue by allowing time (15 minutes) for the students to write individual reflections at the end of the activity. The teachers agreed to follow up on these reflections during the following lesson. This arrangement left 2.5 hours (8.30 am – 11.00 am) for working with the three tasks, including a short break.

As the activity involves interaction with laptops supporting the software GeoGebra that the students have only used on a few previous occasions, the issue of instrumental genesis (Verillion and Rabardel, 1995) was specifically addressed in the design process. We designed the first two tasks as staging activities involving not only mathematical learning objectives but also serving to familiarize the students with the character of the activity and specifically the involved technologies (Edelson, Gordin, and Pea, 1999). Furthermore, it was agreed to give the students sufficient time to explore, investigate and resolve problems by themselves, and that guidance should be given restrictively, although this could imply that they will not manage to complete all the tasks. It was agreed to be sufficient if the students complete two of the three tasks.

The activity was designed for students who are familiar with the Pythagorean Theorem, the square of a binomial, and the equation of a straight line, but with no previous experience of working with the distance formula. The general objective for the activity was to let students explore geometric relationships, pose hypotheses, confirm these hypotheses by producing algebraic proofs, and thus making connections between geometric and algebraic representations.

In the first task, the students are asked to find (other) points equidistant to two given points P and Q, that is, with the ratio 1:1 between the distances (Fig. 1).

This first task involves working only with GeoGebra following instructions that begin with setting **Perspectives** to **Basic Geometry**, thus giving the students a clear background to work on, showing no grid and no coordinate axes in order to stimulate them in attending only to the geometric relations. The students are asked to first place two points P and Q beside each other on the screen. Then they are asked to place a third point in the screen and were given the following information:

The condition in this task is that the new point should be located equally far away from the points P and Q:

The distance from the point to P should be equal to the distance from the point to Q.

One of the teachers objected that one of these sentences could be removed since they both give the same information. The researcher argued that the redundancy could help students who may be able to interpret one of the sentences but not the other. This position was further supported by arguing that the sentences are qualitatively different, as the first sentence addresses the condition from a procedural point of view while the second sentence objectifies the condition. It was decided to not change the phrasing of the sentences but to keep them as in the proposal.

Next, the students are informed that there are many points that satisfy the condition. They are instructed to place several such points on the screen (such a possible construction is illustrated in Fig. 1, left pane) and then answer the following question:

What geometric figure do you get from all the points that satisfy the condition?

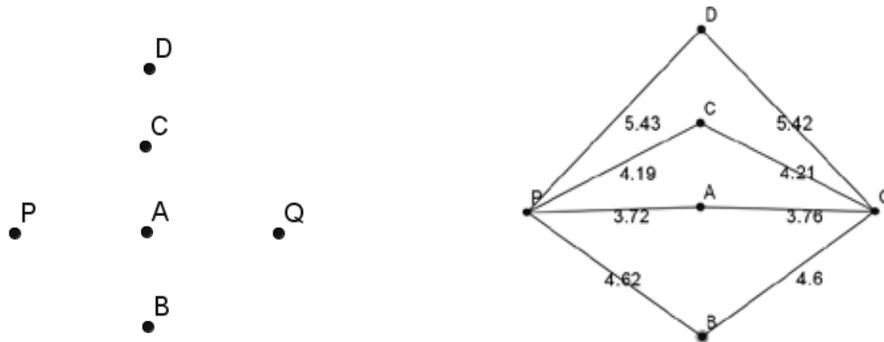

Figure 1: Constructions in GeoGebra according to the instructions for the first task.

On the next page, the students are invited to check the placement of their points, and if necessary adjust their placement, by having GeoGebra measure the distances from each point to P and Q, respectively (Fig. 1, right pane).

The second task addresses the same geometric 1:1 condition and the same question, but now with the points P and Q placed in a coordinate system. The students are instructed to keep their constructs from the first task, show **grid** and **axes**, and place the points at $P = (0,4)$ and $Q = (2,0)$ respectively. A construction according to the geometric 1:1 condition is illustrated in Figure 2 (right pane).

On the next page of instructions the students are asked to work with pen and paper to find the equation of the straight line.

Thus far, the tasks have called for the students to follow instructions. In relation to the Processes and Actions framework (Zbiek et al., 2012) they have been acting on definitions by interpreting and representing them, generalizing from a few points to all points, justifying geometric constructs by using GeoGebra, and acting on a generalization of a visual representation by representing it algebraically.

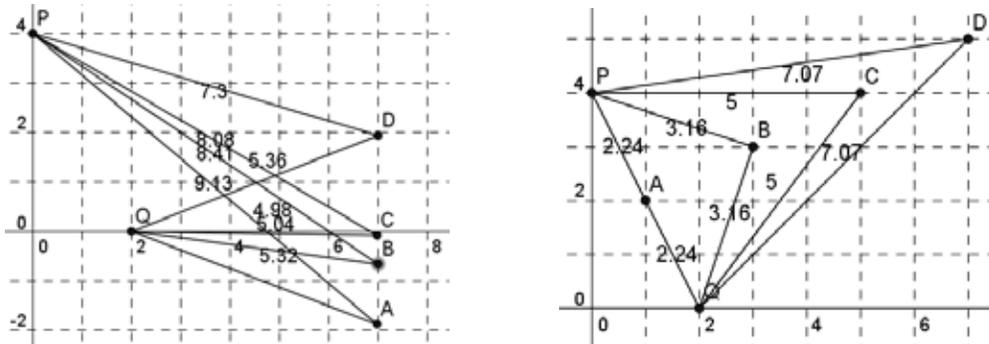

Figure 2: A possible initial setup (left pane) and a correct construction (right pane).

The continuation of the second task is more challenging. The students are now asked to *prove algebraically that all the points (x,y) that satisfy the condition lie on a straight line*. They are first instructed to remove all points except P, Q, A, and remove the labels on the segments AP and AQ. Next, they are asked to change the labels for P and Q so that they show **Name & Value**. Thereafter, they are asked to place the point A upwards and to the right of P and Q, and place a new point B directly to the right of P and directly below A (Fig. 3, left pane).

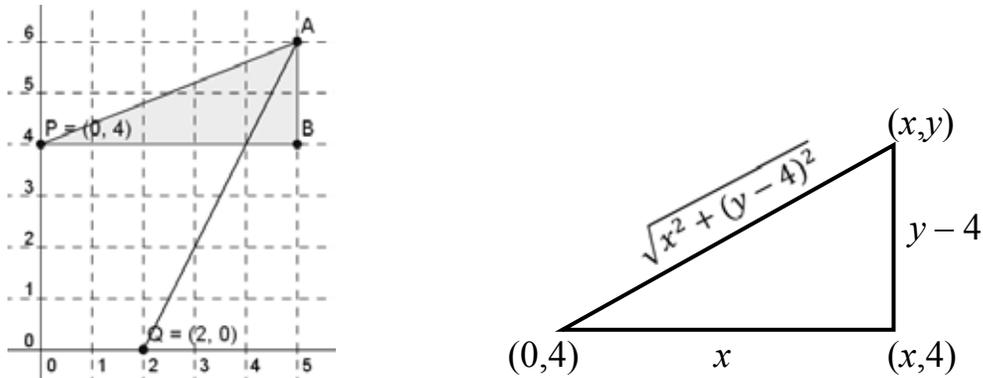

Figure 3: Continuation of task 2 in Geogebra (left pane) and on paper (right pane).

The students are then asked to draw the triangle PAB in GeoGebra (Fig. 3, left pane). Before turning to the next page of instructions, where they are instructed to work with pen and paper, the students are asked how the hypotenuse of the triangle relates to the task they are working on.

They are asked to copy the triangle PAB onto a piece of paper, including the coordinates for P and B. They are asked to set $A = (x,y)$. Their first subtask is to find algebraic expressions for the catheti of the triangle, and the second subtask is to find an algebraic expression for the hypotenuse. In the first iteration, the students were instructed to first determine the coordinates for the point B, but in the discussions

with the teachers it was decided to leave this construct as a challenge to the students. Next, the students were asked to find an algebraic expression for the distance between A and Q, without sequencing any steps in the instructions.

Finally, the students were instructed to set the lengths of AP and AQ equal to each other and simplify the equation. As expected, many students did not simplify carefully and made numerous algebraic errors. However, quite a few groups of students managed the first two tasks more or less on their own. Only one group of three students made a serious attempt on the third task, which we do not account for here. Instead, we proceed to highlight some of the presented results in relation to the research questions. We address both questions under each heading.

DISCRIMINATING AND GENERALIZING VISUALIZED POINTS

Already during the first iteration of the activity, it was confirmed that the reference points P and Q (compare Fig. 1) interfered with the interpretation of the geometric figure. The students' first guess was 'a rhombus'. During the second iteration, several groups initially answered 'a cross' or 'a triangle', even after they had constructed the line segments that allowed them to measure distances. Our interpretation is that the entire picture in Fig. 1 was prioritized before the condition, although the written condition was emphasized in the instructions by being italicized in a large font size. A comment by one of the teachers 'they are not used to working with figures as sets of points' can be seen as further explaining why the picture was favored in the students' work. Interventions by the teachers (and the researcher) involved suggestions to test each point against the condition by reading the condition for each specific point. When the students finally read 'the distance from P to P' they readily concluded that P does not belong to the figure. Furthermore, the teachers pointed out to several groups that the figure consists of all the points that satisfy the condition, not only the points they had placed on the screen. These incidents relate to discrimination and generalization (Bruner, 1966) as cognitive processes that the students need to apply in relation to a mathematical definition. Discriminating a geometric figure in a picture, generalize a geometric figure from a finite set of point, and acting on a formal definition, can all be regarded as threshold concepts in the cognitive domain, related to the self-regulating skills forethought, planning and activation.

CONTROLLING AND REFLECTING ON ALGEBRAIC TREATMENTS

As already mentioned, several students made incorrect treatments of the algebraic expressions in the final part of task 2, for example the classical mistakes of Case 1: replacing the square of a binomial with the sum of the squares of the two terms and Case 2: canceling square roots and squares term by term in the equation

$$\sqrt{(x-0)^2 + (y-4)^2} = \sqrt{(x-2)^2 + (y-0)^2}$$

Several of the student groups attempted to work very quickly with this subtask. When asked to check their expressions, they readily found their mistakes to Case 1 by writing the square as the product of two binomials. Case 2 was mainly handled by the groups themselves, when asked by the teacher to check their work. Our conclusion is that they knew the algebraic rules, but proceeded carelessly by working too quickly and not taking care in structuring and checking their written expressions. Hence, their algebraic mistakes can be explained by insufficient self-regulating skills related to control – as the mistakes are caused by the behavior of working carelessly – and reflection, which is particularly important in the inquiry context.

A SCAFFOLDED THRESHOLD CONSTRUCT BECOMES A CHALLENGE

During the first iteration, the students were instructed to determine the coordinates for the point B in Figure 3. As mentioned earlier, it was decided to remove this particular instruction in the second iteration and instead relying on the teachers to provide guidance to the students, if needed. Instead of providing embedded scaffolding for the particular threshold construct $B = (x,4)$, this part of the activity was transformed into a genuine challenge for the students. Some of the students managed this particular task by themselves, while those who got stuck were suggested by the teacher to attend to the coordinates of B. This proceeded smoothly, as the teachers were aware of this particular threshold construct.

In design-based research, particularly with technologies, the aim is often to work in the opposite direction and attempt to replace teacher scaffolding actions with scaffolds that are embedded in the activity, thus reducing the demands on the teacher and enhancing the possibilities for a teacher accepting to integrate the activity in her classroom (Wong, Looi, Boticki, and Sun, 2011). On the other hand, it is desirable to empower the students, show trust in their capabilities, and thus nurturing their collaborative and self-regulating skills (ibid.). Our approach of negotiating threshold constructs and issues of self-regulation with the teachers allows us to achieve a reasonable balance between teacher scaffolding actions, embedded scaffolds, and challenges intended to empower the students in their collaborative work.

CONCLUDING REMARKS

In a classroom environment where students mainly solve problems in a textbook, most mistakes can be easily adjusted by checking answers or asking peers or the teacher. In such an environment, individual students are not responsible for monitoring, control, and reflection on their work. Mistakes do not propagate and do not affect future work, so students are not stimulated to develop strategies for self-regulation. In comparison, even a minor mistake in an inquiry can have fatal effect on its continuation and may cause the students to fail in achieving the intended learning objectives. The open inquiry is sometimes, but certainly not always, the best format for an inquiry. By initially planning a structured inquiry we expose its inherent challenges regarding threshold constructs and demands for self-regulation.

Negotiating implementation of the activity with teachers creates awareness of these challenges and demands. This process empowers the teachers to take informed decisions about restructuring and possibly open up the inquiry by re-distributing scaffolds on the teacher and peers or embedding them in the activity. The negotiation phase also contributes to empower the teacher as orchestrator of the comprehensive activity and its scaffolds. In our opinion, this is an efficient way to implement research-designed activities in the authentic setting of the teacher's own classroom. From a research perspective, the negotiation phase is a good opportunity to bring teachers' knowledge of content in relation to students and teaching into the research process (KCS and KCT: Ball, Thames and Phelps, 2008).

It is apparent that GeoGebra works well in the upper secondary school classroom as a stable and user-friendly software with commands that align well with mathematical thinking and notation. Minor adjustments of settings are readily handled and specific commands are shared among the students. However, the pedagogical implementation of GeoGebra in the mathematics classroom has to be carefully considered so that it not only supports solving the tasks but also supports the students in achieving the mathematical learning objectives. In our activity, it would have been easier to have GeoGebra provide the equation of the straight line in the second task. Instead, we chose to let the students do this tedious work by hand, particularly since the learning objective was the distance formula and not the equation of the straight line.

Furthermore, it may be noted that the distance formula was not explicitly addressed in our activity, but rather emerged as a useful tool for solving a task in coordinate geometry. The teachers commented on this particular aspect by saying 'this is really a good way to work with coordinate geometry, instead of working with the dull standardized tasks in the textbook'. We wish that this may imply that the students who engaged in our activity have learned to appreciate the distance formula as a good thing to know and not only yet another formula to memorize.

In this study, we have identified threshold constructs that relate to geometric figures, algebraic treatment, and self-regulating skills. In future research efforts, we will continue to characterize the nature of the identified threshold constructs.

GRAPHIC CALCULATOR USE IN PRIMARY SCHOOLS: AN EXAMPLE OF AN INSTRUMENTAL ACTION SCHEME

Per Storfossen

Hedmark University College, Norway

This paper presents an empirically based case study design within a sociocultural theoretical framework. The research aimed to describe the implementation of a graphic calculator in a fifth grade primary school class when four students were engaged in mathematical activities performing tasks and challenges given by the researcher. The students' activities associated with the process of appropriation of a technological artifact played a prominent role in the data analysis. The distinction between artifact and instrument through the instrumental approach was in focus. The schemes of instrumented action were of special interest. The case study concerns students' discovery of the function key exponentiation with the inscribed symbol $^{\wedge}$ at the key button, and an analysis of exponentiation by schemes of instrumented action.

Keywords: graphic calculator, exponentiation, instrumented action scheme, appropriation

INTRODUCTION

This case study is about students-initiated calculator activity. A student named Signe calls for attention about her findings concerning the exponentiation [1] function key on the keypad. The study is part of a larger research project where data was collected from task-based video interviews with students undertaken by the researcher. The focus of the reported research was implementation of an advanced graphic calculator (GC) in a 5th grade primary school class and characterization of its use. The choice of research strategy can be described as a case study design. The study is presented in a sociocultural theoretical framework where a GC is a sociocultural semiotic artifact. Artifact properties, such as the function keys on the keypad were variables considered in this study. The instrument-mediated activity approach was in focus. The theoretical framework referred to as instrumentation (Trouche, 2003) associated with research in technology educational environments is applied as the lens for data analysis. The students were accustomed to using a four-function calculator. Advanced GCs are usually not part of teaching math at the primary school level. The purpose of introducing the advanced GC was to investigate the longitudinal aspects of its appropriation by students. A task portfolio was designed for the project. The students' spontaneously initiated exploration activities of the exponentiation function sustained by the GC, was not part of the task portfolio or the project agenda.

THEORETICAL FRAMEWORK

The main theoretical perspective that frames our investigation is the instrumental approach associated with research in technology educational environments.

Instrument genesis is suitable to analyze processes described as appropriation by which an artifact becomes an instrument in the hands of a student, in terms of transforming an artifact into an instrument to become a cognitive aid for the student to solve a given task. The process of appropriation of an artifact to become an instrument, a tool for the competent user is further elaborated by (Trouche, 2003). The instrumental approach with the human/computer interaction and human use of tools constitutes two main processes of instrument mediated activity. The process directed from the artifact towards the human agent is named instrumentation. The tools convey, shape and transform the human agency, and the subject adapts to its constraints and affordances. The other process, instrumentalization, is directed from the human agent towards the artifact which includes stages such as familiarization with the instrument, mastering and adopting the instrument to one's own personal, specific needs. Rabardel (2002) drew on Wertsch's (1998) key construct of mediated activity. Students mediated calculator activity transferred to individuals-appropriate-technological-artifacts-in-cultural-practice constitutes the unit of analysis.

METHODOLOGY

The choice of research strategy in this study can be described as a case study design on two levels. On the first level, there were 23 students in a fifth grade (students aged 11-12) primary school class. The first level formed a backdrop for the next level, the selection of four students. There were two boys and two girls placed into two small groups, one of each gender. The choice of the two boys and two girls was partly based on pre-tests, achievement tests from a pilot study involving a representative sample of the class, but also on the students' motivation as the two groups of friends wished to participate in this study that lasts over two years. We meant that the latter criterion was a good argument for the participants not losing interest during the period of data collection. The second level of the case study consisted of the two respective groups, and was a continuation and an elaboration of the study where the entire class constituted the background. In this study, each student had a handheld calculator at his or her disposal. The sophisticated icon-driven graphic calculator Casio fx9750G PLUS was introduced by the researcher including a 21-character x 8-line display. The mediated artifacts, among them the graphic calculator, were available and were included in their mathematical activities. The data collected and analyzed in this research study was from video-taped interviews when each of the four students were in work sections working individually, and when they were collaborating in small groups engaged in mathematical activities, challenges and tasks provided by the researcher.

ANALYSIS OF THE TRANSCRIPTION

The analysis of the transcript below is an example of students' appropriation of the artifact function key for exponentiation, a part of the graphic calculator, described by the instrument genesis process.

The built-in artifact exponentiation with its function key \wedge

The term artifact in the case of calculator is material, an example of a physical or touchable object but also a semiotic artifact. Less obviously, algorithms implemented on a computer or on a calculator, in a sociocultural perspective, are regarded as material artifacts. Algorithms are created and used in mathematics and can be programmed into computing devices. Through their materialization in written and spoken entities, algorithms do not exist without socio-historical invented signs. A graphic calculator is a complex technological digital artifact, which is constituted of a collection of artifacts. For example, if one considers the entire software package as a single artifact, a function for calculating the arithmetic mean or a one for solving quadratic equations are both built-in algorithms. Each of these examples is regarded as a single artifact. The physical artifacts such as the screen display, the keyboard or a single key on the keypad is each part of the artifact graphic calculator. The artifacts in focus in this case are the students' appropriation of the exponential application software within the GC and the associated exponentiation function key with the inscribed symbol \wedge at the key button on the keyboard of the GC. The two artifacts can be considered as a consisting unit; a part of the software package which the agent is communicating with via the keystroke \wedge for exponentiation in the context of a keystroke sequence $9 \wedge 2$. The appropriation of the exponential function key means also appropriation of the entire artifact graphical calculator.

Transcript of students' exploration of the exponentiation key \wedge

The following excerpt is a transcript of a video clip of an interview of the students named Hilde, Kate, Signe and the researcher. The video clip is part of a comprehensive video material. The episode is initiated by Signe who enthusiastically requests the researcher's for attention about her findings concerning a new function key for exponentiation with the inscribed symbol \wedge at the key button on the keyboard of her graphic calculator. Signe held out her hand with the graphic calculator towards researcher so he could take a closer look at the screen display.

The circumstances gave the researcher a golden opportunity to put aside the day's interview guide program and instead concentrate on Signe's initiative and encourage her to continue the exploration process by letting her lead the other students on the way. Furthermore, in the interview, the emphasis is on the students, on their own, to take the lead and not be guided or intervention by the researcher. In this context, concerning the role of the researcher as an observer, the researcher saw the necessity of balancing roles between being observer-as-participant and participant-as-observer avoiding unnecessary intrusion or interruption.

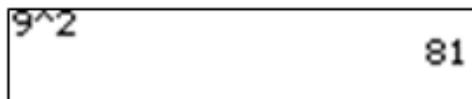

Figure 1: Signe's calculator display

- 112 Researcher: Tell me Signe what do you have on your screen display?
- 113 Signe: It is, eh, $9 (\dots) 2$ up and it is equal to 81.
- 114 Researcher: Could you show Tom and Hilde the calculator's screen display?
- 115 Signe: Have you learned this yet? (Signe is speaking to Tom and Hilde while she is holding her graphic calculator in a position such that each of the students is able to look at the screen display.)
- 116 Tom: I want to see it! What? Tell me, how did you do it? (Tom expresses astonishment at seeing the syntax shown at the screen.)
- 117 Hilde: What does the number 2 mean? (Hilde gets a short glimpse of the screen display of Signe's graphic calculator.)
- 118 Tom: I do not understand why it is 81 when you are taking $9 (\dots)$
- 119 Signe: Yes, because, right?, you take 9 times 9.
- 120 Tom: Wow, I made it! (Tom bursts out a "wow" signaling succeeded in typing in the keystroke sequence 9^2 and calculated 81 that Signe just recently has shown him.)
- 121 Researcher: What does the digit 2 mean?
- 122 Hilde: Yes, times 2.
- 123 Signe: No, 9 times 9. (Signe is making hand gestures to emphasize her answer through visualizing the arithmetic calculation by drawing in the air with her index finger the symbol 9, then the multiplication sign and another 9.)
- 124 Hilde: How do I get the digit 2? Ok! (Signe is pointing with her index finger at the keypad and screen display to show Hilde the keys to be pressed that will generate 9^2 .)
- 125 Tom: There we learned something. This is our secret.
- 126 Signe: Yes, it is our secret.
- 127 Tom: I'm not sure it is a very big secret. (Tom chuckles while talking)
- 128 Researcher: What does the digit 2 mean?
- 129 Signe: What the digit 2 is? It goes like two times up in the brain of the calculator.
- 130 Researcher: Do you understand what Signe means?
- 131 Tom: Yes, it goes twice.
- 132 Signe: Two nines, it is the same as 9 times 9, only that we use the digit 2 to go little faster.

Signe's initiated exploration task is associated with the identification of the keystroke sequence displayed with the syntax 9^2 and the students' experimental circumstances, the discovery of the mathematical identity $9^2 = 9 \cdot 9$. In (112), she has been able to make use of the function key for exponentiation on the keypad and she has managed to calculate $9^2 = 81$ appearing on her screen display. Researcher seized the opportunity by asking her to pronounce what is displayed on her screen. Signe answered in the next text line by reading aloud off the screen display and uttered the syntax "It is, eh, $9 (\dots) 2$ up and it is equal to 81." Signe pronounced the

digit 9 and the digit 2 and then “up”, which could mean her visual perception that the digit 2 is located somewhat up in its position compared to digit 9. She uttered that the answer to the arithmetic calculation is 81. The reason for the researcher (114) for asking Signe to show Tom and Hilde her screen display, was, hopefully, to initiate a dialogue between the students about the new sign \wedge and what the syntax $9 \wedge 2$ mathematically represents.

Making mathematical meaning of syntax for exponentiation

In (115), a dialogue is initiated by Signe’s appeal to Tom and Hilde for attention by letting them see the syntax displayed on her calculator screen. Signe’s utterance suggests she believed that the other two students did not have any experience of using this function key or that they didn't know about its existence and what it mathematically represents. She said this with an overwhelmingly proud smile to underscore her achievement. After Tom and Hilde cast a glance at Signe’s screen, Tom appeared to be surprised (116) over the syntax configuration visualized on Signe’s screen. Hilde’s utterance (117) is associated with the visual appearance of the text string characters. Her focus is on the digit 2 and attention to the relative positions of the signs in the punctuation of the exponential notation (calculator syntax). Tom's utterance (118) is interpreted that he did not understand how Signe has managed to calculate 81 when she typed in 9. Tom is trying to make sense of Signe’s calculator activities and his utterance concerned the mathematical content, the exponentiation. Signe chose to sit down next to Tom on the couch so they both could look at each others' calculator screens. Each of them was holding a graphic calculator in hand while Signe showed Tom the keystroke sequence and how to navigate and manoeuvre among the keystrokes to get the mathematical expression and the arithmetic calculation $9 \wedge 2 = 81$. In (119), Signe answered that it is the multiplication 9 times 9 that gives the answer 81, a result Tom most likely is familiar with. But Signe's answer may not be what he asked for, that was, the role of the digit 2 in the arithmetic calculation. Tom gave an outburst of a "wow" (120), after following guidance and instruction from Signe, signaling that he succeeded in navigating and manoeuvring on the keypad and executed the arithmetic calculation by the use of function key for exponentiation. Researcher intervened three times (121, 128 and 130) in the students' dialogue with control questions to clarify Tom’s and Hilde’s perception of what the digit 2 in the calculator syntax mathematically to them represents. The questions were asked after Signe had given Tom and Hilde her verbal explanation and clarification by gesturing which consisted of keystroke sequence and the related mathematical content of the calculator syntax. Hilde's response (122) to the researcher's question (121) was that the digit 2 stands for the number of nines. However, Signe uttered (123) a definite "no" of what role the digit 2 is playing in the arithmetic calculation, and she corrected Hilde's statement by saying it means 9 times 9. Signe’s utterance was simultaneously accompanied by hand gestures visualizing the arithmetic calculation. Hilde was trying to make sense

of Signe's calculator activities and asked Signe about the role of the digit 2. Signe responded by showing Hilde the keystroke sequence, which constitutes $9^2 = 81$. Hilde's response (124) after being guided by Signe was to outburst the "ok!" to confirm she had managed to type in the keystroke sequence for exponentiation. In a humorous tone (125-127), Tom and Signe proposed that they keep their findings as a secret from the other classmates. The discovery of the exponentiation button and the mathematical operator in the case of 9 raised to the power of 2 equals 81 is their little secret. The students were preoccupied with the fact that they, on their own, without the teacher's help, had learned about a new function key on the keypad on the calculator. The students had managed to give the syntax 9^2 mathematical meaning via the identity $9^2 = 9 \cdot 9 = 81$. Their utterances like "there we learned something" and "this is our secret" are example of a personification of knowledge by making it their own, a characteristic feature of the process of appropriation as the process of "taking something that belongs to others and making it one's own" (Wertsch, 1998, p. 53). They reflected upon the knowledge they had acquired during the dialogue. In a joint activity, they established a shared focus of attention and a kind of working consensus of what they pay attention to in their mathematical activities. Our claim is that the students, in this context, possessed knowledge at a meta-level.

Finally, Signe (132) exhibited a pragmatic attitude to the use of the mathematical operation exponentiation. She probably connected prior knowledge about (repeated) multiplication and saw the opportunity to express the mathematical identity. Signe utilized, in this case, the advantage of exponentiation as a useful and a feasible calculation tool that is faster, more efficient and practical for an agent to perform, rather than performing calculations as repeated multiplication by the use of the calculator. According to (Artigue, 2002), Signe emphasized on the pragmatic value of technique by focusing on their productive potential like cost (time-consuming aspects), efficiency, and field of validity.

Asymmetry in the students' roles in the investigation

In the episode there was an asymmetry in the different roles of the three participating students which is crystallized in the events that unfolded through their respective calculator activities reflected in the dialogue. Signe undertook the role of a mentor and acted as a supervisor to Hilde and Tom. Signe advised the other two students about the function key $^$ and the role it plays in the keystroke sequence, and regarding how they could navigate and manoeuvre between the keys on the keyboard to express the arithmetic calculation exponentiation in the case of 9^2 . Signe was a mediator between Tom and Hilde, relaying her interpretation of how the displayed syntax should be understood and mathematically linking the operator exponentiation to the students' previously knowledge of the arithmetical operation (repeated) multiplication as 9 times 9. Signe answered the other students' questions. She explained and clarified misunderstandings like the digit 2 in the screen display

syntax meant the multiplication 9 times 9 and not 2 times 9 as Hilde had presumed. Signe had the opportunity to guide the other two students and bring them into her knowledge, and which turned out to be correctly understood, her perception and understanding about how the graphic calculator operates with respect to calculating 9 to the power of 2 equals 81. On the other hand, Tom and Hilde were novice users and unfamiliar with the function key \wedge . Tom and Hilde were acting and participating in the role of learners that expressed their wishes towards Signe to be guided about the new function key and the associated syntax of the graphical calculator. They had questions about what the built-in application could perform and what the arithmetic operation represented mathematically with respect to how it operates on numbers. Hilde and Tom were asking Signe information about the new function key \wedge , its place and role in the displayed keystroke sequence and about syntax that enabled Signe to execute the arithmetic calculation. They sought assistance from Signe with their challenge of decoding the mathematical content of the syntax.

Anthropomorphic description of the calculator

It is interesting that Signe used a metaphor to explain and to make sense of the arithmetic calculation by attributing the artifact graphic calculator, which does not have human properties, human properties and qualities. This can for instance be seen in (129 and 132) where she uttered “it goes two times up in the brain of the calculator” and “the digit 2 to go little faster”. Signe’s explanation on how the calculator operates is associated with the human body as a reference where the brain is located within the head. The human brain can perform (mental) arithmetic operations on numbers. The characteristic feature can be compared and transferred to the calculator, which is equipped with a built-in brain with the objective to perform arithmetic calculations. Like in this case with Signe who ascribed the calculator human characteristics, empirical investigations give accounts of examples in which people provide anthropomorphic descriptions of phenomena related to computing devices (Morewedge, Preston, & Wegner, 2007). Signe’s initiated exploration activity associated with the discovery of a new function key and identification of the keystroke sequence that appeared on the calculator syntax 9^2 , which, to the students, corresponded to a new arithmetic calculation. The mathematical operation was exponentiation for positive integers in the case of the mathematical identity $9^2 = 9 \cdot 9 = 81$. Based on the students’ activity directed towards exploring the mathematical operation exponentiation sustained by the graphic calculator, the observations of the unfolding activity was analyzed and interpreted in light of the instrumental approach by the scheme of instrumented action.

Components of instrumented action scheme for the exploration of the mathematical operation exponentiation with the graphic calculator

- (1) Knowing where to find the function key \wedge for exponentiation on the keyboard of the graphic calculator.

- (2) Knowing the existence of the command with the inscription \wedge can be used to express exponentiation (as repeated multiplication)
- (3) Remembering and being able to type in the keystroke sequence and corresponding displayed syntax $9 \wedge 2$ with the aim to perform the arithmetic calculation $9 \cdot 9 = 81$.
- (4) Realizing that $9 \wedge 2$ can be substituted by the mathematical operation (repeated multiplication, that is, recognizing the mathematical identity $9 \wedge 2 \stackrel{\text{identity}}{=} 9 \cdot 9$)
- (5) Being able to interpret the result $9 \wedge 2 = 81$
- (6) Attempts to generalize by a change to a different value for the chosen base 9 and exponent 2.

The bullets (1), (2) and (3) concern aspects of observations of students' concrete gestures [2], restricted to techniques that the students carried out with the artifact graphic calculator. The technical skills, what the instrumental genesis of instrumented action requires of the student, is to be aware of its existence and the location of the function key exponentiation \wedge on the keyboard of the artifact graphic calculator. Further, the student should be able to navigate and to manoeuvre among keys on the keyboard to type in the keystroke sequence. Navigating: by determining the position and course in the sense of orientation among the keypad to locate the keys to be used in the keystroke sequence to express potency $9 \wedge 2$. Manoeuvring: by managing the coordination and the steering of gestures that constitute the movement of the fingers on the keyboard in the agent's performance of keystroke sequence to execute the command exponentiation. Finally, by pressing the exe-button for the execution of the command exponentiation, the student is mobilizing the tool graphic calculator to perform the arithmetic calculation. The described technical gestures of the students' working with the graphic calculator consisting of a combination of keystrokes is an example of a usage scheme directly related to the artifact and oriented towards calculator management. According to (Trouche, 2003, p. 789), "We shall call gesture a student's elementary behaviour that may be observed, component of a scheme". The usage scheme (Rabardel, 2002), the operational manipulation of the tool, constitutes both by observable gestures and knowledge involved in the making of the gesture. The observable appearance of students' gestures on the keypad of the calculator is not to be considered in isolation, because the gesture requires knowledge from each student to carry out the task which is mobilizing, and utilization of the function key for exponentiation and recognition of the identity as repeated multiplication by the $9 \wedge 2 = 9 \cdot 9 = 81$. The enclosed transcript illustrates that Signe, Tom and Hilde not only were keen to know about the keystroke sequence to perform the arithmetic calculation, but they also were interested in the ulterior mathematical content to make meaningful use of the tool. My claim is that the mental process associated with the individual mental developing schemes of Signe, Tom and

Hilde, incorporates mathematical thinking when each of them were trying to attribute mathematical meaning to the technique of typing in the syntax. This can be seen as instrumented action scheme because of the conceptual aspects or conceptual components in the instrumental genesis. The scheme of instrumented action is oriented by the action itself. The students were not questioned, nor did they get into operationalizing the function key $^{\wedge}$ with other bases than base 9 and other exponents than exponent 2.

What would Signe and the other students have said if for example the digit 2 in the syntax was replaced with the digit 3 or the digit 5, and whether they would have been able to calculate 9^3 or 9^5 and mathematically explain the arithmetic calculation? Based on Signe's statement in (132), "two nines, it is the same as 9 times 9, only that we use the digit 2 to go a little faster" and in (129) "two times up in the brain of the calculator.", indicates that Signe mathematically interpreted the exponent 2 in the exponentiation as the number of times the digit 9 shall be multiplied by itself. The screen displays not only the syntax, but also the corresponding answer 81 to the arithmetic problem, which gave Signe the opportunity to connect prior knowledge to the multiplication 9 times 9. The exponentiation corresponded to repeated multiplication and the mathematical identity $9^2 = 9 \cdot 9 = 81$. This is an indication that Signe, for example, could have answered that 9^3 was the same as $9 \cdot 9 \cdot 9$ and that the exponent digit 3 then told her "it goes three times up in the brain of the calculator." However, this is to draw the conclusion too far and remains a hypothesis. Bullet (6) is incorporated and implemented as a component in the instrument action scheme if the students, through a task design, were given the opportunity and challenged to use other bases and exponents and to make generalizations. The bullets (4), (5) and (6) require of Signe, Tom and Hilde to sharpen and extend the conception of multiplication for positive integers to repeated multiplication, and in a longitudinal aspect, relate it to the new syntax and the function type exponentiation a^b . The example illustrates the technical gesture involved in using the artifact graphic calculator interplay and interacts with mathematical thinking. Technical gestures and conceptual aspects are intertwined and co-developed. The three first bullets on the component list have a more technical character, while the three last on the list have more conceptual characteristics.

CONCLUSION

The notion of instrumental genesis is suitable to analyze the process of the transformation of an artifact into an instrument in the hands of a user. Instrumentation schemes distinguish between utilization schemes and instrument action schemes. The former schemes concern activity directly linked to the artifact and functions as building blocks for the more global integrated schemes of instrumented action related towards the artifact (calculator) with the aim of carrying out a given task. Mental schemes describe both technical and conceptual

characteristics mediated by an artifact. In this case study we described an instrument action scheme concerning student-initiated exploration of the exponentiation key with the inscribed symbol \wedge on the key button of the graphing calculator. The component of the instrument action scheme was the theoretical lens to analyze observations of the student's gestures (techniques) when they mobilised the calculator by navigating and manoeuvring among keystrokes to perform the task $9^2 = 81$. The instrument action scheme also offers the researcher the opportunity to analyze the conceptual elements, the math concepts that are involved in students' activities when they are performing a task. This case study illustrates technical and conceptual aspects of the students' exploration activities concerning exponentiation, in terms of dialectical relationship, co-development and co-emergence.

NOTES

1. The mathematical operation exponentiation has not been introduced to the students at this academic level, and the associated function key was new to them.
2. According to Trouche (2003), a gesture is the observable part of usage scheme.

DEVELOPING A GENERAL FRAMEWORK FOR INSTRUMENTAL ORCHESTRATION

Michal Tabach

Tel-Aviv University

The need to understand teachers' actions as they teach mathematics in a computerized environment is greater than ever. A theoretical framework aimed at understanding teacher practice may help the research community guide practicing teachers in their struggle to integrate ICT into their teaching. The theory of instrumental orchestration is suggested as an appropriate lens for studying teacher practice. In the current study, instrumental orchestration types that have already been identified are examined in a variety of educational settings with the goal of further developing the theory from a critical point of view.

INTRODUCTION

Supporting mathematics teachers in their efforts to integrate technology into their daily practice remains a challenge for the mathematics education community. An essential step in meeting this challenge involves formulating a theory to describe teacher practice. Such a theory may then be used to inform and guide teachers in their efforts to integrate ICT successfully. Indeed, in 2004 Trouche introduced the notion of *Instrumental Orchestration* to describe teachers' need to support their students in the process of instrumental genesis. During the last eight years, Drijvers et al. and other researchers have further developed the notion of instrumental orchestration (Drijvers, Doorman, Boon, Reed & Gravemeijer, 2010; Drijvers, 2012; Tabach, 2011). Yet as technology changes, these already identified instrumental orchestration types need to be reexamined and possibly modified or extended accordingly.

The aim of the current study is to critically examine the instrumental orchestration types proposed by previous research. The analysis is based on classroom observations of 30 mathematics teachers who have faced the challenge and begun integrating technology into their mathematics teaching practice.

THEORETICAL BACKGROUND

The mathematics research community must develop ways to conceptually observe mathematics lessons in which teachers integrate technology as part of their everyday practice (Trouche & Drijvers, 2010). Pierce and Stacey (2010) proposed one such comprehensive framework, called *Mapping Pedagogical Opportunities*. According to this framework, ten pedagogical opportunities are clustered into three groups on a pedagogical map to reflect teacher practice: the *tasks* set for students; the *classroom interaction*; and the *specific subject* being taught. While this mapping enables

researchers to characterize the teaching practice of different teachers, it provides little information for teachers who wish to incorporate technology into their lessons.

The powerful theory of instrumental genesis can be used to characterize aspects of student learning in a computerized environment. Vérillon and Rabardel (1995) proposed this theoretical construct based upon empirical findings and used it to describe how computerized tools become instruments for students and how diverse this process can be. That is, individuals and groups from the same classroom who solve a given task using the same tools can employ diverse strategies (Artigue 2002; Mariotti 2002). When students begin to use computerized tools, they construct a schema regarding what these tools can and/or should do for them. This schema is strongly related to their initial experiences and beliefs, the perceived nature and goals of their activities, their dialogue with peers, and the results of spontaneous explorations and serendipitous discoveries. This is especially true when the initiative to use, or not use, the tool is left to the students and their needs. Vérillon and Rabardel (1995) defined *instrumental genesis* as the process by which individuals create and change their perceptions of a tool while performing different tasks. Instrumental genesis is considered a bidirectional process in which both tool and user change. Trouche (2004) referred to these two aspects of the process as *instrumentalization* and *instrumentation*.

Whole-class discussions orchestrated by the teacher (Trouche 2004) can serve as an appropriate forum for talking about and sharing students' personal instrumental geneses for the purpose of further enhancing them. Trouche "introduced the term *instrumental orchestration* to point out the necessity (for a given institution – a teacher in her/his class, for example) of *external steering* of students' instrumental genesis" (2004, p. 296, emphasis in the original). Instrumental orchestration also has a socio-cultural aspect (Laborde 2003; Lagrange et al. 2003), since the technological medium serves as a boundary object between teacher and students, where "mutual negotiation and meaning-construction is the norm for both sides" (Hoyles et al. 2004, p. 321).

Instrumented orchestration is defined by four components: a set of *individuals*; a set of *objectives* (related to the achievement of a type of task or the arrangement of a work-environment); a didactic *configuration* (that is to say a general structure for the plan of action); a *set of exploitations* of this configuration (Guin, Ruthven & Trouche, 2005, p. 208).

That is, while the didactical configuration refers to the arrangement of artefacts in the classroom, the exploitation mode includes "*decisions on the way a task is introduced and worked through, on the possible roles of the artefacts to be played, and on the schemes and techniques to be developed and established by the students* (Drijvers et al., 2010, p. 215)." The teacher prepares parts of his or her instrumental orchestration in advance, while other parts may emerge spontaneously during a lesson. That is, instrumental orchestrations have a time dimension that is related to didactical performance.

The theory of instrumental orchestration¹ does not suggest specific orchestrations. Nevertheless, several orchestration types have been identified based on empirical data from various studies (Table 1, left column including reference), so in this sense the categorization is not theoretically based. In all cases, open mathematical tools such as Dynamic Grapher or electronic spreadsheets were used in a computerized environment. For almost all orchestration types, the didactical configuration involves a whole-class setting in which the students sit facing one central screen.

	Didactical configuration	Didactical exploitation
<i>technical-demo</i> Drijvers et al., 2010	Whole-class setting, one central screen	The teacher explains the technical details for using the tool.
<i>Explain-the-screen</i> Drijvers et al., 2010	Whole-class setting, one central screen	The teacher's explanations go beyond techniques and involve mathematical content.
<i>link-screen-board</i> Drijvers et al., 2010	Whole-class setting, one central screen	The teacher connects representations on the screen to representations of the same mathematical objects that appear either in the book or on the board.
<i>Discuss-the-screen</i> Drijvers et al., 2010	Whole-class setting, one central screen	Whole-class discussion guided by the teacher, to enhance collective instrumental genesis.
<i>Spot-and-show</i> Drijvers et al., 2010	Whole-class setting, one central screen	The teacher brings up previous student work that he/she had stored and identified as relevant for further discussion.
<i>Sherpa-at-work</i> Trouche, 2004	Whole-class setting, one central screen	The technology is in the hands of a student, who brings it up to the whole class for discussion.
<i>work-and-walk-by</i> ² Drijvers, 2012	Students work individually or in pairs with computers	The teacher walks among the working students, monitors their progress and provides guidance as the need arises.
<i>not-use-tech</i> Tabach, 2011	Whole-class setting, one central screen	The technology is available but the teacher chooses not to use it.

Table 1: Orchestration types identified

In the current study the instrumental orchestration types suggested by previous research are examined critically. The following research question was examined in the context of the classrooms of practicing mathematics teachers who integrate technology into their practice: To what extent are the categories of instrumental orchestration identified thus far sufficient to characterize the teaching practice of these mathematics teachers?

METHODS

Participants and data collection

The teaching practice of 30 mathematics teachers was observed and served as data for the current study. All participating teachers volunteered to be observed as they taught. The teachers varied in terms of their years of experience as mathematics teachers (from 3 to 22 years). Note that although the participants were experienced mathematics teachers, they had much less experience using technology in teaching. In fact, at the time the observation took place, the teachers had between six months and five years of experience in integrating technology. The participants also varied in the grade levels they teach: seventeen teach in elementary schools (Grades 3-6), eight teach in middle schools (Grades 7-9), four teach in secondary schools (Grades 10-12), and one teaches adults (see Table 2). Half of the teachers work in Hebrew-speaking schools and the other half in Arabic-speaking schools.

Grade Level	3	4	5	6	7	8	9	10	11	Adults
Number of teachers observed	2	5	7	3	1	1	6	2	2	1

Table 2: Number of teachers observed per grade level

Each teacher was observed for three to four lessons in the same class with the same students, over the course of one month, at a time set in advance with each teacher at his or her convenience. All observed lessons were recorded and transcribed verbatim. For most of the observations a camera was placed at the back of the classroom on a tripod and remained stable throughout the lessons. In a few cases, the researcher used two modes of recording the lesson. During whole-class discussions the camera was placed at the back of the classroom, but while the students worked the researcher followed the teacher as she circulated among the students in order to record the interactions between teacher and students. Understandably, most teachers were not willing to accept such an arrangement, so it was not used in all cases.

Data analysis

Each of the lessons was divided according to the teacher's actions. The researcher looked for the eight identified orchestration types, while at the same time keeping in mind the option of identifying new orchestration types. The process of identifying

the orchestration types was not always trivial and was subject to the following methodological question: When can it be claimed that a particular orchestration type is a variant of another orchestration type? If the didactical configuration and the didactical exploitation of the teachers' actions are the same, we can identify this as the same orchestration type. Likewise, if the didactical configuration and the didactical exploitation differ, we can identify two different orchestration types. But what if only one of the characteristics has changed? In order to identify the orchestration as a variant, must we look for a fixed didactical configuration and allow only for variation in the didactical exploitation? Or is it didactical exploitation that is the core of the orchestration type, while variation in didactical configuration is less significant?

Trouche (2004), who proposed the *Sherpa-at-work* orchestration, pointed to the possibility that one student leads the work or several students consecutively lead the work. He analysed the situation as follows:

This orchestration favours collective management of a part of the instrumentation and instrumentalization processes: what a student does with her/his calculator – the traces of her/his activity – are seen by all, allowing the comparison of different instrumented techniques and giving the teacher information about the instrumented actions schemes being built by the Sherpa-student (p. 298).

Tabach (2011) identified a variant of *Sherpa-at-work* that differs in its didactical configuration. Many screens were used and many students carried out the same action on their screens, but otherwise the essence of the didactical exploitation was the same in terms of the discussion that evolved. Tabach also pointed to a variant of *discuss-the-screen* orchestration, in which many screens were observed as a didactical configuration rather than one central screen. Nevertheless, the exploitation mode, which is the core of instrumental orchestration, remained the same.

The following analysis adopts this same approach. That is, an orchestration type is considered new if it differs both in its didactical configuration and in its didactical exploitation. In cases in which the didactical configuration differs but the exploitation mode remains the same, the instrumental orchestration is considered a variant of its parallel type.

FINDINGS

The following describes the cases of three teachers. These teachers were selected to offer a range of ways to integrate technology into teacher practice, with May at one end of the spectrum and Noam and Rona at the other end. In the case of Rona, an additional element, called *monitor-and-guide* was identified, as was a new orchestration type.

May

May is an experienced teacher who has been teaching mathematics in elementary school for the last 21 years. The observations took place in a sixth grade class comprising 27 students of mixed abilities. The three lessons took place in a computer laboratory, in which each student, or pair of students, sat in front of one computer and worked on various applets. The students worked at the computers for the entire duration of the three observed lessons, while the teacher circulated among them and provided assistance as needed. In this sense all of the lesson time was devoted to the *monitor-and-guide* orchestration type.

The researcher observing May's classroom followed the teacher with the video camera throughout the lessons, making it possible to further elaborate the orchestration types May used. Each lesson began with a variant of *technical-demo* orchestration, during which the teacher helped students enter the learning environment by providing passwords, checking for internet connections, and solving other technical problems. About 20% of the class time was devoted to this type of activity. The orchestration type used during the major part of the lessons (45% of class time) was a variant of *discuss-the-screen*. The teacher engaged in mathematical discussions with a student or a pair of students, at their request. In some cases, this orchestration type was followed up by a variant of *link-screen-board* or *not-use-tech*, mainly when May referred to students' notebook to clarify a mathematical point. These variants of the two orchestration types were used for about 10% of the class time. For the remainder of the time, the teacher walked around the classroom and monitored students' actions.

May's avoidance of any whole-class discussion during the observed lessons was puzzling, as the computer laboratory included a projector and a screen on which data could be projected. During an informal after-observation interview with May, she indicated that she did not know how to use the data projector and did not want to admit this lack of knowledge to her students.

Noam

Noam is an experienced teacher who has been teaching mathematics in elementary school for the last 17 years. The observations took place in a fifth-grade class comprising 30 students with mixed abilities. For the last five years Noam has been integrating technology into her teaching practice. The observations in Noam's classroom were by static camera only. Hence, we do not have a complete record of student-teacher interactions that were not part of the whole-class forum.

In the three observed lessons, a regular pattern emerged in Noam's orchestration actions. She began with *technical-demo* orchestration and then moved on to *explain-the-screen* orchestration. Next she alternated between *link-screen-board* and *discuss-the-screen*. She then returned to *technical-demo* or *explain-the-screen*, and she always finished with *monitor-and-guide* orchestration. In terms of time spent, about

a third of the lesson time was devoted to *monitor-and-guide*, another third to *discuss-the-screen*, and the rest of the time was distributed almost equally among the other orchestration types.

Noam considers the computer to be a tool that helps her offer her students more diverse teaching and allows her to allocate her time to working with individual students who need more assistance. The learning management system allows her to monitor student work and identify students in need of further instruction.

Rona

Rona is an experienced teacher who has been teaching mathematics in elementary school for the last 11 years. The observations took place in a fifth-grade class comprising 30 students with mixed abilities. For the last three years Rona has been integrating technology in her teaching practice, encompassing the entire learning environment. The researcher observing Rona's classroom followed her around with the camera, so we have a record of the interactions between the teacher and her students.

The two double lessons (90 minutes each) that were observed took place in the students' regular classroom. Two student aides brought 20 laptops to the classroom on a wheeled cart and distributed them among the students. During this first phase of the lessons, which took about 9 minutes in each lesson (10% of the lesson time), the teacher led a whole-class discussion about the use of technology. This type of orchestration has not yet been identified. We named it *discuss-tech-without-it* to reflect the fact that possible uses of technology may be discussed even when the technology is not present.

The organization phase was followed by a similar lesson structure. The teacher used a mixture of *explain-the-screen* and *discuss-the-screen* orchestration in a way that did not allow the two types to be separated. Next she used *monitor-and-guide* orchestration while acting in one of three ways: answering technical problems - a variant of *technical-demo* orchestration; explaining the screen to a student or a pair of students - a variant of *explain-the-screen* orchestration; or monitoring students' progress via a learning management system that enabled her to monitor the individual progress of her students. In other words, *monitor-and-guide* orchestration may include an electronic element, in which the teacher may interact with students from a distance by sending messages rather than physically approaching students in need.

This sequence of orchestration types was repeated at least twice during the lesson. In addition, during the second lesson, the teacher used the *spot-and-show* orchestration type at the beginning of the lesson to clarify a homework problem that had been submitted to her via the learning management system.

DISCUSSION

The following question framed the current study: To what extent are the instrumental orchestration categories identified thus far sufficient to characterize the teaching practice of practicing mathematics teachers? The study examined the teaching practice of three experienced elementary school teachers (5th and 6th grades) via the instrumental orchestration lens. Notable differences were observed between the practice of May, a novice in integrating technology, and that of Noam and Rona, who were more experienced in using technology. A possible explanation for this notable difference between their practices lies in their technological pedagogical content knowledge (Mishra & Koehler, 2006). May's lack of technological knowledge limited her actions. It may possibly also have limited her ability to support her students' instrumental genesis process in particular, and their learning in general.

Yet May did use variants of the central orchestration types that involved interactions with students on an individual basis. Similar findings were reported by Drijvers (2012), who studied the practice of an experienced 12th grade teacher who was a novice in integrating technology. This teacher employed the *monitor-and-guide* orchestration type [there referred to as *work-and-walk-by*, as explained in endnote 2], which was further broken down according to the type of discussions taking place between teacher and students. Thus, variants of the orchestration types *explain-the-screen*, *discuss-the-screen*, *technical-demonstration* and *link-screen-board* were identified on an individual basis.

The practices of Noam and Rona were similar in terms of their clear pattern of lesson structure, as can be seen in the relatively stable sequence of instrumental orchestration actions in each of their lessons. Both employed a variety of orchestration types, which the two teachers sequenced in a similar manner. Drivers et al. (2010) reported the same sequences of orchestration types.

An additional orchestration type was identified in the practice of one of the observed teachers: *discuss-tech-without-it*. This new type emerged as a result of observing and analysing technological environments that have not been reported so far. The type refers to a special didactical configuration in which learning does not take place in a computer laboratory or with laptop computers owned exclusively by each student. Bringing laptops to the classroom on a wheeled cart enables the school to make use of any classroom as a potential host for mobile computers. Furthermore, the teacher's use of a learning management system demonstrates an electronic element in the *monitor-and-guide* orchestration.

Identifying a teacher's instrumental orchestration actions enables us to learn about his or her practice. We do not claim that *all* the instrumental orchestration types have already been identified. On the contrary, we hypothesize that as technology changes, new types of instrumental orchestration may begin to emerge. Some of these may be considered variants of already identified types, while others will be new. And yet, as

the three cases discussed above demonstrate, identifying instrumental orchestration types offers a window into a teacher's classroom base practice. This window needs to be expanded by analyzing teachers' knowledge as well. The extent to which categorizing instrumental orchestration types can be used to inform the practice of novice mathematics teachers still remains to be studied.

NOTES

1. The notion of instrumental orchestration should not be confused with the notion of documentation genesis (Gueudet & Trouce, 2009). Although both notions stem from the instrumental approach and both focus on the teacher, documentation genesis includes the documentation work of the teacher outside of the class, while instrumental orchestration focuses mainly on teacher practices in the classroom. Still, the two notions do somewhat overlap, as documentation also refers to a *usage* component and orchestration also refers to a planning element.
2. The term *work-and-walk-by* was suggested by Drijvers (2012). However, in this study we refer to this as *monitor-and-guide*, which refers to the teacher's actions and hence is more appropriate here. I wish to thank Håkan Sollervall for this insightful suggestion.

THE IMPACT OF THE INVOLVEMENT OF TEACHERS IN A RESEARCH ON RESOURCE QUALITY ON THEIR PRACTICES

Jana Trgalová*, Ana Paula Jahn**

*Claude Bernard University, Lyon, France, **UNESP, Guaratinguetá, Brasil

Since four years, a group of seven secondary school mathematics teachers and teacher educators has been involved in a research project dealing with the issue of dynamic geometry resource quality. The aim of this paper is to examine the impact of this involvement on their practices both as teachers and teacher educators. Based on the analysis of various resources produced by the group members before their participation in the research and nowadays, as well as on the group's auto-analysis of the evolution of their own practices, we could highlight a significant evolution in their way of using dynamic geometry in a classroom, as well as in their teacher training offer and content.

Research in mathematics education we carry out relies mostly on participatory methodologies, such as design-based research (DBRC 2003), which involve researchers and practicing teachers who are not mere experimental subjects, but they take an active part in all phases of the research. Like in other research projects, the focus is on the research itself and its outcomes and the issue of the teachers' professional development fostered by their participation to the research is not raised.

The question how the teachers' involvement into a research contributes to their professional development is central (Burns 2010). We report about an experience of a research group composed of three mathematics education researchers and seven secondary school math teachers (called DG-group in the sequel) working on dynamic geometry (DG) resource quality issues. We attempt to highlight the impact of the teachers' involvement into this research on their practices.

The paper is organised as follows. First, we briefly describe the research project on DG resource quality that gathered together researchers and teachers. This project will be referred to as I2G project. Next, we present the theoretical framework and the methodology we used to examine the impact of the teachers' involvement in the I2G project on their practices. Finally, we discuss the most significant findings and propose some concluding remarks.

I2G PROJECT

The I2G project, which ran between September 2008 and June 2012, was conducted in the framework of the Intergeo European project [1], aiming at developing a community of DG users all over Europe around an open web-based repository [2] specifically designed for sharing resources and practices related to the use of DG in mathematics teaching. In order to help platform users identify suitable resources regarding their instructional aim and context of use, as well as to allow the available

resources to be improved, two main tools have been developed and implemented into the repository: a search engine based on mathematical notions and competencies ontology to help searching for relevant resources, and a resource quality review questionnaire helping the users analyse available resources and highlight aspects to be improved. Three mathematics education researchers and the DG-group were in charge of designing and testing the questionnaire. In the next section, we present the questionnaire and its design process, focusing on the roles of the researchers and the teachers involved in the I2G project.

Design of the questionnaire for DG resource analysis

The questionnaire, which is the main tool for the resource quality assessment in the repository (Fig. 1), was designed in a cyclical process consisting in the elaboration of its successive versions, followed by their tests and subsequent improvements.

Figure 1: Online questionnaire for reviewing a DG resource in the i2geo repository

This methodology can be considered as a *design-based research*, in which “development and research take place through continuous cycles of design, enactment, analysis, and redesign” (DBRC 2003, p. 5), blending theory-driven design with empirical research. The first version of the questionnaire was designed by the researchers drawing on research results related to the use of DG in math

teaching and learning. It proposed eight general questions related to the dimensions of a DG resource considered as critical with respect to its quality, such as technical aspect, mathematical content validity, instrumental aspect, and didactical and pedagogical implementation. Later, a ninth dimension related to the resource ergonomics has been added. Each of these questions can be developed into a set of more detailed criteria related to the corresponding dimension (Fig. 1). The theoretical considerations underpinning the choice of the dimensions and the definition of the criteria are exposed in some details in (Trgalová *et al.* 2011).

In order to make the questionnaire accessible to and usable by teachers, its elaboration has been done in a close collaboration with seven secondary mathematics teachers (DG-group), according to the schema in Fig. 2. Each version of the questionnaire was first reviewed by the DG-group who provided suggestions related to the relevance and the clarity of the quality criteria. An improved version was then tested with teachers in various contexts, such as pre-service or in-service teacher training programs or workshops (Jahn *et al.* 2009, Trgalová *et al.* 2011, Trgalová & Richard 2012). The questionnaire was then re-designed to take into account the outcomes of the tests.

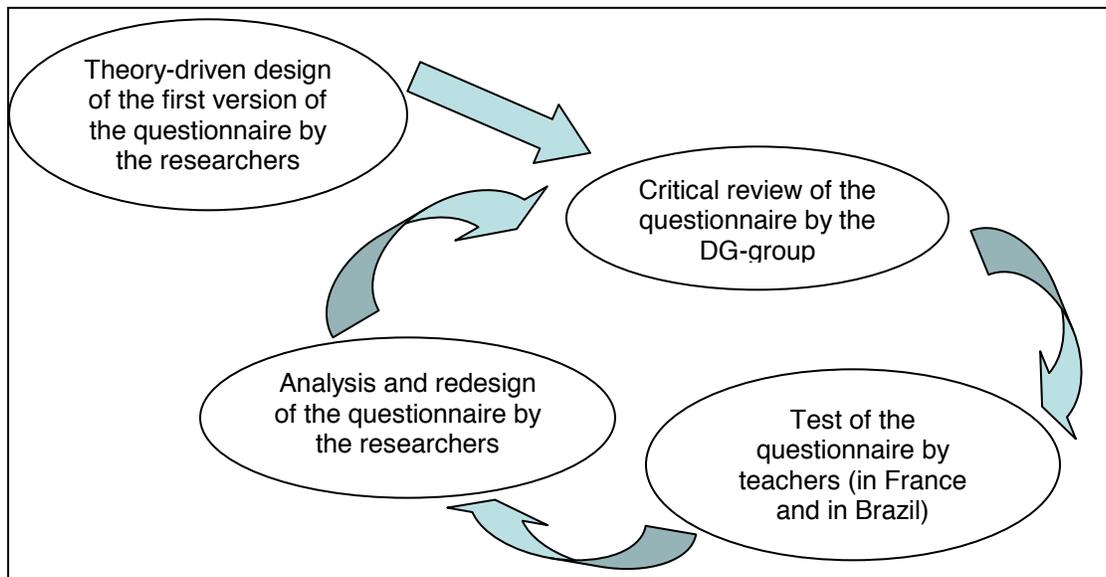

Figure 2: Schema of the resource quality design methodology

As it can be seen in the Figure 2, the teachers from the DG-group played an important role in the I2G research project and contributed to it significantly. During the last year of the project, we became naturally interested in what was the benefit of the teachers' involvement in the project in terms of their professional development. Below we outline the methodology and the theoretical background of this study

METHODOLOGY

The teachers from the DG-group started collaborating in 1996 within the Institute for Research in Mathematics Teaching in Lyon [3] as a group of “users and designers of DG resources” (Bourgeat *et al.*, 2013). In 2008, the group volunteered to join the

I2G project and it collaborated until recently with math education researchers on the DG resource quality issues. Every year since 2003, the group offers training courses aiming at helping other math teachers master and integrate DG systems into their practices. All group members prepare together their courses during their regular meetings and produce various resources (documents, tools...), although only two or three of them, in turn, are in charge each time of the implementation of the courses.

For lack of possibility to set up a long-term observation of classroom and teacher training practices of the DG-group members, we gathered three kinds of data in order to identify possible evolutions of their practices. First we collected teacher training resources the group has produced since 2003. Second, recently the group was asked to reflect on changes in their own practices that the group members could observe since their involvement in the I2G project. This introspective activity, conducted during an informal interview with the teachers and summarized in the form of a workshop communication (Bourgeat *et al.*, 2013), yielded many interesting observations related mostly to the teaching practices, some of which are reported in this paper. Finally, we have analyzed some of the teachers' reviews and comments of resources in the Intergeo platform, which can also shed light on their practices with using DG in math teaching.

THEORETICAL LENS USED TO ANALYSE THE DATA

In the collected data we wished to observe indicators of the evolution of the teachers' practices with using DG in their teaching math or teacher training, as well as indicators of the changes in their sensitivity to teacher training issues. This concern led us to choose the following theoretical frameworks.

Instrumental approach and double instrumental genesis

Numerous research studies on the information and communication technologies (ICT) integration adopt the *instrumental approach* (Rabardel 2002) as a theoretical framework specifically designed for studying teaching and learning phenomena involving technology. The instrumental approach relies on a distinction between an *artefact*, a tool available to an individual, and an *instrument*, which is the result of a process of appropriation of the tool by the individual when s/he uses it in order to achieve a given task. The process of transforming an artefact into an instrument is called *instrumental genesis*. Some of these studies stress the complexity of technology integration, which requires a *double instrumental genesis* in teachers: a first genesis of an instrument for achieving mathematics tasks, and a second one of an instrument for achieving educational tasks (Acosta 2008). Haspekian (2011) evokes a *personal genesis* transforming a given tool into a *mathematical instrument*, and a *professional genesis* transforming it into a *didactical instrument*. According to Trouche (2004), the ICT integration requires from the teacher to be aware of the potentialities and constraints of artefacts, which is necessary to design suitable mathematical tasks. Moreover, the teacher has to be able to implement these tasks

into the classroom and to foresee the spatial and temporal classroom management. The author introduces the term *instrumental orchestration* to refer to the didactical management of the artefact in a classroom. Drijvers *et al.* (2011) define the instrumental orchestration as

“the intentional and systematic organisation and use of the various artefacts available in [a] computerised learning environment by the teacher in a given mathematical task situation, in order to guide students’ instrumental genesis” (p. 1350).

These considerations will frame our analysis of the teacher training resources produced by the DG-group. We will look for elements in these resources showing whether the group is aware or not of the necessity of the double instrumental genesis in teachers wishing to integrate DG. We will also try to highlight the way the group orchestrates DG activities both in math classroom and in teacher training.

Potentialities of dynamic geometry

A dynamic geometry environment is computer-based software that allows the user to create geometrical figures and manipulate them into different shapes and positions by dragging their elements, mostly points. One of the distinctive features of DG is that when dragging, the geometrical properties of the figure defined in its construction are preserved. Three main modalities of dragging have been identified in the literature (Baccaglioni-Frank & Mariotti 2010, Healy 2000, Laborde 2001, Arzarello, Olivero, Paola & Robutti 2002): (1) *dragging for verifying* consists in dragging to check the presence of the supposed (known) geometrical properties in the figure. According to Hölzl (2001), uses of DG are often limited to this modality, in the sense that students are expected to drag figures to confirm empirically the properties which are more or less given; (2) *dragging for conjecturing* consists in dragging to look for new properties of the figure through the perception of what remains invariant when dragging; (3) *dragging for validating/invalidating* consists in dragging to check whether the constructed figure preserves its geometrical properties when dragging.

In the analysis of the DG-group resources we will focus on the modalities of dragging in the activities it proposes and especially whether there are changes in the teachers’ perceptions of the role of dragging.

DATA ANALYSIS

The analysis of the collected data shows a significant shift in the practices of the DG-group teachers in three main aspects. The first two are related mostly to their practices as mathematics teachers, the third one to their practices as teacher educators.

Modalities of dragging

Relying on the teachers’ auto-analysis of their own practices before and after their involvement into the I2G project (Bourgeat *et al.*, 2013), it appears that with their

students, the teachers used DG mostly to obtain robust constructions aiming at highlighting invariants in geometric figures:

“Yesterday, obtaining robust geometric constructions and highlighting invariants were the main goals assigned to students: they should construct a figure by using known properties [...] which they could validate by the invariance of the figure when dragging.”

Nowadays, they propose new types of activities in which they ask students “to explore figures in order to highlight invariants and/or conjecture new properties” (ibid.). The teachers seem to have acknowledged the importance of dragging for conjecturing in students learning and they thus propose various and richer tasks using different modalities of dragging.

The following comment [4], written by one of the DG-group members about a resource in the repository illustrating, with a robust construction, the equality of three ratios in a triangle with a parallel line to one of its sides, shows her awareness of the interest of soft constructions in geometry learning:

“Several improvements are possible: 1. [The point] N can be set free, which will allow visualizing the difference between the case proportional-parallel and the cases where the ratios are not equal”.

Although it is difficult to establish a direct link between the questionnaire and the evolution of the teachers’ awareness of the DG contributions to the teaching and learning geometry, we can suppose that the numerous discussions about this issue, that eventually led to the definition of criteria related to the added value brought by DG to the math activity, are at the origin of this evolution.

Instrumental orchestration

Regarding the classroom management, the teachers confess to have struggled to combine phases of students’ work on computers in a computer lab with collective phases of debate, which often needed to be postponed until the next session in an ordinary classroom, as they say (ibid.):

“Before, the activities with ICT took place in a computer lab in the conditions that postponed the debate and the students-teacher interactions regarding their observations and manipulations in a digital resource.”

Nowadays, the teachers orchestrate their ICT-based lessons in a more effective way: the use of a video projector allows articulating individual and collective phases. Indeed, the teachers say: “[Now] we observe the interactions in a genuine triangle “students – teacher – digital resource” (ibid.).

This shift can certainly be related to the pedagogical implementation of the resource, one of the nine aspects that we consider critical for determining the resource quality.

Awareness of the double instrumental genesis

The analysis of the teacher training resources produced by the DG-group reveals that the training programmes the group proposed before 2007, i.e. before its involvement into the I2G project, aimed mostly at helping trainees to master DG system tools. The training activities consisted in series of exercises to solve with DG chosen to illustrate the use of a particular DG tool. Figure 3 shows a typical training activity: the trainees would solve the exercise and indicate what DG tools they have used.

Exercise n°4:

- Given a segment $[AB]$, construct a square with $[AB]$ as a side.
- Given a segment $[AB]$, construct a square with $[AB]$ as a diagonal.
- Construct a square with a side $[AB]$ without using « parallel line » and « perpendicular line » tools.

N.B. For each question, verify that the construction remains stable.

Figure 3: Example of a teacher training activity proposed by DG-group in 2005

The focus of the teacher training programmes in this period was clearly on technical aspects of mastering a DG environment. In terms of instrumental genesis, the DG-group accompanied trainees' personal geneses of mathematical instruments.

Since 2009, the DG-group teacher training proposals show a significant shift towards considering didactical and pedagogical aspects of DG integration. Indeed, in a training programme proposed in 2009, the group announces the following objective: "The aim of this training programme is to accompany the teacher wishing to take her/his students to a computer lab". After a short phase of solving exercises aiming at getting acquainted with the main DG tools, the trainees are invited to reflect on activities suitable for the DG use, the goal being to bring forward the following aims: introduce a new mathematical concept, construct figures, and put students into a research activity with DG. After having solved a given exercise with DG, the trainees are asked to explore it in light of a possible implementation in a classroom: envisage possible adaptations, anticipate classroom management. Figure 4 shows a training resource, in which the two phases, solving an exercise and exploring it from didactical and pedagogical points of view, are present.

3. Studying polynomials

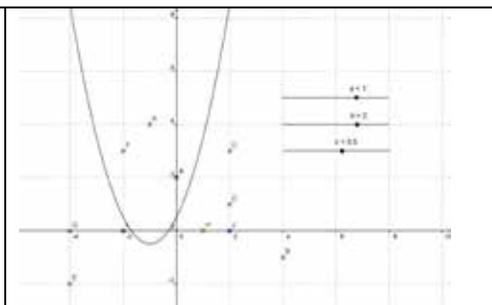

3.1. Relationship between graphical representation and expression of a first and second degree function

The trainees open the file « stage1-exo-fct.ggb »

They are given the document « stage1-exo-fct.odt »

Let the trainees solve the exercise.

Ask them to reflect on possible adaptations for a Grade 11 classroom for the next training day.

2nd day: exploitation of the exercise 3.1 solved during the first day: Ask for possible adaptations. A specific attention should be paid to the method used by the students (successive trials without the properties). The need to review this point with them... how? How to manage this activity?

Figure 4: Excerpt of a training plan elaborated by the DG-group in 2011

The trainees are also led to create their own activities related to a math domain of their choice and adapted to the level of their class. They have to specify the teaching goals and envisage the classroom implementation of the activity.

The DG-group has developed specific resources to help the trainees with this task, such as a description sheet of a session using DG (Fig. 5) or a checklist with questions to ask before using ICT in a classroom, e.g., when to use ICT, do the ICT contributions favour students' learning, or how to integrate an ICT session into an ordinary teaching sequence.

Figure 5: DG session description sheet

These elements show that the DG-group has gotten awareness of the necessity to assist the trainees' professional instrumental geneses so that they can transform DG software not only into a mathematical instrument, but also into a didactical one. Moreover, the resources produced by the group entail signs of the influence of the quality questionnaire, namely considerations of several dimensions such as contributions of DG, didactical exploitation of DG potentialities or instrumental orchestration. This seems to confirm a highly positive impact of the DG-group involvement into a design of DG resource quality questionnaire.

CONCLUSION

In this contribution, we reported about a research on the issue of DG resource quality, conducted by a mixed group of math education researchers and in-service teachers. We attempted to show a positive impact of this collaboration on the teachers' practices both as math teachers and teacher educators. Regarding the use of

DG in their classes, we observe significant changes in the nature of tasks the teachers propose to their students: these are richer and more challenging, asking the students to explore figures and conjecture properties, rather than just verify supposed or known properties or validate robust constructions. The teachers are also able to envisage more productive instrumental orchestrations allowing a genuine integration of DG in their math classes. As teacher educators, the group seems to be now much more sensitive to didactical and pedagogical questions related to the DG integration than before. Initially, it focused mostly on technical aspects of mastering DG software, thus accompanying trainees' instrumental geneses yielding a mathematical instrument, whereas nowadays, its programmes include activities allowing the trainees to develop a didactical instrument as well.

TESTS AND EXAMINATIONS IN A CAS-ENVIRONMENT – THE MEANING OF MENTAL, DIGITAL AND PAPER REPRESENTATIONS

Hans-Georg Weigand

University of Wuerzburg (Germany)

Digital technologies (DT) face new challenges in working with representations in mathematics classrooms and especially while using them in written tests and examinations. There are unexpected solution strategies of students which are not represented in an adequate – student expected – way, there are – beyond the mathematical competencies – tool competences necessary, and working with handheld technology causes the additional problem that the documentations of solutions have to be fixed on paper representations. Moreover, the student has to manage the interrelationship between her or his mental representations, the digital or tool representations and paper representations. How should the paper documentations look like to give the corrector the chance to track the work of the students? In the following authentic written exam, problems and authentic student solutions in a handheld computer algebra system (CAS) environment are analyzed. Finally criteria for documentations of paper solutions of exam problems are developed.

Keywords: digital technologies, examination, assessment, representation, documentation, computer algebra system (CAS), experimental investigation

REPRESENTATIONS AND DIGITAL TECHNOLOGIES

Digital technologies (DT) open new chances and new ways for the use of representations in mathematics education. DT especially simplify generating representations on the computer screen, they emphasize the experimental working by easily changing parameters, and they give access to the simple use of multiple representations. But there are also difficulties and obstacles while working with digital representations. The speed of the creation of screen representations may overcharge the mental abilities of the user, the interrelationship of different representations has to be developed by the user, and the question of the relationship between the traditional working with paper and pencil and with digital representations arises.

There is a long-standing and on-going debate about the meaning of digital representations in mathematics education (e. g. Guin, Ruthven & Trouche, 2005; Ainsworth, 2006; Ladel & Kortenkamp, 2009). Opportunities and problems are already discussed in the 1st ICMI study about DT: The Influence of Computers and Informatics on Mathematics and its Teaching (Churchhouse, 1986), it is an essential aspect of many ICMI activities in the last 25 years (Laborde & Sträßer, 2010), and it is still of essential meaning in the latest 17th ICMI study: Mathematics Education and Technology – Rethinking the Terrain (Hoyles & Lagrange, 2010).

There is not much known about the interrelationship between these different kinds of representation while working with digital technologies in a test or examination environment. There is a huge section (p. 81-284) “Learning and assessing mathematics with and through digital technologies” in the 17th ICMI Study, but it is about theoretical frameworks about learning with DT, changes in mathematical knowledge and practices resulting from access to DT, learning trajectories, automatic assessment and social learning, and it does not give answers to questions concerning the influence of DT on tests and examinations in the classroom. Especially, the use of DT in assessments and examinations is not explained in the frame of empirical investigations or in analyzing students’ work in examinations.

THE LONG STANDING SYMBOLIC CALCULATOR M³-PROJECT

A long-term project (2005–2012) was started to test the use of symbolic calculators (SC [1]) in Bavarian grammar schools (“Gymnasien”) in Germany in grades 10 to 12 (the M³-project [2]). The students are allowed to use SC in class, for their homework and in all tests and examinations (see Weigand & Bichler 2010a, 2010b).

The results of the evaluation of some tests in these classes showed that students in the project classes still have – also after one year of SC usage – difficulties in using SC and (*problem-*) *adequate representations* especially, as well as the *documentation of the solution* with paper and pencil. In a questionnaire at the end of the school year, nearly 40 % of the students in the project classes reported to have difficulties in using the SC, many students assigned these to “technical difficulties”. But from interviews with and video studies from students, we learned that the real reasons for these difficulties are quite often on the mathematical and not the technical side. Students do not know how to use representations and how to get some information out of them.

In May 2010 the first final baccalaureate examination was given to the students at the end of school time in grade 12. In Bavaria, the baccalaureate is a state-wide examination with the same problems for all students, given by the ministry of education.

EXAMPLES FROM THE M³-PROJECT

In the following we concentrate on two main aspects of the above mentioned difficulties: how to choose the adequate representation in a problem solving process and how to document the solution of a problem. We will explain these aspects and difficulties in the frame of test and examination problems and authentic student solutions of these problems.

Adequate representations

A representation may be considered as *adequate*, if it represents situations or helps to solve problems the way one wants. In fact, representations always have to be considered in connection with possible and appropriate operations. The following example is taken from a test written in 10th grade.

Example 1: Given are f and g with $f(x) = \sin(x) + 1$ and $g(x) = 2^x$. How many intersection points have the graphs

- a) in the interval $[10; -10]$ and
b) for $x \in \mathbb{R}$? Give reasons.*

Solving this equation on the symbolic level with the SC gives the result (Fig. 1):

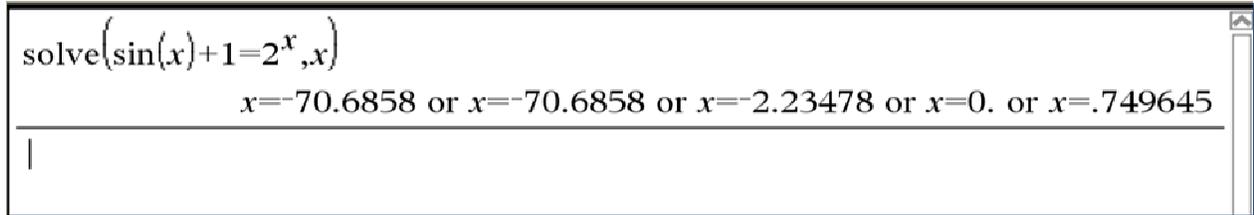

Figure 1: A warning sign appears in the display: “Some more solutions may exist”.

It is quite difficult – for students (nearly) impossible – to interpret this display’s numeric solution. Changing to the graphic screen and zooming into interesting sections is a good strategy. This gives the following graphs:

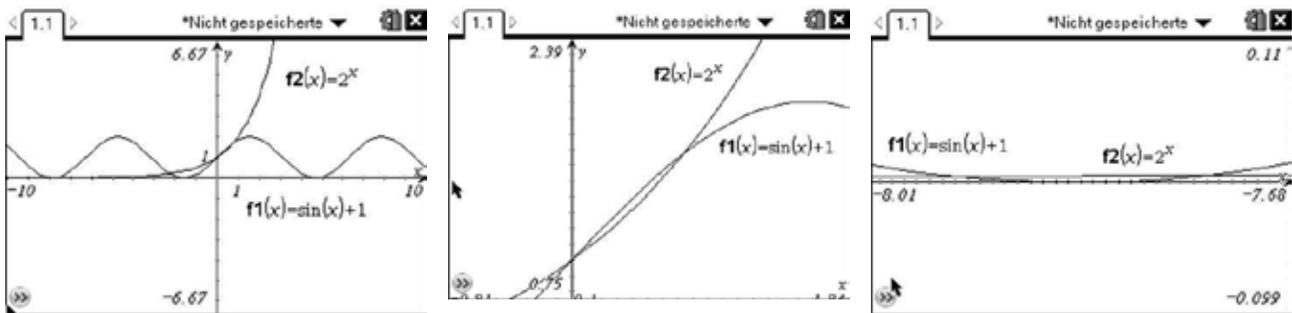

Figure 2: Screen shot of the functions with $f(x) = \sin(x) + 1$ and $g(x) = 2x$.

Indicating the “interesting sections” and interpreting the graphs – for the area $x < 0$ – require advanced basic knowledge of the properties of the sine and the exponential function. The solution – an infinite number of intersection points – cannot be obtained from the calculator screens, it has to arise from the basic knowledge concerning the implied *mental representation* of the functions. 30 % of the students are able to solve the problem 1 a), but less than 5 % are able to solve the problem 1 b) with the general domain $ID = \mathbb{R}$.

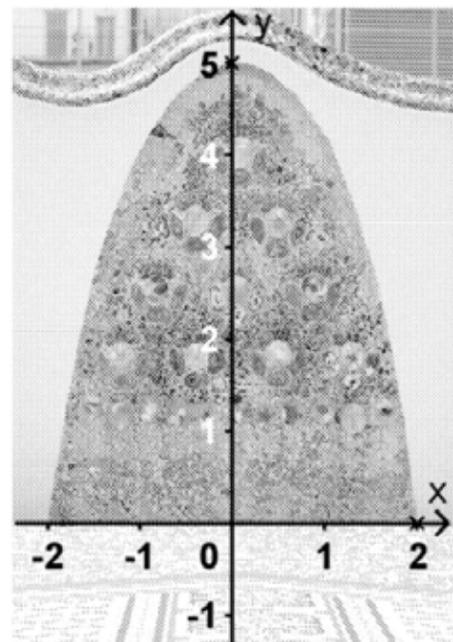

Figure 3: The art work of Gaudi

Unexpected digital representations

The following problem is from the final baccalaureate examination in Bavaria in May 2012. The text is given here only in a short form.

Example 2: A ceramic art in the Casa Batlló (see Fig. 3) has roughly the shape like a parabola.

- Give a model of the shape of the upper prim of the art work by using $q(x) = ax^4 + bx^3 + cx^2 + dx + e$
(For control: $q(x) = -0.11x^4 - 0.81x^2 + 5$)
- ...
- The line g is parallel to the x -axis and divides the work of art into two sections. The area of the above part should be 71.5 % of the whole area.

We concentrate only on the problem c). The situation shows the following screenshot (Fig. 4). You first have to calculate the integral of q from -2 to 2 (Fig. 5).

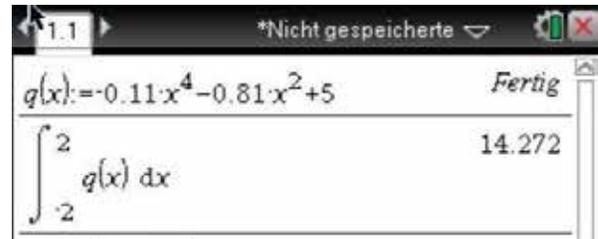

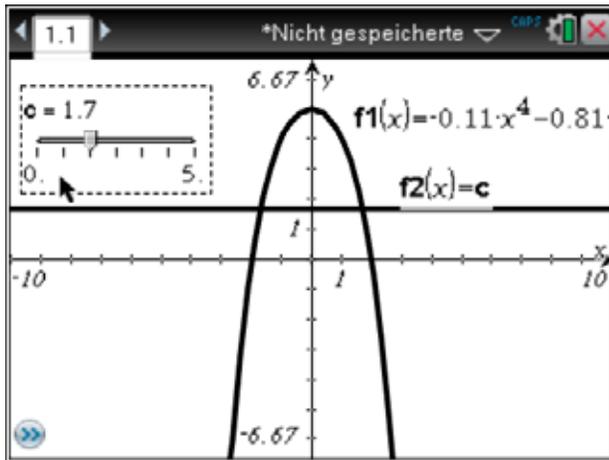

Figure 4: The graph G_q and the parallel line **Figure 5: Calculation of the integral**

If you solve the equation $q(x) = c$ you get – with the handheld TI-Nspire – the following result (Fig. 6).

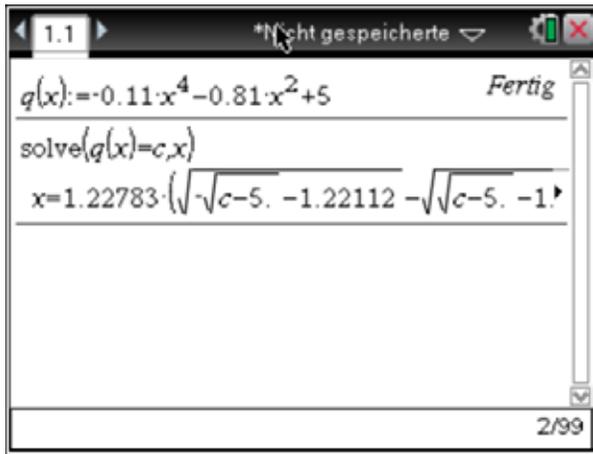

Figure 6: Solution with the TI-Nspire

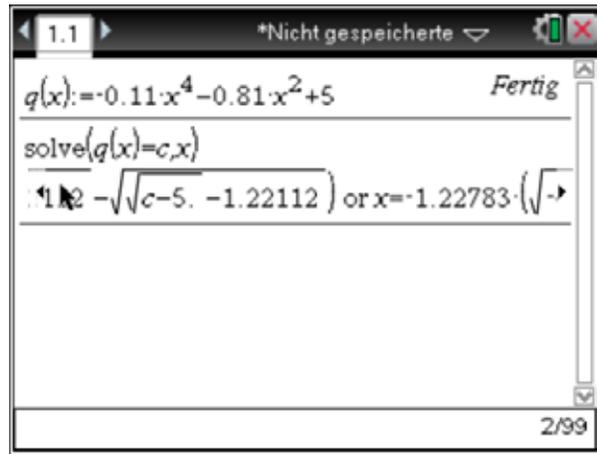

Figure 7: Scrolling right

The small triangle at the right side of the last line of the screenshot shows that the formula is not finished at the end of the screen. Scrolling to the right shows a surprising long line (Fig. 7). It is impossible – not only for students – to interpret this result. But also with a laptop representation (which was not available for the students in the exam), the result stays confusing (Fig. 8).

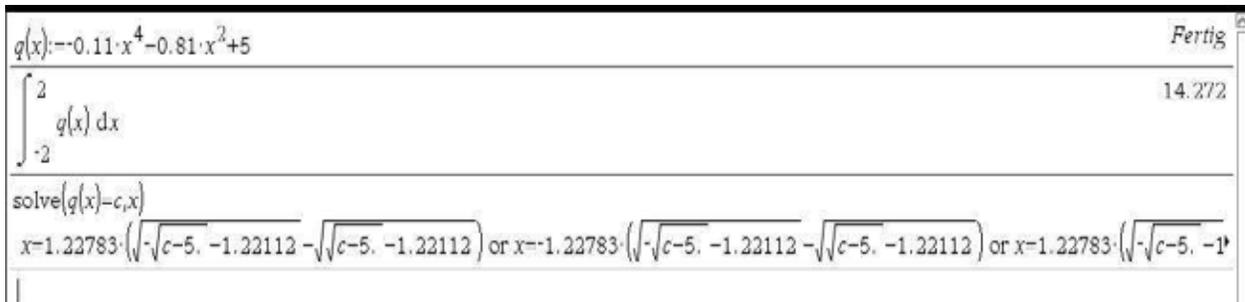

Figure 8: Solution with the TI-Nspire Notebook Version

Moreover, you see that the expression $\sqrt{c-5}$ in all solutions shows that there seems to be no real solution for $c < 5$, which is obviously wrong, because there exist two real solutions for $0 < c \leq 5$ (Fig. 4).

This example shows the problems that occur if the problem poser had another solution in mind and did not think of different solution strategies.

The documentation of solutions

Quite often – especially in written tests and examinations – the solution of a problem has to be documented on paper. This opens the question concerning the *adequate documentation form* of the solution on paper.

Example 3: Given is the function f with $f(x) = (x - 2)^2 + 3$. Determine the equation of the tangent in the point $P(1/4)$.

The following examples give some students' solutions and show different documentations. The underlining shows the use of the handheld device of the student during the problem solving process.

$y = m \cdot x + t$
 $f'(x) = 2x - 4 \left(\frac{d}{dx} (x-2)^2 + 3 \right)$
 $f'(1) = -2 \rightarrow m = -2$
 $4 = -2 \cdot 1 + t$
 $\rightarrow \text{solve } (4 = -2 \cdot 1 + t, x) \rightarrow t = 6$
 $y = -2 \cdot x + 6$

Figure 9a: A student solution quite similar to a paper and pencil solution

$\text{tanLine}((x-2)^2 + 3, x, 1) \Rightarrow y = -2x + 6$

Figure 9b: A student solution using a handheld command

Gleichung Tangente = $-2x + 6$
 main menu $f(x) = (x-2)^2 + 3$ ableiten mit diff
 grafik menu analyse - skizze - tangente
equation tangent = $-2x + 6$
main menu $f(x) = (x-2)^2 + 3$ differentiate with diff
graphic menu analyse - sketch - tangent

Figure 9c: A student solution and the English translation

You might be content with the solution 9a, the solution 9b might be accepted in a DT-environment, but it needs a special knowledge about DT-commands. But – for sure – you will not be content with the solution 9c!

Example 4. Give a sketch of some graphs of f_a with $f_a(x) = ax^3 - 3x + 1$, $a \in \mathbb{R}$. There are still some reasons why it might be useful or helpful to do a sketch of a graph (also) by hand, especially in relation with heuristic problem solving strategies. The question about the function and the expected accuracy of hand sketches arises. Fig. 10a and b show a screenshot and a student's hand draft of graphs of a family of functions. Even for heuristic reasons the hand draft does not fit to an expected accuracy and for sure it is not accepted as a solution of example 4.

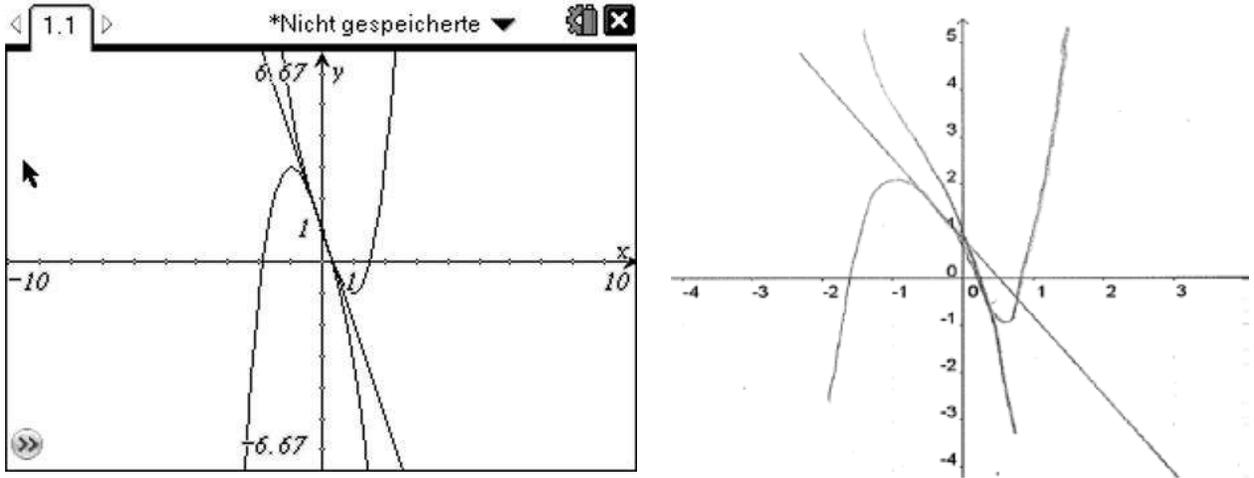

Figure 10: (a) Digital and (b) hand graphs of f_a with $f_a(x) = a \cdot x^3 - 3x + 1$ for $a = -1, 0, 1$

EXAMPLES FROM THE FINAL BACCALAUREATE EXAMINATION

The following example is also from the final written baccalaureate examination in Bavaria in May 2012.

E. 5: Given is the family of functions defined in \mathbb{R} , $f_a: x \rightarrow \sin(ax)$ with $a \in \mathbb{R} \setminus \{0\}$.

a) Give two values of a , such that all zeros of f are integers.

b) Now $a = 2$. Calculate $\int_1^b f_2(x) dx$; b is the smallest zero of f_2 which is bigger than 1. Give a value $c \in \mathbb{R}$ with $c > b$, such that $\int_1^c f_2(x) dx = \int_1^b f_2(x) dx$. Give reasons for your answer using the graph of f_2 .

With the use of DT the solution of example 5b might look as follows:

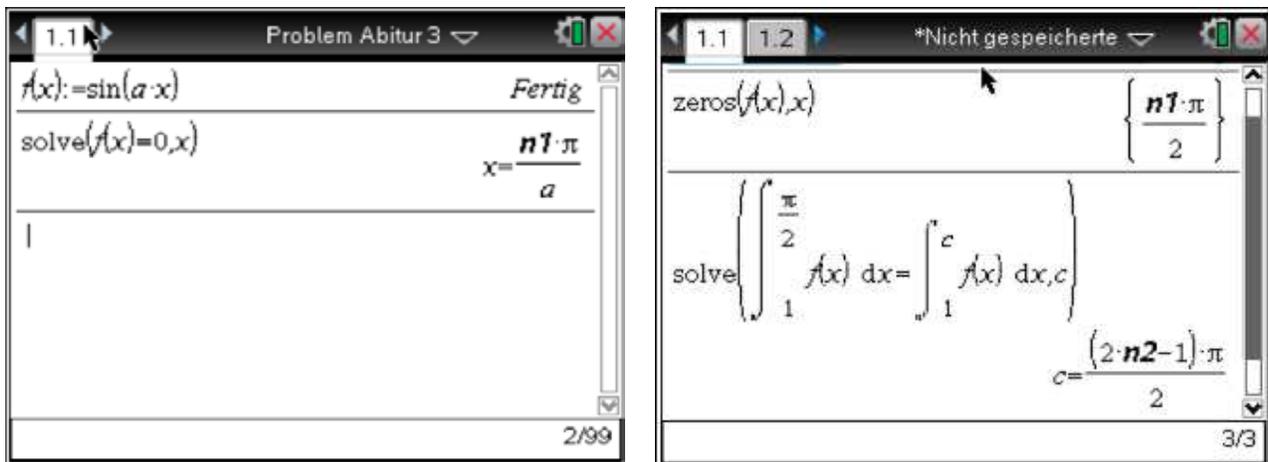

Figure 11: The DT-solution of (a) the example 5 a), and (b) the example 5 b).

These solutions (Fig. 11a and b) are prototypic for DT-solutions. The student has to find the problem solving idea and the starting equation, the calculator takes over the former hand calculations, and finally the student has to interpret the screen notations.

This example especially shows that it is (nearly) impossible to do this interpretation without a basic mathematical content knowledge about the given functions and concepts, e. g. the integral concept.

Working with DT it is always a good strategy to choose different representations of a problem. Fig. 12a and b show graphical representations of the problem which allow a solution of the problem without calculations.

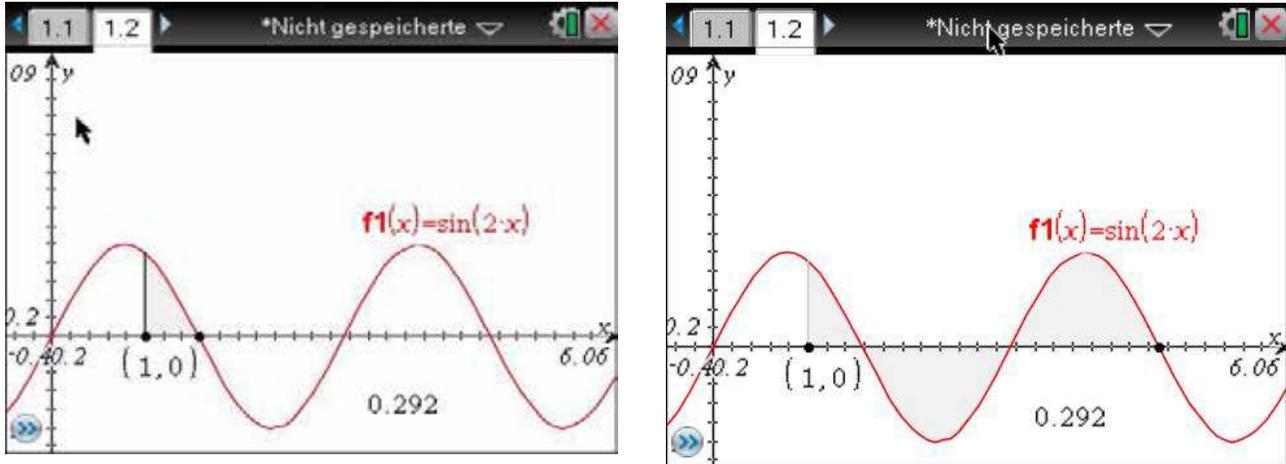

Figure 12: A graphical representation of the solution of (a) the example 5 a), and (b) the example 5 b).

Fig. 13 shows a student solution of example 5b) with a well-written reasoning concerning the solution. The problem for the teacher and the corrector of this examination is that the solution does not show whether and how the calculator was used.

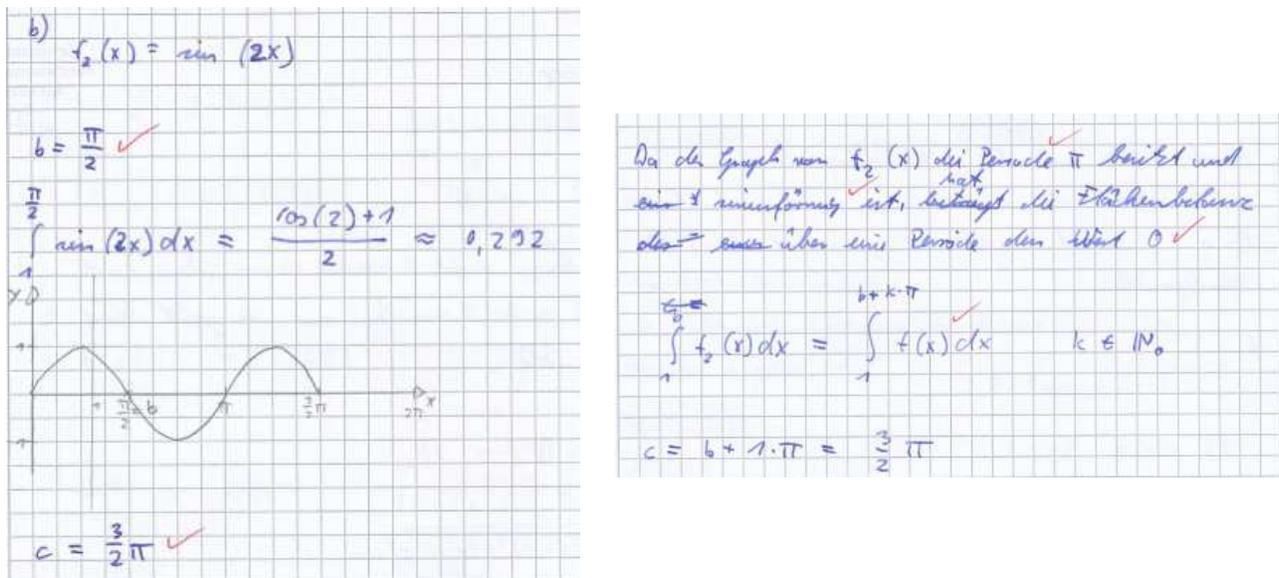

Figure 13. A – correct – student solution of the example 5b).

CRITERIA FOR DOCUMENTATIONS OF SOLUTIONS

Written examinations of students with DT ask for clear instructions for the documentation of written solutions. But there are no algorithmic rules or norms how to document a solution on paper. This opens the question concerning the *adequate documentation form* of the solution on paper.

In our project we started to develop *criteria* for (non-)correct, (non-)accepted documentations of solutions, e. g.

- It is not enough to only write down, what's on the screen!
- The solution has to be understandable „for others“, and it has to be seen when and where the SC was used.
- The solution describes the mathematical activities, it is not only a description in a special „calculator language“.
- The meaning of “keywords” (operators) in the problem definition has to be well-known to the student, e. g. “show”, “explain”, “determine”, “prove”, ...

These criteria have to be discussed, evaluated and refined the next years.

FINAL REMARKS

This analysis shows the problem and difficulty of posing adequate test problems and the problem of the adequate students' paper documentation of the solution of the problem. The ability or the competencies *to use SCs* adequately requires technical knowledge about the handling of SCs. Moreover, the knowledge of when to use which features and for which problems might be helpful.

The use of the adequate representation depends – of course – on the problem and the expected level of accuracy or strength. Furthermore, the problem solving process requires the knowledge about the *relationship* between *mathematical objects* or *concepts* and their *mental representations* and finally between the digital representation and the representations used in the documentation (paper and pencil representations). Despite the importance of different interactive multiple (digital) representations, the most important representation, which had to be developed, are the *mental representations*.

Concerning future developments there are some important research questions concerning the adequate use of representations in a digital examination environment:

- How are mental representations influenced while working with digital representations and vice versa?
- How should examination problems be posed to allow a greater variety of problem solving strategies while using DT?
- Are there general criteria for the documentation of problem solutions which cover a greater range of problems?
- Which documentation criteria are helpful for students?

MATHEMATICS, TECHNOLOGY INTERVENTIONS, AND PEDAGOGY – SEEING THE WOOD FROM THE TREES

Aibhín Bray

Centre for Research in IT in Education (CRITE), School of Education and School of Computer Science & Statistics, Trinity College Dublin

This research explores recent technological interventions in mathematics education and examines to what extent these make full use of the educational affordances of the technology and appropriate pedagogical approaches to facilitate learning. In an attempt to answer this question, a systematic literature review has been carried out, and a classification framework is presented that categorises the types of technology as well as the pedagogical foundations of the interventions in which those technologies are used. The potential of technology to fundamentally alter how mathematics is experienced is further investigated through the lens of the SAMR hierarchy (Puentedura, 2006), which identifies four levels of technology adoption: substitution, augmentation, modification and redefinition. The framework presented to describe the interventions thus ranges from enhancing traditional practice, to transforming teaching and learning through redefinition of how tasks and activities are planned and carried out. The development of such a framework will be beneficial for guiding teaching, increasing our understanding of learning in a technology rich environment, and improving mathematics education.

Keywords: Mathematics Education, Technology, Classification

The aim of this research is to gain some clarity regarding pedagogical approaches to technology interventions in post-primary mathematics education, as documented in recent literature. The objective is to increase the understanding of the kinds of teaching and learning of mathematics that technology has the potential to enhance. A long-term goal is to create, and test, a comprehensive 21st Century model of classroom practice for mathematics education.

Existing classifications of technology for mathematics education are investigated (Clarebout and Elen, 2006; Passey, 2012; Hoyles and Noss, 2003, 2009). The classifications by Hoyles and Noss provide the foundation for the technological aspect of the framework used in this study. In addition to grouping the interventions by technology, this research also classifies them according to learning theory, instructional approaches, and where they fall on the SAMR transformation hierarchy. The data emerging from the literature review is coded and stored in a spreadsheet pivot table. This allows the information to be arranged and visualised in diverse and meaningful ways that contribute to the extraction of a classification framework for technology interventions in mathematics education. From this framework, a set of guidelines relating to the shape that successful interventions might take is explored.

The emerging set of guidelines point to a holistic approach to technology interventions in mathematics education. Both the transformative and the

computational capabilities of diverse technologies should be taken into account, providing for the investigation of challenging and interesting problems and the development of flexible and creative solving strategies. The assessment potential that technology offers needs to be utilised for successful integration. Innovation with regard to the working environment and class routine are seen as necessary in order to fully exploit the potential of technology in the teaching and learning of mathematics.

MobiMaths (Tangney, Weber, O’Hanlon et al., 2010), is an example of an intervention in keeping with the guidelines described. This particular intervention uses smartphone technology and conforms to the socially constructivist pedagogy of Bridge21 (Lawlor, Conneely, & Tangney, 2010) in order to create a learning experience that emphasises collaborative problem solving and contextualised learning. A set of activities pertinent to the curriculum are provided along with the technology in order to facilitate the integration of mobile learning in a pragmatic and meaningful way.

The poster presentation was made up of diagrams to illustrate the data from the literature review, as well as descriptions and illustrations of interventions deemed successful, such as MobiMaths. Further interventions were developed according to the set of guidelines and their implementations were also discussed.

CONTINUING FORMATION AND THE USE OF COMPUTER RESOURCES

Maria Madalena Dullius

Centro Universitário UNIVATES

Keywords: continuing education, computing resources, Math.

The advent of technology always ends up causing revolution and now the computer is causing this effect in different sectors of the society and in education. Are these changes so significant? Is the school able to use this tool to the teaching and the learning? Are teachers prepared to make use of this resource in their classes? We believe that the inclusion of computational resources in pedagogical practice will only happen when the teacher experiences the process and when the technology represents an important means to improve teaching and learning.

Thus, the existence of spaces for teachers to exchange experiences, learning and teaching, is important in their professional development. Concerning the use of media in the classroom, we emphasize that it necessarily implies a review of practices developed so that they can propose real changes.

In this context, we addressed, in continuing education courses, the question of the use of computational resources in the teaching of mathematics and what is the impact on activities developed in the classroom by teachers. We sent an online questionnaire to mathematics teachers. Another questionnaire was sent personally to the municipal secretaries of education, with the objective of investigating the existence of computer labs in schools and how they conceive the offer of continuing education courses contemplating the use of computational resources in mathematics education. We also carried an interview with the Coordinator of Regional Education, in which we sought to investigate the incentive that offers to its teachers with respect to continuing education and the reality of the computer labs in schools.

From the data collected we decided to offer continuing education that problematizes the use of computational resources in mathematics classes.

With the objective of having active participation of teachers in the process of their education, we chose to base this work on the methodology of action research that seeks, starting from a preoccupation or a need in the classroom and from an identification of a specific problem, to formulate possible solutions to be implemented and tested. Participants develop in their pedagogical practice the activities problematized during the meetings and bring the results as well as their concerns and difficulties to be discussed in a large group.

NOTES

PROFESSIONAL COMPUTER ALGEBRA SYSTEMS IN UPPER SECONDARY MATHEMATICS

Niels Grønbæk

Department of Mathematics, University of Copenhagen

We address the issue of use of professional computer algebra systems (CASs) in upper secondary mathematics as opposed to CASs that are designed with school educational purposes more explicitly in mind. We propose a didactical engineering project in which the epistemological analysis of CAS use sets out, through the dictum of C's: Assets of CAS are conceptual, computational and communicative, from the dialectics between CAS as an enhancement of mathematical modelling power and CAS as a virtual reality which itself needs to be modelled and interpreted by mathematics. Design, a priori and a posteriori analysis will be based in part on the theory of instrumental genesis and orchestration (Trouche, Drijvers) in part on ATD (Chevallard). Special emphasis will be given to the secondary-tertiary transition.

SECTIONS OF THE POSTER

The poster will be composed of

Illustrative Maple worksheets

Some sheets demonstrating the potentials and pitfalls of the use of CAS with professional power, such as

- A sheet demonstrating how excessive computational power may lead to shallow understanding and therefore deceptive instrumental genesis.
- A sheet exploring real numbers as (infinite) decimal expansions by exploiting CAS computational power subject to a dogma principle (arithmetic first principles).
- A sheet exploring continuity and fix points by exploiting the power of CAS visualization.

Outline of the epistemology of the impact of CAS use on mathematical content and routines

Vertices in the epistemological coverage will be

- Use towards authentic problems may lead to command of mathematics reducing to ability to choose appropriate CAS applications.
- Taxonomic nivellement of classical routines (i.e. **solve(f(x,y),x)** vs. **solve(f(x,y),y)**).
- Development of mathematical praxis with focus on mathematical core issues.

The epistemology will involve praxeological analysis in the sense of ATD (Chevallard, 1999) as well as mathematical content and concept analysis. For

instance, the announced Maple sheet on decimal expansions can be described as a point praxeology involving direct CAS calls of decimal expansions encompassed by a local praxeology where the dogma condition, arithmetic first principles, determines the local praxeology technology as well as (part of) the point praxeology theory. How various incarnations of the full CAS program influence the scope of mathematical content and didactics will be a key issue.

Outline of implementation of designs in Danish secondary mathematics education through an action research framework for teachers.

This section will primarily be based on the theory of instrumental genesis and orchestration and a model description of a reflective practitioner community.

Outline of further steps in an a posteriori analysis

This section involves analysis of praxeologies (Chevallard, 1999) in the internal institutional setting of the classroom and the institutional setting determined by official regulations - including the didactical transposition in the transitions to higher education.

A NEW INSTRUMENT TO DOCUMENT CHANGES IN TECHNOLOGICAL LEARNING ENVIRONMENTS FOR MATHEMATICAL ACTIVITIES DRAWN FROM HISTORY

Matthias Müller

Friedrich-Schiller-University of Jena, Germany

In Thuringia, one of the federal states of Germany, there was a fundamental shift in education policy last year. In 2014, every student will have to write a school-leaving exam using a computer algebra system (CAS). Thus, many schools have started working with such systems. Following the approach taken in Finnish studies, the expected changes in mathematical education can be documented by observing eight activities or features drawn from the history of mathematics.

THEORETICAL BACKGROUND

Looking at the history of mathematics, there are eight activities which were important for the improvement of mathematics. These activities were shown to lead very often to new mathematical results at different times and in different cultures over more than 5000 years. The activities are strongly connected to each other. In order to illustrate the various connections between all the activities, they can be arranged in an octagon (Fig. 1) (Zimmermann 2003).

This model can be an element in a theoretical framework for the structuring learning environments, as well as in assessing the quality of mathematical education (Haapasalo & Eronen 2010). It is interesting to observe how these features translate into classroom activities and how students perceive these activities in their settled learning environment. Finnish studies have shown a shift in evaluating these activities in classrooms where digital tools such as CAS are used (Eronen & Haapasalo 2010).

METHODS

The Finnish questionnaire was translated and adapted for use in Thuringian schools. The web-based instrument consists of 24 statements ranked on a five point Likert scale. 523 students of grades 9 and 10 were asked how these activities appear in their mathematical education. The instrument was tested by a pilot group of 62 students and then reviewed by math teacher trainers in several rounds of discussions. At this point, only the median and the quartile were calculated to describe the data. To document the teacher's point of view, 21 teachers participated in the survey and answered the same questionnaire as the students.

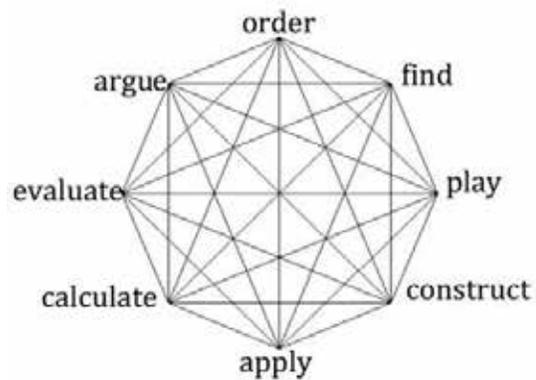

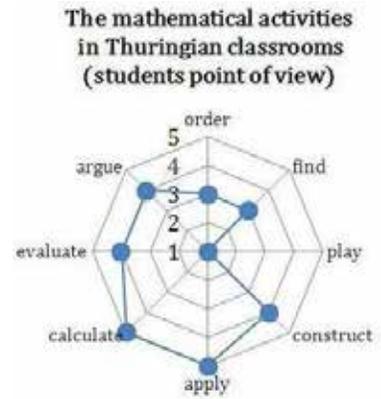

Figure 1: Octagon of math activities

RESULTS AND DISCUSSION

In students' view, argue, evaluate, calculate, apply and construct activities are more important in math lessons than order, find and play activities. In particular, play does not seem to exist in Thuringian math lessons, which is a pity when one considers their importance in the history of math. The range between upper and lower quartiles is low for all activities except argue, evaluate and construct, which indicates that students generally agree about the frequency of these activities in their classrooms.

The teachers' responses suggest that the eight activities are important in math lessons. Of particular importance were order, find, construct, evaluate and especially play. Furthermore, the teachers concur with the appearance of the eight activities in their classrooms. While the teachers understand that these activities are important for math learning, there seems to be a difference between the teachers and the students concerning their appearance. To explore the reasons for these differences, interviews will be done with the teachers.

The results of the students' answers are interesting, but there are limitations to the validity of the research when students are asked just once a year. It cannot be assumed that students have a real overview of the whole year; they can be rather influenced by the most recent experiences in their math lessons. This has to be taken into account when interpreting the results. Despite that, it is expected that their views will develop over the next two years, mostly due to the use of modern technology such as CAS. Therefore, it will be interesting to observe how students will evaluate the appearances of the activities in the next two years following the introduction of CAS. This research will be conducted in the coming years, to investigate changes and to compare the results.

USING ICT TO SUPPORT STUDENTS' LEARNING OF LINEAR FUNCTIONS

Annika Pettersson

Karlstad University, Sweden

In the poster a case study in a PhD project was presented, focusing on ICT and linear functions. The study investigates students' learning on the relation between algebraic and graphical representations of the linear function $f(x)=mx+c$, in particular the parameters. Changes of the scale on the axis also affect the graphical representation. How do the students experience this? Students' conceptions of how parameter values and changes of scale affect the visual representation in a dynamical environment need to be studied more. Students from upper secondary school in Sweden will work in pairs in a laboratory setting. The dynamic computer software GeoGebra will be used and the students will be engaged in two tasks. The students will be video recorded and their activities on the computer screen will be captured. The two tasks and the research design were presented in the poster in order to show examples of how to study exploratory learning in an ICT environment.

Keywords: Exploratory learning, ICT, Linear functions

THEORETICAL BACKGROUND

The role of the parameters is central in this study. In earlier research in connection to ICT one can find that parameters can show the students the differences literal symbols can play and that they can improve their symbol sense (Drijvers, 2003). Drijvers defines symbol sense as “the insight into and the structure of algebraic expression and formula” (*ibid*). “Variation of parameter value acts at a higher level than variation of an “ordinary” variable does; it affects the complete equation” (*ibid* p. 61). One aspect that according to Bardini and Stacey (2006) has not been studied much is students' work with the relation between the parameters m and c in the linear function $f(x)=mx+c$ and their graphical representation. The parameters can be considered from different perspectives and m is more complex for the students (*ibid*). The m value can be seen analytic or visual (Zaslavsky, Sela, & Leron, 2002). From the analytic perspective the property does not depend on the representation, but in the visual perspective the slope depends on the scale on the axis (*ibid*).

AIM AND RESEARCH QUESTION

The aim of the study is to investigate students' conceptions of the linear function in a dynamic software environment.

- How do students' conceptions of the linear function change by exploring the parameters and in what way does the dynamical change of scale affect the students' conception of the linear function in a dynamic software environment?

METHOD

The research will be a case study of eight students, working in pairs, with Geogebra. The students will in the program be provided opportunities to manipulate the parameters and they will get an instant graphical feedback. The students will be asked to create fig. 1 (Magidson, 1992) and fig. 2 by writing the function with different parameter values in the algebraic field. A screen recording program and a video camera will capture the work and stimulated recall interviews will follow the tasks. At the end of the interviews the scale on the axis will be changed dynamically and the students will be asked to explain what happens with the m - and c -values and why.

INFORMATION AND COMMUNICATION TECHNOLOGIES - AND MATHEMATICS TEACHING: RESEARCH CONDUCTED FROM ELEMENTARY TO HIGHER EDUCATION

Nilce Fátima Scheffer

Universidade Regional Integrada do Alto Uruguai e Missões URI ERECHIM RS
BRAZIL

This paper presents results of studies related to the research lines: Mathematics Education and Educational Practices in Science Education and Technology. The studies have been developed from research on different fronts ranging from elementary to higher education. The study presented here involves a description of research conducted with undergraduates, masters and teachers, in order to promote reflections about the integration of ICT in mathematics education.

The proposed works involve reflection on the role of ICT in math pedagogic practice supported by technological resources of the Computer Laboratory and Distance Education to innovate teaching situations in the classroom. The studies of Bairral (2005), Borba and Villareal (2005), Maltempi (2008), Scheffer (2006) and Costa (2010), focus on the context of teaching mathematics among limitations associated with teachers' education, especially in regard to information technology in teaching and the use of different possibilities that ICT offer, seeking to achieve alternatives to minimize this problem, pointing out the difficulties that undergraduates and teachers may have regarding digital inclusion in the school context.

This paper presents a brief discussion regarding inclusion of ICT in math teaching and highlights research studies that were developed and accompanied by the author, related to lines of research. The poster describes some examples, concluding with a brief reflection-discussion carried out up to now at different levels, and master dissertations that have turned more specifically to the study of practical proposals to be applied at school, considering the pressing needs of insertion of math teachers and their pedagogical practice in the digital context.

Scientific Initiation Research studies explored freeware to be used in teaching math. In these studies, Math Freeware and educational and interactive websites were selected and the quality and applicability of the programs to Elementary Education was investigated. Another area of studies turns to the creation of pedagogical proposals for discussion of math concepts, applied to digital classroom and appreciation of math argumentation of students and teachers conveyed in these learning environments. The studies investigated aspects of students' and teachers' Math Language and Argumentation, which considers the argumentative capacity manifested by verbal, non-verbal or written language, emphasizing the development of citizenship in the school context, i.e. in "math classroom", highlighting the importance of research oriented to math education with computer technologies.

Course Conclusion Papers include studies of the importance and use of ICT in math teaching from elementary to higher education, analyze different proposals with respect to how math contents are worked in digital classroom, besides considering the analysis of specific math concepts such as the exploratory study of representation and diagonal definition of a polygon.

Master Dissertations focused on the study of investigative practice proposals of Digital Inclusion, construction of Learning Objects, study of the importance and role of Distance Education, using platforms such as Moodle, with emphasis on initial and continuing education of teachers. The aim of these studies was to promote the intertwining of specific education with technology. The work was conducted with Wingeom and GeoGebra software that mediated resources to approach the Pyramids theme and Analytical Geometry. The results of Math Course undergraduates studies highlighted software benefits, possibilities and also difficulties to work with, although the benefits are great for the visualization process, discussion and reflection on geometric properties of polygons.

The resulting study proposals from researches that are presented in the poster include reflection on the role of ICT in teaching practice of math teachers and also of Distance Education in view of teaching and learning innovations in the classroom. Consequently, it is worth highlighting that the implementation of challenging educational practices and qualitatively significant from ICT is necessary for teachers in the current reality.

Working proposals resulting from these surveys cover reflection on the role of ICT and of Distance Education in pedagogical practice of mathematics teachers.

INTRODUCTION TO THE PAPERS AND POSTERS OF WG16: DIFFERENT THEORETICAL PERSPECTIVES AND APPROACHES IN RESEARCH IN MATHEMATICS EDUCATION

Ivy Kidron, Marianna Bosch, John Monaghan, Luis Radford

Keywords: Inclusion in mathematical practices; iterative unpacking strategy; networking approaches; networking of methodologies; networking and epistemology; object-agents in the mathematics classroom; reference epistemological model; semiotic representation; teachers' identity development; theory and practice.

The idea of the networking of theories has been investigated at CERME since the CERME 4 conference. In their introduction paper to the proceedings of the theory group at CERME 4, Artigue et al. (2005, p. 1242) wrote that “the central term that emerged from the working group was *networking*”. They added that “as a research community, we need to be aware that discussion between researchers from different research communities is insufficient to achieve networking. Collaboration between teams using different theories with different underlying assumptions is called for in order to identify the issues and the questions”. Networking became the topic of the working group at CERME 5 (Arzarello et al., 2007), CERME 6 (Prediger et al., 2009) and CERME 7 (Kidron et al., 2011). These working groups explored ways of handling the diversity of theories in order to better grasp the complexity of learning and teaching processes; and understand how theories can be connected or not in a manner that respects their underlying assumptions. These and other themes, like *the nature of mathematical objects* and the *semiosphere*, are a constant feature of this CERME working group, including CERME8. The *semiosphere* is a multi-cultural space of meaning-making processes and understandings generated by theories as they come to know and interact with each other (Radford, 2008). In the *semiosphere* a theory is considered as a dynamic interrelated triplet (P, M, Q) formed of theoretical principles (P), methodologies (M), and research questions (Q). Strategies for networking depend to an important extent on how “close” or “far” the networked theories are located in the *semiosphere*.

After a two stage peer review process, 12 papers and 3 posters were accepted for discussion in the Working Group. We revisit the manuscripts to raise themes that emerged from the conference discussion. We summarise these under three headings: (1) Methodology and theory; (2) Networking and epistemology; (3) Theory and practice.

DISCUSSION OF THE PAPERS WITH RESPECT TO: METHODOLOGY, EPISTEMOLOGY, THEORY AND PRACTICE

METHODOLOGY AND THEORY

Methodology was an explicit focus in the paper by Hickman & Monaghan on student teacher problem solving. A multi-media data collection artefact was used. Questions raised included:

- how an artefact can enable the networking of methodologies;
- where do “methods” and “methodology” lie in the Anthropological Theory of Didactics (ATD);
- what a methodology is and its relationship with “theory”;
- how to reconsider the work of past CERME “theory group” participants’ views on theories and methodologies?

The paper by Fetzer outlined theoretically and methodologically how object-agents can be integrated into a view on social interaction in classrooms. It employed Actor Network Theory (Latour) as a “background” theory. The focus was to understand (and trace) the role of “objects” in mathematical learning processes. Fetzer employed/networked three other theories: Goffman’s participation framework; Sack’s turn-taking system; and Toulmin’s theory of argumentation. A reason for employing these other theories was to develop an integrated theory-methodology for tracing the influence of objects.

The paper by Palmér focused on primary school mathematics teachers’ identity development. The two theories networked were Communities of Practice (CoP) and Skott’s “patterns of participation.” The paper analysed how the individual’s patterns of participation regarding teaching mathematics are influenced by and influence CoP. A conceptual framework is developed within a participatory perspective, making both the individual and the social possible as units of analysis. Both theories include the individual and the social but with different focus and different emphasis. The focus in the paper is the need for networking (coordination).

The paper by Barrera analysed students’ understanding of multiplication in a geometric context and their difficulties within a mathematics lesson requiring both mathematical frame changes and changes of register of semiotic representation. Barrera presented a combination of different theoretical approaches – Mathematical Work Space, Registers of Semiotic Representation and Semiotic Mediation Theory. Connecting the different theories allows the analyst to enrich the description of students’ work as well as increasing understanding of this work at both cognitive and epistemological levels.

The paper by Koichu demonstrated a new kind of strategy of networking. Specific connections between background and foreground theories are discussed. The

dynamic relationship between theories is described: one theory may serve as an overarching framework in one case and as a source of conceptual tools (for elaborating on elements of another theory) in another case.

NETWORKING AND EPISTEMOLOGY

The role of epistemology in the networking of theories was an explicit focus in the paper by Ruiz-Munzón, Bosch and Gascón. It is addressed through the necessity for research to elaborate its own particular “vision” of the mathematical contents involved in research and to use this “vision” (conception or model) as a reference point from which to observe teaching and learning practices. This idea of a “reference epistemological model” (REM) is used for networking Chevallard’s ATD and Radford’s Theory of Knowledge Objectification (TKO). The paper deals with how each approach addresses the nature of algebraic thinking. It is an invitation for a dialogue between these two approaches that starts by presenting the point of view of the ATD, presenting its own REM about elementary algebra and the kind of questions addressed by this approach, in relation to the TKO.

The paper by Godino, Batanero, Contreras, Estepa, Lacasta and Wilhelmi analyzed two approaches to research in mathematics education: “Design-based research” (DBR) and “Didactic engineering” (DE), in order to study their possible networking. DE (closely linked to Brousseau’s theory of didactical situations) focuses on epistemological questions; DBR does not adopt a specific theoretical framework, nor does it explicitly raise epistemological questions. The following question was discussed: is the epistemological focus only a question of “cultural and intellectual context” or is an epistemological reference necessary for each theoretical approach used in design based research in math education?

The paper by Janßen and Bikner-Ahsbals offered insights about the processes through which algebraic structure sense develops. They described the specific contribution of two coordinated theories, Theory of Knowledge Objectification and Interest Dense Situation, focusing on the boundary between the theories and on the process of crossing it during the research that leads to a deeper insight into the development of structure sense. Questions about networking and the boundary between the theories were discussed.

Networking and epistemology was a focus as well in Castela’s poster concerning ATD and CoP.

THEORY AND PRACTICE

The papers in this category gives substance to the hope of this Working Group, that exploring issues in networking theories is not a purely academic exercise; through this work we aspire to better understand the construction of mathematical knowledge towards the end of enriching learners' mathematical experiences. After networking and enriching our own theoretical frames, we need to consider questions how to apply our work.

The paper by Roos focused on CoP and inclusive pedagogies. The main aim is to understand the phenomenon of inclusion in mathematics and see how to problematize it. The connection between the theory of CoP and the framework of inclusion is done at the level of the principles of the theories since they both look at learning as a social phenomenon.

Verhoef, van Smaalen and Coenders reported on an empirical study exploring how six mathematics teachers investigated their teaching practices using a lesson study approach to determine characteristics of 'sensible mathematics'. Their study is essentially built on recent work of Tall and his colleagues on long-term mathematical thinking with regard to the approaches of Bruner and Freudenthal.

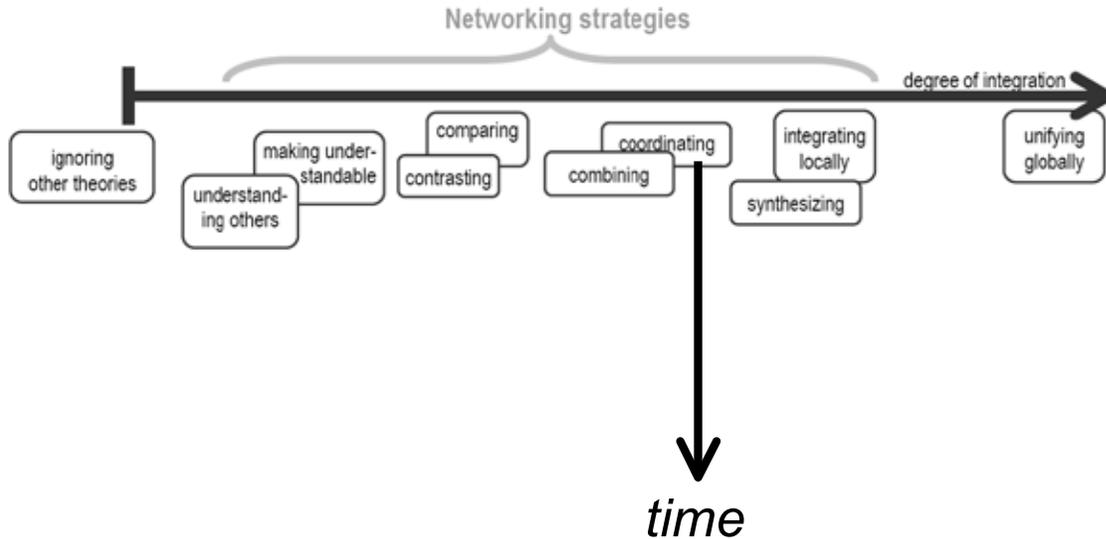

Two posters belong to this category of theory and practice: Czarnova's poster on Garcia & Piaget's triad and fairy tales and Godino's poster on instructional design tools based on the ontosemiotic approach.

CONCLUDING REMARKS AND THEMES FOR FURTHER CONSIDERATION

At CERME 7, we started work towards a *theory of networking theoretical approaches* in order to help the community develop in the direction of scientifically based multi-theoretical empirical research. At CERME 8, we continued the work but with a new focus on what a methodology is and the "irreducible link" between theory and methodology. Questions were raised about the place of methodology in theoretical frameworks and the relation of this issue to the methodology for networking theories as described in Radford's semiosphere (2008) and Artigue et al. (2012). The dynamic character of theories and how improving the methodology means improving the theory was discussed as well.

At CERME 8, the focus on networking and epistemology was stronger than in the previous working groups on theory. New issues compared to the last CERME included the impact of research approaches in the problem of professional development and teaching practices as well as in the formulation of research problems and the description of phenomena. In a sense, theoretical approaches need to be considered by what they enable researchers and practitioners to do, the questions raised, the regularities identified and described, that is, in a sense, the "results" obtained. .

The paper by Palmer raised a new issue, the dimension of “time” in networking strategies. If we consider the landscape of networking strategies proposed by Prediger, Bikner-Ahsbabs & Arzarello (2008) (see the figure below) and, for example, the strategy of “coordinating”, then this coordination takes place in time. This temporal dimension is usually overlooked in consideration of networking and we look forward to taking this forward at the next CERME

We have experienced progress in our efforts on “networking theories” but at the same time our feeling is that, in the next working groups on theory, the stress on theories should be reintroduced and not only the focus on networking.

ON THE GEOMETRICAL MEANINGS OF MULTIPLICATION: GEOMETRICAL WORK SPACE, SEMIOTIC MEDIATION AND STUDENTS' CHOSEN PATHS

Raquel Barrera

Laboratoire André Revuz – Université Paris Diderot – Paris 7

In this article, I briefly present an attempt to combine different theoretical approaches – Mathematical Work Space, Registers of Semiotic Representation and Semiotic Mediation Theory – in order to analyze students' paths within an experimental lesson connecting multiplication and some of its geometric meanings. I will also present reasons for combining these theories and I will illustrate how they have been used to analyze results from our experiments conducted in French high schools. Finally, I will conclude with some ideas and perspectives discussed in our working group and which I think could provide interesting perspectives for future research.

FROM INITIAL QUESTIONS TO A THEORETICAL COMBINATION FOR ANALYZING STUDENTS' CHOSEN PATHS

Geometry as a link between multiplication and its meanings for different sets of numbers

The fact that the notion of multiplication is closely associated with the idea of calculation can impede students from imagining a geometrical representation of the product. In the same way, the association between real numbers and the notion of magnitude can also get in the way when representing negative numbers, as well as when giving meaning to the product of two negative numbers. Thus, the multiplication of negative integers does not allow a geometric representation unless the “quantities” are treated in terms of orientation and direction (Argand, 1806). The extension of the operations' definition for complex numbers is linked to the representation of imaginary quantities by vectors. As a result, transformation is the only context in which multiplication and some of its geometric meanings can be connected. We are establishing a relationship between the different meanings of our mathematical object, with geometry as the glue holding them all together.

Geometric representations encourage the use of cognitive variables favoring the understanding of a mathematical object. The abstraction of arithmetic and algebraic concepts also stems from the fact that they are only represented through a symbolic diagram (Radford, 2003). So, it seems to us that it is always necessary to have an intermediary between a conception and access to its meanings, given that “there is not mathematical thinking without using semiotic representations” (Duval, 2008, p.1).

Consequently, we can formulate a key question related to the empirical context of our research: will students be able to establish connections between multiplication and geometry? We will see how we have integrated these three elements – multiplication, its meanings and geometric transformations – in an original experimental situation, which has been created to respond to this question.

Our main theoretical framework: The Geometrical Work Space

After analyzing the notion of Mathematical Work Space (MWS) (Kuzniak, 2011), we determined that this theoretical approach could suitably account for the complexity and richness of students' mathematical work. This notion assumes that a network has been created on two levels, one cognitive and the other epistemological. This network relies on a certain number of *geneses*, which can be *semiotic*, *instrumental* or *discursive* (cf. Figure 1). The analysis of this bilateral relation allowed us to expand our theoretical knowledge of mathematical work spaces and to determine the theory's flexibility. As we will see, this flexibility allows us to combine several theories in order to analyze students' chosen paths within an empirical mathematical working space.

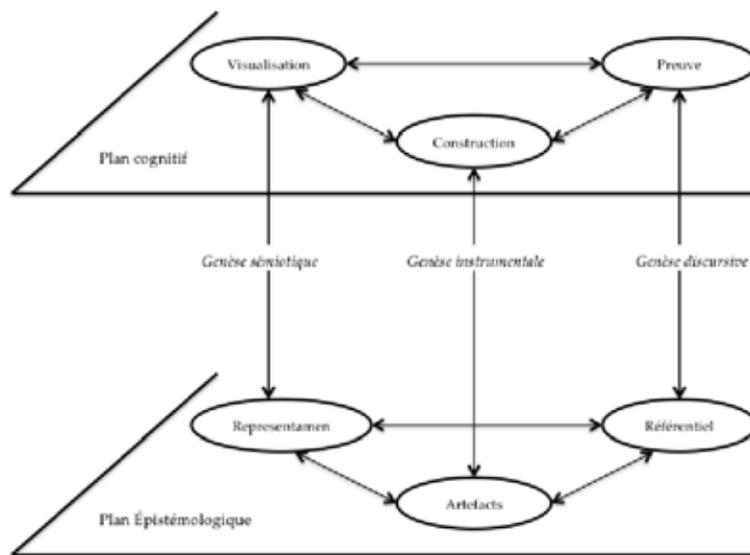

Figure 1: A genetic approach to the Geometrical Work Space

The starting point for the *geneses* linking the two levels of the MWS is traditionally placed on the epistemological level: for example, the visualization of an abstract mathematical object in a real or material space can be produced by the manipulation of artifacts in the construction of a figure. Still, the components on the epistemological level can be set in motion by needs on the cognitive level. A construction with artifacts can respond to a need for demonstration; the construction of a figure in a *paper-pencil* environment can be the result of a visualization allowing certain properties to assume a new configuration, or it can assemble the elements necessary for a proof. Thus, within these processes, called *geneses*, we can

see not only the existence but also the permanent interactions between different registers of semiotic representation: we can make the transition from proof to construction through a change in register of representation (cognitive entrance); a geometric configuration, a sign or *representamen* (epistemological entrance) can prompt a visualization (cognitive action) making use of the properties and axioms (epistemological action) leading to a proof.

Finally, we have the makings of a hypothesis: being conscious of the metaphorical meaning of a mathematical object could allow a point of entry starting at the cognitive level of an MWS, which at the same time would encourage manipulating the components of the epistemological level:

“Metaphors are not just rhetorical devices, but powerful cognitive tools that help us to build or grasp new concepts, as well as solving problems in efficient and friendly ways” (Soto-Andrade & Reyes-Santander, 2011, p. 2).

The combination of theories: Mathematical Work Space (MWS) and the role of sign-artifacts in a socially interactive space

All of the different studies dealing with semiotic notions present in the process of learning/teaching mathematics—whether they include information technology or not, whether or not they talk about registers of semiotic representation or pay special attention to the role of language and the understanding of mathematical objects—all of these positions “[revolve] around the relationship between mathematics and semiotics, concern questions of an epistemological, cognitive and sociocultural order” (Falcade, 2006, p. 3-4). However, within an MWS, the didactic question does not include explicit interactions between different individuals. Additionally, the MWS does not necessarily include other intermediaries, aside from the teacher, between the learners and the knowledge to be acquired or developed. It seems appropriate, then, to explicitly include *mediator intermediaries* where mathematics and semiotics can be found, where the different *geneses* occur, at the point where *semiotic mediation* and, when possible, *social mediation*, can facilitate access to research and the acquisition of meaning of mathematical objects. That said, given our special interest for semiotic genesis within a mathematical work space, the limitations of the existing semiotic approach as well as the theoretical definition of artifacts (Kuzniak, 2004) led us to look for other theoretical approaches dealing with semiotic mediation and the social construction of mathematical knowledge. We concentrated on Bartolini Bussi and Mariotti’s (2008) work on Semiotic Mediation Theory, aspects of which we associated with Radford (2004) and Sfard’s (2008) reflections on the social construction of mathematical knowledge and the complexity of the process of understanding a mathematical object. From a didactic point of view, Semiotic Mediation Theory includes elements such as the direct manipulation of tools, either in the form of concrete objects taken from the history of mathematics, or in the form of technological artifacts.

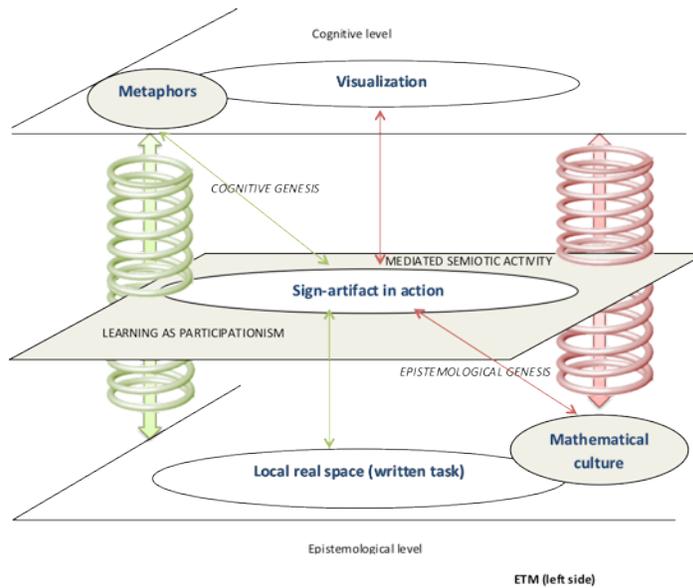

Figure 1: Diagram showing our theoretical combination. The dynamic arrangement of the MWS's components and of the epistemological and cognitive levels is due to the action of the sign-artifact in a context of semiotic mediation.

The theory also considers the precise organization of work in the classroom, where the relationships between the individual dimension, work in pairs and the collective dimension all play a role, and where oral and written activities complement one another. Finally, the theory also considers students' reading and interpretation of historical primary sources, aided by the teacher (Falcade, 2006).

The inclusion of historical and/or technological mediators as sign-artifacts on the one hand, and on the other hand the importance of collaborative work within the learning-teaching process, were the key elements that brought us to integrate Semiotic Mediation Theory and the Mathematical Work Space. Thus, we've included the MWS in a socio-constructivist learning process where the sociocultural and semiotic dimensions are included in the proximal development zone defined by Vygotsky (1934-1997).

AN OUTLINE OF OUR METHODOLOGY

Our desire to study the understanding of multiplication in a geometric context led us to design experimental course material. Observing several students' work on this non-traditional material allowed us to study their ways of solving problems in a mathematics lesson requiring changes of register of semiotic representation in a process of semiotic mediation.

Students in *Terminale S* (twelfth grade scientific track) were asked to solve a series of five questions suggesting a geometric approach to the multiplication of real and complex numbers (Appendix 1)¹. The activity was introduced in four *Terminale S* classes by their teachers. Thirty-four groups of two to four students worked on the activity for two hours in class. This session was integrated into the usual series of

lessons by the teachers, who had just begun a chapter on complex numbers. At first, the students were instructed to make a geometric construction of the product of two real numbers in the plane, as proposed by Descartes in his *Geometry* (1637). Next, the students had to find a relationship between the points given on a plane and the multiplication of complex numbers. The final question of the series² called on students to think back on the entire activity. It played a fundamental role in the exploratory process, and its analysis allowed a first description of the paths followed by students moving between Descartes' multiplication and the understanding of the geometric meanings of multiplication for different sets of numbers. In order to describe the role of geometrization in students' approaches to multiplication, we studied their way of solving geometric construction problems involving the multiplication of real and complex numbers. Gradually, we've began forming a response to our research question (cf. Introducing the mathematical content of analysis: linking multiplication to geometry) "now transformed" and seeing it through the eyes of our main theoretical framework: are there interactions between the cognitive and epistemological levels of the MWS employed by students showing evidence of a geometric understanding of multiplication? Through this methodology, we determined students' chosen paths between Descartes' multiplication and the understanding of the geometric meanings of multiplication for different sets of numbers. In this article, we outline two paths so as to illustrate some of the experiment's results and the way we used our combination of theories to analyze students' mathematical work. In this work we analyzed the use of previously studied mathematical content and the way students employ it; interactions produced between the components of the MWS employed by students; the role played, as a *sign-artifact*, by the configuration of Thales' theorem corresponding to the geometric representation of Descartes' multiplication; the identification the *origin of geneses in a geometrical work space*. The mediating sign-artifact is therefore an essential element of our didactic proposals. As we will see, our artifact is a sign: a mathematical sign, a geometric representation and an icon of Thales' theorem. Recognized by students in the first question of the series as a tool to be employed in a proof, the sign must evolve throughout the collaborative lesson. The goal of its systematic use in the activities is the collective production of new signs, which correspond to new interpretations of the same artifact. We can associate this last point, especially concerning the evolution of signs and the way they influence discourse, with what Anna Sfard calls a "visual mediation." This is the place where "visual mediators have been defined as providers of the images with which discursants identify the object of their talk and coordinate their communication" (Sfard, 2008, p.147). We hope that our theoretical combination will allow us to study whether geometric representations, either given to or produced by the student, recognized as psychological tools or *sign-artifacts*, are capable of producing a precise mathematical object—in this case, multiplication.

STUDENTS' PATHS: ANALYZING A FEW RESULTS THROUGH THE EYES OF OUR THEORETICAL COMBINATION

The individuals (groups) taking part in our experiment were initially classified by hand (i.e. we studied each sequence and each response to the final question, looking for elements of an answer that either corresponded to or differed from our initial determination) according to their responses to the last question of the series, leading to a first classification with three possible types of responses: Transformation (T); Proportionality and Thales' theorem (PTTh); complex (C), without explicit references to geometric transformations. The determination of students' paths was thus based on an analysis of the entire process leading them to their response to the last question.

Comparison between two groups showing different conclusions: Proportionality and Thales' theorem (PTTh) and Transformation (T).

The two groups were initially given two different classifications. We will examine the groups' differences beyond certain similarities in their responses to the final question. Group C1-I9 (T) bases its conclusion on an immediate visual connection between multiplication and the sign rule as seen in the Cartesian plane. Then the group extends this relation to Descartes' multiplication as well as any multiplication with any type of factor. The most striking observation we can make about their response, and which shows the close links between figural and discursive geneses, is the connection made between the sign rule and vectors' angles. The change of frames related to the sign rule is due to our activity, because the geometric manifestation of the sign rule does not appear in the French curriculum. In order to reinforce this idea, we emphasize that the group specifically identified the nature of the angles, especially the zero angle and the flat angle which allow a connection between real and complex numbers in this geometric configuration.

Group C3-I1 (PTTh) arrives at a conclusion that takes into account the different parts of the lesson. They show the properties of multiplication of real and complex numbers, justifying them with Thales' theorem.

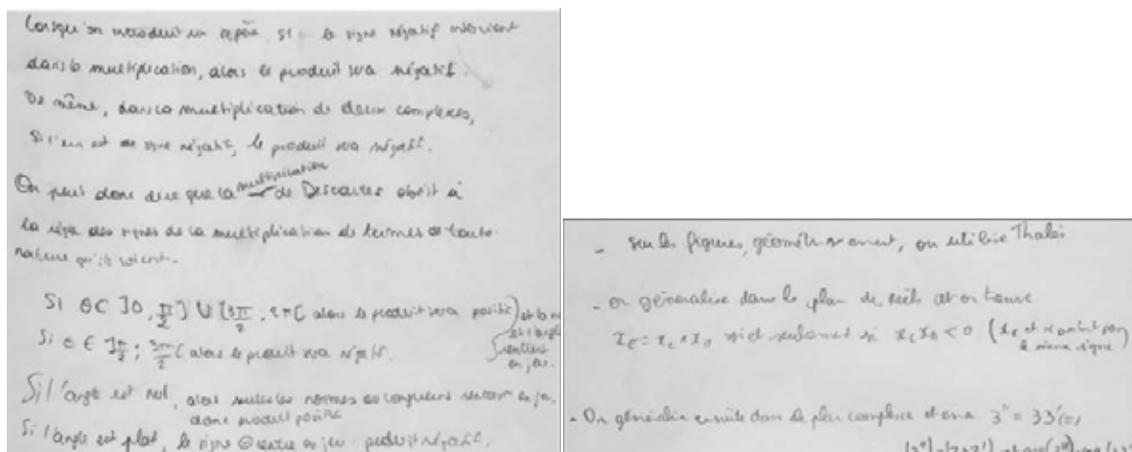

Figure 4: Left, pair C1-I9's conclusion (T). Right, pair C3-I1's conclusion (PTTh)

They present their geometric interpretation of multiplication of real and complex numbers as a generalization of Thales' theorem in the Cartesian plane and then in the complex plane. Can we say that the word “generalization” clearly accounts for a connection between the different aspects of the lesson? In a way, yes, because the lesson requires students to extend different sets of numbers.

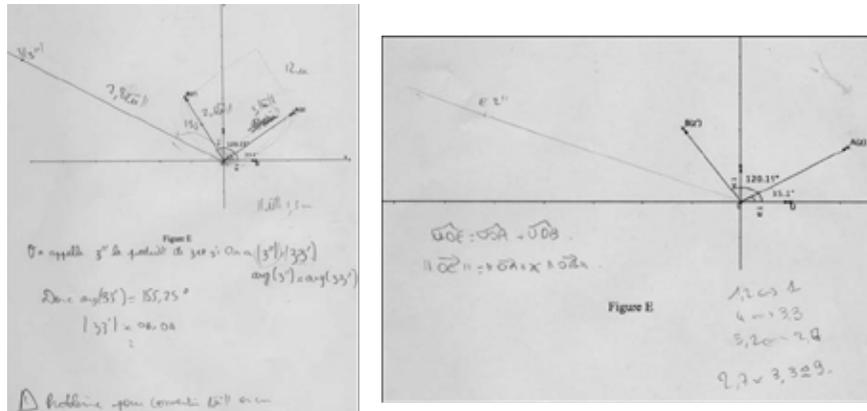

Figure 5: Left, C3-I1's answer to 4.b (PTTh). Right, C1-I9's response to 4.b (T)

For a more complete view, the figures above show the complete responses of both groups to question 4.b. It seems clear that the groups' algebraic knowledge of complex numbers guided their geometric construction, which shows no connection with the lesson's previous constructions. The algebraic properties of the multiplication of complex numbers are already part of students' *theoretical references* and they orient the students' construction, which is correct but isolated from the rest of the lesson. In their responses, nothing explicitly accounts for the visualization and geometric comprehension of complex numbers as a transformation in the plane. The entrance into the MWS for this question is epistemological, then, resulting in a *construction* with a ruler allowing the students to visualize the placement of the product of two complex numbers in the plane. In this lesson, the two groups take different approaches to question 2b. Here, only group C1-I9 (T) has used *transformations* in its response to one of the activity's first questions.

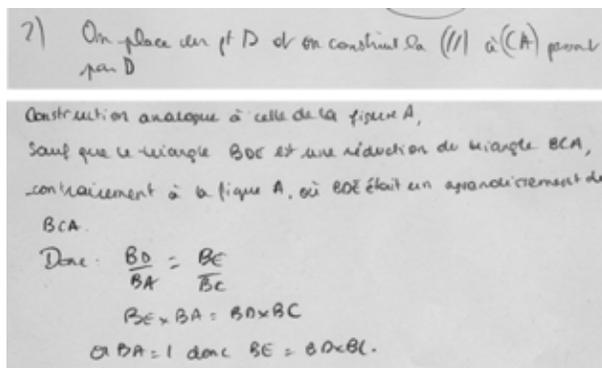

Figure 6: Above, group C3-I1's response to question 2.b. Below, response 2.b for group C1-I9.

In analyzing this response, it is quite interesting that the students refer to the *reduction* and *enlargement* of triangle BCA. The relationship of proportionality implied in Thales' Theorem and the geometric representation of Descartes' multiplication were not approached according to the segments-factors and the segment-product representing the proportionality. The visualization of similar triangles favors the immediate use of Thales' theorem because the students interpret this reduction-enlargement using their already available knowledge. These *paths* present their own specific characteristics. The "T" group mentions transformations quite early, in the second question, and their conclusion (final response) is very rich, relating the sign rule and geometry. The group using Thales produces a response describing multiplication for different sets of numbers but does not explicitly link the icon of Thales to a geometric representation of multiplication for different sets of numbers.

Synthesis of the analysis

Variable	Analysis results
Entry into the MWS	Mixed but largely epistemological.
Semiotic genesis/links between different registers of representation	Semiotic genesis of unknown origin, especially in the response given by C1-I9 to the second question. A semiotic genesis of cognitive origin may have occurred with the visualization of similar triangles, followed by the visualization of a transformation (reduction-enlargement) of these triangles through multiplication. A significant link between registers of representation was made during the association between the sign rule and the representation of the product of a positive and a negative number in the "affine" plane (C3-I1).
Semiotic mediation of the sign-artifact	The action and evolution of the <i>sign-artifact</i> were identified thanks to a specific explanation of the existence of a zero angle in Descartes' product (which was necessarily transposed into the "affine" plane). A link was therefore produced between the properties of the icon of Thales' theorem and the properties of multiplication of complex numbers.
Geometrical meaning of multiplication	Hypothetically, the product was interpreted as resulting from a transformation in the plane. This could have been a possible interpretation of the sign rule in terms of angles and by generalizing the meaning of any product to the product of two complex numbers.

Conclusion

We based our theoretical framework on a unified conception of cognitive and didactic elements. Several interests informed its development: the social dimension of learning processes; the study of semiotic mediation processes favoring the collaborative construction of a mathematical object; and the construction of meaning of mathematical objects. New lines of questioning emerge as a result of the diversity of concluding responses and the similarities and differences between the different students' chosen *paths*. They also demonstrate the difficulty of organizing the different *geneses* of the MWS. We realize that this is quite a complex cognitive activity since there is no direct conversion between one register of representation and another. This leads us to position the students' activity within a mathematical work space where the meaning of mathematical objects *emerges* as a result of a *cognitive genesis*. This *genesis* assumes the presence of complex semiotic interactions, such as those described by D'Amore and Fandino (2007) in order to describe the difficulties of moving between different representations. For example, the transposition of Descartes' product to a product operating directly on numbers, represented geometrically, positioned on a plane: this can only be the result of realizing that the activity is based on a *mathematical idea* (Lakoff & Nunez, 1997) that completely departs from the traditional knowledge of the mathematical object in question, i.e. the geometric meanings of multiplication. We are no longer working on the techniques of calculation or proof. Thus, because of the richness of the MWS introduced by the teacher as well as the diversity of students' personal MWSs, we must highlight the importance of our theoretical combination (MWS (Kuzniak, 2011) and TSM (Bartolini Bussi & Mariotti, 2008)). Through the lens of these theories, we have seen and analyzed students' ways of looking for the meanings of a mathematical object, dealing with a mathematical sign-artifact between an epistemological and a cognitive level, within a context of social interactions. This theoretical connection can still be improved if we look deeper, for instance, in Radford's semiotic approach (as suggested in our working group). Finally, the process of connecting theories must start with the analysis of their epistemological basis, which could help us understand the main focus of each one. Thus, I think we could better determine their complementarity, pertinence and even the most appropriate way – for example, in terms of chronology – to analyze students' mathematical work through them.

COUNTING ON OBJECTS IN MATHEMATICAL LEARNING PROCESSES.

NETWORK THEORY AND NETWORKING THEORIES.

Marei Fetzer

Goethe-Universität Frankfurt, Germany

Latour's actor network theory proposes a sociology of objects, accepting objects and things as participants in the course of action. Mathematics education has to deal with all sorts of objects, didactical tools and manipulatives, diagrams and signs. Mathematical learning appears to be closely connected to objects. Latour's approach is fascinating and irritating and provokes the research question, if and respectively how actor network theory can be a fruitful background theory to get a better understanding about the role objects play in mathematical learning processes. How is it possible to do research in mathematics education respecting Latour's perspective on social interaction? This paper outlines how a change of paradigm might be implemented through local integration of theories.

EXPOSITION: NETWORK THEORY AND NETWORKING THEORIES

On the one hand there is an empirical phenomenon: In the mathematics classroom all sorts of things, objects and visualisations are offered to improve mathematical learning and understanding. However, those objects prove to be resistant. They often neither function nor work the way teachers or learners expect or intend them to. On the other hand there is a theory: Introducing the Actor Network Theory (ANT) Latour reassembles the social. He develops a sociology of objects, accepting objects and things as participants in the course of action (Latour, 2005).

Studying Latour's sociological approach is fascinating and provoking. But is ANT a suitable background theory in the field of mathematics education? (How) is it possible to do *empirical* research in mathematics education referring to ANT? Even more precisely: (How) Can we investigate the role objects play in mathematical learning processes if we adapt Latour's perspective? What ways of acting can be empirically reconstructed, how do objects *act* in the mathematics classroom? This article performs the change in perspectives and focuses objects in the mathematics classroom through sociological lenses.

Latour himself does not suggest any methods of empirical analysis. Exploring appropriate heuristics means firstly to take additional approaches into consideration and secondly to connect them with ANT. In this paper, the networking of theories on the background level is the basis for the development of a local integration of theories (see Bikner-Ahsbals & Prediger, 2010). Closely connected is the discussion and compilation of appropriate heuristics.

In this article, four approaches come into interaction: Latour's ANT, Goffman's Participation Framework, Sack's Turn-Taking system and Toulmin's Model of Argumentation (Latour, 2005; Goffman, 1981; Sacks, 1996; Toulmin, 2003). Footing on their networking, two methods of reconstructing the ways objects take effect in learning processes are introduced. The first analytic approach meets the sequential character of interactional processes: A systematic analysis of turn-partaking is implemented relying on own works (Fetzer, 2007, 2009, 2010, 2013), Goffman's participation framework (Goffman, 1981) and Sacks's turn-taking system (Sacks, 1996). The second analytic approach comes up with the lasting quality of objects: The functional orientated concept of argumentation analysis referring to Toulmin (2003) is adapted to trace objects' marks in mathematical learning processes. Aiming at the function of single actions, this analytic approach offers the opportunity to escape the sequence of interaction.

ACTOR NETWORK THEORY: AN 'ANT' IN THE RESEARCHER'S EAR

Latour's actor network theory ANT is a radical change of perspectives proposing a sociology of objects. He recommends a broader understanding of agency as well as action and extends the list of actors assembled as participants fundamentally.

"Any thing that does modify a state of affairs by making a difference is an actor." (Latour, 2005, p. 71). All actors, human or not, are "participants in the course of action" (ibid., p. 71). "Objects too have agency" (ibid., p. 63), and appear associable with one another, but only momentarily. They assemble as actor entities one moment and combine in new associations the next minute. Accepting objects as participants in the course of action, Latour gives in the idea of stable and pre-defined associations and actor-entities.

Looking through Latour's sociological lenses, not only the traditional understanding of agency has to be re-defined, but also the notion of action has to be re-thought. Objects participate in the course of action and take effect. But apparently their mode of action is different from the way human participants contribute to the social interaction.

Latour's approach fascinates and provokes. It puts not a bug, but an ANT in my mathematic researcher's ear. It triggers re-thinking of traditional ideas of the role of visualisations, manipulatives and other objects in mathematical learning processes. In this article, I introduce a local integration of theories in order to develop a new piece of synthesised theory on the role objects play in mathematical learning processes.

NETWORKING THEORIES: TRACING OBJECTS IN MATHEMATICAL LEARNING PROCESSES

Tracing objects' marks in the course of mathematical learning processes referring to ANT means to substantiate the notion of action empirically. How do objects act or

take effect in the course of action? This research issue entails the question, how objects' actions can be empirically traced and observed. What analytic methods prove to be suitable for reconstructing non-human actions? Below, two approaches to explore object's traces systematically are developed. Both are founded on micro-ethnographic research.

Micro-ethnographic approaches to classroom investigation like the method of interaction analysis help to reconstruct the development of interactional processes (see Fetzer, 2007; Krummheuer/Naujok, 1999). Interaction analysis is based on conversation analysis (Sacks, 1996; ten Have, 1999) and reveals, how the sequential organization of interaction is constituted. Accordingly interaction analysis is bound to be a sequential analysis. Every single *action* is interpreted extensively in the sequence of emergence. To investigate the aspect of *inter-action*, every single action is understood as a "turn" (Sacks, 1996) on a previous action. Turn-by-turn the emergence of the course of action is reconstructed. Traditionally, interaction analysis captures human actors as participants of an interactional process and investigates their actions. Own works on a micro-ethnographic approach to an object-orientated analysis of classroom interaction prove theoretically as well as empirically, that this interactionistic tool is a suitable and powerful basis for analysing the *networking* of all sorts of actors (Fetzer, 2009, 2010, 2013). Both approaches introduced below to trace objects' participating in the course of mathematical learning processes are methodologically based on an object-integrating analysis of classroom interaction referring to Fetzer (2009, 2010, and 2013).

Participation Framework

Goffman's "participation framework" (1981) provides "an essential background for interaction analysis" (ibid., p. 3). His approach offers the chance to distinguish between different forms of participating in "moments of talks" (ibid., p. 313). Right from the start Goffman tells hearing and speaking apart from the social slot in which these activities usually occur. "When a word is spoken, all those who happen to be in the perceptual range of the event will have some sort of participation status relative to it." (ibid., p. 3). Some might have the official status of participants. As "ratified participants" (ibid., p. 130) they may be listening or not be listening. Others might not be official participants, but still be following the encounter closely in the status of "eavesdropping" or "overhearing" (ibid., p. 132). Goffman discriminates ratified and non-ratified participants on a phenomenological basis. Besides, he introduces the status of "bystanders" (ibid., p. 132). Those not ratified participants find themselves in visual and aural range of the social encounter. The crucial aspect of this participative status is the fact, that their access to the moment of talk is perceptible by the official participants. Perceiving them as someone having the opportunity to follow the social encounter, the ratified participants assign them the status of bystanders. Thus, a bystander's role is determined in the *interactional* process.

Goffman's participation framework does pay no special attention to objects. Nevertheless, it proves to be a fruitful basis for investigating object-actors participating in the course of action empirically. Below, three connecting points are outlined. First, empirical research on the basis of ANT has to face the rapid change of networking and the unstable boundaries of associations. How is this flood of potential associations manageable? Who respectively what has to be considered as a participant in the course of action? Goffman takes a micro perspective and suggests focusing on "moments of talks" (ibid., p. 131) concerning the framework of participation. That combines well with an object-integrating analysis of classroom interaction. Investigating *moments of networking* in the sequence of emergence may capture the intermittent existences and permanent changes in assembling appropriately. Accordingly, ratified participants as well as bystanders are understood as participants at a certain moment of networking. Second, Goffman stresses, that not sound alone is at issue in social encounters, but also *other ways of perception* as sight or touch (ibid., p. 129f.). Opening the perceptual variety of interaction he clears the way for a wider range of observable actions and participating actors. Object's actions might rather be seen, felt or otherwise perceived than heard. Third, the introduction of the *bystander's role* is promising in the context of object's agency. Objects might be in the perceptual reach of ratified participants as potential actors. Assigned as bystanders, they might come into play, associate with other actors and take effect in the interactional process.

Turn-Taking System

Trying to differentiate empirically the way objects participate in learning processes remains unaccustomed. Nevertheless, own works on the development of an object-integrating analysis of classroom interaction (Fetzer, 2009, 2010, 2013) approve, that objects' contributions to learning processes become accountable in the process of interweaving. As soon as object-actors assemble with other actors they enter the course of action. Their traces render perceivable and can be captured by analysis. *Turn by turn* it can be reconstructed, how objects participate in the emergence of social reality. A closer look on the theoretical basis of the sequential organisation of conversation is a matter of consequence. Referring to Sacks's approach to conversation analysis, conversation is a coordinational problem (Sacks, 1996, VI, II, p. 32). A basic challenge is to preserve "one party at a time" (ibid., p. 32), namely that any time there is at least one, but no more than one participant speaking. In matters of the "order of speakers" (ibid., p. 32; p. 521), it is decided on the next speaker or the next action, but not on the speakers or actions afterwards. Sacks refers to this sequential organisation of speaker change recurs as the "turn-taking system" (ibid., p. 524). He specifies several techniques of speaker-selection. Some of them correspond to the *next* speaker: "Current speaker selects next actor/speaker" (ibid., p. 524). Others are connected to the *current* speaker: "Next speaker may self-select himself." At this point Sacks's approach to conversation analysis may be connected

to an interactionistic approach: Inter-action is based on mutual exchange. Actions are related to each other as turns. The current speaker may select the next actor. However, this turn-“distribution” (ibid., p. 533ff.) needs to be understood by the designated next speaker. Solely in this case he/she/it may either accept this distribution or refuse to pick up the offered turn. Eventually actors may simple take over the turn. Sacks does not specify in *turn-distribution* and *turn-partaking*. Indeed, this determination proves to be continuative and fruitful when combining conversational and interactionistic approaches in order to grasp objects’ traces analytically.

Whenever participants in interactional processes change their status and become active actors, their current action can be interpreted as a turn on previous actions. The question arises, who or what provoked or initialised the change of participation status. Investigating the way objects participate in the course of action, especially a second aspect turns out to be crucial. Moments of networking and changes in participation status permit to reconstruct the *previous role* of the current active actor. Methodically, an “*analysis of turn-partaking*” is implemented (Fetzer, 2007, p. 126 ff.). This method of analysis stood the empirical test earlier in reconstructing actions, that are observable only indirectly (Fetzer, 2007, 2009). Turn-partaking and turn-distribution are linked very closely when investigating object-actors (Fetzer, 2013). In order to differentiate the notion of action in the context of objects’ participating empirically, sequential analysis benefits from this strong connection. It is reconstructed backwards or indirectly how objects take effect in the course of learning. When a human actor is operating as a turn on an object, it can be deduced, that the object must have been kind of active before. It must have ‘told’ the human actor something. The object must have *made the offer to partake the next turn*. As a consequence, the human actor, namely a learning child, brings an active return to the previous objects action.

Empirical research on the basis of this analysis of turn-partaking confirmed, that several ways of taking over offered turns by object participants can be reconstructed. Sometimes human actors accept directly-offered turns. Sometimes humans pick up unspecific offers to take over the next turn (see Fetzer, 2013). In particular this method of analysis facilitates the reconstruction of the ways, in which objects take effect in social interactions and learning processes (see Fetzer, 2013).

Theory of Argumentation

Objects have a lasting quality. Following Latour, objects and things render more durable the constantly shifting interactions (Latour, 2005, p. 68). A book might be standing disregarded on a shelf for weeks, some-thing written on the board might remain unchanged a whole school morning, a bunch of manipulatives may lie on a desk untouched for minutes. Due to their (potential) durability, objects may take effect spreading place and time. Those moments of networking when objects take part actively might be temporarily delayed. Objects may overcome temporal bounds

and limits. This fact brings up a methodological issue. Investigating objects' traces exclusively on the basis of a sequential analysis appears to be too short-handed. In addition, a second approach has to be implemented, that breaks up the narrow boundaries of sequential emergence. Referring to a sociological perspective on learning, mathematical learning processes emerge predominantly in (collective) argumentations (see Miller 1986; Krummheuer/Fetzer 2005). Consequently, investigating the role objects play in mathematical learning processes means to focus argumentative processes. In my research, I refer to the theory of argumentation and the "Toulmin Model" to capture objects' traces in mathematical learning processes analytically (Toulmin, 1958/2003).

Based on Toulmin's approach, arguments show a specific structure. The pattern of an argument has certain constituent elements, namely data, conclusion and warrant. These three functional categories are the core of an argument. The conclusion is the claim that needs to be established. When it is challenged, it has to be proven justifiable. The data is our personal knowledge, the facts we appeal to as a foundation for the claim. It is the ground we produce as support for the original assertion. It is the answer to the challenge: "What have you got to go on?" (ibid., p. 90). The shortest possible argumentation would be: Data D is the basis *so* the conclusion C can be established.

"We already have, therefore, one distinction to start with: between claim or conclusion whose merits we are seeking to establish and the facts we appeal to as foundation for the claim – what I shall refer to as our data." (ibid., p. 90).

No amount of facts may establish any conclusion. There needs to be a connection of data and conclusion on another level.

"Our task is no longer to strengthen the ground on which our argument is constructed, but is rather to show that, taking these data as a starting point, the step to the original claim or conclusion is an appropriate and legitimate one. At this point, therefore, what are needed are general, hypothetical statements, which can act as bridges, and authorize the sort of step to which our particular argument commits us." (ibid., p. 91).

These connecting links are warrants (ibid., p. 91ff.). They indicate the bearing on the conclusion on the data already produced and answer the question "How do you get there?" (p. 91). You can get from D to C *since* the warrant W .

Toulmin's analytical model is a methodological tool to reconstruct the *function* a certain action fulfils within the argument (see Kopperschmidt, 1989). It focuses on verbal as well as non-verbal actions. It is not restricted to analyse questions in dispute, but is open to all sorts of argumentative processes. Even implicit parts of an argument might be captured by analysis, as empirical research proves (Fetzer, 2007; Meyer, 2007; Schwarzkopf, 2000). Eventually, the Toulmin model connects well with the idea of tracing objects agency.

IMPACT ON RESEARCH AND PRACTICE: COUNTING ON OBJECTS IN THE MATHEMATICS CLASSROOM

Latour put an ANT in my researcher's ear, to re-think the way objects participate and take effect in the emergence of mathematical learning processes. Especially in primary mathematics education it is an expedient effort to change perspectives and explore approaches to "follow" the object-actors (Latour, 2005, p. 12, 156) and their traces. In this article the theoretical basis for empirical analysis on objects' participation in learning processes is outlined. Based on a micro-ethnographic approach to empirical research on mathematical learning processes, Latour's ANT, Goffman's Participation Framework, Sack's Turn-Taking system and Toulmin's Model of Argumentation are networked on the background level.

Actually, this local integration of theories proves to be a theoretical basis that renders empirical analysis well possible. Investigating how objects participate in the course of action leads to the development of a new piece of synthesised theory on the role objects play in mathematical learning processes. Several forms of object-participation can be reconstructed in the development of social learning processes. However, due to space restrictions, no examples of empirical analysis are given here. To learn more about the implementation of analysing objects traces see Fetzer (2013). Below, empirical results on the methodological level as well as on the theoretical level are abstracted. They outline the impact, this new approach might have on research and practice.

Methodological level

An object's opportunity to become an active participant in the course of action is strongly connected to human-actors interpretations and perceptions. It is only in moments of networking, that their acting becomes observable. When inter-acting with other actors, objects traces render perceivable. Accordingly, the basic idea of analysis is to grasp the acting of objects *indirectly*. The *analysis of turn-partaking* is the core of investigation. As soon as a human-actor takes over the turn offered by an object-actor, the current action (human) allows concluding on the previous action (object). In other words: The way students or teachers act as a turn on an object suggests how objects participate. What has the object 'told' them, when it was the object's turn?

The analysis of turn-partaking captures the *sequential* emergence of mathematical learning processes. However, one dominant feature of objects and things is their durability. As a consequence, the second methodological approach to investigate objects traces is the *Toulmin model* on argumentation. This method of analysis aims at the *function* single actions fulfil within an argument. Both tools of analysis prove to be empirically successful. They combine well in order to differentiate empirically the notion of 'action' in the context of objects.

Theoretical level

Objects take effect in the social learning process in a different way than students or teachers do. They may hold different *status of participation*. On the one hand, ratified actors might allocate them the role of *bystanders*. This is the case, if active actors perceive the object-actor as some-thing in the perceptual reach of the interactional process, but not directly involved in the course of action. On the other hand, object-actors may hold the role of *ratified participants*. In this participation status the other participants in the social learning process accept them as participants that take effect in the course of action.

The status of participation of an object is no stable allocation. An object-actor might be perceived as a bystander one moment and become a ratified participant the next minute. These changes of the participation-status from the bystander to ratified participant are triggered by other participants of the social encounter. The transition might be either initiated by human actors or by ratified active object-participants. Different conditions of emergence may be reconstructed concerning the change of participation-status:

- Objects become ratified participants, if the *process of problem solving stagnates* within the current ratified participants. Stretching the group of ratified participants and opening it to an object, which has held the bystander-status so far, often restarts the interactive learning process. These conditions for changing participative roles in case of stagnation emerge predominantly in group working phases, when teacher's interventions are minimal.
- Objects change their participative status, if *teachers* call students' attention to the turn an object offers.
- As soon as *objects* turn to be ratified participants, they often initialise the change of participative status of further objects. This might happen at the beginning of a problem solving process, if the task (an object-actor in the role of ratified participant) claims integrating manipulatives or visualisations (object-actors in the status of bystanders).

Empirical analysis provides a *differentiation of the notion of action* in the context of objects and offers answers to the following questions: How can actions be described, that are performed by object-actors? In other words: How do objects act, and what do things do in the course of action?

- As bystanders, *objects hold unspecific offers in readiness* to take over the next turn. Other participants might *pick up* this unspecific offer and get active in the interactive process.
- Taking the role of ratified participants, *objects partake turns*. At the same time they *make an offer to take over the next turn*. This specific offer addresses other participants. Its stimulative nature may vary from *volunteering* to

provoking to take over the next turn. Following, participants *accept* these volunteered or provoked offers to take over the next turn and get active.

- Objects *take part in the emergence of interactive processes*. They might contribute to the ongoing interaction especially if the problem solving process stagnates. Sometimes object-actors take over the role of a student's partner in interaction. In this case, they might not only contribute to the emergence, but *give the direction to the course of action*.
- As ratified participants *objects take over elements of an argument*. Playing the role of *data*, they clarify what there is to start from. In other cases they contribute to the conclusion. If objects take over the warrant, they legitimate the conclusion. It can be reconstructed, that objects particularly take over data and warrant. Accordingly, objects play a central role in mathematical argumentation and learning processes.

The ANT in my ear triggers a change of perspectives and shows objects through sociological lenses in a different light. Accepting objects as participants in the course of action and following the idea of objects having agency raises a scientific discussion and results in networking theories. This article shows that empirical research on the basis of Latour's approach is possible. It gives an example of how local integration of theories can lead to the development of a new piece of synthesized theory, a theory of objects participating in mathematical learning processes. Besides, the empirical results have impact on the practice of mathematics education. (For more detailed information on that aspect see Fetzner (2013)). I found out that objects may influence learning processes especially if they take over the role of ratified participants. As a consequence, our didactical efforts should aim on the following points: We should try to get objects out of the bystander-status. As mentioned above, conditions are good in group works, when students integrate objects as participants in a stagnating solving process. In other situations teachers might call students' attention to the turn an object offers. Once objects turned their status and became ratified participants, we should try to extend this participative constellation. And last but not least, objects play an important role in mathematical arguments. The empirical analyses revealed that objects participate in argumentative processes by taking over data and/or warrants. Thus they contribute to 'clearer' and 'deeper' argumentations. The more explicit and the more complex an argumentation is, the easier it becomes to follow the argumentative line and the more mathematics there is to learn.

Objects leave their traces in the emergence of social learning processes and take part in the course of action. We should count on objects in mathematical learning processes!

DIDACTIC ENGINEERING AS DESIGN-BASED RESEARCH IN MATHEMATICS EDUCATION

Juan D. Godino¹, Carmen Batanero¹, Ángel Contreras², Antonio Estepa², Eduardo Lacasta³ and Miguel R. Wilhelmi³

¹Universidad de Granada (Spain); ²Universidad de Jaén (Spain) ³Universidad Pública de Navarra (Spain)

In this paper we analyze two approaches to research in mathematics education: "Design-based research" (DBR) and "Didactic engineering" (DE), in order to study their possible networking. The problem addressed in both approaches is the design and evaluation of educational interventions, providing research-based resources for improving the teaching and learning of mathematics. They also try to contrast existing theories, or characterize new educational phenomena. We conclude that DE could be seen as a particular case of DBR, linked to the "Theory of didactical situations", or that DBR is a generalization of DE that use other theoretical frameworks as foundations for designing teaching experiments.

Key words: networking theories, didactic engineering, didactic design, teaching experiment, didactic resources.

INTRODUCTION

The view of Didactic of Mathematics as a "science of design" is highlighted by several authors (Wittman, 1995; Hjalmarson & Lesh, 2008a; Lesh & Sriraman, 2010). Lesh and Sriraman consider mathematics education as a science oriented to design processes and resources to improve teaching and learning of mathematics and reflect on the purpose of research in mathematics education:

Should mathematics education researchers think of themselves as being applied educational psychologists, or applied cognitive psychologists, or applied social scientists? Should they think of themselves as being like scientists in physics or other "pure" sciences? Or, should they think of themselves as being more like engineers or other "design scientists" whose research draws on multiple practical and disciplinary perspectives— and whose work is driven by the need to solve real problems as much as by the need to advance relevant theories? (Lesh & Sriraman, 2010, p. 124).

Recent interest in Anglo-Saxon literature on design-based research (handbooks; special issues of high-impact journals) and on its role in mathematics education complements the traditional French literature on "Didactic engineering" (Artigue, 1989), which provided significant contributions from the 80's, but was virtually ignored in this literature. This suggests a certain isolation of the French didactic engineering regarding the research done in other countries with similar objectives.

The purpose of this paper is to establish some connections between both research approaches or paradigms by trying to answer the following questions:

- Can didactic engineering be included within the family of design-based research?
- What kind of synergies can be established between these research paradigms?

The problem of comparison and coordination of theoretical frameworks is a topic of relevance discussed by various authors and in discussion forums, such as the CERME Working Group "Different Theoretical Approaches and Perspectives in Mathematics Education Research" (Prediger, Arzarello, Bosch, & L'enfant, 2008). Bikner-Ahsbals and Prediger (2010) make a plea for exploiting theoretical diversity as a resource for richness and consider this diversity as a challenge and starting point for further theoretical development through networking theories.

In this paper we compare "Didactic engineering" (DE) and "Design-based research" (DBR), starting with the identification of their basic features and later carrying out a rational comparison of them. In the next two sections, a summary of the characteristics of DBR (Collins, Joseph, & Bielaczyc, 2004; Kelly, Lesh & Baek, 2008), and DE (Artigue, 1989; 2009, 2011) is carried out. Then we identify similarities, differences and possible complementarities in the problems addressed, the theoretical principles, methodology and intended results.

DESIGN-BASED RESEARCH MAIN FEATURES

Design-based research¹ (DBR) (Brown, 1992; Kelly, Lesh & Baek, 2008) is a family of methodological approaches for the study of learning in context. It uses the design and systematic analysis of instructional strategies and tools, trying to insure that instructional design and research be interdependent. It is assumed that educational research separated from practice cannot take into account the context influence on the complex nature of the results, or cannot adequately identify their constraints and conditioning factors: "We argue that design-based research can help create and extend knowledge about developing, enacting, and sustaining innovative learning environments" (DBRC, 2003, p. 5). This group of authors used the term design-based research methods to differentiate their approach from the classic experimental design in teaching, attributing five characteristics to this method:

1. The central goals of designing learning environments and developing theories or "prototheories" of learning are intertwined.
2. Development and research take place through continuous cycles of design, enactment, analysis, and redesign.
3. Research on designs must lead to sharable theories that help communicate relevant implications to practitioners and other educational designers.
4. Research must account for how designs function in authentic settings. It must not only document success or failure but also focus on interactions that refine

¹ It is also known as *design research* or *design experiments*.

our understanding of the learning issues involved.

5. The development of such accounts relies on methods that can document and connect processes of enactment to outcomes of interest. (DBRC, 2003, p.5).

As methodological paradigm, DBR, specifies how to conduct design studies, i.e. investigations of some length on educational interventions induced usually by a designed set of innovative curricular tasks and/or instructional technology. "Often, what gets designed is a whole 'learning environment' with tasks, materials, tools, notational systems, and other elements, including means for sequencing and scaffolding" (Reimann, 2011, p. 38). Usually there is no strict separation between development and theory test, but rather both are interconnected in a way reminiscent of "grounded theory" (Glaser & Strauss, 1967). However, in DBR there is no particular interest to avoid using previous theories; on the contrary it encourages theory building that incorporates elements beyond the observations. "Design experiments are conducted to develop theories, not merely to empirically tune 'what works'" (Cobb, Confrey, diSessa, Lehrer and Schauble 2003, p. 9). DiSessa and Cobb (2004) highlight the role of theory in what they call the "ontological innovation"—the invention of new scientific categories, specifically categories that do useful work in generating, selecting among, and assessing design alternatives.

Three phases are considered along a design experiment (Cobb and Gravemeijer, 2008): 1) Planning of the experiment, 2) Experimentation to support learning; 3) Retrospective analysis of the data generated along the experiment.

According to Collins, Joseph and Bielaczyc (2004), design experiments, incorporate two critical elements to guide us in improving educational practice: the focus of design and the evaluation of critical elements. These experiments complement other empirical methods, such as ethnographic studies, clinical research, experimental or quasi-experimental studies to assess the effects of independent variables on dependent variables. But they also pose challenges that may be common to other research on education, such as:

- Difficulties arising from the complexity of real-world situations and their resistance to experimental control.
- Large amounts of data arising from the need to combine ethnographic and quantitative analysis.

DIDACTIC ENGINEERING MAIN FEATURES

The notion of "Didactic engineering" (DE) was introduced in the French Didactic of Mathematics in the early 80's to describe a research approach in mathematics education comparable to an engineer work. When carrying out a project the engineer relies on scientific knowledge from his/her domain; he/she agrees to submit the project to scientific scrutiny, while at the same time, is forced to solve issues more complex than those of science, and therefore to address problems that science cannot yet take over (Artigue, 1989, p. 283). Since its origin, didactic engineering was

fundamentally linked to educational interventions (experiments) in classrooms, usually sequences of lessons; these experiences were guided by and tried to test some theoretical ideas (Artigue, 2011, p. 20). That is, DE is conceived as the design and evaluation of theoretically justified sequences of mathematics teaching, with the intention of trigger the emergence of some educational phenomena, and to develop teaching resources scientifically tested.

Considering the state of the French research in mathematics education at the beginning of the 80s, it is not surprising that the natural theoretical framework for didactic engineering was the Theory of didactical situations (TDS) (Brousseau, 1986; 1997). In fact, didactical engineering has been the privileged didactical research methodology in France. Some features of DE in its original sense are:

- It is based on classroom teaching interventions, i.e. on the design, implementation, monitoring and analyzing teaching sequences.
- The validation is essentially internal, based on the confrontation between a priori and a posteriori analysis (there is no external validation, based on comparison of performances in experimental and control groups).

Didactic engineering addresses case studies where the following phases are distinguished (Artigue, 1989): a) Preliminary analysis b) Design and analysis a priori of teaching situations; c) Experimentation; d) A posteriori analysis and evaluation. Perrin-Glorian (2011, p. 59) suggests that didactic engineering from the beginning "is more than a research methodology: it is also intended a didactic transposition viable in the ordinary teaching". That is, the view of didactic engineering as a product is as important as the method.

The evolution of didactic engineering was linked to the change of the Theory of didactical situations (TDS) itself, or the application of other theoretical models derived from the TDS, such as the Anthropological Theory of Didactics (Chevallard, 1992), or research about teachers practices. Perrin-Glorian (2011) distinguishes two types of didactic engineering according to the primary research objective: 1) didactic engineering for research aims to produce research results with experiments depending on the research question, without worrying about a possible wider dissemination of the scenarios used, 2) didactic engineering for development and training; here the short-term goal is the production of resources for teachers and for teacher training.

Although didactic engineering is not uniform, because of the changes that have been introduced, some sensibilities remain: epistemological sensitivity (expressed or not in terms of fundamental situation), emphasis on building tasks, concern for the organization of a *milieu* that offers a strong a-didactic potential, the key role played by the a priori analysis and the insight into the validation processes. As a result didactical engineering has become an object of fuzzy contour (Artigue, 2011, p. 23).

COMPARING AND RELATING BOTH METHODOLOGICAL APPROACHES

In this section we try to build a bridge between didactic engineering (DE) and design research in education. Already Hjalmarson and Lesh (2008b) compared design research with engineering:

Our view of design in education research is based, in part, on the similarities and parallels to be drawn between education and engineering as fields which simultaneously seek to advance knowledge, impact human problems, and develop products for use in practice (Hjalmarson y Lesh, 2008a, p. 526).

For these authors engineering primarily involves the design and development of products that operate in systems, and includes the process of design and the tangible products of that design:

The parallels between engineering design and education design begin with the nature of the systems where the products of design are used. The systems are not fixed even if they are often stable. The systems require innovation, respond to innovation (e.g., a curriculum, a piece of technology), and are changed by innovation (Hjalmarson y Lesh, 2008b, p. 107).

It is clear that the use in the field of education of design-based-research, and the comparison with engineering as design technology, is restricted to the "instructional design", which becomes synonymous with "didactical design". Didactical design in mathematics education, "Includes all types of 'controlled intervention' research into the processes of planning, delivering and evaluating concrete mathematics education. It also includes the problem of reproducibility of results from such interventions" (Winslow, 2009, p.2).

There is, however, a substantial difference between DBR and DE, which is closely linked to the methodological approach provided by the interpretive framework of a didactical base-theory, as the Theory of didactical situations (TDS). The close relationship of DE with the TSD provides explicit criteria, in the design, implementation and retrospective analysis, and an orientation to test and develop the theory itself. By contrast, although design-based research has similar goals, it does not adopt specific theoretical frameworks. DBR is, therefore, a family or category of educational research perspectives bonded for the interest or focus in the design, implementation and evaluation of educational interventions in naturalistic contexts, without explicit interest in epistemological questions. "A very noticeable aspect of the design research literature is the absence of discussion of epistemological issues. In the recent Handbook of Design Research Methods in Education (Kelly et al., 2008), for instance, the word 'epistemology' is not even used as an indexing term, and, while the word is not totally absent from the general DBR literature, there is no serious discussion of epistemological issues" (Walker, 2011, p.53). On the contrary, in DE epistemological questions are central because they are crucial in Theory of didactical situations.

While in DBR the focus is the design and search of instructional resources, DE goes further, trying to analyze the characteristics of these resources (and in general,

everything that constitutes the *milieu*); the idea of a didactic situation, where students are involved in solving a problem, without the direct guidance of the teacher, and the dialectic between didactic and a-didactic situations are particularly important.

Although both approaches are mainly qualitative (or mixed), an important difference is the establishment in DE of a priori hypotheses (before the experience design), while DBR tends to a qualitative posture, assuming that theories emerge from the data. Although the methodology stages are very similar, there is a greater influence of the previous theory in DE that seeks explicitly validation (even if internal) of the previous hypotheses, and the previous analyses of the design are detailed and complete.

In Table 1 we summarize the comparison between the DBR and the DE, considering the three key elements proposed by Radford (2008) as constituting a theory: paradigmatic issues, principles and methods. We also identify the results expected in its application.

Table 1. Comparison of DBR and DE (TSD)²

	DBR	DE (TSD)
Paradigmatic issues	<ul style="list-style-type: none"> -How to improve mathematics learning in realistic school contexts based on research results? -What instructional resources can be used to improve teaching and learning mathematics? 	<ul style="list-style-type: none"> -What type of problem-situations give meaning to a specific mathematical knowledge? ² We introduce the notation DE (TSD) to indicate the dependence of the "Didactic engineering" from the Theory of Didactic Situations. This will help to express possible generalizations of didactic engineering changing the base-theory used to support the instructional design.

	-Local emerging theories	base-theory -Fundamental situations -Instructional resources
--	--------------------------	--

The paradigmatic issues stated for DE (TSD) are somewhat similar to the DBR, although oriented and specified in the light of the underlying theory. The "fundamental situations" are models or representations of mathematical knowledge, i.e. characterizations of knowledge through the issues or problems for which that knowledge is an answer. The constructivist epistemological position about mathematical knowledge supporting DE, does not explicitly question an institutional relativity for that knowledge. This relativity was later highlighted by the Anthropological Theory of Didactic (ATD) (Chevallard, 1992, 1999) and the Onto-semiotic Approach (OSA) (Godino, 2002; Godino, Batanero and Font, 2007) assuming that the "raison d'être" of knowledge change in different institutions, or from its original construction in the history of mathematics, as regards its current use.

Consequently, we could view DBR as an extension of DE (TSD). While the former does not have a single or preferred theoretical framework, DE rests on a theory of intermediate level, the Theory of didactical situations which provides criteria to develop mathematical situations (search of fundamental situations for specific mathematical knowledge), and also for implementing and conducting the teaching situations in seeking students' autonomous learning. From the methodological point of view the preliminary study proposed in DE (TSD) may be a distinction, motivated and oriented by the base-theory towards the epistemological analysis of the mathematical knowledge to be taught.

FINAL REMARKS

As we have mentioned, the main problem of DBR is to develop instructional resources to improve the teaching and learning mathematics in naturalist school contexts, based on research. Since the research on educational interventions depends critically on the theoretical frameworks used to support the design, implementation and interpretation of results, different DBR will depend on the base-theory, or lack of theory. Therefore, we could conceive DBR as a family of methodologies or educational research approaches. Given that the aim is to develop a product based on research (curriculum, sequence of lessons, educational software, etc.), as Hjalmsen and Lesh propose, this type of research can be considered as a form of engineering inquiry. With a wider tradition, the French didactic engineering addresses a similar problem, and is supported by an explicit base-theory of intermediate level, the Theory of didactical situations. Therefore, we may consider it as an antecedent (in time) of the family of DBR, and a particular instance thereof.

It is also clear that instructional designs based on theoretical models different from the Theory of didactical situations are carried out and produce varieties of design-based research. These varieties share some paradigmatic issues, theoretical

assumptions, methodologies and intended results, but may differ in others, as it is indicated in Figure 1 for didactic design based on the Anthropological Theory of Didactic (ATD), the Onto-Semiotic Approach (OSA), Realistic Mathematics Education (RME) (Freudenthal, 1991; Heuvel-Panhuizen, & Wijers, 2005), or, for example, the Lesson Study in Japan (JSL) (Fernandez & Yoshida, 2004). In this figure we also suggest to consider the expressions, DBR - Design-Based-Research, DE - Didactical Engineering, ID - Instructional Design and DD - Didactical Design, as synonymous, i.e. with equivalent meaning.

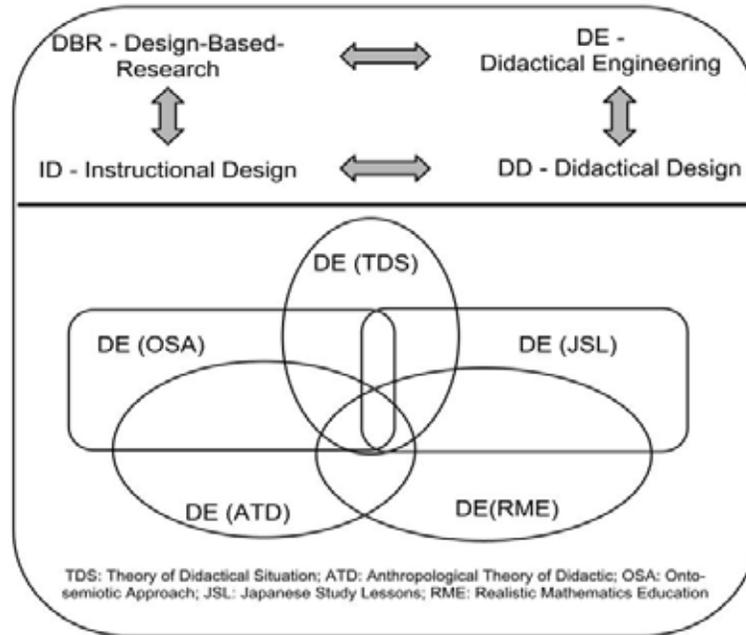

Figure 1. Varieties of design-based researches

All these types of didactic engineering (instructional design, didactical design, ...) share similar issues. However, new analyses are needed to clarify in more detail that that carried out in this paper the methodological consequences that arise from a change in the base-theory supporting each particular engineering, and to explain the types of results that can be obtained in each case.

NETWORKING METHODOLOGIES: ISSUES ARISING FROM A RESEARCH STUDY EMPLOYING A MULTI-MEDIA ARTEFACT

Mike Hickman & John Monaghan

York St John University & Leeds University, UK

This paper focuses on the methodological matters arising from using a multi-media artefact in an empirical study of student teacher collaborative mathematical problem solving. The use of this artefact in post-task stimulated recall interviews allowed two distinct methods of collecting data to be 'networked'. Issues raised by this 'networking of methodologies' include: how an artefact can enable the networking of methodologies; what a methodology is and its relationship with 'theory'; and a consideration of the work of past CERME 'theory group' participants' views on theories and methodologies.

Key-words: methodology, networking, think-aloud protocols, task-based interviews, stimulated recall.

INTRODUCTION

In the course of investigating student teacher collaborative mathematical problem solving we employed a specific multi-media artefact (the *Livescribe* pen, described later). The use of this artefact in post-task stimulated recall interviews suggested that two apparently distinct methods of collecting data on collaborative problem solving, think-aloud protocols (Ericsson & Simon, 1993) and task-based interviews (Goldin, 1997), could be 'networked'. In this paper we foreground methodological aspects of the investigation to explore issues related to networking theories.

This paper is structured as follows. We begin by describing think-aloud protocols and task-based interviews approaches. We then consider stimulated recall methodologies and *Livescribe* pens. We then outline our investigation of collaborative problem solving, to provide readers with the context of the research and a rationale for the approach we adopted. This is followed by an outline of past CERME 'theory group' participants, Radford (2008) and Artigue, Bosch & Gascón (2011), with particular regard to the place of methodology in theoretical frameworks. The paper ends with a discussion of issues raised and a consideration of the implications of our work for issues raised in the CERME 8 *call for papers*.

THINK-ALoud PROTOCOLS AND TASK-BASED INTERVIEWS

Think-aloud protocols (T-AP) and task-based interviews (T-BI) can be regarded as methodological approaches for capturing data on domain specific problem solving. Both rely on participants' verbal reports and allow opportunities for participants to engage in 'live' reflection on their 'free' problem-solving performance in order to elicit reasoning. Both were developed in the last quarter of the 20th century and were relevant to research foci in expert-novice thinking, which was in vogue in this period. T-BI, but not T-AP, were developed within the mathematics education field. Neither

was initially tied to a specific theoretical framework and both have been used by researchers espousing various constructivist and socio-cultural positions. Ericsson & Simon (1993) and Goldin (1997) are comprehensive expositions of each approach.

A key difference between the two approaches is that T-AP ask participants to ‘think-aloud’ during task performance whilst T-BI do not encourage this; T-AP afford reflection ‘in the moment’ by a self-directed participant whilst T-BI afford reflection ‘after the act’ via interviewer prompts on strategies undertaken. Ericsson & Simon (1993) note that there are different kinds of think-aloud verbalisations, from free association utterances (their Type I and Type II verbalisations, as discussed by Robertson (2001, p.13) involve ‘direct verbalisation’ and ‘recoding of short term memory’) to verbal descriptions of everything that the participant is conscious of whilst engaged in the task (Type III verbalisations); a risk with the latter type is that this will frustrate participants’ problem solving. The exploration of learner thinking in T-BI has four stages and two goals:

- (a) posing the question (“free” problem solving) ...[with] nondirective follow-up questions (e.g., “Can you tell me more about that?”);
 - (b) heuristic suggestions if the response is not spontaneous (e.g., “Can you show me by using some of these materials?”);
 - (c) guided use of heuristic suggestions ... (e.g., “Do you see a pattern in the cards?”);
 - and (d) exploratory (metacognitive) questions (e.g., “Do you think you could explain how you thought about the problem?”).
- The clinician’s goal is always to elicit (a) a complete, coherent verbal reason for the child’s response and (b) a coherent external representation constructed by the child ... (Goldin, 1997, p.45).

From a T-AP perspective such ‘after the act’ verbalisations are ‘suspect’ as they may provide data on what participants think they thought rather than on their thoughts-in-action; there is also a danger that the interviewer may co-produce knowledge (Hobson & Townsend, 2010). A T-AP approach, however, may not establish coherent verbal reasons for actions and much may remain unspoken, even if the interviewer encourages verbalisations of descriptions of everything in the participant’s consciousness. There appears to be no scope for a hybrid form (‘networking’) of the two approaches¹ to capture data during problem solving since interrupting the think-aloud process with task-based interview style questions or establishing a protocol in which there is a strong emphasis on explaining and describing thinking, may impact upon free problem solving (that both approaches arguably require as a first step). Indeed, Ericsson and Simon (1998, p.180) state that “participants’ efforts to describe and explain thinking can change the sequence of thoughts and lead to the intrusion of additional thoughts” thus potentially leading to “interfere[ence] with normal [mathematical] problem solving [processes] by either slowing...[them]...down or affecting the sequence of problem solving steps” (Robertson, 2001, p.13).

STIMULATED RECALL AND *LIVESCRIBE* PENS

Stimulated recall "is one subset of a range of introspective methods that represent a means of eliciting data about thought processes involved in carrying out a task or activity" (Gass and Mackey, 2000, p.1). A stimulated recall interview (SRI) typically involves the use of a stimulus such as an audio or video tape to "enable the participant to 'relive' the episode to the extent of being able to provide, in retrospect, an accurate verbalised account of...original thought processes" (Calderhead, 1981, p.212). Mason (2002, p.63) claims (and we agree) that SRI allows researchers to explore participants' "knowledge, views, understandings, interpretations, experiences and interaction"; there is thus a sense in which SRI and T-AP share ontological and epistemological principles (in the sense that Radford (2008) uses the term 'principles'). Given that a SRI is an 'after the act' replay, there is no reason why a SRI cannot be in two stages: (i) no interviewer prompting; (ii) interviewer prompting. The use of such a two stage SRI could then follow the protocols of both T-AP and T-BI.

Livescribe is the brand name of a digital pen with a built-in digital audio recorder. While it can be used as a regular pen on ordinary paper, when used with special proprietary paper, it records writing to be uploaded to a computer (which can then be played back/animated in real time) alongside the audio of sounds recorded at any point in the script. In addition to this, touching the pen to any point on a 'completed' page of notes/jottings also enables the instant replay of the precise sounds (for example, any conversation occurring at that point in the writing), thereby facilitating recall, should it be required, even without upload to a computer. This last point is very interesting in student playback of problem solving talk/writing as students can hear the talk associated with specific written symbols. *Livescribe* pens thus afford being used as a stimulus in SRI.

AN INVESTIGATION OF COLLABORATIVE PROBLEM SOLVING

Part-time postgraduate primary student teachers at York St John University took part in a pilot project (for the first author's PhD) exploring how digital audio recordings may provide opportunities to engage in closer consideration of, and reflection on, their mathematical problem solving performance. The research question was: how does thinking aloud, supported by digital audio recording, support student teachers' understanding of problem solving. Like most research questions, this one did not appear 'out of the blue', it arose from academic dialogue which tried to 'intellectualise' the first author's prior 'success' in engaging student teachers in 'real' problem solving and his prior experiments in using *podcasts* with his student teachers (*podcasts* were seen as a means to keep part-time students engaged in mathematics during periods of absence from the University). The practical idea 'behind' the research question is: if student teachers can critically reflect on their own problem solving, then this reflection may help them to design learning environments which support 'real' problem solving for their future pupils. The following (supplemented

by a picture of an abacus) is one of the problems the students worked on in self-selected small groups:

Make as many three digit numbers as possible with 25 beads on one abacus.

An assumption behind this work was: student-student discourse during problem solving is important for mathematical development. We value Mercer's (1995) work in this area and consider his category 'exploratory talk' (where participants engage critically but constructively with each other's contributions) as important for mutual development. We also wanted a framework for problem solving and used that of Hošpesová and Novotná (2009), largely due to the connections that can be drawn between their categories and Mercer's (1995) work. A hybrid 'talk and problem solving framework' is detailed in Hickman (2011). This framework includes Mercer's (1995) three categories of talk (disputational, cumulative and explorative) but the explorative category is sub-divided into that in which relevant information is offered for joint consideration in: mathematical form; non-mathematical form.

Independent of this work the second author purchased *Livescribe* pens because he thought they might be useful for research. The first author 'tried these out' and we agreed that they were potentially useful for this research.

The research consisted of student teachers thinking aloud whilst engaging in group problem solving activities with *Livescribe* pens; at this point the interviewer employed a T-AP protocol. Just over a week later the students revisited (with the aid of the *Livescribe* pens) their work to identify potentially beneficially exploratory dialogue; at this point the interviewer employed a T-BI protocol. This 'revisitation' of their work included students using the hybrid framework to categorise particular responses.

It could be said that this 'revisitation' falls short of what some researchers regard as a SRI, for example, "the stimulated recall group...[speak]...their thoughts into a microphone as if talking to [themselves]" (Egi, 2008, p.226). However, the T-BI approach supported by the recorded material picked up by the *Livescribe* pens afforded the students the opportunity to identify themes, to talk to themselves and to reflect on the performance of their earlier 'selves'.

This pilot study was not without problems. Sometimes connections with mathematics recently engaged in were not noticed and this appeared to be linked to the presence of the digital audio recorder and the associated talk protocol, which, some students in the SRI claimed, impacted on their performance:

Well, we knew that we *had* to discuss it in this way...

Some began speaking *before* they had fully considered the problem:

I would have preferred to have had time on my own to look at it first and then come into it because...solutions started being talked through before I was at that point.

This indicates that, however important talk protocols may be, additional ‘ground rules’ are required before beginning a task of this kind. The same issues may have impacted upon the use of the *Livescribe* pens (i.e. making jottings because they felt they ‘had’ to) but the presence of the notes and the *Livescribe* pen often provided evidence of exploratory contributions that would not otherwise have been evident, ‘making up for’ and, ultimately, enhancing the quality of the original mathematical discussion. Participants were able to identify their exploratory comments more effectively within the *Livescribe* supported SRI than had been the case via their original T-AP (one potential cause of their less successful listening to each other’s contributions being their level of concentration on their own verbal contributions and awareness of being recorded). For example, in the SRI (but not in the T-AP) of the *abacus problem*, participants noted that they had, in fact, been presented with a problem similar to one that had previously been encountered (indeed, the problem had been chosen for this reason). Therefore, the *Livescribe* supported SRI afforded students the opportunity to make connections, from their original contributions and working, that had not been explicitly identified in the original problem solving session. In the original recording, one participant cautiously observed:

This is like one of the problems we did last week where after a certain number, you have to ... you have ... yeah...

Given the ‘unfinished’ nature of the verbalised thought, it is unsurprising that it was not effectively built upon (in Mercer’s (1995) ‘cumulative’ fashion); it took the *Livescribe* SRI to make it clear to participants what had originally been propounded.

CERME PARTICIPANTS’ VIEWS ON METHODOLOGY

In this section we outline our interpretation of the views of ‘methodology’ in Radford (2008) and in Artigue, Bosch & Gascón (2011). We select these papers because they deal with ‘networking theories’ and we critically value them.

Radford (2008, p.320) suggests that “a theory can be seen as a way of producing understandings and ways of action based on: ... *basic principles* ... a *methodology* ... paradigmatic *research questions*”. The principles (P) are a ‘system’ of unequally weighted ‘elements’ (views or statements) on pertinent constructs such as cognition, learning and social interaction; Radford would say that our statement above, “student-student discourse during problem solving is important for mathematical development”, is a principle. Radford adds that “there is a *hierarchy* that organizes and prioritizes them” (ibid.). Our statement was explicit, behind our statement is an implicit view that development is cultural and is mediated by language.

Radford (ibid.) states that a ‘methodology’ (M), “includes techniques of data collection” and may go beyond ‘positivistic’ data collection. The word “includes” suggests that there is more that can be said about a methodology – we agree! Further to this a methodology must have *operability* (produce data to address research questions and distinguish between relevant and irrelevant data) and *coherence*

(consistency with principles); relevant data is that in which there is coherence between the principles and the methodology of a theory.

Paradigmatic *research questions*, Q, are “templates or schemas that generate specific questions as new interpretations arise or as principles are deepened, expanded or modified” (ibid.). “Expanded or modified” suggests a ‘state of flux’ in the ‘lives’ of theories with Radford further stressing ‘flexibility’ and interrelations between P, M and Q. Both of these aspects endear us to Radford’s approach but, despite the interrelationships, P, M and Q are distinct in Radford’s exposition. We return to this in the next section and now turn to Artigue et al. (2011).

Artigue et al. (2011) is a novel but straightforward application of Chevallard’s (via Mauss’s) construct ‘praxeology’ to the phenomena of theorising. We refer the reader to Chevallard’s CERME address (Chevallard, 2006) for an exposition of this construct but outline the terminology below.

A praxeology consists of four elements [T/τ/θ/Θ] in two pairs, “[T/τ] corresponds to the ‘practice’ ... *types of problems* T that are approached and the *techniques* τ ... [θ/Θ] forms the *technological-theoretical* discourse used to describe, justify and interpret [the practice]” (Artigue et al., 2011, p.2). This language underpins an epistemological model. An immediate insight from this perspective is that “talking about ‘theories (as in the expression of ‘networking theories’) is the result of a metonymy used to point to the whole – *research praxeologies* – by only indicating one part, the theoretical block of praxeologies.” (Artigue et al., 2011, p.2) It appears possible to replace the word ‘technique’ with ‘methodology’ in the case of research praxeologies and this certainly can be done in some research praxeologies but we feel that part of a methodology can be located in the technological component in our research.

An important adjunct in Artigue et al.’s (2011) consideration of research praxeologies is the construct (didactic) ‘phenomenon’, “empirical facts, regularities that arise through the study of research problems” (Artigue et al., 2011, p.3). Our informal interpretation of such phenomena is *what is important/striking in the research under consideration?* As an aside, we believe that this construct could be used to partition papers in recent CERME ‘theories working group’ into those with a (and those with no) central phenomenon; in the latter case there would appear to be a sense of ‘networking for the sake of networking’.

Artigue et al. (2011) state “our approach is fully coherent with that developed by Radford (2008)”. We too see commonalities in these two approaches but their distinct ontologies means that there can be no isomorphic mapping between them.

DISCUSSION

Our focus in this section remains on methodological issues. We address two issues: the role of *Livescribe* pens in ‘networking methodologies’; whether T-AP and T-BI are simply methodological approaches for capturing data. In considering the second

issue we explore the views of methodology in Radford (2008) and Artigue et al. (2011) with regard to our research.

We present an argument above that there is no scope for ‘networking’ the two approaches to capture data during problem solving. However, the *Livescribe* pen allows for an initial T-AP interview to be ‘played back’ in an SRI with a T-BI protocol. There is a real sense in which this artefact affords networking these interview approaches. With regard to Radford’s (ibid.) view that a ‘methodology’ (M), “includes techniques of data collection and data-interpretation as supported by P” our use of both T-AP and T-BI could be seen as ‘opportunistic’ research which compromises basic principles (using the principles of T-AP in the initial interview and the principles of T-BI in the SRI). We, however, consider that the *Livescribe* pen allows the researcher to ‘link’ the initial T-AP activity and the subsequent T-BI activity whilst retaining the principles of both (but separately in the two stages of the activity). In terms of Goldin’s (1997) four stage exploratory process T-AP are used (appropriately) in the free problem solving first stage and the remaining three stages (heuristic suggestions; guided use of heuristic suggestions and metacognitive questions) follow within the SRI. There is thus a sense in which the *Livescribe* pen does more than network interview approaches; it contributes to a ‘stronger’ T-BI protocol as heuristic suggestions, for example, may be more readily identifiable via a combination of ‘jottings’ and comments (most especially those that are, as discussed above, not fully verbalised) than through a written record or audio recording alone. Furthermore, it is arguable that, knowing that the *Livescribe* recording will preserve and actively connect these ordinarily disparate elements ensures that there is less necessity for an onerous verbalisation protocol, thus supporting the initial free problem solving.

We now consider whether T-AP and T-BI are simply methodological approaches for capturing data. We continue with a consideration of the Radford (2008) quote above but now focus on the word ‘includes’. Radford is ‘hedging’ here. A methodology certainly includes data collection and analysis techniques, but many researchers, we feel would replace ‘includes’ by ‘are’. We support Radford’s ‘includes’ but (like Radford, we suspect) find it difficult to state (in the abstract) what a methodology holds beyond data collection and analysis techniques. We prefer to approach the abstract in this matter via the concrete: are T-AP and T-BI simply data collection and analysis techniques? Our view is ‘no’, they have evolved into quasi-theoretical approaches where an implicit (and flexible) ‘theory’ is intertwined with an explicit methodology. We have not explicitly researched their evolutions but both approaches were developed over a period long before the publication of Ericsson & Simon (1993) and Goldin (1997). We further suspect that each has two types of ‘principles’, explicit principles associated with data collection and analysis techniques and flexible implicit principles which may be appropriated by researchers of a variety of ‘theoretical’ approaches (e.g. constructivists and activity theorists

amongst others). We hold that there is an historical ‘irreducible bond’ between theory and methodology in the various research uses of both T-AP and T-BI.

We now turn our attention to Artigue et al.’s (2011) research praxeologies but continue to consider the ‘includes’ vs ‘are’ matter above. In the language of Artigue et al. (2011), being in the ‘are’ camp would place methodology in the [T/τ] ‘practice’ pair of a praxeology. In the words ABG use, there are indications that they are in the ‘are’ camp; “Some of these phenomena enrich the initial theoretical framework to produce new interpretations and techniques or research methodologies” (p.3). But Artigue et al. (2011) was the first paper on this matter. In a more recent paper (Bosch, 2012, p.3) there is a suggestion that a part of the methodology can reside in the *technology* (θ) part of the *technological-theoretical* [θ/Θ] pair.

Dans le cadre des PR, le niveau technologique permet de distinguer, dans le bloc théorique de description, interprétation et justification de la pratique, un ensemble d’éléments plus variables et mobiles que constituent le premier niveau de description des techniques, la « technologie », de la « théorie » formée par des principes et hypothèses plus stables qui font partie du « noyau dur » de la praxéologie et qu’il est plus difficile de faire évoluer sans que la construction complète en soit altérée. De cette manière, la prise en compte du niveau technologique des praxéologies de recherche permet de clarifier la relation, généralement assez obscure, entre une théorie scientifique et sa méthodologie de recherche.

In the framework of research praxeologies, the technological level permits one to identify, in the ‘theoretical block’ of (or which contains) the interpretation and justification of the practice, a body of more variable and mobile elements which make up the first level of descriptions of techniques – the ‘technology’. The ‘theory’ IS formed by the more stable principles and the hypotheses which are part of the ‘hard core’ of the praxeology and which are difficult to evolve without the complete construction being altered. Taking into account the technological level of research praxeologies allows a clarification of the relation, which is generally obscure, between a scientific theory and its research methodology.

This certainly ‘makes sense’ to our way of thinking, as a technique requires a rationale, a *technology* in the language of Artigue et al. (2011). We look forward to discussing this matter with the authors at CERME 8.

Summing up the considerations above, on what a methodology is, we focus on the concrete practice of researchers. ‘Methodology’ is a word to describe a part of this practice. The word should not be reified to hold mysterious qualities beyond concrete practices. In the concrete practice of some, but not all, researchers, a methodology ‘is’ a technique (resonances to Marx’s 8th thesis on Feuerbach in this paragraph are intentional).

IMPLICATIONS

Our considerations in this paper impinge on the following themes in the ‘call for papers’:

- Examples of strategies for connecting theories [methodologies]
- Conditions for a productive dialogue between theorists [methodologies]
- Difficulties and strategies when gathering results from different frameworks
- The role of the empirical material (research data) in the networking and design of theories
- The interaction between contexts and theoretical approaches: the diversity of approaches towards context in different didactic cultures

Specifically this paper raises three issues for the on-going discussion of the CERME ‘theory group’. First, it raises the issue of what a methodology is and its relationship with ‘theory’; this is useful as methodology has been somewhat of a ‘poor relation’ in the past considerations of the CERME ‘theory group’. Second, it suggests that an artefact, the *Livescribe* pen (together with SRI), can enable the networking of theories/methodologies (and possibly build a stronger theory-methodology in the process). Third, it encourages a reconsideration of the work of past CERME ‘theory group’ participants, Radford (2008) and Artigue et al. (2011), views on theories and methodologies; we say above “there can be no isomorphic mapping between them” but perhaps we can consider how these two meta-theoretical stances can be networked.

NOTES

ⁱ Individual researchers are, of course, free to do whatever they want in their research but, from the point of view of this paper, taking a bit of T-AP and bit of T-BI in a single research protocol would result in an approach that was neither T-AP or T-BI in principle.

NETWORKING THEORIES IN A DESIGN STUDY ON THE DEVELOPMENT OF ALGEBRAIC STRUCTURE SENSE

Thomas Janßen & Angelika Bikner-Ahsbabs

University of Bremen (Germany)

In this paper, we discuss how two different theoretical approaches are networked using a coordinating methodology with the aim to describe the development of algebraic structure sense in classroom interaction. From cycles of gathering, connecting, and structure-seeing in the social situation individual structure sense emerges in moments of objectification and subjectification, and can become visible in later instances of structure-seeing.

INTRODUCTION

The networking of theories has shown to be a helpful research frame for linking theories respecting their diversity as richness (Bikner-Ahsbabs & Prediger, 2010; Gellert, Barbé, & Espinoza, 2012). On the one hand it is a way of improving research by benefitting from the strengths of different theoretical approaches, on the other hand it may deliver an epistemological contribution to mathematics education through empirical studies on the networking of theories and through theoretical reflections on the matter and its meta-theoretical and methodological ideas (Arzarello, Bikner-Ahsbabs, & Sabena, 2009; Bikner-Ahsbabs et al., 2010; Kidron, Bikner-Ahsbabs, & Dreyfus, 2011). Radford (2008) postulates the semiosphere as a space for the networking of theories, where theories are distinguished by their identities and boundaries towards other theories. Theories can then be seen “as a way of producing understandings and ways of action based on the triple (P, M, Q)” (Radford, 2008, 320) where P is the set of basic principles, M in this pragmatic approach is a set of methodologies as a way of data collection and interpretation based on P and related to Q, while Q is a set of paradigmatic questions deeply related to P and M. However, methodology in our view also includes the meta-rules connected to P that imply specific ways of data collection, analysis, and interpretation. Concerning this definition, networking takes place between these three components. The degree of integration through networking may vary according to the *networking strategies* from understanding other theories and making understandable the own theory to coordinating or integrating theories locally and synthesizing them (Bikner-Ahsbabs & Prediger, 2010, 495 ff.). In this paper an example of empirical research exploring the strategy of coordinating is presented. It is part of a design study on the development of algebraic structure sense in grade 8. The specific contribution of two coordinated theories is pointed out focusing on the boundary between the theories and on the process of crossing it during the research that leads to a deepened insight into the development of structure sense.

RESEARCH BACKGROUND: ALGEBRAIC STRUCTURE SENSE

The research literature on algebra education has stated a demand for a better support of students' *algebraic structure sense* in many instances—most explicitly Linchevski and Livneh (1999), similarly Arcavi (2005). However, the only systematic attempt thus far to define such a sense has been undertaken by Hoch (2007, also see Hoch & Dreyfus, 2004). In her operational definition of algebraic structure sense for high school algebra (Hoch, 2007, 40) she refers to algebraic structures as a defined set of terms and expressions, which can be worked on using appropriate operations. On this basis, specific forms of algebraic structure sense are ascribed to a student, if he or she can recognize a familiar structure in its simplest form, deal with a compound term as a single entity and through an appropriate substitution recognize a familiar structure in a more complex form, and, most sophisticated, choose appropriate manipulations to make best use of a structure. Based on this definition, Hoch in a first step shows that many students lack the described competencies and then demonstrates that through individual training a sustaining improvement can be accomplished. Hypotheses are presented regarding the factors that have an effect on the individual's acquisition of algebraic structure sense. For everyday classroom instruction Hoch proposes to let the students work on tasks only vaguely described as “adapted to make them suitable for group work”, the teacher could then help if necessary (Hoch, 2007, 133). However, both the construction and the implementation of the learning environments may be a very difficult task for many teachers, considered that almost half the students do not show structure sense in the tests, and that many teachers neither do (Hoch & Dreyfus, 2004, 55). Deeper insight into the development of algebraic structure sense is needed. The question thus is how students develop algebraic structure sense in everyday classroom interaction. The shift in attention from states to processes implies a shift in the theoretical understanding of algebraic structure sense: With a static definition referring to a hypothetical final product of algebra instruction no reliable insights will be gained about the processes through which algebraic structure sense develops. This leads to the approach of investigating the development of algebraic structure sense by means of networking two appropriate theories.

THEORIES CONSIDERED

To investigate structure sense as an ever developing attitude rather than as a spotty competence was inspired by the GCSt model that is part of Bikner-Ahsbabs' (2005) theory of interest-dense situations. It assumes seeing structures as the last of three collective epistemic actions performed to answer a mathematical question. Preceded by the *gathering* (G) of smaller units of knowledge and their successive *connecting* (C), *structure-seeing* (St) means the perception of mathematical structures, represented by regularities, rules, or exemplary solutions (Bikner-Ahsbabs, 2005, 202, our translation). When seeing structures, students refer to a unity of relations built on gathered and connected mathematical meanings. Theoretically, students may see new

structures or known structures within new mathematical task contexts when producing mathematical meanings through gathering and connecting is saturated. This definition of structures allows for an open-minded view on algebraic structures as they are learned in school, defined rather by the possibilities of the learners than by the curriculum. The background theory for this approach is social constructivism linked with an interpretative view according to which people construct meanings about things through interpreting them in the situation. Thus, the epistemic actions are reconstructed through the interpretation of the students' utterances.

A basis for a deeper understanding of the connection between collective structure-seeing and the development of individual, enduring structure sense can be found in the *activity theory* of Leont'ev (1978). In this theory, the individual's *personality* develops in *activity* under the given cultural conditions. Activity in this theory does not mean some undirected motion but is characterized by its inherent *motive*, e.g. to solve an equation. On lower levels one can find *actions* directed to more specific *goals* and *operations* which are determined by the given *conditions*. This set of ideas has been made fruitful for mathematics education by Roth and Radford (2011; regarding algebraic structures see Radford, 2010). Their dialectic account describes mathematical meaning-making as *objectification*, i.e. the disclosure of an activity motive to the learner, and *subjectification*, i.e. the development of personality as the reordering of the subject's structure of motives in the very same process. Regarding methodology, an activity-theoretical account calls for a deep analysis of the societal, social, and individual processes. Roth and Radford concretize this by arguing for a semiotic approach.

Regarding the research question, the GCSt model may offer a clarification of the situational and social prerequisites of objectification/subjectification, where structure sense develops as a stable feature of the individual student's personality. A more detailed empirically based description of this interplay of the theories is the subject of this article. This first requires a consideration of methodology and method.

METHODOLOGY AND METHOD OF THE EMPIRICAL STUDY

The intended development of both theory and practice is precisely the kind of setting that *design research* has been developed and proven useful for over the last two decades (for an overview see van den Akker, Gravemeijer, McKenney, & Nieveen 2006). In a broad definition, the intent of this approach "is to investigate the possibilities for educational improvement by bringing about new forms of learning in order to study them" (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003, 10). This design study took place between December 2011 and July 2012 in a grade 8 class of a comprehensive school in a socioeconomically deprived area of Bremen, Germany. Three factors led to this choice: First and most importantly, the teacher had to be interested in the reflection and improvement of her teaching. Second, a certain degree of heterogeneity was appreciated, for students' problems with algebraic structures are very

likely to differ with school performance, however intense and directed the causality may be. The third argument was about the grade to investigate. Due to the given curriculum (Die Senatorin für Bildung und Wissenschaft, 2010) we could hope for a variety of algebraic structures that students can acquire a sense for in grade 8.

In this paper, learning processes regarding linear equations and linear functions are considered. The teacher was committed to patiently leave room for the learning process to take place, as this is regarded helpful not only in the theory of interest-dense situations, but also in Arcavi's (2005) considerations regarding symbol sense. In both cases the students were encouraged to make on-hand experiences in the initial phase of the unit. For the introduction to linear equations a variant of the matchbox algebra as presented in some German-language textbooks (first of all Affolter et al., 2003) was implemented. In this approach equations are materialized by matches (representing integers) and matchboxes (each holding the number of matches that is the solution of the equation, see fig. 1a). Already at this early point a focus was laid on the equations' structures. The idea was that there is a natural impetus to structure a pile of unsorted matches and boxes. Linear functions were introduced referring to the changing water level in a straight container steadily filled or emptied. The anchor representation of steady change with an initial water level was consciously chosen based on analyses of the experiences previously made in the unit on linear equations.

Qualitative analyses were conducted focusing on the cases where structure-seeing takes place. The goal was to clarify the connection between structure-seeing and objectification/subjectification. Assuming with Roth and Radford (2011, 25) that "subjects of activity ... exhibit to each other whatever is required to pull off an event as that which it is", the analyses built on a comprehensive record of the classroom interaction and the expressed thinking of the students. It includes photographs as well as the written texts of the students, and, as the anchor of analysis, video footage. One camera provided an overview of the class, while two selected pairs of students were filmed by one video camera each to document their long-term learning process in depth. Each group included a boy and a girl, and a high and a low achiever according to the levels defined by the local board of education. Furthermore, the students were selected to represent a range in language proficiency as valued by the teacher.

Networking strategies: an approach for linking two theories

The initial networking strategy was *combining*, i.e. juxtaposing the theories in order to better understand a specific data set from each perspective. This implies clarifying what structure-seeing means in the current epistemic process from the view of the GCSt model on the one hand, and on the other hand how the motive that constitutes objectification can be observed. In order to answer our research question the following *coordinating* analysis method is conducted linking the two theories' methodologies: a situation of structure-seeing is identified and the corresponding episode is transcribed. Then the epistemic process of this episode is analyzed by the use of the GCSt model. This way, the specific structure seen by the students is captured. Based

on this, hypotheses about the motive of objectification and its relation to the development of structure sense are expressed and then validated by the successive data (methodical link). Before performing a developmental cycle of analysis, the a priori status of the design theory will be described. It serves as a hypothetical model that illustrates the coordination of the two theories and will be the basis to further the design theory through data analysis.

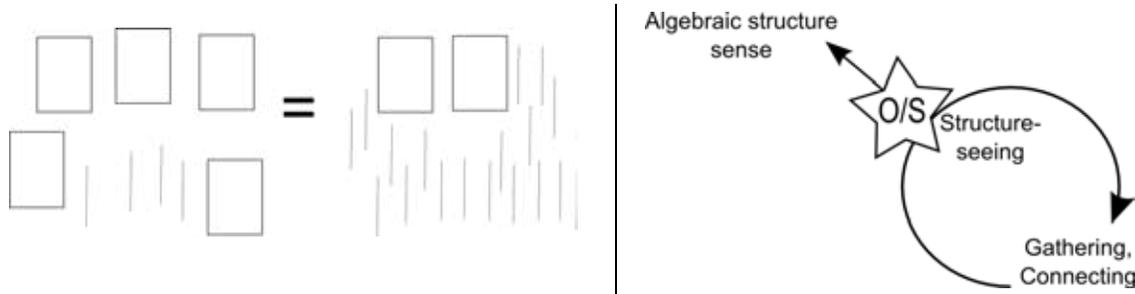

Fig. 1a (left): The matchbox equation the students worked on in the scene described below; **Fig. 1b (right):** The moment of objectification (O) as a special case of structure-seeing where algebraic structure sense develops through subjectification (S).

A HYPOTHETICAL MODEL AS A CASE OF COORDINATING

Coordinating theories is performed “when a conceptual framework is built by well fitting elements from different theories” (Bikner-Ahsbabs & Prediger, 2010, 491). This is especially used in the building of conceptual frameworks when complementary insights are approached. Hence, the networking strategy of coordinating is appropriate in the networking case presented in this paper.

In activity theory, one can assume that through processes of objectification the students individually change their view of the algebraic world. Subjectification, being the development of the student’s personality in this very process, can thus describe the development of algebraic structure sense. Algebraic structure sense in these terms is a developing attitude towards specific algebraic structures, for example linear equations or linear functions. However, the theory of objectification remains unspecific about fostering conditions for objectification (and thus the development of algebraic structure sense). From the theoretical perspective of the GCSt model, objectification can be seen as an individual process emerging from instances of collective structure-seeing. This given, cycles of gathering, connecting, and structure-seeing are the soil for the development of algebraic structure sense. These processes may go on for some time until the specific moment of objectification. This moment constitutes a substantial change in quality: the students not only see the entity, they are also able to use it driven by the disclosure of the motive. The development of personality also passes through this change in that the structure of motives is reorganized towards the inclusion of the new motive that the students become aware of.

The connection between the models at the point of objectification deserves deeper consideration. Two states concerning a specific activity can be distinguished: in per-

forming cycles of gathering, connecting, and structure-seeing, students look at the task with a tendency to perceive all kinds of structures in the situation. These are not necessarily mathematical and correct. After the point of objectification the students' attitudes have changed, they are able to use the specific structure within the activity and work it out. Before objectification the GCSt model is the foreground model to investigate epistemic processes that can lead to objectification. After the instance of objectification the GCSt model has taken the back seat and the dialectic of objectification and subjectification comes to the fore providing the frame to reconstruct the development of algebraic structure sense as a general attitude of the subject. The two models are complementary in the sense that they enable us to describe different aspects of one overarching process, with the moment of objectification being the tipping point. With this model (fig. 1b) in mind the development of structure sense before and after the instance of objectification can now be investigated through a coordinating analysis.

COORDINATING ANALYSIS AT THE MOMENT OF OBJECTIFICATION

The first scene presented here shows how the model presented above helps understand the crucial moment of objectification. In this case, it is supported by a metaphor that the teacher provides. Previously, the students have tried to keep “it equal, but more simple”. However, the “it” is not clear. As part of the riddle only the mutual equality of the two sides must be provided, but the students additionally try to keep each side materially equal over time. In a first step they relax this rule by exchanging matches and boxes between the two sides, but notice that this does not bring any improvement of the situation. This material equality concept keeps the students stuck, and first the teacher is so with them, but then she gives a decisive hint:

- | | |
|---|---|
| <p>1 /Teacher: okay so what can one do now on both sides (<i>taps the table on both sides</i>) so that it gets clearer you always have to do the same. (<i>H draws some dirt off the table, T looks at S, S looks at the table, still having three boxes in her hand</i>) (...) (<i>gets up and walks away, whispering in Sabine's ear</i>) ,take away something.</p> <p>2 Sabine: (<i>looks at H, leaves one of the three boxes on the table and takes the two closer to herself</i>) Take away something</p> <p>3 Herbert: A-h- ,man are you smart. (<i>S laughs, puts the boxes on the table again, slightly left of the others</i>) ,Mrs. Kahn is totally mean. ,take away something okay-</p> <p>4 Sabine: (<i>looks at H, points at the right side</i>) so if we nine are five ,ah just take away four' (<i>both students each take away four matches from the right side, H to the bottom right, S towards the equal sign</i>)</p> | <p>Transcription key:
 w-e-l-l speaking slowly

|---|---|

5 Herbert: One two three four I have.

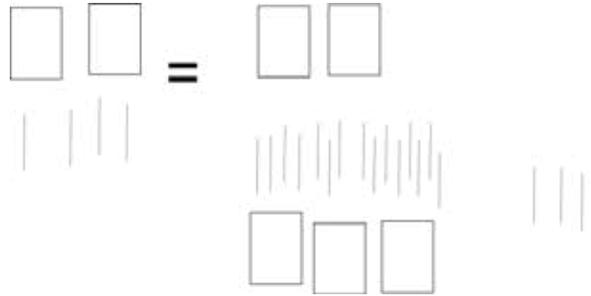

6 /Sabine: I have taken away here-

7 /Herbert: a-h-r. (*puts his matches back, S laughs*) ,are fifteen.

8 Sabine: Yes. ,and fifteen- (*points at the right side, looks at the left side*) (...) (*points at the five matchboxes on the left side one by one*) ,one two three four five- (*takes three of the boxes and puts them further to the middle*) ,divided by three- ,are five.

9 Herbert: Yes. (*looks at S, smiles*)

10 Sabine: And now we have (*puts the three boxes beneath the matches* (*see figure on the right*), *first points at the matches and then at everything around the equal sign*) this here and the three (*moves backwards with her chair*) we (*claps her hands*)

HAVE IT. (*H looks at the table in front of him, S leans forward again*) ,look. ,because now you (plural) have (*first points at the 15 matches, then at the three boxes*) ,if these were in here (*looks at H*) ,right' (*points at the four matches put aside*) we still have four outside.

11 Herbert: Eehh'

12 Sabine: (*first points at the 15 matches, then at the three boxes*) And those are in there right. (*H looks at S, first grinning broadly, then with his mouth closed, then grinning again*) (4sec) ,do you think that works' (*puts the three boxes on the left side again*) (...)

13 Herbert: Well once more. (*puts his right hand on the right side*) ,there are fifteen.

14 /Sabine: (*takes the three boxes on the left side in her hand and shakes them while talking*) yes and her are also fifteen then because fifteen divided by three are five

15 /Herbert: (*joins in, holds up his right hand with all fingers up*) divided by three are five.

Sabine says “Yes” and calls the teacher (who is busy with other students). The students look at each other. “who” they shout, raise their arms and Sabine says: “Herbert we are good.” Then the two students turn to a neighboring table and Sabine starts explaining her solution. The metaphor „take away“ (1-4) enables the students to overcome the material equality concept and to rivet on solving the equation: having permission to “take away“ they can ignore the parts materially identical on both sides (four matches and two boxes) (8-10). The remaining three boxes and 15 matches are connected by bringing them spatially together (10). The students see the divis-

ibility by three and repeatedly check their result (10-14). Hence, the possibility of taking away helps seeing structures and experiencing objectification. The emotionality of the scene hints at both the leap the students do regarding the structure of linear equations and at the change in their personality regarding this specific situation.

In the second scene presented here we can see how the motive from the objectification described above is *conserved* in *key situations* expressed by the metonym “matches”. It takes place five months after the first scene and more than three months after the last time the class worked on equations. The (higher track) students are asked to identify the moment in which the water level in two bathtubs is the same, when one of them starts at a higher level but drains at a higher speed. In the group the students and the teacher have argued that to find out the unknown, for which the terms of the functions deliver the same value, the terms have to be equal. This results in an equation on the blackboard, which is not named as such. Now the teacher asks:

/Teacher: okay so what is that here now. (*briefly points at the blackboard, Rico puts his hand up, T briefly points at him*)

Rico: (incomprehensible)

Teacher: That are two terms yeah' (*many students talk, incomprehensibly*)

Sabine: (*wags her right index in the air*) ISN'T THAT THE THING WITH THE cigarette things ,matches- (*T as well as Herbert and Ahmed look at her, the rest of the group looks at the blackboard*)

/Teacher: p-s-t- ,o-h-

SX1: equation'

Teacher: (*looks at SX1, still points at the equation with her right hand*) An equation. exactly.

SX2: A-h-

This is a case of structure-seeing in a new context. After a long period where equations did not play a role in the classroom, the word “matches” activates all the procedures that were developed based on the matchbox environment. Especially the repeated use of the metaphor “take away” in the following collective solution of the equation indicates the importance of the situation in which the earlier objectification took place (cf. Lakoff & Johnson, 1996). That means that in objectification knowledge can be conserved and made long-term-accessible in key situations. Structure-seeing activates this knowledge, not only for an individual, but available for the whole group by a metonym substituting the whole situation. This coordinating analysis expands the hypothetical model by the aspect of *conserving knowledge* and makes clear how previous processes of objectification/subjectification can again become part of remote discussions in the classroom.

REFLECTIONS ABOUT THE NETWORKING PROCESS

In this contribution two theories were networked by a coordinating methodology while investigating the impact of structure-seeing for the development of structure sense through objectification/subjectification. Objectification was characterized as emerging from instances of structure-seeing, thus forming a concept at the boundary of both theories. This leads to a temporal divide in the data: With the GCSt model the preparation of this moment can be investigated. Activity theory according to Radford and Roth provides the tools which capture how structure-seeing impinges the development of individual algebraic structure sense. Objectification seems to initiate a leap of quality: disclosing a motive it immediately enlarges the potential to act. The simultaneous emotional and valuing expressions indicate subjectification. Objectification seems to be experienced so deeply that it is conserved in the situation and can be activated in further situations, which are also prepared by gathering and connecting. Using the described coordinating analysis, objectification will be worked out more comprehensibly by further analyses leading towards local integration.

NETWORKING THEORIES BY ITERATIVE UNPACKING

Boris Koichu

Technion – Israel Institute of Technology

An iterative unpacking strategy consists of sequencing empirically-based theoretical developments so that at each step of theorizing one theory serves as an overarching conceptual framework, in which another theory, either existing or emerging, is embedded in order to elaborate on the chosen element(s) of the overarching theory. The strategy is presented in this paper by means of reflections on how it was used in several empirical studies and by means of a non-example. The article concludes with a discussion of affordances and limitations of the strategy.

INTRODUCTION

A long-term program of our research group focuses on identifying and characterizing learning that possibly occurs when individuals or groups of individuals are engaged in problem solving and problem posing. In several of our studies, a typical data set consists of a series of recorded observations of how a learner or a small group of learners approaches an insight problem or tries to openly generalize a known theorem or pose a mathematical problem, which would be interesting to solve also to the posers. Many events, interactions and developments occur in such situations, so we, as many other researcher groups, repeatedly face the following research choices:

- Which of the observed developments are worthwhile enough in order to call them "learning"?
- The learners' successes and failures with problem-solving and problem-posing tasks are functions of many conditions and variables, some of which are out of our reach. So, which variables and conditions should become a focus of our attention, if we wish not only to describe the learners' actions and "learning," but also to explain what stipulated them?

These questions presume different theoretically-laden answers in different circumstances. Though individual studies in our group heavily rely on selected theories, their elements or their combinations, we are not adhered, as a group, to a particular theory or conceptual framework¹. Thus, the need to develop certain strategies of calling into play several theories in one study as well as in a sequence of studies emerged for us. The goal of this paper is to introduce one of such strategies, which I would like to term *networking by iterative unpacking*.

ITERATIVE UNPACKING STRATEGY: AN INTRODUCTORY EXAMPLE

Let me introduce an iterative unpacking strategy by an example taken from a recent article by Simon et al. (2010). Simon and his colleagues presented a novel approach to studying learning through mathematical activities. The approach was developed

for capturing subtle processes of transition the learners come through when progressing from one conceptual step of knowledge construction to a subsequent one. The scholars contrasted their approach with an approach developed by Thompson (1994) and Steffe (2003). That approach includes identifying sequences of developmental steps in students' mathematical actions and analysing them, in particular, in Piagetian terms of perturbation, accommodation and reflective abstraction. To further situate their approach in the literature, Simon et al. asserted:

Our work also builds on the work of Hershkowitz, Schwartz, and Dreyfus (2001) who took on the challenge of explicating the formation of abstractions. Toward this end they described three 'epistemic actions' in the process of abstraction: 'construction, recognition, and building with.' They emphasize that construction is the key part of the process. *Our work can be seen as attempting to unpack construction* [italics is added] (p. 80)

Notably, Simon et al. refer to the Hershkowitz, Schwartz and Dreyfus's (2001) work in a dual way. On one hand, they refer to it as a theory, which unpacks a particular element of a previously developed theory. To this end and consistently with the Bikner-Ahsbahs and Prediger's (2006) terminology, the former theory can be seen as a foreground one, and the latter—as a background one. On the other hand, they use the Hershkowitz et al.'s (2001) work as a background theory or as an overarching framework, in which their own foreground theory is embedded. Simon et al. specifically point out which theoretical construct of the overarching framework they are going to unpack. They then perform the unpacking by developing an elaborated kit of tools for analysing the process of construction/transition in terms of seeing commonalities between the tasks in a sequence of tasks and anticipating solutions.

My point is that Simon et al. utilized two networking strategies, one of which had been explicated in the literature (e.g., Bikner-Ahsbahs & Prediger, 2006; Prediger, Bikner-Ahsbahs & Arzarello, 2008) and another was not. First, they utilized a *comparison strategy* by pointing out the differences between their approach and the Piagetian-oriented approach developed by Steffe and Thompson. The main difference was that Simon et al. suggested exploring learning without necessarily focusing on perturbation. Second, though Simon et al. did not use the “construction, recognition, and building with” language in their analysis, they considered it as an overarching conceptual framework for their own theorizing. To this end their contribution is in unpacking one of the key constructs of the Hershkovitz et al.'s (2001) theory. Therefore—*unpacking strategy*. Furthermore, the whole process of theorizing presented in the Simon et al.'s (2010) article includes the following chain of iterations: (1) from focusing on perturbation, accommodation and reflective abstraction to unpacking the formation of abstraction in terms of construction, recognition, and building with, and then (2) to unpacking construction in terms of seeing commonalities between the tasks and anticipating the solutions. Therefore—*iterative unpacking strategy*.

In sum, *iterative unpacking strategy* consists of sequencing empirically-based theoretical developments so that at each step of theorizing one theory serves as an overarching conceptual framework, in which another theory, either existing or emerging, is embedded in order to elaborate on the chosen element(s) of the overarching theory. Note that different ways to embed an additional theory into an overarching theory may exist. For example, the way of unpacking "construction" offered by Kidron, Bikner-Ahsbahs and Dreyfus (2010) is very different from the way offered by Simon et al. (2010). It is also of note that, though an overarching theory and an embedded theory are, in a way, complementary, iterative unpacking does not necessarily imply that all the constructs of the overarching theory are to be preserved. In other words, the use of iterative unpacking strategy may influence also an overarching theoretical framework, as follows: unpacking a particular aspect of a theory may shed new light on the role of the rest of its aspects. For instance, the role of perturbation—one of the main concepts of the highest-level overarching theory in the above example—was reconsidered in the second iteration.

ADDITIONAL EXAMPLES

In this section an iterative unpacking strategy is illustrated by reflective accounts of two sequences of studies, in which I am involved during the last years. The first example concerns problem solving, and the second one—problem posing.

Example 1: iterative unpacking of problem solving

Problem solving as a research field is being attracting keen attention of the mathematics education community for more than 50 years. Foreground models of problem-solving are originated in seminal work of Polya (1945/1973) and developed in the eighties (e.g., Schoenfeld, 1985). Generally speaking, the models attempt to elaborate on how learners solve mathematical problems in terms of phases and attributes. For instance, a model offered by Carlson and Bloom (2005) postulates four problem-solving phases: orientation, planning, executing and checking, and operates with five problem-solving attributes: conceptual knowledge, heuristic knowledge, metacognition, control and affect.

First iteration

A heuristic knowledge component was chosen to be unpacked in the study reported in Koichu, Berman and Moore (2007). The study included a five-month teaching experiment in two Israeli 8th grade classes. The aim of the experiment was to test a particular approach to developing *heuristic literacy* in students. By *heuristic literacy* we meant an individual's capacity to use the shared names of heuristic strategies in classroom discourse and to approach (not necessarily to solve!) mathematical problems by using a variety of heuristics. Changes in students' heuristic literacy were explored in three rounds of thinking-aloud interviews conducted at the beginning, in the middle and at the end of the experiment. The interviews were based on so-called *seemingly familiar problems*, that is, problems that looked similar to the problems

previously offered in the students' mathematics classrooms, whose solutions, however, were essentially different. The following problem is an example:

The sum of the digits of a two-digit number is 14. If you add 46 to this number the product of digits of the new number will be 6. Find the two-digit number.

Indeed, at first glance the problem has a solution by means of a system of equations, as many similarly looking problems approached by the students in the classroom have had. However, composing a system of equations appears ineffective at a second glance. Such problems were used as opportunities to elicit as many heuristics as possible from the students' thinking-aloud speech without discouraging the students from the beginning by facing unfamiliar problems. The interview protocols were segmented into content units and coded in terms of 10 pre-defined heuristic processes:

(1) Planning, including (1a) Thinking forward, (1b) Thinking from the end to the beginning and (1c) Arguing by contradiction. (2) Self-evaluation, including (2a) Local self-evaluation and (2b) Thinking backward. (3) Activating a previous experience, including (3a) Recalling related problems and (3b) Recalling related theorems. (4) Selecting problem representation, including (4a) Denoting and labelling and (4b) Drawing a picture. (5) Exploring particular cases, including (5a) Examining extreme or boundary values and (5b) Partial induction. (6) Introducing an auxiliary element. (7) Exploring a particular datum. (8) Finding what is easy to find. (9) Exploration of symmetry. (10) Generalization.

Success or failure in solving the interview problem was obviously dependant on circumstances under which the problems were dealt with as well as the whole bunch of problem-solving attributes. Consequently, the rates of success were considered irrelevant to unpacking a heuristic component of problem solving. Instead, we introduced a notion of relative *heuristic richness* of solutions. We used the following comparison criterion: One solution was called *heuristically richer* than another if the number of different heuristic processes indicated in the first solution was greater by three or more than in the second solution. Given that 10 different heuristics were considered in our study, we considered the criterion "...three or more" very demanding, and, in turn, sufficiently robust. This criterion was applied to each student individually, for comparison of her or his solutions by pairs of corresponding problems given in the first, second and third interviews. We then developed an integrative measure of individual heuristic literacy development based on the number of the pairs of the corresponding problems, in which a solution to the second problem was heuristically richer than a solution to the first one.

The measure helped us to adequately account for some of the learning effects of the teaching experiment. One of the central findings was that positive changes in heuristic literacy occurred in most of the students, yet they were unequally distributed among the students, who were defined as "stronger" and "weaker" with respect to their achievements in SAT-M (Scholastic Aptitude Test - Mathematics)

administered at the beginning of the experiment. In particular, those students, who were "weaker" at the beginning of the experiment, demonstrated more significant heuristic literacy development than their "stronger" peers. We explained this result by suggesting that the heuristic content of the teaching experiment was more novel and useful for the "weaker" students, whereas the "stronger" students might have possessed the strategies prior to the experiment. The novelty of this result was in the exposure of the role and the learnability of heuristic component of mathematical problem solving, which was identified in (relative) isolation from the rest of problem-solving components. In addition, this result enabled us to formulate some pedagogical implications.

Towards the second iteration

To recap, the study quoted above attempted to unpack the heuristic component of problem solving in terms of selected heuristic processes. Heuristic literacy was chosen as an object of learning. However, though the developed measure of heuristic literacy worked well for describing some of the learning effects of the experiment, it was too simplistic in order to capture how particular heuristics are called into play. This was particularly evident when we looked at the students' solutions containing comparable numbers of heuristics, which however differed in some other respects, such as the appearance of repetitions and cycles in the students' reasoning and the nature of their decisions when facing dead ends. Thus, we feel the need for further unpacking. Specifically, we are interested in unpacking a "heuristic richness" notion. To achieve this goal, we now experiment with three interrelated ideas.

Ovadia (Ph.D. in progress) studies how particular heuristics come into play depending on how the students perceive similarities and differences between problems that were discussed in a classroom and new ones. In particular, her study focuses on the ways by which the students learn to make connections between known and new mathematical problems at the level of common heuristics needed for solving these problems. To this end her study can also be seen as an attempt to unpack the process of seeing commonalities between the tasks pointed out by Simon et al. (2010) as one of the process underlying the process of construction.

Another study (Koichu, 2010) was conducted in order to better understand why those students who possess all necessary strategic and conceptual knowledge for solving given problems sometimes miss within-the-reach solutions. In this work, I consider alternative explanations of this well-documented phenomenon in terms of three theories developed within mathematics education research, point out the limitations of these explanations with respect to a particular data set and offer an explanation in terms of the Principle of Intellectual Parsimony. The Principle states that when solving a problem, one intends not to make more intellectual effort than the minimum needed. In other words, one makes more effort only when forced to do so by the evidence that the problem cannot be solved with less effort. The explanation is built on that *efforts* in problem solving can be of a different nature.

Finally, my interest in heuristic component of mathematical problem solving and Leron's interest in proving and applying cognitive science theories to mathematics education have fruitfully intersected in our common work "Proving as problem solving: the role of cognitive decoupling" (Koichu & Leron, in prep.). In this work, we re-analyse two thinking-aloud protocols from Koichu et al. (2007) study in terms of a conceptual framework representing the increasing importance attached to working memory capacity by researchers in cognitive psychology working on problem solving and decision making. The key notion of the framework is that of cognitive decoupling, i.e., human ability to form more than one mental model of the problem situation and attempt to hold them at the same time in working memory, all the time resisting the tendency for the models to be mixed and confused. Unpacking the heuristic component of problem solving in terms of cognitive decoupling seems us instrumental for better understanding the appearance of cycles in repeated problem-solving attempts and for the use of multiple representations.

Example 2: iterative unpacking of problem posing

Koichu and Kontorovich (2012) conducted a study, in which a group of pre-service mathematics teachers was asked to pose interesting mathematical problems based on a particularly rich problem-posing situation, the Billiard Task. Our goal was to identify those traits of problem-posing processes, which are involved in the posers' attempts to formulate *interesting* problems.

A coherent conceptual framework which would be sensitive to the subtleness of the problem-posing processes and simultaneously applicable to a broad range of problem-posing tasks is not yet established. However, the literature offers several conceptualizations of problem posing, which could be utilized in our study. We decided to adopt in our study a definition of problem posing by Stoyanova and Ellerton (1996) as an overarching conceptual framework. The definition states that problem posing is "the process by which, on the basis of mathematical experience, students construct personal interpretations of concrete situations and formulate them as meaningful mathematical problems" (p. 518). This definition required a great deal of unpacking, and, as will be evident shortly, we saw this fact as an opportunity rather than as a limitation. I present here our attempts to unpack two key components of the definition: the process of constructing personal interpretations of a given situation and the notion of a mathematically meaningful problem.

Iterative unpacking of the process of problem posing

Problem posing is a natural companion of problem solving, so we decided to unpack it in terms of attributes and stages, as it had been fruitfully done regarding problem solving. In line with our earlier research (Kontorovich & Koichu, 2009; Kontorovich et al., 2012), we focused on *mathematical knowledge base*, *problem-posing strategies* and *individual considerations of aptness*.

Mathematical knowledge base for posing problems includes the knowledge of mathematical definitions, facts, routine problem-solving procedures and relevant competencies of mathematical discourse and writing. In addition, it requires knowledge of mathematical problems that can serve as prototypes. Recalling and using a system of prototypical problems relies, in turn, on three components of the problem-solving ability, which were pointed out by English (1998): the ability to recognize the underlying structure of a problem and to detect corresponding structures in related problems, the ability to perceive mathematical situations in different ways and the ability to favour some problems over others in routine and non-routine situations. Notably, this conceptualization of mathematical knowledge base for problem posing can be seen as a result of iterative unpacking by itself.

Problem-posing strategies that emerged in our data (but had also been pointed out in prior studies) included constraint manipulation, symmetry, chaining, data-driven reasoning and hypothesis-driven reasoning. A part of our analysis was directed to unpacking the chaining strategy. *Considerations of aptness* are conceptualized as the poser's comprehensions of explicit and implicit requirements of a situation within which a problem is to be posed; they also reflect her or his assumptions about the relative importance of these requirements. Three types of considerations of aptness showed up in our data: aptness to the posers, aptness to the potential evaluators and aptness to the potential solvers of a posed problem. In the framework of Koichu and Kontorovich's study, considerations of aptness were indicated but not further unpacked. Their unpacking is one of the goals of a Ph.D. research of Kontorovich. Furthermore, one of the findings of the Koichu and Kontorovich's study was an identification and characterization of four problem-posing stages: warming-up, searching for an interesting mathematical phenomenon, hiding the problem-posing process in the problem formulation, and reviewing. Further refining and unpacking of these stages is another goal of a Ph.D. research of Kontorovich.

Interpreting a "mathematically meaningful problem" notion (a non-example)

For some time, we looked for a way of interpreting a "mathematically meaningful problem" notion among the existing ways of unpacking the closely related notions, such as "beautiful problem" and "interesting problem". However, the resulting interpretation has not been done by an iterative unpacking strategy. Thus, the chain of theoretical considerations presented below can be seen as a non-example of iterative unpacking strategy.

On one hand, the literature on aesthetic aspects of mathematics informed us that an agreement about what constitutes a beautiful problem is elusive, but offers quite stable lists of general characteristics of such problems and their solutions, such as clarity, mathematical deepness and complexity, cleverness, novelty and surprise. Second, we accepted the Crespo and Sinclair's (2008) argument that problems' descriptors such as "meaningful" belong to the rarefied discourse of mathematicians rather than that of learners. Crespo and Sinclair (2008) suggested that the learners'

normative understanding of what qualifies as a worthwhile problem may develop around the notions of "mathematically interesting" or "tasty". Third, we decided to build on the Goldin's (2002) idea that general characteristics of problems, such as "meaningful," "beautiful" or "interesting," should be seen as instantiations of one's internal multiply-encoded cognitive/affective configurations, to which the holder attributes some kind of truth value, and not as "objective" qualifiers of the problems.

Consequently, we decided to treat in the study the descriptor "meaningful" in the manner that have been developed in past research for treating the descriptors "interesting" or "beautiful". Namely, we operationally considered a posed problem mathematically meaningful (or interesting or beautiful) if it was evaluated as such by the poser of the problem, its readers or solvers. This decision suited our research needs, but could not be seen as unpacking, in the meaning specified in the rest of the examples. We rather bypassed delving in the cognitive and affective mechanisms underlying one's use of the descriptors and just explicated how the posed problems were operationally qualified in our data.

AFFORDANCES AND LIMITATIONS

In terms of Kuhn (1962/2012), the growing interest of the mathematics education community in networking theories might suggest that mathematics education as a research field is in transition from *pre-paradigm phase* to *normal science phase*. An iterative unpacking strategy discussed in this article is reminiscent of the accumulation-by-development strategy considered by Kuhn as the main developmental force of science during normal science periods. Indeed, the "further elaborating on..." discourse is typical for the periods of normal science, but not for the periods of paradigmatic shifts and scientific revolutions.

The presented strategy can also be seen as a particular case of the strategies of coordinating and combining (Prediger et al., 2008), the case that emphasizes accumulation of knowledge on local phenomena by establishing a specific connections between background and foreground theories. The specificity of the strategy is, in particular, in the dynamic relationship between the theories: one theory may serve as an overarching framework in one case, and as a source of conceptual tools for elaborating on elements of another theory in another case. These observations provide a background for pointing out some of the affordances and limitations of the strategy.

From a practicing researcher perspective, an iterative unpacking strategy can be instrumental for:

- situating a study in the literature and highlighting its theoretical contribution;
- wording research questions in terms of a particular conceptual framework without suppressing the possibility to further use additional conceptual frameworks in a coherent manner;

- justifying the chosen level of granularity in data analysis.

More generally speaking—here I follow the argument presented in Prediger et al. (2008)—an iterative unpacking strategy can be helpful for "better collective capitalization of research results, [adding] more coherence at the global level of the field,..., gaining a more applicable network of theories to improve teaching and learning and finally guiding design research" (p. 170).

As mentioned, one limitation of the iterative unpacking strategy is that it stops being important outside of the normal science periods (cf. Kuhn, 1962/2012). At the pre-paradigm periods, the strategies of ignoring, comparison or contrasting are typically in use. At revolutionary science periods, further elaborating on the elements of previously developed theories falls out of the mainstream. The use of the iterative unpacking strategy is limited also within the normal science periods. Briefly, all the conditions for the use of the strategies of coordinating and combining discussed in Prediger et al. (2008) apply.

CONNECTING THEORIES IN A CASE STUDY OF PRIMARY SCHOOL MATHEMATICS TEACHERS' PROFESSIONAL IDENTITY DEVELOPMENT

Hanna Palmér

Linnæus University, Sweden

This paper focuses on a connection between two theories used in a case study of the professional identity development of primary school mathematics teachers. The two theories connected are communities of practice and patterns of participation. The reason for the connection was the need for a framework that would make it possible to analyse both the individual and the social parts of professional identity development. In this paper, the connection is presented, illustrated briefly using empirical examples and evaluated.

Keywords: Identity, identity development, framework, networking strategies

INTRODUCTION

The focus of this paper is a framework used in a case study of novice primary school mathematics teachers' professional identity development. The teaching profession, with or without focus on mathematics teaching, is often described in terms of a changed profession which lacks continuity between teacher education and schools (Cuddapah & Clayton, 2011; Frykholm, 1999; Goodman, 1998). Graduating from teacher education and starting work as a teacher is described as a transfer or shift in professional identity where the interplay between the individual and the context is highlighted as a central part about which understanding should be developed (Bjerneby Häll, 2006; Cuddapah & Clayton 2011; Persson, 2009). The reason for the connection between theories in the framework used in the present study was the need for a framework making it possible to analyse this interplay between the individual and the context.

Eistenhart (1991) distinguish between three types of research frameworks (theoretical, practical and conceptual) whereof the here presented framework is a conceptual framework. Such a framework is built from different sources, e.g. previous research and literature that the researchers argue as being relevant and important when addressing the research problem.

EPISTEMOLOGICAL STANCES

In the study of novice primary school mathematics teachers' professional identity development, two notions in particular are focused on: identity and professional competence. Both of these notions are objectifications which, according to Sfard (2008), imply that, instead of talking about them as processes expressed as verbs, we

talk about them as nouns as if they were physical objects. Objectification is not only a way of talking about the “same thing” it is also what creates the “things” we talk about and it is accomplished in two steps. The first step is reification which refers to how talk about processes and actions is converted into talk about objects. We observe actions but talk about them as objects (*he has got a lot of knowledge*). The second step in objectification is alienation where the objects are presented in an impersonal way as if they existed independently without the presence of specific people (*the level of knowledge in society is too low*). As objectified notions are originally based on actions they need to be de-objectified for it to be possible to study them. In the development of the framework in the present study, such a de-objectification of the objectified notions *identity* and *professional competence* needed to be done.

According to Lerman (2000), research into mathematics education has “been turn[ed] to social theories” (p. 20). He bases this on mathematics education research since the late 20th century, sees meaning, thinking and reasoning as products of social activities where learning, thinking and reasoning are seen as situated in social situations. The term situated refers to a set of theoretical perspectives and lines of research which conceptualise learning as changes in participation in socially organised activities and individuals’ use of knowledge as an aspect of their participation in social practices (Borko, 2004). Whereas cognitive perspectives focus on knowledge that individuals acquire, situative perspectives focus on practices in which individuals have learned to participate (Peressini, Borko, Romagnano, Knuth and Willis, 2004). To participate means both to absorb and be absorbed in a community and Sfard (2006) describes this duality as “*individualization of the collective*” and “*collectivization of the individual*” (p. 158, italics in the original).

From a situative perspective, teacher learning is a process of increasing participation in the practice of teaching and, through that participation, becoming knowledgeable in and about teaching. To understand teacher learning, it must be studied within the multiple contexts within which teachers do their jobs, taking into account both the individual teachers and the social systems in which they are participants (Borko, 2004).

THE DEVELOPMENT OF THE CONCEPTUAL FRAMEWORK

A connection between theories depends on the structure of the theories involved and the goal of the connection (Radford, 2008). As mentioned, the goal of the connection presented in this paper was to better understand an empirical phenomenon by including both the individual and the social parts of identity development. Also, based on the epistemological stances, the theories was to be within a situative perspective with identity and professional competence as processes and not objectified objects.

The starting point in the search for a theory suitable to describe and understand the professional identity development of novice primary school mathematics teachers became theories focusing on identity and identity development. After exploring several theories, Wenger's (1998) theory regarding communities of practice was found to be suitable and in line with the epistemological stances. However, his theory doesn't focus on mathematics education and/or teaching. There is no one definition of what constitutes professional competence for mathematics teachers but in research beliefs and/or mathematical knowledge for teaching is often focused on. However, traditional definitions of beliefs and mathematical knowledge for teaching are objectifications and the *situative* participatory perspective to be used in the here presented study was not in line with the acquisitionist perspective often used in research of beliefs and mathematical knowledge for teaching.

According to Skott (2010), the social turn that has been developed in research regarding other areas within mathematics education also needs to be developed within beliefs research. If beliefs research is to become social, the pre-reified and the pre-alienated processes of teachers' participation need to be focused on. Skott suggests a shift from focusing on objectified beliefs to focusing on patterns-of-participation as searching for patterns in how teachers participate in immediate situations and prior social practises. Skott's theory is in line with the epistemological stances of the study and focuses on those parts that were missing (mathematics education and/or teaching) in Wenger's theory and became the second starting point of the conceptual framework. Below first Wenger's theory will be presented followed by Skott's theory and after that the connection will be focused on.

Identity and identity development

According to Wenger (1998), identity formation is a complementary dual process in which one half is identification in communities of practice and the other half is the negotiation of the meaning in those communities of practice. A community of practice is a set of relationships between people, activities and the world; it is a shared learning history. The system of activity in a community of practice involves mutual engagement, joint enterprise and a shared repertoire. Mutual engagement is the relationships between the members, about them doing things together as well as negotiating the meaning within the community of practice. Joint enterprise regards the mutual accountability the members feel in relation to the community of practice and it is built by the mutual engagement. The shared repertoire in a community of practice regards its collective stories, artefacts, notions and actions as reifications of the mutual engagement. The shared repertoire proceeds from, and is a resource in, the negotiation of meaning within the community of practice.

An individual can participate in a community of practice through engagement, imagination and/or alignment (modes of belonging). These three ways of identifying and negotiating involve different approaches and different conditions and they do not require or exclude each other. Participation through engagement implies active

involvement in a community of practice and requires the possibility to participate in its activities. Participation through imagination implies going beyond time and space in a physical sense and creating images of the world. Participation through alignment implies that the individual aligns in relation to the community of practice the individual wants to, or is forced to, be a participant of. Imagination and alignment make it possible to feel connected to people we have never met but whom, in some way; match our own patterns of action.

According to Wenger (1998), identity is a never ending negotiation and identification in communities of practice and, as such, identity is not an object but an endless becoming. Identity is temporary and identity development is constantly ongoing as a learning trajectory through a cluster of communities of practice. Our identities are shaped in the tension between our different memberships in various communities of practice and the identification and negotiation within these.

Professional competence

Pattern-of-participation research has been developed as a de-objectified participatory alternative to traditional research of beliefs (Skott 2010; Skott, Moeskær Larsen & Hellsten Østergaard, 2011) and mathematical knowledge for teaching research (Skott, in press). According to patterns-of-participation research a teacher participates in multiple simultaneous practices in the classroom and there are patterns in the ways in which the teacher participates in these practices. Researching patterns-of-participation is searching for patterns in teachers' participation in immediate situations and prior social practises, whereof some are mathematical. The aim in patterns-of-participation research is to understand patterns in how a teacher's interpretation of and contribution to immediate social situations relate dynamically to her prior engagement in a range of other social practices, not to her beliefs or mathematical knowledge as objectified mental constructs.

As such, patterns-of-participation are valid as the pre-reified and pre-alienated statements and/or actions previously objectified as mathematical knowledge for teaching or beliefs. Which statements and/or actions that were previously objectified as beliefs or mathematical knowledge for teaching respectively is no longer of interest. If the aim is to understand mathematics teachers and their mathematics teaching, their patterns-of -participation, their pre-reified and pre-alienated processes of participation, are of interest.

Connecting patterns of participation and identity development

The shift from beliefs and mathematical knowledge for teaching to patterns-of-participation makes a connection to identity and identity development according to Wenger (1998) possible. Wenger analyses identity development while Skott (2010) and Skott et al. (2011) analyse teaching situations. Both theories include the individual and the social but with different focus and different emphasis.

In all of this, patterns from the teacher's prior engagement in social practices are enacted and re-enacted, moulded, fused and sometimes changed beyond recognition as they confront, merge with, transform, substitute, subsume, are absorbed by, exist in parallel with and further develop those that are related to the more immediate situation (Skott, Moeskær Larsen & Østergaard, 2011, p.33).

[...] it [identity] is produced as a lived experience of participation in specific communities. What narratives, categories, roles, and positions come to mean as an experience of participation is something that must be worked out in practice. An identity, then, is a layering of events of participation and reification by which our experience and its social interpretation inform each other (Wenger, 1998, p.151).

In the citation of Skott et al. above, the focus is on the immediate situation with “prior engagement in social practices” in the background. In the citation of Wenger, the relationship between situations and social practices is the opposite, with communities of practice in the foreground and the imprints must be “worked out in practice”. What Skott et al. (2011) call social practices can be treated as communities of practice. A conceptual framework can be developed within a participatory perspective, making both the individual and the social possible as units of analysis where patterns-of-participation can be used to describe the-social-in-the-teacher-in-the-social (*individualization of the collective*) and communities of practices can be used to describe the-teacher-in-the-social-in-the-teacher (*collectivization of the individual*). Patterns-of-participation offer a language with which to explain what is happening in situations while communities of practice offer a language with which to explain the emergence of the patterns-of-participation.

The participation of the teacher is double. At the same time as an individual participates in an immediate situation (the focus of Skott), she participates in several communities of practice (the focus of Wenger). Horn, Nolen, Ward and Campbell (2008) distinguish between a situation as an arena or as a setting. Arena refers to the “physically, economically, politically and organized spaces-in-time” (p. 63) whilst setting refers to “personally ordered and edited versions of the arena that arise as individuals interact in these contexts” (p. 63). If connected to the coordination between patterns-of-participation and communities of practice an individual's interpretation of an immediate situation (an arena) into a setting is based on his or hers nexus of memberships in communities of practices.

Wenger's theory becomes useful when analysing an individual's different participation in different communities of practice. Skott's theory becomes useful when analysing how such different memberships in communities of practice influences how the individual interprets and acts in immediate situations. Skott et al. (2011) write that it is the responsibility of the researcher to disentangle if and how a teacher's participation in past and present practices influences the classroom. Through combining patterns-of-participation and communities of practice such an analysis is possible. Based on analysis of the individual's participation in forms of

engagement, imagination and/or alignment, interpretations can be made about communities of practice the individual seems to negotiate and/or identify with and how these memberships influence the merged patterns-of-participation.

According to Wenger (1998), identity development is an individual's learning trajectory through different communities of practice. That learning trajectory can be viewed through changes in the individual's patterns-of-participation in settings over time. To talk about professional [primary school teacher] identity based on participation in communities of practice means freezing the ongoing process. To talk about professional [primary school teacher] identity development based on learning trajectories in communities of practice means freezing the ongoing process several times over a prolonged time. By freezing and objectifying the ongoing process, one can talk about professional [primary school teacher] identity; however, it is important to remember that the identity is not an object within the individual but an objectification of an ongoing process.

USING THE CONCEPTUAL FRAMEWORK

In this section some short examples are given of how the conceptual framework may be used when analysing empirical material. The excerpts are from analysis made in the case study of novice primary school mathematics teachers' professional identity development. However, here the aim is not to analyse the identity development of these novice teachers but to show how the conceptual framework may be used when analysing empirical material.

The empirical material in the study was collected through self-recordings made by the respondents, observations and interviews. These varying empirical materials have different characteristics but are treated as, named by Aspers (2007), complete-empiricism, implying all the material constitutes a whole on which the analysis is based. Based on the conceptual framework research questions can be asked about the patterns-of-participation of one or several teachers, why these patterns-of-participation occurs, the modes of belonging in communities of practices of one or several individual and the influence of these memberships on patterns-of-participation.

The first example is an analysis of the mathematics teaching of Nina, one of the respondents, when she one day is teaching mathematics outdoors. In the example, the communities of practice are given names based on their shared repertoire so as to be distinguishable. As seen the analysis is not based solely on what is observed in the specific situation but on the complete-empiricism in the case of Nina.

Three communities of practice are visible in Nina's patterns-of-participation in this teaching situation, the community of reform mathematics teaching, the community of teachers working in grade two and the community of teachers at Aston School. Her actions seem to be a merger of the shared repertoires in these three communities. Working with mathematics outdoors is part of the shared repertoire in the community

of reform mathematics as well as the focus on students' communication. The emphasis on working fast to finish as many questions as possible is part of the shared repertoire in the community of teachers working in grade two. Finally, Nina's worries regarding if the students really learn and how she is to prove to her colleagues that they do is her participating in the community of teachers at Aston School.

Further different communities of practices can be analysed based on their mutual engagement, joint enterprise and shared repertoire. Similarly, the respondent's modes of belonging (engagement, imagination and/or alignment) in them can be analysed. The imprints of these modes of belonging can be analysed both with focus on the teacher as the social-in-the-teacher-in-the-social or on the communities of practice as the-teacher-in-the-social-in-the-teacher. Such analyses shed light on how the individual's patterns-of-participation regarding teaching mathematics are influenced by and influence communities of practice.

Below is first an example where the focus is on the teacher when analysing a pattern that occurs in several of the mathematics lessons taught by Barbro, another of the novice teachers in the study. In the next example the focus instead is on the community of practice.

Barbro's mathematics teaching is strongly influenced by the community of teachers working in preparatory class. Her mode of belonging in this community of practice is engagement and also imagination as becoming "totally qualified" by writing her essay. The mutual engagement in the community is students learning Swedish. Even when Barbro is teaching mathematics her main focus is on the students learning Swedish and she gets positive feedback regarding this from other members in the community of teachers working in preparatory class.

The mutual engagement in the community of teachers working in preparatory class is students learning Swedish. This joint enterprise is negotiated by the members in a harmonious way. Even so, there is a visible hierarchy between the members which seems to be based on their education. One part of the negotiated shared repertoire is not to speak English even when it could be a possible help for the children to understand the tasks in the mathematics text book.

Finally, analyses focusing on individuals, over a prolonged period of time make professional identity development visible as learning trajectories in nexus of communities of practice. The conceptual framework helps to answer questions regarding how and why, for example as below when analysing one changed pattern in Nina's mathematics teaching.

The merger of the shared repertoire in the community of teachers working in grade two and the community of reform mathematics teaching has changed Nina's pattern regarding mathematics teaching. Last semester, before she became a member of the community of teachers working in grade two, she expressed the repeated pattern of the text book as something less good but now she stresses it as something good since "it is easy for the children to understand". The same expression is often heard by the other

members of the community of teachers working in grade two. In the community of teachers working in grade two, Nina is a member by engagement and she is active in the negotiation of its shared repertoire. Regarding the community of reform mathematics teaching, her new employment this semester is preventing her membership by engagement. As such, her mode of belonging is now in the form of imagination and it doesn't seem to influence her pattern regarding talking about and using (or not using) the text book in the same way as it did last semester.

EVALUATING THE CONNECTION IN THE FRAMEWORK

The connection between Wenger's (1998) and Skott's (2010) and Skott et al's (2011) theories implies a conceptual framework enclosing the process of professional identity development. The goal of the connection is to better understand an empirical phenomenon (identity development as a primary school mathematics teacher). Connections between theories could, according to Radford (2008), be made at the level of principles, methodologies, or questions or as a combination of these. In this study, the question constituted the need of the connection. The cores of Wenger's (1998) and Skott's theories may appear rather different at first sight. The two theories have different ranges. Skott's theory is new and under development, while Wenger's theory is better established. Wenger's starting point is learning and Skott's is beliefs. However, the two theories have a common starting point when looking at old phenomena (learning – beliefs) but from a (new) social perspective.

Wenger's (1998) starting point is to make a social theory of learning and Skott's (2010) is to turn beliefs research social. Social may, however, imply different things in various degrees. Wenger asks the question, "what if we [...] placed learning in the context of our lived experience of participation in the world?" (p.3). Similarly, Skott suggests, "that a more participatory stance is adopted in research on the role of teachers for classroom practice" (p.1). The basic claim behind the notion of participation is that "patterned collective forms of distinctly human forms of doing are developmentally prior to the activities of the individual" (Sfard, 2006, pp.157). Further comparison shows that there are some connections between notions in the two theories. Wenger (1998) writes that knowledge always undergoes construction and transformation in use, and that things assumed to be natural categories, such as "bodies of knowledge", "learners" and "cultural transmission", require reconceptualisation as cultural, social products. This can be compared with Skott's (2010), Skott et al's (2011) and Skott's (in press) re-reification goal. What Wenger calls "cultural transmission" and "bodies of knowledge" respectively can be seen as similar to traditional reified beliefs or mathematical knowledge for teaching. Both Skott and Wenger work with re-reification focusing on processes. Certainly, a community of practice is a reification, but Wenger's theory is about the process of identity and identity development in and of those communities of practices.

Regarding methodology, neither Wenger (1998) nor Skott (2010) or Skott et al (2011) mentions it in their theories. However, based on the conceptual framework, inferences can be drawn about what kind of data should be collected. To be able to discover patterns-of-participation and communities of practice, an attended approach, e.g. ethnography, is needed. Regarding the basic principles both theories are within a participatory perspective focusing on processes involving both the individual and the social.

Österholm (2011) compares patterns-of-participation research with traditional beliefs research and writes that when researching patterns-of-participation, all prior experiences are of interest and that there seems to be a need for some form of separation between the different practices and different kinds of memberships. This separation is acquired by the connection between patterns-of-participation and communities of practice. Further, Österholm writes that within patterns-of-participation research, it seems to be difficult to talk about change since there is nothing to change. The connection between communities of practice and patterns-of-participation presented here makes visible the process of constant mutual change in patterns-of-participation and communities of practices.

In summary, if, using the words of Prediger, Bikner and Arzarello (2008), the conceptual framework implies coordination as built by well-fitting elements from different theories, being useful when the empirical elements of the theories complement each other and, coordinated thus, support a more complete analysis.

INCLUSIVE MATHEMATICS FROM A SPECIAL EDUCATION PERSPECTIVE – HOW CAN IT BE INTERPRETED?

Helena Roos

Linnaeus University, Sweden

The aim of this paper is to present a way of understanding the phenomenon of inclusion in mathematics. The theoretical framework consists of the connection between two theoretical perspectives and is tested in an empirical example of inclusive mathematics from the perspective of special education. The theory of communities of practice is used as an overall theoretical perspective along with a theoretical framework regarding inclusion. Sub codes were extracted from the empirical example to create a more fine-grained conceptual framework. The results show that the conceptual structure is beneficial for extracting a fine-grained conceptual tool in understanding and developing inclusion in mathematics.

Keywords: connecting theories, framework, inclusive mathematics, special education

INTRODUCTION

This paper discusses the connection of the theoretical perspectives in a research project focusing on the development of inclusive mathematics education, based on special education needs in mathematics. The connection is tested in an empirical example for understanding inclusion in mathematics from a pedagogue perspective.

The pedagogues that usually are involved in the situation of teaching students in special needs in mathematics are the mathematics teacher and the remedial teacher. The remedial teacher in mathematics needs to interpret the students' knowledge to be able to ensure that students' needs are met at all levels. On an overall epistemological level this can be made from a categorical perspective or from a relational perspective (Sjöberg, 2006). From a categorical perspective the problem is situated within the student. In contrast, the relational perspective investigates the environment surrounding the student and the influence it has regarding students' knowledge (Emanuelsson, Persson, & Rosenqvist, 2001). A relational perspective on mathematics difficulties stresses the need to consider how the teaching and learning activities in question affect the students' learning in mathematics (Dalvang & Lunde, 2006). The present project adheres to the relational view in striving to reach an understanding of inclusive mathematics. Specifically an inclusive perspective on mathematics education is adopted. In an inclusive perspective knowledge and mathematical understanding are viewed as cultural and social phenomenon.

Research (e.g., Ballard, 1999) regarding inclusion is a major field of research, which mainly looks at inclusion from the pedagogical perspective. However, little attention has been paid to the meaning of inclusion in mathematics and the identification of

barriers or factors that appear critical in the students' learning of mathematics. Many Swedish schools use ability grouping in mathematics and the teachers envisions better goal achievements for students in special educational needs. Thus, research concludes that organisational differentiation does not give the positive impact on students' knowledge development the teachers expect (Boaler, 2008; Slavin, 1990). Educational differentiation and individualisation is a complex issue, which requires more investigation. Moreover, there is still much to learn regarding how different factors work and connect in the pursuing of an inclusive teaching of students in special needs in mathematics. On account of that, the present paper aims at discussing the connection of theories in the overall conceptual framework trying to frame inclusion in mathematics from a special education view with the perspective of pedagogues. The perspective is also inclusive, where inclusion is seen as a social process of participation in the mathematical practice. This requires identification of both the students' participation and the communities they have access to. To capture and put words to the offered communities in the practice and the students' participation, a conceptual framework is needed.

Eisenhart (1991) recognise three types of frameworks (theoretical, practical and conceptual). Since this framework is built from different sources, it is a conceptual framework.

THEORETICAL PERSPECTIVES

In the overall study two theoretical perspectives are used, a participatory perspective and an inclusive perspective. These two perspectives are used to capture the research questions of the study, namely: What can inclusion in mathematics be and how is it possible to develop inclusive mathematics education, based on special education needs in mathematics?

Conceptualizing inclusion

The concept of inclusion is complex and difficult to define (Brantlinger, 1997). Nonetheless, it is a well-used term in schools today, even in mathematics education. Historically, inclusion is a relatively new concept. It was first used during the early 1990s, before that, the term integration was used (Farrell, 2004). Then what is the difference between these two concepts from a school context perspective?

The concept of integration was developed towards the end of the 1960s, as a critique to the various institutions created for deviant groups in society. Within a school context this term was used to emphasize an assimilation process, children with special needs would be fitted into an existing school context (Nilholm, 2006). In the 1990s it was perceived that the concept of integration not fully covered the importance of participation and the term inclusion began to become more common (Rosenqvist, 2003). The concept inclusion aims at "that the school (the whole) will be organized based on the fact that children are different (the parts)" (Nilholm, 2006 p.14, own translation). The concept of inclusion refers to a continues process (Asp-

Onsjö, 2006) in schools. The introduction of the concept inclusion had an intention, a wish to change the perception regarding work with students in special needs (Nilholm, 2006), from exclusion to inclusion.

As previously mentioned, this project aims at investigating inclusion in mathematics from a participatory perspective. From this perspective inclusion does not just mean being in the classroom physically, it means to be included in the mathematical practice of the classroom, which can be anywhere, this form of inclusion has no physical condition, it is imaginary. Asp-Onsjö (2006) talks about *spatial*, *social* and *didactical* inclusion. Spatial inclusion basically refers to how much time a student is spending in the same room as his or her classmates. The social dimension of inclusions concerns the way in which students are participating in the social, interactive play with the others. Didactical inclusion refers to the ways in which student's participation relates to a teacher's teaching approach and the way in which the students engage with the teaching material, the explanations and the content that the teachers may supply for supporting the student's learning. In this study the content of learning is number sense, since it is the content covered in teaching observed. These three analytical categories will be used as an overall frame in developing a fine-grained explanatory framework. This framework aims at increasing our understanding of how students in special needs in mathematics are participating, develop their way of participating or become restricted from participating in the school mathematical practice.

Students in special education needs in mathematics in communities of practice

This investigation of inclusion in mathematics education is grounded in a social perspective on learning. The overall principle of this perspective is that learning is considered to be a function of participation (Wenger, 1998). Participation is to be seen as “a process of taking part and also to the relations with others that reflect this process” (Wenger, 1998, p. 55). Participation is an active process that involves the whole person and combines “doing, talking, thinking, feeling and belonging” (Wenger, 1998, p. 56). It “goes beyond direct engagement in specific activities with specific people” (Wenger, 1998, p. 57). The practice “exists because people are engaged in actions whose meanings they negotiate with one another” (Wenger, 1998, p. 73) and the practice reside in a community of individuals with *mutual engagement*. Members of a community of practice are practitioners who develop a *shared repertoire*, such as experiences, tools, artefacts, stories, concepts etc., the *joint enterprise* keeps the community of practice together. It is a collective process of negotiation of the participants in the process of pursuing it.

As previously mentioned, I will investigate inclusion from the perspective of pedagogues. In terms of participation this means that I look at how the teacher and the remedial teacher in mathematics allocate the problem of including students in special needs in mathematics to the mathematical practice. The prior presented learning theory that focuses on communities of practice (Wenger, 1998) is intended

to be used. In this theory learning is seen as a process of social participation. The unit of analysis in this theory is the community of practice which is an informal community where people involved in the same social setting form the practice (Wenger, 1998). Although the social setting is important regarding special education needs in mathematics, the students' conceptual understanding also has to be taken into consideration. In order to capture the students' conceptual understanding I will follow Graven and Lermans (2003) interpretation of Wenger (1998). The reason for this choice is that they argue that the primary unit of analysis in Wenger's theory is communities of practice, but for teacher learning it permits the primary unit of analysis to be "the teacher-in-the-learning-community-in-the-teacher" (p.192). In the first phase of this project I will use Graven and Lermans (2003) unit of analysis, "the teacher-in-the-learning-community-in-the-teacher" (p.192). To reach the students (in the second phase of the project) I will modify Graven and Lermans unit of analysis into "*the student-in-the-learning-community-in-the-student*". These units of analysis are coherent with Lermans (2000) unit of analysis from the social perspective, "person-in-practice-in-person" (p.38), where the person has an orientation toward the practice and the practice has become in the person. This will give access to the individual in the community as well as the community of practice.

THE CONNECTION OF THEORIES

When connecting theories it is crucial to know how the connection is made and what it is in the theories that make them work together. According to Wedege (2010) the connection can take place at different levels of the theories. In this project a connection is made between the theory of communities of practice (Wenger, 1998) and the theoretical framework of inclusion (Asp-Onsjö, 2006) at the level of principles of the theories, since they both look at learning as a social phenomenon. Hence, the theories have compatible cores in their view of learning. Although the complexity and size of the theoretical frameworks vary widely, they grasp the different aspects of the research question. Communities of practice are here seen as an overarching theory of learning. To this theory a connection is made to the three modes of inclusion that Asp-Onsjö (2006) presents.

Different strategies can be used connecting theories according to Prediger, Bikner-Ahsbals, and Arzarello (2008). These strategies include having an understanding of different theories, to combine, coordinate or integrate them (Prediger et al., 2008). I coordinate communities of practice with inclusion, since they contain assumptions that are consistent. These assumptions are located in their social approach. The coordination creates a conceptual framework with well fitting elements that help in identifying both the students' and teachers' participation and the communities they have access to regarding learning in mathematics. The three modes of inclusion (Asp-Onsjö, 2006), which are deeply interconnected and constantly interacting with each other, puts words to and allows the development of a fine-grained framework regarding inclusion in mathematics. This framework may inform theory and therefore

it has the potential to gain new contributions to the field through its explanatory power. The framework may also be able to contribute to the solution of the overall research questions: What can inclusion in mathematics be and how is it possible to develop inclusive mathematics education, based on special education needs in mathematics? This is done by identification of factors regarding inclusion in mathematics and their connection in the communities.

In this study the aim is to empirically investigate what inclusion in mathematics can be and how it can be developed by using necessary theoretical concepts. That is, what is and what is not inclusion in mathematics is an empirical question. In the overall study this is investigated through observations, group interviews and interviews with both teachers and students. In this paper the pedagogue perspective is in focus. The data used to capture inclusion in mathematics from their perspective is interviews. In order to identify what inclusion in mathematics can be from the interviews, the conceptual framework will be used as an overall frame.

METHOD

In the present project a large primary school, Oakdale School, located in a suburb of a medium-sized Swedish town is being observed. The on-going project is a longitudinal study with an ethnographic approach, which according to Aspens (2007) is a study where the researcher tries to understand a phenomenon through interpersonal methods. In this study the phenomenon of inclusion in mathematics is to be understood, hence the methods used are interpersonal. Interviews, discussions and lessons with teachers and the remedial teacher were observed and recorded during the first year of the project. 14 interviews, 24 observations at lessons and 3 group interviews were made. The construction of data is intended to continue for another year. In this article four interviews have been used in an empirical example. The interviews are with Ellie, Anna and Barbara. Ellie and Anna are primary teachers working at Oakdale School. They both teach mathematics in lower primary school. Two of the interviews are with Barbara. She is a remedial teacher in mathematics and her current assignment is as a remedial teacher with focus on mathematics.

In the interviews a qualitative, semi structured approach was used. The teachers were invited to elaborate on their view on students in special education needs and factors they consider crucial to for students participation in the mathematical practice. The interviews were recorded and transcribed in full. The analysis was made using coding of the data by labelling the empirical material. This type of coding is the ground for creating new theoretical categories (Aspens, 2007). In the coding of the data, sub codes were identified. Using these sub codes a few major codes arose. Subsequently, an analysis of how these major codes relate to the theoretical concepts was made. Using the concept of “communities of practice” (Wenger, 1998) the analysis started by identification of communities of mathematical practice from an inclusive perspective (step one). Step two in the analysis was using the framework of Asp-

Onsjö (2006) and make identifications of how pedagogues expressed their view of how to work with students in special education needs in mathematics. Digging deeper into the interviews fine-grained codes regarding inclusion and communities of practice in mathematics were identified. Then the analysis went between step one and two several times again.

RESULTS

Communities of mathematical practice at Oakdale Primary School

Analysing the interviews, three communities of mathematical practice were constructed. The first practice is the *community of inclusive mathematics (CIM)*, which is created from the fact that the research project started at Oakdale School and the teachers are invited to collaborate in this project. Barbara is a core member in this community, since she is the remedial teacher in mathematics, and is eager to develop inclusion in mathematics at the school. She wants to develop the teaching of mathematics for all students at the school, because it is “very easy to see the problem within the student instead of what it is in the teaching that does not benefit all [students]” (Barbara). Ellie and Anna are members of the community, since they are interested in developing their teaching of mathematics, and to “get more time to plan together” (Anna). The mutual engagement in this practice is the development of mathematics teaching for students in special education needs. Their shared repertoire is the talk about how to help the students understand, and their experiences of special education needs in mathematics.

The second practice visible in the data was the *community of mathematics classroom (CMC)*. This community is created in the classrooms and is thus two different communities of practice, one in Anna’s classroom and another in Ellie’s classroom. Ellie points out that it is important to “be involved” in the classroom activities, and Anna points out that it is “valuable that the students are present when the teacher presents the content”. Barbara is a peripheral participant in these practices in her role as a remedial teacher and wishes to become more engaged, she wants to be “open about our roles in the class [room]” and “that we discuss together, what can I do”. The mutual engagement in these practices is the mathematics learning for all students, that you work according the curriculum. The shared repertoire is the talk about the mathematics teaching, the curriculum and the use of teaching materials.

The third identified practice was the *community of special education needs in mathematics (CSENM)*. This practice is created by the fact that special education needs in mathematics exist at the school. It involves all mathematics teachers, though Barbara is a core member, since she is the only remedial teacher in mathematics at the school, “I shall serve from the first grade to the sixth grade”. She points out that “I have been interested [in mathematics] and the others [remedial teachers at the school] not”. Other remedial teachers in other nearby schools is part of this community, because Barbara points out that “we need to talk about how we do things

[...] talk about the subject and help each other”. In this practice the students in special education needs are participants. They participate and influence the teaching, since “You ask them: How do you want it to be?” (Barbara). The mutual engagement is the students in special education needs development of mathematical knowledge. The shared repertoire consists of the artefacts involved in the teaching, such as materials, games and tasks. It is also the individual education plans and their content. All these three practices intercalate and influence each other, but there are differences of participants, mutual engagement and shared repertoires in these practices that might influence the talk about inclusion.

Inclusion in the communities of practice

As mentioned earlier, in the screening of the data several sub codes regarding inclusion in mathematics were found. These were grouped into major codes and have been categorized into the three different communities of mathematical practice at Oakdale School. The three aspects of inclusion have also been taken into account in the categorisation. The role of mathematics is most visible within didactical inclusion, where the understanding of number sense becomes important. The codes in the matrix (Figure 2) are a fine-grained conceptual tool regarding inclusion in mathematics. Some of the codes occurred in more than one community of practice, but most of them only occurred in one of them.

Inclusion in the community of inclusive mathematics

In the community of inclusive mathematics practice (CIM) all the three aspects of inclusion were discussed. Within spatial inclusion the issue of being sensitive as a teacher regarding if the students in special education needs should be in the classroom or be in a small group with the remedial teacher were central to Barbara and Ellie. Ellie expressed that “they don’t have to go away somewhere else if they don’t like it”. Barbara pointed out that “some [of the students] don’t what to leave the class [room] so you have to think about how to help in the classroom”. Acceptance was an issue within social inclusion referring to a permissive climate in the practice. Barbara pointed out that “it is an upbringing issue, you may not laugh at anyone”. Barbara here connects “the knowledge process with the work with values”. Ellie also emphasise this, referring to the classroom practice in saying “we have different needs [...], [we] have taught the kids to accept that we work different, a permissive climate”. The category referring to didactical inclusion in this community was teaching approaches. All the three teachers referred to this with impact. It referees to how to work with the students in special education needs in concrete. Anna talks about to “give everybody tasks that they can work with and understand” and Ellie says that one aspect of inclusion is to “give them questions that you know they will be able to answer”. She emphasises that “you [the teacher] need to be aware of that you have the lesson at three different levels” referring to have several teaching approaches within the classroom. Here, Barbara points out “it is about how

you ask the question” so that you include everybody.

Inclusion in the community of mathematics classroom

In the community of mathematics classroom spatial and didactical inclusion was visible. Within spatial inclusion Anna expressed her eager that all the students in the class attended the briefings in mathematics in the classroom, Ellie mentioned it, but was not so explicit. Looking at didactical inclusion three codes emerged: individualisation within the classroom; teaching approaches; and mathematical knowledge. Regarding the first, this refers to being able to “individualise tasks within the class” (Barbara) and to “think about to come to them [the students in special education needs] often” (Ellie). Talking about teaching approaches in this practice is practically the same as presented above in Inclusion in the community of mathematics classroom. The difference is that the students are more visible and engaged in this practice, “they support each other” (Ellie). Mathematical knowledge is here to be seen as knowledge about the mathematical content the current teaching includes, how to present it and to do different approaches to the content more specific. The content discussed is number sense, within the number range 1-1000. A central question here is “what are we going to teach them and who is responsible?” (Barbara), referring to the mathematical content.

Inclusion in the community of special education needs in mathematics

In the community of special education needs in mathematics all three aspects of inclusion are visible. Terms for teaching is within spatial inclusion and deals with issues regarding organisational aspects such as access to study rooms nearby and time to collaborate and be two pedagogues in the class at the same time. Within social inclusion Barbara emphasises students co-decision, “that you really ask, how do you want it?” that you [as a student] get to “be a part in the decisions”. The didactical aspect of inclusion is mathematical knowledge, which refers to the mathematical knowledge of content the current teaching includes, as above. There is one distinction though, in this practice it is specifically how to deal with the knowledge that is difficult for students in special education needs. To be able to use different representations and have a “learning path that is truly systematic” (Barbara).

Inclusion Community		Spatial inclusion	Social inclusion	Didactical inclusion
CIM	Barbara	Teacher’s sensitivity	Acceptance	Teaching approaches
	Ellie	Teacher’s sensitivity	Acceptance	Teaching approaches
	Anna			Teaching approaches
CMC	Barbara			Individualisation
				Teaching approaches

				Mathematical knowledge
	Ellie	Attend the briefings		Individualisation
				Teaching approaches
				Mathematical knowledge
	Anna	Attend the briefings		Teaching approaches
				Mathematical knowledge
CSENM	Barbara	Terms for teaching	Student's co-decision	Mathematical knowledge
	Ellie	Terms for teaching		Mathematical knowledge
	Anna	Terms for teaching		Mathematical knowledge

Figure 1. Inclusion in the communities of practice at Oakdale School

The matrix in Figure 1 sums up the result of the analysis, with major codes of the teachers' expressions of how to work with students in special educational needs.

CONCLUDING REMARKS

In this paper the connection of the theoretical perspectives in the current research project has been presented and tested in an empirical example for understanding development of inclusive mathematics education based on special education needs in mathematics. The overall framework has been shown beneficial for extracting a more fine-grained conceptual tool in understanding and developing inclusion in mathematics. The empirical material has been instrumental in the development of the conceptual tool, and in the connection of theories. This is visible in the extracted codes in figure 2, where the three identified practices have served as a filter to identify inclusion at different levels at Oakdale School from a pedagogue perspective. Within didactical inclusion teaching approaches, mathematical knowledge and individualisation emerged with different emphasis within the three practices. The practices interact and influence each other, but inclusion looks a little different in the practices and this might influence the understanding and development of inclusive mathematics at Oakdale School. The identified codes have the potential to be generalised and it may be possible to identify other codes analysing the material in its entirety.

COMPARING APPROACHES THROUGH A REFERENCE EPISTEMOLOGICAL MODEL: THE CASE OF SCHOOL ALGEBRA

Noemí Ruiz-Munzón, Marianna Bosch, Josep Gascón

Escola Universitària del Maresme (Spain), Universitat Ramon Llull (Spain),
Universitat Autònoma de Barcelona (Spain)

Luis Radford and Yves Chevallard, whose research programmes in mathematics education were awarded with the last Hans Freudenthal medals, have both given a prime place to the problem of teaching and learning elementary algebra. However, their approaches are far from being similar. Are they comparable? We are starting a dialogue considering how each approach, in a more or less explicit way, defines what algebra is and how it characterises ‘algebraic thinking’ or ‘algebraic activities’ with what we call a reference epistemological model (REM) of elementary algebra. The dialogue starts by assuming the point of view of the Anthropological Theory of the Didactic, presenting our own REM, and the kind of questions addressed by this approach, in relation to the Theory of Knowledge Objectification developed by Radford.

1. TWO WAYS OF APPROACHING SCHOOL ALGEBRA

For more than twenty years, Luis Radford’s and Yves Chevallard’s investigations have dealt with school algebra as a research domain. Nonetheless, the problems approached present very different formulations and scopes. They seem to deal with completely different worlds and there are very few mutual references, if any. It is clear that we are here considering two approaches that have been ‘personalised’ by the researchers mentioned but that, as the Hans Freudenthal award states, they represent two research programmes, involving several researchers from different countries. At the same time, the way each programme approaches the research problem of school algebra does not need to be exclusive. As in a case study, we are considering Luis Radford’s approach as a representative of research dealing with ‘algebraic thinking’ (Radford 2002, 2008, 2012, Radford & Puig 2007). The other case, represented by Yves Chevallard’s work, corresponds to the latest investigations carried out within the Anthropological Theory of the Didactic (ATD), mostly by our research team, around what we have called the ‘process of algebraization’ (Bolea et al. 1998, 2004; Ruiz-Munzón 2010; Ruiz-Munzón et al. 2012; Bosch 2012).

We will start by briefly formulating some of the main problematic questions or research problems addressed by each of the approaches, before pointing out some of their main differences and common points. The main questions addressed by the research approach proposed by Radford can be summarised around the notion of

“algebraic thinking” and its characterisation: What are the relationships (filiations and ruptures) between numerical or arithmetical and algebraic forms of thinking? Could embodied forms of algebraic thinking observed in adolescents be accessible to young students? What is the evolution of the different components of algebraic thinking in young students? How do students interpret the meaning of algebraic symbolism? What characterises algebraic generalisations and what distinguishes them from arithmetic ones? These are only a few of the many questions that could be formulated in terms of the “iconicity” and “semiotic contraction” in the development of algebraic thinking, the “process of objectification”, etc., in the sense these notions adopt in the Theory of Knowledge Objectification (TKO).

In the case of the ATD, the main question is the characterization of “*algebraized*” mathematical activities. Let us first remind that, in ATD, mathematical activities are described with the general model of “praxeologies”, the inseparable union of *praxis* and *logos*, used to depict any human activity (Chevallard 2006). It is assumed that the algebraic character of mathematical activity is relative, a question of degree, and some indicators to measure the “*algebraization* degree” of a mathematical praxeology are defined and used to describe the process of *algebraization* of mathematical praxeologies. The questions that can then be posed are, for instance: What conditions are required for elementary algebra to normally exist as a modelling tool in an educational institution (for instance at lower secondary school, grades 7-10) so that the school mathematical organisations can be progressively *algebraized*? In what sense can lower secondary school mathematical organisations be considered as poorly *algebraized*? What aspects of the *algebraization* process are difficult to introduce at school and what constraints hinder their introduction?

When comparing both approaches, the first obvious observation is that they question and problematize different aspects of the ‘didactic reality’ they wish to study: “algebraic thinking” *versus* the “process of *algebraization* of mathematical activities”. It may seem that considering problems of such a different nature can make the dialogue between them rather difficult, at least if we stay at the level of the formulation of research problems. In fact, our postulate is that the differences in how problems are formulated are deeply dependent on the way of interpreting and describing algebra in each framework, that is, the *reference epistemological model of school algebra* used. Depending on how we define or consider the mathematical content involved in a didactic problem (school algebra, in our case), we will be able to formulate some research questions rather than others, to delimit the empirical unit of analysis considered, and to look for acceptable answers to these questions. Therefore, the distance between the two ways of approaching the problem of school algebra can be explained by the differences between the epistemological models assumed. We thus propose to start the dialogue between the approaches at this level.

2. WHAT ARE REFERENCE EPISTEMOLOGICAL MODELS?

When analysing any teaching or learning process of mathematical contents, questions arise related to the interpretation of the mathematics involved in it. For instance, what

is elementary algebra or geometry, or statistics? How is it interpreted in a given educational institution? Why is it taught? How is it related to other contents? Etc. The different institutions interfering in the didactic processes propose more or less explicit answers to said questions. If researchers assume those answers uncritically, they run the risk of not dealing with the empirical facts observed in a sufficiently unbiased way. Therefore, the ATD proposes to elaborate what are called *reference epistemological models* (REM) for the different mathematical sectors or domains involved in teaching and learning processes (Bosch & Gascón 2005). In the ATD, those REM are formulated in terms of local and regional praxeologies and of sequences of linked praxeologies of increasing complexity.

It is important to insist on the fact that the epistemological models built by didactic research should be considered as *working hypotheses*. As such, they are always provisional and constantly need to be contrasted and revised. Even if they are given other names, other approaches in mathematics education use analogue theoretical constructs. For instance, the Theory of Didactic Situations proposes to describe mathematical bodies of knowledge in terms of fundamental situations (Brousseau 1997); the APOS theory (Dubinsky & McDonald 2002) uses the “genetic decomposition” of a concept; the Onto-Semiotic Approach (Godino, Batanero & Font 2006) talks about “systemic configurations”; the theory of “Abstraction in Context” (Dreyfus, Hershkowitz & Schwarz 2001) is concerned with “epistemic actions”; etc. In the case here considered, TKO is supported on a model of *algebraic thinking* proposing a specific way of interpreting and describing elementary algebra.

From the point of view of the Anthropological Theory of the Didactic, the kind of reference epistemological models considered have certain specific features. The empirical data taken into consideration do not only come from school mathematics, but also from the different institutions involved in the process of didactic transposition (the school and its environment, policy-makers, “scholar mathematicians”, professionals, etc.). REM should not uncritically assume any of the viewpoints that are dominant in these institutions. In the ATD, epistemological models do not take into account the idiosyncrasy of the persons involved in the teaching and learning processes, or the specific conditions in which they take place. What they explicitly include are the concrete activities that can be considered as the *raison d'être* of the mathematical content involved in terms of problems to be solved or questions to be addressed, as well as the way it evolves to give rise to new problematic questions.

3. THE ATD REFERENCE EPISTEMOLOGICAL MODEL FOR SCHOOL ALGEBRA

With respect to school algebra, the ATD proposal is to interpret it as a *process of algebraization* of already existing mathematical praxeologies, considering it a *tool* to carry out a modelling activity that ends up affecting all sectors of mathematics. Therefore, algebra does not appear as “one more content” of compulsory

mathematics, at the same level as the other mathematical praxeologies learnt at school (like arithmetic, statistics or geometry) but as a general modelling tool of *any* school mathematical praxeology, that is, as a tool to model previously mathematized systems. In this interpretation, algebra appears as a practical and theoretical tool, enhancing our power to solve problems, but also as the possibility of questioning, explaining and rearranging already existing bodies of knowledge.

This vision of algebra can provide an answer to the problem of the status and rationale of school algebra in current secondary education. On the one hand, algebra appears as a privileged tool to approach theoretical questions arising in different domains of school mathematics (especially arithmetic and geometry) that cannot be solved within these domains. A well-known example is the work with patterns or sequences where a building principle is given and one needs to make a prediction and then find the rule or general law that characterises it. This feature highlights another differential feature of algebra that is usually referred to as “universal arithmetic”: the possibility of using it to study relationships independently of the nature of the related objects, leading to “generalised” solutions of a whole type of problems, instead of a single answer to isolated problems, as is the case in arithmetic. Another essential aspect of the rationale of algebra is the need to organise mathematical tasks in *types* of problems and to introduce the idea of generalisation in the resolution process, a process making full use of letters as parameters.

In this perspective, the introduction of the algebraic tool at school needs to previously have a system to model, that is, a well-known praxeology that could act as a *milieu* (in the sense given in the Theory of Didactic Situations) and that is rich enough to generate, through its modelling, the different entities (algebraic expressions, equations, inequalities, formulae, etc.) essential to the subsequent functioning of the algebraic tool. In the model proposed, this initial system is the set of *calculation programmes* (CP). A CP is a sequence of arithmetic operations applied to an initial set of numbers or quantities that can be effectuated “step by step”- mostly orally and writing the partial results - and provides a final number of quantity as a result. The corpus of problems of classic elementary arithmetic (and also some geometrical ones) can all be solved through the verbal description of a CP and its execution: what was called a “rule” in the old arithmetic books. The starting point of the REM is therefore a compound of elementary arithmetical praxeologies with techniques based on the verbal description of CP and their effectuation “step by step”. However, working with CP soon presents some technical limitations and raises theoretical questions about, for instance, the reasons for obtaining a given result, justifying and interpreting it or the possible connections between different kinds of problems and techniques. All these questions lead to an enlargement of the initial system through successive modelling processes giving rise to *different stages of the “algebraization”* process that we will briefly summarize hereafter. A more detailed description can be found in (Ruiz-Munzón 2010; Ruiz-Munzón et al. 2012).

The *first stage* of the algebraization process starts when it is necessary to consider a CP not only as a process but as a whole, representing it in a “sufficiently material” way—for instance written or graphically—to manipulate it. This does not necessarily mean the use of letters to indicate the different numbers or quantities intervening in a CP (the “variables” or “arguments” of a CP). However, it requires making the global structure of the CP explicit and taking into account the hierarchy of arithmetic operations (“bracket rules”). This new practice generates the need of new techniques to *create and simplify algebraic expressions* and a new theoretical environment to justify these techniques. The notions of “algebraic expression”—as the symbolic model of a CP—and of “equivalence” between two CP appear. Following the standard terminology, we can say that this stage requires the operation of “simplifying” and “transposing”, but not the operation of “cancelling”.

The passage to the *second stage* of algebraization occurs when the identity between CP needs to be manipulated. In this stage, algebraic techniques include considering equations (of different degrees) as new mathematical objects, as well as the technical transformations needed to solve them. This case includes the resolution of equations with one unknown and one parameter, that is, the case where problems are modelled with CP with two arguments and the solutions are given as a relationship between the arguments involved. In the specific case where one of the numeric arguments takes on a concrete value, the problem is reduced to solving a one-variable equation. Nowadays, school algebra mainly remains in this last case (without necessarily having passed through the first one): solving one-variable equations of first and second degree and the word problems that can be modelled with these equations, without achieving the second stage of the algebraization process.

The *third stage* of the algebraization process appears when the number of arguments of the CP is not limited and the distinction between unknowns and parameters is eliminated. The new mathematical organisation obtained contains the work of production, transformation and interpretation of *formulae*. It is not much present at current secondary schools even if it appears under a weak form in other disciplines (like physics or chemistry). At least in Spain, the use of algebraic techniques to deal with formulae is hardly disseminated outside the study of the general “linear” and “quadratic” cases. However, they play an essential role in the transition from elementary algebra to functions and differential calculus, a transition that is nowadays quite weakened in school mathematics. Furthermore, secondary school mathematics does not usually include the systematic manipulation of the global structure of the problems approached, which can be reflected in the fact that letters used in algebraic expressions only play the role of unknowns (in equations) or variables (in functions), while parameters are rarely present. However, it can be argued (Chevallard & Bosch 2012) in which sense the omission of parameters—that is, the use of letter to designate “known” as well as “unknown” quantities—can limit the development of efficient modelling algebraic tools and constitutes a clear denaturalisation of the algebraic activity carried out at school.

Let us consider a short example to illustrate the three stages of the process:

Take a problem of the sort: “Think of a number, multiply it by 4, add 10, divide the result by 2 and subtract the initial number”, a process that we will represent by the CP: $P(n) = (4n + 10)/2 - n$. A problem where we know that $P(n) = 7$ can be solved in the first stage by first simplifying $P(n)$ and finding the equivalence $P(n) \equiv n + 5$, which gives the result $n = 2$. If the problem is $P(n) = 3n - 7$, the passage to the second stage seems more natural (even if we can always find complex techniques to solve it remaining in the first stage). If the CP is $P(n,a) = (4n + a)/2 - n$ (“Think of a number, multiply by 4, add another number, etc.”) and the problem states that $P(n,a) = 2n - a$, the same type of techniques and theoretical environment enables to find a solution, which here appears as a relationship between n and a . The third stage corresponds to CP with more than 2 arguments, requiring new techniques to describe the relationships obtained, especially when we do not only work with linear equations.

This three-stage model of the algebraization process is a tool to analyse what kind of algebra is taught and learnt in the different educational systems, what elements are left out of the teaching process and what other elements could be integrated under specific conditions to be established. It is complemented with four general *indicators of the degree of algebraization* of a given mathematical content (or praxeology), as proposed by (Bolea, Bosch & Gascón 2001) to analyse the different possible constructions of the algebraic process by looking at the mathematical activities resulting from it. They correspond to: (1) the possibility to manipulate the global structure of the problems; (2) the need to “objectify” or “thematize” the mathematical techniques used and to question them; (3) the unification and ostensive reduction of praxeologies (their types of problems, techniques and theoretical discourses); (4) the emergence of new problems independent of the modelled systems.

The effort to explicitly state an epistemological reference model for elementary algebra has different purposes. It can first be used as a descriptive tool to analyse the kind of algebraic praxeologies that exist at school and to study the ecological effects (conditions provided and constraints imposed) of these praxeologies in other mathematical contents. It is also a productive tool when trying to connect investigations concerning school algebra carried out from different theoretical perspectives, as it helps specify the reference epistemological model of algebra more or less explicitly assumed by each research and compare the results provided by each one. For instance, one can consider what aspects of elementary algebra are not taught at school and inquire about the possible reasons of their absence, as well as the ‘nature’ and ‘origin’ of these reasons (Chevallard & Bosch 2012). Another interesting exploitation would be comparing different research works, as for instance the “structural approach” of the research strand on *Early algebra* or the “algebrafying” paradigm promoted by J. J. Kaput (2000) and the first stage of the algebraization process and its possible implementation in the classroom.

4. THE TKO AND THE PROBLEM OF SCHOOL ALGEBRA

Luis Radford's works present some answers to the questions addressed by the TKO to the problem of school algebra. First of all, *algebraic thinking* is characterized not by the use of symbolism but by its “analytical” character (Radford 2012b, pp. 16-17):

I suggested, on both historical-epistemological and semiotic grounds, that algebraic thinking cannot be reduced to an activity mediated by notations. Although the modern alphanumeric symbolism constitutes a very powerful semiotic system, in no way can it characterize algebraic thinking. [...] Algebraic thinking, I suggested, is rather characterized by the *analytic* manner in which it deals with indeterminate numbers—something where, as two fathers of algebra, Viète (1983) and Descartes (1954), explicitly stated, no difference is made between known and unknown numbers.

From this viewpoint, and based on different teaching experiences, algebraic thinking is postulated to emerge early among young students, even if this finding raises new difficulties related to the description of its evolution (Radford 2012b, p. 16):

From a sensuous perspective on human cognition, it is not difficult to appreciate that 7–8-year-old students can effectively start thinking algebraically.

When considering algebraic symbolism and students' difficulties with *the interpretation of its meaning*, the operation with the unknown and the use of the first algebraic techniques to solve first degree equations is described in terms of the coordination of different systems of signs and the articulation of levels of abstraction. In this case, algebra is considered as a problem-solving tool:

More precisely, our approach to algebra as a problem-solving tool means the development of an analytic technique based on a conceptually complex kind of mathematical thinking relying on the calculation of known and not-yet-known numbers or magnitudes that acquire a meaning as they are handled in the pursuit of the goal of the activity. [...] EISL [*elementary iconic symbolic language*] soft syntax allowed the students to accomplish the translation of elementary word-problems into an iconic statement and to suitably transform these statements in order to reach the solution. These iconic statements form an iconic text that, in the end, appears as a didactic device reducing the gap between the statement of the problem in natural language and a formal symbolic treatment of equations. The didactic goal was not to remove the gap (which is, I believe, an impossible task). The goal was to provide the students with an intermediary semiotic system from where to derive certain meanings to be used later in the semiotic system of symbolic algebra.

Algebraic generalisations are considered fundamental algebraic activities and should be defined in relation to *arithmetical* ones. More generally, the relationship between arithmetic and algebra must be clarified. Here, Radford assumes that the gap is located in the equations of the form $Ax + B = Cx + D$ where arithmetic methods (consisting in carrying out inverse operations) fail and the students should learn to operate on the unknown (Filloy & Rojano 1989), thus moving to *analytical* thinking:

In order to operate on the unknown, or on indeterminate quantities in general (variables, parameters), one has to think analytically. That is, one has to consider the indeterminate quantities as if they were something known, as if they were specific numbers.

It is considered that, from a genetic point of view, arithmetic differs from algebra in this *analytical thinking* with indeterminate quantities, where unknown and known numbers are treated in the same way. An important consequence of this difference is that *algebraic formulae are deduced*, which is essential to distinguish algebraic generalisations from arithmetic ones. The production of a formula in the generalisation of patterns is not necessarily a sign of algebraic thinking (it can be the result of a guess, for instance). The use of algebraic symbolism is not a condition, neither necessary nor sufficient, to algebraic thinking and this conclusion opens new ways to the study of elementary forms of algebraic thinking in young students.

5. STARTING A DIALOGUE BETWEEN THE TKO AND THE ATD

Our proposal to initiate a dialogue between the TKO and the ATD approaches to school algebra is to start from some questions and assertions formulated within the ATD about how the TKO considers algebra, as a way to compare the *reference epistemological models* proposed by each approach. It is only the very beginning of the dialogue, since it has to be complemented with the reciprocal viewpoint: the vision of the ATD investigations from the TKO's own interpretation of algebra. In the ATD, the degree of algebraization is a characteristic assigned to mathematical praxeologies as a whole, not to the types of tasks or mathematical techniques considered separately. This point is certainly an important difference regarding the TKO approach. In our opinion, it is necessary to address it by looking more deeply into the general epistemological model *of mathematics* used by the TKO and the way it can be specified in the case of algebra. What is considered as “thinking” and “activity” (or “modes of reflexion” and “action”) in the TKO could be related and contrasted to the notion of “praxeology”. The ATD approach agrees with the TKO that a mathematical praxeology can be relatively algebraized without the need to explicitly use algebraic symbolism. A clear example is shown in Bolea, Bosch & Gascón (2001) related to “figurate numbers”. Reciprocally, a mathematical praxeology can make extensive use of algebraic symbolism and still remain very poorly algebraized. There are, however, some issues where the points of view differ and need to be considered more deeply. The first one is related to the tasks dealing with equations of the form $Ax + B = D$. In the ATD model, these tasks only occupy a small part of the first stage of algebraization and, if simplification techniques are not required, they can even remain in the non-algebraic stage, needing only arithmetical operations to be solved. The same happens with the tasks dealing with equations of the form $Ax + B = Cx + D$ when the solutions obtained are numerical: they are only a small part of the second stage of algebraization. According to the three-stage model, other kinds of equations-or calculation programmes-should be considered in order to let algebraic techniques appear with all their functionality. The issue of the so-called “analytic character of algebra” that appears to be central in the TKO also plays an important role in the ATD characterization of algebra (see for instance Gascón 1993 and Chevallard 1989), related to the first indicator of the algebraization degree. The question arises about how this “analytic character” can be defined in the TKO when

one moves beyond early algebra. Finally, one of the main functionalities of reference epistemological models is to let researchers get free from the institutional vision of the educational facts they are considering, as has been shown by Bosch (2012) in the case of the ATD approach to algebra. It is important, from this point of view, to consider what aspects of this institutional vision of the teaching and learning of algebra are questioned by the TKO's proposal and what others are assumed as valid ones. The dialogue between approaches requires specific work, like the one suggested in this paper, as well as specific tools such as the scrutiny of the epistemological models constructed and assumed by each frame.

NETWORKING: THEORY AND TEACHING PRACTICE

USING LESSON STUDY

Nellie Verhoef, Daan van Smaalen & Fer Coenders

University of Twente, the Netherlands

This paper describes the search of six Dutch teachers for the integration of theories to make sense of mathematics. The mathematics teachers investigated their teaching practices using lesson study. Two successive research lessons about the introduction of the derivative were jointly planned, implemented, and live observed. The teachers revised and re-taught the research lessons based on collaborative discussions at school and reflections at the university. The results of the study show that making sense of the derivative starts with encouraging students to communicate intuitively using own words. This is followed by the iconic development of visualizations and finally results in the use of symbols: operations with numbers and reasoning about operations with numbers.

INTRODUCTION

This study focusses on teachers' collaborative investigation to integrate theories of teaching and learning to make sense of mathematics. In 2008 the Dutch government recognized a stagnated progress in numeracy at scientific studies as a consequence of a lack of students' mastering of mathematical skills. This resulted in an increased attention for algorithms and correct calculations at secondary schools. The balance moved from a focus on Skemp's (1976) relational understanding to instrumental understanding of mathematical concepts.

Research at the University of Twente focusses on the effects of teacher design teams. In this context a number of mathematics teachers collaborated with the intention to improve mathematics education. The researcher (first author) invited six mathematics teachers to start a lesson study team. Teacher selection was based on good experiences the researcher had with the teachers during teacher trainee supervision. Lesson study is a professional development strategy in which teachers collaboratively investigate teaching and learning practices by means of live classroom observations and post-lesson discussions (Stepanek, Appel, Leong, Mangan, & Mitchell, 2007). We used lesson study to collaboratively investigate the integration of theories to make sense of mathematics.

Making sense of mathematics arises initially through coherent perception and action, and develops through coherent use of operations in arithmetic and algebra (Tall, 2012). The lesson study team's investigation of making sense of mathematics builds on Skemp's (1976) types of understanding and Tall's (2008) framework of long-term mathematical thinking in relation with Bruner's (1966) representations.

PROBLEM DEFINITION AND RESEARCH QUESTION

Lesson study is in Japan widely used and deeply rooted for over a century. Lesson study makes teaching approaches more practical and understandable to teachers through a deeper understanding of content and student thinking (Murata, 2011). In 2009 a four-year lesson study project was initiated at the University of Twente. The first project year focussed on the effects of lesson study on teachers' professional development. The results showed complexities with regard to culture differences with Japan (Verhoef & Tall, 2011). The second project year showed a positive effect of the use of GeoGebra in the context of the introduction of the derivative. This paper reports the third project year in which the search for the integration of theories to make sense of mathematics was central. Our research question is:

How to make sense of mathematics integrating theories in the context of the introduction of the derivative?

THEORETICAL FRAMEWORK

(a) A sensible approach to mathematics

A sensible approach to mathematics takes account of the structures of mathematics and of the increasing levels of sophistication as learning progresses from sense through perception, then through the relationships of operation and a developing sense of reason (Chin & Tall, 2012). This approach relates to Bruner's (1966) successive modes of representation. Bruner distinguished: (a) action based enactive representation, (b) image based iconic representation, and (c) symbolic representation including not only written and spoken language but also the symbolism of arithmetic and the language of logic. Enactive means gesture, movement of the body, and physical showing of ideas. Iconic, incorporating enactive, is visual and includes all forms of sensory recognition, touch and smell etc. In his framework Tall (2008) puts enactive and iconic together as conceptual embodiment. The enactive and iconic modes of human perception and action develop into the mental world of perceptual and mental thought experiment. Operational symbolism develops from embodied actions, such as counting and measuring, and encapsulates as symbols in arithmetic. The higher level of logic specified by Bruner is seen as a distinct level based on set-theoretic definitions and formal proof.

We suggest that, to make sense of mathematical thinking, the teacher should be aware of the changing needs of the student in new situations, to build on previous success and to realize that what worked before will need a new approach to make sense of the new situation. To do this we consider how the learner makes sense through perception based on fundamental conceptual embodiment and thought experiment, then through the coherent relationships in operational symbolism, and later in terms of reasoning based on definition and deduction. In school mathematics, reasoning develops in various forms, like the transition from the practical tangent $(f(x+\Delta x)-f(x))/\Delta x$ measuring the slope from x to $x+\Delta x$ to the theoretical tangent the ratio of the component of a tangent vector. In this paper we typify sense making of mathematical thinking in terms of *perception*, *operation* and *reasoning*. We

distinguish the practical enactive and iconic representations, and the theoretical symbolic representation of the derivative. Perception means the dynamical look along the curve to *see* the changing gradient as the changing curves direction. Operation applies the changing practical slope and the relationship between the visual changing slope and symbolic computation of the slope that stabilizes on the derivative function. Reasoning develops practically (perception and operation) based on experiment, and theoretically based on definition and deduction.

(b) Lesson study as a strategy for professional teacher development

Lesson study can be typified as a *live* research lesson. The live research lesson creates a unique learning opportunity for teaching. Lewis, Perry and Murata (2006) describe three specific areas that develop through the lesson study process: (1) teachers' knowledge, (2) teachers' commitment, and (3) community and learning resources. While teaching is considered an independent and often isolated practice in many countries, lesson study brings teachers together to share goals, discuss ideas, and work collaboratively.

Murata (2011) reports the following five attention points. Firstly, lesson study is centred around teachers' interests. Teachers should perceive lesson study goals to be important and relevant for their own classroom practice. Secondly, lesson study is student focussed. The lesson study activities should direct teachers' attention to student learning and the relation between learning and teaching. Thirdly, lesson study has a research potential. Teachers share physical observation experiences and these provide research opportunities. Fourthly, lesson study is a reflective process. Teachers have to reflect on their teaching practice and subsequent student learning in an educational community. Fifthly, in lesson study teachers work interdependently and collaboratively. Isoda (2010) characterized the lesson study cycle process as consisting of the following collaborative elements: planning (preparation), doing (observation), and seeing (discussion and reflection). He advocated the use of scientific literature as a basis for deepening teaching strategies.

RESEARCH METHOD

Participants

Six mathematics teachers from different secondary schools participated in the lesson study team during the school year 2011-2012, see Table 1. The first three teachers participated in previous years. School management facilitated the teachers by giving them half a day weekly for participating in the lesson study project.

Table 1: Description of participants

	Work experience in 2010	Education and teaching experience
A	17 years	BSc math + MSc math education; lower level to upper level high school students
B	14 years	BSc math + BSc math education; mostly upper level high school students
C	one year	BSc engineering + MSc math education; mostly upper level high school students
D	26 years	MSc math + MSc math education; mathematics teacher team leader
E	19 years	BSc math + MSc math education; lower level to upper level high school students

Besides the teachers, the lesson study team consisted of four staff members of the University of Twente: a mathematician, a mathematics teacher trainer, a PhD-candidate (second author) and the researcher (first author). The staff members had specific roles in the lesson study team.

Research instruments

The research instruments consisted of three lesson plans, field notes of student observations and written reports of the discussions at the teachers' school, and the plenary reflections at the university. The observers were participants of the lesson study team plus interested school colleagues.

Context of the study

The teachers revised the textbook with regard to the introduction of the derivative with a focus on sense making. They intended to pick up the textbook approach, with a focus on mastering differentiation rules, after the introduction.

Based on last year's experiences with lesson study, the teachers decided to use GeoGebra for sense making of the derivative. The teachers started a process of zooming in at a fixed point on the graph being aware of the rate of change using the visualization (Bruner's enactive representation). They wanted to introduce an icon to develop a link to the use of numbers (Bruner's symbolic representation).

The teachers worked in three pairs (P1, P2 and P3). In each pair, one teacher did not have any previous experience with lesson study. The pairs started successively teaching two lessons. Firstly, P1 started with the first research lesson. P2 continued the same day at another location. Secondly, P1 continued with the second research lesson next day while P2 continued later. The lessons were planned collaboratively, observed and discussed at the teacher's school. The first four lessons (from P1 and P2) were evaluated in a plenary meeting at the university. This resulted in a revision of the research lessons, and this was used in class by P3. This lesson was collaboratively discussed at the teacher's school and plenary evaluated at a university meeting.

Data collection, processing and analysis

P1's lesson plan was summarized. The other lesson plans were described in relation with P1's lesson plan. The field notes of the student observations were classified with regard to Chin and Tall's (2012) categorizations: perception, operation and reasoning. Remarkable (discussion and reflection) report statements were coded as practical (enactive, iconic) or theoretical (symbolic) based on Bruner's (1966) framework of representations. The classifications, codes and analysis were member checked with the teachers afterwards.

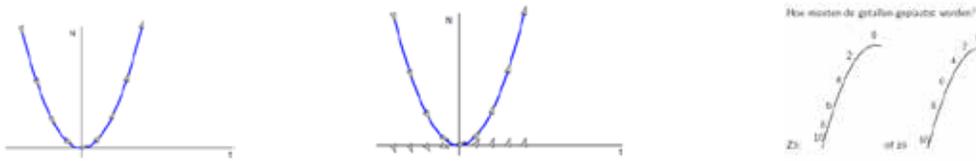

RESULTS

Lesson plans

Below, first the results of the lesson plans will be reported, followed by field notes of student observations, and finally elements from the discussions and plenary reflections. P1's lesson plan emphasized student interaction. The teachers tried to make sense by activating students' communication explicitly in their lesson plan (Figure 1).

The teacher introduces the increasing and decreasing graph in comparison with a jumping frog in the first lesson. The Power Point sheet shows the words: increasing/decreasing; monotonic; tangent; slope. The teacher gives each student pair one assignment. One student of each pair, sitting with backs against each other, receives an arbitrary graph on paper. The student describes the given graph in own words, the other student tries to draw the graph on his empty paper.

The teacher continues plenary with the graph of a parabola. He has drawn arrows on the graph (first two figures below). The teacher reminds the students of the computer game Angry Birds, making sense to the graph's change in one point. The teacher shows the third figure below and asks 'Do you know the right place of these numbers?'

The teacher continues the second lesson using numbers (slopes) illustrating a change each. He uses squares on his board and puts line segments in here with the comparable slopes. The students get an arbitrary graph on paper each. The teacher asks to put numbers – illustrating a change each - at some fixed points on the delivered graph.

The teacher ends plenary with the calculation of the slope of a straight line through two closed points on the graph, suggesting this gives one answer exactly: the change in one point on the graph.

Figure 1: Lesson plan of the first pair

P2's lesson plan emphasizes operations with symbols. The teachers replace student interaction with worksheets. They want to reveal students thinking on paper as much as possible. The worksheet focusses on reasoning about numbers as rates of change. Figure 2 lists the core problem.

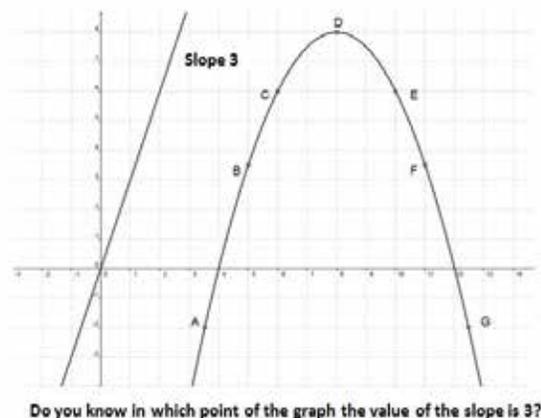

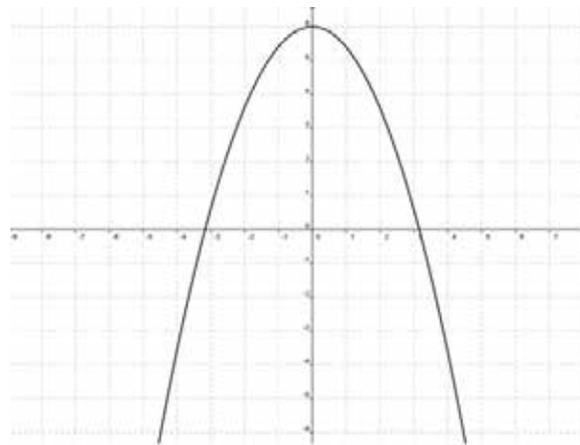

Figure 2: The slope in a point on the graph

The teachers use the problem in which students describe a graph in own words at the end of the lesson instead of in the beginning. The teachers don't use arrows. They emphasize local straightness in a point nearby the top (more curved). They introduce the zooming in process as an analogy with a view at the earth from space. The

teachers continue the procedure of zooming in according to two closed points using GeoGebra suggesting that the process of zooming in gives the same result (one slope). After that they calculate the derivative in different points on the graph and establish that the numbers are elements of one straight line. They end with the ratios $\Delta y/\Delta x$ and $(f(x+\Delta x) - f(x))/\Delta x$.

P3's first lesson starts again with a student describing a graph in own words, and continues with the graph of the parabola with arrows, see the first graph in Figure 1. The students solve problems on a worksheet in pairs. The teachers ask the students to add numbers to the arrows on the graph. They continue with asking numbers as rates of change, see Figure 2. They end with asking the right numbers on the right places, see Figure 3.

Put the following rates of change as accurate as possible on the graph -4, -2, 0, 2 and 4

Figure 3: Right number on the right place

Field notes of student observations

Table 2 lists characteristic field notes of the student observations. The first column lists the successive pairs and the successive two lessons. The rest of the columns shows the classifications *perception*, *operation* and *reasoning*. The cells contain characteristic field notes of student observations per pair. The dotted line marks the reflective meeting at the university after P2's lessons.

Table 2: Characteristic field notes of student observations

	Perception Students see:	Operation Students:	Reasoning Students wonder whether:
P1-1	- the words 'increasing/ decreasing; monotonic; tangent; slope' standing on the board	- draw arrows (dove tails) on the graph	- does it involve the ratio on the coordinate system or the rate of increasing?
P1-2	- line segments in a square on the board indicating the change from picture to number	- fold paper and slide with it - calculate the difference quotient	- why numbers are important, if you are able to fold the change?
P2-1	- no data	- draw chords, not the tangent line in a point on the graph - try by calculating - calculate x- and y-coordinates	- make no comments
P2-2	- zooming in with GeoGebra - local straightness - a chord on a small interval - zooming out giving the tangent	- slide the lines, estimate and calculate - calculate the difference quotient	- make no comments

P3-1	- the words 'increasing/ decreasing; monotonic; tangent; slope' are given in advance	- sketch on the worksheet - slide a line with a ruler - draw chords instead of a tangent line - don't mention the word tangent	- do arrows on a straight line be the same ? - do the closer the arrows on the x- axis be, the flatter the graph? - does an arrow on the x-axis show the height of the graph?
P3-2	- zooming in with GeoGebra - local straightness - that Δx becomes smaller	- make a curve straight - slide the lines, estimate and calculate - formulate a straight line	- what happens if A coincides B? - what happens if Δx becomes zero? - does dy/dx not be defined, $dx=0$?

Perception: the perception moves to the visualization of symbolic representations during the lesson study process. The words 'increasing/ decreasing; monotonic; tangent; slope' in P1's first lesson stimulates students' communication. P1's students start to fold paper spontaneously when the teacher asks numbers – illustrating a change each - at some fixed points on the delivered graph (Figure 1, the last sentence of the last but one paragraph). P2 does not focus on perception in the first lesson.

Operation: the number of student activities increases during the lesson study process.

Reasoning: the intuitive reasoning becomes more important. P2 does not focus on reasoning at all. P1's students are trying to refine the icon 'arrow' (as a dove tail) to a line segment in a square. P2's students are impeded by the incorrect use of the 'tangent line method' - indicating some kind of smoothness of the graph -, learned from the physics teacher. They start with chords on a large interval (to prevent measurement errors as in physics). P3's students start to reason about the icon 'arrow'. They move to reasoning about Δx and dx without any transition. These students have to use symbols to be able to differentiate functions.

Reports from discussions and reflections

Table 3 shows the characteristic teacher comments from the discussions and the reflections based on the student observations. The first column lists the successive pairs and the successive two lessons. The rest of the columns shows the components in types of mathematical thinking: practical (enactive and iconic) and theoretical (symbolic subdivided in local or global). The cells contain characteristic comments from the reports. The dotted line marks the reflective meeting after P2's lessons.

Table 3: Teachers' reflections

	Practical		Theoretical	
	Enactive Reflection on action	Iconic Reflection on visualization	Symbolic (local) Reflection on symbols	Symbolic (global) Reflection on symbols
P1-1	- no words increasing/ decreasing; monotonic; tangent; slope in advance	- an arrow with direction refers to a move, preference an 'arrow' without any direction	- students not simply work with numbers after working with arrows	- differentiation globally should develops gradually
P1-2	- maximum and minimum are not a problem	- preference of an arrow without direction	- awareness of coaching to numbers	- support with calculations /difference quotient
P2-1	conflict with physics: derivative means chord	- the use of an icon is necessary	- change the context to a coordinate system	- calculations with a difference quotient
P2-2	- misconception that drawing a chord on a small interval when zooming in, gives a tangent line	- the use of an icon is necessary without giving a direction	- give equations of parabola and line and support students to reason about the slope	- calculations with a difference quotient
P3-1	- cut with a scissors, sew like a sewing machine does and emphasize two sides	- line segment with a dot halfway works best	- avoid stagnation in a chord, continue in coordinate system	- local discontinuous; connect increasing and monotonic increasing
P3-2	- zooming in on paper is not possible - calculation with small Δx takes time!	no data	- students think that a Δx of 0,0001 works exactly!	- there is a lack of numeracy

The teachers prefer to stimulate students' intuitive communication in own words, *not* giving the words 'increasing/ decreasing; monotonic; tangent; slope' in advance (enactive representation). They introduce new ideas like cutting with a scissors, and sewing like a sewing machine does and emphasizing two sides. The icon develops during the lesson study from a dove tail shaped arrow (suggesting a movement), via an arrow with a direction, to a line segment with a dot halfway – the picture of the graph magnified so highly that it looks like a straight line. For the students the transition to the use of numbers is impeded by a too large gap between perception (practical) and calculation (theoretical) by themselves. For the teachers the idea grows to introduce a coordinate system to insert both a line segment related to the slope value and a graph in relation with its equation. The teachers agree to stimulate communication with the students regarding three possibilities to calculate the slope at an interval: the interval $[A-x, A+x]$, the interval $[A, A+x]$ and the interval $[A-x, x]$. The discussions focus on a too large or a too small number. Another possibility is the use of counter examples like the relation with the graph of $y=abs(x)$.

CONCLUSIONS AND DISCUSSION

The study shows that the use of an icon influences operational symbolism positively when the icon is chosen practically incorporating enaction and visualizing including sensory recognition, touch, smell etc. The 'dove tail icon' at the graph, seems to hide a line segment inside from the top to the bottom of the arrow, which may give rise to the idea that the concept of the derivative is inseparable from a difference quotient. Subsequently, the difference quotient gives rise to the differential quotient with which dividing by zero appears as an obstacle. The 'arrow icon' as a line segment

and a v-sign on top, may give rise to the assumption that there is a continuous move because the direction is given and it resembles a vector used in physics. The ‘line segment icon’ with halfway a dot, gives rise to Skemp’s (1976) relational understanding of the concept of a vector field as a basis for understanding differential equations in a later phase (Figure 4).

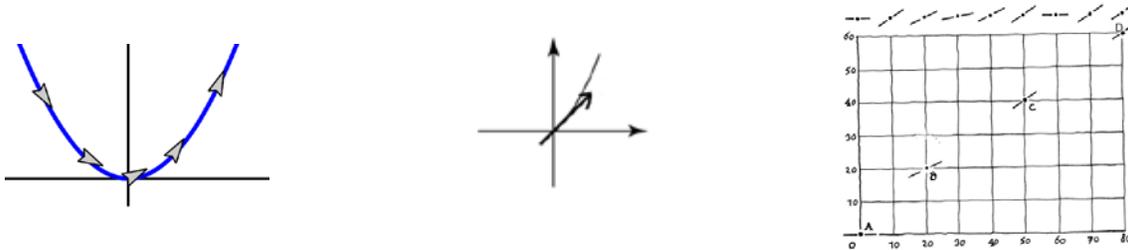

Figure 4: The development of an icon

The experiences with the development of an icon as being useful for sense making of mathematics were based on the student observation, discussion and reflection. Essentially, lesson study focused on classroom practices. The discussions after class and the plenary reflections contributed to teachers’ own relational understanding of the derivative. The different theories encouraged the teachers to re-think and to refine the lessons in spite their textbook approach. Teachers’ epistemological perspectives changed by the networking of theories (Oshimaa, Horinoa, Oshimab, Yamamotoc, Inagakid, Takenakae, Yamaguchif, Murayamaa, & Nakayamaf, 2006).

The Dutch textbooks are strongly influenced by Freudenthal’s (1984) philosophy of mathematics as an activity, the principle of re-invention. Teachers’ plenary reflections with regard to the ‘line segment icon’ with a dot halfway in a vector field gave rise to the derivative related to modelling of changing processes using differential equations. Being aware of this, the teachers made sense by thinking on the introduction of the derivative as a phenomenon. The teachers discussed the possibility to introduce the derivative on a curved area whereby student activities focused on describing the changing curved area. The teachers indicated students’ instrumental understanding of a differential equation. They argued that students’ tend to solve differential equations algorithmically and that students were unable to set up a differential equation, not being aware of the derivative as a rate of change necessarily for setting up a differential equation (Verhoef, Zwarteveen, Van Joolingen, & Pieters, 2013).

This study indicates that networking of theories - Skemp’s (1976) types of understanding and Tall’s (2012) framework of long-term mathematical thinking integrating by Bruner’s (1966) representations – refines teaching practices. Lesson study stimulates the process of refining teaching practices.

WORKERS' COMMUNITIES AS POTENTIAL INSTITUTIONS: A CONVERGENCE ISSUE TO ANTHROPOLOGICAL AND SOCIOCULTURAL COGNITIVE THEORIES

Corine Castela

LDAR-Université Paris Diderot-Université de Rouen (France)

This poster introduces a new presentation of the praxeological model within the anthropological theory of the didactic (ATD) and intends to show that this new model favours connections with cognitive theories inspired by the Activity Theory.

General context: the epistemological anthropology

What are the processes by which individual or local findings turn to be shared and recognized within an institution and then spread into other institutions? How do these social resources get transformed while circulating from their emergence institution to others? These are the issues that epistemology tackles.

The original notion of praxeology

ATD provides this epistemology with what is intended to be a general model for all human activities as well as for the resources to achieve these activities. This is the praxeological model $[T, \tau, \theta, \Theta]$ (Chevallard, 1999). In the case of mathematics, the common use of this model limits θ to theoretically proved mathematical results. Such a restricted conception fails to take into account the totality of what is known about mathematical techniques in the institutions where they are employed, whether in mathematics research, mathematics education or in any professional context.

A reorganisation of the praxeological model

Castela (2011) proposes the following presentation of the praxeological model of the resources institutionally available in a professional institution I_p :

$$\left[\begin{array}{c} \theta^{*r}, \Theta^* \\ T^*, \tau^*, \theta^p \end{array} \right] \begin{array}{l} \leftarrow I_r^* \swarrow I_r \\ \leftarrow I_p \end{array}$$

This model distinguishes the category of research institutions (I_r) and supposes that one of them has produced a praxeology $[T, \tau, \theta^r, \Theta]$ (ΠI_r). I_r specificity is that their social function includes developing praxeologies for other institutions, basing the legitimacy of the different components on a systematic process of validation which depends on the institutional paradigm. In I_p , some subjects carry out types of tasks deriving from T , ΠI_r is known but the professional use has a transposition effect on its different components. It is assumed *a priori* that the transposed praxeology $[T^*, \tau^*, \theta^{*r}, \Theta^*]$ is submitted to a new legitimating process (\leftarrow) implicating both concerned institutions. Besides, the model considers that I_p contributes to the technological development, producing a practical work oriented technology θ^p , empirically validated within the professional activities. Yet the above representation

does not make apparent the net of various sized institutions implicated in the praxeological institutional life, both in *Ir* and *Ip*. In the workplace, local institutions contribute to *Ip* cognitive development, by completing praxeologies coming from upper levels or by being the source of a new invention process initiated.

Possible connections with research inspired by the Theory of Activity

One French school of work psychology referring to the Theory of Activity is considered here, it has developed an interventionist approach, the Clinic of Activity (Clot & Kostulski, 2011). One major specificity of this school is to consider that the development process in working contexts produces socially shared resources, the “professional genre”, variety of recommended ways of doing and ways of telling, which at the same time frames and sustains individual and collective activity. The genre retains the profession historical memory, it is also a living capital submitted to constant maintenance efforts to adapt to the changing working conditions. Producing and maintaining the professional genre is considered as a matter of the “transpersonal dimension of work” which, being socially oriented, goes past simple interpersonal interactions within local working communities. The Clinic of Activity group is commissioned to intervene on working contexts in crisis; its experience is that the elimination of the transpersonal is generally at the core of such crisis.

Interest of such a connection: asking new questions

These notions of genre and of transpersonal dimension of work address the epistemological anthropology with questions such as: under which conditions does a working collective turn into an institution producing and legitimating praxeologies renewing the genre? Under which conditions does this development turn itself towards the transpersonal perspective and contribute to the profession’s cognitive productivity? Conversely these issues may be returned to the Communities of Inquiry Theory and other collaborative research perspectives, especially if their intention is to contribute to the development of the mathematics teacher profession.

THE TRIAD OF PIAGET AND GARCIA, FAIRY TALES AND LEARNING TRAJECTORIES.

Bronislaw Czarnocho,

Hostos Community College, CUNY, New York (USA)

The paper formulates a conjecture concerning the generality of learning trajectories based on the unusual similarity between observed elementary trajectories of learning in mathematics and learning progressions identified in a class of fairy tales. Both cases are explicated with the help of the Triad of Piaget and Garcia, (1989), clarifying their structural and interpretative similarity. The “learning triple” thus identified is conjectured to be one of the simplest progressions of learning, which can underline the general structure of learning trajectories in mathematics

RATIONALE

The central question of the presentation can be formulated as follows: *is there a “general strategy of human learning” that, already extant in fairy tales and their stories of heroes and heroines, could be drawn upon to inform learning in the mathematical sphere?* The presentation seeks to uncover the relationship between the Theory of Discovery method of teaching based on the work by Dewey, Piaget and Vygotsky and the structural approach to the analysis of fairy tales represented by Propp, Levi Strauss and Dundes. The methodology of comparison is the structural analysis of the small teaching sequences designed in the context of Discovery method with the structure of progressions of a hero’s (or heroine’s) struggle to succeed in the Heroic Quest class of fairy tales. The methodology of this investigation follows the doorsteps of the methodology used by Piaget and Garcia (1987) in formulating the Triad—that is a mechanism of thinking through which a schema of a mathematics concept can be constructed. The central idea of Piaget and Garcia’s work is to demonstrate that “the mechanisms mediating transitions from one historical period [in the development of scientific concepts] to the next are analogous to those mediating the transitions from one psychogenetic stage to the next... That this dialectical Triad can be found in all domains and all levels of development seems to us to constitute the principal result of our comparative efforts.” (*op. cit.* p. 28). A series of papers utilizing the Triad in explicating the construction of basic concepts of calculus such as chain rule or the limit had been published by a group RUMEC (e.g. Clark et al 1997; Cottril et al 1996). The presented approach is similar in that we are looking for a common mechanism to account for (1) learning progressions in mathematics identified during the Discovery method of teaching and (2) progressions of an adventure hero’s (or heroine) struggle to succeed in a class of fairy tales. We demonstrate that the common mechanism which can account for both progressions is “a triple”—a contraction of the Triad. It is reminiscent of the term “trebling” in the scholarship of fairy tales, which refers to the pattern of three consecutive events occurring in a succession and structuring some fairy tales (Propp,

1975). The structural analysis of the trebling did not advance very much till the present day. Dundes (1961) analysis of Lithuanian fairy tales focuses on binary opposition between the triples rather than on their inner structure. Croft (2005) shows that the “triplicity” of “trebling” extends to the Russian culture at large, following the call of Levi-Strauss (1955) to extend the paradigmatic structural analysis of the myth to the world at large. This presentation proceeds along the path outlined by Levi-Strauss in relating the structure of fairy tales to “other aspects of culture” such as mathematics education.

METHODOLOGY

1. Discovery of the structural similarity between the mathematics classroom dialogs encountered during the teaching by the Discovery method and the adventure paths of heroes and heroines in the class of fairy tales.
2. Contraction of Piaget and Garcia’s Triad reduces it to the triple in the case there are only two different individual cases or manifestations.
3. Showing that Piaget and Garcia’s Triad correctly interprets the encountered sequence of triples in the mathematics classroom dialogs.
4. Showing that in the Fairy tales with Triples, triples can be explicated with the help of the Piaget and Garcia’s Triad.

CONCLUSIONS

Since the structure of the triples and their meaning in each of the two so different domains, mathematics education and wisdom of the folklore, is similar, there may be a structure underlying both, and this structure is, I am conjecturing, an element of the “general strategy of human learning”. Rates teaching sequence appears as an example of a Learning Trajectory construction based on the triples.

INSTRUCTIONAL DESIGN TOOLS BASED ON THE ONTO-SEMIOTIC APPROACH TO MATHEMATICAL AND DIDACTICAL KNOWLEDGE

Juan D. Godino

University of Granada (Spain)

Key words: instructional design, mathematics instruction, onto-semiotic approach

We present a set of diagrams in which we summarize the theoretical tools developed under the “Onto-semiotic approach” (Godino, Batanero and Font, 2007) (OSA) in mathematics education, from the perspective of the instructional design. We assume that the focus for the didactic-mathematical analysis should be the mathematical instruction processes, which involve the teacher and students working in a specific mathematical content, within an educational context, and with specific technological tools. We consider three analysis dimensions along the design and evaluation of a mathematics instruction process: phases, facets, and levels of analysis, for each of which the OSA provides specific theoretical tools. The potential of using a base-theory in design-based research (Kelly, Lesh & Baek, 2008) for mathematics education is also highlighted. The system of notions that constitute the mentioned base-theory can help not only to describe the processes and explain the educational phenomena, (goal of a scientific discipline), but also to develop instructional research-based resources (technological design component).

Within the OSA we have built a system of theoretical notions useful for the design and didactic analysis of mathematics instructional process (Godino, Contreras & Font, 2006). We distinguish three planes or dimensions of analysis: (a) The design phases dimension, that includes the preliminary, design, implementation and evaluation phases; (b) The facets dimension, consisting of the epistemic, ecological, cognitive, affective, interactional and mediational facets; and (c) the levels of analysis, where we consider the levels of practices (pragmatic meanings), configurations of mathematical objects and processes, configurations of objects and didactic processes, norms and didactical suitability.

As suggested by D'Amore and Godino (2006), the OSA approaches the didactic-mathematical problems from the epistemic and ecological dimensions. Firstly we problematize the nature of the institutional mathematical knowledge, in the same way that it is done by the Theory of Didactic Situations (Brousseau, 1997) and the Anthropological Theory of Didactics (Chevallard, 1992), two theories which are considered as the OSA starting points. The anthropological assumption about the nature of mathematical objects -conceived as emerging from mathematical practices-, is shared with the TAD, and is complemented by the notion of configuration of objects and processes, which allows a detailed epistemic and cognitive analysis of the

mathematical knowledge involved in the planning and implementation of an instructional process. Moreover, the notions of didactic configuration and didactic trajectory (Godino, Contreras & Font, 2006), normative dimension (Godino, Font, Wilhelmi & Castro, 2009), didactical suitability (Godino, Batanero & Font, 2007) are new tools used in the detailed analysis of didactic objects and processes, the norms conditioning and enabling the teaching and learning processes, and to assess the relevance and adequacy of the various design components and decisions made.

INTRODUCTION

This working group addresses mathematics teachers and teaching, an area that has been given particular attention in mathematics education research for the last decades. Current research has started to consider theoretical and methodological frameworks that can capture the complex relationship between mathematics learning, teaching, teacher practices, and mathematics teacher education. This attempt was apparent in many papers submitted to the group and in the discussions that took place. Research in this area is exploratory and interventional with a main focus on teacher knowledge and its development while most studies adopt qualitative methodological approaches. Professional development and teacher education approaches are often based on collaboration and promote reflection.

Group 17 received 69 proposals (54 papers and 15 posters), which involved authors from 22 different nationalities. Each paper was reviewed by one of the group leaders and two authors. For most proposals we asked for some revisions. In the sessions of the working group during the conference, 44 papers and 11 posters were presented; 40 papers and 11 poster proposals are included in the conference proceedings.

Because of the large number of papers presented, the working group split into two subgroups (WG17A and WG17B). The group met as a whole for only the first part of session one and for the last session. All the papers were grouped into five thematic

areas and distributed to the two subgroups. All the participants were informed in advance of the paper distribution in the two subgroups.

All participants of WG17 were expected to read papers previously to the session in which they were presented. In each session, three, four or five authors sketched the key ideas of their report (5 minutes each). One of the group leaders or participants then gave a prepared reaction to the set of papers (up to 10 minutes). In most cases, the reactor attempted to make links between the papers and suggested issues emerging from the papers that might form the basis for discussion.

In general, the work in the group seemed to be productive and most authors felt that they got useful comments to develop further their paper.

Thematic areas

We present the issues and ideas that emerged in reference to the five central themes.

Studying mathematics teaching

The complexity of studying mathematics teaching is overtly addressed in the six papers categorised in this thematic area. In some the focus is on detailed investigations of communication, for instance the process of questioning or orchestrating mathematical discussions in the classroom. Others discuss the design of an analytical tool to explore and characterise the complexity of mathematical classrooms, or teachers' actions during introductory activities to algebraic modelling. A broader perspective is taken for inquiring in the role played by the teacher in terms of patterns of participation or investigating the challenges teachers and students meet when introducing technology in teaching practice.

These articles all seek to conceptualise teacher-student interactions, even though the chosen theoretical perspectives differ. Several theoretical frames address the complexity of mathematical discourse where knowledge is viewed as co-constructed during teacher-students interactions in the classroom. A different approach is needed to conceptualise the role played by the teacher during teaching practice where the idea of "Patterns of Participation" enables the authors to analyse teaching practices as

a dynamical process. The introduction of technology requires the elaboration of a framework where combination of Activity Theory and instrumental orchestration are central elements.

From a methodological perspective, all papers in this thematic area follow an interpretative paradigm, conducting research through case-studies focusing on in-service teachers and based on classroom observations and interviews.

Taking an overall perspective it is possible to identify the following three emerging issues: *Communication in mathematics classroom* is one of the main foci with emphasis on teachers' orchestration of mathematical discourse, on the practice of arguing and on good questioning. Another central issue emerging from these six papers concerns *mathematical content of teachers' teaching practice*, that is to what extent the mathematical content is brought to the fore during a lesson, and how this relates to the potentials and limitations of teachers' knowledge. The last issue addresses *reflection on and development of teachers' teaching practice* with emphasis on the dynamical nature of classroom interaction. These issues are discussed both from an in-service and pre-service teachers' perspective. Common to all these papers is recognition of the complexity and richness of teachers' teaching practice while developing theoretical and analytical tools as a means to conceptualise it further.

Resources for Teaching: Teacher knowledge and Teacher beliefs

A number of papers categorized in this thematic area were discussed in WG17A while others in WG17B.

The contributions discussed in WG17A (11 papers) were diverse, taking into account the teaching level they refer to (primary or secondary), the mathematical contents they attend to (e.g., fractions, functions, algebra, divisibility, and geometry), and the expertise of the teachers involved (from prospective to seasoned teachers). This diversity notwithstanding, all the contributions revolve around one or more of three key concepts: teacher knowledge, teacher beliefs, and teacher/teaching practice. For

example, some papers focus on the link between teacher knowledge and teaching practice, others attend to the connection between beliefs and practice, while still others explore the interactions between beliefs and knowledge or even teachers' beliefs about the knowledge needed to teach effectively. In what follows, we discuss four central issues we see to collectively emerge from the contributions of this subgroup:

(a) *Explorations situated in the context of teaching practice*: Almost all contributions discussed examine teachers' knowledge and/or beliefs as made explicit in some context of teaching practice. This can be the discussion of a real classroom episode, different real students' answers to a common problem, or working with and unpacking students' ideas. In doing so, collectively these contributions suggest that teacher knowledge and beliefs should be analyzed in the context of teaching practice. We consider this an important step that research has made over the past few decades, and one which has been fuelled by increasing realizations that knowledge and beliefs are inseparable from practice.

(b) *Tendency to gain information about how different resources relate, more than a partial understanding of one of them*: Several of the contributions in this subgroup investigate interactions between teacher knowledge and practice or beliefs and practice; fewer are the investigations that explore interactions between knowledge and beliefs, and much scarcer are those that are situated at the nexus of all three components: knowledge, beliefs, and practice. Based on the promising findings of these contributions, we believe that working at the intersection of these components offers a very promising perspective for future research.

(c) *Use of multiple theoretical and analytic frameworks and methodological approaches*: The contributions of this session capitalize on multiple theoretical and analytic frameworks, including, for instance, Shulman's framework, the *Mathematical Knowledge for Teaching*, the *Mathematical Pertinence of Teachers' Actions*, and the *Structure of the Milieu* frameworks—just to name a few related to investigating teacher knowledge. Given the complexity of the phenomenon under investigation—we believe that this diversity can help better understand the phenomenon at hand. However, as the number of these frameworks increases, we

think that scholarly efforts should also be channeled in bringing together these frameworks, exploring if and how they talk to and complement each other, examining their affordances and limitations, and investigating how combinations of frameworks can prove helpful. Along the same lines, different methodological approaches pursued in the contributions of this session, ranging from qualitative case studies to quantitative experimental designs. (d) *Attention to the role of teacher preparation programs and in-service professional development programs*: Some of the contributions of this session report on research made in the context of teacher education programs for prospective or practicing teachers. We see a lot of value in this research strand and we encourage more systematic reflection on the role of teacher education programs in the development of teachers' beliefs, knowledge, and practice; at the same time, future works could invest more systematically in reflecting on how research results could inform the design of teaching programs.

The four issues just discussed are indicative of the multiple directions in which we see research evolving in the next decades. Collectively, these issues underline the multiple opportunities that lie before us as well as the various challenges that future research will face attempting to better unpack and understand the knowledge-beliefs-practice conundrum.

The contributions discussed in WG17B (10 papers) also adopt different perspectives on the way they use knowledge models. The importance to establish a general understanding on what meanings entail the content knowledge and how it affects the practice of teaching was highlighted both in the papers and in the group discussion. Moreover, models that allow conducting a more precise analysis of each knowledge component related to effective mathematics teaching were discussed. Mathematics knowledge for teaching (MKT) (Ball, Thames and Phelps 2008) as the mathematical knowledge needed to carry out the work of teaching mathematics was elaborated. It was stated that subdomains of the MKT model are not composed of mathematical knowledge only. As processes used in the creation of this knowledge were

characterized (a) decompressing (working from a more compressed understanding of mathematics to a more unsophisticated form), (b) trimming (teachers present an advanced or sophisticated mathematical idea to students in a way that the fundamental nature of the topic is preserved but it is less rigorous), (c) bridging: making connections between mathematical topics or between mathematics and other subject areas.

From amongst the most recent conceptualizations of teachers' knowledge in the course of mathematics education, the MKT model and especially the development of the components of CCK and SMK, HCK (common content knowledge, specialized content knowledge and horizon content knowledge, correspondingly) were discussed. More precise clarification of the concepts and their deeper analysis was requested. Questions as: How could different types of knowledge (especially HCK) be promoted in pre- and in-service teacher education? Which research method should/could be use when analysing them? What is the evidence? Should the teachers be aware? More general questions like "what is the purpose of having a knowledge model?" were also addressed.

Teacher Education and Professional Development

Nine paper were discussed in this thematic area. The papers' topics comprise issues like curriculum development, the enhancement of mathematics teacher education practices through research, the integration of mathematics and science in teacher education, different approaches for professional development, or the sustainability of the impact of professional development programmes. In particular, some papers deal with teacher knowledge and students' work, some other highlight teacher education and classroom issues. Besides these empirical studies, some further papers deal exclusively with theoretical models and perspectives, and try to link theories or knowledge from other disciplines with mathematics teacher education.

The empirical studies' participants comprise both in-service and pre-service teachers, from primary and secondary level. The papers related to this thematic area use

various theoretical frameworks, ranging from teacher knowledge theories, over theories of didactics, up to theories of learning. The methods used in this thematic area's papers are manifold; for example: questionnaires, document analyses, pre- and post-tests, teaching experiments, exploratory studies, or literature reviews.

A significant discussion in the working group concerns the question, whether and which theories are needed to analyse the impact of teachers' professional development and its sustainability. Another emerging issue is teacher educators' responsibilities regarding their research and its impact on improving mathematics teaching and mathematics teacher education. Yet another emerging question is how to become aware of unexpected impact of research results.

Teacher Collaboration

In the last decades, collaboration between teachers and academic researchers or research –practice oriented tasks has become the focus of research. In other words, in the study of mathematics teaching and teacher professional development, collaboration may be considered as a means for professional development, as a means to study teachers' innovative practices or even as a research focus. However, in WG17, collaboration appears in a very few papers (3) and never as an object of research.

Speaking about collaboration means to consider a joint work in order to provide mutual support and the achievement of goals, not necessarily the same for each member of the group. It is also assumed that the participants may have different roles, but necessarily contributing for a shared general goal that gives meaning to the collaborative work. Participants must be attentive to the needs of others and be open to negotiate understandings emerging from the collaborative effort. A confident environment is an essential condition for the development of collaboration. But this condition may raise some difficulties to the collaborative work between participants, in particular in the case of teachers and academic researchers, because they don't have, at the starting point, equal social status. What strategies, settings and content

can we design to promote a collaboration between teachers and academic researchers in order to achieve a real collaborative work?

Using a collaboration setting for studying innovative practices seems, on the one hand a promising strategy, and on the other hand, a challenge for teachers and academic researchers. Successful situations have been presented in the papers. In a collaborative work, teachers and academic researchers were able to design a teaching intervention where innovation was included and studied. Collaborative practices were important for teachers during their teacher education and afterwards when they are all team teaching and collaborating with colleagues. But collaborative work is time consuming for all participants and needs time for reaching results. This is a challenging issue for us as to consider.

Teacher Reflection

Reflection was made the focus of the research in few papers. Three papers were categorized in this thematic area, but – while only two appear in the proceedings and are discussed here. Both papers focus on how to promote prospective teachers' reflection. One paper sees reflection to be promoted in situations of tensions and studied prospective teachers' reflective process on learning and teaching mathematics. In particular, emphasis was given on the nature of tasks that can promote reflection and a model of analysis with different dimensions of reflection was used to study prospective teachers' reflection. The other paper focus on how the prospective teachers reflect on the process of division with remainder through role-play. The paper describes how role-play has been used in the process of actualizing teacher –pupils-like interactions. The results indicate that prospective teachers through this reflective experience develop mathematical and pedagogical understandings. Issues that seem to emerge are: whether reflection requires always situations of uncertainty; how reflection is conceived in more social perspectives and what kind of research questions and methodologies such perspective will support.

Critical issues

We would like to close our introduction by including some critical issues that the participants of the two subgroups expressed during the closing session.

Critical issues addressed in WG17A

- We are working on multiple frameworks. What are the advantages and disadvantages of doing so?
- It is not clear to what extent our frameworks and results take into account the character of mathematics, especially for theoretical “imports”. How can we achieve this?
- The role of the “Context” is not always sufficiently clear. How can we become better at it?
- The deficit model of teacher is still alive in our community. Are we aware of the consequences?

Critical issues addressed in WG17B

- What could be considered as a suitable model for teacher knowledge?
- What could be the purpose for developing new theoretical models or for modifying/revising the existing ones?
- How can teacher educators help students/teachers to develop different components of their knowledge? Are they different for prospective teachers’ education and in-service teachers?
- What are the ways of promoting teacher knowledge? Should be the teachers aware of different theoretical models?
- How can we analyse the influence (occurrence) of different types of knowledge?
- How can we study the mutual relation between teachers’ knowledge and practice?
- What is the evidence? Which research method should we use?

GOOD QUESTIONS OR GOOD QUESTIONING: AN ESSENTIAL ISSUE FOR EFFECTIVE TEACHING

Einav Aizikovitsh-Udi*, David Clarke **, Jon Star***

* Beit Berl College, Israel; **University of Melbourne, Australia, ***Harvard Graduate School, USA

It is the contention of this paper that it is not good questions that are essential for good teaching, rather, it is good questioning. We illustrate the significance of question-asking in mathematics classrooms by presenting the case studies of two teachers teaching the same topic to two different classes. Comparison of the two cases highlights important differences between “good questions” and “good teacher questioning practice.” Our analysis suggests that good questions cannot be meaningfully considered or promoted independent of good questioning practice and that this distinction has significant implications for teacher education.

Key words: questioning practice; mathematics education; effective teaching

INTRODUCTION

Teacher questions are viewed as a critical teaching tool by many researchers and educators (e.g. Cunningham, 1987; Dillon, 1988; Ellis, 1993; Morgan & Saxton, 1991; and Martens, 1999). A question is an expression of inquiry that invites or calls for a reply. In a classroom, questions are used by teachers as instructional cues to assess student progress and to motivate student thinking. ‘To question well is to teach well’ (De Garmo (1911), p. 179 as cited in Wilen (1991), p. 5). It is clear that teacher questioning is universally viewed as a highly important instructional practice. Yet even this apparently unequivocal endorsement of the importance of teaching questioning conceals the essential distinction between “good teacher questioning” as instructional practice and the concept of a “good question” as an instrument of that practice (eg Benedict, Kaur & Clarke, 2007; Clarke & Sullivan, 1992). This distinction and the two constructs of “good question” and “good questioning” provide the theoretical and empirical focus of this paper.

The value of good teacher questioning is particularly endorsed in mathematics education. Yet teacher questioning can take many different forms and serve many commendable purposes. Therefore, within this general recommendation about question asking are many interesting and important questions about how teachers might implement question asking. The purpose of the analysis reported in this paper was to investigate some of the issues associated with the implementation of this important practice. The characteristics of a “good question” or of “good teacher questioning” as a practice can only be identified once the teachers’ goals are known. A question intended to provide information on the current state of a student’s understanding is likely to take a different form from a question intended to promote student self-regulation of learning and this would be different again from the sort of question that might stimulate engaging and productive whole class discussion.

Many researchers (Bingham, 2005; Black, 2001; Boyer & Piwek, 2010; Hufferd-Ackles et al. 2004, Moberg, 2008; Sigel & Kelley, 1986) have examined the culture of asking questions in class. Although there is consensus on the importance of question-asking, a variety of research has indicated that math teachers are not particularly good at asking questions (and/or at asking good questions). For example, studies have shown that teachers in an average class ask between 12 and 20 questions, yet approximately half of the questions are procedural questions regarding timetable, attendance, clarifying various technical issues, etc. Furthermore, most of the questions are closed questions for testing knowledge (straight recall). Only a very small percentage of questions encourage higher-order thinking. In addition, teachers tend not to allow students opportunities to think about questions; wait time has been found to average 1.2 seconds. Finally, 70% of the students' answers consist of three words and their duration is five seconds or less (eg Nystrand, 1997).

Curricula have been designed to help teachers improve their question posing, but based on the existing research it is not clear how successful these question-asking curricula have been at improving teachers' ability to ask good questions. It is this relationship - between curricula that aim to improve teachers' question asking and teachers' implementation of these curricula - that provided the focus of the analysis reported in this paper. More specifically, does teacher experience in using curricula explicitly focused on improving question asking lead to their regular and independent use of such advanced instructional strategies? Is good questioning a matter of using good questions or of questioning well? Are we talking about tools (good questions) or practice with those tools (good questioning)? The two case studies reported in this paper exemplify this distinction very clearly.

RESEARCH QUESTIONS

This study aims to provide evidence for the following research questions: What constitutes good teacher questioning and what contribution does the provision of “good questions” make to the enhancement of teacher questioning practice? That is, our research investigates the difference between good questions as an instructional tool and good questioning as instructional practice.

METHODS

We explored the question above through two case studies, each of which involved a teacher teaching the same content in a junior high school Algebra I class. The two teachers, Robert and Naomi (fictional names) were experienced algebra instructors (20 and 15 years of math teaching experience, respectively), who participated in a larger year-long project from which the present data are drawn. The data collection central to the analysis reported in this paper consisted of classroom observations and interviews with each of the teachers. We have analyzed two types of lessons taught by these two teachers. The first type was a regular lesson according to the curriculum adopted at the teachers' school, while the second type was a lesson provided to the

teachers by the researchers, which was designed to promote the skill of question-asking. Both teachers participated in a one-week professional development institute in the summer prior to the data collection year. The institute focused on the use of the supplemental question-asking curriculum materials and was intended to facilitate the teachers' implementation of particular questioning strategies.

The advocated instructional approach focused on stimulating student reflection and discussion about “contrasting cases” of pairs of student responses to the same task. The questions provided to teachers emphasised the comparison of the students’ strategies, such as: “How do you know which answer is correct?” and “How similar or different are these two strategies?” and “When does the difference between using one or the other strategy matter?” A “discussion phases guide” offered teachers a three-phase approach to their questioning, providing sample questions that sought to *understand* the pair of student responses, *compare* the student responses and *make connections* between the two responses. Very specific sample questions were provided for each phase (as in the three examples above). In this study, the questions were intended to stimulate student (and teacher) reflection about two students’ strategies in solving a particular mathematical task. Potentially, the questions could scaffold student reflection on alternative mathematical methods (consistent with Holton and Clarke, 2006), and the guide provide a structure for teacher questioning.

RESULTS

The findings presented here examine the practices and the character of interactions in the classes of the two teachers. We use these two teachers' cases to help illuminate important and unexplored issues in the implementation of question asking: the teacher’s role in asking questions, the character of questions directed at students, and the way the questions are asked.

The Role of the Teacher

There were differences in the attitude of teachers to their role as “questioners.” One teacher, Naomi, defined her teaching style as “direct teaching.” She delivered each topic stage by stage, being responsible for every stage (e.g. choosing every step in solving a problem). She provided many instructions during the process of solution: how to solve equations, perform calculations, work with models, when to contract, etc. Her teaching was very detailed and precise and was accompanied by oral and written explanations. Naomi solved each equation completely and did not skip stages in problem simplification, including detailed substitutions and making all necessary calculations. Such teaching as Naomi’s is well-described in literature about traditional teaching (Aizikovitsh-Udi & Star, 2011; Metz, 1978; Chazan, 2000). In contrast to Naomi, who saw herself as responsible for giving the suitable formula with explanations to the students, Robert preferred to allow the students to be the primary agents in finding solutions, while only assisting them to do so. Robert consistently applied methods that appear in recent educational literature as “innovative.” For instance, he encouraged reliance on intuition and gave a minimum

of laws and rules. Also he did not function as an authority for deciding whether an answer is correct (Cazden, 1988). The practices of these two teachers embody the alternatives discussed by Lobato, Clarke and Ellis (2005) in their reformulation of “teacher telling” as the strategic alternation of initiation and elicitation.

Naomi

Naomi taught her class according to traditional patterns of teaching (Aizikovitsh-Udi & Star, 2011; Bauersfeld, 1988; Voigt, 1989). In this tradition, the place of the teacher in the teaching process is central. She gave ample explanations and instructions directly to the students while solving problems. In Naomi’s practice, the teacher served as a source of knowledge and was responsible for establishing correctness or incorrectness of answers. The teacher dominated the discourse in class, posing multiple questions but answering most of them herself. She did not encourage discussion. Most of the questions were focused on mathematical content and were intended to obtain information and evaluate answers rather than attempting to understand the individual student’s way of thinking. The students’ answers to the teacher’s questions were very brief, and their own questions aimed at clarifying points they did not understand rather than furthering their investigations.

Robert

Robert taught his class in a method that was characterized by features of the contemporary “reform agenda” (Darling-Hammond, 1996; NCTM, 2000). While Naomi’s place in teaching was central, Robert’s place was central as well, but with different emphases: he guided the students, gave few rules and laws and allowed the students to choose different ways for solving a particular problem.

Robert did not answer his own questions, but waited for students to respond. In cases when the answer was slow to arrive, he repeated the question in different ways. He encouraged discussion in class, which can be seen from the encouragement he gave to students who replied, from his repeated questioning of students who could not reply, and from the fact that students asked investigative questions themselves. The purpose of the teacher’s questions was not only to evaluate knowledge of mathematical content but also to understand how the students think. Davis (1997) called this mode of listening to answers “interpretive listening.” In this practice, the teacher does not function as the authority for establishing the correctness or incorrectness of the solution or for correcting the solution, but directs students by means of questions to correct their mistakes. Such a pattern has been termed by Wood (1998) “the focused pattern” and contrasted with the more directive and convergent “funneling pattern.” The two teachers offered a remarkable contrast: each employing instructional practices that have come to be identified with the stereotypes of “conventional” and “reform” teaching. In the following discussion, we juxtapose their actual practices in order to facilitate reflection on the role of questioning in both instructional models.

DISCUSSION

Although both teachers were considered good teachers and lesson structure was the same in both classes (an important point), the practice and “culture of question asking” of the two teachers were quite different and were shaped and applied differently. This has to do with the differences in the patterns of the teachers’ discourse. For instance, the pattern of Naomi’s discourse can best be described from the literature as the “funnel” pattern (where the teacher directs the students by means of questions toward the expected answer), while the pattern of Robert’s discourse is similar to the “focused” pattern (where the teachers leaves the responsibility for arriving at the solution to the students, while helping them to focus on the important aspects of the problem), as described by Wood (1998). Also the ways of listening of the two teachers were different, where Naomi predominantly exercised evaluative listening, while Robert applied both evaluative and "interpretive" listening (Davis, 1997). While most questions by both teachers were concerned with mathematical content, Naomi's questions were not directed personally to the students, that is, the purpose of the question was to receive a mathematical answer and not to emphasize the individual student (we have termed this type of question "technical"). By contrast, most of the questions in Robert’s classes required more explanation and argumentation than those in Naomi’s classes (we have termed this type of question "investigative").

In evaluating the teachers’ implementation of the practices advocated in the question-asking institute, we observed that both Naomi and Robert essentially preserved their teaching styles both in the supplemental question-asking portions of their classes and in the regular classes that adhered to their regular curriculum. Thus, in order to foster and encourage question asking in class, it appears that it is not enough to provide the questions to the teachers. The way in which the questions are asked, the timing and the number of times each question is asked have a central role in the culture of question-asking. In other words, even investigative questions can be asked in a technical way and consequently not give rise to any significant process of investigation. In particular, in relation to the professional development program that provided a key research site for this study, our results suggest that in order to change traditional teaching styles, it is not enough to give the teacher a small, narrowly focused exemplary learning unit (in this case, the supplemental questioning materials), even if, like Robert and Naomi, the teacher has previously taken a course in implementing related innovative teaching methods.

The initial evidence shows that teachers such as Robert, who have already assimilated some of the practices of the reform agenda into their teaching, are more likely to incorporate advanced instructional strategies into their practice than more conservative teachers, such as Naomi, whose pedagogical practice mirrors a personal commitment to stability and the inviolability (non-negotiability) of mathematical knowledge. However, the exposure of both teachers to the question asking teaching methodology was very brief, and it remains to be seen whether a more extensive

exposure might or might not change a less innovative teacher's questioning strategies. Certainly, consistent with the existing literature on teacher change (eg. Clarke & Hollingsworth, 2002), neither the brief program nor the provision of the questioning material was sufficient to catalyse serious reconstruction by Naomi of her existing practices. And it may be that the efficacy of her existing practice was never seriously challenged by the institute. A new tool is less likely to be used, if the teacher's goals can be achieved successfully with existing, more familiar, tools.

Many in-service programs aim at enhancing teachers' teaching capabilities and expanding their repository of instructional strategies by emphasizing the connections between theory and practice. Indeed, making the connections between educational theories and practice in the classroom has been identified as essential (Zoller, Ben-Chaim, Ron, Pentimalli, & Borsese, 2000; Osborne, Erduran, & Simon, 2004). Certainly, the institute in which both teachers participated sought to establish or at least demonstrate this connection. However, it would appear from the two case studies that we have reported, that the motivation to change practice requires more than logical argument. We suggest, consistent with existing teacher change literature, that the inclination to change either resides in a teacher's existing willingness to experiment in the on-going improvement of her practice, or in a desire or need to change, arising from dissatisfaction with her ability to achieve her teaching goals. In the case of Naomi, neither condition was met. In the case of Robert, the institute and the materials provided, did not really constitute a change in practice, but rather an extension of existing practice and of an existing inclination to experiment and to innovate.

Questioning is so fundamental to a teacher's practice that a change in questioning methods may require a fundamental shift in teacher beliefs (similar to that documented by Tobin et al., 1994). Certainly, the two cases that we have reported suggest that this is the case. We have two distinct issues here: the nature of good question-asking by teachers, its form and its function; and, the means by which teachers can be led to change their practice in the direction of good question-asking. The two teachers that we have described, Naomi and Robert, exemplify two distinct questioning styles. Each style is in such widespread use that it is clear we are dealing with two sets of pedagogical beliefs and aspirations characteristic of two co-existing constituencies within the teaching community. The advocacy of one model of teacher questioning over the other (focusing over funnelling) is based on contemporary curricular aspirations to promote more than just facility with mathematical concepts and skills but rather more ambitious conceptions of "mathematical thinking" that integrate identifiable components, such as algebraic thinking, statistical thinking, critical thinking and metacognition¹.

¹ Do these categories of "thinking" represent different modes of "thought" or are we categorising either the context in which thinking is undertaken (that is, mathematics) or the type of objects that are the subject of our reflection (mathematical objects)? Our success in promoting student

In summary, good questioning is central to good mathematics teaching and it is essential that teachers understand the importance of good question-asking skills in mathematics lessons. Good questioning involves the use of good questions as part of good questioning practice by teachers. What constitutes good questioning practice is directly reflective of the goals of the curriculum and the teacher and will differ significantly according to the cultural setting (Clarke, 2012). Teachers must create situations in which their own questions relate to the mathematical problem in hand, as well as modelling the skill of question asking for their students' benefit immediately and in the longer term (Holton & Clarke, 2006). To achieve this, it is necessary to plan teaching by choosing questioning tools that suit the student population, the teaching goals, the different needs and the teacher's own teaching style (and, we might add, the cultural milieu and traditions of practice that frame the classroom and constrain possibilities of change). The two case studies discussed in this paper demonstrate that the provision of good questions, even when these are presented as components of a coherent, structured questioning framework, was not enough to stimulate significant change in teacher questioning practice. For many teachers, the implementation of good questioning practices may involve profound change, not only in teacher practice, but also in teacher beliefs about the goals and purpose of mathematics teaching. Practical exemplars of good questioning practice must become a key resource in teacher education programs. Some interesting experiments have already been undertaken in this regard (Aizikovitsh-Udi, 2012).

PRACTICES TO ENHANCE PRESERVICE SECONDARY TEACHERS' SPECIALIZED CONTENT KNOWLEDGE

Fatma Aslan-Tutak, & F. Gunes Ertas

Bogazici University, Turkey

In this paper, the authors discuss practices to enhance preservice secondary mathematics teachers' subject matter knowledge specifically specialized content knowledge. The mathematical knowledge for teaching model (Ball et al., 2008) and Usiskin's perspective of teachers' mathematics (2001) were integrated to develop a content course for secondary mathematics teachers in Turkey. The focus of this paper is the nature of mathematical tasks used during the course. Those tasks are discussed from four approaches; unpacking concept definitions, applications and modeling, procedures and generalizations, and historical perspective of concepts. Pre- and post-test results and the participants' opinions showed that these practices were influential on their SCK.

Keywords: Preservice Secondary School Mathematics Teachers, Teachers' Content Knowledge, Specialized Content Knowledge, Mathematical Tasks, Content Course

INTRODUCTION

As the definition of teacher knowledge of Shulman (1986) consists of three types of subject matter knowledge (SMK), pedagogical content knowledge (PCK) and curriculum knowledge, SMK has an important role in this model. Brown and Borko (1992) asserted that preservice teachers' limited mathematical content knowledge is an obstacle for their training on pedagogical knowledge. Furthermore, according to the mathematical knowledge for teaching (MKT) model, developed from observations of elementary school teachers' classroom teaching, (Ball, 2000) there are six domains of teacher's content knowledge which can be categorized under Shulman's different types of knowledge (Ball et al., 2008). There are three domains under SMK: common content knowledge (CCK, mathematics knowledge not unique to teaching), specialized content knowledge (SCK, mathematics knowledge unique to teaching), and horizon content knowledge (knowledge of mathematics throughout the curriculum). Also, there are three domains under pedagogical content knowledge: knowledge of content and students (KCS, interaction of knowledge of mathematics and students' mathematical conceptions), knowledge of content and teaching (KCT, interaction of knowledge of mathematics and teaching methods), and knowledge of content and curriculum (interaction of knowledge of mathematics and mathematics curriculum). Among the three domains of SMK, specialized content knowledge stands out as teachers possessing deep understanding of the mathematics they will teach.

Furthermore, one of the most important features of this model is its emphasis on interweaving content and pedagogy for mathematics teaching (Ball, 2000). This model also describes kinds of practices which may be helpful to improve teachers'
